Immediately upon the meeting of the Long Parliament in 1640 Prynne was liberated. On Nov. 28 he entered London in triumph, and on March 2, 1641, reparation was voted by the Commons, at the expense of his persecutors. Prynne now attacked the bishops and the Roman Catholics and defended the taking up of arms by the parliament. He showed a vindictive energy in the prosecution of Archbishop Laud. He manipulated the evidence against him, and having been entrusted with the search of Laud's papers, he published a garbled edition of the archbishop's private "Diary," entitled *A Breviate of the Life of Archbishop Laud.* He also published *Hidden Works of Darkness brought to Light* in order to prejudice the archbishop's case, and after his execution, *Canterbury's Doom . . .* an unfinished account of the trial commissioned by the House of Commons. Prynne supported a national church controlled by the state, and issued a series of tracts against independency. He denounced Milton's *Divorce at Pleasure,* was answered in the *Colasterion,* and contemptuously referred to in the sonnet "On the Forcers of Conscience." He also opposed violently the Presbyterian system, and denied the right of any Church to excommunicate except by leave of the state (e.g., *Four Short Questions* [1645]; *A Vindication of Four Serious Questions* [1645]). He was throughout an enemy of individual freedom in religion.

Prynne took the side of the parliament against the army in 1647, supported the cause of the eleven impeached members, and visited the university of Oxford as one of the parliamentary commissioners. In 1648 Prynne was returned as member for Newport in Cornwall. He at once took part against those who called for the execution of Charles; the result was his inclusion in "Pride's Purge" on Dec. 6, when, having resisted military violence, he was imprisoned. After recovering his liberty Prynne retired to Swainswick. On June 7, 1649, he was assessed to the monthly contribution laid on the country by parliament. He not only refused to pay, but published *A Legal Vindication of the Liberties of England,* arguing that no tax could be raised without the consent of the two houses. He was imprisoned in various places from 1650 to 1653, and on his release renewed his pamphleteering activities.

On the restoration of the Rump Parliament by the army of the 7th of May 1659 fourteen of the secluded members, with Prynne among them, claimed admittance. He was prevented from taking his seat, and a second attempt in December also failed. He was returned for Bath to the Convestion parliament and to the parliament of 1661. During 1663 he served constantly on committees, and was chairman of the committee of supply in July, and again in April 1664. The last time he addressed the House appears to have been in Nov. 1667.

Prynne died unmarried, in his lodgings at Lincoln's Inn, on Oct. 24, 1669, and was buried in the walk under the chapel there.

PRYOR, ROGER ATKINSON (1828–1919), American soldier and jurist, was born near Petersburg, Va., on July 19, 1828. He graduated at the law school of the University of Virginia in 1848, and in 1849 was admitted to the bar. He served as a Democrat in the National House of Representatives, 1859–61, and was re-elected for the succeeding term, but owing to the secession of Virginia did not take his seat. He served in the provisional Confederate congress (1861) and also in the first regular congress (1862) of the Confederate constitution. He entered the Confederate army as a colonel, became a brigadier-general (April 16, 1862), and took part in the battles of Williamsburg, Seven Pines, second Bull Run and Antietam. Owing to a disagreement with President Davis he resigned his commission in 1863, and entered Gen. Fitzhugh Lee's cavalry as a private. He was taken prisoner Nov. 1864, but was released on parole by order of the president. In 1865 he removed to New York city, where he practised law. He was judge of the New York court of common pleas, 1890–94, and of the New York supreme court, 1894–99, when he retired from the bench. He died in New

York city on March 14, 1919.

PRYTANEUM AND PRYTANIS. 1. In ancient Greece, each State, city or village possessed its own central hearth and sacred fire; the fire (cf. at Rome the fire in the temple of Vesta) was kept alight continuously, tended by the king or members of his family, The building in which this fire was kept was the Prytaneum (Πρυτανεῖον), and the chieftain (the king or prytanis) probably made it his residence. The word prytanis is applied to those who, after the abolition of monarchy, held the chief office in the State. Rulers of this name are found at Rhodes as late as the 1st century B.C. The Prytaneum was regarded as the religious and political centre of the community. When colonists Went out they took with them a brand from the Prytaneum altar to kindle the new fire in the colony; the fatherless daughters of Aristeides, regarded as children of the State at Athens, were married from the Prytaneum as from their home; foreign ambassadors and citizens who had deserved especially well of the State were entertained in the Prytaneum as public guests. In Achaea, this central hall was called the *Leïton* (town-hall), and a similar building is known to have existed at Elis. The site of the Prytaneum at Athens cannot be definiteiy fixed. The Prytaneum mentioned by Pausanias, probably the original centre of the ancient city, was situated somewhere east af the northern cliff of the Acropolis. Curtius places the original Prytaneum south of the Acropolis in the old Agora, and regards that of Pausanias as a building of Roman times (*Stadtgeschichte,* p. 302). Many authorities hold that the original Prytaneum of the Cecropian city must have been on the Acropolis. From Aristotle's Constitution *of Athens* (ch. 3) we know that the Prytaneum was the official residence of the archons, but, when the new Agora was constructed they took their meals in the *Thesmotheteion* for the sake of convenience. There was also a court of justice called the court of the Prytaneum; it tried murderers who could not be found, and inanimate objects which had been the means of causing death.

2. For the PRYTANEIS of the Boulē see BOULE.

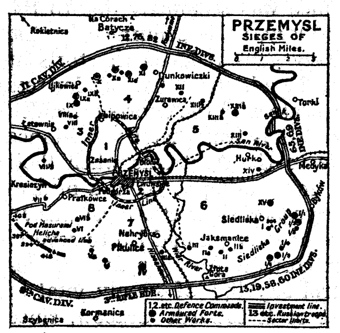
PRZEMYSL, a town of Poland, in the province of Lemberg (Lwow), 60 mi. W. of Lwow by railway. Pop. (1931), 51,379, mostly Polish. It is situated on the river San, ahd is the seat of a Roman Catholic and a Greek Catholic bishop, the cathedral dating from the 15th century. The industries comprise the manufacture of machinery, the refining of naphtha, corn-milling and the sawing of timber. On the hill above the town are the ruins of an old castle, said to have been founded by Casimir the Great,

Przemysl was founded at an early date on the borderland between Poland and Russia. Russian princes founded a state there in the 11th century, which became absorbed in the principality af Galich or Halicz and was annexed by Casimir the Great after 1340. It was occupied by Austria from 1773 to 1915. Polish after 1918, it was occupied by the U.S.S.R. in 1939 and Germany in 1941.

PRZEMYSL, SIEGES OF, In 1914 Przemysl was protected by a ring of forts 36 m. in circumference. Some of the forts were of recent construction, but the fortress as a whole was not strictly up-to-date. To clear the foreground in front of the fortified line no fewer than 18 villages and some five miles of forest were levelled to the ground on mobilization, The armament of the fortress included four large modern howitzers of about 12in. calibre and some gin, and 6in. howitzers of older pattern. There were in all about 1,000 guns in the fortress, but more than half of these were old, short-range weapons of little value except for close defence. There were 114 machine-guns, of which two-thirds were mobile.

The eventual garrison left in the fortress when the Austrian armies retreated from the San on Sept. 18, 1914, consisted of: $61\frac{1}{2}$ battalions (of which $40\frac{1}{2}$ were Landsturm), seven squadrons, four field batteries, 43 fortress artillery companies, 48 Landsturm artillery brigades, eight sapper companies, and various technical and administrative units. The total strength was approximately 130,000 men and 21,000 horses. Provisions were available for three months.

The First Siege.—The Austrian armies withdrew from the San on Sept. 18; by Sept. 24 the investment of the fortress was complete. On the south-west front the garrison held a line a mile or two in advance of the ring of forts; elsewhere the Line of the forts was held. The siege of the fortress was undertaken by Radko-Dimitriev's III. Army. While the arrival of the siege artillery material was still delayed by the state of the communications, the Austrians renewed the offensive in the early days of Oct. (bee VISTULA-SAN, BATTLES OF THE). In the hope of capturing Przemysl by a coup de *main* before the progress of the enemy offensive compelled the raising of the siege, Radko-Dimitriev carried out several violent assaults between Oct. 5–8 against the Siedliska group of works to the south-east of the town. These assaults broke down with heavy loss, and the approach of the Austrian III. Army necessitated the withdrawal of the investing forces. The fortress was entered by Austrian infantry of the field armies on Oct. 11, on which date Radka-Dimitriev's III. Army retreated to the east bank of the San.



BY JOHN BARTHOLOMEW & SONS

Period Between the First and Second Sieges.—During the Austrian attempts to force the San line, which lasted throughout October, the fortress lay in the centre of the battle line and its garrison took an active part in the operations. Its reserves of supplies and material were also largely drawn on by the field armies to make good the deficiencies caused by the poor working of the lines of communication. During their retreat the Russians had systematically destroyed the railways and bridges, and the continued wet weather had rendered the roads almost impassable. Thus it was natural that the reserves of Przemysl should be used for the benefit of the field armies, from whose operations great results were expected at the time. But when the offensive proved fruitless and Russian pressure necessitated a retirement which would leave the fortress again isolated, special efforts were made hastily to reprovision it. They were so far successful that the fortress was enabled to hold out for $4\frac{1}{2}$ months in the second siege.

Second Siege, Nov. 6,1914–Match 22,1915~—Thestrength of the garrison was approximately the same as in the first siege, but a detachment of aeroplanes had been added. Kusmanek had how laid out new entrenched positions from one to two miles in advance of the line of forts, to give more depth to the defence and to keep the Russian siege artillery at a greater distance. On Nov. 9 the investment of the fortress for the second time was complete. The siege was now undertaken by a specially formed XI. Army under General Selivanov, consisting of four divisions of second-line troops. It had been decided to reduce the fortress by blockade rather than by assault. During November and December such fighting as occurred was initiated rather by the sorties of the garrison than by the attacks of the besiegers.

During February and the first half of March the Austrian field armies made repeated efforts to advance to the relief of the fortress, but unsuccessfully (see CARPATHIANS, BATTLES OF THE). Meanwhile the Russians had gradually closed in and had commenced a systematic bombardment of the fortress. On March 13 they carried the advanced positions on its north front. Kusmanek's situation was now desperate; his supplies and munitions were almost exhausted, and the final effort of the field armies to come to his rescue had definitely been abandoned. He determined on an attempt to save a portion of the garrison by a breakthrough to the east. The effort was made on the morning of the 19th, but was soon brought to a stand. The fate of the fortress was now sealed. On the morning of March 22 Kusmanek surrendered, after destroying the works and military stores as far as possible. The numbers of the garrison then amounted to about 110,000.

Recapture of the **Fortress.**—The Russians did not hold the fortress for long. At the beginning of May Mackensen's offensive on the Dunajec broke through the Russian line and drove their armies back to the San (see DUNAJEC-SAN). On May 30 the

Austrians attacked on the south-west and the Germans on the north of the fortress. The former made little progress, but the German heavy artillery, which included 42 cm. howitzers, made short work of the northern group of forts. On the night of June 2 the Russians abandoned the fortress.

Conclusions.—Przemysl was the only land fortress of the World War which stood a prolonged siege after complete investment, but the length of its resistance was seemingly due to the Russians' lack of efficient siege artillery, as is confirmed by the speed with which Mackensen's heavy guns reduced the forts at the time of its recapture. Nor can it be admitted that the fortress served any strategical aim commensurate with the efforts expended on its defence and attempted relief. It is true that its resistance during the first siege was of value to the Austrians when their armies again advanced to the San, in assuring to them a bridgehead over the river. But during the second siege Przemysl was an embarrassment rather than a source of strength and led to several ill-considered efforts at relief which cost the Austrian field armies dearly. The fortress did not control any line of supply vital to the Russian armies operating west of it towards Cracow, since there was a railway available through Jarostow. The Russians could therefore afford in the second siege to resort to a simple blockade by second-lme troops, so that the fortress did not even weaken their field armies to any appreciable extent.

PSALMANAZAR, GEORGE (c. 1679–1763), French adventurer. After various escapades, including a pilgrimage to Rome in the guise of a Japanese convert, he came to London, where he imposed on many people, notably on the bishop of London, who employed him to translate the Catechism into what was supposed to be Japanese. In 1704 and 1707 he published fictitious works on Formosa. Eventually he confessed to his imposture. He died in London on May 3, 1763. His memoirs, Memoirs of . . . commonly *known* by *the name* of George Psalmanazar (1764) do not disclose his real name or the place of his birth.

His fictitious publications include: Historical and Geographical Description of Formosa (1704); *Dialogue* between a Japanese and a Formosan (1707); *An Enquiry* into the Objections . . . *with* George *Psalmanazar's* Answer (undated).

PSALMS, the first in order and importance (cf. Luke xxiv. 44) of the third division of the Hebrew Old Testament, known as the "Writings." The Hebrew name of the Psalms is tehillim, or "praise-songs," which expresses a predominant, though by no means the entire, character of the collection. This anthology of Hebrew poetry also includes petitions (iv.), laments (xliv.), imprecations (lviii.), meditations (cxix.), historical reviews (cvi.), and even a marriage ode (xlv.). But there can be no doubt that the purpose of the collection was to gather the sacred poetry of Israel for use in the post-exilic worship of the temple. This is shown by the technical and professional titles of the psalms, as well as by their general character and their occasional references (note the definite allusions to the destruction of Jerusalem, the exile or the dispersion in li. 18, lxxxix. 38, 44, cvi. 47, cxxvi. 1, cxxxvii. 1, cxlvii. 2).

As the book lies before us, it is a collection of collections, being divided into five books, which themselves contain certain smaller distinguishable groups of psalms. The first four books are each closed by a doxology, at least as old as the Septuagint version (second half of 2nd century B.C.). In Bk. I. (i.–xli.) practically all the psalms are ascribed to David (the exceptions can be explained). In Bk. II. (xlii.–lxxii.) there is more variety, xlii.–xlix. being ascribed to "the sons of Korah," l. to Asaph, li.–lxv. to David. lxvi., lxvii. simply to "the chief musician" or choir-conductor, lxviii.–lxx. to David, lxxii. to Solomon (lxxi. is anonymous). The editorial note at the end of this book, "Finished are the prayers of David the son of Jesse," shows there was once a collection of "Davidic" psalms, and that there has been a rearrangement of material bringing psalms of other groups above the rubric. In Bk. III. (lxxiii.–lxxxix.) there is an "Asaph" group (lxxiii.–lxxxiii.) followed by a miscellaneous appendix (Korah, David, Ethan). We have clear evidence of other editorial work in the overwhelming predominance of the name "Elohim" for God in Psalm xlii.–lxxxiii. as compared with the personal name, "Yahweh" (the occurrences are 200:43; in Psalms, i.–xli. 15:272); this is confirmed by the fact that Ps. xiv. of the first Book reappears as Ps. liii., with its fourfold "Yahweh" changed into "Elohim" (so also in Pss. xl. 13–17 and lxx.). In Bks. II. and III. alone do we get psalms ascribed to guilds of temple-singers. Bks. IV. and V. are divided by the doxology of cvi. 48 (cf. 1 Chron. xyi. 35, 36, where a liturgical formula has been transformed into a historical statement). But the division seems artificial (perhaps made to get five books of psalms corresponding with the five books of the law), since Psalms cv.–cvii. are closely related in subject-matter. If, therefore, we take Bks. IV. and V. together, we find in them a distinct group of "Pilgrim" psalms (cxx–cxxxiv.), and a scattered one of "Hallelujah" psalms (civ.–cvi., cxi.–cxiii., cxv.–cxvii., cxxxv., cxlvi.–cl.) largely liturgical. Ps. cviii. seems to have been made by combining lvii. 7–11 and lx. 5–12, which again proves the existence of separate collections, since the same material would not originally appear twice in the same collection.

The Hebrew psalms are in rhythmical, but unrhymed verse, the most frequent type being that of the three-beat line. The other characteristic of Hebrew poetry is its parallelism ("synonymous," li. 2; "antithetic," i. 6; "synthetic," cxxi. 4). The musical accompaniment was melodic unison, not the harmonies of modern music, so that its chief use, beyond support to the singers, was to synchronize the beats, as by cymbals (1 Chron. xv. 19, xvi. 5). Six distinct instruments are named in Ps. cl. (see Wellhausen, Psalms, Appendix, "Music of the Ancient Hebrews"). The singing was by professional choirs with a response ("Amen," "Hallelujah") from the worshippers (1 Chron. xvi. 36, 2 Chron. xxix. 27, 28). For a glowing description of the ritual see Ecclus. l. 11–21.

At first sight, the contents of the Psalter may seem to occasion relatively little difficulty to the exegete, as compared with the prophecies. The psalms are for the most part simple and often conventional in language, and without those references to obscure historical events which make the writings of the prophets so difficult. But the apparent gain is really a great loss to historical exegesis. Whilst the absence of reference to contemporary events makes the psalms much more capable of use then than now in worship and devotion—it was in some measure due, we may suppose, to elimination and adaptation—yet it also makes the investigation of the original meaning more difficult. Thus it is usually impossible to give a precise historical background to a particular psalm. The titles professing to do this, and to ascribe authorship, are of little use for critical purposes, and represent a late and usually worthless conjecture. Scholars have now generally abandoned the earlier attempts to ascribe particular psalms to precise events from the Davidic down to the Maccabean age; there is considerable variety of opinion as to the nature, date, authorship and origin of the psalms considered individually.

Four main questions arise: (1) to what extent are the psalms primarily and originally "cultic," more or less officially composed for use in public worship, and to what extent are they private religious lyrics, gathered from many sources, and subsequently adapted to use in the temple-services? (2) In close relation with this question comes another as to the significance of the speaker in many of the psalms; does the "I" mean the whole community, or is it an individual person who is speaking? (3) To what period of the religious history of Israel do the psalms chiefly belong, and to what extent are they pre-exilic in origin, though admittedly post-exilic in present adaptation and arrangement? (4) Are they a native product or are they dependent on Babylonian or Egyptian models, as the creation stories of Genesis are dependent on Babylonian mythology? It will be seen that these are not merely academic questions, for each of them may affect the exegesis of a particular psalm. A quarter of a century ago, the answers to these four questions generally given by critical scholarship were as follows: (1) the psalms are chiefly poems of the individual, though some were intended from the outset for use in the temple; (2) the "I" of the psalms usually represents the community; (3) the psalms are almost wholly post-exilic in origin; (4) they are native products. All these answers are now being met with vigorous criticism. At the present moment the protagonists in this criticism are the German scholar, Gunkel, and the Norwegian scholar, Mowinckel. Some account of their views must be given, as they cannot be neglected by the modern student of the psalms.

Gunkel's leading principle is that the psalms should be studied in their "classes" (Gattungen) or types, of which he finds four of chief importance, viz., "hymns" (*e.g.,* cxlv., cxlvii., cxlviii., cl.), "national laments" (*e.g.,* xliv., lxxix., lxxx., lxxxiii.), "individual laments" (iii., xiii., liv., lxxxviii.) and "individual thanksgivings" (xxx., lxvi., 13 seq.). These classes are differentiated by the use of regular formulae, such as "Deliver us, Yahweh," or "I will thank Yahweh," and by more or less regular forms of composition, so that we are not left to subjective impressions only when deciding as to what class a particular psalm belongs. On the basis of this differentiation Gunkel constructs a general history of the "classes," partly from internal evidence, such as the greater length, individualization, or composite character of the later representatives of the class, and partly from the parallels with psalm-like compositions found elsewhere in the Old Testament, which it is possible to date with confidence, such as the Song of Miriam (Exod. xv. 21), the song of the seraphim heard by Isaiah in the temple (vi. 3), the lyrics of Jeremiah and the "Psalms of Solomon" (1st century B.C.). Gunkel's general conclusion is that hymns of praise and national laments were found at an early date, whilst individual laments arose later, but prior to Jeremiah. He admits that prophecy influenced the language, eschatological outlook and spirituality of the Psalms, but claims that this influence was exerted before as well as after the exile. He argues that the existence of similar compositions in Babylonia and Egypt at a much earlier date confirms the intrinsic evidence that "Psalm-composition belongs to the earliest periods of Israel's history."

Mowinckel, whilst recognizing and using the classification of psalms by their type, throws his emphasis on their cultic character, and indeed barely admits the existence of any psalms not cultic in origin (his exceptions are i., cxii., cxxvii.). The psalms were composed by the temple-singers, whom he regards as existing from the early days of the temple. The class of psalms to which he gives primary attention is that containing references to the enthronement of Yahweh as king (xlvii., xciii., xcv.–c., with which many others are to be linked). These he connects with an alleged festival of the New Year (originally beginning in the autumn), a festival after the analogy of that celebrated at Babylon in honour of Marduk. The cultic acts of this festival (*e.g.*, the procession bringing the ark into the temple) were realistically conceived, *i.e.,* they were supposed to help in bringing about that which they "dramatized." Thus they anticipated the future (eschatology) while recalling the past (mythology). There is a similar "realism" in Mowinckel's interpretation of the numerous petitionary psalms, which are held to attribute misfortune and sickness to magicians and sorcerers, who are the original "workers of iniquity" so frequently mentioned. Such psalms were employed, with suitable accompanying rites, as part of the temple-cult; they counteracted adverse magic by exorcisms and imprecations of these "enemies." There were prophets as well as priests, or priest-prophets, attached to the temple, who gave oracles; thus the petition of Ps. lxxxv. 1–7 is answered by the oracle of vv. 8–13. It should be said that a "cultic" interpretation of the psalms as a whole has been independently urged by other scholars, *e.g.,* by J. P. Peters, who further conjectures that the "Elohistic" psalms belonged to northern temples (cf. the northern "Elohistic" saga-writers), the Korahite to Dan, the Asaphite to Bethel, and were afterwards incorporated in the liturgy of Jerusalem.

It will be seen, therefore, that there is considerable division of opinion at the present time in regard to our first question, the cultic element in the Psalter, Mowinckel regarding practically the whole Psalter as cultic in origin, whilst Gunkel regards the majority of the psalms as of private and occasional origin, though subsequently introduced into the cult. On this point Gunkel's view seems more convincing, from the intrinsic evidence and from the general probabilities. Like a modern hymn-book, the Psalter seems to contain many poems not originally intended for use in worship, but subsequently adapted to it—indeed, the religious wealth of the Psalter seems largely due to this variety of origin. On the other hand, Mowinckel does make a strong case for the special interpretation of the psalms of the enthronement of Yahweh, even though he brings far too many under this head. His explanation of the "eschatological" features is also attractive; less so seems his too sweeping connection of sickness and misfortune with magic, though there is probably an element of real truth in his contentions (the tendency of those who discover some neglected truth is to generalize to excess on the basis of it). In a collection so extensive and varied as the Psalter we need not regard any one explanation or theory as necessarily applicable to more than a part of the material. Variety of origin almost follows from variety of date, and their issue is most naturally variety of meaning, even where the same conventional phrases may be used.

In regard to the closely linked question as to the collective or individual interpretation of the speaker in the psalms, Gunkel follows Balla in reaction from the view that was general a quarter of a century ago (*e.g.,* Smend, Cheyne), *i.e.,* that the "I" of the Psalms is collective, personifying the nation. Mowinckel agrees with Gunkel so far as the "individual laments" are concerned, but recognizes a primitive "corporate personality" finding utterance through the leader or king as its representative. We may ask whether this principle does not admit of a wider application than even Mowinckel allows. It seems to go a long way towards explaining the puzzling combination of "collective" and "individual" elements in such a psalm as the xxii., and the rapid transitions so often found (cf. xliv. 5–7 and 14, 15). The same phenomena occur in relation to the Servant of Yahweh in Deutero-Isaiah, and admit of the same explanation—that the primitive mind draws no such hard and fast limits between the individual and the community as we do (see *The* Cross of the *Servant,* by H. Wheeler Robinson, pp. 32–36; The Psalmists, ed. D. C. Simpson, pp. 82 seq.). We may often find it impossible to decide whether a psalm is collective or individual—because the ancient category was neither one nor the other, but a third category including both.

In regard to dating the composition of individual psalms, there seems to be some danger of a similar excessive reaction from the view associated with the name of Wellhausen, open as that is to criticism. The arguments of Gunkel and Mowinckel, amongst others, do show in their different ways that psalms were composed in the pre-exilic period, a fact which has been too grudgingly admitted. The intrinsic evidence of some of the psalms, such as the reference to a human king, or the processional features of the second part of xxiv. ("Lift up your heads, O ye gates"), or the primitive cosmology of the first part of xix., confirms the probability that some of these pre-exilic productions would survive in a post-exilic Psalter. So long as we are thinking of the origin and original meaning of a particular psalm, we must always be prepared to admit that it may go back to a relatively early date, however much modified in its present adaptation to the needs of the second temple. On the other hand, we use any psalm in its present form as an early document only at considerable risk; we may conjecture, but we cannot prove. The main reasons for regarding the contents of the Psalter as largely post-exilic remain unaffected by recent criticism, *i.e.,* those that spring from the general relation of the religion of the psalms to the prophetic religion. If with Gunkel we regard the majority of the psalms as the expression of individual piety, we have to ask whether such wide-spread piety is conceivable before the work of the great prophets. The psalms represent a partial fulfilment of the prophecy of the New Covenant made by Jeremiah; is it likely that they preceded it? We cannot reasonably doubt that the prophets of the 8th and 7th centuries were pioneers, and that they taught truths that were new to their contemporaries, even though they may have used forms of expression and even of thought which were more or less conventional. Nor can there be any doubt that the religion of the Psalter as a whole is closely related to the prophetic teaching. We seem to have parallel phenomena, in the formulation of Israel's laws (Deuteronomy, the Law of Holiness, the Priestly Code) and in the Wisdom Literature; in all three cases ancient elements are given a new setting, but the new setting gives them a pew meaning. Laws, proverbs and psalms are alike reinterpreted and restated in the light of the prophetic teaching, which had certainly taken time to permeate the nation's religion. Nothing has come to us through the editorial sieve that could not be given a plausibly orthodox meaning according to post-exilic standards. Thus the psalms as a whole must still be treated as a post-exilic book. This might be confirmed by the subtler test of psychological usage, hardly to be simulated; the word "spirit," for example, is used of man in the psalms with psychical predicates in a way not found elsewhere in the pre-exilic literature of the Old Testament.

As for the relation of the psalms to the similar compositions of Babylonia, we find many interesting and instructive parallels of form, language and thought, but not less striking differences which must not be ignored, due to the far higher religious standpoipt of Israel, and the suppression of magic in the interests of religion (though some of the older forms and expressions doubtless continued to be used). The resemblances may be partly explained by the independent development of closely related peoples (G. R. Driver, in The *Psalmists,* pp. 109 seq.), and partly by the entrance of the Hebrews into a land dominated by Mesopotamian influence (as the Tell el-Amarna tablets prove); but it is quite possible that there was some direct influence also, even prior to the exile. This possibility also applies, but in a much smaller degree, to the influence of Egypt; there is the well-known parallelism of the "Hymn to the Sun" af Ikhnaton with Ps. civ., which matches the close relation of the "Teaching of Amenophis" to our canonical Book of Proverbs. But whatever contributions came directly or indirectly from without, there is good ground for holding that in all that really matters the Psalter is a native prqduct, and that to Israel still belongs the undiminished glory of carrying the religious lyric to its highest point of development.

Any attempt to characterize the teaching of this anthology must be made with the full consciousness of its variety of authorship, purpose and date. It is the most varied of the books of the Old Testament, and offers many unreconciled antitheses. Devotion to the sacrificial system and ritual of the temple is found side by side with prophetic protests against the popular reliance on them. Faith in the exact retributive justice of God within the limits of earthly life does not exclude the perplexities of those who could not be blind to the sufferings of the innocent and the prosperity of the wicked. The nationalistic demand for supremacy over, and even for vengeance on, enemies is neighbour to the universalistic sense of Israel's missionary stewardship for all the world. The recoil from the shadow of death, which leaves no light of Yahweh's presence beyond the grave, does not wholly prevent the conviction of a fellowship with God that virtually conquers death. But certain comprehensive truths may be usefully remembered in the study of the Psalms.

The central religious principle is, of course, the idea of God. The monotheism is sometimes implicit rather than explicit, for there are a number of references to other "gods" (lxxxvi. 8, lxxxix. 6, xcv. 3, etc.); yet these are perhaps no more than the survival of ancient phraseology. The general standpoint of the psalms is that of an exalted and imageless monotheism (cxv.), unlimited in power, universal in range. The most prominent attributes of Yahweh are "lovingkindness" (*chesedh*) and "righteousness" (*ṣedheḳ, ṣedhaḳah*), combined in cxlv. 17, expanded in xxxvi. 6–11; they are complementary, not antithetical. To these must be added the mystery and majesty of God—the quality which we have come to call "the numinous," best expressed in Ps. xc.; the wrath of God cannot be measured by human norms of right and wrong. This great God is omnipresent (cxxxix. 7–12), and eternal (xc. 1, 2; cii. 26–28). Around this great and exalted personal centre in heaven, but on the lower level of earth, we may trace a series of concentric circles in nature, history, human society, the temple, narrowing at last to the personal religion in which man can look right up to God. Nature is directly controlled in all its detail by God, and no "laws of nature" come between Him and His creation. The cosmology of the "nature" psalms (viii., xix. 1–6, xxix., lxv., civ., cxlviii.) is crude; man walks on a flat earth, with the "shades" of Sheol beneath his feet, and Yahweh with His angels above his head, on the solid firmament; round about the earth is the primaeval ocean and its monsters, overcome long since by Yahweh's creative power. The great facts which emerge from this primitive setting of man's life are the dignity and glory of his high place (viii.) amid the glories of Yahweh's creation (xix. 1–6) and His universal providence (civ.), The power of the enthroned Yahweh is manifest in the majesty of the thunderstorm which sweeps the earth, whilst in the heavenly palace His angels glorify Him (xxix.).

The peculiar providence of God is, however, best seen in the redemptive history of Israel (lxxxi. 10). At great crises. Yahweh has intervened to save His chosen people (cxiv.). The God of the past (cv., cvi.) will be the God of the future, when His rule shall be proved supreme over all (xlvii., and the other "enthronement" psalms). A prince of the house of David shall be his vicegerent (lxxxix. 35 *seq.; cf.* ii., lxxii.) and the final judgment of men shell vindicate His righteousness (i. 5). This is the essential faith of the righteous, the company of those who fear Yahweh and are remembered by Him (*rf.* Mal. iii. 16), the group to whom we seem to owe the most "spiritual" of the psalms. They live in a society of mingled elements, and have many enemies, without and within, for there are imprecations against unworthy Israelites (lxix., cix.) as well as against the ungodly heathen (cxxxvii., lxxxiii., lix., lviii.), and they may be under unjust rulers (lii.). Their great problem is that which troubled the best minds and hearts of Israel, and found no solution within the Old Testament, *i.e.,* the strange and perplexing prosperity of the wicked and the adversity of the righteous in a world governed by an omnipotent and righteous God (xlix., xxxix., xxxvii., lxxiii.).

The sacramental centre of this faith is the Temple in Jerusalem, to which the exile turns with passionate longing (xlii., xliii.—originally a single psalm). (The devotion to the "Law" came later, except for i., xix. 7–14, cxix.) To the temple come the pilgrims from afar (cxx.–cxxxiv.), full of pride in the holy city (xlviii.), the spiritual home af many proselytes as well as of Jewish exiles (lxxxvii.). The temple is Yahweh's earthly dwelling-place (cxxxii. 13, 14) to which His "guests" may come (xv., xxiv.) ; its sacrifices (lxvi. 13–15, cxvi. 13) and processions (lxviii. 24–27, cxviii., xxvi. 6) mark supreme moments of religious experience. This is the normal attitude of the Psalmists towards the temple; but the emphasis of the Book is prophetic rather than priestly, and this finds utterance sometimes in the contrast of "spiritual" religion with external rites (xl., l., li., except for the added verses, li. 18, 19). The personal religion of the psalmists is marked by trust in Yahweh based on history and experience (xvi., xxiii., xci., ciii.), by the consciousness of "righteousness" (xviii. 20–24), not divorced from fundamental ethical qualities (xv., xxiv., ci., l.), by the awakening to a sense of sin and of the need of forgiveness, usually, it would seem, through misfortune, sickness, the fear of death (xxxii., li., cxxx.), and in the highest examples, by a victorious conviction of fellowship with God (lxxiii. 23–26) which even death will not be able to break. This last is the more noteworthy, because there does not seem to be either here or elsewhere in the psalms any explicit teaching of immortality or resurrection (some have found the hope in xvi., xvii.. xlix j.

Such is the relatively simple faith of the most influential book of the Old Testament, which has claimed so supreme a place in the public worship and private devotion of Jew and Christian. Its magical secret lies in its simple and concrete expression of universal religious experience. Its value is altogether independent of our enquiries into its sources; indeed, it has won its place by its lowly submissiveness to reinterpretation in order to meet the ever-changing needs of the unchanging human heart.

PSALTERY, PSALTERION or **SAWTRIE,** an ancient stringed instrument twanged by fingers or plectrum, and mentioned many times in the English Bible, though precisely what form of instrument is implied by these various references is doubtful. In its mediaeval form it consisted of a shallow box-sound-chest over which strings varying in number were stretched, being fastened at one side to pegs and at the other to wrest pins. In the early rectangular form the strings, numbering 10 to 12, were of uniform length, the pitch being varied by their thickness and tension. When the triangular form succeeded the rectangular, the stringing was that of the harp, pitch being dependent on the length. The psaltery was held in an upright position against the chest of the performer, until, owing to the increasing number of strings, it grew too cumbersome, when it was placed flat on a table or on the knee. From the psaltery descended the spinet and the harpsichord.

THE PSALTERY, A MEDIAEVAL INSTRUMENT PLAYED BY FINGERS OR PLECTRUM

PSAMMETICHUS (Egypt. *Psammetk*), the name of three kings of the Saite, XXVIth Dynasty, called by Herodotus respectively Psammetichus, Psammis and Psammenitus. The first of these is generally considered to be the founder of the dynasty; Manetho, however, carries it back through three or four predecessors who ruled at Sais as petty kings under the XXVth, Ethiopian, Dynasty. It is known from cuneiform texts that 20 local princelings were appointed by Esarhaddon and confirmed by Assur-bani-pal to govern Egypt. Niku (Necho), father of Psammetichus, was the chief of these kinglets, but they seem to have been quite unable to hold the Egyptians to the hated Assyrians against the more sympathetic Ethiopian. The labyrinth built by a king of the XIIth Dynasty is ascribed by Herodotus to the Dodecarchy, or rule of 12, which must represent this combination of rulers. If the dynasties were numbered thus before Manetho, the numeral may be the cause of Herodotus's confusion.

After his father's death Psammetichus I. (664–610 B.C.) was able to defy the Assyrians and the Ethiopians, and during a long reign marked by intimate relations with the Greeks restored the prosperity of Egypt. The short reign of the second Psammetichus (594–589 B.C.) is noteworthy for the graffiti of his Greek, Phoenician and Carian mercenaries at Abu Simbel (*q.v.*). The third of the name was the unfortunate prince whose reign terminated after six months in the Persian conquest of Egypt (525 B.C.). It has been conjectured that the family of the Psammetichi was of Libyan origin; on the other hand, some would recognize negro features in a portrait of Psammetichus I., which might connect him with the Ethiopian rulers.

See EGYPT: *History;* on the name, F. Ll. Griffith, *Catalogue of the Rylands demotic papyri;* the portrait H. Schäfer in *Zeitschrift für aegyptische Sprache*, xxxiii. 116. (F. LL. G.)

PSELLUS, MICHAEL CONSTANTINE "the younger," (1018–*c.* 1079), Byzantine writer, was born at Nicomedia, or Constantinople, of a consular and patrician family. Under Constantine Monomachus (1042–1054) he became one of the most influential men in the empire. As professor of philosophy at Constantinople he revived the cult of Plato at a time when Aristotle held the field. At the height of his success as a teacher he was recalled to court, where he became state secretary and vestarch, with the honorary title of Ὕπατος τῶν Φιλοσόφων (prince of philosophers). Presently he entered the monastery of Olympus (near Prusa in Bithynia), where he assumed the name of Michael. But, finding the life little to his taste, he resumed his public career. Under Isaac Comnenus and Constantine Ducas he exercised great influence, and was prime minister during the regency of Eudocia and the reign of his pupil Michael Parapinaces (1071–1078). It is probable that he died soon after the fall of Parapinaces.

In character Psellus was servile, unscrupulous and weak. But as a literary man, he will be remembered as the forerunner of the great Renaissance Platonists His works embraced politics, astronomy, medicine, music, theology, jurisprudence, physics, grammar and history.

Of his works, which are very numerous, many have not yet been printed. We may mention: *Chronographia* (from 976–1077); three Epitaphioi or funeral orations over the patriarchs Cerularius, Lichudes and Xiphilinus, and nearly 500 letters. The most important of his works have been published by C. Sathas, who has also edited the *Chronographia* in Methuen's Series (1899), in his Μεσαιωνικὴ βιβλιοθήκη, iv. 5. On Psellus himself *see* Leo Allatius, *De Psellis et eorum scriptis* (1634); J. E. Sandys, *Hist. of Classical Scholarship* (1906), i. 411; P. Würthlein, *Rhetorische Studien*, Paderborn (1919).

PSEUDO-DIPTERAL, in architecture, a term applied to a temple in which the single row of columns at the side of the cella is separated from the cella wall by a space equal to the distance between two pairs of adjacent columns, so that the width of the whole is the same as if the colonnade on each side were a double one.

PSEUDO-PERIPTERAL, in architecture, a term applied to a building or temple in which the cella or enclosed portion has engaged or attached columns which line with the side columns of the front porch or portico, and thus simulate a surrounding colonnade. Examples are: the temple of Zeus at Agrigentum in Sicily (probably late 6th century B.C.), in which the cella wall includes all the columns of the exterior; and the more normal *Maison Carré* at Nîmes (probably about A.D. 1). In certain Roman examples, such as the temple at Tebessa in Algeria (probably of the Antonine period), pilasters replaced the engaged columns.

PSEUDOPOD, PSEUDOPODIUM, an extension of the naked protoplasm of certain Protozoa for crawling or for the prehension of food, but not for active swimming (*see* AMOEBA).

PSICHARI, ERNEST (1883–1914), French author, grandson of Renan, and son of Jean Psichari, director of studies at the École des Hautes Études in Paris, was killed on the Western Front on Aug. 22, 1914. He was one of the leaders of the young generation before the World War who sought to "rationalize" war and the defence of their country; he sought to provide the psychological basis for heroic action. His work is that of an intellectual who must justify the "great sacrifice." In the year before the World War *L'Appel des armes* had a powerful moral effect among young intellectuals. It is the story of a captain in the Algerian army who converts to the military ideal the anti-militarist son of an internationalist, who finds mental peace in military obedience. This book was followed by *Les Voix qui crient dans le désert. Le Voyage du Centurion* appeared as the finished form of this work. In 1917 Jean Psichari presented to the Luxembourg library his collection of 25,000 volumes on mental subjects, in memory of his son Ernest. A second son, Michel, was killed in May 1917.

See Henri Massis, *La Vie d'Ernest Psichari* (1916); L. Aguettant, *Ernest Psichari* (1920); H. D Noble, *Ernest Psichari; sa conversion religieuse* (1924); A. M Goichon, *Ernest Psichari, etc.* (1925).

PSILOMELANE, a mineral consisting of hydrous manganese oxide with variable amounts of barium, potassium, etc., of importance as an ore of manganese. The amount of manganese present corresponds to 70–80% of manganous oxide with 10–15% of "available" oxygen. The mineral is amorphous and occurs as botryoidal and stalactitic masses with a smooth shining surface and submetallic lustre. The name has reference to this characteristic appearance, being from the Greek ψιλός (naked, smooth) and μέλας (black); a Latinized form is calvonigrite, and a German name with the same meaning is Schwarzer Glaskopf. Psilomelane is readily distinguished from other hydrous manganese oxides (manganite and wad) by its greater hardness (H=5·5); the sp.gr. varies from 3.7 to 4.7. The streak is brownish-black and the fracture smooth. The mineral is soluble in hydrochloric acid with evolution of chlorine, and occurs under the same conditions and has the same commercial applications as pyrolusite (*q.v.*). It is found at many localities; amongst those which have yielded typical botryoidal specimens may be mentioned the Restormel iron mine at Lostwithiel in Cornwall, Brendon Hill in Somerset and Hoy in the Orkneys. With pyrolusite it is extensively mined in Vermont, Virginia, Arkansas, Nova Scotia and India. A distinctly crystallized variety from India has been called hollandite.

PSITTACOSIS, an acute disease often with typhoid-like characteristics (see TYPHOID FEVER) and ending fatally in a large proportion of cases. It is conveyed to man by parrots suffering from the disease, either directly or by way of their dried excreta. A bad outbreak of the disease occurred in Argentina in 1929 and in England in 1928–29. Cases have also occurred in other parts of Europe and in the United States. It is doubtful whether the cause is due to Bacillus psittacosis, first isolated in 1892 or to a filter-passing virus (*q.v.*). (See Brit. Med. Jn. 1930, i. 197.)

PSKOV, in German, Pleskau, a town of Russia in the Pskov district of the Leningrad area, in 57° 48' N., 28" 22' E., situated on both banks of the Velikaya river, 9 m. S.E. from Lake Pskov. Pop. (1933) 52,600. The chief part of the town, with its kremlin on a hill, occupies the right bank of the river, to which the ruins of its old walls (built in 1266) descend. The old cathedral in the kremlin has been four times rebuilt since the 12th century; the present edifice (1691–99) contains some very old shrines, as also the graves of the bishops of Pskov and of several Pskov princes. The church of Dmitriy Solunskiy dates originally from the 12th century; there are others of the 14th and 15th.

History.—Pskov, formerly the sister republic of Novgorod and one of the oldest cities of Russia, maintained its independence and its free institutions until the 16th century, being thus the last to be brought under the rule of Moscow. It already existed in the time of Rurik (9th century); and Nestor states that in the year 914 that Olga, wife of Igor, prince of Novgorod, was brought from Pleskov (*i.e.,* Pskov). The Velikaya valley and river were from a remote antiquity a channel for the trade of the south of Europe with the Baltic coast. Pskov being an important strategic point, its possession was obstinately disputed between the Russians and the Germans and Lithuanians throughout the 11th and 12th centuries. It became in the 12th century a *prigorod* of the Novgorod republic—*i.e.,* a city having its own free institutions, but included in certain respects within the jurisdiction of the metropolis, and compelled in time of war to march against the common enemy. Pskov had, however, its own prince (*defensor municipii*); and in the second half of the 13th century Prince (Timotheus) Dovmont fortified it so strongly that the town asserted its independence of Novgorod, with which, in 1348, it concluded a treaty wherein the two republics were recognised as equals. Its rule extended over the districts of Pskov, Ostrov, Opochka and Gdov (farther north on the east side of Lake Peipus). The *vyeche* or council of Pskov was sovereign, the councils of the subordinate towns being supreme in their own municipal affairs. The council was supreme in all affairs of general interest, as well as a supreme court of justice, and the princes were elected by it; these last had to defend the city and levied the taxes, which were assessed by 12 citizens. But while Novgorod constantly showed a tendency to become an oligarchy of the wealthier merchants, Pskov figured as a republic in which the influence of the poorer classes prevailed. Its trading associations, supported by those of the working classes, checked the influence of the wealthier merchants,

Its strong walls and its 40 large and wealthy churches bear testimony to the wealth of the inhabitants, who then numbered about 60,000. As early as the 13th century Pskov was an important station for the trade between Novgorod and Riga. A century later it became a member of the Hanseatic League. Its merchants and trading associations had factories at Narva, Reval and Riga, and exported flax, corn, tallow, skins, tar, pitch, honey and timber for shipbuilding. Silks, woollen stuffs and all kinds of manufactured wares were brought back in exchange. In 1399 the prince of Moscow claimed the privilege of confirming the elected prince of Pskov in his rights; and though, 50 years later, Pskov and Novgorod concluded defensive treaties against Moscow, the poorer classes continued to seek at Moscow protection against the rich.

After the fall of Novgorod (1475) Pskov was taken (1510) by Basil Ivanovich, prince of Moscow, and a voyvode or deputy was nominated to govern the city. Moscow, at the end of the 17th century, abolished the last vestiges of self-government at Pskov, which thenceforward fell into rapid decay. Near this city the Teutonic knights inflicted a severe defeat upon the Russians in 1502. Pskov became a stronghold of Russia against Poland, and was besieged (1581) for seven months by Stephen Bathory during the Livonian War, and in 1615 by Gustavus Adolphus of Sweden. Under Peter the Great it became a fortified camp. Under the Tsarist régime the government of Pskov extended from Lake Peipus to the sources of the western Dwina, and after the 1917 revolution the province of Pskov, though much diminished, remained an pdministrative unit. In 1927 it was incorporated in the newly created Leningrad area (*q.v.*).

PSORIASIS, a skin affection characterized by flat dry patches of varying size covered with silvery white scales. It occurs frequently during infancy and early adult life, and rarely begins after fifty. Though a parasitic origin has been suggested, no bacteriological factor has yet been found. The usual starting point is either the elbows or the fronts of the knees. It is nearly always symmetrical in its distribution, and spreads over the trunk and the extensor surfaces of the limbs, in contrast to eczema, which selects the flexor surfaces. The hairy scalp may also be affected. The symptoms are usually slight, there is little itching, and no pain except in a form which is associated with osteo-arthritis. The disease, though chronic, is subject to sudden exacerbations. The most effective local application is chrysarobin used as an ointment. After a hot water or alkaline bath, in order to remove all the scales, the ointment is applied, but must be used over a small area at a time, as it is apt to set up dermatitis. Unguentum picis liquidae, creosote ointment or liquor carbonis detergens, the sulphur-water baths of Harrogate, Aix-les-Bains and Aachen, radium and X-rays are also useful in some cases. The internal administration of antimony in acute cases, or of arsenic in chronic cases, is beneficial.

PSOROSPERMIASIS, the medical term for a disease caused by the animal parasites known as psorosperms or Gregarinidae, found in the liver, kidneys and ureters.

PSYCHE, in Greek mythology, the personification of the human soul. The importance, in Platonic philosophy, of love (in the highest sense) as an agent of the soul's progress leads, in art from the 4th century B.C., to representations, allegorical or playful, of Psyche (generally represented as a winged girl, a relic of the old conception of the soul as a bird or insect) in company with Eros (*q.v.*), usually in amatory scenes. The tale of Cupid and Psyche, in the Metamorphoses of Apuleius, is interesting as the only ancient fairy-tale which is told as such. In it Psyche, the youngest daughter of a king, arouses the jealousy of Venus, who orders Cupid to inspire her with love for the most despicable of men.

Cupid, however, falls in love with her and carries her off to a secluded spot, where he visits her by night, unseen and unrecognized by her. Persuaded by her sisters that her companion is a hideous monster, and forgetful of his warning, she lights a lamp to look upon him while he is asleep; in her ecstasy at his beauty she lets fall a drop of burning oil upon the face of Cupid, who awakes and disappears. Wandering over the earth in search of him, Psyche falls into the hands of Venus, who forces her to undertake the most difficult tasks. The last and most dangerous of these is to fetch from the world below the box containing the ointment of beauty. She secures the box, but on her way back opens it and is stupefied by the vapour. She is only restored to her senses by Cupid, at whose entreaty Jupiter makes her immortal and bestows her in marriage upon her lover.

BIBLIOGRAPHY.—See O. Waser in Roscher, *Lexikon*, III., 2,327, et seq.; L. C. Purser, *The Story of Cupid and Psyche* (1910).

PSYCHIATRY, a special branch of medical science dealing with the causes, symptoms, course and treatment of disorders and diseases of the mind. The ultimate aim of this branch of medicine should be to ascertain the best means to promote normal thought and action individually and collectively, and to apply the knowledge so obtained to the causation and prevention of mental defects, disorders and diseases. See ABNORMAL PSYCHOLOGY; PSYCHOSIS, etc.

The causes of mental disorders and diseases are never single, but they naturally fall into two great groups: (1) Endogenous (from within) and (2) Exogenous (from without). They may be somatic, psychical or social. The hereditary factor is the most important endogenous cause.

The Endogenous Factor of Mental Disorders.—The life of the individual begins at the moment of conception, *i.e.*, at the conjugation of the male and female germ cells. The raw material of character is a complex of inherited tendencies and dispositions impressed upon the individual by sex, species, race and ancestry, giving each individual a specific predetermined plasticity to receive and store stimuli and react to them in a particular way. Like tends to beget like—as Galton's History of Similar *and* Dissimilar *Twins* shows, in the dispositions and temperaments of the offspring.

A well-balanced mind is due to an inherent equipoise of the latent potentialities of character, and its efficient activity depends upon the potential psychophysical energy derived from the parental stocks. The study of heredity (1) by statistics, (2) by pedigrees and (3) by experience shows the importance of this factor in the causation of the true insanities which are not due to organic brain disease, where chance counts for everything and heredity for little or nothing. The raw material of mentality is conditioned by the innate potentialities of the fertilised ovum as it starts its course in life. At later stages of development, the fertilised ovum is influenced by pre-natal and post-natal exogenous environmental factors in addition to the hereditary factors.

Pre-natal Exogenous Factors.—Much may happen while the embryo is developing in the mother's womb. Owing to abnormal conditions of growth, interfering with the circulation and nutrition of the great brain, various degrees of arrest of development of the highest and latest evolutional structures of the brain may occur, viz., the cerebral hemispheres, which by their size especially distinguish the brain of man from the lower animals, and to which he owes his superior intelligence, may suffer from various congenital effects. (See INSANITY.) Likewise prolonged labour or unskilful use of instruments may damage the brain and arrest growth.

Hereditary Factors.—Study of the hereditary factor in psychoses and psychoneuroses by the construction of a large number of pedigrees extending to three, four and five generations with collaterals, and by a card system of 4,000 relatives who were or who had been in the London County Council asylums, proves that heredity plays a very important part in neuroses and psychoses.

Neuroses may be classified as follows: (1) hysteria, (2) neurasthenia, (3) obsessional psychasthenia, (4) epilepsy and (5) migraine; and psychoses as (1) paranoia (systematised delusional insanity), (2) dementia praecox, (3) manic-depressive insanity, of which there are several types, viz.: alternating periods of excitement and depression (folie *circulaire*) and recurrent periods of maniacal excitement or of melancholic depression, alternating with periods of sanity, (4) involutional melancholia occurring at the climacterium in women, also in men between the ages of 55 and 65, though less frequently met with than in women. Both the latter forms of mental disorder may terminate in dementia.

These three last-named types are in some ways related to one another, and their onset is associated with the maturation or waning of the sex instinct. An involutional melancholic or senile dement may have offspring in whom manic-depressive insanity or dementia praecox may occur in adolescence, or a parent with manic-depressive insanity may have one or more offspring with dementia praecox. This phenomenon together with the fact that not infrequently several members of the same co-fraternity suffer with either dementia praecox or manic-depressive insanity or an atypical form, coming on at puberty or adolescence, at about the same age, shows antedating and hereditary predisposition as the important factor. There may be atypical cases in some respects resembling both these forms of mental disease, and it is a matter of opinion to which category a particular case should belong. This shows how fallacious classifications may be. The many changes which Krapelin has made in his classification emphasise the fact that each case must be regarded as a biological problem with two factors to consider, viz.: what an individual was born with; and what happened after fertilisation of the ovum—that is, pre-natal and post-natal conditions. There is, it seems, a causal correspondence in these three types of insanity connected with the "life reaction" of the primal instinct of propagation.

Disintegration of Psychic Unity.—The biological concept of mental disease propounded by Hughlings Jackson in his Theory of Evolutional Levels will help in the understanding of the causes and symptoms of insanity—dissolution of the highest level bringing into relief lower levels. Thus a negative condition of the highest evolutional level of control permits of over-action of the lower level of ideation, *e.g.*, the delirium of fever. In mental disorders there may be a negative condition of the highest level of control with disordered ideation manifested by hallucinations and delusions, owing to partial disintegration of the psychic unity. Such hallucinations and delusions may determine various active uncontrolled and irresistible impulses—disorders of conduct. When the disease has sunk to a lower depth of dissolution of evolutional levels there may result emotional indifference and apathy reflected in a mask-like expression, and motor inertia or katatonic stupor with *flexibilitas* cerea. Stuporose states with mental confusion indicate a more diffuse toxic influence on evolutional levels and are more hopeful of recovery than the persistence of hallucinations and delusions, the mind remaining clear.

Post-natal Exogenous Causes.—These do not play an important part per se in the production of the true insanities. They may, however, act as exciting or contributory causes in individuals with an hereditary latent tendency. Stress per se from disease and disasters of every kind cannot be the important factor believed to be in the production of the true insanities as distinct from organic brain disease, *e.g.*, general paralysis and lethargic encephalitis. This was clearly shown during the World War by the fact that Bonhoffer, an eminent Austrian psychiatrist, only found five insane among 10,000 Serbian prisoners.

Organic brain disease may cause various symptoms of irritations such as fits, headaches, pains, stiffness of muscles, and delirium or drowsy stupor, loss of memory, paralysis and dementia, according to the pathological process and the structures affected.

PSYCHICAL RESEARCH is the study of the supernormal faculties (real or supposed) of human personality. The word "supernormal" is merely a short equivalent for "not recognized by general scientific opinion," and is free of all implications of the "supernatural." The function of psychical research is to collect and weigh all the available evidence for and against all such supposed faculties, to the end that they may either be accepted by general scientific opinion, or may safely be consigned to oblivion.

Thus some of the subjects mentioned in the original programme of the Society for Psychical Research (founded 1882) have already passed out of its scope, "hypnotism" for example, and "Reichenbach's rays." Mainly as the result of the labours of members of the S.P.R. in different countries, the study of hypnotism was brought to a point where it could be handed over to specialists in medical psychology, while the existence of "Reichenbach's rays" was fairly well disproved.

But, for the most part, the "debatable phenomena" of 1882 remain almost as debatable in 1929. This would be a surprising fact, in view of the number of scientists and philosophers of the highest eminence, who have interested themselves in psychical research, if the study were not one of exceptional difficulty.

"Mental" and "Physical" Phenomena. — It is customary to divide the phenomena of psychical research into two classes, "mental" and "physical." If a table is moved without the application of any force known to science, that is a "physical" phenomenon. If a medium in trance gives information outside his normal knowledge, that is a "mental" phenomenon; there is not necessarily anything supernormal in trance-speaking: the supernormality is to be found, if anywhere, in the content of the words spoken. If, however, the information is given through a trumpet floating in the air at a distance from the medium, that is both a "physical" and a "mental" phenomenon. The main problem of psychical research on the "physical" side is whether the alleged phenomena in fact occur; with the "mental" phenomena the evidence permits us to accept the occurrence of some of them as a working hypothesis, and to proceed to the further stage of attempting an explanation.

The reasons why the two branches of research vary so widely as to the progress made are not far to seek. The student of mental phenomena can avail himself of three lines of approach, and compare the results obtained along one line with those obtained along the other two. He can compare the records of professional trance mediums with a large quantity of good evidence for spontaneous phenomena on the one hand, and with the results of experiments conducted with quite non-professional automatists of good repute on the other. The student of physical phenomena is more limited: such spontaneous phenomena as Poltergeists do not, for reasons discussed later, give him much serious assistance; the unprofessional "physical" medium has been, since the death of Stainton Moses, hard to discover; he is, therefore, practically confined to the observation of professional mediums.

Unfortunately the quality of professional "physical" mediums has declined since the golden age of D. D. Home (died 1886). Home, who accepted no fees, but lived by his mediumship, and may therefore be classed as semi-professional, sat under conditions, as regards light in particular, much more favourable for observation than modern mediums will submit to, and enjoyed an immunity from exposure which most of his successors may envy. Against this it must be noted that the technique of investigation was then in its infancy, and that while many of Home's sitters were persons of distinction, such as Crookes, they were not experts in this particular line.

Spontaneous **Physical** Phenomena. — Poltergeists (a German term meaning "Racketing Spirits") constitute the principal type of spontaneous physical phenomena. The word, which has now became a technical term without any spiritistic implications, is used to describe those frequently recurring cases of strange noises, movements of furniture and breakages of crockery which appear inexplicable to the inmates of the houses where they occur, and also similar cases of stone-throwing out of doors. Cases of this kind have been recorded for many hundreds of years, and from all parts of the world, civilized and barbarous; familiar instances in England are the Tedworth Drummer (1662) and the occurrences in the Wesley household at Epworth (1716–1717).

It would at first sight appear as if Poltergeists should provide a useful standard of comparison for arriving at an opinion as to what causes, supernormal or otherwise, produce similar phenomena in the séance room. Unfortunately, they give little assistance. In the earlier cases (up to, say, 1850 or thereabouts), the observers, even where they were intelligent and responsible persons like the Wesleys, did not know what were the significant points to which to direct their attention; and nowadays the investigator who knows what to look for does not usually arrive on the scene until a crowd of enterprising journalists, dogmatic spiritualists, and sensation-hunting members of the public has hopelessly "queered the pitch," and prevented the collection of first-hand, uncoloured evidence. The best Poltergeist cases, from the student's point of view, are those investigated in the latter half of the 19th century. There is a good collection of cases occurring between 1883 and 1896, and analysed by F. Podmore, in S.P.R. *Proceedings* vol. xii.; and the spirited controversy between Podmore and Andrew Lang in vol. xvii. of the *Proceedings* is instructive.

Poltergeist cases show a degree of uniformity which is remarkable, in view of their being so widely distributed in time and space. It can almost invariably be shown that there is some one agent whose presence is essential for the production of the phenomena, although occasionally a secondary agent assists in their production; if the principal agent is removed the phenomena cease at once. The agent is usually a person of some marked mental or physical abnormality, often a girl in her "teens," less often a boy of the same age, and only rarely an adult. In some cases there is obvious trickery, easily discoverable by any fairly good observer; in others the trickery is so cleverly done that only a skilled investigator can find it out; in a few cases trickery does not seem to be an adequate explanation of the facts, assuming these to have been accurately reported. Finally, there is an absence of any apparent motive sufficient, from the point of view of a sane adult, to account for all the trouble to which the agent puts himself and others; nothing is gained by the agent but the notoriety of a nine-days' wonder.

The problem is whether the undoubted existence of fraud (usually "hysterical fraud") in many of the cases justifies us in assuming that the same factor has operated in the unexplained residue. Podmore thought that it did; Lang that it did not. The controversy remains very much where they left it, owing to the paucity of well-recorded cases in recent years.

Although Poltergeists, for the reasons stated, are not as helpful in the study of experimental physical phenomena as might be expected, or as they would be if competent observers were given a fair chance to observe them, there are, nevertheless, two ways in which they throw a useful light on doubtful problems of the dance-room. First, on the question of motive: with the evidence derived from Poltergeist cases in mind, it is less difficult to imagine that "physical" mediums, who often have a strong vein of childish vanity, may think that the sensation they create by their performances is in itself, quite apart from any material advantage, a sufficient compensation for maintaining over a long period an elaborate scheme of deception, sometimes imposing on the medium no little physical discomfort. Secondly, as to the ease and rapidity with which skill in deception is acquired: a child after a few weeks' practice and relying on its own perverted ingenuity, may produce phenomena as baffling as a professional medium who has had years in which to perfect his technique, and who has some knowledge of the methods of other mediums.

Experimental Physical Phenomena. — The word "experimental" is open to misunderstanding; the investigator of séance-room phenomena soon discovers that the limits within which he is permitted to experiment are extremely narrow, that the subject-matter of his proposed "experiments," the medium, dictates most of the crucial conditions of the investigation, and that for all practical purposes he is simply an observer.

It is impossible to classify, or eveh enumerate, all the kinds of "physical" phenomena which have been reported; they include apparent breaches of all the generally accepted laws governing matter. Two kinds, however, have received closer study and attained more credence than the rest, telekinesis and teleplasm (also called ectoplasm).

Telekinesis is the movement of objects without the application of any physical force known to science, and has a history dating back to the early days of spiritualism. Horne, Eusapia Palladino, Kathleen Goligher, Willy Schneider and "Margery" (Mrs. Crandon) may be named amongst the best known telekinetic mediums.

Teleplasm is a "substance" extruded from the medium's body; it may be either wholly invisible, or visible but amorphous, or it may take the form of a complete human figure, apparently endowed with energies of its own, like "Katie King," to whose reality Crookes testified. Among recent teleplastic mediums may be mentioned Eva C., Kluski, Kathleen Goligher, "Margery."

It will be noted that two names are common to the telekinetic and teleplastic lists, and as the result, especially of Crawford's experiments with Kathleen Goligher, it is a general opinion among those students who accept the genuineness of both classes of phenomena (and they include several scientists of repute, especially on the Continent), that it is by force exerted through teleplastic rods or structures that telekinetic movements of objects are effected. For teleplasm itself the "ideoplastic" theory has gained wide acceptance. According to this theory, teleplasm is moulded into definite shape by the thoughts of the medium and the sitters; attempts have been made to fortify the theory by analogies from the real or supposed facts of normal biology, the influence, *e.g.,* of a mother's thoughts on the development of the child within her womb.

For telekinesis pure and simple it is easy to formulate methods of control, adequate to prevent deception without being harassing to the medium. Telekinesis would rest on a firm basis if it were certain that in all cases where positive results are reported, the conditions of control stated in the reports had, in fact, been continuously exercised throughout the sittings. But telekinesis has, of recent years, become very closely associated with teleplasm, and the control adequate for telekinesis is not adequate for teleplasm. This substance is reported to possess at different times such contradictory properties as to make the task of formulating conditions for sittings where its production is anticipated extremely difficult. Too delicate to endure even the lightest touch, but strong enough to shift heavy weights; sometimes so sensitive to light as not to be able to endure even the dim glow of a red lamp, at other times so insensitive as to be capable of being photographed by flash-light; how is the researcher to plan conditions in advance, when he cannot know in which form the substance may appear?

At present there is a deadlock in the research into "physical" phenomena, owing to the encouragement given to mediums who pick and choose their sitters, and dictate conditions which seem to serve no purpose except to make control more difficult (*e.g.,* the constant presence of a "next friend" at all sittings). Such mediums can find no lack of investigators willing to take them seriously, and all the publicity they need in the all too hospitable columns of many "psychic" periodicals. Unless and until an international pact between researchers is made (and observed) not to print any report of mediums who decline to sit under reasonable test conditions (without a "next friend") to any responsible investigator who asks for a sitting, no progress can be made. Much of the literature on telekinesis and teleplasm is worthless, but a good *prima facie* case for further investigation can be found in the reports in S.P.R. *Proceedings* on Eusapia Palladino (vol. xxiii.), Eva C. (vol. xxxii.) and Willy Schneider (vol. xxxvi), and in Schrenck-Notzing's records of his sittings with the two last-named.

Combined Mental and Physical Phenomena. — Slate-writing, "spirit photography" and trumpet-mediumship all seem convincingly fraud-proof to those who have not made themselves familiar with the records of what can be, and has been, done in the way of reproducing these phenomena without recourse to the supernormal; see, *e.g.,* Hodgsop and Davey's paper in S.P.R. Proceedings, vol. iv. The "mental" and "physical" elements should be judged separately, neither being permitted either to support or to discredit the other. Thus, though the trumpet business is, in general, open to suspicion, there is some evidence for super. normality in the content of messages received through some trumpet-mediums (*e.g.,* Valiantine and Mrs. Blanche Cooper),

Mental Phenomena. — These consist, for the most part, in some form of "supernormal cognition," that is, knowledge shown by a percipient of matters which he has no normal means af knowing. ("Percipient" is here used, for lack of a better word, to include not only percipients in telepathy, but automatists of all kinds, trance mediums, etc.) The supernormal knowledge may relate to another person's thoughts, or to events distant in time or space; it may arise spontaneously, so far as the percipient is concerned, or as the result of deliberate experiment on his part. The percipient may be in the normal waking condition, or asleep, or in trance, or in the state of slight dissociation produced by *crystal-gazing* (see separate article) or other similar devices.

Telepathy and Clairvoyance. — It is best to treat these two terms as complementary and mutually exclusive, assigning all manifestations of supernormal knowledge derived from another person's mind to telepathy, and all manifestations of supernormal knowledge not so derived to clairvoyance. It is not, however, easy to say under which head every particular case should be classified: to meet this difficulty Richet has coined the inclusive word "cryptaestheoia."

Supernormal cognition in some form is the most generally accepted phenomena of psychical research. The evidence for it, both spontaneous and experimental, is impressive alike in quantity and quality. Some of it is ambiguous as between telepathy and clairvoyance; so far as discrimination is possible, the first is better attested than the second.

Spontaneous and Experimental Phenomena. — The spontaneous evidence is particularly strong. One of the first tasks of the S.P.R. was to undertake a "census of hallucinations" of various kinds, particularly of apparitions of dying or recently dead persons, seen by friends who were at a distance, and who had no normal reason for anxiety. Gurney, Myers and Podmore, who analysed the results *(Phantasms of the Living,* 1886) came to the conclusions: (1) That such apparitions occurred too frequently to be explicable by chance-coincidence: elaborate statistics are given in support of this conclusion; (2) that in the majority of cases the most probable explanation was the transmission of an impression from the mind of the dying man to the mind of his friend, and these externalized in the form of a "subjective hallucination," rather than the presence of any semimaterial wraith. The society has continued to investigate cases of this kind; a large number are collected and classified by Mrs. Sidgwick in vol. xxxiii. of its *Proceedings.*

If the experimental evidence for clairvoyance were as good as that for telepathy, veridical hallucinations could, in most cases, be attributed with equal probability to either faculty, although the rare cases, in which the agent has succeeded in consciously willing that the percipient should see an apparition of him, are clearly telepathic. At the time when *Phantasms of the Living* mas written the experimental evidence for clairvoyance was so slight as to lead the authors decisively to reject it as an explanation of the cases they were considering. The evidence for clairvoyance is rather stronger now, and in cases of veridical hallucinations not coincidental with the death of the person whose phantasm is seen, or with any other crisis, such as illness or accident, from which telepathic activity on the part of his sub-conscious mind might reasonably be inferred, the possibility of clairvoyance pure and simple cannot be excluded.

Experimental Telepathy and Clairvoyance.—Experiments in thought-transference have been conducted for many years past in most civilized countries, and the conditions of the experiments have been diverse. Sometimes the percipient has been in a normal waking condition, sometimes in hypnosis; sometimes in the same room or house as the agent, sometimes at a distance of many miles, or even in a different country. The subject matter has also varied greatly; attempts have been made to transfer impressions of numbers, simple or complex diagrams, the suit and value of playing cards, landscapes or pictures, incidents from books and imaginary scenes. Records of various experiments on these lines will be found in S.P.R. Proceedings passim, and in books such as N. W. Thomas's Thought Transference (1905), Tischner's *Telepathie und Hellsehen*, Warcollier's La *Télépathie*.

In experiments with numbers or a pack of cards it is possible to make a statistical computation as to how far (if at all) the successes exceed those which can be assigned to chance; the mathematics are not quite as simple as is sometimes supposed (see Proc., vol. xxxiv., p. 185 sq.). In experiments with diagrams, scenes and incidents, no such computation is, of course, possible.

Where agent and percipient are in the same room, the possibility of hyperaesthesia (*i.e.*, an unusual acuity of the normal senses of sight, hearing, etc.) must be taken into account. This is the explanation which Prof. Gilbert Murray is disposed to accept for the remarkable successes obtained by him in receiving impressions of incidents from books or imaginary scenes (see S.P.R. *Proceedings*, vols. xxix. and xxxiv.). Prof. Murray was not, in fact, in the same room as the agents, and for this and other reasons it is difficult to accept hyperaesthesia as the explanation. It is greatly to be regretted that Prof. Murray has not continued the experiments under conditions which would leave no reasonable doubt as to the operative cause.

Another factor, which does not always receive sufficient attention, is that of fatigue or boredom on the part of the percipient. From recent experiments in clairvoyance by Miss Jephson in England (S.P.R. Proc., vol. xxxviii.) and Estabrooks in America (Boston S.P.R. *Bulletin* 5) it is clear that there is a well-marked "fatigue curve," that is to say, there is a tendency for percipients to score most of their successes in the early stages of an experiment, while in the later stages the results may fall definitely below the line of chance probability, apparently as the result of some inhibition due to boredom or confusion.

For experiments where the agent and percipient are widely separated see S.P.R. Proceedings, vol. xxi. Experiments are now in progress between a French group, organized by Warcollier, and an English group organized by S. G. Soal.

Reference has already been made to Miss Jephson's recent experiments in clairvoyance, but so far much less has been accomplished with clairvoyance than with telepathy. The usual form of experiment is to set the clairvoyant to "guess" the suit and value of cards taken from a shuffled pack held face downwards, or the content of writings enclosed in envelopes externally identical in appearance; if the experiment is properly carried out nobody has normal knowledge of the correct answer, and telepathy is therefore excluded. Where the clairvoyant is not a person whose *bona fides* is absolutely above suspicion, the same precautions against deception and the same alertness on the observer's part are necessary as in investigating "physical" phenomena. The reading of the contents of sealed letters, in particular, is a favourite trick of dishonest mediums. For some successful experiments with sealed envelopes, in which the investigators were fully on their guard, see the Report of the Warsaw International Congress (1923), p. 201.

The **Modus** Operandi in Telepathy and Clairvoyance, While taking the spontaneous and the experimental evidence together, there is a strong case of accepting telepathy, and a fair case for accepting clairvoyance, there are still many obscure problems as to the manner in which these two faculties function. It may, for instance, be asked: Are the faculties common to all humanity, or confined to particular individuals? How far does the exercise of them depend on conscious effort? In what form are impressions conveyed, as words, as ideas, as visual images? Are they conveyed by means of any physical "waves" or "effluence"?

To some of these questions it is possible to suggest a tentative answer. Ideas may be telepathically transmitted without conscious deliberate effort on the part of either agent or percipient, transmission taking place between their subliminal minds direct. In some cases the agent justifies his name by deliberately willing to transmit impressions; in others it is possible that it is the percipient's subliminal mind which goes to look for impressions, so to speak, rather than passively receives them. The fact that the process takes place subliminally makes it impossible to estimate how frequently it occurs. It has even been suggested that every subliminal is constantly transmitting impressions to, and receiving them from, every other subliminal, and that from time to time something happens which, as regards a particular percipient, raises the height of the unperceived, ever flowing stream above the level of consciousness. It is hard to imagine any kind of evidence which could either prove or disprove such an hypothesis, which seems to have been invented simply as a weapon to be used against spiritists, when all others fail (see p. 671, "Evidence for Survival").

As regards the distribution of the faculty the experimental evidence and the spontaneous evidence taken separately would suggest different conclusions. In all the experiments which have been conducted few percipients have been discovered capable of receiving impressions as complex as those which give rise to phantasms of the dying, with the same degree of vividness and accuracy that the numerous percipients of such phantasms have displayed. The divergence seems to be due to the presence in the case of phantasms of an emotional stimulus lacking in experiments. The probable inference is that most persons are potential agents and percipients, but that some are better than others; with some the faculty is brought into action by the ordinary non-emotional type of experiment with cards or diagrams; with others the faculty will only be aroused by some strong emotion. Differences of age, sex, race, culture, education, seem to have no bearing on the distribution of the faculty.

If, as is generally supposed, telepathic impressions pass first from the agent's conscious to his subliminal mind, then from his subliminal to that of the percipient, and finally emerge from the percipient's subliminal mind to his consciousness, there are three stages at which the impression may become distorted; it is from the distortions observed in experiments where only partial success is obtained that it is possible to form some opinion as to the form in which impressions are transferred. For instance, the difficulty experienced in transmitting unfamiliar names suggests that, whatever form the impressions take, it is not usually that of definite words, still less sentences. Visual images are more easily transmitted, but it would appear that what is usually transmitted is a series of more or less generalized ideas from which the percipient, as each idea floats up into his consciousness, builds a complete impression more or less resembling that which the agent sought to convey.

This inference has an important bearing on the question whether the process of transmission is physical, by some sort of "waves" or "effluence" or purely psychic. All normal modes of communication depend on the existence of some pre-arranged code of sounds, symbols, dots and dashes, etc.; what is the code by which generalized ideas can be transmitted as such, and who arranged it? Those who assume that telepathic transmission is by some kind of "waves" may fairly be asked to be rather more precise about the nature of these waves, their length, etc., and to indicate what organ of the human body is capable of transmitting physical waves to the opposite side of the globe. Why, again. does telepathy appear to be an exception to the general law of the inverse square? There is abundant evidence, both spontaneous and experimental, that it is not affected by distance.

Until these and other questions have been satisfactorily answered, we must provisionally assume that the mode of telepathic transmission is psychic and not physical.

Psychometry and Dowsing.—"Psychometry" is the clumsy name given to supernormal knowledge of the past history or associations of objects handled by the medium. The experiments of Pagenstecher and Walter Prince reported in vols. xv. and xvi. of the Proceedings of the American S.P.R. are, perhaps, the most notable, but much more evidence will have to be obtained before psychometry receives general acceptance.

If "dowsing" (the discovery of underground water by other means than calculation based on geological knowledge) is to be reckoned one of the forms of clairvoyance, it is the best attested of them all. It is the only branch of psychical research which has yet established itself in the world of practical commercial utility. Government departments, business firms and landowners in many countries regard the employment of a dowser as an every day matter. Dowsing has a long history; it was formerly used to find other things hidden underground besides water, metals for instance, and even dead bodies *(see* Barrett and Besterman, *The Divining Rod,* 1926); and Barrett, who had made the subject a special study for many years, maintained the view that the faculty of dowsing was purely psychic, and did not depend on any electrical current or other physical nexus between the dowser and the invisible water supply. Certain German investigators, on the other hand, consider that they have established that the dowser is influenced by electricity.

Dowsers habitually, though not always, hold a forked twig, which twists in their hands when they approach underground water; the movements of the twig are, it is generally agreed, "automatic," *i.e.,* due to unconscious muscular action stimulated by the impression sub-consciously received by the dowser

Precognition. — The bulk of alleged instances of supernormal knowledge of future events will be considerably reduced if we discard: (1) "Prophecies made after the event," or so vague that they are only recognized as prophecies after the event; in no branch of psychical research are authentic contemporary records and corroborative testimony so necessary, and in none are they usually so lacking; (2) "Prophecies that bring their own fulfilment"; or the fulfilment of which rests wholly with the prophet; under this head were many of the cases where persons have accurately foretold a future illness, the fulfilment following by auto-suggestion; in some cases where a person has predicted his own death by accident, the cause of death has, on more careful investigation, been found to be suicide. (3) Intelligent anticipation based on normal knowledge. The last class shades off imperceptibly into the class of apparent true precognition. The knowledge may be normal, *i.e.,* acquired through the ordinary channels of sense, but not conscious. For instance, a quarry-owner who, however, had little expert knowledge of quarrying, shortly after visiting a quarry where everything seemed going well, was so impressed by a sense of danger that he sent a telegram to the manager instructing him to remove the men at work in a particular part of the quarry. The manager, who had not, while the owner was visiting the quarry, seen any ground for alarm, acted on the telegram. An hour later the whole face of the rock fell in. Did the owner's comparatively inexpert eye note and pass on to his subconscious mind something dangerous in the state of the rock, which the manager's expert eye had failed to detect, and did this idea lurking in his subconscious mind force its way later into consciousness, or was this a true case of precognition? *(See* S.P.R. *Proc.,* vol. xxxiii., p. 119.) This ambiguous type is not infrequent.

The outbreak of the World War set a large part of the public in all countries hunting up old prophecies to see whether any of them fitted, and some were found to fit quite well after they had received a little judicious alteration. (For a parallel in ancient times *see* Thucydides, ii. 54 on the oracle supposed to have foretold the plague at Athens.) Many of the prophecies were, however, bad misfits; a well-known medium, whose supernormal powers are undoubted, had several years before the war predicted that in the next war England and America would be leagued against France and Russia, with Germany neutral!

The "Forecasts in Scripts concerning the War," published in vol. xxxiii. of S.P.R. *Proceedings,* derive their interest not so much from the fact that they foretold the war for several years before it occurred (many persons made similar forecasts by the ordinary processes of reasoning) or that they foretold a few particular incidents of the war, *e.g.,* the sinking of the "Lusitania" (which may have been due to chance-coincidence), but from the fact that the forecasts were distributed piecemeal among several automatic writers, each ignorant of the others' scripts, so that they could only be understood by putting all the scripts together; they formed, in fact, a very complicated "cross-correspondence" (*see* p. 672). The scripts were not confined to forecasting the war; they also foretold certain developments of human affairs not to this date realized: at any rate no one can say rhey are "prophecies made after the event."

Perhaps, however, the case for precognition is strongest where the things foretold are in themselves most trivial, and farthest removed from the probability of normal inference. Instances can be found in any book dealing with "mental" phenomena. The chapter on premonitions in Richet's *Traite' de Me'tapsychique* is instructive not only for the cases quoted by the author, but for the excellent analysis and classification.

Precognition, if it is a genuine phenomenon, does not fit very easily into any theoretic scheme based on the more generally accepted phenomena, such as telepathy. Some people, however, seem to find modern ideas as to a "space-time complex" of assistance in enabling them to accept precognition. Dunne's *An Experiment with Time* is interesting on the theoretical side.

The Evidence for Survival. — Recent discussions in the daily press suggest that most persons make up their minds on the issue of survival without considering the evidence furnished by psychical research; for them the question is finally settled one way or the other by revealed religion or the dogmas of physiology. The psychical researcher must, however, politely but firmly insist that any judgment is premature which ignores the mass of well-attested relevant facts that he has accumulated. He will, of course, base his claim only on such phenomena as are above suspicion of fraud, the mental phenomena in particular, and will candidly admit that these are difficult of interpretation. To meet the objections of *à priori* materialism, he will have to put the case for telepathy as a non-material process, and will at once be answered that, unless he can put some definite limits to the operation of telepathy between living persons, he has proved too much and left nothing further to be explained.

The issue, therefore, is whether there are any mental phenomena, ostensibly spiritistic, which cannot be accounted for by telepathy between the living; and the answer depends, largely but not entirely, on whether telepathy be accepted in its widest conceivable form, a sort of universal subconscious leakage, or whether it is to be confined within the limits, vague as they may be, of the spontaneous and experimental evidence, with a reasonable margin over. Telepathy between the living must not be assigned *ad hoc* a wider field than mould be conceded if the ostensibly spiritistic phenomena had not *got* to be accounted for.

Communications Through Trance-mediums. — Several trance-mediums, whose *bona fides,* after prolonged investigation by critical sitters is generally accepted, have made correct statements of verifiable facts which, humanly speaking, were quite outside their normal knowledge, and these statements purport to have been communicated to the medium (through the "control") by discarnate intelligences. Among such mediums may be mentioned Mrs. Piper, Mrs. Thompson and Mrs. Leonard.

The verifiable matter is sometimes mixed up with quite non-evidential utterances, moral platitudes, descriptions of a future state, etc. A large proportion of "padding" is a sign of an incompetent sitter; good sitters are not seriously afflicted with it. In any case the presence of the "padding" does not depreciate the value of the evidential matter, of which there is sufficient on record in the *Proceedings* of the S.P.R. to satisfy the most diligent student. This may relate to facts present to the sitter's conscious mind; or facts once known by him and since forgotten; or facts never known to him, but known to persons with whom he is in close touch; or facts which can only be verified by enquiry among persons with whom neither he nor the medium has any close connection. At each stage telepathy between the living can be put forward as a possible explanation, but at each stage with diminishing plausibility, until at the last stage nothing will serve but the hypothesis of universal leakage, which is unsupported by any evidence. For a case which raises this problem in an instructive way *see* S. G. Soal's paper, S P.R. *Proceedings,* vol. xxxv.

"Personal Control." — But there may be more than communications of fact. The "control" may recede and allow the "communicator" to address the sitter direct. Sitters who have experienced this declare that the characteristic turns of speech and habits of mind of persons whom the medium never knew are reproduced in a startlingly lifelike way. Granted that the subconscious mind has a flair for dramatising whatever comes its way, including knowledge gained telepathically from the sitter, will this enable the medium to build up a recognizable personality complete in everything but corporeal appearance? The affirmative is argued by T. W. Mitchell (*Hibbert Journal,* Jan. 1928), but he has not, so far, succeeded in convincing those who have had experience of "personal control" at its best,

Cross-correspondences. — It was on the phenomena of trance-mediumship that Myers mainly based his argument for human survival in the work on which he was still engaged at his death in 1901 (*Human Personality and its Survival of Bodily Death*). Since then, however, a new type of phenomenon has arisen, which it is even more difficult to fit into any theory of telepathy between the living than "personal control," namely "cross-correspondences" in automatic writing. Neither the faculty of automatic writing nor much of the content of automatic scripts can claim to be supernormal. In the case, however, of a particular group of automatists (all persons whose good faith is above suspicion) it was observed that the same phrases occurred in the scripts of different automatists with a frequency not to be explained by chance-coincidence. As the scripts continued (and they have now gone on for more than 25 years), a further development was noticed: Automatist A would write a phrase X, Automatist B a phrase Y; there was no apparent connection between X and Y, but automatist C would write a phrase Z which connected X and Y and gave a coherent meaaing to the three phrases. That, in bold outline, is what is meant by a "complementary cross-correspondence," of which numerous examples are to be found in S.P.R. *Proceedings* from 1906 onwards. The importance of them is that they seem to indicate a *design* originating outside the group. In point of fact, they purport to originate with the surviving intelligence of Myers. Claims of this kind need not always be accepted at their face value; in judging, however, the validity of this claim, it must be noted that the cross-correspondences began shortly after Myers' death, that they seem to supply a defect in the evidence existing at his death of which he was fully conscious, and that their literary content is very characteristic of him.

Cross-correspondences are a difficult study. They present a tangle of quotations from authors, ancient and modern. In this maze which the plain man of ordinary literary tastes is apt to wonder whether the alleged orderly arrangement exists outside the subtle imaginations of the annotators. The sceptic of literary training will admit the orderly arrangement, but will say that it is due to telepathic influence from some living person, possibly one of the automatists.

But the automatists may fairly be acquitted. It is not suggested that any one of them was a deliberate or conscious agent, and there is no evidence which would support the view that an elaborate design could be first subconsciously formulated and then subconsciously transmitted. Moreover, practically all the original members of the group have dropped out, for death or other reasons, and still the cross-correspondences pour out with no important change of type, just as if the original group had not been replaced by a new one.

Looking, then, outside the group, we may ask, who is this remarkable person who has for 25 years been transmitting ideas to a round dozen of automatists with a success unrivalled in the history of experimental telepathy, and who still remains mute, inglorious and incognito? Unless we are prepared to accept indefinitely a verdict of telepathy by some person or persons unknown, we may have to take seriously the claims of the scripts to be inspired by Myers.

The only case in which there is any evidence for telepathy from a living person influencing cross-correspondence is the "Sevens Case" (S.P.R. *Proceedings,* vol. xxv.). But in that case, if telepathy from the living is to be involved at all, we must suppose that the subconscious minds of *two* living persons conspired to produce a design not in the conscious intention of either.

The question of design is raised in a slightly different form in the literary puzzles produced by one member of the S.P.R. group. The most interesting of these is *The Ear of Dionysius,* reported in S.P.R. *Proceedings,* vol. xxix. Readers who find the cross-correspondence too complex and tedious are recommended to study this case.

"Inspirational" Literature — When William Blake claimed to have written poems "from immediate dictation" of his "friends in Eternity," "without premeditation and even against my will" (letter April 25, 1803), was he merely mistaking the efforts of his more or less dissociated subliminal mind for the promptings of discarnate intelligences? That the sublirpinal mind can produce poetry of the highest order is shown by *Kubla Khan,* and Blake was at least as much a poet born and bred as Coleridge. For a test of external inspiration we must look for literature of a high order produced by someone not so permeated through and through by imagination as Blake. We naturally cannot expect to find work of the same quality as Blake's, but coming a little down in the scale we may find cases of work of considerable merit, purporting to be inspired by discarnate intelligences and produced by persons who, in their ordinary life, are entirely commonplace. A striking example is *The Case of Patience Worth,* examined by W. F. Prince (Boston S.P.R., 1927). Until the age of 23, Mrs. Curran had no literary tastes and was mainly interested in outdoor pursuits; she then began to write novels and *vers libres* purporting to be inspired by "Patience Worth," who said she was a settler in New England in the 17th century. The writings show a power of vivid expression and a historical knowledge which those who know Mrs. Curran well declare to be altogether beyond her normal capacity. Prince's conclusion is: "Either our concept of what we call the subconscious must be radically altered, so as to include potencies of which we hitherto have had no knowledge, or else some cause operating through but not originating in the subconsciousness of Mrs. Curran, must be acknowledged."

BIBLIOGRAPHY.—(1) Books: The "classics" of psychical research in the English language are undoubtedly *Phantasms of the Living* and *Human Personality and its Survival of Bodily Death,* both already mentioned. Abridged editions of both have been published. Next in importance come Podmore's books, especially *Modern Spiritualism, a History and a Criticism* (1902). Other important books dealing comprehensively with psychical research are Richet, *Traité de Métapsychique* (1922) (Eng. trans., *Thirty Years of Psychical Research),* and *Der Okkultismus in Urkunden,* edited by Max Dessoir (1925). This book is in two parts, dealing with physical and mental phenomena respectively, and is highly critical both of physical phenomena, and of the evidence for survival. The battle as to physical phenomena rages furiously in Germany, the positive side being ably upheld by Schrenck Notzing, *Materializations Phiinomene* (1914), (Eng. trans. 1920); *Experimente dev Firnbewegung* (1924), etc. For a good short discussion of the evidence for survival *see* Whately Smith's *The Foundations of Spiritualism.* (1920). *See* also separate articles MEDIUM, SPIRITUALISM.

(2) Periodicals: The *Proceedings* of the S.P R, are of first importance; much of the evidence regarding trance-mediumship, cross-correspondences,etc., is not to be found elsewhere. The publications of the American S.P.R. until the recent "split," and since then of the Boston S.P.R. are also important. Of Continental periodicals, *Zeitschrift fur Parapsychologie* and Z. *f. Kritischen Okkultismus* (the latter recently discontinued) may be mentioned. (W. H. SA.)

PSYCHOANALYSIS: FREUDIAN SCHOOL. In the years 1880–82 a Viennese physician, Dr. Josef Breuer (1842–1925), discovered a new procedure by means of which he relieved a girl, who was suffering from severe hysteria, of her various symptoms. The idea occurred to him that the symptoms were connected with impressions which she had received during a period of excitement while she was nursing her sick father. He therefore induced her, while she was in a state of hypnotic somnambulism, to search for these connections in her memory and to live through the "pathogenic" scenes once again without inhibiting the effects that arose in the process. He found that when she had done this the symptoms in question disappeared for good.

This was at a date before the investigations of Charcot and Pierre Janet into the origin of hysterical symptoms, and Breuer's discovery was thus entirely uninfluenced by them. But he did not pursue the matter any further at the time, and it was not until some 10 years later that he took it up again in collaboration with Sigmund Freud. In 1895 they published a book, Studien *über* Hysterie, in which Breuer's discoveries were described and an attempt was made to explain them by the theory of *Catharsis*. According to that hypothesis, hysterical symptoms originate through the energy of a mental process being withheld from conscious influence and being diverted into bodily innervation ("Con*version*"). A hysterical symptom would thus be a substitute for an omitted mental act and a reminiscence of the occasion which should have given rise to that act. And, on this view, recovery would be a result of the liberation of the affect that had gone astray and of its discharge along a normal path ("Abreaction"), Cathartic treatment gave excellent therapeutic results, but it was found that they were not permanent and that they were dependent on the personal relation between the patient and the physician. Freud, who later proceeded with these investigations by himself, made an alteration in their technique, by replacing hypnosis by the method of free association. He invented the term "psycho*analysis*," which in the course of time came to have two meanings: (1) a particular method of treating nervous disorders and (2) the science of unconscious mental processes, which has also been appropriately described as "depth-psychology."

Subject Matter of Psychoanalysis. — Psychoanalysis finds a constantly increasing amount of support as a therapeutic procedure, owing to the fact that it can do more for certain classes of patients than any other method of treatment. The principal field of its application is in the milder neuroses — hysteria, phobias and obsessional states, but in malformations of charactet and in sexual inhibitions or abnormalities it can also bring about marked improvements or even recoveries. Its influence upon dementia praecox and paranoia is doubtful; on the other hand, in favourable circumstances it can cope with depressive states, even if they are of a severe type.

In every instance the treatment makes heavy claims upon both the physician and the patient: the former requires a special training, and must devote a long period of time to exploring the mind of each patient, while the latter must make considerable sacrifices, both material and mental. Nevertheless, all the trouble involved is as a rule rewarded by the results. Psychoanalysis does not act as a convenient panacea ("cito, tute, jucunde") upon all psychological disorders. On the contrary, its application has been instrumental in making clear for the first time the difficulties and limitations in the treatment of such affections.

The therapeutic results of psychoanalysis depend upon the replacement of unconscious mental acts by conscious ones and are Qperative in so far as that process has significance in relation to the disorder under treatment. The replacement is effected by overcoming internal resistances in the patient's mind. The future will probably attribute far greater importance to psychoanalysis as the science of the unconscious than as a therapeutic procedure.

Depth-Psychology. — Psychoanalysis, in its character of depth-psychology, considers mental life from three points of view: the dynamic, the economic and the topographical.

From the first of these standpoints, the dynamic one, psychoanalysis derives all mental processes (apart from the reception of external stimuli) from the interplay of forces, which assist or inhibit one another, combine with one another, enter into compromises with one another, etc. All of these forces are originally in the nature of instincts; that is to say, they have an organic origin. They are characterised by possessing an immense (somatic) persistence and reserve of power ("repetition-compulsion"); and they are represented mentally as images or ideas with an affective charge ("*cathexis*"). In psychoanalysis, no less than in other sciences, the theory of instincts is an obscure subject. An empirical analysis leads to the formation of two groups of instincts: the so-called "ego-instincts," which are directed towards self-preservation and the "object-instincts," which are concerned with relations to an external object. The social instincts are not regarded as elementary or irreducible. Theoretical speculation leads to the suspicion that there are two fundamental instincts which lie concealed behind the manifest ego-instincts and object-instincts: namely (a) Eros, the instinct which strives for ever closer union, and *(b)* the instinct for destruction, which leads toward the dissolution of what is living. In psychoanalysis the manifestation of the force of Eros is given the name "libido."

Pleasure-Pain Principle. — From the economic standpoint psychoanalysis supposes that the mental representations of the instincts have a cathexis of definite quantities of energy, and that it is the purpose of the mental apparatus to hinder any damming-up of these energies and to keep as low as possible the total amount of the excitations to which it is subject. The course of mental processes is automatically regulated by the "pleasure-pain *principle*"; and pain is thus in some way related to an increase of excitation and pleasure to a decrease. In the course of development the original pleasure principle undergoes a modification with reference to the external world, giving place to the "reality-principle," whereby the mental apparatus learns to postpone the pleasure of satisfaction and to tolerate temporarily feelings of pain.

Mental Topography. — Topographically, psychoanalysis regards the mental apparatus as a composite instrament, and endeavours to determine at what points in it the various mental processes take place. According to the most recent psychoanalytic views, the mental apparatus is composed of an "id," which is the reservoir of the instinctive impulses, of an "ego," which is the most superficial portion of the id and one which is modified by the influence of the external world, and of a "*super-ego*," which develops out of the id, dominates the ego and represents the inhibitions of instinct characteristic of man. Further, the property of consciousness has a topographical reference; for processes in the id are entirely unconscious, while consciousness is the function of the ego's outermost layer, which is concerned with the perception of the external world.

At this point two observations may be in place. It must not be supposed that these very general ideas are presuppositions upon which the work of psychoanalysis depends. On the contrary, they are its latest conclusions and are in every respect open to revision. Psychoanalysis is founded securely upon the observation of the facts of mental life; and for that very reason its theoretical superstructure is still incomplete and subject to constant alteration. Secondly, there is no reason for astonishment that psychoanalysis, which was originally no more than an attempt at explaining pathological mental phenomena, should have developed into a psychology of normal mental life. The justification for this arose with the discovery that the dreams and mistakes ("*parapraxes*," such as slips of the tongue, etc.) of normal men have the same mechanism as neurotic symptoms.

Theoretical Basis. — The first task of psychoanalysis was the elucidation of nervous disorders. The analytical theory of the neuroses is based upon three ground-pillars: the recognition of (1) "*repression*," (2) the importance of the sexual instincts and (3) "transference."

Censorship. — There is a force in the mind which exercises the functions of a censorship, and which excludes from consciousness and from any influence upon action all tendencies which displease it. Such tendencies are described as "repressed." They remain unconscious; and if the physician attempts to bring them into the patient's consciousness he provokes a "resistance." These repressed instinctual impulses, however, are not always made powerless by this process. In many cases they succeed in making their influence felt by circuitous paths, and the indirect or substitutive gratification of repressed impulses is what constitutes neurotic symptoms.

Sexual Instincts. — For cultural reasons the most intensive repression falls upon the sexual instincts; but it is precisely in connection with them that repression mast easily miscarries, so that neurotic symptoms are found to be substitutive gratifications of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it teaches a first culminating point at or before the fifth year ("early period"), after which it is inhibited or interrupted ("latency period") until the age of puberty, which is the second climax of its development. This double onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution, form the dispositions for the subsequent development of character or disease. It is a mistaken belief that sexuality coincides with "genitality." The sexual instincts pass through a complicated course of development, and it is only at the end of it that the "primacy of the genital zone" is attained. Before this there are a number of "pre-genital organisations" of the libido—points at which it may become "fixated" and to which, in the event of subsequent repression, it will return ("regression"). The infantile fixations of the libido are what determine the form of neurosis which sets in later. Thus the neuroses are to be regarded as inhibitions in the development of the libido.

The Oedipus Complex.—There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations, that is, upon the relative strength of the forces concerned. The most important conflict with which a small child is faced is his relation to his parents, the "Oedipus complex"; it is in attempting to grapple with this problem that persons destined to suffer from a neurosis habitually fail. The reactions against the instinctual demands of the Oedipus complex are the source of the most precious and socially important achievements of the human mind; and this probably holds true not only in the life of individuals but also in the history of the human species as a whole. The super-ego, the moral factor which dominates the ego, also has its origin in the process of overcoming the Oedipus complex.

Transference.—By "transference" is meant a striking peculiarity of neurotics. They develop toward their physician emotional relations, both of an affectionate and hostile character, which are not based upon the actual situation but are derived from their relations toward their parents (the Oedipus complex). Transference is a proof of the fact that adults have not overcome their former childish dependence; it coincides with the force which has been named "suggestion"; and it is only by learning to make use of it that the physician is enabled to induce the patient to overcome his internal resistances and do away with his repressions. Thus psychoanalytic treatment acts as a second education of the adult, as a correction to his education as a child.

Within this narrow compass it has not been possible to mention many matters of the greatest interest, such as the "sublimation" of instincts, the part played by symbolism, the problem of "ambivalence," etc. Nor has there been space to allude to the applications of psychoanalysis, which originated, as we have seen, in the sphere of medicine, to other departments of knowledge (such as anthropology, the study of religion, literary history and education) where its influence is constantly increasing. It is enough to say that psychoanalysis, in its character of the psychology of the deepest, unconscious mental acts, promises to become the link between psychiatry and all of these other fields of study.

The Psychoanalytic Movement.—The beginnings of psychoanalysis may be marked by two dates: 1895, which saw the publication of Breuer and Freud's Studien iiber *Hysterie,* and 1900, which saw that of Freud's Traumdeutung. At first the new discoveries aroused no interest either in the medical profession or among the general public. In 1907 the Swiss psychiatrists, under the leadership of E. Bleuler and C. G. Jung, began to concern themselves in the subject; and in 1908 there took place at Salzburg a first meeting of adherents from a number of different countries. In 1909 Freud and Jung were invited to America by G. Stanley Hall to deliver a series of lectures on psychoanalysis at Clark University, Worcester, Mass. From that time forward interest in Europe grew rapidly; it showed itself, however, in a forcible rejection of the new teachings, characterised by an emotional colouring which sometimes bordered upon the unscientific.

The reasons for this hostility are to be found, from the medical point of view, in the fact that psychoanalysis lays stress upon psychical factors, and from the philosophical point of view, in its assuming as an underlying postulate the concept of unconscious mental activity; but the strongest reason was undoubtedly the general disinclination of mankind to concede to the factor of sexuality such importance as is assigned to it by psychoanalysis. In spite of this widespread opposition, however, the movement in favour of psychoanalysis was not to be checked. Its adherents formed themselves into an International Association, which passed successfully through the ordeal of the World War, and at the present time comprises local groups in Vienna, Berlin, Budapest, London, Switzerland, Holland, Moscow and Calcutta, as well as two in the United States. There are three journals representing the views of these societies: the *Internationale Zeitschrift* fur Psychoanalyse, *Imago* (which is concerned with the application of psychoanalysis to non-medical fields of knowledge), and the *International* Journal of Psycfto-Analysis.

During the years 1911–13 two former adherents, Alfred Adler, of Vienna, and C. G. Jung, of Zürich, seceded from the psychoanalytic movement and founded schools of thought of their own. In 1921 Dr. M. Eitingon founded in Berlin the first public psychoanalytic clinic and training school, and this was soon followed by a second in Vienna. (See ABNORMAL PSYCHOLOGY.)

BIBLIOGRAPHY.—Breuer and Freud, *Studien iiber Hysterie* (1895); Freud, *Traumdeutung* (1900), *Zur Psychopathologie des Alltagslebens* (1904), *Drei Abhandlungen zur Sexualtheorie* (1905); *Vorlesungen zur Einfuhrung in die Psychoanalyse (1916)*. Freud's complete works have been published in Spanish (*Obras completas*) (1924), and German (*Gesammelte Schriften*) (1925); the greater part of them has been translated into English and other languages. Short accounts of the subject-matter and history of psychoanalysis will be found in: Freud, *Ueber Psychoanalyse* (the lectures delivered at Worcester, U.S.A.) (1909); *Zur Geschichte der psychoanalytischen Bewegung* (1914); *Selbstdarstellung* (in Grote's collection *Die Medizin der Gegenwart*) (1925). Particularly accessible to English readers are: *A. A.* Brill, *Psycho-Analysis (1922)*; E. Jones, *Papers on Psycho-Analysis* (1923); S. Ferenczi, *Theory and Technique of Psychoanalysis (1927)*. (S. FR.)

PSYCHOGALVANIC REFLEX. The term psychogalvanic reflex (P.G.R.) was first used by Veraguth to describe the change in electrical properties of the human body (or any living animal body) in response to nocuous (emotional) stimuli. The terms *galvanic* skin *reflex,* skin constrictor reflex and sweat *secretion reflex* have been used synonymously. This reflex is usually demonstrated in one of two ways. (a) Electrodes connect the hands directly to a galvanometer. When the subject is stimulated by a pin prick, threat of injury, etc., the galvanometer, after a latent period of about two seconds, will show a deflection indicating an increased output of electromotive force from the human body. This rises to a maximum within 2 to 10 seconds and subsides in about the same time. (b) The human subject forms the fourth arm of a balanced Wheatstone bridge electrical circuit. On stimulation the galvanometer will deflect as described above. In this case, the deflection indicates a decrease and increase in apparent ohmic resistance of the body.

This phenomenon was first described by Vigouroux (1879). It remained, however, for Veraguth (1909) to draw the attention of a large scientific audience to the psychogalvanic reflex. The physics of the "reflex" is still a matter of dispute. According to Gildemeister it is due to a change in conductivity of the human body which is dependent upon polarization of the membranes of the cells of the skin, so changing the cellular permeability to different ions. The anatomical control of the psychogalvanic reflex has been shown to lie in the sympathetic nervous fibres which lead to the smooth musculature of the walls of sweat glands and capillaries. Any stimulus resulting in activity of the sympathetic division of the autonomic nervous system will consequently result in changes in tonicity of the involuntary musculature of the skin surfaces of the body which are shown by the secretion of sweat, changes in circulation, local skin temperature, etc. This combined action leads in turn to variations in electrical conductivity (psychogalvanic reflex).

Psychologists have, for the past twenty years, been interested in this phenomenon, particularly following the suggestion of Binswanger (1907) that only emotional stimuli elicit the reflex. This view has been held by many subsequent investigators. The work of Radecki (1911) and more recently of Aveling questions the validity of this assumption. It is probable that the psychogalvanic Reflex is elicited most frequently by nocuous stimuli, but that it is not specific to "emotional" situations.

The reflex has found application in many fields of research, Otologists have used it to detect the feigning of deafness in dubious cases. Psychoanalysts have used the phenomenon together with word association tests as a means of discovering hidden complexes. Many investigators have made use of the Psychogalvanic Reflex for the demonstration of individual differences in emotionality. There seems to be fairly good evidence that such differences may be established in this fashion. Psychiatrists have made use of the reflex in differential diagnosis of organic and functional orders. Attempts toward the practical application of the reflex as an indicator of emotional stability of men who were applying for positions in hazardous occupations have not met any great success.

PSYCHOLOGICAL ARTICLES. The section of psychology is in some points closely bound up with philosophy. The outstanding psychological articles in the present edition are—ABNORMAL PSYCHOLOGY; APPLIED PSYCHOLOGY; EXPERIMENTAL PSYCHOLOGY; FEELING, PSYCHOLOGY OF; INDUSTRIAL PSYCHOLOGY; INSTINCT IN MAN; PHENOMENOLOGY; PSYCHICAL RESEARCH; PSYCHOANALYSIS; PSYCHOLOGY; PSYCHOLOGY, HISTORY OF, and WILL.

PSYCHOLOGISM, in philosophy, is the view that problems of epistemology, that is, problems relating to the validity of human knowledge, can be solved satisfactorily by the psychological study of the development of mental processes. Locke's *Essay on the Human Understanding* may be regarded as the classic of psychologism in this sense. A more moderate form of psychologism only maintains that psychology should be made the basis of other studies, especially of logic.

PSYCHOLOGY is the study of the mind, or of "mental phenomena," or of the higher functions of beings "endowed with mind." The last definition emphasizes the fact that ordinarily the term is restricted to the study of mental functions connected with living organisms.

Though psychological studies may be said to have begun with the *De Anima* of Aristotle they were merged in what would now be regarded as purely biological questions. An absolute separation of the two sciences only came about through the general acceptance among scientists, twenty centuries later, of the Cartesian Dualism.

A sharp distinction was drawn between matter and mind, as radically different substances with mutually incompatible attributes; psychology became then the science of mind and biology was assimilated to the group of studies concerned with material things. With this ontological dualism, a dualism of method was combined. To the study of mind was allowed a special source of information—"introspection"—the use of distinctive concepts, and explanation by reference to ends. On the other side of the chasm a rigid discipline was established. In the material sciences, facts are only admitted when guaranteed by common observation (in contrast to the alleged privacy of introspection), descriptions must be couched in purely physical terms, and the phenomena must be given a physico-chemical or "mechanistic" explanation. From the success of this discipline there has come about the general leftward trend of the sciences; chemistry is reduced to physics, biology to chemistry, and psychology has tended to play the part of the poor relation to the natural sciences.

The culmination of this movement in the twentieth century has taken the form of an attempt to establish a purely "objective" psychology—a science of the higher functions of an organism physically conceived. Since, then, both in its origin and in one of its latest developments, the postulate of a distinctive mental substance has been absent it is undesirable to embalm in the definition of psychology any reference to "the mind." To begin with, the conception of "vital functions" will cover the relevant facts. Further enquiry will show which of these may be regarded as of distinctively "mental" nature.

The wider field has come to be embraced in the psychologist's sphere of investigation in the course of a tendency to retreat psychological problems only as part of another science which might be better described as general psycho-physics. Originally, this latter term applied only to the study of certain relations obtaining between sensations and their physical stimuli. The term, however, admits of application, with equal propriety, to the study of all the inter-relations between psychical phenomena, on the one hand, and their physical and physiological antecedents, concomitants and consequents, on the other. Whatever further relations may be involved there is certainly an extensive parallelism between mental process and certain kinds of physical process. Sensations are generally paralleled by certain modes of stimulation, and probably quite invariably by certain cerebral processes. Similarly pleasure, desire and aversion correspond to certain cerebral conditions and have their outward manifestations. One consequence of this parallelism is that almost every mental state has an obvious "behaviouristic" equivalent; and where direct introspective evidence is uncertain it is natural to seek for information from the external manifestations. But the facts of behaviour admit of independent systematization from the objective point of view, and terms originally applied to the mental state come to be used for the connected bodily process in relative isolation. Sensation comes to stand simply for receptivity, perception is identified with the behaviour which constitutes its external criterion, desire means restlessness of a certain kind, and purpose is defined in terms of the behaviour by which it is expressed. In this way there has arisen a systematic duplication of the meanings of psychological terms. So far has this tendency gone that a complete presentation of contemporary psychology must involve a corresponding duplication in exposition—an account of mental process in itself, and an account of the correlative bodily life from an external point of view. In what follows we shall explore first the possibilities in the purely objective standpoint, but the reader may proceed at once to the exposition from the traditional point of view which opens in the section on *Psychology* as *the Science of Individual Experience.*

THE OBJECTIVE APPROACH

Introduction.—Among the objects presented by nature for our contemplation are living things endowed with powers which call for explanation. Vital functions, externally observed, consist primarily in movements. Movements, then, constitute our data; and so far psychology would conform to the traditional dynamical scheme of the natural sciences as a whole. The activities with which we are concerned can be arranged in hierarchical order, the lowest being found in all, even the simplest forms of life; the highest, only in beings of a very elaborate type. Nowadays, the distinction between the higher and lower functions would receive an evolutionary interpretation, but the older, Aristotelian, way of defining it has also important implications: the lower, whilst presupposed by the higher, may occur in independence. Among the former are the processes of metabolism which result in self-conservation and growth, by reference to which the animate is defined. The cycles of self-conservation are repeated in movements of a higher order, in the grosser movements of a body supplied with organs and limbs. In the higher organism we find complex forms of behaviour involving a sensitive and discriminating responsiveness to stimuli and more highly organized movements which, whilst maintaining a general self-conserving tendency, appear as the intelligent pursuit of widely differentiated ends. The hierarchy appears to be continuous, but whilst the lower functions fall clearly within the province of biology, the higher are more particularly what interest the student of psychology. Rigid demarcations are out of the question. The most that can be said from this point of view is that the psychologist commences higher up the scale, whilst the biologist is working down to foundations. The psychologist follows on a higher level, or perhaps he starts with the biological data most explored, and works in the other direction, linking up the line of explanation to the facts of those who are working higher still. Such is the programme from the objective point of view.

Reflex Action— The familiar observation that movements are often the outcome of stimulation suggests a generalization whereby these grosser movements of the body can be viewed in an orderly way. If movements are universally the result of stimulation the vertebrate organism can be treated as simply a jointed frame actuated by muscles which respond to various forces which play upon sensitive areas of the body, the link consisting in some conductive process. Stimulation starts the process, releasing potential energy expended in movements which directly or indirectly are the means of restoring the balance of energy so expended. This is self-conservation at a higher level.

The abstract unit of this secondary type of self-conserving system is the response to stimulation, based on a structural counterpart — the simple reflex arc. Three essential components are here involved, a specific receptive organ, a conductive neural bond, and a responsive muscle or gland. Receptor, Conductor and Effector are thus invariably to be sought in the interpretation of conduct. The receptors, which in their higher elaborations constitute the sense organs, are primarily specialised structures with delicately selective sensitivity to certain forms of stimulation. As contrasted with the generalized responsiveness of undifferentiated protoplasm each type of receptor has a "lowered threshold" to some specific "adequate" stimulus, such as heat, light or sound. The conductive filaments consist of chains of elongated neurones periodically interrupted by points of junction, the highly important "synapses" through which the receptor not only gains communication with its "own" effector, but also becomes functionally integrated in the system as a whole. The process terminates in contractile or secretory organs, stimulation thus evoking two distinctive modes of response — movements proper and glandular activities. The latter is an important element in emotional excitement. The two reactions are neither independent nor mutually exclusive. They are quite frequently combined. Earlier studies of reflex action led to an over-emphasis of the fixity and the inevitable character of the response, but neither feature would seem to be invariable or of fundamental importance. The total organization is of an extremely labile constitution, adaptable in the extreme and subject to various forms of inhibition and control. "Volitional" so far from being opposed to reflex action emerges from it by progressive integration.

To trace the steps of this elaboration we must commence with a modification of the foregoing abstract scheme The unit reflex arc is an undue simplification. In no developed organism do we find a single receptor linked with only one effector. Every receptor has a path to various effectors, every effector is at the behest of many receptors, the system so comprising a network of converging and diverging arcs. In this way the effects of a simple stimulus may irradiate a group of effectors producing extremely complex movements. These movements, in their turn, or their external effects, may provide the adequate stimulus for a further series of reactions. Thereby complex co-ordinated movements (simultaneous or successive) are secured, the orderly arrangement of which is further guaranteed by a system of inhibitions. A dominant reflex being evoked, all reactions of an antagonistic nature are automatically prevented from occurring.

The guiding principle of the reflex thus directly explains the more uniform and the more mechanical functions, simple "involuntary" actions such as blinking, sneezing, and withdrawing the limbs from harmful stimuli. Such rhythmic functions as breathing and orderly series of movements in processes such as swallowing all fall easily under the general scheme. Many constituent acts in locomotion and in instinctive behaviour are similarly explained. But as yet no clear light is thrown on many important features of animal behaviour. All is exceedingly wooden. We may test the theory in more detail by inquiring into four such characteristics as variability, apparent spontaneity, educability and intelligence.

Variability. — Clearly the conduct of an organism is far from comparable to the antics of a mechanical doll. Even the best established reflex has its refractory phase and is subject to inhibition. variability takes several forms. A stimulus repeated may fail to elicit any overt response at all, different responses may be called out at different times, and the same response may be provoked in various ways and in greatly varying degrees. The organization by which a receptor may distribute the Outcome of stimulation among many diverging tracts, and by which impulses separate in origin may converge upon a final common path to some effector, provides a structural basis for such variability. The problem, however, is far from being merely structural, nor are the prevailing paths of conduction, and their variations. adequately explained by the original distribution of resistance and accidental variation in conductivity, which changes in temperature or nutrition, for example, might produce. The variations in question subserve self-conservation too efficiently to be wholly explained along these lines. They suggest the presence of some specific regulative machinery.

The fact that the uniformities of behaviour are only approximate, and formulated as tendencies, not as invariable laws, suggests that we are only inadequately acquainted with the operative conditions. Generally, responses seem to depend upon multiple stimulation, or upon some receptive "pattern." Were this wholly a matter of the external receptors there would still be unexpected failures of the organism to respond to an apparently adequate stimulus, on account of certain contributory factors being overlooked, or on account of other factors working in an antagonistic sense. But sole dependence on the external receptors is (if real) the exception, not the rule. The majority of movements depend on the co-operation of internal receptive organs inaccessible to direct observation. The dog reacts to food, but only if he is hungry, and "hunger" may for the present be conceived as implying only a certain organic state. The "touchiness" of an organism "out of sorts" is proverbial. Changes in organic state would seem generally to disorganize (or adaptively re-organize) the conditions of collateral internal stimulation upon which our normal conduct depends To these factors must be added the progressive ripening and decay of instincts, involving no doubt concomitant modification of neural structure. The senile cat is unresponsive to things that fill a kitten with delight.

Spontaneity. — If spontaneity be taken to imply absolute independence of causal process, the notion can find no place in a system of thought which aims at explanation. On a less extreme interpretation, it has a certain descriptive value in relation to vital process. The causal relations between a self-conserving system and its environment are essentially reciprocal and cyclical in nature. It is therefore inappropriate to endow either with the priority which the notion of stimulus and response on the one hand, and of absolute spontaneity on the other, inevitably suggest. But the two notions are mutually corrective, The organism reacts to stimuli, but such reactions are frequently conditioned by preparatory adjustments, and themselves consist, as it were, in the search for further stimulation The organism gives as much as it receives, and if it does not receive, it will go out to find. Absence of stimuli is the occasion of exploratory movements, to which the concept of spontaneity would most directly seem to refer. But whilst worthy of emphasis in this sense the notion will serve to justify neither the conception of action from a purely central origin, nor the assumption of an intruding "mind," to supplement on occasion the function of the receptors. For facts which appear to call for such an interpretation the objective psychologist can find a ready explanation, in principle if not in detail. We wake to an alarm, but if the clock has stopped we wake "of our own accord." In this spontaneous awakening internal organic stimuli probably play their part, but even a purely cyclical process of sleeping and waking would explain the facts. Spontaneity here refers to a causal process immanent in the organism. Many apparent cases of this sort, moreover, are probably due to variable factors delaying a response to prior stimulation. The influence of contributory internal stimulations invoked in the case of variability is also relevant here.

Educability. — "Education" may broadly be taken to cover every change in conduct resulting from prior stimulation and response, excluding what is due to native constitution or natural unfolding in accordance with immanent laws. The hard outlines of our original mechanical model, slightly tempered perhaps by the qualifications so far introduced, are further softencd as we study the progressive modifications which our native constitution undergoes. The problem of learning, relating as it does to changes in neural paths, inevitably suggests the very fundamental question how a reflex arc comes to exist at all; for the factors responsible for their modification would seem, in large measure, to be responsible for their original formation. But to discuss this question would take us beyond the purview of the standpoint here adopted. For objective psychology the existence of the primary arcs is usually taken as a datum, and the questions to be raised are: how is a new response produced? and, how is an old response linked to a newer mode of stimulation? We may conveniently consider the latter, and simpler, question first.

A partial account is afforded by the principle of the conditioned reflex. Given an original connection between a stimulus A and a response R, then any other stimulus, say B, which is applied concomitantly with A tends to acquire the capacity to evoke the response R independently of the presence of A. The case is well illustrated by the "salivary reflex." Certain kinds of substance being placed in a dog's mouth (stimulus A) directly provoke a flow of saliva. If concomitantly with this a bell is rung (stimulus B).—the conjunction being repeated many times—the ringing of the bell will provoke the flow of saliva without the presence of the original stimulus. A response so acquired is said to be a conditioned reflex and the novel mode of stimulation a substitute stimulus. Much that is called education may be so explained.

Clearly, however, education covers a much wider range of modification. The principle, at best, would only account for a transference of established modes of behaviour to new situations. Our problem also relates to actual change in behaviour. *Prima facie,* four types of such modification call for explanation.

Firstly, we may note the atrophy or weakening of an old response; secondly, facilitation or the strengthening of an existent response; thirdly, the co-ordination of old responses into new and complex modes of behaviour; and lastly, the intrusion of responses absolutely new.

It is one of the present limitations of the purely objective approach that no complete and satisfactory explanation of any of these forms of modification can be offered apart from teleological considerations or some reference to mind The simplest account, as we shall later see, involves a reference to conation and to the satisfaction experienced in the course of such modification. Apart from this, all that we can do is to enumerate the quite specific conditions under which these modifications occur, and to attempt to describe the facts in purely bodily terms. The difficulties are well illustrated in the more "original" forms of response. Two cases call for consideration. First, any given response may admit of progressive modification until something quite different has emerged. This commonly occurs when partial facilitation is combined with partial atrophy. In learning a new and complex movement certain constituent acts come to be more pronounced whilst others undergo progressive elimination. We can describe the phases of the process quite objectively, but if we inquire why *this* particular movement becomes pronounced whilst *that* progressively disappears we are in general forced to refer to the utility of the change and more particularly to utility *appreciated as such.*

The second case is that in which there is a relatively abrupt intrusion of a novel mode of action, as when, for instance, we learn to manipulate a lock. But by this we are led to the question of practical intelligence.

Intelligence.—Intelligent action would seem the most difficult to reduce to a purely reflex scheme, since it essentially involves a departure from routine. But to this problem, too, objective psychology can offer some relevant contributions. Structural organization in virtue of which the organism becomes increasingly adaptable involves the integration of reflex arcs—and such adaptability is one factor in intelligence. A convenient starting point for analysis is the complex behaviour cycles which are illustrated in instinctive action. But such a cycle differs in important ways from a mere chain reflex. In the latter the unit is the simple reflex and each response to stimulation constitutes at ieast the principal factor provoking the subsequent act. Such systems are found in their greatest purity in purely immanent processes where the internal resources of the organism supply all that is necessary for the cycle to be performed. Where intercourse with the external environment is involved, variability will arise, except where the needed cues are always ready to hand. In locomotion, for instance, there is the ground to walk upon or water in which to swim. It is series of acts such as these, not unitary reflex acts, which constitute the links of a behaviour cycle, but the latter does not merely consist in a longer chain. The sections, in the first place, are of variable dimensions, and transitions from phase to phase are conditioned by critical clues. The rhythm of locomotion continues until the prey is caught, mastication ensues until it is consumed, or appetite appeased. Even here the individual actions are adapted to the character of the ground and the nature of the food. There is in short a second characteristic of the behaviour cycle of paramount importance—the organization of alternatives. One must first catch one's hare, but when caught it can be cooked in various ways. The alternatives, of course. are not wholly arbitrary, and selection will be determined by a variety of subtle factors in the total situation, including the state of the body. The organization of alternatives may proceed until an almost inexhaustible repertoire of responses is available. Such is the endowment of the fortunate beings who are never at a loss in all the emergencies of life. The elaboration of such alternatives is the function of intelligence.

We are concerned, however, not so much with the constitution of an intelligent being, as with the specific intelligent act. The critical moment is that in which a fresh alternative is found. Once discovered, its conservation as a possible neural path is merely a function of retention.

The conditions under which the intelligent act occurs would seem invariably to involve the thwarting of some pre-established cycle. There is set in action some sequence of behaviour such as the quest for food. But a cycle which uneventfully works itself out in the usual way is not itself an exercise of. intelligence. Some obstacle must arise with which the alternatives so far organized in the nervous system are inadequate to deal. The intelligent act consists in the completion of the cycle by a novel route. In this we have an objective definition of intelligence, or at least an objective criterion of its presence. The usual means of securing food constitutes such a cycle. An obstacle is provided, for example, by placing the food out of reach; whilst the intelligent act may consist in the novel use of a tool.

How does the novel route arise? Attempts have been made to explain the process of discovery by reference to the conjoint action of two factors: (a) one that maintains persistent action until the consummatory act occurs, (b) a tendency to vary, and subsequently to avoid, all responses which fail to terminate the process. On this hypothesis, given time and the physical possibility of giving the right response, every persistent tendency would, by a process of elimination, sooner or later be "successful." Perhaps success is sometimes so attained. But it would seem that the problem is sometimes solved more quickly than this hypothesis would explain—even if we assume that groups of responses are eliminated together. The facts, in short, suggest that the problem may be "thought out." What this phrase implies can no doubt be reinterpreted in purely neural terms, but the fact is, we have reached a stage of investigation at which—as a principle of method—objective psychology calls for supplementation from another point of view. In dealing with the higher functions we find it profitable to observe the process from within, and in the light of clues so gained to formulate hypotheses with regard to neural process. The study of simple reflex acts does not so obviously call for an introspective approach, but as we ascend to higher functions introspective evidence increasingly takes the lead. We may turn therefore to the study of mental process "from within," but before doing so may briefly summarise the merits and limitations of the objective method.

Value of the Objective Approach.——First, we may note that as a science in its own right, or as a sub-department of

Biology, the study of behaviour needs no defence. Its limitations are only such as are self-imposed, or such as further research is likely to remove. It cannot be condemned for its failure to solve the problem of mind, for with what is in strictness "mental" it is not directly concerned. If the principle of physico-chemical explanation is to be rejected here, it has also to be rejected wherever we deal with life. There is little plausibility in the hypothesis that, whilst the behaviour of lower organisms is explicable in purely mechanical terms, teleology is required to explain the later phases of evolution.

Secondly, as a part of what we called general Psycho-physics the objective study of behaviour provides one-half of what is required. It may, however, in addition, provide subsidiary sources of information with regard to mental process. Just as the physiology of the sense-organs has been advanced by the introspective observation of sensory experience, so are clues afforded to the nature of mental process by the correlative physical facts. In both cases, however, certain general hypotheses are required with regard to the relations of body and mind, and each presupposes a correlative but independent approach.

Limitations of the Method.—Considered as a substitute for Psychology, as some ardent exponents regard it, a purely objective study of behaviour suffers from more than a limitation. It fails to touch the essential facts. From a knowledge of bodily processes alone the existence of mental facts cannot even be presumed, much less explained. This is a limitation which is not paralleled in the distinctively psychological point of view; for, as we shall see, the analysis of experience reveals an awareness of the body. But the body as internally perceived is in strictness a different thing from the body as observed from an external point of view. Hence arises a danger of confusion, and hence, too, a need for a clearer demarcation of the alternative methods of approach.

But even in the more restricted purpose of extending our biological kno ledge it is pedantic and inconvenient to restrict ourselves to the purely objective method. Any method is justified which succeeds in advancing knowledge. So far as the parallelism holds it avails us in both directions, and it is an increasingly exemplified fact that the analysis of experience provides a valuable indirect means of securing knowledge of cerebral process. Which method has priority will depend on circumstances. To laud the objective approach in the study of lowly functions is to make a virtue of necessity, and to restrict the study of higher functions to this method is surely, when other means are available, to impose a gratuitous limitation upon the psychologist. What is required would seem to be a psycho-physical point of view which, whilst keeping the methods distinct, employs each to correct and supplement the other.

PSYCHOLOGY AS THE SCIENCE OF INDIVIDUAL EXPERIENCE

The Problem.—The desire to know "what is going on in the mind" is natural and legitimate. So far from being one that the psychologist may ignore, it is precisely that which he is called upon to meet. The challenge of those who deny the feasibility of the venture hardly calls for a *priori* argument; the answer lies in the facts which the so-called Introspective Method has succeeded in bringing to light.

The question is: what exactly do we discover, when, leaving to others the observation of behaviour from the standpoint of the natural sciences, we make ourselves subjects of investigation? The answer, in general, is that we find ourselves living through an experience which to us is "immediate" but which can be only indirectly revealed to anyone "outside." Experience admits of verbal description, and description is "behaviour," but it "makes sense" only to one who interprets it by reference to experience of his own, which he might similarly describe. It is with the nature and laws of experience that Psychology is primarily concerned. We have first to consider in a general way some fundamental concepts in the analysis of experience.

Presentations.—A tree is a physical and not a mental fact; propositions about a tree fall within the province of botany but not of Psychology. On the other hand, an idea of a tree is mental and not physical; propositions about ideas (*e.g.,* that they are distinct or indistinct, or that one is associated with, and suggests, another), are distinctively psychological. What, then, is the difference between a tree and someone's idea of a tree? The answer is that the idea of a tree is the tree itself as it seems to be to an experiencing individual, who is in some way cognisant of it and interested in it. As it appears variously to different individuals, or to the same individual in different stages of his history, we say that the idea changes and varies. Such change and variation is properly psychological. We are however debarred from using the term "idea" comprehensively for objects so far as they enter into individual experience. The reason is that, in present usage, both popular and technical, the word "idea" is applied only to what is thought of without being perceived. In perceiving a tree, we do not say that we are having an idea of it. We may remedy this defect by calling the tree as it appears in sense perception a "percept." But we still need a comprehensive term to cover both percepts and ideas. Following Ward we shall use the term Presentation in this wide sense. Anything whatever is a presentation if and so far as someone is cognisant of it and interested in it.

Sense and Thought.—Nothing can be thus present to the mind unless it is thought of. Otherwise we could not be said to be cognisant of it or interested in it at all. But presentations are not merely thought of. In part they are also sensibly experienced. In a cold bath cold is sensibly experienced. But the bather may, in anticipation or reminiscence, think of the cold as sensibly experienced without actually experiencing it. Similarly, when he sees someone else plunge into cold water, he may think of the other's sensations without having them himself. In such instances the object of thought is itself intrinsically capable of being sensibly experienced. But this is very far from being universally true. Universals and possibilities cannot as such be sensibly presented. Physical objects and their objective characters and relations, as apprehended by common sense and science, cannot be resolved into actual and possible sensations.

Thought essentially involves something in the nature of judgment however rudimentary—including under the term "judgment" questioning and supposition as well as assertion and denial. What we think of we characterise in some manner and degree as being this or that, such and such, so and so related. If we ask what the object of thought is, we cannot express it without using propositions. The bather thinks of the coldness before entering his bath as something which he may actually experience, or is about to experience. When he is actually feeling it, he thinks of it, *e.g.,* as being coldness, as actually present, as about to continue for some time, as felt by him, etc. He does not know anything unless he knows something about it; but "knowledge about" is thought or judgment.

The distinction between sense-experience and thought is not a distinction between separate and independent classes of presentation. In general neither exists without the other, so that every complete presentation involves both as essential elements. Change and development in the mental life is change and development at once on the side of thought and of sense, each conditioning, and conditioned by, the other.

Sensations and Images.—Sense-presentations are of two kinds: (a) Sensations proper, or Impressions, and (b) Images. Images are secondary and derivative, inasmuch as they presuppose the previous occurrence of sensations. They also, at least when they are definite, more or less resemble the sense-impressions from which they are derived. Hence they have been called "copies" of impressions.

Sensations are commonly defined by reference to the manner in which they are produced, as experiences immediately consequent upon the passage of an afferent impulse from a receptive organ to some region of the cerebral hemispheres. But such a definition is inappropriate to our present line of approach, the first task of which is to describe experience itself without regard to the conditions under which it may arise. A formal definition, however, is difficult to give. A typical sensation can but be pointed out and attention drawn to certain characteristics in respect of which it resembles other members of the class with which we are concerned. The clearest and most undisputed examples are afforded by bodily aches and pains. These are sensations both in the most popular and the most technical senses of the term.

Such an experience as a twinge of pain we find tc be an occurrence which manifests a certain specific quality, a certain intensity and a more or less clearly defined extensity and duration. It is also localised or felt in a certain position in a larger spatio-temporal whole. It is referred to some part of the body (of which we are aware as a larger sensory complex), and in popular usage the term sensation tends to be restricted to what is so located. Psychologists, however, have found it inconvenient so to restrict it, so that presentations of sound and colour, and other occurrences which manifest the fundamental attributes are comprised within the meaning of the term.

Theoretically, the attributes of sensation might be found in perfect duplicate in the mental image. A flash of light—say from the bursting of a rocket in the sky—is seen to wax and wane and to pass through various changes in quality and extension. The visualiser might therefore, on closing his eyes, "see" the whole performance repeated "in his mind," the image corresponding in a peculiar way in every attribute to the original impression. Practically, however, images are in various ways defective. They lack the definition, the vividness, the clearness, richness and complexity of the primary impression. But mere imperfections do not provide a suitable basis of definition, however much they may assist effective discrimination in ordinary life.

More fundamental is the relation of the image to subjective activity. An image of a statue can be "immediately" produced and does not require to be modelled by the hands, and upon this the relation—or want of relation—of the image to concomitant-impressions very largely depends.

Images have places relatively to other images within the same extensive field; so have impressions relatively to other impressions. But images and impressions are not thus related to each other. An individual's mental picture of a horse may be contained within his mental picture of a stable, but neither fall within the field of visual impressions which he experiences together with them. If they did, there would be an hallucination, and hallucinations are not images but sensations. It should be added that the place of physical objects in space cannot be identified with the place either of impressions or of images. When a candle flame is seen doubled two impressions are sensibly experienced with an interval between them; but there is only one candle flame.

The Subjective Modes of Experience.—The facts of mental life are not adequately expressed by saying that such and such presentations and simple feelings occur in such and such an order of co-existence and sequence. Objects are presentations only so far as some one is cognisant of them and interested in them. But "cognisant of" and "interested in" are predicates, not of the presentations themselves, but of the experiencing individual whose presentations they are. It is I who believe, disbelieve, doubt, suppose or inquire into, this or that. It is I who am pleased with a melody or with a piece of news. It is I who crave after a drug or choose to take a walk. Even if we abstractly consider mere sense-presentation apart from thought, the distinction is still applicable. It is I who experience colour-sensations, and sound-sensations; but what is sensibly experienced, the sensum or sensatum, as distinguished from the sensating or sensation, is not predicable of me. I am not blue or loud.

It is to subjective modes of experience that the traditional threefold scheme of Cognition, Feeling and Conation most directly refers, and to them it is most conveniently restricted. We shall first consider how the experiences distinguished under these heads are connected with each other. We shall then, for purposes of exposition, treat each of them separately, so far as it is legitimate and convenient to do so.

Interrelations Between Cognition, Feeling and Conation.—The three subjective components of experience certainly are irreducibly distinct. They are not, however, events which may occur independently. The terms refer, rather, to "aspects" of a concrete unitary whole. Even so, they are not simply concomitant and independent attributes, as colour and sound would seem to be. A better analogy is afforded by the relations of colour and extension. As the former implies the latter so the so-called elements of experience would seem to occur in a similar intimate connection.

Conation clearly implies cognition. A striving which is wholly blind is an unintelligible conception. The experient always has at least a vague awareness of the sort of thing he wants, either to "have" or to avoid. But cognition, it may reasonably be argued, equally implies conation. The relations, however, are not reciprocal, for in any given case the immediate objects are not exactly the same. It is on account of this difference that there is progressive development of experience. We apprehend an object because of some interest in the whole of which it forms a part. We become aware of it because we want to know what is there, though having found out *what,* we may in consequence lose interest. That is to say conation is presupposed only in relation to an object presented as admitting of further determination, not as already fully determined. In this lies the significance of attention Conative activity, whatever its remoter end, presupposes cognition of the situation to be changed, a fuller awareness is required of that which is, and to some extent of that which is to be. So far as conation is so directed simply to fuller cognition, the process is one of attention.

The place of feeling in the cycle of cognition, feeling and conation presents a peculiar problem. Is it the immediate consequence of cognition or does it depend upon conation? Here, as is so often the case, each of the rival theories is strong in what it affirms, and falls into error only in what it denies. It is indisputable that the apprehension of various things and their qualities (such as the taste of a dose of quinine) immediately gives rise to affective experience. But it is also plausibly contended that all pleasures are ultimately "pleasures of pursuit." In so far as conative activity is successful, pleasure is experienced, in so far as it is thwarted, pain is the consequence. Difficulties of detail arise in regard to some of the sensory pleasures and pains, and even granting that these can be shown to conform to the rule, a place will still remain to be assigned to cognition. No conative tendency can, from the standpoint of the experient, be regarded as progressive unless it is recognised as such. Travelling in the dark we may be on the right road, but if there is any serious doubt about it, we gain little satisfaction from our progress. It is the sight of familiar landmarks which conditions our satisfaction. In general it is presentational cues, *i.e.,* percepts and ideas, which mark the progress of conation. This is as true of purely instinctive action as of intelligent self-direction. The mutual implication of cognition and conation would thus seem to resolve the apparent contradiction between these rival views.

COGNITION

In the genetic treatment here adopted we may dispense with any attempt to classify the "cognitive faculties." There is only one cognitive function, which, according to the nature of its object or of the presentations which condition its exercise, is described as visual, auditory or tactile perception, and according to temporal marks, as memory, expectation or imagination. According as the object is determined as actual or possible, so the difference of mental attitude is expressed by such terms as "belief," "assumption" or "supposal." These, however, with their many subtle variations can hardly be regarded as distinct and separate functions.

For this very general function there is no wholly satisfactory term. If "Cognition" is retained, care must be taken to avoid, in a purely psychological treatment, epistemological implications. In the theory of knowledge, as often in every day speech, what is said to be cognised is thereby implied to be "true." The term in fact is restricted to what, from the psychological point of view, may be the end or terminal state of a complex process, and possesses in addition certain characters in virtue of which it is recognised as true. With these criteria the psychologist as such is not concerned, except in so far as the marks of truth are discovered by the experient himself in the course of his development. In psychology, however, the term "cognition" is required to cover the process as a whole. Believing and supposing are in the psychological sense cognitive processes. But how far what is supposed or believed really is as it is supposed or believed to be is not properly a psychological question. It is not indeed a question which the psychologist can safely ignore. In tracing the conditions under which a belief arises, it makes an important difference whether the belief is assumed to be false or true. But whether it is false or true cannot primarily be decided on psychological grounds but on grounds which the psychologist shares with others. The appeal is primarily to common sense and science. It is only in a secondary way that the psychologist can supply relevant data. Where there is otherwise room for doubt, he may show that the psychological conditions are such as to account for the genesis of a belief, without assuming it to be true or even assuming it to be false. Is a mountain which looks near really near? It is relevant to this question to point out that whether it is near or far it would for psychological reasons seem to be near,

The Development of Cognition.—Two closely connected problems are presented; to trace the development of the knowing function, and to disentangle the various phases of growth in our apprehension of the world in which we live and of ourselves as agents. In these inquiries we have to determine the primary and irreducible elements with which development could theoretically begin, and to formulate the laws of growth by the operation of which our present complexity of experience has been brought about.

It is clear that we can start neither from blank unconsciousness nor from any absolute beginning. If conscious life has had a beginning at all the point of its emergence is not known, nor can we observe such forms of experience as we plausibly postulate in primitive animal life. What is literally irreducible may perhaps never be known. It is sufficient, however, to treat as primitive that which resists analysis and cannot be derived by accepted genetic laws. How, then, are such laws to be known? The answer might also naturally seem to depend upon the evidence of primitive experience, and the difficulty has sometimes been supposed to constitute an objection to any serious attempt to solve the problem at all. There are, however, means at our disposal. The conscious life of which we have immediate awareness is consciousness in process of development, and from such changes as we there observe the principles of growth can be defined.

Primary Laws.—"Suppose that in the course of a few minutes we take half a dozen glances at a strange and curious flower. We have not as many complex presentations, which we might symbolize as F_1 F_2 F_6: But rather, at first only the general outline is noted, next the disposition of petals, stamens, etc., then the attachment of the anthers, position of the ovary, and so on; that is to say, symbolizing the whole flower as (p' [ab] s' [cd] o' [fg]), we first apprehend, say (p' s' o'), then (p' [ab] s'. o') or (p' [a] s' [c] o' [f]) and so forth." The case, adduced by Ward (Psychological *Principles,* p. 81), provides in miniature an example of the principal laws with which we are concerned. The changes admit of precise determination by experimental methods. If the object is exposed in momentary flashes by means of an instrument through which the duration of the appearance and other conditions can be accurately controlled, the phases of cognitive growth admit of clear delineation.

In general, we find that when the object is a complexly variegated whole the context immediately apprehended undergoes a process of differentiation either until its detail is exhausted or until certain limits are reached which are set by the so-called "span of attention" and the observer's powers of discrimination. Certain phases of this growth call for special attention.

(a) Differentiation.—Sense experience is sensibly continuous, each fresh item intruding not as something absolutely new, not as a presentation replacing a total absence of experience, but as a change in a pre-existent sensible field, part of which remains as a relatively indeterminate background. The darkness which is experienced in the absence of external stimulation is wholly different from the insentience of a stone. What is earlier in the process is usually lacking in variety. At first a cloudless sky will appear as a uniform blue, but attention will reveal a variety of hues between the zenith and the horizon. Differentiation which in normal perception occurs with extreme rapidity admits of detailed analysis, when, by experimental means, this process is slowed down. Under such conditions a definite order is observed in the emergence of specific colours and forms—an order which perhaps more or less accurately repeats that of cognitive development in the race. Despite the marked contrasts which now obtain between the specific qualities of a given sense the variety they manifest has only come about by slow degrees. This well may be the case with regard to the more fundamental difference of modality as well, for the hypothesis finds indirect support from the physiology add pathology of the receptive organs, ahd from what is known of sentience in the lower animals.

(b) Outline to Detail, **Implicit** to **Explicit Apprehension.**—It is the broader and larger characters of a whole which first receive attention, but '(broader" and "larger" must be interpreted in a psychological sense. It is not what is "objectively" largest that is first to be perceived. Ptoverbially, the wood may not be apprehended for the trees. The point is rather that attention is first attracted by certain convenient wholes (and convenience is relative to development) which unite within themselves a number of components which escape explicit discrimination, and it is as units in such wholes that they are subsequently known. But before discrimination they are not wholly unknown. The whole appears different on account of their existence. Hence they may be said to be implicitly apprehended. Thus in noting a "certain strangeness" about my friend I have implicitly apprehended that he is growing a moustache before I have "located" where the strangeness resides.

Even when the items of a whole are singled out by attention, the characteristics they possess are conditioned by their context. This fact is strikingly illustrated in many familiar illusions. In general, cognitive development does not proceed simply by accretions and associations. If an analogy be required it will be found rather in the emergence of structure in an organism rather than in the growth of a snowball or a crystal.

(c) **Progressive** Determination.—The original apprehension of any object is characterised by "vagueness." What is given is given to be determined, to be rendered determinate. What exists must be in its own intrinsic nature perfectly determinate, whether it be a sense-presentation or a physical thing, but as apprehended it is originally and probably always more or less vague. We perceive a thing as of a "reddish hue" and as more or less angular in shape before we apprehend it to be a perfectly determinate shade of red, and of such and such determinate angles. In the same way it is possible to be aware of something moving when we know neither what it is that is moving nor in what direction it goes.

(d) **Extension of** Temporal Range.—As we proceed from the lower to the higher forms of cognition we observe a further characteristic, one that is not involved in the example which we have so far had before us,—the extension of temporal range.

Primitive experience, there are good (though indirect) reasons to suppose, is limited in reference to the present, conceived not, of course, as a point in time, but as a short duration, involving a retrospective and a prospective phase. Just as, in general, cognition refers beyond the limits of actual sense experience, so it refers directly to the future and the past. In this sense expectation and memory are original capacities of the mind. Development consists in the gradual extension of range, though how far such immediate reference may extend is difficult to decide. Certaihly not so far as instinctive pre-adaptation might lead one to suppose. Instinctive action involves prospective cognition, but probably only a step or two ahead, and in much that passes for memory we only directly know that this is what has previously been recalled.

Apart from the extehsion of immediate cognitive range reference to past or future depends upon the emergence of "free ideas."

Retention.—Advance in mental life depends upon the fact that the effects of past experience are retained and carried forward into subsequent experience. The law may be simply espressed by saying that every experience in part owes its specific character to prior experience, and modifies in turn the nature of that which follows. Increasing familiarity in cognition and progressive facilitation in behaviour are the obvious results. It is important, however, to distinguish the effects of retention at the purely perceptual level from those which arise from association of potentially "free" ideas. Mental imagery, in its present form is a comparatively late development and cognitive development has proceeded far before it is acquired.

In its qualitative aspect the general results of retention are to be found even in the case of the repeated presentation of a comparatively simple object which does not admit of internal differentiation—say in the successive strokes of a clock. Herg the physical occurrences are identical in nature, but the successive presentations vary in a systematic way. The case may be symbolised as follows:—

$$\begin{array}{ccccc} o & \cdots & o & \cdots & o \\ \searrow & & \searrow & & \searrow \\ p & \ldots & p_{m_1} & \cdot\,.\,. & p_{m_2}, \end{array}$$

where o stands for the physical occurrence, p for the corresponding presentation and the subscripts m_1 and m_2 for the peculiar modifications which distinguish the more or less familiar from the novel.

The case may be compared with that in which the successive presentations are originally various in nature, as say in the successive notes of a melody. Here the effects of retention do not modify an experience which would otherwise be identical with what had gone before, but blend in a cyrious way with the features of a novel presentation. The case here can be represented:—

$$\begin{array}{ccccc} a & \cdots & b & \cdots & c \\ \searrow & & \searrow & & \searrow \\ p_a & \cdots & p_{b(m_1)} & \cdots & p_{c(m_2)}, \end{array}$$

a b c standing for the physical occurrences, $p_a \ldots p_{b\ m_1} \ldots p_{c\ m_2}$ corresponding presentations, m_1 and m_2 again denoting the modifications due to retention. The question is what precisely is the nature of these modifications?

The process has been described as one of "acquirement of meaning:" The later strokes of the clock have acquired a meaning which the initial experience lacked. The meaning of a presentation depends upon its place within a whole. What, then, we may ask, is meaning?

Meaning.—At a relatively developed level of mental life meaning may be conveyed by an associated image. I hear a word in a foreign language which I do not understand; it is devoid of meaning. The object to which it refers is pointed out. Thereafter the word being repeated an image of the abject may be revived. This will then convey for me the meaning of the word. In this sense meaning depends upon associated context. But this is not its most primitive form. The kitten on its second encounter with a dog has neither the time nor the inclination to call up a mental picture of its earlier adventure, but the present impression is "charged with meaning."

Meaning might here appear to consist in the altered intrinsic nature of the sense-presentation, yet this cannot be the case, No change merely in quality, intensity, extensity and duration can constitute a meaning though no doubt such changes will concurrently occur.

Primarily, meaning consists in -'objective reference," in the primary judgments of perception. What is important to the so-called "feeling" of familiarity is the implicit judgment, "this has occurred before." But the primary judgments of perception depend upon sensory experience. What, then, is the sensory basis in this case?

If it consists neither in changes in the primary attributes of sensation, nor in a distinct imaginal context, it is plausible to suppose that it lies in the less differentiated background in which the sense-presentation is set. Such background need not be all of presentational nature, but may include subjective components, *e.g.,* the experience of difficulty or ease in the process of perception. The shocks of surprise and the general "organic reverberation" of sensory experience may also play a part, though whether familiarity is a positive quality over and above the mere absence of the feeling of strangeness is difficult to decide.

Similar considerations apply to the more complex case of a succession of varied presentations. The separate items have potentially characters in their own right, but each is modified in accordance with what has gone before. The particular sense-presentation is part of a larger whole and as such it is apprehended.

Nevertheless changes in the internal nature of a sensory experience in virtue of what has gone before follows in accordance with an even wider law—what we may call the principle of the unity of experience. Physical things are thought of as remaining constant in their characters in total independence of environmental change except in response to specific *causal* laws. The colour or size of a flower does not depend upon its background. Within experience, on the contrary, there is universal relativity. The nature of a sense-presentation depends on what has gone before and upon much that simultaneously occurs. Even apparent exceptions to this rule are becoming increasingly difficult to discover as quantitative investigations become more exact and refined.

The Transition from Percepts to Free Ideas.—It is distinctively characteristic of Percepts that on the side of sense they involve impressional experience,—sensations proper as contrasted with images. But we are now able to have thoughts and trains of thoughts which are quite independent of present sense impressions. Such thoughts are free ideas and they are possible only inasmuch as on the side of sense, images are substituted for impressions, How then do images first arise? They are, as has already been remarked, a relatively late development. All the evidence would seem to point to their absence in lower stages of mental life. They emerge only when impressional experience has become sufficiently complex and differentiated. How this takes place we have already partly indicated in treating of Differentiation, Retention and acquirement of meaning. We have now to take account of another side of the same process which we have so far not expressly considered—Complication. When we see snow we are perceptually aware of it as cold, soft and wet much in the same way as we are aware of it as white and extended. There is a "forefeel" of its coldness, softness and wetness (Ward, *Psychological Principles,* p. 186). But this is inexplicable if all that is sensibly experienced in perceiving the snow is the visual impression. There must also be, and introspective analysis shows that there are, revivals of what is retained from past impressionable experiences in which we have not only seen but handled snow. Such revivals are inseparably one with or "tied to" the original impression, and, except that they are derivative not primary, are themselves impressions rather than images, or have a character intermediate between the two. They are not substituted for impressional experience but only make it more complex. Hence the process through which this comes about is fitly called Complication, which corresponds at the perceptual level to Association of Ideas.

When differentiation and complication have reached a certain stage, sensory revival is no longer tied to a present primary impression. It is capable of being set free as a mental image. Other conditions being fulfilled, this takes place when subjective interest requires it, and is coincident with the endeavour to take measures beforehand to meet situations remote in time and place.

Besides this general principle we may also refer to two special conditions which facilitate the emergence of free ideas. The first is the continued effort to attend to a percept after it has ceased to be present to the senses. There thus arises an image which is peculiarly vivid because it blends with and is reinforced by a fading impression. This is what is called the "primary memory image." The second is disappointed perceptual anticipation. What, owing to complication we preperceive as hot turns out to be cold, what we expect to resist our movements crumbles beneath our touch, the egg we are about to eat is found to be an empty shell. What is thus excluded from impressional experience becomes contrasted with it as an image and perception gives place to an idea.

Association. — The topic of association has traditionally been treated, firstly, so as to account for "complex presentations," and secondly, to explain the sequence of ideas in the course of thought.

In regard to the first problem it is important to note that association proper presupposes the prior and more fundamental phases of development with which we have been concerned. Though the various forms of complication and association are genetically continuous, the last of these terms is conveniently restricted to the organisation of the tissue of experience in which the related terms are explicitly distinct as free ideas.

The Laws of Association. — Associative processes have traditionally been formulated in terms of specific "Laws." Thus it was supposed, in the early days of the history of Psychology, that associative revival depends upon certain relations obtaining between the items of Perception: contiguity, in time or place, similarity and contrast. Reflection, however, clearly shows that there is nothing in the relations as such, in virtue of which one of the related items should recall the other. Contiguity of objects on a table would not determine the idea a percept of one or reinstate an idea of another unless the contiguity had itself been apprehended. There is no reason, independently of experience, why thought of anything whatever should induce the idea of that with which it stands in contrast. The basis of association is the co-presentation of the associated terms in some relation to each other, and any kind of relation whatever, provided that it is perceived and thought of, may serve as an associative link.

So called "association by similarity" may not, at first sight, seem to come under this general principle. A tiger may suggest a cat to a person who has had no previous knowledge of tigers such as would enable him to notice their resemblance to cats. But this difficulty is easily met. The phrase "Association by Similarity" is misleading. The associative link may be more accurately defined as the relation of both the associated terms to some common class or kind of which they are both members or instances. When we see a cat we are aware of it as a certain sort of animal. When we see a tiger we are also aware of it as a certain sort of animal. In some interesting respects and to an interesting degree, the tiger, in spite of specific differences is referred to the same general class as the cat. This is the associative link between them. A red patch may suggest a blue patch not because of any spatial or temporal contiguity between either the patches as a whole or any of their parts, but because red is apprehended as a colour and blue is apprehended as a colour too. We may speak of a partial identity in red and blue in virtue of their being colours, but the phrase here takes on a meaning radically distinct from that which it has when applied to overlapping areas or events.

It is not only in association by similarity that we have to take account of universals. The "items" of association are never bare particulars of sense. That this is the case is seen in a detailed analysis of the operation of the law. What is revived is never a simple photographic copy which is constantly related to the original impression. When such is specifically required, it calls for deliberate reconstruction. In general, however, the photographic image would be of no advantage. What is required is something much more plastic. In the reinstatement of the context of an object seen near at hand, but imaged as at a distance, such context is correspondingly reduced, and different adaptations are required in every case. Such plasticity is in fact involved in the sensory forms of reinstatements such as pre-perception or hallucination. The principle has been formulated as that of Relative Suggestion (Stout: *Analytic Psychology,* vol. ii. ch. 1), and it is in this way, rather than in terms of sensory atomism that the law of association requires to be expressed.

The point is of vital importance for a theory of imaginative construction. The vague conception that imagination works with the data of disintegrated memory, variously recombined much as a mosaic pattern might be rearranged, fails to fit even the simplest facts. Perceiving a red square and a blue triangle makes possible the immediate presentment of these figures to the imagination with their colours interchanged. With a row of such figures each of a different colour, material is provided for endless permutations. This principle affords an answer to the question with regard to that "so singular" possible exception to the rule, that we can only image that which has first been given to sense, that the mind cannot form a novel "simple impression." Could we imagine a given shade of blue when this had never been presented, given acquaintance with every other shade and every other colour? No doubt is felt if the question is raised with regard to shape, but no difference in principle would seem to be involved. Subject to the limits of discrimination (which in imagery is coarser than in sense) we can produce a number of novel members to a series which is presented to sense.

The concept of "contiguity" calls for further analysis in respect of the temporal relation between the contiguous items. The term co-presentation might, literally taken, suggest "simultaneous apprehension"; but the question may be raised whether such simultaneity when it does occur is not, to a great extent, the fruit of succession. Items successively apprehended by the "movements" of attention come, through primary retention, to be co-present to the mind. We seem to see a picture all at once, but more precise observation would reveal a progressive apprehension in which what is prior in experience is retained until the object is seen as a whole. This is quite evident in hearing a spoken sentence.

Where two items are, in this sense, co-presented, they may be simultaneously revived, and each will revive the other with equal ease. Where, however, there is succession in presentation, there is strong presumptive evidence that associations are formed primarily in the "forward direction." That which follows in experience is revived more readily than that which precedes. Nevertheless there is also undeniable evidence that weaker associations are also formed in the reverse direction. Though we repeat the alphabet more easily in the order in which the letters were learnt, we can, if necessary, say it backwards too. This, however, may be due to primary retention.

In so far as that which is presented is retained, it is carried forward in experience side by side with "objectively" later impressions, and may later become again the object of attention. In hearing a spoken sentence, the earlier words are in this way carried forward, and after attending to the meaning of the sentence as a whole we may note the mispronunciation of one of the earlier words. In which case, we may later associate with the memory of this statement the speaker's offending pronunciation rather than his subsequent conversation. In any case it is the order in experience rather than the order of stimulation which is psychologically important. And the order of experience is the order of attention. For this reason the law may be described as the "Law of Association by Continuity of Attention."

The Sequence of Ideas. — The course of experience is never wholly objectively determined nor wholly determined by subjective factors. Nevertheless, we may broadly say that perceptual process is predominantly determined by external circumstances whereas over the sequence of ideas we have a more direct control. The question arises how far does the law of association explain this latter type of sequence. As ordinarily stated the law of contiguity would suggest that the course of our ideas, whilst free from the domination of the present, is still in fetters to the sequences of the past. Except in so far as similarities provide, so to speak, a series of cross references, we find no escape from a merely historical order in our passages of thought. Obviously, however, the facts are against any such simple view. The law of association calls for considerable amplification.

In the first place a given item of experience occurs in a variety of contexts. Which of these is likely to be revived, and what of all that is similar will be selected by thought?

To these questions a partial answer is provided by what we may call the sub-laws of association, the principles of Frequency, Recency and Intensity.

Given that the revival of any item in experience will tend to reinstate its context, the more frequently any given context has occurred the more probable that specific context will be the one revived.

Similarly, with regard to Recency: the more recently any specific context has accompanied a given item, the more likely that context is to be revived.

These two sub-laws admit of a fairly precise quantitative formulation, the first being expressed by the "curve of learning," the second by the curve of oblivescence.

The "Law of Intensity" admits of a variety of interpretations, the term standing ambiguously for the intensive attribute of sensation, for intensity of feeling, or the "intensity" of attention. It is doubtful whether the mere intensity of sensation (apart from the effects upon feeling and attention) is of great importance. So far as it is, it occupies a still more subsidiary rôle among the very special laws which relate to the sensory attributes in general. Probably the best expression for the law of Intensity is as the law of Interest. The more interested the transition of attention from an item of experience to its context, the greater the tendency for the sequence to be revived. So stated, the formula is closely related to the so-called "Law of Effect," which latter refers, however, more particularly to the acquisition of skill, and to the formation of habit. In the association of movements much depends on whether the action is followed by pleasure or pain. When the "effects" are pleasant the association is "stamped in," when painful it tends to be impaired.

To speak of a law of Interest has the required impartiality of emphasis as between conation and feeling, though if the hypothesis defended in another section turns out to be justified, the emphasis should ultimately be placed upon conation. So interpreted the three sub-laws would fall into line in a general formulation: *that the strength (or revivability) of an association depends upon the frequency, recency and intensity of conative activity in a given direction.*

These laws, however, are not independent. Strictly, we should say: the more frequently or recently a conative tendency of given intensity has been furthered by the passage of thought from A to B the greater *ceteris paribus* the tendency for B to be revived by **A.** There is the possibility of interference or compensation between the effects of recency and frequency and greater frequency or recency may balance a weakness in intensity, but no amount of frequency will increase the tendency for B to be revived, when its revival would be adverse to the general conative trend. This is most evident in the special case of motor associations. The more frequently or recently a certain end has been furthered by a given response, the greater the tendency for the response to be confirmed. But where the movement is adverse to the fulfilment of purpose neither frequency nor recency will serve in the least to confirm it.

The same principles are operative in the association of ideas. Ideas tend to be revived in accordance with the conative trends of thought. It is true that painful as well as pleasant ideas tend to be revived. But, painful ideas may be relevant to the trends of thought. Apart from such relevance they fail to be revived. Similarly unpleasant actions tend to be repeated and painful habits formed in the pursuit of remoter ends, though not otherwise.

But this law, however much it may be amplified, refers only to the past, to the conditions of co-presentation and to prior conation. Explanations of mental process by reference to such conditions alone fail to take account of the influences of the present, which determine the direction of associative revival. These are factors which are selective of what is relevant to and consonant with the present direction of endeavour. Hence, "necessity is the mother of invention." Associations relevant to the present exigency are preferred.

Chief importance attaches in this connection to specific conative experiences, in particular to the awareness of the nature of the problem to be solved. The conceptual formulation of conation is what constitutes a "question," and the more clearly the question is defined, the narrower is the range of associative relevance. Associative process is thus subject to multiple control. The train of ideas does not consist in a simple linear sequence, each item directly and independently leading to the next. Any particular sequence is under the general control of a governing idea—the idea of the end more or less clearly conceived. Such governance may depend upon a complex hierarchical organization of the controlling ideas, with the most general logical notions standing at the head, and various kinds of "schemes" controlling the general lines along which the problem is treated. Where specific conation is absent we can still detect the influence of the vaguer emotive "moods." Depression favours unhappy memories, and gloomy prognostications. In joy, the train of ideas is similarly congruent with the mood. Such emotive states may be conatively defined.

PERCEPTION OF PHYSICAL THINGS

The Problem. — The second of the general problems of cognition is to account for the growth of our apprehension of a world of physical things and of the self in relation to which this world is described as "external." In this development three distinct levels would seem to be involved. There is the normal adult human perception of daily life. Below it there is a much more primitive level of perceptual apprehension, and above, the level of conceptual thought and ideal construction. Through a window I perceive a not too distant mountain In spite of appearances I take it to be of enormous size, and to be covered with white snow. This is the normal interpretation of perception. But it *appears* extremely small and, on account of the setting sun, of a distinctly reddish hue. These are the perceptual data. But neither of these accounts would seem to correspond with "scientific fact." The apparently solid and motionless mountain is explained as a whirling mass of electrons, and endowed with properties which I neither do nor can perceive nor directly infer from what I perceive. The immediate problem, however, is to disentangle the earlier levels of apprehension.

Primary **Data.**—Whatever else may be involved sensible experience must be accepted as primary. But mere sense-presentations strictly and abstractly conceived alone are not enough. The processes we have considered, operative only with such material, would not suffice to explain our apprehension of a world of physical things. It must be taken as a datum for Psychology—as a fact of experience—that we are cognisant of and active about objects which are not themselves capable of being sensibly experienced. Thought or judgment transcends not only present sense-experience but sense-experience in general.

So far as cognition is concerned thought may be psychologically considered as a tissue of beliefs and suppositions. Belief as a mental function is an irreducible component of experience, but particular beliefs are primary in another sense. The majority of beliefs are inferential or arise from mere suggestion. Beliefs not so derived may be described as "original," and original beliefs must be involved in the explanation of our apprehension of the material world.

Corresponding to every sense-presentation, involving an act of attention, there arises an original belief that something is there and is characterised in a more or less definite way. There are original judgments involved in recognition, and memory judgments asserting past experiences, as such, may similarly be "original."

Discrimination between original and derivative beliefs can only be effected in the course of a detailed investigation of the development of cognition. One very general principle, however, would seem to be involved in all the fundamental modes in which the mind refers to its objects. Such reference is conditioned by sense-experience. Every variation in the thought depends upon some variation in sense and every variation in sense-experience makes possible some variation in thought. Hence therefore, parallel to, and based upon, the development of sensory experience, thought advances in complexity, determination and range. The simplest presentation is endowed with primary meaning, secondary meaning being acquired through retention. Retention, association and reproduction of thought, depend upon analogous processes in the sensory field. The parallelism, however, is subject to complications in detail. Sometimes likeness among sense-presentations means only a corresponding likeness among the objects to which thought refers; sometimes likeness of presentations provides the basis for a judgment of *identity.* Change in the sensory field points to changes in its conditions, but not necessarily in the object singled out as the thing that is being perceived. Sensible movement in immediate experience conditions the primary judgment "something moves." According to the context the movement may be referred to various things, to the things which appear to move, to the otherwise unperceived medium or to the bodily self. In fact the explanation of the development of cognition consists in one aspect (the abstractly cognitive) in determining the nature of the sensory experience which conditions our developing apprehension.

We must start with the simplest appearances, but paradoxically the simplest appearances are not the easiest to observe. Generally one perceives that the mountain is large and covered with white snow without noticing its apparent smallness or its reddish hue. To become aware of the latter the direction of attention must be changed in a subtle way. It must be diverted from the mountain and directed to sensuous presentations in themselves. Nevertheless from such appearances we must start though not in their artificial form. What is artificial is the restriction of attention to isolated data in the field, and to certain of their characters in a similar isolation. There is no such complete restriction either in primitive or in normal developed perception. Our original apprehension is of a complex whole all the ingredients of which co-operate, without being individually apprehended, to determine the judgments of perception. The colour constituent of the sense-presentation largely determines the colour attributed to the physical object, size and shape in the sense-presentation, size and shape in the object but these factors do not operate independently of each other. Ellipticity, for example, in the sense-appearance of a plate *combined with differences in sensible depth* in different parts of the ellipse jointly determine the judgment that the plate is round, and similar considerations apply to perceptual judgments of colour and size.

Such joint determination is not wholly acquired. Moreover, not only is a given character, say ***A,*** as applied to a physical object, jointly determined by a combination of characters, say $a' + b'$ in the particular sensation, but the characters of a conjunction of distinct sense-presentations, say P', Q' and R', may also determine the character assigned to a particular physical object, say P, which corresponds to only one of them. This is exemplified by the laws of confluence and contrast.

Appearance and Reality. — Sensuous presentations, which practically may be sensibly experienced without being discriminated, singly or jointly determining our judgments of perception. The problem is to assign to these judgments their sensory conditions. We are thus concerned not with the evolution of perception out of bare sensation but with two lines of parallel and correlated growth. Knowledge of sense-presentation is not prior to knowledge of physical things. The most that we can say is that originally there is no explicit distinction between judgments with regard to such presentations and judgments with regard to physical things. The occurrence of a sense impression having the attributes a, b, c, occasion the immediate awareness that there is *something* to which these properties belong. This object is thought of neither as "my sensation" nor as "that physical thing." The distinction between sense-presentations as such and physical objects, as well as the connected distinction between appearance and reality, depends upon experienced contradictions, and more especially upon the thwarting of conative activity.

The child before he reflects upon the illusions of sense attempts to grasp the moon. Disappointed expectations of this kind imply a faulty objective reference. The awareness of coetradiction depends for its possibility upon judgment transcending the limits of actual sense-presentation, it pre-supposes in particular the reference of different sense to an identical physical thing. Only in so far as that which visually is elliptical is regarded as identical in shape with that which to touch feels round can contradiction arise. But the reference of characters of separate sensation to a single thing cannot be determined on the basis of the particular sensum considered in isolation. It depends more particularly upon concomitant variation between the sense-presentations involved and between these and the experience involved in practical experiment.

The experience of contradiction arises when conditions largely favour, but do not wholly sustain the judgment of identification. But in such cases contradiction is never complete and absolute. Where there is no approximation to concomitant variation, no synthesis, and hence no contradiction, can arise. If a series of visual forms are wholly independent of a series obtained by touch we do not treat one as a distorted appearance of the other, but refer them to wholly different things. The significant contradictions are those which constitute exceptions to a general rule, an incoherence which is partial, not complete, and calls not for the abandonment of the rule but only for a better formulation.

Some degree of truth is required even in a mere appearance. The stage at which we are aware merely of the conflict between appearances without further determination of the situation leaves open two further lines of cognitive development: which of these appearances best presents the real? And how must the false appearance be accounted for?

In the solution of these problems attention is still directed to concomitant variations. In the mere conflict between visual and other presentations (tactile and kinaesthetic) there is nothing to suggest that one is more veridical than the rest. There is no peculiar veracity, as has sometimes been supposed, in the testimony of touch. Examples are easily found where vision is the better guide. It is the series of perceptual judgments which find support and corroboration from other sources which comes to be accepted as the revelation of the real, whilst those which fail to be reinforced by independent evidence are rejected as illusion. Were it possible to reinforce the double images which arise in displacing the eye ball by a corresponding duplication of touch and to preserve the correlation through varied forms of manipulation the faulty judgment would thereby be confirmed, but such conditions are in detail impossible to obtain.

With the consciousness of the real the elementary practical requirements are generally secured, and the illusory appearances are allowed for or ignored. In fact, however, the experient does not leave the matter here. Incoherence in experience, like any form of problem, provides a motive for further activity of attention. Moreover, the data from illusions are of practical utility, and assist the growth of knowledge in other ways. Variation in the appearance of an object may provide no information about its intrinsic nature, but through it knowledge is obtained of the medium in which it stands and of the embodied self as percipient.

In the course of our practical dealings with physical things, sense-presentations arise and change in various ways independently of our own activity, In this way knowledge is primarily gained with regard to objects other than ourselves. When however, changes occur concomitantly with and follow from the exercise of our volition, we obtain a fuller apprehension of the nature and powers of the embodied self. But we cannot sharply divide sensation into two separate groups, those which are wholly independent of ourselves and those which are wholly dependent. In general changes which are partly independent and partly dependent on ourselves occur in all alike. Hence through the same sensible change knowledge is gained concerning both ourselves and other things. But what is only apparent change in external objects means real change in the percipient self, or in the medium of perception. "Appearance" and "reality" are thus relative terms. Nothing is *mere* appearance, nothing *sheer* illusion. Originally knowledge is vague and confused. Attributes within the presented field are loosely and indiscriminately referred. But the properties of things are gradually sorted out, as being either the real and inherent properties of the thing perceived, or of the medium through which we apprehend it, or of the organs of the self. Before discrimination is complete the real properties of one thing are the apparent properties of another, but nothing which enters into perception would seem to be able to stand as the property of nothing at all. There is no doubt a tendency to refer too much to that which at the time is the centre of interest — usually the physical thing perceived — and too little to the medium through which it is observed, and hardly anything at all to the organ of perception.

So far then from our apprehension of the world commencing in the awareness of "subjective modifications" giving rise to a subsequent process of "projection" of their properties to external physical things, the reverse description would be much nearer the truth. If anything, we start with an objective bias, and what is most inward is the last to be observed. A long inductive inquiry is required in order to determine just where each property is properly to be referred. The process serves to illustrate the fact that "scientific method" is implicit in cognitive development throughout. Our pre-scientific knowledge both of the external world and of the embodied self involves the use of principles which later may admit of explicit formulation and deliberate use. The employment of hypothesis, the search for verification and the use of "methods of induction" so far from being superimposed at the level of pure conceptual thought are implicitly involved at every stage. Conceptual formulation arises from reflective analysis upon processes which have practically been employed without abstract formulation or generalised expression. Here, as elsewhere, science is but the refinement and extension of common sense.

CONATION

In reviewing the functions of the embodied mind, priority of treatment, in conformity with tradition, has been accorded to cognition It is, however, very widely held that priority belongs by natural right to the experience of conation. Primarily, it is said, we are practical beings, we cognize only as a means to action. It would further seem to be implied that cognition as divorced from practical action is a late and unnatural growth.

We can in fact go further and assert that cognition is itself a mode of action, and any separation is possible only by abstraction. This, however, can be granted whilst denying priority either way. If mere cognition is an abstraction, conation divorced from it is unintelligible. The object of conatioa must be also in some manner an object of apprehension.

In the study of conation we return to the problems which are central from the objective point of view; for the experience of conation is the normal psychical antecedent to a bodily movement. But many psychologists have been curiously unwilling to endorse this common sense opinion that an action is normally the outcome and expression of a *wish* or of our wanting some change In a given situation. It is often said, for example, that for a movement to occur all that is necessary is that attention be directed to a representation of that movement or of its effects. This is the doctrine of *ideo-motor action.* It fails, however, to do justice to the unique and irreducible nature of conative experience and to assign it any intelligible function when it in fact occurs. Whilst "wanting" implies attention the latter does not exhaust the meaning of the former. It is in fact only a special case, Attention is conation directed to further cognition. Bodily action, however, implies more than curiosity with regard to the presentation of movement. We *want* the movement to occur and external effects to be produced. We shall find that a more coherent theory of behaviour can be founded on the view that conative action is primary and that ideo-motor and even reflex action are specific types of simplification of what was originally more complex.

Whenever there is experience there is the experience of conation. The statement is difficult to establish only when it is difficult to prove anything at all—in the very beginnings of mental life. But we are not dependent upon the direct observation of beginnings Here, as in the study of cognition, we rely on the analysis of mental life in its clearest form and upon the postulate of genetic continuity. Explicit desire, directed to ideally represented ends, is obviously not the beginning of conation. We strive and struggle at the perceptual level. The wish to be rid of a toothache does not involve ideal representation of the state of affairs we aim at. In its most primitive form, the aversive attitude is directed to the removal of the present pain; its end is "anything but this," and need not be further defined.

It has been asserted that the development of purposive action depends, in primitive experience at least, on the aversion which goes with present pain and not with any appetition accompanying present pleasure. In positive enjoyment, it is said, there is only a tendency to maintain the pleasant situation as it already is; and for this all that is required is attention to it and such motor adjustments as subserve attention. Aversion to a present pain, on the contrary, can be satisfied only by getting rid of the painful conditions, either by removing them or by escape from them. Its success therefore gives rise to a new state of affairs, not to a mere continuance of the pre-existing situation.

It may be doubted whether this account of the conative side of pleasant as contrasted with painful experiences is tenable. It is by no means always true that the continuance of enjoyment depends only on the uniform continuance of certain agreeable conditions. In the most important cases, what is enjoyed is enjoyed as a stage in a progressive process leading up to relatively new stages, so that, to quote Hobbes, "There is no content save in proceeding." In such experiences the end to which conation is directed is not merely "this" but "something more than this" or "this and something more." As examples at our present level of development we may refer to the pleasant excitement of reading a novel, or the pursuit of knowledge or of adventure. At a lower level, we may refer to the pleasant excitement of an animal in pursuing a prey or in courting a mate, or in other activities along the general lines of inherited instinct. If we suppose a most primitive experience in which inherited instincts as yet play no part, the experiencing individual will have to find out purely by tnal and error how to treat a given situation so as to continue and enhance the enjoyment of it. But it is equally true that under such conditions he would have to learn'partly by trial and error how to get rid of pain.

If we lay exclusive stress on pain and aversion in the first development of purposive action, it is hard to see how the development on the appetitive side can be accounted for at all. For if we adhere consistently to the general principle underlying this view, our only motive in seeking anew pleasures which we have enjoyed before, would be pain in their absence. Our only motive, for example, for eating a good dinner would be the pangs of hunger or at any rate some felt discomfort when we see it or think of it. The pleasant excitement of a healthy appetite would not suffice. If we begin only with the coercive and repressive discipline of pain it would seem that we never get beyond it. To do justice to the past we must from the outset begin with both pain and pleasure as mutually complementary. The first accounts for the development of conation, in its negative or aversive aspect, the second in its positive or appetitive aspect. Through the first we learn what to avoid, through the second what to pursue for its own sake. In one respect, however, pain is more important than pleasure. Especially in primitive experience it is frequently more intense and immediately urgent leading to more strenuous and violent action. From the biological point of view this is necessary to provide against imminent dangers which imperatively require to be met with the utmost promptness and vigour.

Levels of Conative **Development.**—Conative experience varies in respect of its qualitative modes, in intensity and duration, in the nature of its ends, and in the character of the action in which it finds expression. The most important changes in the course of mental development will be found to depend upon cognitive growth. Given presensory experience with correlative objective reference, there will be primary objects of appetition and aversion Further differentiation, itself conditioned by prior conation, will yield further objects of conation. Responses at first conditioned by isolated sensations will be increasingly controlled by attendant circumstance. The more determinate the objects of cognition, the more determinate will become the connected objects of conation, and with the extension of the cognitive range simple impulsive actions will give place to responses conditioned by retention and the presence of free ideas. In general, the laws of cognitive development apply *mutatis mutandis* to the development of conation. Our problem now is, starting from primitive conation, to trace the main phases of this development.

The Primitive **Impulse.**—With reflex action, in the physiological sense, we are not here concerned, so far, at any rate as there is no concomitant experience. But many actions which, externally viewed, appear to be purely reflex have conscious concomitants. The response to the prick of a pin involves not only an awareness of sensory pain, but also the impulse to remove it. Such experience might seem to provide a convenient point of departure for the study of conation.

In a sense, the presentation of pain is the object of the aversion, but the statement requires guarded interpretation. Sense-presentations as objects are essentially incomplete. The response is concerned with a physical source of stimulation more or less clearly so perceived. There is, moreover, a further way in which conation here relates to something beyond what is sensibly present. The object of aversion is thought of as something alterable and as something to be altered in some way. The kind of alteration required is probably never wholly indeterminate.

In conative activity at the perceptional level there is a group of presentations of paramount importance. So far as changes are effected in the external world, and thereby in the sensory field, they can only be produced by means of bodily movements similarly presented. Conation is thus subsidiarily concerned with presentation of bodily orientation and of movements to be performed. Whilst in simple reflex action awareness of bodily movement may be extremely vague, and perhaps entirely absent, this is far from being invariably the case. Thought of the movement to be performed is often quite distinct, and the awareness of the body an important controlling factor throughout the operation. If we regard such simple deliberate acts as the primary form of conation, it is possible to exhibit the reflex and the habit as a specific modification resulting from exercise. From this approach the simplest formulation of primary reactions turns out to be somewhat complex, but the path is more than proportionately smooth for an account of subsequent development. We may state the case as follows: The presentations of external objects which call for alteration, when accompanied by an awareness of bodily orientation (apprehended as admitting of similar alteration), directly evoke a movement producing change in the required direction. Symbolically:

P_1 apprehended as alterable to P_2 (P_1, P_2 being respectively objects of aversion and appetition) in conjunction with M_1 apprehended as alterable to M_2	directly evoke M_2 and indirectly P_2

Even this formulation involves excessive simplification. In the first place P_1 is apprehended in a context which from the outset plays an important part in determining the response; and a similar complexity is involved in the presentation of bodily orientation (M_1). Moreover, the latter is not simply a matter of muscular sensation. It comprises all that is relevant to an awareness of the general "organic state," such as the conditions of appetite in the narrower sense of the term. Further, the movement to be performed is apprehended as possessing a number of possible characteristics of speed, extent and direction, and the performance will vary according as one or other characteristic is relevant to the intention.

Modifications of **Conative** Process. — Primitive conative tendencies may be modified in various ways. The cognitive context admits of various forms of simplification and elaboration. Activity is not in general conditioned by single presentation but by complex presentational cues, the features of which are more or less clearly discriminated and jointly operative in producing the effect. Central features will have a context more or less stable or variable. When it is relatively stable a single subsidiary feature or merely a general impression will serve to guide activity. When the context is variable, response may call for similar variation. A second type of change relates to intensity. At first sight the frequent occurrence of the same situation appears to work in either of two directions. Conation may be intensified and specific tendencies confirmed, or there may be progressive weakening of the original impulse. Practice in a game may lead to what is at first a mild diversion becoming a ruling passion. On the other hand we become adapted to sources of irritation and lose interest in pursuits which previously held our attention. A third kind of change arises in the progressive integration of the primary tendencies. Several cases call for special consideration.

Automatisation. — It is a familiar observation that actions originally requiring attention come to be performed "unconsciously." We do not, for instance, give the same attention to the buttoning up of a coat as a child who is learning to do so. There would seem to be two stages whereby a movement becomes automatic. The first is that in which attention is merely withdrawn from the movement and concerns itself with the external cues alone. In threading our way through a crowd we do not think of the movements of turning to right or left, or increasing our speed or stopping as occasion requires. Action follows directly upon the perception of the obstacles which we have to avoid. In variable situations automatisation does not advance beyond this stage; but in relatively constant sequences of events attention can also be withdrawn to a very large extent from the external cues as well. Thus in walking on even ground we do not attend to the sensations in touching the ground though these in fact condition each successive step. If the process advances so far that attention is wholly withdrawn an act originally conscious is then indistinguishable from a reflex.

Variations in Strength. — Repetition or exercise we have noted sometimes results in a tendency becoming more pronounced, sometimes in its progressive disappearance. Behind this diversity a single principle would seem to be involved. So far as the performance of any movement produces satisfaction the tendency to perform it is confirmed, so far as it fails to promote the ends in view the tendency is weakened.

This is the well known "Law of Effect" expressed in conative terms, and is identical with the principle already dealt with as the "Law of Association." Here, too, the law has sometimes been supposed to operate in conjunction with other laws — Recency and Frequency, and the same modification is here required. Recency and Frequency are dependent and possibly counteracting laws but further determinations of the primary law. The more frequently and the more recently a given response has proved successful the more likely it is to recur.

Transference of Interest. — Interest may be transferred from one object to another, and conative activity from one direction to another. The simplest cases are among those which externally viewed, may appear to be conditioned reflex actions. An object B originally accompanying A evokes the interest and acquires the power to provoke the response originally due to **A.** Sounds of a certain kind provoke the response of fear, and attendant circumstances may acquire a similar power. So far, however. there is merely an extension of the range of objects possessing a frightening character. The term "transference" may be employed when the acquisition of interest in B is accompanied by loss of interest in A. There must, however, be conative continuity between the two situations; the interest in B must be derivative from the interest in A or both must have a common origin. Many examples are to be found in the changes in theoretical interest. Practical construction may generate an interest in Physics, and this in turn may lead to Mathematics, the original practical interest being weakened or wholly lost. A more primitive case of great importance is transference in the tendency to respond to a specific situation in a given way. The primitive response to opposition is destructive and aggressive. Under certain conditions this may be displaced by subtler and more delicate reactions. In general, the relative efficiency of different modes of response is the chief determinant of this form of modification.

Chains of Action. — Particular importance attaches to constant secondary features in a perceptual situation when they have the advantage of temporal priority. They serve then as signs and portents of what is about to come, or may be brought about. This fact accounts for the increasing predominance of the "distance receptors" such as eye and ear, in perceptual development. The secondary features will according to circumstances either immediately evoke the original response or elicit a new one calculated to hasten the situation in which this response will be appropriate. At the sound of danger, flight may ensue without awaiting the arrival of the enemy. But the distant perception of prey tends not to an immediate attempt to seize it, but to antecedent pursuit, until a situation arises in which the use of the jaws will be effective.

Situations to which the right response is known and productive of satisfaction themselves become the object of appetition. In this way chains of activity, considerable in length, will in course of time develop. This would seem to be the origin of the familiar "behaviour cycles." In following out such cycles awareness of the ultimate end is by no means likely to be present. Each step need only involve prevision of the initial phase of the next.

But as we have noted, from another point of view, such developments do not consist merely in the elaboration of actions in single file. Attention is directed not only to the central feature of the situation and its antecedents but extends to all attendant conditions. More particularly, when a given response is not consistently successful a certain hesitancy will arise conducive to further discrimination and further variation. The successful response will vary according to the context. Hence, relatively to any given presentation there will be alternative responses. The whole will constitute an extremely complex conative disposition.

Primary and Secondary **Tendencies.**—Within such complex systems a distinction must be drawn between conative tendencies which are relatively independent in their ends, and others which only come into play in a purely subsidiary rôle. The former have primary ends, but the secondary tendencies have only derivative ends. The distinction is clearly present in certain classifications of the instincts. Whilst the search for certain sensory pleasures may, *prima facie,* be regarded as providing an "absolute end," "pugnacity" is dependent upon the thwarting of some more primary impulse. The instinct of escape in some of its forms at least would also seem to presuppose some prior tendency.

The distinction is to some extent, obscured by the fact that, in accordance with the tendency for means to become ends, secondary trends may acquire a certain primary character. "Pugnacity" may become an art, and danger may be sought, but the primary and the secondary forms in this case may still clearly be distinguished by their ends. In the secondary form, pugnacity involves a tendency to break down some opposition in *order to get on with something else,* whereas, when indulged in for its own sake, a conventional or fictitious opposition. is established *in order to break it down.* "Means" and "end" from the standpoint in the first case are in the second reversed.

The secondary tendencies in general are adaptive differentiation of conative activity in response to certain typical vicissitudes of the primary conation, but such terms as "pugnacity" and "anger," "flight" and "fear" are wholly inapplicable to these tendencies in their primitive forms. The first clear lines of differentiation correspond to the distinction between relative success and failure as appreciated by the experient. "Nothing succeeds like success." Partial success, in other words, exercises a special directive influence upon the course of future endeavour. Action tends to be restricted to the lines which have proved successful, whilst in failure there is a corresponding increase in the range of experimental variation. This, relatively to any given direction of activity implies a corresponding variation in the intensity of conation. But whilst success does not admit of great difference of kind, there are many forms of failure, and certain typical kinds of obstacle call for special kinds of adjustment. The characteristic difference between pugnacity and fear will thus gradually emerge. Both have their origin in hindrance and opposition, and it is not easy to determine with precision the conditions under which one rather than the other is likely to find expression. Roughly, one may say that fear is more commonly the adjunct of an aversive reaction, whilst pugnacity is employed in the service of appetition. Exceptions, however, are many and obvious. Pugnacity tends to arise in relation to other wills or in regard to objects which admit of "personification," and when the opposition is from a source not disproportionate to the agent's powers. Fear on the other hand is more readily evoked by dangers which are inadequately understood, by impersonal forces of nature, and by opposing wills of such overwhelming power that resistance will not avail.

But in the course of conative differentiation and elaboration, many complex systems may develop, which blend in such varied ways as to render hard and fast classification, totally misleading. In tracing the course of such elaboration, certain typical systems may be selected for brief analysis.

Emotion.—Emotions have been supposed by various thinkers in turn to be almost everything which might theoretically be imagined, sensations, the memory of past feelings, peculiar mode of present affective tone, or specific forms of conation. The principal issues involved may perhaps be indicated by a brief consideration of the doctrine espoused by William James (1842–1910) that emotions are the sensations which arise from the reflexly determined actions which are generally regarded as emotional *expressions.*

The objections to this view—which it is generally felt must be mistaken—do not arise from the data of physiological observations (which at present are inconclusive) but from a question of general principle. The matter is primarily one of psychological analysis. To those who adopt a strict sensationalism (and to the sensationalistic tradition this doctrine is largely due) the issue is predetermined in favour of James's view; but once distinctively affective and conative modes of experience are elsewhere recognised, their place in the experience of emotion is not difficult to observe.

It is significant that in the most natural way of describing an emotion we refer to conative tendency. Anger is the "feeling" that we should like to break or injure the object of aversion, fear the impulse to cringe or run away, and embarrassment a wish "to drop through the floor." So far from it being adequate to say, with James, that if sensation is "thought away" nothing distinctive of the emotion will remain, it would be more to the point to assert that removing its distinctive impulse from the experience of an emotional upheaval, we should find it difficult to decide whether we were angry, frightened or in love.

The fact would seem to be that an emotion is an extremely complex state of mind, involving each of the fundamental "elements." Sensations are undoubtedly essential, but cognition feeling and conation are equally implied.

The nucleus of this complex "psychosis" consists of the primary impulses involved in emotional expression, whether of muscle or gland. Emotion is not the mere experience of sensation, but it well may be conation with sensations of the expression (as such expressions are presented to the subject) as the primary objects. In anger, there is a certain satisfaction to be derived from a clenching of the fist and biting the lips. The emotional expressions are, in fact, constituents of the total object of desire. But in themselves "expressions" are incomplete. They are at best but preparatory adjustments, and from the standpoint of the experiment there is reference to an external object, in relation to which further co-ordinated action is required. For this reason it would be untrue to say that emotional tendencies do not admit of modification. Primitive tendencies persist side by side with later developments; expression of emotion shades off imperceptibly into the manifestation of instinct, and instinctive action will be found to admit of considerable modification.

Instinct.—Earlier approaches to the subject of instinct were purely biological, the term being employed to designate certain complex trains of activity, serving a useful purpose, which are perfectly executed from the first in total independence of past experience, but blind and invariable, in the species, and, through their period of exercise, in the individual life. Close observation, however, has revealed that none of these characteristics can in strictness be assigned to actions admittedly instinctive.

The Blindness **of** Instinct.—The distinctively psychological treatment of the subject relates to the nature of the experience which accompanies the performance of instinctive actions. But once it is admitted that there is an experience at all—and the fact is indisputable—it becomes impossible to maintain that the action is wholly blind. Perception of the exciting situation is at least required, and with the possible exception of the first performance some dim recollection of the effects of prior action would seem also to be involved. But even on a first performance apprehension is not restricted to the present. The perception of a given situation as one which calls for change would seem to be an essential characteristic of conative experience. The total apprehension includes a specific reference to the future, and a vague awareness of the sort of change required. There is presumably a measure of expectation, too. The moor-hen on its first dive would at least experience surprise if, as a result of its reaction to the provocative agent, it found itself in a wholly unmodified state of affairs. How determinate expectation may be in such circumstances it is hardly profitable to inquire. What is of general importance'is that to explain the development of instinctive experience, and of intelligent foresight, some reference to the future is originally involved. Growth in respect of such experience consists not in the introduction of such reference at a certain point, but in a gradual extension of temporal range, and in progressive definiteness in what is apprehended.

The "Perfection" of the Instincts.—Here, too, closer observation has called for a modification of earlier ideas. Some more qualified term than "perfection" seems to be required, and it has reasonably been suggested that the most that we can say is that instinctive action is good enough to be serviceable when it is first employed. But serviceability is relative to the situation. The first flight of the bird will save it from falling to the ground, but will not enable it to evade the attacks of enemies from which in later life it can easily escape. A distinction, too, must be drawn between the earlier and later phases of a chain of instinctive acts. The terminal links may appear to be almost reflex, whilst the earlier may be comparatively inexpert. The distinction is obscured by the somewhat artificial restriction of such terms as "instinct" to the more automatic phases of a continuous sequence of behaviour. The distinction is of importance in regard to the range of variability, and the dependence upon previous practice. The laying of the egg may be perfectly performed, whilst the search for material with which to construct the nest may leave much to be desired. The latter, too, will allow of variability on account of local conditions, and perhaps on account of individual difference of temperament. The former does not allow the same degree of scope for originality.

The Sentiments.—The higher levels of conative activity are characterised by the organisation of many and varied tendencies in the service of dominant ends, by the formation of abiding "attachments" to persons, places and things, and by the conscious pursuit of remote and ideal ends.

In contrast the lives of the lower animals appear to consist in casual and conflicting instinctive responses to what is sensibly present, without memory, constancy or foresight.

Here, as elsewhere, the advance is conditioned by a parallel development in cognition. Permanent attachments presuppose the capacity to recognize an individual as such and not merely as a member of one's kind. It presupposes also a uniformity of emotional response. So far as in virtue of past experience an object acquires the capacity to evoke a constant emotional reaction it is said to be an object of an *emotive disposition.* But objects which evoke one emotional response will generally call forth several according to circumstances, and an organisation of a system of such dispositions constitutes a *sentiment* as the term is psychologically employed.

But the mere occurrence of a variety of emotional responses towards a single object is not enough. A mere business acquaintance may on various occasions arouse a series of distinct emotional attitudes, in consequence of which we may develop nothing more than a tendency to regard him with mingled feelings. Nor do we develop in the ordinary course of events any distinctive sentiment in relation to the weather.

Organization of conative tendencies is only brought about when some dominant impulse is in control. In such typical sentiments as love and hatred, or devotion to a cause the distinction previously drawn between primary and secondary tendencies is seen on a higher plane. A dominant conation with persistent attachment to a central object maintains in its service a system of subsidiary trends. Joy, Sorrow, Anger and Fear are four subsidiary tendencies which are generally involved. In Joy we recognize, at a later stage of development and suffused with a distinctive affective tone, the primitive reaction to success. Fear and Anger, as previously observed, may be regarded as corresponding developments of the responses evoked by difficulty. Of these too Sorrow would seem to be a further special case, being in the extremer form a tendency not only to desist from any given line of action but to abandon the pursuit of the end by further variation of means. It is seen in its purest form in the ultimate defeats of the primary trend.

Theoretically, any conative tendency of primary and independent order, so far as it is enduring and concerned with a central object to which a permanent "attachment" can be formed, may provide the basis of a sentiment. It is rare, however, in normal development for tendencies to be found in such isolation. In so far as there is approximation to such simplicity the disposition is more appropriately described as an obsession, monomania, or "complex," all of which terms involve a reference to some degree of dissociation which alone can produce such isolation. The typical sentiment is complex and more or less controlled by the character as a whole.

The parental sentiment involves a tendency to seek the presence of the child, to foster its development and to anticipate all that a mature and enlightened self regard might lead it to desire.

As the simple tendency occurs only in a more complex system so the sentiment forms part of a larger whole. The parental sentiment is usually bound up with what would otherwise be regarded as ego-centric ambition and both are modified in proportion to the extent to which they blend and interact.

In general the structure of character as a whole may be interpreted as a resultant of such modes of synthesis.

GENERAL SURVEY OF THE SCIENCE

General Psychology.—In the foregoing exposition an attempt has been made to present the central problem of the science, and to indicate certain representative lines along which its topics may be treated. It need scarcely be said, however, that the subject is controversial, and that even fundamental issues are still matters of dispute. In particular, we have noted two sharply opposed tendencies which have contended for priority throughout the history of the science. On the one hand the distinctive nature of conscious life has given encouragement to the project of constructing a pure Psychology, a science of mind treated in absolute separation from its physical and physiological connections. This conception of the science has been fostered not so much perhaps by psychologists themselves as by the development of the physical science through which Nature has come to be treated as a system "closed to mind," a doctrine inevitably suggesting that Mind is equally closed to Nature. On the other hand, mental life has a bodily counterpart and in a variety of ways appears to be bound up with the more elementary functions of the organism. Hence the tendency to approach the problem of mind from a biological point of view.

On each side of this broad division subsidiary schools are aligned. It is important to avoid each of these extremes, and more particularly important to avoid the assumptions upon which the antithesis is based. What is revealed to "introspection" is not wholly exclusive of the world revealed to external observation. Without assuming two separate and independent fields of investigation, Psychology may be comprehensively treated as the science of individual experience, its conditions and its expressions in behaviour. In practice it is generally so treated whatever the view professed. Primarily it is concerned with the analysis of experience, and with the laws of psychical process. Herein its most distinctive concepts emerge, and for the conduct of the inquiry introspective observation is essential. In determining the bodily processes with which mental life is connected it is in the main committed to the procedure of the biological sciences. These studies are psychological so far as the facts revealed are related to mental life. The two methods are systematically combined in the use of experiment. The distinctive feature of the psychological experiment is that it involves a two-fold process of observation: external observation by the experimenter who arranges the physical setting, and introspection on the part of the subject of the experiment.

More specifically, Psychology is concerned with mental process in relation to a certain cycle of events in which five phases may be conveniently distinguished:

1. A process of stimulation commencing externally to the body,

II. Receptive physiological processes,
III. Central processes,
IV. Responsive physiological processes,
V. Physical products and other changes, again external to the body.

The fundamental relations between body and mind call for formulation primarily with regard to mental process and the third phase of the cycle. It is doubtful if these be causal in tbe ordinary sense of the term. But there is a considerable mass of evidence that a close parallelism holds between mental and central physiological process. How close it is as yet impossible to say; but the further we pass from central to peripheral events the less exact it becomes. Nevertheless it is possible to establish certain correlations between stimuli and experiences and between experiences and expressions In fact upon such relations depends in very large measure our knowledge of minds other than our own.

Traditional Psycho-physics is concerned with the precise relations which hold between experience and the phase of the process, though a complete solution to the problems raised involves some reference to phases II. and III. In this connection there arose the first important attempts at mental measurement. (*Cf* EXPERIMENTAL PSYCHOLOGY and PSYCHOLOGY, HISTORY OF.) The central problem here is to determine the quantitative relations between stimulus and sensation.

The psycho-physics of perception is paralleled by a psychophysics of expression. Mental process finds expression in movement and in the activity of the glands; and the form of expression, either in itself or in its products admits of precise determination. Though little advance has been made in the direct measurement of the mental state expressed, much has been done in the measurement of the expression, and the results obtained admit of important application. Under this head falls the subject of Mental Tests, and the study of the conditions of efficiency in work. (*Cf.* INTELLIGENCE TESTS.)

The study of mental life in relation to the last phase of the cycle provides Psychology with many points of contact with the anthropological sciences. The mind of primitive man is known only by the products of his work and thought; and extending the concept of mental product to embrace spoken and written language an enormous field of research is opened up. In this way, for example, Philology and Folklore bring grist to the psychological mill.

Genetic, Comparative, Individual and Abnormal Psychology. — General Psychology is concerned with what is true of all experiments alike. But experiments differ, and there are many branches of the science concerned with their differences. Some differences are the product of development, and so far as interest is directed to tracing the course of growth, the study is said to be genetic. In one sense all Psychology is genetic, since development is a universal property of mind, and with its development we have been concerned throughout, so far, at any rate, as its course can be reconstructed from the general laws of mental process. But the term "Genetic Psychology" tends to be restricted to certain special studies; that of the development of mind in general, and the inquiry into the course of growth in the individual life. The former has lent a special interest to the study of the animal mind; the latter has fostered the growth of a child Psychology.

Not only do races and species differ, individuals differ too. "Differential" Psychology, or the study of individual differences is one of the fruits of measurement. For one person differs from another not so much in the presence or absence of fundamental characteristics, as in the relative degree to which various common functions may be operative.

Applications of Psychology. — After a long period of slow development the science has reached the stage at which it may be profitably applied. For the purposes of a general survey it will suffice to distinguish formative, directive and curative applications. Prominent under the first head are the applications of Psychology to education. In general, educational practice aims at the formation of cognitive, affective and conative dispositions which are likely to be serviceable in later life and in the pursuit of some career; in other words, to develop knowledge and ability, taste and character. Educational Psychology attempts to formulate the theory relevant to this process. In many respects, no doubt, the unsystematized "wisdom of the ages" and the genius of the teacher counts for much more than does psychological theory. This is notably the case in the training of taste and character. But in regard to the acquisition of knowledge and to the cultivation of ability, Psychology can offer a more effective contribution. Even here, however, the contributions are largely negative. Theoretical consideration and experimentat findings have largely succeeded in dislodging many deeply rooted practices based on mistaken doctrines concerning the growth of the mind. The discovery, for example, that training in one direction is not necessarily transferred to others apparently similar has exerted considerable influence upon educational procedure. So, too, has the development of mental tests, the utility of which is by no means limited to the definition of the natural course of development and the limits of educability. If positive and constructive contribution to the training of character are less obvious one can at least point to a promising ferment of ideas in relation to these problems. This has largely been directed and inspired by psychological theory.

Given minds equipped with appropriate dispositions, there is still scope for guidance, for directing energy and ability into appropriate channels and for controlling its economic use. What we have called the directive applications of Psychology are notably illustrated in vocational guidance (*q.v.*) and by the study of the conditions of efficiency in work. This field of application is rapidly expanding. It largely depends upon the close co-operation of psychologists and physiologists. The distinctive contribution of the former, however, lies not so much in detailed application of psychological theory as in providing a new approach to problems hitherto conceived — when conceived at all — in purely physical terms.

The treatment of mental disorder provides another example of the intrusion of the psychological point of view. Mental like bodily function may become deranged, but so-called treatment for both alike had for centuries been conceived in a purely physiological way. In the later years of the nineteenth century a reaction set in against this conception, and methods more psychological began to be employed for the treatment of "nervous" disorders. It is too early, perhaps, to pronounce with assurance upon the results of modern psycho-therapy, or to adjudicate between its rival schools, but here, too, there is great promise in the change of standpoint and undoubted value in the ferment of ideas. Not less important than the changes in treatment for mental disorder and the connected preventive and educational applications which advance to this field may be expected to provide. (See PSYCHOANALYSIS.)

Psychology **and Philosophy.**—As yet it is not possible to treat Psychology simply as a special science. In view of its distinctive concepts it cannot be wholly divorced from philosophical thought. The analysis of these concepts raises fundamental questions as to the nature of mind, its causal and other relations to the material world. Special topics may be treated in the empirical way of the natural sciences without raising metaphysical issues. This is the case, for instance, in the study of the details of sensory experience and of its physical conditions, in the investigation of the laws of learning and of forgetting, and in the quantitative treatment of individual differences. But outside such special inquiries, and more particularly in the attempt to give an account of this science as a whole the Psychologist is continually on the verge of metaphysical issues. To a great extent the successes achieved in the sciences of the material world have had to be paid for by the science of mind. This success has in part been attained by regarding as purely mental all phenomena which fail to fit into the purely physical theory. In this way, for example, the secondary qualities of material things were presented to the Psychologist as examples of what is distinctively "mental" to the consequent confusion of his field. Hypotheses and methods employed in the natural sciences have tended to be regarded as essential to science in general, and to these psychological data are supposed to conform. There has been no purely psychological hypothesis, generally acceptable, which has done for Psychology what the atomic theory, for instance, has been able to do for Chemistry. Such very wide hypotheses have often been proposed, but following physical and chemical models, each sooner or later has become the victim of a reaction. There is thus much to suggest that Psychology must employ hypotheses and methods which are peculiar to itself. In any case the psychologist must be critically occupied with a variety of questions which for other sciences are mainly predetermined. He can escape controversy only by restricting himself to co-operation within the narrow limit of a "school." In the later phases of the history of Psychology, new schools of thought have arisen in almost every decade, each proclaiming a Copernican revolution. Whilst this, no doubt, is evidence of vitality and progress, the multiplicity of claims suggests that the Copernican revolution is yet perhaps to come.

PSYCHOLOGY, COMPARATIVE. This article deals with Comparative Psychology in its biological aspects. The aspect of the subject from the pure psychologist's point of view will be found under COMPARATIVE PSYCHOLOGY. In everyday life we are accustomed to look upon the behaviour of animals in the same way as we judge the actions and conduct of our fellow men. We do this as if the actions of animals were dictated by a consciousness such as we know from our own experience. In this way we attribute to animals sensations, perceptions, ideas, feelings and impulses, dictated by will. We suppose that these faculties control the behaviour of animals as they do our own actions. The driver talks to his horse, the sportsman to his dog. We say that the worm writhes with pain, the moth flies into the flame out of curiosity, the dog is faithful, the serpent false. The hen which has acted as foster-mother to ducklings looks on with anxious feelings as the young take to the water. And the aquarium naturalist maintains that mussels, sea-snails, starfishes or sea-anemones, feel happy when they move or expand in the fresh water he has given them. This common-sense view, which represents the natural attitude of unprejudiced man to animals, has been usual from the earliest days. Savages and primitive peoples to-day feel themselves closely related to animals. On such a conception of the relationship of the minds of animals to those of men reposes the widespread belief in a transmutation of souls with intermediate stations in animals, the so-called metempsychosis.

Since ancient times, however, there have always been investigators who opposed this anthropomorphic conception of animal behaviour. Descartes maintained that animals are mere machines, moving purely as automata in response to stimuli received. But above all it is modern advances in science which have caused men to study the behaviour of animals more closely and more critically. The nervous system and the sense organs have become better known. The rising science of physiology, concerned with the functions of living organisms, has been able to show that many actions of animals can be submitted to a scientific study and to a causal explanation. Thus it came about that at the end of the 19th and beginning of the 20th century, a number of workers, such as Beer, Bethe, von Uexküll, maintained that the behaviour of animals is solely a subject for physiological research. According to these and other more recent workers, the concern of science in studying animal behaviour should be strictly limited to the investigation of visible movements and of their causation. One of the principal reasons why these researchers disagree with the anthropomorphic view-point sketched above is that *objectively we can never obtain information about the inner life of animals, i.e., about the phenomena of consciousness going on in their minds.* Indeed, the same thing is really true for the conscious life of our fellow men. For from direct experience we only know our own conscious self. But since our fellow men in like situations behave as we do, therefore we conclude by analogy that they think and feel just like ourselves. Further, they tell us the same thing in speech, so that the conclusion by analogy seems all the more sure. The science of human psychology is founded on these facts. But the behaviour of animals leads to a similar analogy, especially the behaviour of those animals most nearly related to man and of those in whose ways man has most confidence, since they surround him as his household animals. For this reason comparative psychology, which is concerned with the origin of human conscious phenomena in children and lower human races, is led to deal with such analogies in animals when it is seeking, in the animal, phylogenetic antecedents of the human mind. And so, with the coming in of the present century, a new science has arisen, the goal of which is to study animal behaviour, in particular such phenomena as resemble those connected, in man, with particular mental occurrences.

A further circumstance must be taken into account. The behaviour of animals in their natural environments tends throughout to be purposive and concerned with preservation of life. Now, we are accustomed to derive the purposefulness of human conduct from the action of will, which reasons and has an aim. And so we incline, on superficial reflection, to ascribe purposive animal conduct to the action of a similar will. Only a closer inspection of the nature of many actions of animals shows that the matter is not so simple as to justify such an analogy. We find a remarkable purposefulness not only in the behaviour of the animals but also in their bodily structure. The development and functions of organs are purposeful throughout. This shows that not all purposefulness need be the result of the conscious workings of will. At the same time, this fact is a further ground why science should concern itself with the causes of animal behaviour. This new science, whether called the science of animal behaviour or animal psychology, is concerned not only with the behaviour of animals under normal circumstances, but it attempts, by experiment, to penetrate more deeply into the connections between cause and effect in animal conduct.

REACTION TYPES

Animal reactions can be divided into four groups, according to the degree of complication of the physiological processes which accompany them. These types of behaviour represent to a certain extent four different levels at which the reactions of animals proceed. The behaviour of animals may take the form of tropisms or taxis, which are not very common; reflex movements or reflexes, which are universal; instinctive reactions; and lastly intelligent actions, found only in the highest animals. Although reflexes and instincts occur both in animals which, as regards their performances, stand at the very summit of the animal series, and also in the lower animals, nevertheless within the animal kingdom a gradual increase is recognizable in the degree of accomplishment of reactions. Instinctive behaviour assumes a higher degree of complexity and at the same time a greater plasticity as we ascend the animal series. This is correlated with the higher development of bodily structure and the greater efficiency of the nervous system which goes with this.

Tropisms.—Many animals exhibit a particular response to stimuli affecting particular regions of their bodies. They turn either towards or away from the source of the stimulus. When a turning of the body alone is concerned the reaction is called a *tropism* (Gr. τρέφειν, to turn). If the animal moves in the direction which the body has assumed we speak of the behaviour as a *taxis*. According to the kind of stimulus concerned, the reactions are named *thigmo-*, *stereo-*, *geo-*, *thermo-*, *chemo-*, *photo-*, *helio-*, or *tropho-taxis* or *tropism*. The names refer to the stimuli due to pressure, touch of a solid body, gravity, temperature, chemical substances, light, sunlight or food. The tropism or the taxis is positive when the animal turns towards the source of stimulation, negative when it turns or moves away. Sessile animals attached to the substratum can only perform bending movements with their free anterior ends or organs. These animals, then, exhibit chiefly tropistic movements. Thus the hydroid polyps in the sea turn their hydranths towards the light. New branches of the colonies grow naturally towards the light falling on them from above. If a branch of such a polyp stock is suspended in an aquarium lighted from above, so that the end normally uppermost hangs lowest, then the newly budded branches grow upwards once more. This is a result of a negative geotropism and a positive phototropism inherent in the animal. Most lower animals, especially worms, but also many small mammals, exhibit a positive stereotropism. They come to rest only when the greatest possible extent of their body-surface is in contact with solid objects. This is one of the reasons why, in an aquarium or cage, the inmates seek out the angles and corners. The bottom-dwelling catfish *Amiurus* takes up these positions owing, on the one hand, to thigmotaxis — its feelers seek to touch solid objects — and on the other, to phototropism. When the two types of stimuli do not coincide in the directions they tend to impose on the animal, the latter takes up a position which is the resultant of the two directions. Many lower animals show a definite phototaxis. Thus, not only small crustacea but also fishes and amphibian larvae swim towards light; though this does not occur unconditionally. If, for instance, a number of tadpoles are placed in a round glass vessel filled with water, and the vessel is allowed to float on the surface of an aquarium in which other tadpoles are present, then the individuals in the aquarium itself are uninfluenced by the light. They swim about in all directions. But the tadpoles in the small dish all turn toward the source of light (fig. 1). Numerous small fishes and crustaceans behave in the same manner under like circumstances. It is the confined space which in this case calls forth or awakes the positive phototaxis.

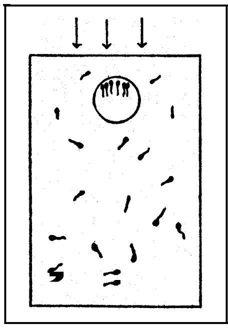

FIG. 1.—TADPOLES NOT INFLUENCED BY LIGHT IN LARGE VESSEL; ARE POSITIVELY PHOTOTACTIC IN GLASS

Although tropisms and taxis such as we have already described are widely spread throughout the animal kingdom, yet the conception of a tropism was originally much less wide. Jacques Loeb used the term in a much narrower sense, maintaining that the position assumed by an animal as a result of the direction of the stimuli affecting it is assumed in a purely automatic manner. The reaction he considered to be just as purely mechanical as the movement of a floating needle towards a magnet. It was, in particular, the way in which many animals react to light stimuli that caused Loeb to formulate his Tropism Theory. When a bilaterally symmetrical animal receives a stimulus, for example a ray of light, on one side, the stimulation of that part of the body, or of the sense organs affected, results automatically, through the intermediary of the nervous system. in setting into activity the locomotor organs of that side. By this means the body is turned and the rotation continues until the long axis of the animal is brought into the direction of the light rays. In other words, the animal turns until the two symmetrical sides of the body each receive an equal amount of stimulation. Then the locomotor organs of the other side commence to function and the whole animal moves forwards. Numerous investigations have shown, however, that such a regulation of behaviour purely through symmetrical stimulation, *i.e.,* where the stimulus — in our instance light — directly causes the movement, is extremely rare in the animal kingdom. It is found particularly in such animals as harbour symbiotic algae in their bodies and therefore seek out the light. Examples are the flagellate protozoan *Euglena* and the flat-worm *Convoluta roscoffensis.* In most other cases the circumstances are not so simple. In particular, the processes are complicated by the interaction of the central nervous system, which so largely controls behaviour. Through this the reactions lose their apparently automatic character. It is true that many animals place themselves symmetrically to the stimuli. Examples have been given above. Indeed, we frequently make use of the fact by allowing animals to carry out their tropisms and so to collect together in a certain spot when we wish to catch a considerable number of individuals quickly and easily. In this general sense we may continue to use the expression tropism, which of late has been so hotly attacked. We must realize, however, that it is not a simple mechanism that we have before us. If we scatter a number of young caterpillars of certain species of butterflies on the surface of a table standing at a window most of them will certainly crawl towards the light. But it is probable that one or two will move in another direction. This depends upon other stimuli which influence the central nervous system. The effect of these stimuli may then conflict with the tropism which would otherwise manifest itself.

We have seen already, from the example of the tadpoles and other animals in small vessels, that there is no necessity for a tropism to be present in an animal equally under all circumstances. Rather, it is called forth by certain definite stimuli. Conversely, the tropisms which are present are frequently *reversible.* When a stimulus becomes too strong, a positive may be converted into a negative tropism. Thus, many lower crustaceans such as *Daphnia,* become positively phototactic when the temperature is lowered, negatively when it is raised. *Daphnia* which has become adapted to a light of medium intensity swims towards the source of light when the intensity of the light is diminished and away from the light when it is increased. The previous *milieu* is an optimum which the animals seek to re-attain after it has been altered.

Reflexes.—We have seen that animal tropisms are automatic in appearance only. Reflexes, on the other hand, are stimulation effects which are really purely mechanical. Reflexes are invariably dependent upon the presence and interaction of a nervous system. The morphological basis of every reflex consists, in the first place, of a *receptor,* or *sensory neurone.* This is a ganglion cell with definite processes which take up the stimulus and conduct the excitation to the cell-body and to other processes which transmit the excitation further on. The second component of the reflex path is another ganglion cell, an *effector,* or *motor neurone.* One outgrowth of this is in connection with the last-mentioned process of the sensory neurone, which conducts the excitation received to the cell-body of the motor neurone. The excitation is then sent on by other processes of the motor neurone and conducted to a muscle or gland, which is thereby activated. The sum total of these nerve conduction paths is called a *simple reflex arc.* The connection between the sensory and the motor neurone constitutes a simple nerve centre, or reflex centre. But in the animal kingdom *composite reflex arcs* are most usually found. This comes about by further ganglion cells, called *association* or *internuncial neurones,* being intercalated between the sensory and the effector neurones of the arc. These association neurones are in communication with yet other centres. Further, the reception of a stimulus usually takes place through particular sense-cells, which are normally found as parts of sense-organs having complicated structures. Yet the essential physiological elements of a reflex are invariably reception of stimulus, conduction of stimulus, and final result. Reflexes were so named by Descartes (Lat. *reflexus,* reflection). The stimulus coming from the sensory neurone is conceived as being reflected on to the motor neurone. Such reflexes are widespread in the animal kingdom wherever a nervous system has been developed. It can truly be said that by far the greater number of movements of animals, or of their organs, depend upon reflexes. These can be observed in numberless cases from the coelenterates upwards, to the highest mammals, and in man himself. Quite apart from the purely reflex movements of inner organs, a number of reflexes can be observed in the external actions of human beings. The contraction of skin in the cold and the reddening or turning pale of the face are examples.

Among animals sea-urchins show most clearly to what an extent the whole behaviour can be dominated by such reflexes. Von Uexküll rightly says of these creatures that they are purely reflex animals. All their reactions can be explained by reflexes. If a mechanical stimulus affects a spot on the skin of a sea-urchin, the neighbouring spines incline towards the spot in question. This occurs because the excitation is conducted by nerve paths towards those muscles surrounding the bases of the spines, which lie nearest to the stimulated spot. Von Uexküll was able to show that the movement of a sea-urchin along the ground, following such stimulation, depends upon these reflex movements of the spines. The same is true of the so-called "turning-over reaction" of the sea-urchin, in which an animal that has accidentally fallen on to its back rights itself again by purposeful movements of the spines. Between the spines of the sea-urchin are found so-called *pedicellariae.* These are small three-clawed pincers, each on a long stalk. At rest, the slender stems lie on the body of the animal. There are four kinds of these pincers, each of which is erected and brought into action only by quite specific stimuli. Long, thin, motile *snap pedicellariae* shut to the light touch of any small animal which may serve as prey and happens to be swimming by. The short strong *biting pedicellariae* rise to a stronger mechanical stimulus and then open, closing again on further touch. They will bite, for example, slowly but strongly into the leg of a small crustacean. Quite weak mechanical stimuli, such as those produced by small foreign bodies falling on to the surface of the sea-urchin, excite the small *cleansing pedicellariae* which serve to clean the surface. The disposition of the reflex arcs is such that when a stronger stimulus occurs, suitable pincers are held ready while the type which is too weak stands back. Thus a chemical stimulus repels the biting pincers and causes the spines to bend away from one another, so that room is made for the fourth set, the *poison pedicellariae.* This type, which possesses poison glands, now enters into activity. For if a mechanical stimulation of a region of the body-surface now occurs, the stalks of these *pedicellariae,* together with the spines, all bend towards the stimulus. The jaws of the pincers close together as soon as they come into contact with the object. The erection of the stalks as a result of the chemical stimulation is an essential preliminary to the functioning of the snap-reflex. The weapon may be said thereby to be loaded and put into a state of tension. Thus for the poison-pincers to act a coupling of two small stimuli is essential.

Similar reflexes are found in the other groups of echinoderms, particularly among the starfishes and brittle-stars. These are able, by reflexes, to free themselves from all sorts of difficult situations. Preyer fastened *Asterias* by sticking five nails with big heads into a board close to the angles between the five arms of the starfish, but without injuring the latter. The confined animals, which could not escape upwards owing to the large heads of the nails, freed themselves in various manners by squeezing, bending and turning the body now in this, now in that way (fig. 2). This they did, not according to any definite plan, nor from any insight into their position or of the necessary steps to be taken to attain freedom, but solely as a result of their physiological constitution and of the various possibilities of movement at their disposition. Brittle stars, when an india-rubber tube has been passed over one of the five arms, escape very quickly by propping the neighbouring arms against the rubber and so pushing it off. A starfish turned on its back first extends all its tube-feet which then feel around as if seeking for a solid object on which to attach themselves. Then several of the tips of the arms turn the right way up. So far all this takes place in no definite order. Apparently each part works independently of the others. Only after a period of indecision, a co-ordination of the movements is brought about through the radial nerves. The tube-feet of one or two of the arms which have turned over (the directive arms) attach themselves to the sub-stratum, whereupon the body with the remaining arms turns over. This *directive influence* assumed by one or two of the arms consists in the inhibition by impulses from the directives of the independence of the remaining arms. Something similar occurs when the starfish frees itself from the pentagon of nails. Now, it is both interesting and important that an amputated arm of a starfish, or indeed any isolated part of an echinoderm, behaves to stimuli as if it were still connected to the whole animal. It does this so long as its nervous reflex paths are uninjured. This is the real proof of the purely reflex character of the different reactions observed in the normal animal.

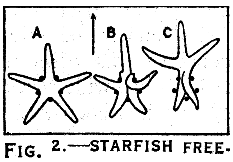

FIG. 2.—STARFISH FREEING ITSELF AFTER BEING HELD BETWEEN FIVE PINS

Hermit-crabs hide their unprotected naked abdomen in the shells of sea-snails which, as occasion offers, they exchange for more comfortable shells. Before slipping into such a new shell, they first put their claws inside, as though they wished to begin by investigating the new abode. Conical snail-shells are held in such a manner that the crab's telson to a certain extent holds the tip of the house and the crab, standing almost on its head, turns the shell round. This appears eminently purposeful, for by this means small stones and grains of sand which may happen to be inside the shell fall out. If these were not removed they might injure the soft hind-parts of the crab. If a number of empty shells of sea-snails are placed in an aquarium, containing hermit-crabs, the animals change their habitations continuously. As soon as a crab happens upon an empty shell, it feels it over and then steps in. The fact that frequently in this pursuit a shell which suits the crab admirably is exchanged for another obviously smaller and less suitable, shows plainly that a purely reflex action is involved. Bohn expresses himself thus:

> "The animal carries out a quite definite series of movements, from the moment when it touches the shell until the instant when it hides its abdomen in it. Each movement causes the next one to follow on. Hence it is possible, to a certain extent, to cheat the crabs. If one places them upon a round stone or wooden ball, then they turn this round in all directions, press their bodies against it and seek for the mouth, which of course does not exist. They look for the opening likewise in an unusually convex oyster shell."

Thus the hermit-crabs, too, behave in this respect like automata. The stimulus supplied by the snail-shell, acting through the appropriate reflex paths, mechanically causes the movements just described. And this seems just the same when the movements are unnecessary or even quite meaningless.

A peculiar type of reflex is found in many animals, which under certain circumstances serves as a defence when the animals are seized by an enemy. This is the *autotomy* or *self-mutilation reflex,* By it animals are able to throw off the parts of the body or limbs which have been caught, so that with this loss they can still escape. In this way many annelid worms throw off certain parts of the body, starfishes and brittle-stars reject their arms. Crustacea, especially shore-crabs and lobsters, break off legs and claws which are caught and held. Spiders and many insects behave in a like manner. Since the place at which the limbs break off is usually suited morphologically to this purpose, a definite adaptation is involved.

A good example of behaviour made up almost wholly of reflexes is afforded by the ant-lion, the larva of *Myrmeleo formicarius.* These animals construct funnel-shaped hollows in sandy soil and dig themselves in up to their heads at the bottom of the funnel. Then they lie in wait for passing ants. When an ant approaches the margin of the funnel, the ant-lion, in response to the stimulus supplied by the sand-grains rolling down the walls of the funnel, performs the *jerk-reflex; i.e.,* it throws its head upwards and backwards with a mighty jerk. Consequently the surrounding fine sand is thrown up and causes the ant, already advancing with difficulty in the heavy soil, to slip completely down. The jerk-reflex may be repeated a couple of times if further sand particles continue to fall down. If the ant chances to touch the inner side of the widely-open mandibles of its enemy, the *snap-reflex* follows. This involves the closing of the sharp jaws to seize the prey. This snap-reflex can be induced artificially by the touch of a fine needle. The construction of the funnel, too, is said to be performed reflexly. Such reflexes are very widespread among insects. The larvae of dragon-flies, for example, live in water as predaceous animals. They catch their prey with their so-called mask. This is the modified underlip, consisting of pincers which can be projected rapidly for a considerable distance in front of the head. Since in this case optical stimuli bring the mechanism of snapping into action, the movement to and fro of any small object about the size of the normal prey is sufficient to cause these larvae to snap at them. If one lightly strokes the wing of a fly, *Eristalis tenax,* once or twice with a thread, the insect raises the hind-leg of that side and wipes the wing-surface with it. The numerous cleaning movements of insects come about, too, in a purely reflex way. As in echinoderms, amputated portions of the body behave just as when they still formed a part of the whole animal, provided that the necessary nervous connections are still present. The stinging apparatus of the honey-bee, which remains fixed in the human skin after stinging owing to its backturned hooks, and is thus torn out of the abdomen of the bee, continues to bore even deeper into the wound. And it is common knowledge that one must beware of the hinder portion of a freshly killed wasp, even when this part of the body is cut off, for it continues for quite a time to execute stinging movements. The trunk portions of ants, after the head and hind part of the body have been cut, off, continue for a half hour or an hour to walk around haltingly with short steps and rise up again if they fall over.

Fishes and amphibians supply examples proving that among vertebrates, too, such essential movements in the life of the animals as are concerned with the catching of prey still take place in a purely reflex manner. Many fishes and most amphibians react only to moving prey. Thus they make no distinction if instead of real food one waves other objects of corresponding size to and fro before them Sharks seize all small objects thrown overboard from a ship, even when these are empty tins. The possibility of angling for many kinds of fish with artificial bait is due to automatic response of the animals to stimuli. A frog would starve before snapping at a motionless earthworm. It seizes it only when the worm moves. The frog reacts to a fly only when the latter cleans itself or moves from the spot in which it was standing. Indeed, for the frog as for other animals a *summation* of stimuli is often necessary. On the first movement of the prey on coming into the field of vision, usually a mere turning of the head results. More movement causes farther turning, the body also participating. Additional stimuli then result in a raising or a lowering of the head in the direction of the prey, and finally snapping or extension of the tongue follows. If the prey is missed, as not infrequently happens, the frog only snaps again when the animal moves anew.

INSTINCTIVE BEHAVIOUR

The Nature of Instincts. — Whereas generally speaking reflexes are made up of single movements of an animal or of its organs in response to a stimulus, instincts are those reactions which are composed of numerous movements (Lat. *instinctus*, impulse). A requisite condition is that the responses in question be shown by all normal individuals of the species in an almost identical manner. This type of behaviour is inherited from the ancestors of the animals in exactly the same way as any visible morphological character. Since this mode of behaviour is inborn, it has not to be learnt by the individuals of the species. Instincts are always adapted to the normal mode of life of the animals and for this reason they appear to be essentially purposeful in character. But, like reflexes, they are quite automatic and give a certain stamp to each different species of animal. We are concerned, then, with all behaviour and modes of action of which it can be said that the animals are impelled by a motive from within. Physiology rightly regards instincts as series of reflexes or so-called *chain-reflexes* (Loeb). This means that they can be analysed into a greater or lesser number of individual reflexes of which the occurrence of one is always the cause of the initiation of the next. Thus an animal disturbed during one instinctive action, so that the series of reactions is interrupted, is often incapable of continuing the action where it has left off, but must restart the whole series from the beginning. This, however, is frequently impossible, since often the first stimulus, which set the series going, is no longer present, or the physiological conditions of the body of the animal have become altered. An instinct, then, is a sum of reflexes, whose connection with one another is rigid and immutable like the reflexes themselves. Formerly all those complicated and purposeful actions which take place as inborn impulses, without any realization on the part of the animals as to their significance or object, were classed as instinctive behaviour. As just explained, however, the modern view is unconcerned with the presence or absence of consciousness or of purpose in the behaviour under consideration. In a later section, we shall return to this question. But it may be stated here that in most cases of instinctive behaviour no realization exists on the part of the animals as to the purpose of their conduct. From the nature of the case, no such realization could exist. Ziegler *(1920)* has given a comprehensive account of the historical development of the concept of instinct. The often amazing purposefulness of instincts has given rise to numerous explanatory hypotheses, none of which has supplied a satisfactory solution of the problem involved. Nothing therefore remains but to attribute the purposeful character of the conduct of the animals to the same factors which are responsible for the adaptive structure and functioning of their organs. Selection co-operates as a secondary but very important factor.

Instincts can be subdivided according to their objects into those of nutrition, migration, cleansing, protection, defence, metamorphosis, pairing, egg-laying, care of young, nest construction and social life. To the last-mentioned belong all the complex social instincts. We meet with instinctive actions in all divisions of the animal kingdom in which a central nervous system has been developed. Instincts are present from worms up to mammals, and many human actions are purely instinctive. Instinctively the newborn seek the mother's breast and the drowning man clutches instinctively to any solid object which offers. In point of fact, by far the greater number of the actions of invertebrate animals depend upon such inherited inflexible instincts, as also do those of many lower vertebrates. Just as reflexes are found to be particularly characteristic of echinoderms, so the higher arthropods, in particular certain crustaceans and above all the insects, are instinctive animals *par excellence.* A few examples only of the instinctive actions of animals will be cited here.

Earthworms have the habit of dragging into their tubes leaves, pine-needles, bits of straw and other small objects, in order that the decaying plant-remains may serve them as nourishment. As early as 1881 Charles Darwin, who devoted a comprehensive work to the activities of worms, drew attention to the fact that the dragging down into the earth of these objects is done in a remarkably purposeful way. The worms tend to catch broad-based leaves, such as those of limes or cherry trees, by the top, so that the leaf rolls itself up on being drawn into the narrow worm-tube. It would have been useless to catch hold of the leaf by the stalk, for the broad base would have offered an almost insurmountable obstacle. The worms behave in an opposite manner with pine-needles, which are attached in pairs to a short basal piece. The worms take hold of them at the point where the two needles are joined together. Had one needle been dragged by its tip, the other would have been prevented from entering the hole. Mangold (1924) lately showed that there is a difference in the chemical make-up of leaf-blade and stalk, of needle-tip and basal piece. The worms scorn the taste of the leaf-stalks or of the needle-tips. In addition, further help is afforded by the fact that the leaf usually turns round on being drawn along on the ground, so that the point goes foremost while the stalk acts as a rudder.

The strange marine crab *Dromia* possesses the instinct of holding a sponge or an anemone, as if for protection or as a concealment from view, with its last pair of legs which are bent up towards the back. On strong stimulation however, and when fleeing from enemies, the crabs drop these foreign bodies and scamper away hastily. In the aquarium they just as readily take up living or dead companions, heads of fishes, or even transparent pieces of glass which naturally could not conceal them from the gaze of their enemies. The spider-crab, *Maia,* conceals itself from its enemies by tearing off with its claws pieces of seaweed growing in the neighbourhood and sticking these on to the spines and hairs growing on its back. These spines are provided with back-turned hooks. A well-known habit of hermit-crabs is to plant the surface of their shelly dwelling with actinians, and indeed with particular species of anemones. Many of these crabs transfer their companion to their new dwelling when they move. Violent fights often take place between the inhabitants of an aquarium for possession of the anemones. Lloyd Morgan (1908) describes a very specialized adaptation to the circumstances of life in the yucca moth *(Pronuba yuccasella)* of tropical America. The instinct involves the most minute details of the creature's life-history. The caterpillars of this species pupate a fortnight before the commencement of the flowering season of the yucca plants (*q.v.*). Each of the large, yellowish-white, bell-shaped flowers, opens for a single night only. This occurs at the same time as the straw-coloured yucca moths with their silvery sheen, hatch out. A female of this moth fetches the sticky pollen from the flowers, kneads it together and holds the big ball so formed with her strong, hairy labial palps. She then visits another flower and with her ovipositor lays an egg in the rudiment of the seed in between the egg cells of the plant. Then she betakes herself to the stigma on the pistil and there sticks the pollen she has brought with her. It is asserted that the same individual several times repeats the alternate egg-laying and pollen-seeking in the same flower. Four or five days afterwards, the larvae creep out and begin to devour the seed-rudiments, of which about 200 are present in the flower. Three or four larvae are found in one flower and each needs about 20 eggs for its food. Thus, about 100 eggs are left for the yucca for its own reproduction. As soon as the larvae have grown to full size, they creep through a hole they have gnawed in the wall of the fruit and let themselves down on a thread to the ground. Here they spin an egg-shaped cocoon in the earth. They remain there until the following summer, when they pupate. The yucca plants can be pollinated by no other kind of moth. Conversely, the caterpillars of the yucca moth require the seed-rudiments of their own particular species of yucca as nourishment. Each species of yucca has a special species of moth adapted to itself alone. The yucca moth brings her business to completion without seeing or hearing what happens, without knowing the result, the fate of her eggs or the necessity for plant-pollination.

Even the most complicated behaviour of the social insects (*q.v.*) turns out in most instances to consist of inborn instinctive actions. Thus bees and wasps have been isolated as soon as they hatch, so that they could learn nothing of the life and activities in the hives or nests whence they came. Nevertheless, these animals occupied themselves in exactly the same way as all workers of the particular species, as soon as the necessary material was placed at their disposal. They built, collected food, and fed larvae which were given them. Ants and termites, too, afford an excellent example of the fact that instincts may be purposeless. Quite a number of definite species of lower animals, particularly beetles of the family Staphylinidae, habitually steal into the nests of social insects. These ant guests and termite guests are not only tolerated but often even cared for and fed. Ants, indeed, care for the brood of many of these guests. They are induced to do this by certain secretions furnished to them by special glands of their guests in compensation for the trouble they have taken. This tolerance of and caring for definite guests has become with them a definite instinct, the so-called *symphily instinct.* And this is essentially harmful to the success of the ants' or termites' own colony. For the ants are often so intensely occupied by their guests and offspring of these, that they go so far as to neglect the proper care of their own brood and thus jeopardise the continued existence of their colony.

Capacity **for** Learning. — Although we have so far represented instincts as unalterable and inflexible inherited modes of action, this does not apply to all instincts. There exist numerous cases in which animals are able more or less to modify their inborn types of conduct in relation to prevailing circumstances, *i.e.,* to adapt their behaviour to the given situation. This applies to such cases as web-construction by spiders or nest-building by birds. It is true that each species of spider makes its web according to a definite plan, which may be considered as a specific character. It is equally true that each kind of bird builds its nest in a very definite manner, easily recognizable by the ornithologist. But in each different case the locality in which the web or nest is constructed is a different one. Moreover, the available material for making the bird's nest often varies, for instance, as regards the shape and length of the twigs collected, etc. The spider, too, in spinning its web must adapt itself to the space at its disposal, and the bird must suit its behaviour to the conditions of the locality in which it is working, to the fork of the branch, the hollow in the trunk of a tree in which it makes the nest. And in other ways we see that animals, particularly those which as regards their conduct stand high in the animal series, break away from the inborn inflexibility of instincts and behave in this or that manner according to the circumstances. Thus instincts are frequently plastic and can be adapted to conditions. The experiences which the particular animal has had during its lifetime here play a definite part. For this reason we must next describe two faculties on which the power to accumulate experiences depends.

Memory. — First comes the power of memory. This is present in all branches of the animal kingdom, even in the Protozoa. But this fact is not very astonishing, since one can consider "memory" in a certain sense as a general characteristic of matter. The properties of a colloid can depend upon the way in which it reached its present state, that is on previous history, age, temperature, duration of physical processes, and so on. Hysteresis of metals is somewhat similar. In animals, memory consists in the fact that a stimulus, when it acts on an animal causing a certain excitation in the body, leaves behind itself a residuum or trace. In consequence of this the organism is to a certain extent physiologically different when later on the same stimulus acts upon it again. And so the possibility arises of an animal reacting first in one way and later in another, to the same stimulus. When a certain stimulus is repeated a number of times in a short interval, an animal may accustom itself to the stimulus. That is, on the first occasion the animal will answer the stimulus by the reaction which normally follows it. But later, the reactions become weaker and in the end the animal no longer reacts at all to this stimulus. This is not due to fatigue of the organs of motion, the muscles, but it is the result of becoming accustomed to the stimulus. Only after a period of rest does the animal once more react normally to the stimulus. On the other hand, an animal which is reacting in a certain way to a stimulus repeated at frequent definite intervals can "exercise" the movement in question. The animal gradually executes the movements more promptly and more rapidly than it did without the practice. Human beings find a similar gain in performance through frequent repetition or exercise. The paths of the nervous system which conduct the excitations become better and better "trodden," better suited to take up and transmit this excitation. In the end, through repetition, a given action can become a habit.

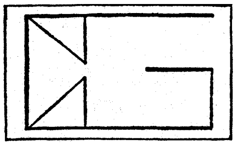

FIG. 3.—YERKE'S EXPERIMENT TO MAKE A CRAYFISH FAMILIAR WITH AN EXIT FROM A BOX

Association. — In so far as animals possess a true central nervous system with higher, dominant centres, we find in them a further and more important faculty, that of forming associations If, at the same time as a stimulus which has a definite resulting reaction acts, another stimulus occurs which in itself would cause no change in the conduct of the animal, then, provided the two stimuli always act together, after a certain number of repetitions the reaction follows on the indifferent stimulus alone, whereas in the beginning it results only from the first stimulus. In the nerve paths, a *coupling* of the courses of excitation has occurred An association of the two stimulation and excitation phenomena has been formed. The number of repetitions necessary for such an association to be established differs both with the species of animal and with the nature of the stimulus. One or two examples will make this clearer. An earth-worm was placed in the middle limb of a T-shaped tube system so that it was possible for the animal to creep into the right-hand or into the left-hand portion of the cross-piece of the T. In one of the arms of the cross-piece, the electrodes of an induction coil were placed, so that when the worm touched these it received an electric shock. Five or six experiments were made daily with each animal tested. Whereas in the beginning the animals went as often to the left as to the right, it became apparent that after about 80 or 100 experiments, the side with the

A. Entrance: B. Intermediate space; C. Wire grid connected to electric battery; P and G. Glass partitions electrodes was visited less often. After about 120 to 180 trials, in every 20 experiments there were at most 1–3 errors. The animals, then, had learnt to avoid the place associated with an "unpleasant" stimulus. In other words, they had been "trained" to go to a certain side. This habit of turning always to the right side, acquired by training, could be reversed by a further training. This was done by placing the electrodes on the side which previously had been the right one for the worms to turn into. Not only could normal earthworms be trained in this manner, but also animals from which the brain had been removed, and even worms lacking the whole portion of the central nervous system contained in the first six segments.

Yerkes instituted experiments with *Cambarus affinis,* a relative of the fresh-water crayfish. He placed these crustaceans in a specially shut-off portion of a box, from which they could get out into the main portion of the box through an opening in the middle. From the main portion two outlets, separated from one another by a partition, led into a vessel of water (fig. 3). The animals as often made use of the right as of the left exit. Next, the right hand outlet was closed by a glass plate. During a period of 30 days each crayfish underwent 60 experiments, in which the boxes were always carefully cleansed to exclude the presence of possible smell stimuli. The average results of the performances showed in the first ten trials 50% of correct solutions, in the second ten 60%, in the third 75·8% and in the sixth 90%. By a correct solution is meant that the experimental animal immediately chose the correct exit. One of the crayfishes, after 450 experiments, made only one mistake in 50 trials. It is plain that such a method permits the investigator to test how long the lesson is retained by the experimental animal when no practice takes place in the interim. After a *Cambarus* had progressed so far in its lessons that it made one error only in ten trials, the experiments were interrupted for a fortnight. When, on the fourteenth day, the experiments were recommenced, it was evident that the animal still remembered what it had learnt. But now three errors were made per ten trials.

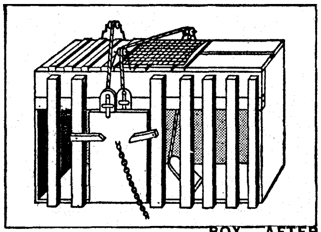

FIG. 6.—PROBLEM BOX AFTER THORNDIKE

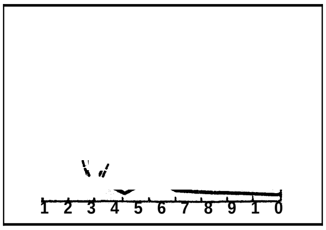

FIG. 7.—CURVES SHOWING RATES OF LEARNING BY APES (HEAVY LINE), IN THE LABYRINTH (LIGHT LINE), IN THE PROBLEM-BOX (DOTTED)

Yerkes carried out experiments on frogs similar to those already described with *Cambarus.* He used a box like that mentioned above, except that the two exits were contrived in a rather more complicated manner. The outlets led to a tank of water but the direct path was closed by a transparent glass plate, so that the animals were obliged to make a *détour* (fig. 4). Daily series of ten experiments were made. After 100–120 trials the frogs no longer made mistakes. They made for the water by the shortest path. The effect of the training was measured by the number of correct and incorrect attempts at the two critical spots, the entrance and exit of the labyrinth (fig. 5). After the experiments had been discontinued for one month, it was found that the frogs had not yet forgotten their lesson.

It is generally known that birds and mammals can learn or be trained. But in addition we see everywhere in nature how the most varied types of animals turn their acquired experiences to account. It is the faculties just described, the plasticity of instincts, the capacity for memory, and the ability to form associations, which permit of such conduct. But the foundation for the behaviour resulting from these faculties, which is frequently complicated, is always provided by inborn reflexes and instincts. With the object of analysing animal conduct more closely, numerous experiments have been made, particularly by American workers, utilizing apes, dogs, cats, hedgehogs, rabbits, rats, mice, various birds and even reptiles, such as tortoises. The object of these experiments is to discover the capacity for learning, the ability to acquire experience. The outlet from more or less complicated labyrinths or mazes has to be found and learnt, or problem boxes are used, in which the animal must open a door to get out by latches which are more or less complicated according to the nature of the animal studied. These fastenings consist of levers, hooks, bolts, wires, that must be pulled, levers to be pressed down with the foot, and so on (fig. 6). The animal is obliged to discover the mechanism of opening the door for itself by chance trial in the course of its planless efforts. The duration of the learning, or here of the formation of a habit (the dropping of useless movements), is judged by registering the failures (figs. 7 and 8). Companions are sometimes placed in the company of animals which have already learnt the solution of such a task, to see whether they will themselves learn more rapidly by imitating the movements of their fellows. It has been proved that this rarely occurs. Even when the animals are shown the necessary manipulations by the experimenter putting the limbs of the animals through the movements, this does not help. Each animal is obliged to learn everything through its own experience. A mass of results has been accumulated by these American "behaviourists," the value of which will only become apparent when they have been co-ordinated.

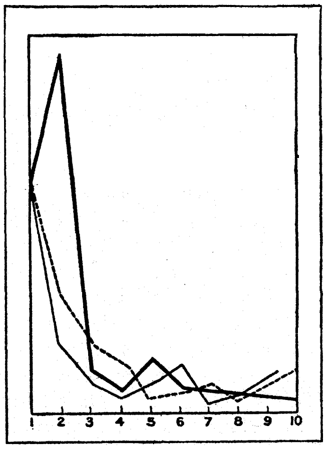

FIG. 8.—CURVES SHOWING RATES OF LEARNING THE WAY OUT. FOR APES (HEAVY LINE); A WHITE RAT (LIGHT LINE); A SPARROW (DOTTED LINE)

In conclusion of this section it must be pointed out that in experiments with animals it can easily happen that the subject trains itself to small occurrences unnoticed by the experimenter and not taken into account by him. Slight noises, movements, for instance the reversal of an electric switch, and so forth may unwittingly be the cause of the establishment of a habit. Then the results obtained from the experiments do not give a picture of the capabilities of the animals which it was attempted to test, but of their capacity of turning experiences to account. Many animals are able to take note of movements so small that they are hardly or not at all observable by men. The so-called "thinking" and "calculating" horses and dogs owe their fame to this ability. Naturally they really know neither how to calculate nor how to read. Often unknown to their owners they have trained themselves to very slight signs given by the trainer on the accomplishment of the right solution of the task, without his

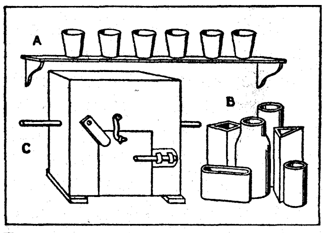

FIG. 9.—EXPERIMENT FOR TRAINING APES TO OPEN LATCHES: (A) COLOURED VESSELS, (B) VARIOUS VESSELS, (C) PROBLEM-BOX CONTAINING FOOD

own knowledge. The animals have learnt by experience that they receive a tasty morsel when they cease to tap with paw or hoof as soon as the sign in question appears. Their master, however, thinks he is rewarding them for having correctly solved their problem. But the real signs consist of very slight movements of the body, of the head or even only of the features of the questioner. These signs are the expression of the conclusion of a state of tension on the part of the questioner, which occurs as soon as the correct number of beats has been reached,

INTELLIGENT ACTIONS

The highest type of action is represented by intelligent action, that is, conduct which depends upon an insight into the connection of things and events and upon their causal relationships. Intelligent actions, above all, distinguish men from animals. Formerly it was said that animals act on instinct, man on reason. And in truth this insight is lacking in most animals. It is only recently that it has been shown that in a small group of animals there is a mode of conduct which recalls reasoned actions of men and is certainly a precursor of such. These animals are the anthropoid apes, man's nearest relatives. From observations on anthropoids in zoological gardens the conclusion had long been reached that as regards their conduct these creatures are to be placed far above all other animals. The way they handle objects at their disposition, and employ the most diverse means of attaining their end, whether it be a fruit or other desired object, makes their whole conduct appear highly human. Our knowledge has been very considerably advanced by the carefully planned experiments made by W. Kohler (1917), with chimpanzees in the German Anthropoid Station on Teneriffe, under conditions which were as natural as possible and in a climate similar to that of their home. The work of Yerkes, S. J. Holmes and Miss Kohts is also of great value.

Kohler's experiments were of quite a simple nature. They resembled those now employed with quite small children. For the experimental animal it was always a question of attaining some object, such as a fruit, which could not be reached directly by grasping it with the hand. A banana with a string attached to it, which lay out of reach of the arm, was at once pulled in by the chimpanzees with the aid of the string. Hungry dogs, cats or horses in a similar situation would simply have starved. Experiments have demonstrated that dogs will not of their own accord drag meat from a table, even if they have been trained to gain possession of the meat on a word of command by pulling at a string attached to the meat and hanging down from the table. In other words, although they are physically capable of accomplishing the task, it is too difficult for them. If a loose fruit lay out of reach of the chimpanzees, in front of the bars of their cage, they soon succeeded in pulling it in with the aid of some object such as a stick, a wire, a loop of cord or a stone. Thus they interposed between themselves and the thing desired a material intermediary object which was not a portion of their own body. We can therefore speak here of the use of tools. Probably something similar was involved when the animals fetched packing cases which were placed at their disposal and climbed on to them in order to reach fruit hanging from the roof of the room in which they were confined. Or again when, in order to attain the same object, they placed a bamboo stem vertically, quickly climbed up it and seized the banana whilst jumping off. One of the apes used pieces of bamboo four metres long for this purpose. The chimpanzees accustomed themselves to use the sticks for all possible other purposes, such as for levers to force open packing cases, tools to dig up roots, for touching a mouse or lizard held out to them, and finally even as a weapon, although not for hitting but for throwing. The animals learnt all this on their own account without its having been shown to them by men. A curious use, of straws became the fashion with them for a time. They used these for catching ants, which they waylaid and licked up whenever they could gain possession of them, doubtless on account of the taste of formic acid in the insects. In the present instance an ant pathway led over the outside of a cross-beam of the wire-netting enclosure. Kohler describes how first one of the chimpanzees, then another, and finally the whole company, held out straws and spikes through the netting on the beam so that in a short time the straws were covered with ants. Then the prey was quickly drawn in and licked off in the apes' mouths. All the animals in the station could be seen squatting next to one another along the ant pathway, each with a straw, looking like a row of anglers along a stream. Such a use of tools, which is evidently intentional, is found in no other animals. It is true that certain sand-wasps pound the sand at the entrance to their nests with a small stone held between the jaws. This, however, is a purely instinctive action. The blood-red weaver ants, *Oecophylla smaragdinea,* found especially in Ceylon, stick together the leaves out of which they form their nests with spun thread. In the preparation of this they use their larvae, somewhat like living distaffs. The worker ants take hold of the larvae with their, jaws and force them by a gentle pressure to extrude the secretion from the large spinning glands. In so doing they move the larvae to and fro, pressing them now against one now against the other of the two leaves which are gradually being stuck together, so that eventually a dense and strong fabric results. This behaviour, too, in contrast to the real use of tools, is an instinctive action.

When one packing-case did not suffice as a foothold for reaching a banana which was hanging particularly high up, the apes placed one or more cases on top of the first. They managed to erect tower-like constructions of four cases. It is true that the boxes were placed on top of one another in such an inexact manner that it was only the inborn gymnastic dexterity of the apes that prevented the dangerous construction from collapsing in use. The problem of fetching food which had been thrown down behind a trellis out of reach, by circumventing the trellis, was solved by the chimpanzees without more ado. Dogs often and fowls always fail at the same task because they are so attracted by the sight of the near-by food that they take no notice of the round-about way leading to it, although they may know this route already. On the other hand, it was extremely difficult for the chimpanzees to shove away a box which prevented them from seizing a fruit lying in front of the bars of their cage. It was always apparently considerably easier for them to make a détour with their own body, *i.e.,* to run or climb by a roundabout way to the object of their desires, than to achieve their purpose by means of a tool. This was the case when a small-meshed wire net was placed before the fruit and the net had to be pushed aside with a stick. The most difficult case was when it was necessary to push the fruit away first of all to drag it in afterwards. A complete solution of this problem was only arrived at by the two most intelligent of the apes. For the different chimpanzees showed a definite gradation in their capabilities. Such individual differences in the ability to adapt themselves to a given situation are found everywhere in the animal kingdom. These differences are present, too, when pure but modifiable instinctive actions are concerned. Probably the highest accomplishment attained in the Teneriffe experiments was the case of an animal which itself manufactured a tool. Only one chimpanzee did this. The sticks at its disposal proved all to be too short to drag in a fruit lying in front of the netting of the cage. After many efforts, the animal eventually succeeded in sticking a narrow tube inside a wider one and so lengthening the stick. After this had succeeded once, the animal used the same method every time there was a necessity for it. In doing this he always held the wider tube in the left hand and pushed the end of the narrower tube into it with the right. Eventually, he perfected it to an instrument composed of three tubes, the narrowest being in the middle between the two wider ones.

An important element in the manner in which the chimpanzees mastered all of these tasks was the fact that the solution frequently occurred suddenly, the animal as it were giving itself a jolt. In this respect the manner of solution differs notably from the solutions discovered by other trained animals purely by chance. Lower apes have been presented with the same problems and it has been found that these animal's too can work with intermediary tools and intermediary actions. But the action is always towards the animal. A preliminary movement of the tool away from the animal is never carried out. Whereas it occurs to the anthropoids to push a rake behind a banana to drag it towards them, or to move a bolt which closed a case in the direction away from themselves, the lower apes abandon such tasks. Thus the actions of the anthropoids are actually the highest attained in the behaviour of animals. In this respect, their conduct is a real intermediary between animal and human behaviour.

THE BEHAVIOUR OF THE PROTOZOA

Reflexes, instincts and intelligent actions are bound up with the presence of a nervous system. In consequence of this, out of the various existing types of behaviour, tropisms alone would seem applicable to the Protozoa. But this in no way covers the facts. The behaviour of the Protozoa is to a certain extent of a special nature and may be contrasted with that of the Metazoa. In spite of an outward simplicity of organs of locomotion, the behaviour of these unicellular animals can nevertheless be very varied. The cause of the movements of the pseudopodia of rhizopods, *e.g. Amoeba,* has been ascribed to surface-tension. When, in spite of this, under apparently identical external conditions one individual behaves differently from another, the difference depends upon the varying physiological states in which the two animals happen to be. The apparently arbitrary spontaneous movements are accounted for by inner causes, which depend upon the alteration in the chemical reactions going on inside the cell, caused chiefly by metabolic processes. Not only pseudopodial movement, but also the intake of food by these animals, and the construction of the shells of shelled amoebae, have been imitated by artificial models. In this way it has been demonstrated that all. these phenomena can be explained by chemical and physical laws equally applicable in inorganic nature. Yet it has up to now been impossible to construct a model which unites in itself all the life processes. Many questions remain still to be answered. The living organism possesses such a complex organization, having a definite structure made up out of numerous spatial parts, that we are still far removed from being able to unveil all its secrets.

The infusorians and flagellates, which, owing to the possession of cilia or flagella, are much more motile than the rhizopods, tend, so long as they are swimming freely in the water, to move forwards in a spiral path, rotating continuously on their long axis. The sessile forms produce currents with their motile organs, bringing food towards them from the neighbouring water. These animals almost invariably respond to external stimuli—touch by a solid object, chemical substances in solution, etc.—with one and the same definite reaction. This is the *"flight movement"* or avoiding reaction (Jennings). The cilia of a swimming infusorian, which, to take an example, has hit against a solid object, reverse the direction of their beat, so that the animal is driven backwards for a short distance. Then the animal slows down its rotation on the long axis. The beating of the cilia of the mouth region diverts the front end towards the aboral side so that the body of the animal now describes a conical figure. Finally, the infusorian again swims forwards as in the beginning, but owing to the previous swinging round of the long axis, the movement forwards is now in a different direction. If the infusorian again hits against the solid object, the action is repeated until, in the end, the obstacle is avoided. It is noteworthy that it is immaterial from which direction the stimulus comes and on which part of the body it impinges. The infusorian invariably responds by the same avoiding reaction, the different phases of which are merely carried out with different intensities according to the strength of the stimulus. Since such a flight-movement is the reaction of infusorians and flagellates to almost all stimuli (indeed it occurs in corresponding circumstances in many of the smaller Metazoa), the response of these animals is fundamentally always negative. The final result may, nevertheless, often be positive. Thus *Paramaecia* collect in a drop of water rich in oxygen because they swim into this drop from the surrounding water without any reaction but on arriving at the boundary of the drop they are stimulated to execute the avoiding reaction so that they can no longer get out of the drop. Since they hardly possess any positive reactions these Protozoa do not pursue their prey but only happen by chance upon their food. On this behaviour Jennings based his theory of the *"method of trial and error"* which he supposes applies to the whole animal kingdom. In point of fact the behaviour of many Metazoa, right up to the mammals, frequently gives the impression that the animals attain their goal through methodless trials and final chance success. In spite of this, the theory has turned out not to be of general application. It is in contradiction to Loeb's *tropism theory* which assumes forced movements, since chance plays a considerale rôle in Jennings's theory. Our description of the different types of behaviour has shown that in reality more complex factors intervene.

Among the Protozoa, particularly among many of the larger infusorians, other reactions in addition to that just described are possible. Thus *Stentor roeseli,* attached inside its tube of mucus, first bends to the aboral side when carmine particles are dropped into the water which it whirls past its body. Since, in spite of this, the particles continue to reach its surface, it next reverses the direction of beat of its cilia and then once more moves them in the normal sense. After this has been repeated several times without result, the animal withdraws into its tube, at first for a short, then for a longer, period. If the carmine particles are still there, a fourth type of reaction eventually supervenes. The *Stentor* contracts forcibly, loosens its foot and swims away. The series of reactions employed by *Stentor* is graduated according to degree of effectiveness. In a certain measure the animal makes a purposeful choice out of its different reaction possibilities. The term "action system" has been used to designate the totality of the possible reactions which an animal possesses in consequence of its bodily structure and which characterize its various reactions under different circumstances. The action systems of the Protozoa only include a relatively small number of definite movements. Animals are able to respond to the stimuli they encounter only with one or other of these movements, or with a combination of them.

THE SENSORY FACULTIES

As we have seen already, very frequently the behaviour of animals has led to a mentality being ascribed to them similar to that of human beings. We have seen, too, that a mind, *i.e.* the phenomena of consciousness, cannot be experienced objectively. Nevertheless, we can attempt to form at least some idea of how the surrounding world in which animals live would appear to them if they possessed a consciousness analogous to our own. For human beings the sense-organs are the gates through which we receive the impressions of our surroundings. They constitute the only path through which what we know of the outside world reaches us. The totality of all the things and processes in our surroundings, among which our own bodies must be included, is the *Umwelt* or "surrounding world." In this surrounding-world animals too are comprised. The question now arises as to how much the animals themselves can take in through their sense-organs of these surroundings in which we see them. Since the type and structure of the sense-organs in animals is often quite different from what it is in ourselves, it follows that the *Umwelt* of an animal must generally appear quite different from what it does to man. By documenting ourselves concerning the sensory capabilities of animals we can obtain a conception of how their *Umwelt* must appear, assuming that they possess a consciousness similar to our own.

Sense of Time.—A sense of time, which exists in a number of animals, is the result of complex stimuli, affecting various sense-organs. Often animals which are regularly fed, brought into their stalls, or put into the open at stated times, show by their behaviour as the moment approaches that there exists in them some feeling of what is about to happen. This may have various causes. Frequently it is the preparatory actions or other behaviour of men themselves that the animals know from experience to be the precursors of the event. Then again, certain physiological processes go on in the animal's body with a definite rhythm, which, in consequence of a long-standing connection with the event in question, have acquired for the animal a time-relationship with it. Such physiological processes are hunger, fatigue, etc. We find, too, in a number of the lower animals a definite rhythm due to regular repetition of recurring external stimuli. Sea anemones open and close with the rhythm of the tides and retain this same rhythm for some time in an aquarium. But a real conception of time is lacking in all animals, even those which are mentally the most gifted, namely the anthropoids. Animals, then, live solely in the present. They know no past and no future. They are unable to survey the span of life, youth and old age, as we do.

Influence of the Central Nervous System.—In the Protozoa the whole protoplasm of the animal body is irritable. In Metazoa the sense-organs take over the task of receiving stimuli. These sense-organs exercise a certain selection among the innumerable changes going on in the environment, all of which might act as stimuli. Each sense-organ responds only to those stimuli to which it is adapted. These are the so-called adequate *stimuli* of the particular sense-organ. This is very expedient, for if all the changes going on all the time in the environment were able to act upon an animal as stimuli, animals would never be at rest. Nevertheless the number of stimuli sent on as nerve impulses by the sense-organs to the nervous system is very large. But we may often observe how the behaviour of an animal does not alter at all although certainly one or several of its sense-organs are receiving stimuli. The explanation is found in the activity of the central nervous system. In general, reflex movements take place as a consequence of stimuli acting on the organism. But we have seen above that the morphological basis of reflexes is formed by the reflex arc, which is usually composite. Association neurones interposed in the reflex path are connected with other nerve cells, and by the massing together of such ganglion-cells centres are constituted. The centres of the separate senses are in communication with one another through numerous nerve fibres. This permits of the working-up of the stimuli received by the different sense-organs. Other nerve centres are interposed between the principal ones. These are, in a sense, subordinate, having the function of co-ordination and purposeful conduction of the impulses coming from the sensory centres. Finally a ganglionic mass, the brain (*q.v.*), has been developed in the course of evolution, to which the whole of the nervous system is subordinate. The brain takes over the regulation of the highest functions, those involved in purposeful behaviour. This brain development commences in flat-worms and in annelids. It attains its greatest development, on the one hand, in the supra-oesophageal or cerebral ganglion of certain invertebrates, and, on the other, in the vertebrate brain with its five divisions and far greater complexity. With the brain, that very important part of the central nervous system, the ventral nerve cord of annelids and arthropods, and the spinal cord of vertebrates, is in closest connection. The brain merits our particular attention above all because in man it is rightly considered to be the organ or seat of the mind.

The Highest Centres.—The brain, using this term generally to include the highest centres of the nervous system, has the function of co-ordinating movements. Here the decision is made as to which impulses shall be conducted further on, when the results of stimuli arrive simultaneously from several sense-organs. In addition the brain decides into which nerve-paths these impulses shall be switched for conduction to the effector organs. This highest connecting centre is at the same time the most important inhibition centre. It intervenes as the highest court of appeal in the course of reflex and instinctive activities. The brain, just like the lower centres, can stop or inhibit these actions. An example will make this clear. When the mouth-parts of a normal crab come into contact with a piece of food, the chemical stimuli derived from the food cause the appendages, in a reflex manner, to tear up the food and to put it into the mouth. The action stops when the stomach is full, when the animal's hunger is satisfied. If, now, the commissures which unite the crab's brain to its ventral nerve-cord are cut through, the mouth appendages continue to work as long as food is presented to them. The result is that the stomach and the gut of the animal are eventually so crammed with food that they burst. This shows clearly that the brain, which is normally kept informed of the state of repletion of the stomach through special nerves, exercises an inhibitory influence on the reflexes concerned in feeding. Whereas it is impossible to persuade a normal frog to croak by any stimulus whatsoever, this croaking invariably follows when a frog whose forebrain has been removed is stroked down the back with the finger. Here, too, the inhibitory function of the highest centres is apparent.

Further, the brain functions as an organ of summation. It is a sort of reservoir for separate impulses, in themselves perhaps too small to result in action. The nervous energy thus stored up in the brain is from time to time liberated into motor paths in response to further incoming impulses, which can be due to internal causes. In this manner, so-called *spontaneous actions* arise, that is to say actions which take place without external cause, apparently in an arbitrary manner. Together with its functions as centres for the voluntary distribution and switching of impulses, the brain also includes the centres concerned in the formation of associations. It brings about the inter-connections between nerve impulses due to different but simultaneous stimuli. Upon this the faculty of association depends. Finally, the centres are also situated here through the activity of which a certain continuous tension of the body muscles, the so-called muscular tone, is brought about.

The more an animal is endowed with highly developed instincts, the less does it stand in need of a large number of individually acquired experiences, memory-images, and associative faculties, to be able to behave in the most adaptive manner possible. Thus we find that in insects in spite of the complexity of their instinctive lives, the brain remains relatively small. Added to this, the whole bodily design of these creatures, particularly the presence of an external skeleton, prevents the volume of the body from exceeding a certain size. Thereby absolute limits are further set to the size of the brain, and hence, also, to the further development of mental qualities, the beginnings of which are actually present. In vertebrates there are no such special limits set to the growth of the brain. Hence we find in the different classes of vertebrate animals a progressive development of the mental faculties. This reaches a high point in the birds, but the highest pinnacle is attained among the mammals. It is true that in the latter the lower groups are inferior to birds. It is only in the monkeys, and finally in the anthropoids, that the highest level is attained, forming an intermediate step to the intellect of man. The highest centres, particularly the association centres, lie in birds and mammals in the cortex of the fore-brain, the surface of which increases proportionately to the mental faculties.

Deficiency Phenomena.—When the hemispheres of the fore-brain are removed from an animal, a number of deficiency phenomena are evident in the animal's behaviour. These become the more apparent the higher the animal in question stands in the evolutionary series. Thus fishes or frogs without these fore-brains show no noticeable difference in their behaviour from normal individuals. Such frogs catch flies as usual. They avoid obstacles, dig themselves into the mud in winter, and betake themselves to water during the warmer months. They even possess memory, although it lasts but a short time. All this is accomplished by the centres situated in the intact parts of the brain. Reptiles and birds without fore-brains are no longer capable of spontaneous movements. A few days after the operation, when shock effects have disappeared, a pigeon thrown up into the air flies with co-ordinated movements. It alights in the ordinary way on a perch and avoids obstacles. It can still see and hear well. But all memory has vanished. It does not recognize its food and consequently does not eat or drink of its own accord. It recognizes neither friend nor enemy and if it has young it does not care for them. In mammals, the deficiency phenomena vary according to the mental capacities of the particular animals. Dogs without their fore-brains have been kept alive for years. They appear completely blind and they take no food of their own accord. For the most part they lie quietly sleeping. Such a dog no longer shows any signs of joy. Rather it exhibits fear. It goes without saying that the dog is incapable of learning anything new.

If the whole brain is removed from a vertebrate animal, the effect is always fatal. But whereas in man section of the spinal cord is followed by instantaneous death, the decapitated trunk no longer showing any reflex movements whatever, brainless animals (spinal animals) are well able to carry out such movements. This is the more true the lower the animal stands in the vertebrate series. In apes there are indications only of such movements. A spinal dog makes running movements when the under-surface of the paws is pressed. Its tail can be caused to wag. A decapitated rabbit makes one or two last jumping movements. Fowls and pigeons with their heads cut off run around with wings beating. In these spinal animals all complicated faculties have disappeared owing to the loss of all the higher centres and of the main sensory centres. But the co-ordination of normal locomotory movements persists because this depends on centres in the spinal cord. Lower vertebrates can be kept alive even longer after being deprived of their fore-brain. A spinal frog still plainly exhibits all reflexes. If the skin of such a frog is moistened with dilute acetic acid, the animal makes movements with the foot of the side touched, as if to remove the stimulus. If this extremity is prevented from moving, the frog uses the other leg in an apparently purposeful manner. This experiment proves that biologically useful actions can take place without the presence of consciousness. Such experiments have the further value of showing which actions of animals can take place in an apparently purposeful fashion, but without any intervention of the highest centres, that is without conscious intention.

Reactions to Form-stimuli. — A question to which physiology for long supplied no satisfactory answer arises whenever animals react to form-stimuli (fig. g B). This is the case when the image of a definitely shaped object thrown on the retinal cells calls forth a reaction. And it is equally the case when any other stimuli having a spatial combination are followed by a definite reaction. This is particularly so with the sense of touch and the topo-chemical sense. Von Uexkiill has attempted to supply an explanation of the phenomenon. According to him, each combination of important stimuli corresponds to a model or schema in the brain. The effects of such a stimulus-complex upon a particular group of sensory cells, for example the retinal elements upon which the separate points of the image of an object fall, are conducted by definite appropriate groups of nerve fibres, past the association neurones and the lower centres, until they arrive finally at the highest centres. There the sensory nerve paths reach their end-points. But these end-points must from the nature of things have some spatial arrangement. Von Uexkull assumes that the impulses conveyed to these end-groups are transferred to the corresponding schema somewhat after the manner of electrical induction. The stimulation of the schema then causes a particular reaction of the animal in a relatively simpler manner. The discrimination of spatial boundaries of objects by the most highly organized central nervous systems and brains thus requires a fixed spatial arrangement of nerve paths. The higher brains, as it were, reflect a portion of reality in their schemata through the spatial interrelationship of their parts. In this way there arises in the central nervous systems of the higher animals a new individual universe. Von Uexkull calls this the counter-world (Gegenwelt). Although the things in the outside world which are important to the animal may correspond to definite schemata, the spatial arrangement of the elements of the schema need not be identical with the spatial structure of these objects. And it certainly is not identical. The immense complication of structure of the highest centres which this discussion implies to be necessary must be the reason why reactions to form-stimuli only occur in animals possessed of well-developed and highly complex brains. But that this faculty may exist in relatively low animals is shown by the fact that hermit-crabs have been trained to use as dwellings snail-shells of a particular shape only, and to shun other shells. It is evident, therefore, that these animals, through responses to stimuli in their nerve centres, must be able, then, to distinguish the shapes of these objects from one another.

THE CONCEPTION OF THE ANIMAL MIND

The opinions as to what is meant by the conception of mind are very divergent. Many investigators (Häckel, Famynzin, Bechterew, Claparède, and others) are of the opinion that animal psychology must assume a mind in all animals, even the lowest. According to the view of many modern authors, animal psychology is the science of animal reflexes, instincts, plastic behaviour, and the co-ordination of these actions. Others again consider the capacity for learning, associative memory, as a proof of the presence of mental phenomena. At the root of many of these views lies the thought that the mind is a factor regulating the organic being, that it intervenes in the causal connections between material physiological phenomena. The mind is supposed to be super-added to organisms, and hence to be super-imposed on the laws of physics and chemistry applicable in lifeless nature. The mind is supposed to intervene as a factor directing events towards the attainment of definite ends and purposes, a finalist, teleological principle added to the causal laws of nature. It is especially the purposefulness of animal behaviour, observable everywhere, which is the reason for this assumption. Frequently the name of "consciousness" is given to a mind so conceived, or to the sum total of the phenomena corresponding to such a mind. It leads to misunderstandings when some authors identify the object of animal psychology with the study of consciousness, while others use the conception of consciousness in the sense explained above as a "psychic factor." We here use mind as identical with consciousness or the totality of inner experience. Everyone knows this changing play of conscious phenomena arising out of his own personal experiences. For this reason there can be no definition of the conception. With all phenomena of consciousness, physiological processes occur in the central nervous system which are indissolubly bound up with them. The physiological processes in question cannot take place without the accompaniment of mental phenomena. And mental phenomena never appear without corresponding physiological changes going with them. The course of the physiological processes is continuous. The phenomena of consciousness are discontinuous, being interrupted by unconsciousness, sleep, or fainting. On this view an intervention of the mind in the course of physiological occurrences is impossible. Further the psyche, soul or mind, is not a substance, as has sometimes been supposed, but it is a course of mental events. From all this it follows, as already indicated, that the mind cannot be objectively experienced. No other course remains open to us, then, but to see in animals a mind analogous to our own consciousness, and to attempt to picture to ourselves what sort of knowledge animals can obtain through the functioning of their sense organs of the things and happenings in their environment and how in consequence the world may appear to them.

The Surrounding-world and Inner-world of Animals. — For the lowest animals stimuli alone exist. The whole manifold environment surrounding us does not exist for them. Hence they are ignorant of enemies or dangers. The capacity to choose between different reactions is almost wholly lacking to these animals. Their reactions to external stimuli are fixed reflexes. In many instances this is so striking, as for example with the echinoderms, that the animals might rightly be called reflex automata. It is in just these animals that a unified central nervous system is absent. Hence their bodies cannot receive any directed stimuli. In the worms the development of a brain commences, and in higher groups this more and more takes over the co-ordination and direction of movements. The spontaneous movements likewise derive from this brain. The sense-organs become more and more complex. In the most highly developed molluscs, the cephalopods, the structure of the nerve centres and with them the behaviour, is so complicated that one can credit them with a counter-world (Gegenwelt), with schemata. The brain of the arthropods is the highest switch-centre and the organ of inhibition. In the higher Crustacea associative memory appears clearly for the first time. Behaviour based on reflexes and instincts can now be modified, for the instincts are plastic up to a certain point. The surrounding-world (*Umwelt*), although certainly not yet objectively perceived, becomes nevertheless ever more and more manifold. In insects these faculties become even further enhanced. Reactions to colours and to shapes exist. Nevertheless instincts still heavily outweigh plastic actions.

It is only in the vertebrates that plastic behaviour steps gradually into the foreground, although the lower groups of vertebrates are little in advance of the highest invertebrates. Since memory replaces intellect in the animal, we frequently find quite amazing instances of memory, particularly in relation to the sense of locality and of finding the way home. It is remarkable that the types of animal which exhibit a complex faculty of association and capacity for learning from experiences composed of numerous details, are phylogenetically young forms which developed only a little before the Chalk age. These are the social insects, dragonflies, robber-flies, birds, and higher mammals. But the faculty of association is not in itself sufficient to build up higher psychic functions by the summation of simpler psychic elements. The so-called psychology of association, which held the field for some time, came to grief in the attempt to maintain this view. The capacity for highly compiex performances and in the end for single-purposed actions depends upon the fact that the method of trial and error, which is exhibited by most animals as a testing of various reaction possibilities, is now moved up into the brain, where it intervenes in the various physiological processes due to experience.

Reflexes and **Consciousness.**—We have seen that reflexes are the basis of most animal movements. It is therefore natural to enquire into the relationship of reflex movements to psychic happenings and all the more so since in man there can be a connection between reflexes and the phenomena of consciousness. There is a whole series of reflexes which take place without our being conscious of them. Thus the pupil of the eye enlarges or contracts according to the intensity of the light falling on the retina quite without our knowledge. Nor are we able to alter the size of the pupil aperture at will. In other cases at least the end result is known and often the stimulus also. If one sits with one leg crossed over the other and hanging down loosely, a light tap with the edge of the palm on the front of the shin just beneath the knee-cap causes a jerking up of the leg. The movement and the touch-stimulus are felt. But we are not able to suppress or alter the course of this reflex by an effort of will. There are other reflexes which we can inhibit at will. Such are the closing of the eye-lids when the lashes are lightly touched or when an object comes rapidly towards the eye. Since in ourselves some reflex phenomena take place with, others without, consciousness, and some can be suppressed by the will, while others cannot be so influenced, we can draw no conclusions as to whether consciousness accompanies reflex behaviour seen in animals.

Even though many instinctive actions appear to be accomplished with conscious intention owing to their remarkable adaptiveness, yet we can often convınce ourselves by appropriate experiments that the animal has no consciousness of the purposeful nature of its actions. When the conditions are so altered that the actions of the animal are turned into nonsensical, non-adaptive ones, they still continue to run their course, which corresponds to an inborn plan. From this it becomes evident that the animal acts in reality merely by instinct, that is without knowledge of the object and meaning of its behaviour. We see that instinct is really only a concatenation of reflexes. The burying beetle, *Necrophorus vespillo,* attracted by the smell of the corpse of a small animal, commonly buries the latter beneath the soil by undermining the ground. Then it lays its eggs in the corpse, thus providing for its brood when it hatches out. It has been observed that the animals are able to gain possession of a corpse, hung purposely on a small gibbet, by digging around the posts and so making it fall. H. Fabre had proved by a series of extremely ingenious experiments that this bringing down of the gibbet is in no way the result of a special cleverness on the part of the beetles, but that it happens by mere chance. For if the suspended corpse just touches the ground next to the posts of the gibbet, the beetles commence to dig there. As a result, the gibbet often falls down owing to a loosening of the soil. But if the spot at which the corpse touched the ground happened to be some little distance from the posts of the gibbet, the beetles never dug close to the posts. Hens in the open scrape at the ground in a purposeful manner to unearth worms, insects, and so forth. Yet the following experiment shows that they have no knowledge of the intention nor the meaning of their behaviour. A hen climbed into the earthenware plate in which grains of corn were brought to her and, once inside the plate, continued the scraping movements which were now completely purposeless. The only effect of tbe movements was that the corn flew out and was scattered. Next the hen was given her corn in a small box with sides 15cm. high, which was firmly fixed to the floor of the chicken-run. The hen walked up to the box, began to peck at the seeds inside it, and in so doing made powerful scraping movements on the bare wooden floor of the box, which movements were of course completely senseless. Such observations must warn us to examine very critically actions of animals which appear to us purposeful, and not to interpret them straight away in an anthropomorphic manner. If consciousness exists in the hen which behaves as we have observed, it is certainly quite another kind of consciousness than that which we should feel in the animal's position.

Nigher **Mental** Faculties. — The grasping of the objective inner relationship between two things is a performance superior to instinctive action. Such a capacity has been proved for anthropoids, lower apes, dogs, white rats and fowls. We may accordingly assume that the faculty is present generally in higher mammals and in birds. Fowls were trained to pick corn grains from one of two grey papers of different tints, for instance from the lighter of the two. Then the two papers were replaced by another pair. Of these the grey paper to which the birds had previously been trained was now the darker of the two. The fowls went by preference to the now lighter paper. They behaved in the same way with any other arrangement of pairs of papers chosen out of the four used. There is then a relative but no absolute knowledge. The same kind of relative appreciation regarding pairs of grey papers has been shown to exist in lower apes and in a pointer dog. In the case of the rats two spaces were lit to different intensities. One of these two was the place in which they were fed. Köhler's chimpanzees were offered two boxes distinguished by having front boards of different sizes. One of these, for instance that with the larger front board, contained food. After the animals had learnt to go to the right box, other pairs of front boards were put in. The animals always chose that which was the bigger at the moment, without regard to the absolute size. In all these cases, a comprehension of relation, a transposition, occurs just as when we recognize a tune even when it is transposed into another key.

Until lately no psychological explanation had been suggested for this faculty. The *Kohler-Wertheim theory of Gestalt (form)* which has been developed in the last decade and was first applied in human psychology appears to fill this gap. For it relates as much to the physiological as to the psychological side of the phenomenon. Our perceptions are not simple summations or additive configurations of sensations, composed of separate elementary sensations. Rather the sensory impressions make themselves felt to us as specific, rigid, unified impressions of the whole situation. These are more than the sum of the parts. Rather they are spatial forms, meiodies or intellectual associations *(Gestalten).* According to the theory in question these *Gestalten* can be transposed. The physiological processes which form the basis of the phenomena or experiences of *Gestalten* themselves participate in the character of these phenomena. And Kohler has actually attempted to show that in physics there exists a non-additive, super-geometrical form arrangement which may have a real meaning. The physiological occurrences, according to the *Gestalt* theory, have themselves the properties of a *Gestalt.*

Finally the highest accomplishment of animals, the capacity *to abstract,* has been demonstrated in anthropoids. Nadie Kohts first showed a chimpanzee a number of bone disks of various colours and shapes. Then she succeeded in getting the animal to choose these particular disks out of a heap containing others as well. The chimpanzee succeeded further in solving an even more difficult problem. A hemispherical bowl of a certain colour was shown to it and then the ape chose out of the collection of variously coloured bone disks a disk having the identical colour of the bowl. The animal abstracted the idea of the colour from the very different shapes of the two coloured objects. It considered the colour alone. It was due likewise to such a faculty of abstracting that the Teneriffe chimpanzees were able to drag in a fruit lying out of arm's reach by using all sorts of objects without regard to their shapes, as if they were sticks. Possibly the *Gestalt* theory might provide a physiological explanation, at least in principle, for this most complex behaviour. Yerkes has corroborated the presence of this faculty by quite other methods.

Whether or not animals have ideas or conception is still most debatable. If a dog or a cat makes no effort to reach its food from the moment when the food is removed from its sight, it may well be concluded that these animals have no memory-image of what they have just seen. In spite of the highly perfected training performances of many higher animals, there is no reason why independent ideas should necessarily be associated with the accompanying memory processes. The observed behaviour can well be explained by the associated coupling of the sensory impressions with inborn instincts, or body movements which have become habit through practice. Up to now, it is impossible to decide whether in animals, as in ourselves, a conscious separation of immediate and reproduced sensory impressions exists, or if such is at least foreshadowed. The anthropoid apes form an exception once more. Their "insight," the fact that they make "discoveries," would appear to be explicable only on the assumption that they are gifted with objective conceptions. Kohler is of the opinion that the higher animals know "separate things," and not only diffuse "experience complexes." He points to the enormous importance of the "comprehension of meaning" for the formation of concepts, for an insight into the "meaning" of the connection between events. "To be able to see things in the surrounding world, it is necessary for an animal to have experience of the meaning, of the structure, of that part of its surroundings." (Koffka.)

THE EMOTIONS

The mental life of human beings has both an objective and a subjective side. The objective side of consciousness includes perception, sensation and conception, or in short all that is connected with the outside world surrounding us. The subjective side, on the other hand, concerns that part of our inner lives which belongs to us alone, our real interior world, or in other words emotions and the phenomena of will. The importance of the emotions in the whole mental life is so great that many psychologists see in them the basis of all mental phenomena. But what is the state of affairs in animals? S. J. Holmes regards pleasure and displeasure as the most powerful factors regulating the conduct of animals. Whilst in dealing with the objective side of the animal mind we were obliged to resort to analogies with our own mental experiences in order to attempt to form a picture of this part of a possible inner life of animals, we are even worse off in regard to their fkelings. Objectively the mind cannot be experienced. How then is it possible to arrive at the innermost emotions of animals? Here, too, we are obliged to depend on our only means of study of the animal mind, namely analogy, which unfortunately is very uncertain. In the animals most nearly related to ourselves we observe behaviour which coincides closely with certain expressions of our own inner life. This is so convincing that the objection that the mode of procedure is questionable might easily be overridden. It becomes difficult for our emotions to refuse to accept these connecting links. Yet even with the mammals our confidence in the analogy is shaken. In the remaining vertebrates, and more particularly in the invertebrates, which are so differently constituted from ourselves, this convenient tool must be foregone.

It is the "expressive movements" visible to the eye which permit of the argument by analogy. There are the gestures of animals nearest related to ourselves, and added to these there are finer changes which can be shown physiologically. These agree fully with those changes in ourselves accompanying our sensations. If there is any mental correlative to the expressive movements of animals, it must be represented by the so-called emotional side of our own mind. Our sensations are those of pleasure or displeasure, of excitement or calm, of tension or relaxation. The rise and fall of our feelings are accompanied by definite changes in the rhythm and in the intensity of respiration and pulse. Exactly similar changes can be observed in animals either directly or with the help of special apparatus. All small animals, such as rabbits, rats or birds, show this when seized or even when approached by the hand in their cage. Changes in the rate of respiration, on stimulation, have been found to occur not only in fishes but even in arthropods, particularly in insects. Are these purely physiological processes, or may we argue from analogy and attribute to these animals feelings such as we ourselves know? In men these respiratory and vasomotor phenomena occur when particularly strong and lasting emotions are concerned. It is just these, for example joy, sorrow, care, fear, anger, fury and others, which are normally accompanied by typical expressive movements. In us these movements consist of mimicry, the expression of the eyes, particular movements of the limbs, the whole attitude of the body. They are involuntary and take place in a reflex manner. We find a number of these expressions repeated by our nearest animal relations.

Of greatest interest to us are the expressions of the emotions in apes, which in many ways resemble our own to a remarkable degree. Nevertheless, differences exist, as Kohler points out as a result of his experiences with the Teneriffe chimpanzees. A shake of the hand was a sign of displeasure. Greater discontent was expressed by striking the ground rapidly with the hand. Indignation was made known by a forceful beating with both fists on the ground and an excited jumping up and down. Animated nodding of the head was the sign of joyous expectation. Fits of anger in anthropoids, as has long been known from experience in zoological gardens, are wont to be of uncommon intensity and long duration. Travellers relate how the hunted gorilla makes the most enraged assaults on its enemies, accompanied by roaring and beating of the chest with its hands. Just as men do in similar circumstances, chimpanzees scratch their head or the side of their body as a sign of uncertainty, indecision or embarrassment. When very astonished they leave their mouth wide open. They are even capable of a sort of weeping, although without tears, when afflicted with grief. And so, too, they laugh in a certain measure, as an expression of pleasure or joy. When tickled in the palm of the hand their face is drawn into a sort of grin, while they titter or squeal with apparent pleasure. In common with human beings apes can blush and grow pale in the face.

In birds, too, movements exist which may be interpreted as the expression of feelings. These animals seem likewise to be subject to moods and humours corresponding to physiological conditions. On the other hand, the interpretation of particular movements of invertebrates is most uncertain, although they too have been regarded as expressive movements. The bee-keeper believes he hears the moods and feelings of his wards from the note given out by the inhabitants of a hive. In cephalopods a lively play of colours of the chromatophores is observable which makes the whole body or separate parts of it appear now light, now dark. At the same time, particularly in *Sepia,* the arms are held in a peculiar manner. It appears certain that these changes reflect definite excitations in the nervous system. But whether or not they are the expressions of definite feelings can only be guessed at.

One of the most emphatic feelings in human beings is that of pain. It is usually accompanied by particularly marked expressive movements. The most characteristic signs are violent withdrawal, warding off of the stimulus which causes the pain, and other movements, the use of the voice being a common accompaniment, rising on occasions to a shout. In the vertebrates we find quite similar expressive movements and sounds, following on stimuli which we can suppose, on the analogy of their effects on ourselves, to give rise to perceptions and feelings of pain. It is true that these expressions are much less intense in herbivores than in the more agile carnivores and more especially in the apes. In the lower vertebrates, and even in birds, these signs of a sensation of pain are even less apparent. Must we then suppose that these animals have a duller sense of pain than the higher vertebrates? In invertebrates, the existence of a sense of pain becomes very questionable indeed. Certainly here too we often find violent defensive and other movements following on corresponding stimuli. But we have no means of testing whether these are the expression of a sensation of pain or merely the consequence of a very strong excitation of the nervous system'. The following experiment is suggestive. If an earthworm is suddenly cut into two pieces with a spade, the front half creeps on apparently unaffected while the hinder end writhes violently. Yet the latter contains only the ventral nerve-cord, with its lower centres, whereas the cerebral ganglion or brain is in the front portion. But the brain being the seat of the highest centres must be regarded as the bearer of consciousness, including the feeling of pain. It is worthy of remark, too, that in the highest organized invertebrates, the insects, injuries and mutilations tend usually to have no externally apparent effects. These animals usually behave in a quite unconcerned manner in response to extremely powerful stimuli, from which we would, from our own experience, be inclined to assume a violent feeling of pain. An ant continued quietly to suck honey after first the antennae and then the whole abdomen had been cut off. When the whole lower portion of the head, including the mouth, was cut off in bees and wasps (leaving the antennae intact), the animals went back again to some honey which they had found. When a caterpillar is wounded in the posterior part of the body and the head is turned round to the wound, the animal will eat its own flesh. It is possible to place the hinder end of a dragon-fly's abdomen between its jaws, upon which it begins at once to consume its own body. This seems to indicate that a sensation of pain is lacking in arthropods. We conclude that to all appearances a pain sensation is present in the higher vertebrates and that the lower we descend in the animal scale, the more doubtful it becomes whether or not pain exists, until in the lowest animals it is almost certainly absent.

In many of the higher animals, mammals and birds, expressive movements are to be observed which by comparison with similar movements in ourselves may be taken as signs of fear. In addition to the changes in respiration and pulse-rate referred to already, trembling of the body is seen, together with timid withdrawal or, in the case of animals living in herds, panic-stricken flight. Numerous analogies are found, too, in the animal kingdom, again particularly in the higher mammals, for the outward and visible expressions of our own feelings of pleasure. And while we cannot be certain in the lower animals that there are any expressions of pain, almost all animals, right down to the worms, show a violent excitement during pairing and in other actions connected with sexual life. One might be inclined to interpret these as the expression of greatly heightened feelings of pleasure, of the same nature as our sensations of sexual satisfaction.

THE LANGUAGE OF ANIMALS

By animal language we understand not only the various productions of sound but we must also include in the conception all those movements and modes of behaviour by which animals influence their fellows from a lesser or greater distance away. Hence, animal language may consist of sound language or of sign and gesture language. Naturally we find animal language developed principally where the conditions of life are such that animals are in close relationship with their fellows. This is more particularly so in the mutual quest of the opposite sexes for one another for the purpose of pairing. Since it is usually the males which are the active partners in seeking out the females or in enticing them to come to them, they are possessed of the most expressive speech, or it may even be the males alone that have the power of speech. Of insects the males alone are capable of sound-production. For the enticement of the opposite sex the language of gestures plays at least as great a part as that of speech. Frequently certain bodily positions serve as signals. The calls and warning notes of parent animals have a great importance, particularly of mother animals that keep their young with them for a time. But such calls are always found, in addition, where animals live in close contact with one another, when they possess a social life as a family or a herd. Finally, a kind of battle language is to be observed in animals, both in the form of expressions on the part of the attacker and on that of the attacked. Naturally the necessary conditions for the development of such a language are only present where not only the animal expressing itself is capable of producing the requisite sounds or signs, but where also the other individual is equally capable of receiving and interpreting the signs produced. A sound language, for example, can only exist when the individuals for which it is of import possess ears. Consequently, every observed production of sound or noise, every apparent gesture, must not immediately be interpreted as a form of language.

In one respect all animal languages are fundamentally different from human language. Whilst we speak or make gestures to explain our thoughts or wishes to others, in the language of animals something far more primitive is concerned. For there is never any conscious intention involved. It is never anything but the instinctive expression of a definite physiological condition, under certain circumstances also of a particular sensation. Nor is the second animal, to which the first addresses itself, ever capable of giving a definite meaning to the sign or sound emanating from its companion, nor of understanding it as a conscious message. An utterance in the language of animals means nothing more than a certain stimulus, sign or signal, the reception of which is answered by certain reactions. It is true that in this way animal speech to a certain extent attains the meaning of a communication. And this is all the more so since once more we can observe here how a purposeful adaptation co-operates. Normally the language signs are answered correctly, that is purposefully, in accordance with their meanings. Further, the words or definite sounds used even by the highest animals refer always to their feelings, and never designate objects,

Insects.—In addition to the sound-language of certain insects, other modes of communication are found in this group. More particularly among social insects the capacity of inter-communication has reached a high pitch. The mode of expression to be observed here is spoken of as antennal or feeler-speech. Ants induce their companions to regurgitate food from the crop by gentle tapping or stroking of the head with the antennae. The ant guests have adapted themselves to these conditions and imitate the speech-signs of their hosts. But the feeler-speech of ants is much more comprehensive than this, so that the celebrated myrmecologist Wasmann was able to compile a sort of dictionary of the ant language. The strength and rhythm of the antennal tappings are concerned and the parts of the body to which they are applied. An ant which has found an object too heavy to be carried alone fetches companions to help in the work. The termites possess a similar highly developed language. They do not, however, use the feelers, but the whole head, with which they rain rapid blows on the head of a companion.

Von Frisch has made exact studies on the mode of communication of honey-bees. The worker bees, on returning to the hive from a productive food-source which they have found, dance a recruiting dance. During this the scent organs, situated between the fifth and sixth abdominal segments, are extruded. The dance moves in a quite definite and peculiar manner in and out between other workers that happen to be in the hive, inducing them now to fly out to work. The type of dance varies according to whether a source of nectar or of pollen has been discovered.

Birds.—The sounds and speech of birds are extremely varied. Sounds are produced by the lower larynx, or syrinx. In true song-birds the sounds can become songs which charm the human ear. Yet even these sounds are the mere outlet of a state of excitement. The birds have no intentional purpose in mind. According to the most recent view the song of birds is not necessarily connected with pairing, but it bursts forth whenever the bird is labouring under strong excitement. This occurs, of course, most frequently in the pairing season. No song is given when a bird is unwell. The calls, warning notes, etc., of song-birds must be distinguished as inborn instinctive impulses, distinct from the sexually differentiated song of the males. This is a secondary instinct and is in many species not entirely inborn, but it must be acquired by the young males through imitation of older birds. Quite a number of birds have the desire and the capacity of imitating strange noises. Such, for example, are the jay, the butcher-bird, the starling, the mocking-bird and others. Ravens and their relatives and parrots, especially grey parrots, are best able to imitate the human voice. But even in these cases, nothing ever exists beyond the satisfaction of this curious imitative impulse. There is never any real speech, in the sense of any meaning being attached by the animal to the sounds which it makes. In the majority of cases the speech of parrots is merely an automatic reaction to external stimuli. In the case of those very rare parrots which apparently speak in a purposeful manner, as for instance by crying "Come in" when a knock is heard at the door, or by demanding food, training has undoubtedly taken place, although this training need not have been given intentionally by the owner of the bird. The parrot in question may very well, without any intention on the part of the owner, have associated, in its impulse for phonetic imitation, the words with the consequential arrival of food or other reward. It goes without saying that an "understanding" of the words on the part of the bird is completely excluded, since even the best instructed parrots can never say any other words or sentences than those which they have learnt.

Mammals. — These produce sounds with the larynx. In their language also there are cries of appeal, cries for warning and mating calls. Horses neigh, snort, whinny and mares squeal in addition. Dogs bark. growl. whine or howl and they can modify these sounds in loudness, pitch and duration. The sound-language of apes has been investigated on more than one occasion. Garner (1900) was the first to use the phonograph in studying the language of apes. With capuchin monkeys he succeeded in establishing 30 different sounds having different meanings. Mammals in general have at their disposal a more or less well-developed gesture-speech in addition to sound-speech and this is particularly evident in apes. Every species of ape and each group of nearly related species has its own inborn sounds, lip-signs, bodily postures and movements, by which the animals make known to one another their feelings and intentions. The means of imparting information are particularly numerous in the anthropoids. The Teneriffe chimpanzees, when pleasurably excited, gave vent to a repeated sound of "och" (as in "loch"), their tears were accompanied by a deep "oo," and grief was expressed by a high "ee" sound.

Possibly the reason why animal sound-language has undergone no further progress is that animal speech is always an expression of the prevailing feeling of excitement, humour and perhaps also emotion. The sound-expressions of animals never represent facts. They are not names for things. Hence animals have no vocabulary. Animal language is concerned wholly with feelings, giving no expression at all to intellectual events. Even those animals which have at their command a multiform sound-language are never able to carry on a "conversation." The same statement is true of gesture-speech.

CHILDHOOD AND PLAY OF ANIMALS

Real childhood and youth are found only in birds and mammals. It is the period of life in which young animals, while moving around and forming impressions more or less independently, still enjoy the protection of their parents. It is true that young mammals and birds are equipped from birth onwards with the necessary inborn reflexes and instincts to enable them to maintain their lives and to conform to the habits peculiar to their species. Nevertheless, in these animals, numerous faculties require practice. The young have to learn the use of their limbs by experience. At birth chicks and ducklings are endowed to different degrees. Both possess the inborn reaction of standing on one leg and scratching the head with the other. A chick succeeds from the very beginning, but a duckling loses its balance in its first efforts. It learns by experience how to balance its body while carrying out the movements. Through practice the co-ordination of the instinctive movements is improved. In the chick the instinct to drink and the co-ordination of the necessary movements is inborn. But to set the train of movements in action a releasing stimulus is necessary. Normally this is supplied by the sight of the hen drinking. But the mere sight of water, or the feeling of standing in water, in no wise acts as a stimulus. If, however, grains of corn are thrown into the water, the chick pecks at them at once, and the drinking reflex is immediately set in action by the wetting of the beak. Next time, the stimulus of water on the feet is sufficient. Sucking of the mother's milk by a young deer is an inborn instinct, just as is the action of following the parents through a wood. But the commencement of the act of sucking is a reflex depending on its own adequate stimulus, which is normally supplied by the mother's teats. A fawn in captivity will only suck at a feeding-bottle after the teat has been moistened with milk. The voice of many birds can be heard after they hatch out of the egg. But when, for instance, the mother bird makes it known by a warning call that a bird of prey is flying by, a young moorhen immediately ceases to hammer at its egg-shell and to tweet. It keeps still until informed by a different call from the mother that the danger is past. This is a further example of the purposeful nature of instincts, although the animal has not the faintest conception of the significance, object or result of its behaviour.

In species of animals where the struggle for existence makes particular demands on the abilities, parents usually "instruct their young." (See EDUCATION IN ANIMALS.) Normally there is again no question of any intentional, conscious, systematic instruction. Young birds are obliged to learn how to fly correctly. Under the protection of their parents, young storks and birds of prey copy their movements, and young swifts practice fly-catching. Young water-birds have often to learn to swim and to dive. Whereas young ducks go at once to water, young swans and gulls must be taken there by the mother. Male and female falcons together teach their young to hunt. They let captured prey drop do n on to the young which have followed them up into the air.

Play (see also PLAY IN ANIMALS) affords a means of practising the use of the limbs, of gaining the skill requisite for independent life and of acquiring strength. Hence play is principally found in young animals, but it is seen too in the adult. This is particularly the case with predaceous animals, where it has the same significance as in young animals, being a sort of gymnastics or sport. This conception of play, first brought forward by Groos (1907), is now generally accepted. It has replaced the earlier opinion of Herbert Spencer that play is the expression of an overflow of energy. Types of play may be subdivided into movement, hunting and fighting games. The so-called "love-play" of adult animals is of quite a different nature. .4s an instinctive activity for the heightening of sexual excitement love-play is an aid to sexual reproduction.

A few examples of the play of young animals may be given. Young predaceous animals and some ungulates have the instinct of running in pursuit of a moving object. They jump after one another or after the parent animal, often stimulated by the sight of the tip of the tail or the brush of the mother. Young ungulates carry out amusing leaps and capers. Young climbing animals practise climbing and jumping from branches. Predaceous animals push stones, tufts of grass, or pieces of wood with their paws and then jump after them as if at a living prey. When they fight together they seize each other with teeth and claws, but without using their weapons in earnest. The young of animals which have horns or antlers frequently butt at one another before the horns have grown out. The play of apes is particularly lively, consisting usually of movement-games. In the play of chimpanzees something manifests itself which might well be termed joy in performance. The games of the anthropoids kept at Teneriffe often took the form of a sort of sport or fashion. Thus, for some time, they took pleasure in breaking open the cover of the drain in the animal-house. On another occasion they occupied themselves in offering bread to fowls which were outside the bars of their cage. When the fowls pecked at the bread the chimpanzees would draw it back quickly, or would hit at the birds with a stick or a piece of wire.

ETHICS AND AESTHETICS

Ethics. — Man is wont to ascribe all manner of moral sentiments to those animals with which he is most familiar. But it must be borne in mind that morality in the strict sense is impossible in animals for the reason that they are incapable of abstract thought. On the other hand it is quite certain that many moral actions of human beings have their roots in animal behaviour. Whenever the mode of life of animals involves a number of individuals remaining together temporarily or permanently, we find the beginnings of morality. Of course, the actions in question are always purely instinctive. First of all the numerous instincts for the care of offspring by parent animals must be mentioned. Social life in larger or smaller groups requires a mutual consideration of the individuals for one another. Often a special impulse for companionship exists. This is, no doubt, the reason why many animals attach themselves so easily to men. Among birds we find the highest and fullest development of conjugal life. Lifelong mating is known in the stork, the partridge, the swallow and the dove. It is true that we must not exaggerate our interpretation here. In these animal marriages, if they may so be called, there is no question of a relation of friendship or love between the partners. They are rather brought together again and again because instinct always drives them back to the same place where they first built their nest. The reason for conjugal fidelity in these cases is a fidelity to locality or nest. To be sure, in certain birds, the pairs cleave together with a measure of tenderness. The love of monkeys for their young is well known, not only for their own, but for the offspring of others or even the young of different species of animals. Yet observations in zoological gardens have shown that the mother ape in captivity, in spite of her tenderness, allows no food to get to her young when little food is available. It is noticeable, on the other hand, with what care carnivore mother animals bring food to their young, and can even be persuaded in zoological gardens to suckle strange young.

Aesthetic Feelings.—These have also been ascribed to the higher animals. Thus the decorative colours of male animals play an important part in Darwin's theory of sexual selection (*q.v.*). It appears to be certain that the capacity possessed by birds of distinguishing between colours will, in most cases, certainly not permit of the female taking note of all the details of the decorative feathering of the male, though for the purpose of Darwin's theory, the stimulatory effect of the general impression is all that is required. Many birds, such as magpies, undoubtedly are stimulated by bright objects and colours (see C. G. Levick, Antarctic Penguins). The ornamental bowers of the bower-birds of Australia and New Guinea undoubtedly impress the females merely by the quantity and brightness of the heaped-up leaves, fruits, berries, bones, shells and so forth. For these collections are for the most part quite disorderly. In general it is characteristic that regular houses or constructions which appeal to our sense of beauty are found only in those animals which certainly build them by instinct alone. As soon as the building activity, owing to a greater plasticity of the instincts, is no longer restricted so exactly to quite definite materials, we notice at once a deviation from the forms appealing to our own aesthetic sense. Animals have no true sense of beauty. Yet the roots of such a sense lie in the animal kingdom. Among the anthropoids it appears timorously in a singularly engaging form. Thus the Teneriffe chimpanzees were wont to deck their bodies with all sorts of objects, such as twigs, plants, cord, rags. It would appear as if these objects, hanging on the body, had a decorative function in the widest sense. On occasions the chimpanzees, when left to themselves, ran around in a circle after one another in a peculiar manner, stamping their feet. Indeed, an attempt at a certain rhythm could be noticed in their movements. Kohler is of the opinion that these games are comparable with the play of children, and, in their extreme forms, with the primitive dances of aborigines.

ANALOGIES WITH PARTICULAR HUMAN MENTAL STATES

Sleep and Dreams of Animals.—A condition corresponding to our sleep exists in vertebrates, particularly in mammals and birds. All sensory activities are then reduced. The capacity of executing voluntary muscular movements is interrupted,-while the automatic movements and activities continue as usual. The eyes are generally protected against optical stimuli by the lids or nictitating membranes. At the same time many animals assume a characteristic sleep-position. A distinction between diurnal and nocturnal animals can be made according to the time of day at which the animals rest in this way. But not infrequently animals go through several phases of rest and activity during the 24 hours. In the mouse the number of these periods is particularly great. Sleep is more especially a necessity for animals high up in the scale as regards their mental capacities. Thus it is comprehensible that guinea-pigs spend only 11% of the whole 24 hours in resting and their longest periods of rest are only 10 minutes' duration. They feed continuously so long as food is offered to them.

Many reptiles and amphibians likewise assume typical sleeping postures. Snakes, lizards and urodele amphibians frequently curl themselves up, while tortoises withdraw their head, tail and extremities beneath their protective shield. But whether or not this outward rest is really accompanied by an internal recuperation as in our own sleep must remain questionable. The opinion has also been advanced that sleep appeared first in the animal series with the development of the forebrain. Against this is the fact that numerous fishes exhibit a state of rest with reduced sensory activity and cessation of movement. Both in nature and in aquaria fishes may not infrequently be observed to rest motionless on the bottom or against a stone with scarcely a movement of the gill-covers or fins. Others float right up against the surface of the water as if lifeless. This resting condition is known in the big shark of the North Atlantic, in the moon-fish *Orthagoriscus,* and in bream, all of which are met with in calm water drifting motionless at the surface. Their sensory activity is so much reduced that they may be approached unperceived. Finally, in various invertebrates temporary motionless states are known. Particularly is this to be observed in insects. According to the time of day at which they are active insects can also be divided into day and night animals. The males of many species of bees "sleep" in bell-shaped flowers which protect them from rain and dew. The position assumed by resting insects is generally that of the normal motionless state. Certain South African Hymenoptera of the genus Ammophila rest at night in a very peculiar fashion. They hold on to twigs with their jaws, and, letting go with the legs, allow the body to hang down freely. Among the higher Crustacea, too, and also in the flat-worms (planarians) resting states are known, with diminished sensitiveness to stimuli. In general, it may be stated that a condition of sleep comparable with our own exists in the higher vertebrates, but that the lower down we descend in the animal series the more we encounter resting states which differ from sleep. Among the lower invertebrates sleep is certainly absent.

During the sleep of higher mammals, particularly apes and carnivores, sounds and spontaneous movements may be observed which suggest a comparison with what can be seen to occur when our fellow men dream. During sleep a dog may bark, growl, wag its tail and jerk its limbs, while a cat will spit. Ungulates also frequently make movements in their sleep. Presumably phenomena take place in the central nervous system of these animals similar to those occurring in ourselves when we experience a dream. But we must be clear that the content of the animal's dream can never overstep the picture of the world with which the waking animal is endowed. A number of investigators prefer to deny the existence of animal dreams altogether and to see in the sleep-movements nothing but the effects of internal nerve stimuli. But if we concede any conscious life to the animals in question there is no reason for denying dreams to them. By analogy with our own dreams we are then obliged to suppose that in animals likewise the dream content is more confused and poorer than the waking consciousness.

Animal Hypnosis.—Many animals, in response to particular stimuli, fall into a remarkable state which has frequently been compared to the physiological phenomenon of human hypnosis. A so-called "fear-rigor" is known in the brittle-stars. In higher Crustacea a "cramp-reflex" can easily be called forth. As early as the middle of the last century the so-called "magnetism" of river crayfishes was known. By stroking the animals in a direction from head to tail they can be rendered motionless. But holding them on the back will suffice, or making them stand on their head with the claws bent outwards. The "feigning death" of many insects, particularly beetles, comes into the same category. The "cataleptic rigor" of the stick-insect, *Dixippus morosus,* is particularly remarkable. Vertebrates, too, can be put into a state of rigor. It usually suffices to place the animal on its back and to hold it there for a while, at the same time preventing all movement. Not only fishes, frogs, snakes, crocodiles, but also all sorts of birds, rodents, goats, pigs and dogs can be rendered temporarily motionless.

As to the meaning of these phenomena, in the invertebrates inborn, mostly useful, reflexes are involved, by which the animals are able on occasion to escape from their enemies. In the vertebrates the state of rigor is probably the result of peculiar inhibitions in the central nervous system which are brought into action by the cessation of all movement. Whereas the duration of the state of rigor may in the lower animals be considerable, in vertebrates it is the shorter as the brain of the particular animal is more highly developed. The lengths of time during which certain animals remain in a state of rigor are as follows: a stick insect, up to $4\frac{1}{2}$ hours; a crayfish, $\frac{1}{2}$ to 4 minutes; a frog, several hours; a goose or a hen, about $\frac{1}{2}$ hour; a rabbit up to 6 minutes; a dog, usually only $\frac{1}{2}$ minute. At the end of this interval, or of a shorter one, the animal wakes up spontaneously. But this can be brought about at an earlier time by weak external stimuli. From the physiological phenomena occurring during rigor, which have been noted in numerous investigations, it is certain that this state is something quite different from human hypnosis. It is only lately that hens and dogs have been put into a condition of true hypnosis, *i.e.,* into a state of rigor exactly corresponding to that assumed in human hypnosis. The means employed to induce this state were the same as those customary for human beings. A shining object is held before a hen, or when sitting on the experimenter's hand the bird is moved slowly up and down. Forthwith the animal sinks into sleep. The state of hypnosis is so profound that the bird can be lifted up by one leg and set down again, without being wakened up.

There exist analogies in animals, too, for the mass-psychosis observable in human beings under certain circumstances. Usually it is an aimless wild flight of a group of animals without any reasonable cause. Travellers describe such stampedes of immense troops of ungulates such as antelopes, zebras and so forth, in the tropical steppe country. Stampedes of the half-wild horses which live in huge herds on the South American pampas are highly undesirable happenings for the owners of the animals. The cause of these occurrences is the action of a purposeful instinct by which a warning signal from a leader or other member of the company causes all the animals to take to flight. As soon, however, as the resulting general excitement and flight movement increases out of all proportion to the cause, we have a definite case of mass-psychosis.

Mental Diseases of Animals. — Individuals occur, particularly in higher animals, exhibiting a behaviour which varies in greater or lesser degree from that which is characteristic of the species in question. This is due to disturbances caused usually by diseases or pathological changes in the nerves or brain. Parasites are frequently responsible for the abnormal behaviour. Spirochaetosis of fowls is due to a blood parasite which causes the animals to fall into a state resembling a deep sleep. Rabies in dogs changes the behaviour of the animals so that they become capricious, bite at the air without reason, and eventually become extremely excited and may finally pass into a state of frenzy. The cyst of a tape-worm, *Taenia* coenurus, in the brain of sheep causes the disease known as staggers. Dogs in the brains of which tumours were found by sectioning after death were, during their lives, in full possession of all their sensory faculties, but exhibited a continual desire for restless movement. Endemic cretinism in dogs is due to faulty development of the brain. The animals in question are good-natured but extremely apathetic. Staggers in horses is caused by a chronic enlargement of the ventricle of the brain, known as internal hydrocephaly, and a resulting inflammation of the brain. The animals are apathetic, sleepy, and stand for the greater part of the day with closed eyes, hanging head and ears down. A whole series of other nerve and brain diseases of animals, harmfully influencing their behaviour, is known to veterinary science. The true mental diseases of human beings have their counterpart in animals in cases perhaps best described as inborn weakmindedness, hereditary mental deficiency and cretinism.

THE HISTORY OF ANIMAL PSYCEIOLOGY

According to the conception of primitive peoples, man is in some way related to the animal world which surrounds him. Every person has his symbolic animal, his totem, into which he believes he is changed at death. This animal represents the-embodiment of the soul, either of individuals or of the whole race. For this reason it is sacred and may not be hunted. Gods in ancient Egypt and in India had human bodies of gigantic proportions with the heads of animals. Apes and other animals kept in the temples were considered holy. The belief in a migration of souls through different animals has always been widespread. All of these points of view are based upon the assumption that the animal soul is closely related to the human soul, that there exists no essential difference between the two. The ancient Greek philosophers, too, who engaged in detailed discussions of the animal soul were dominated by the belief in an essential relationship to men. It is true that the belief that the animal soul is on a lower level than the human soul makes itself gradually more and more felt. The Pythagoreans and Empedocles, on the contrary, believed in a transmigration of souls with intermediate stages in animals. The natural philosophers, the Epicureans, and later Lucretius Carus and Plutarch, ascribe more or less human attributes to animals. Particularly in Plutarch do we find many examples, in the nature of anecdotes, purporting to demonstrate the intellect, memory, deliberation and reason of animals. Quite a number of really good observations are included in these tales. This purely anthropomorphic mode of thought was maintained by individual thinkers for a long period. The neo-platonist Porphyrius subscribed to this view and even as late as the 16th century Montaigne used it to humble the pride of man. In the 18th century, Condillac and Leroy were influenced by the same idea.

Parallel to this humanizing conception another point of view made itself felt quite early in Greek philosophy, maintaining that there is a great and unbridgeable gap between human and animal souls. The great exponents of idealistic philosophy, Socrates, Plato and Aristotle, insisted on the distinction between man and beast, as did the Stoics. They denied the faculty of thought to animals. According to Aristotle, man possesses a reasoning soul (*anima intellectualis*), and, in addition, a purely sensory soul (*anima sensitiva*), whereas animals possess the latter alone. An animal is gifted only with the faculties of sensation and movement, while man has, in addition, the power of thought and understanding. He alone has an immortal soul. This great cleft in the modes of conception of the animal soul continued until long after the middle ages. The middle ages were dominated by the teaching of the Church which was strongly influenced by Aristotle. In the same way as the Greek philosopher, the Scholastics differentiated between a sensory and a reasoning soul, the latter being present in man alone. Instinct was considered to be a contrivance of nature permitting the animal to perform purposeful actions without understanding the reason for its behaviour. Further, sense-perception and sense-memory were ascribed to animals, while man had, in addition to this, intellectual perception and true memory. Descartes (Cartesius, 1596–1650), too, thought that animals had no share in the intellectual substance. They ranked as mere machines.

As early as the 16th and 17th centuries a number of thinkers, such as Montaigne, Rotarius, Thomasius, Jenkin, opposed themselves to this conception of rigid instincts. They conceded memory and comprehension to animals and thus pointed the way to a new animal psychology. The view taken during the English and French period of enlightenment of the 17th and 18th centuries was also in sharp opposition to the mediaeval idea of instinct, although it had been arrived at in quite another manner. The sense-impressions and perceptions were here considered to be the basis of thought. The distinction between a thinking and a perceptive soul no longer held. According to Hume animals are able to store up sensory impressions and make experiences. But, in addition, they possess numerous inborn instincts. The differences between animal and human modes of thought are gradual only. In the 19th century the tendency made itself felt, under the influence of the free-thinkers, to avoid the word *instinct* altogether for there was once more a movement towards an anthropomorphism which soon became unbounded and conceded thought and feeling to animals in the same way as to man. This was the period in which Alfred Brehm, Karl Voigt and others attempted to bring animals and man together.

The teaching of Charles Darwin had great influence on the conception of the animal mind. He sought to explain the purposefulness of instincts by natural selection. The mental faculties of man have developed out of those of animals. The desires of human beings derive from the instincts of animals. Romanes and Lloyd Morgan subscribe in a general way to the Darwinian view of the animal mind. Commencing with the 19th century the "modern animal psychology" began. According to this, many physiologists, as a reaction against the previous grossly anthropomorphic standpoint, were led to abandon all treatment of the mental life of animals and to investigate nothing but outwardly recognizable movements and actions of animals. The young science received its first imprint from the fact, brought to light particularly by the foremost investigators of social insects, that animals are not rigid machines but that their inborn modes of behaviour too are plastic. The fashions in which workers in different countries attacked the main problems were to a certain extent different from one another. In France, G. Bohn and his pupils laid stress on the faculty of associative memory as being the most important phenomenon in animal behaviour. In North America, particularly, stress was laid on the exact determination of the various aspects and phases of learning or habit formation in animals. J. B. Watson is one of the most prominent representatives of this "behaviourism," as the whole tendency is termed. In addition to admirable special lines of investigation in animal behaviour, H. S. Jennings, L. T. Hobhouse, Ll. Morgan, E. L. Thorndike, M. F. Washburn and others have supplied important theoretical contributions to the study of the animal mind. S. J. Holmes lays emphasis on the feelings of like and dislike as factors regulating behaviour. During the last few decades in Germany it is principally our knowledge of the sensory faculties of numerous different animals that has been investigated, often in great detail. We will mention only the work of von Frisch on the olfactory sense, the power of distinguishing colours and the language of bees. To this must be added the investigation of the intelligence of apes carried out by W. Köhler, which has been so fruitful of conclusions. Here, too, numerous theoretical contributions have been published. The comprehensive work of H. Ziegler on the concept of instinct should be mentioned, as being the only comprehensive summary of the history of animal psychology.

During the last decade, however, the influence of novel trains of thought has made itself felt, taking possession of comparative psychology in a revolutionary manner. We refer to the recognition of the importance, for understanding the behaviour of animals, of the qualities of form and totality. No longer, as hitherto, are separate and isolated stimuli regarded as the dominant factors, but it has been recognized that the separate actions of animals arise usually from the totality of the situation at the moment. Undoubtedly this mode of dealing with animal psychology is destined to produce numerous important conclusions. The most outstanding result of modern animal psychology is the proof that the first steps towards numerous phenomena of the human mind are to be found in animals. Through this, comparative psychology, which is concerned with the development of the mind in children and in primitive man, has acquired much valuable material. Just as man has long been known to be linked to the animal kingdom by his bodily origin, so now the gap is bridged which up to the present has separated him from the animals on the mental side.
(*See* also ANIMAL BEHAVIOUR.)

BIBLIOGRAPHY.—A recent comprehensive survey of the whole subject is contained in F. Hempelmann's *Tierpsychologie* (Leipzig, 1926), which has a full bibliography; other books of note include:—L. T. Hobhouse, *Mind in Evolution* (1901); H. S. Jennings, *Behaviour of the Lower Organisms* (1906); C. Lloyd Morgan, *Habit and Instinct* (Leipzig, 1896), *Animal Behaviour* (2nd ed., 1908), *Instinct and Experience* (Berlin, 1912); G. Bohn, *La Naissance de l'intelligence* (1909), *La nouvelle psychologie animale* (1910); E. Claparède, *Die methoden der tierpsychologie Beobachtungen und Versuche* (Leipzig, 1909); S. J. Holmes, *The Evolution of Animal Intelligence* (New York, 1911); E. L. Thorndike, *Animal Intelligence* (New York, 1911); W. S. Hunter, *The Delayed Reaction in Animals and Children* (Behaviour Monographs, No. 2, 1912); G. Kafka, *Einführung in die Tierpsychologie, I. Die Sinne der Wirbellasen* (Leipzig, 1914); *Tierpsychologie* (Munchen, 1922); J. Loeb, *Forced Movements and Tropisms* (1918); J. B. Watson, *Psychology from the Standpoint of a Behaviorist* (1919); H. Ziegler, *Der Begriff des Instinktes einst und jetzt* (Jena, 1920); N. Checchia, *La psicologia degli animali* (Turin, 1922); M. F. Washburn, *Animal Mind* (1923); R. M. Yerkes, *Almost Human* (1925); Marie Goldsmith, *La psychologie comparée* (1927); I. Pavlov, *Conditioned Reflexes* (1927). (F. HE.)

PSYCHOLOGY, HISTORY OF. In the earliest times psychology is a part of the general description of human conduct. Though the details are no longer valuable, the general classifications originally used are historically interesting on account of the way in which they have persisted.

Greek Psychology.—The oldest records which are sufficiently elaborate to be important belong to the sixth and fifth centuries B.C. and constitute part of the natural philosophy of the Greeks. Earlier traces are found in Homer and the Greek tradition represents a growth of opinion from the tenth century before Christ or even earlier. The medical schools of the sixth century B.C. seem to have advanced far enough to establish the common distinction between sense and reason on anatomical grounds: the importance of the brain was recognized and an attempt made to connect the sense-organs with the brain. The physiology was very crude but the important principle established was the necessity of integration so that the different sense impressions could be unified. The clear assertion that the mind sees and hears (not the external organs separately) is the beginning of psychological investigation. At the same period the original doctrine of temperaments appeared. A temperament was regarded as a peculiar disposition, both physical and mental, which owed its character to the ratio in which the humours were mixed in the body. These humours were four substances which, by analogy with the four elements (earth, air, fire and water) were regarded as composing the body. They were called blood, phlegm, black bile and yellow bile. The terms for the different temperaments (sanguine, phlegmatic, melancholic, choleric) were introduced in the Middle Ages by an Arab physician: though not actually Greek they represent faithfully the original idea. The work done at this period (600–400 B.C.) is part of the development of medicine. While common observation referred to the "wits" of men or to their senses as different kinds of ability, there is throughout this period complete lack of any idea of a soul as the distinct agent in any activities either of sense or reason. The origin of Western Psychology was in the study of the organism and not in speculations about a supernatural "soul." This is so far the case that Aristotle considers the thinkers before Socrates were exclusively concerned with physical nature, and for that reason unphilosophical.

The idea of a soul as something distinct from the body and capable of existence apart from the body, seems to have become definite at the close of the fifth century B.C. The Pythagoreans are credited with the view that the body is the tomb of the soul and that life on earth is a period of time during which the soul uses the body as its instrument. This leads naturally to a doctrine of release by purification and a theory of immortality. Such matters do not belong to the sphere of psychology. But they need to be mentioned because the first elaborate synthesis of doctrine was deeply affected by this type of thought. Plato was responsible for this synthesis and his work was destined to persist for many centuries as the kind of psychology most acceptable to western Christianity. Its most obvious characteristic was the dualism of soul and body which satisfied ethical and religious demands. But while the dualism can be admitted as a characteristic of the Platonic philosophy, there has been a tendency to exaggerate its significance for the actual teaching of Plato as to the functions of the soul. In harmony with the trend of Greek thought Plato emphasizes first the idea of activity: the soul is the origin of all movement, it is self-moving, in other words it is the dynamic factor as opposed to matter. The functions ascribed to the soul fall into three classes. These functions are nutritive, sensitive and rational. They may be regarded as the kinds of activity which are found at different levels of development in the scale of nature. They are seen distinctly in the plant, the animal and the human forms of organization. Of these the higher includes the lower and man may be regarded as a complex nature in which are included the capacities for assimilation of food, reception of sense-impressions and ideation. Though Plato was chiefly interested in the problems of moral conduct he was well acquainted with the natural science of his day and employs it to formulate his general psychology. The basis for this is the concept of Eros, the fundamental drive or conation which fulfils itself in all the forms of life. This appears at different levels in the forms of desire or natural appetite, courage or aggressiveness and reason or the love of truth and beauty. The idea of development is introduced as a progress from the first random impulses to fully co-ordinated and purposive action. In the course of this development there is a stage at which desire and reason are in conflict. The recognition and the analysis of this moral conflict is one of the most significant points in Platonic psychology. The argument is based on the sound principle that character implies definite aims. co-ordination of efforr and selection of impulses. This requires the acts of deliberation and reason, the full waking consciousness of principles. In dreams Plato sees the tendency of desire to satisfy itself in imagery when the higher faculties no longer inhibit the passions.

In the localization of functions Plato adopts the current doctrine that the liver, the heart and the brain are the seat of desire, courage and reason. Democritus was probably responsible for this, and he was the leader of the scientific school which cultivated anatomy and favoured a materialistic doctrine based on the theory of atoms. From Democritus comes the long-lived theory that sensation is produced by the action on the body of atomic forms (eidola) which are given off by objects, travel through the air and enter the body through appropriate channels of the five sense-organs. Plato had very little interest in the detail of sense-perception. He concentrates attention on the experience rather than its physical or physiological basis and is content to take sensation as the beginning of knowledge. He treats knowledge as a growing sense of meaning, a form of reaction rather than a reception of impressions. This idea of activity as the most fundamental element in experience is the peculiarly Platonic element in all the schools which are opposed to a pure empiricism. The whole development from sense to reason is an inner development, a gradual evolution of the power of the soul to interpret events as they are given in the field of sensation. With a shrewd insight that has been justified by modern tests of intelligence, Plato considered that the distinctive mark of intellectual capacity was the understanding of relations. The synoptic mind, capable of seeing all things in their relations and therefore concerned primarily with meaning, is the highest product of human development. In this connection Plato elaborated his famous scheme of education. It is the first great example of applied psychology and also presents the germs of a social psychology. For education is regarded by Plato as a process in which the powers of the soul develop through the interaction between the individual and the environment. The first stage is the formation of a disposition as a result of influences unconsciously assimilated. The social environment is like an atmosphere: it furnishes the subtle influences which the mind feeds upon, analogous to the healthy or unhealthy air which imperceptibly produces health or disease in the body. This unconscious assimilation of influences is called imitation. It is not conscious mimicry but the tendency to form ideals of action under the influence of the patterns which are ever before the eyes of the young. The later stage of education is comprised in definite forms of instruction of which the psychological character is that they develop the power of abstract thought.

Plato wrote no separate treatise on psychology: the subject appears at different points in his work whenever the questions of knowledge or conduct are under consideration. Aristotle is therefore usually considered the first teacher of a scientific psychology in the western schools. This title is well deserved, for the *De Anima* in particular and the other minor works associated with it in subject-matter are the sources from which have been drawn most of the psychology taught in Europe down to the close of the eighteenth century.

The main points of Aristotle's theory may be stated as follows: The animal organism begins its independent life with an endowment of heat and motion. The material body has a connate pneuma: something corresponding to what a modern writer would call nervous energy is distributed throughout the body and makes possible the first functions. Aristotle knew nothing about nerves: he accepted in general the medical view that life is dependent on the presence of air in the blood vessels. This organic air was called pneuma, a word which means breath or wind, equivalent to the Latin aninta or *spiritus*. The animal spirits were accepted almost without question to the end of the eighteenth century. They fulfilled in a confused manner all the functions of the breath as basis of life, of the nerves as conductors of sensation and of the more refined substance which was the assumed agent of rational thought. In a sense, therefore. the pneuma is the material soul, a phrase which is not self-contradictory before the time when the soul as immaterial is opposed to the hody as material But Aristotle does not identify the soul with the pneuma. With considerable subtlety he defines the soul as the entelechy of a natural body capable of life. The word entelechy means the final state of development, natural completeness: and Aristotle really defines the soul as the functions of an organism when all its parts are united and active. The importance of this definition lies in its complete rejection of any attempt to make the soul a thing or an entity. The definition indicates a class of functions to be studied, snd Aristotle proceeds to deal with them. All functions come under the general head of motion, so we are now really studying a particular class of motions. The body is a material structure subject to impact from the outer world: the genesis of sensations is found in the action of outer forces or stimuli on the organs of sense. Aristotle paid careful attention to the characteristics of touch, taste, smell, hearing and vision. In general all sense-affection is a form of touch: the differences are in the medium and the sense-organ. In the case of vision a motion is transmitted from the source through a particular medium called the diaphanous and continued along the pneuma of the optic passage to the sensorium. The form of this explanation is perfect: but the medium would now be defined as luminiferous ether (if any) and the optic passage with its pneuma as optic nerve. After the separate senses comes the problem of unity. This requires a common sensorium, a meeting place for all the special senses and also the centre for the perception of the common qualities of all objects, such as shape and size. Aristotle considered that the heart was the seat of all psychic functions, an unfortunate aberration from the earlier and Platonic view that the brain was the organ of the soul. Probably Aristotle was led to this view by the fact that very little was known about the brain, nothing about nerves, and most emphasis was laid on the blood as the seat of life and of the pneuma. The error seems to have had little effect on the general description of functions. Aristotle saw the futility of defining sensation as the reception of any material image of the object or even as an impression: he evaded the difficulty by saying that sensation receives the form of its object without the matter: in other words sensation is a significant change of the mind corresponding to the physical motion in the sense-organ. As the original motion dies away a variety of different phenomena occur. After-images are motions continued in the organ of vision and are the most obvious example of the way in which motions persist. Imagination is a "decaying sense" and can be described as analogous to after-images. But here we have really begun to move away from any positive and perceptible motion: the words become metaphorical. If we admit a certain permanence in sense-affections we can suppose that some sensations persist and that this is the origin of memory. The word in Greek conveys the idea of remaining or abiding (Mneme) and that is nearly all that can be said about memory. The accumulation of memories makes what men call experience. This is passive reason: but the passive must not be confused with the active. In spite of the strong empiricism of his method Aristotle does not confuse the mind with its physical basis or its acquired contents. Reason as the act of the soul is underived: whether the soul is or is not immortal Aristotle refuses to say.

Parallel with the range of functions from sensation to reason there is a similar sequence from desire to will. All living creatures have some degree of conation, some innate will to live, which Aristotle calls *orexis*. This is the dynamic aspect of behaviour. It coexists with the different degrees of knowledge and so acquires different values. When the object which gives satisfaction is presented to the senses the tendency to possess it is the simplest form of *orexis*, called by the Latin writers *appetitus* and in English appetite. If the want or striving is correlated with an image of the object desired or the object is the work of imagination, the psychological state is called wish. If finally the object is one about which it is possible to deliberate, the outcome of deliberation is called will. Here we find Aristotle using his principle of development to state in simple terms a naturalistic theory of will. There is no suggestion that will is a separate faculty and no discussion of freedom of the will. Aristotle defines will simply as that desire which embodies the results of deliberation and discusses individual responsibility, but not freedom of the will. He considers also the difference between those who do not stop to deliberate and those who tend to paralyse action by excessive deliberation. These are the types known to modern writers as impulsive and obstructive. These topics were regarded by Aristotle as belonging to the science of conduct and are discussed in his Ethics. The word ethics is derived from the word meaning character (*ēthos*) and this is a variation of the word for habit (*ĕthos*). The Greek sense for individual qualities made their ethics primarily a study of character and therefore a branch of psychology. The keynote of individual development is habit-formation and Aristotle's ethics has for its centre a doctrine of character as the product of habits. The habit is not mechanical: it is a disciplined attitude of mind which makes the act of judgment an expression of principles: morality is dependent on reason and reason can only act efficiently when impulses are properly organized.

This brief and summary statement will serve to indicate how far Aristotle covered the whole field of psychology. His treatment of knowing and willing as the main classes of functions remained with little alteration for many centuries. Such subjects as sleep and dreams he treated in a scientific manner, and showed an interest in abnormal phenomena. His successors in the Peripatetic school tended more and more towards purely scientific work. The first head of the school after Aristotle was Theophrastus whose fame rests chiefly on his work in botany but is supported also by the fragments of a work on the senses. This is exclusively concerned with questions that belong to empirical psychology and seems to show an increasing tendency to separate this subject from the sphere of speculative philosophy or religion.

HELLENISTIC AGE

With the death of Alexander in the year 323 B.C. the Hellenistic Age began and with it there came a period of speculative thinking more Oriental than Greek in its character. On the other hand at Alexandria itself the sciences began a triumphant progress which soon eclipsed all previous efforts. The greatest scientific achievements of antiquity belong to the third century before Christ and show that religion was by no means the only interest of that age. In addition to the work done in geometry, astronomy, mechanics and other sciences, special mention should be made of the work of the medical men Herophilus and Erasistratus. Though these men were not the first to discover the nerves, they so far enlarged and established the knowledge of their structure and function that they deserve to be called the discoverers of the nervous system. This was a great contribution to the knowledge of animal organisms and one which in the end could not fail to affect psychological theory. At the time it produced no revolution. The Stoic philosophers used the pneuma of their predecessors and showed considerable skill in the analysis and classification of functions. Though their interests were mainly ethical the earlier Stoics (c. 300 B.C.) took pains to elaborate their psychological basis. They seem to have realized more clearly than their predecessors that psychologically a sensation is only an event in consciousness, a mere awareness of an inner state: they emphasized the relation between imagination (fantasy) and hallucination (phantasm) with the associated problem of the relation between subjective conviction (illusion) and objective truth. The Stoics delighted in extravagances and talked about universal Reason or Logos: but out of much speculation they evolved some important ideas. Because reason was to some degree innate in all creatures they attributed to animals an unreflective wisdom which was known to the Roman Stoics as instinct. Similarly from the belief that all men were endowed by nature with a knowledge of natural laws and rights they derived the concept of conscience (syneidēsis), the inner sense of conformity or lack of conformity with this innate reason.

The extraordinary brilliance of the classical period of Greek thought was neglected for nearly five centuries after its decline. The Stoics carried on the work when Greece became a Roman province, but their power was soon exhausted and their history became a record of mere repetitions. The only factors that had any significance in the Hellenistic Age were the various religious movements which tended to create a division between the natural and supernatural elements in the description of man. The Jews of Alexandria in the last century before Christ adopted the language and ideas of the Greeks but recognized the sphere of scientific investigation as relevant only to the corporeal nature: the spiritual life was not to be studied by such methods. As the Hebrew tradition always distinguished between the vital principle and the supernatural spirit (*neshem* and *ruah*) this method of adopting Greek psychology to explain the facts of sense-experience was easily adapted to the general body of their thought. Philo Judaeus (c. A.D. 40) was the most effective author of this Jewish-Alexandrian School. The same principles were followed by the Christian Platonists of Alexandria (about A.D. 180) and in this way a large amount of pagan teaching became established as part of the tradition of the Christian schools. In the third century of the Christian era the pagan philosophy was revived by Plotinus. While this was definitely intended to be a return to Platonism it was so far affected by the spirit of the age that it emphasized primarily the inner experience and made its psychology a description of those activities of the soul which seemed to be independent of bodily processes. A pure psychology built on introspective study of such phenomena as attention and memory was the result. The influence of Plotinus was continued in the work of Augustine; and through the position of authority which Augustine retained in the Middle Ages, this type of introspective thought was never wholly forgotten. The development of ancient psychology may be said to have concluded in a separation between the physiological and the religious interests. Galen (A.D. 200) was the last great physician. He added to the knowledge of the nerves by distinguishing sensory from motor nerves and made some acute observations on the relation between mind and body. Galen was sufficiently interested in philosophy to discuss many questions which belong to the field of physiological psychology, but always from the point of view of the medical man. Augustine (d. A.D. 430) studies the problems of psychology from the standpoint of an observer who can describe the actual experiences. The passages in the *Confessions* which describe memory and spiritual exaltation are permanent contributions to the literature of psychology.

The general decline of western culture brought to an end all progress in the natural sciences and philosophy. From the fifth to the twelfth century nothing important is achieved. The revival of learning in the twelfth century and its more complete restoration in the thirteenth was due in large part to the rise and progress of the Arab empire. When the victorious progress of Islam in the seventh century made the Arab master of the Persian empire, the Greek culture which survived in Syria and elsewhere was eagerly absorbed by the conquerors. From Baghdad in the East it travelled to Spain in the West, and, with additions from Constantinople and Sicily, it reappeared in the thirteenth century as the new learning of Christendom. So far as concerns any material that is important the psychology taught in the thirteenth century is simply the Greek psychology so far as it was recovered and understood. Aristotle and Augustine together account for all the available material.

EARLY MODERN THEORIES

Progress in psychology depends mainly on two kinds of interest. One is the interest in the structure and functions of the body which provides new material in the fields of anatomy and physiology. The other is the interest in the variety of human behaviour as it is observed in personal or social relations. During the period from the thirteenth to the sixteenth century there was a slow accumulation of efforts in both these directions and the result was seen in a great revival of activity which must be regarded as a subsidiary effect of the main progress in the sciences and in humanism. The work of Vesalius in human anatomy (1543) is the principal landmark in the study of the structure of the body: its ultimate significance was the tendency to abandon the view that a number of faculties were located in the body (such as the faculty of digestion or excretion) and to reduce all processes to the terms of physiological mechanism. By successive attacks on the idea of the soul as something reciding in the body and distinct from its material organization, the writers of the Renaissance built up a new science of man which had for its main principle the idea of natural functions entirely distinct from the activity of a supernatural soul. This movement was part of the whole development by which science became separated from theology.

The first part of the movement was quite unsystematic and was achieved as the expression of new values in the estimate of human conduct. The real beginnings are found in the work of such writers as Machiavelli who sweep away the formal descriptions of conduct as uniformly rational and openly declare that man is ruled by elementary passions. This example was followed by many others. Whether they accepted the idea that man is by nature evil or preferred to describe human nature more generously, they all agreed that conduct depends on natural impulses, that desire is more important than reason, and behaviour expresses temperament. As temperament could be explained in physiological language and related to the humours, it is evident that this kind of theory ceased to have any connection with the traditional doctrine that man was made in the likeness of God. A powerful movement toward reform in education assisted the progress of these views. A good example of the relation between psychology and education at this period is the work of Juan Luis Vives, a Spaniard who travelled widely and produced a marked effect on English thought after his lectures in Oxford (1523–28). The interest felt at that time in the study of personality was shown by the great popularity of a book called *The Examination of Men's Wits,* translated from the original Spanish work of Juan Huarte. A flood of writings too numerous to mention followed the fashion of this age. Discussion of individual differences as due to age, sex, climate or other causes filled many volumes and anticipated the better known works of the late eighteenth century. The programme carried out by later investigators was outlined by Francis Bacon in his *Advancement of Learning* (1605). Bacon appreciated fully the new attitude in psychology and advocated research along lines which have only been adequately treated in modern times. Among Bacon's suggestions are such topics as the use of aids to memory, the importance of connecting concepts with impressions on the senses, and the whole range of studies by which the foundations of character can be discovered in the constitution of the body and the social environment. In this way Bacon directed attention to the kind of material which now belongs to social psychology.

Thomas Hobbes (1588–1679) is often described as the father of modern psychology. The phrase is justified by the fact that Hobbes produced a concise summary of psychology which included both the individual and the social aspects. Taking as his guiding principle the idea of motion, Hobbes explicitly rejected the scholastic phrases and developed a mechanistic scheme. Sensation is defined as a mode of motion excited in the physiological organism: imagination is a continuation of this motion after the object ceases to act on the senses: dreams are imagery caused by external conditions, such as a sensation of cold, which produce internal motions equivalent to imagination: reason is the adding and subtracting of ideas derived from experience. The method used by Hobbes was derived from the physical sciences and particularly from the mechanics of Galileo. It was deductive and arbitrary in character but it influenced the whole trend of thought by showing the possibility of a psychology which conformed to the new ideas of scientific procedure. In general Hobbes drew upon Aristotle for much of his material and some of his most striking phrases owe their origin to his knowledge of the original Aristotelian language. In a famous passage of the *Leviathan* (Ch. 3) Hobbes explains the connection between ideas as due to the "trayne of imaginations" and gives an example of the way in which one idea may draw another after it. Hobbes deserves credit for the way in which he treats the will. As sensation is a movement inward, due to the action of objects, so volition is a movement outward and a kind of reaction which is primarily a form of vital movement. Hobbes thus begins the account of will from the basis of a natural striving or activity which was called at that time appetite. This elementary striving is connected with pleasure or pain; and is accordingly a movement toward or away from the exciting cause. As the creature develops, this activity is associated with images, becomes modified by deliberation, and so finally appears as will. Will is therefore defined simply as "the last appetite." This again is really a version of Aristotle's doctrine in the Ethics, but it was restated in a style unsurpassed for virility and may be accepted as original on account of the new value which the ideas received from the form in which they were presented. The ultimate aim of Hobbes was to give an account of human conduct in social relations and to explain the necessity of political order to control natural passions. His views are those of a sociologist who requires to begin with a scientific description of the human species. Hobbes was essentially a behaviourist who lacked the necessary knowledge of biology and was compelled to employ the methods of a mechanistic age.

The scientific work of the seventeenth century was brought to its highest level by Galileo and Newton. The brilliance of these men set a fashion which extended to all branches of science and created the belief that the science of organisms could be reduced to the terms of a mechanical explanation. Descartes led the way by making a sharp distinction between mind and matter, with the intention of treating the organic activities by the method of the physical sciences. On this basis he was able to describe bodily movements as due to impressions on the sense-organ which set in motion the animal spirits: when this motion arrives at the brain it causes the opening of a valve through which the current then flows down the motor nerve. To this total motion, inward and outward, Descartes gives the name *undulatio reflexa.* As at that time the animal spirits were supposed to perform the operation of conduction along the nerves, this theory may be recognized as a laudable attempt to state the principles of reflex action, not unlike the modern scheme of afferent and efferent currents with connection at a synapse. Descartes grasped very clearly the possibility of purely mechanical action, as it is actually seen in reflex movement. He decided that animals act always in this manner and stated the view that animals are machines. As he admitted a soul in human beings, they were not described as machines: the soul could direct the movement of the animal spirits by its action on the pineal gland in the brain, and this action constituted voluntary motion as superior to reflex action. The general idea of animal spirits and their motions was also used to explain emotions. Descartes saw the difficulty of explaining emotions as consisting only in perceptions or ideas. He grasped the point that in emotions the peculiar element is the bodily disturbance, and that the state of emotion is due to the combination of a perception with some tendency to motion, *e.g.,* flight in the case of fear. This theory was further elaborated by Malebranche who adopted the Cartesian doctrine and through Malebranche it was handed on finally to modern times when it was more adequately stated by Lange (1887). What is called the James-Lange theory of the emotions is the modern version of the views expressed by Malebranche. In the eighteenth century La Mettrie drew the further conclusion that man is a machine. His work, *L'Homme Machine* (1748), was resented at the time as atheistic, but in fact it was little more than a conscientious attempt to construct a complete physiological psychology.

Meanwhile in England the Cartesian principles inspired John Locke to attempt a fresh analysis of the mental powers. Locke's *Essay concerning the Human Understanding* (1690) was not strictly a work on psychology but it suggested a method of analysing experience which led others to adopt views that were more distinctly psychological. Locke himself was interested in the analysis of knowledge and proposed to show that all human knowledge is acquired during life by the use of natural faculties. Dispensing with innate ideas and obscure "powers" of the soul, Locke employed only sensation and reflection. Sensation accounts for knowledge of the outer world: reflection enables us to perceive the inner events and attain ideas of such objects as memory. The problem which Locke created by this analysis, which is only partly genetic and never purely psychological, was that of finding a principle of unity which would hold together the separate ideas got by experience. The soul was no longer invoked as the principle of unity. In its place was put the process of association. Locke barely mentions this and only recognized it as a form of connection when no rational union between ideas was evident. But his successors created what is known historically as the doctrine of association of ideas. David Hume (1711–1776) reduced experience to its lowest terms, impressions and ideas. He revived Aristotle's doctrine of connection by similarity and contiguity, adding for reasons connected with his own philosophy the form of connection called cause and effect. In this way a completely empirical plan was evolved. Nothing was required except the phenomena of consciousness and the bonds between them established by habitual coexistence or succession. In the question of method Hume established the guiding principles of modern psychology. From Hume through James Mill to Bain, this standpoint was retained as a practical method of psychological investigation. Its great merit was the emphasis laid on primary data and actual experience, with no metaphysical principles to confuse the issues. Its defects could only be seen when biological principles showed its limitations.

The psychologists of the eighteenth century in England were dominated by their ideals of scientific method. To make the mind intelligible they were ready to break it into atomic parts and invent ways of putting it together again. From England this idea spread to France. Already in France the spirit of Descartes had developed into a rationalism which tolerated nothing but the most sharply defined objects. The age of La Rochefoucauld's epigrams, La Bruyère's characters and all the wit of the salon, was a period when the psychological mood triumphed. The last phase was presented by Étienne Bonnot, Abbé de Condillac, chiefly in his *Traité des Sensations* (1754). Condillac's way of using the analytic method was to imagine a statue and endow it with one sense only, the sense of smell. In this way Locke's method is simplified: for while Locke began with sensation and reflection, Condillac starts with an isolated sensation and gradually builds up the mind by adding other sensations, the functions of attention and memory emerging in the process. If this procedure had the virtue of avoiding all mysticism and requiring no such hypothesis as a soul, it demonstrated all the vices that ruin the attempt to build a psychology out of logical abstractions. The successors of Condillac, the Ideologists of the Napoleonic period, were conscious of the failure but unable to remedy the situation. For a time psychology in France ceased to be important.

The German historians date the beginning of their historical achievements in psychology from the work of Leibniz who died in 1716. Though Leibniz wrote no separate work on psychology he made a number of suggestions which gradually acquired importance as the basis of a reaction against the tradition derived from Locke. Leibniz struck at the root of Locke's influence by insisting that the activity of the intellect must be assumed from the first. This doctrine was characteristic of the German way of thinking and was partly due to the religious mysticism which persisted in that country from the 14th century onwards. Leibniz united his faith in the original activity of the intellect with the idea that all perceptible quantities can be divided into infinitesimal parts. Assisted by the new ideas of the calculus in mathematics, Leibniz evolved the theory that perception and will could be traced back to elementary forms which were too undeveloped to be presented in consciousness. He argued that the sound produced by a wave of the sea must be compounded out of the sounds made by each drop, and therefore that a perceptible sound would be the sum of a number of imperceptible causes. These were called "petites perceptions" and the level at which they enter consciousness was called apperception. Similarly a fully conscious act of will is the complete form of minute unnoticed tendencies to action. In this way Leibniz opposed the view that mental processes must either be clearly apprehended or not exist at all. He asserted the reality of obscure and confused states of mind, and thus introduced views which were to be developed later into the theory of the threshold and the Unconscious.

The work in which Leibniz made clear his opposition to Locke (*Nouveaux essais sur l'entendement humain,* 1704) was not published until 1765. This explains the appearance in Germany of a vigorous but brief period of purely empirical work. Taken directly from English sources and constructed largely by translating the works of Locke and other British writers, this empiricism for a time changed the current of German thought. But experience was interpreted in terms of feeling rather than sensation. The German writers were most interested in recording their inner states: the diary with its intimate introspective entries became fashionable. The Berlin Academy became a centre of psychological activity and the ultimate product of much tentative discussion was the recognition of the "three-faculty" doctrine. Henceforth sensation, feeling and will were regarded as the three classes of mental states. Before this time only cognition and volition were recognized: the feelings came in as obscure ideas. Several minor writers contributed to produce this result, but the most authoritative work was due to Tetens. Johann Nicolas Tetens (1736–1807) wrote his *Philosophische Versuche über die menschliche Natur und ihre Entwickelung* in 1777. This book has considerable historical significance. The speculative psychology of the period did not attract Tetens. Bonnet, the Swiss naturalist, had brought into vogue a "fibre psychology," in other words, a premature attempt to explain mental processes by associating each activity with a neural fibre and describing it in terms of the motion excited in the fibres. Tetens more correctly relied on the observation of experiences and his treatment of the subject is on the whole well-balanced and sound in its principles. Kant was well acquainted with the work of Tetens and derived from that source the psychological groundwork of his philosophy. The critical philosophy of Kant does not enter into a history of psychology, though its principles have had great influence on later theories, chiefly in the direction of eliminating from psychology the idea of the soul and confining attention to mental phenomena. The successors of Kant followed lines of thought that moved further away from the experimental basis, and consequently added nothing of importance to psychology as a natural science. German idealism from Kant to Hegel (1830) was not concerned with the mind as understood by the empiricists but with the concept of a universal mind. In spite of the sterility of this doctrine so far as concerns the data of individual psychology, its tendency to look beyond the individual to the race and to the historical evolution of thought was the incentive which impelled the next generation to begin enquiries into folk-psychology and social psychology. But before this could become a distinctive field of work the spirit of the exact sciences had to be revived.

At the close of the eighteenth century the French were admittedly supreme in the sciences of anatomy and physiology. Their influence tended to restore psychology to its place among the sciences of the organism. The treatment of mental derangements as natural conditions and not as possession by evil spirits was greatly advanced by the attitude of Pinel, a doctor in Paris. About the same time (1798) the treatment of defectives was put on a more rational basis. The idea of the mind as a mysterious occupant of the body was discarded: empirical philosophy and medical science combined to establish the idea that it was the product of the experiences which were supplied through the senses. This theory was responsible for the work of men like Itard (1774–1838) who definitely formulated the principles of re-education for defectives, and others who began to study methods for training the deaf and dumb. A growing tendency to regard the mind as a group of functions dependent on the brain and indirectly on the whole physical organism was given explicit form in the writing of Pierre Jean George Cabanis. Adopting the medical profession and training his mind not only on the modern literature but also on the works of Hippocrates, Cabanis became in effect the advocate of physiological psychology. The famous expression attributed to him, that the brain secretes thought as the liver secretes bile, was not a piece of materialistic cynicism but a vigorous way of declaring that mental functions were always brain functions. Cabanis wrote a work entitled *Rapports du physique et du moral de l'homme* (1789 and 1802) which is one of the modern classics on the relation of mind and body. In this field Cabanis was soon surpassed by Franz Josef Gall (1758–1828) an Austrian surgeon who deserved more recognition than he obtained. Religious fanaticism and political intrigue combined to suppress his efforts, but Gall established his reputation in Europe for unequalled knowledge of cerebral anatomy and his own work was the foundation of the doctrine of cerebral localization. Gall was unfortunate in having a pupil, Spurzheim, who was a charlatan. Spurzheim found an ally in George Combe of Edinburgh and their misguided zeal produced the literature of Phrenology, a fantastic combination of bad anatomy with an absurd theory of faculties. In spite of the ill repute which this foolish theory of "bumps" brought on the excellent work of Gall, it is necessary to recognize that Gall's own work was very important and was known to the best anatomists of Europe. Gall knew the difference between the sensory and motor nerves and that they had different points of origin in the spinal cord. This important discovery, which ultimately made clear the nature of reflex action, was announced in England by Sir Charles Bell (1811), and was presumably the result of independent research.

THE NINETEENTH CENTURY

In the first quarter of the nineteenth century psychology was not making much progress. In England the associationism of David Hartley was regarded as orthodox doctrine. Hartley came under the spell of Newton's work and proposed to explain all mental phenomena by assuming that they were due to vibrations of the nerves and that these vibrations could be communicated by one nerve to another if the other had at any time been excited together with the first. This was obviously a theory of association stated in the language of Newtonian mechanics. Hartley's work, *Observations on Man, His Frame, His Duty and His Expectations,* was completed in 1746. It was a diffuse production and included the theory of vibrations, the theory of association and a considerable amount of comment on the Christian religion. Priestley, interested in all kinds of scientific work and inclined to atheism, saw the advantages of this associationism and produced in 1775 an edition which omitted everything else. In 1801 a complete edition appeared in England and this gave the theory a new lease of life. The development of British psychology was affected for a time by attempts to break away from the strict principles of empiricism. Thomas Brown (died 1820) was inclined to lay emphasis on the activity of the mind. His use of the term "suggestion" indicated a desire to escape from the narrower limits of association and give the mind a creative activity. Sir William Hamilton (d. 1856) also provided a new term, redintegration, which denoted the tendency of one experience to return as a whole when any part of it was given independently. But the masterpiece of the period was James Mill's *Analysis of the Phenomena of the Human Mind* (1829). This work was strong in its consistency and was constructed on the most uncompromising use of associationism, the doctrine which British readers accepted as being simple, practical and devoid of any tendency toward metaphysics. James Mill wavered occasionally but there were no serious lapses. The work was well done and everyone felt that the school had found its final exposition. When John Stuart Mill edited his father's work in collaboration with Bain it was already possible for him to see that the complete absence of any kind of spontaneous activity was a defect which before long would make the *Analysis* interesting only to the historian. The French School had found the same defect in Condillac and for a time Maine de Biran's *Essai sur les Fondements de la Psychologie* (1822) seemed likely to initiate a new kind of activism. But the new light was extinguished in mysticism and Maine de Biran was almost forgotten until the followers of Bergson revived him as a forerunner of their master. In Germany after the decline of the idealistic philosophy there was a strong revulsion in favour of the material sciences and out of this interest grew a new crop of psychological data and theories.

Herbart. — Before the physiological school began to dominate the field, a very influential system of psychology was produced by Johann Friedrich Herbart (1776–1841). Reacting from the fashionable idealism of the day, Herbart made an attempt to construct a realistic doctrine which so far imitated the natural sciences as to be presented in the language of statics and dynamics. The original and most elaborate statement of the theory was cumbered with numerous mathematical formulae which had no real significance and were ignored even by the most faithful disciples. The fundamental thesis is that the soul is a real quantity of energy, an idea which comes directly from Leibniz. Every experience demands expenditure of this energy, a perpetual effort of the soul to maintain its unity against the force of impressions. Since the total energy is always the same, formulae for the distribution of energy can be devised. As any one impression gains strength, others lose it. Thus there is a continual rise and fall of presentations. When an idea first claims attention it has least energy and is said to be below the threshold of consciousness: if it acquires energy it rises and is apperceived: it may then be reduced again to the subconscious region. The picturesque language of summits, arches and wavecrests doubtless assisted to make Herbart popular. The fusion and complication of the elements served to explain the variety of mental states. Above all the Herbartian scheme gave new meaning to the ideas of attention and learning. Like his contemporary Beneke, Herbart had a sense for the pragmatic value of psychology. They both took a direct interest in the processes of education and Herbart became almost a gospel for generations of teachers. The principle of connecting ideas so that new material could derive strength from ideas already present in the mind and the use of existing knowledge as the instrument by which to assimilate and "apperceive" new information were sources of inspiration to teachers. Among Herbart's numerous works the most important were the *Lehrbuch der Psychologie* (1816), the essay *De Attentionis Mensura* (1822) and *Psychologie als Wissenschaft neu gegründet auf Erfahrung, Metaphysik und Mathematik* (1824). Some of the best known writers of the Herbartian school were M. W. Drobisch, Theodor Waitz and W. F. Volkmann. Waitz in his *Anthropologie der Naturvolker* (1859) initiated a new development and directed attention to the field of racial psychology which occupies an important place in the literature of psychology after 1860.

NEW METHODS

In spite of its many good qualities the work of Herbart definitely belongs to the old tradition which had its chief affinities with the philosophical doctrines of the soul. A new departure required a point of view which was radically different and this was supplied by the progress of physiology. The work of Sir Charles Bell in England *(An Idea of a New Anatomy of the Brain,* 1811), of Magendie (1822) and others culminated in the general physiology of Johannes Müller (1835) and changed the whole direction of thought. The new interest centred upon the structure of the nervous system and the demonstration of reflex action. To appreciate the importance of these topics it is necessary to remember that general psychology was at that time still essentially a study of the spirit of man rather than his organization. In spite of the Cartesian tendency to animal automatism and the mechanistic character of some later theories, there was no body of scientific facts which could be used to build up an adequate account of the conscious life. The Hegelian introspective methods were losing support. In France Comte openly rejected the whole procedure and was one of the first to adopt the standpoint of behaviourism. There was little or no conception of the end to which their scattered impulses were leading, but the movement gathered strength. The more speculative minds saw the importance of classifying many human actions as reflex: for this meant that a large part of a man's life was put beyond the boundaries of reason. About 1851 Claude Bernard, Brown-Séquard and Ludwig contributed in different ways to the doctrine that the constriction and dilatation of the blood vessels is governed by the action of the nerves belonging to the sympathetic system. The sympathetic system has some connection with the brain but is partly independent and cannot be regarded as under the control of reason: it is to a large degree self-regulating and for that reason is also called autonomic. The bodily changes which take place in the regions where the sympathetic nerves operate affect the whole condition of the organism, and, since they are not a part of the voluntary *activities,* must be regarded as destroying the idea that *psychic* life is limited to the field of rational conduct. A speculative interpretation of these facts was given by Schopenhauer who taught that reason was secondary to will and that the dominant factor in life was to be found in the unconscious impulses which belong to the organism before the cerebral growth makes it possible to have ideas. This philosophy of the Unconscious was a premature attempt, but it served to make popular the view that outside the sphere of ideas there is a wide range of activities, and that impulse is more dynamic than thinking.

The group of experimentalists who gathered round Johannes Muller were responsible for the creation of a definite physiological psychology. Muller himself made important experiments on the phenomena of vision, on the action of the vocal chords and on colour contrast. He taught the doctrine of specific energies of the nervous system, believing that each class of nerves was limited to one kind of action. This view has been modified as it seems more likely that the nerve-terminals are the important factors in determining the nature of the sensation. But though not wholly accurate Muller's view was important in making clearer the fact that every experience is conditioned partly by the stimulus and partly by the structure of the nervous system. It was necessary, therefore, to study these as correlated events and physiological psychology became the science of these correlations. Miiller was the first to give a satisfactory explanation of binocular vision. He demonstrated the fact that there are points on the retina of each eye which correspond in such a way that an object stimulating two corresponding points is seen as one visual object. Contemporary with Miiller was E. H. Weber who studied experimentally the sense of touch and of temperature. Weber's Law, one of the landmarks of modern psychology, was first stated in 1834. In 1846 the article on *Der Tastsinn und das Gemeingefühl* appeared in Wagner's *Handworterbuch der Physiologie.* The formula known as Weber's law was derived from experiments which showed that if a stimulus increased by definite quantities the differences could only be perceived when the increase was a certain proportion of the previous quantity. In the case of hearing, for example, to obtain equal increases in the sounds as perceived it is necessary for the stimuli to increase by $\frac{4}{3}$ (1, $\frac{4}{3}$, $\frac{16}{9}$, etc.). The original statement of the law has been modified in details but Weber established the general principle and was the author of that branch of psychology which is called psychophysics. Weber's own work was a modest report of experiments. The notice which the facts and methods ultimately attracted was due to writings of Gustav Theodor Fechner. Fechner had considerable knowledge of science and was able to reduce his general theory of psychophysics to the forms of experimental research. He soon realized that the main points had already been stated by Weber. In fact it seems probable that he did little more than revise and co-ordinate a number of existing formulae. The methods he used were (1) that of just noticeable differences, (2) of right and wrong cases, (3) of average error. The first had been used by Delezenne in 1826 and Weber in 1831: the third by Steinheil in 1837: the second by Vierordt in 1852. The particular merit of Fechner lay in the industry with which he investigated the working of these principles. He gave direction and inspiration to a large number of workers who found in his methods a basis for exact experiments in the laboratory. His main work, *Elemente der Psychophysik,* was completed in 1860. G. E. Müller's work *Zur Grundlegung der Psychophysik* caused Fechner to write in 1882 a *Revision* which was to supersede the *Elemente.* Fechner also made researches in the field of aesthetics and was a pioneer in the study of aesthetic proportions.

While the physiologists were progressing in the study of sensation a new attempt was made to adjust the old traditions to fresh circumstances. This was undertaken by Rudolph Hermann Lotze, a man peculiarly fitted for the task because he combined with his knowledge of the philosophical doctrines a grasp of the developments in general science and especially in physiology. Lotze's *Medicinische Psychologie oder Physiologie der Seele* (1852) deserves to be remembered as a powerful influence in directing the thoughts of its readers toward a new valuation of the psychological problems. Lotze's study of medicine convinced him that the approach to psychology must be through the study of the organism and that all psychic functions were dependent on neural processes. The significant feature of Lotze's psychology is its concreteness. The reader feels that even the more speculative parts are written in a spirit of critical caution and that the independent status of the soul is not asserted as an abstract dogma but as a necessity due to the fact that physiological explanations are so often inadequate. Before 1852 Lotze had written a work on general pathology (1842) and on physiology (1851). He moved gradually from the study of the body to the study of mind. Among the many suggestive ideas which Lotze expresses in his work the theory of local signs is best remembered. The problem of space-perception is peculiarly difficult because it involves relating the actual extension of the outer world to an inner consciousness which has no such extension. In other words the quantity of space must be stated in terms of a qualitative order. To do this Lotze assumed that the sensations reaching the mind from different parts of the body had different values and were in this way capable of suggesting to the mind their relations to each other in space. The term "local sign" was the name given to this quality of the bodily states by which we get not only the sensation itself but also a recognition of its position. The theory has many difficulties and is by no means generally accepted, but it remains as a possible solution of the problem.

Wundt.—In the work of Fechner and Lotze it is easy to see the process by which modern psychology was created. The metaphysical tendencies gradually died away and attention was concentrated on the facts which lay nearest to the border-line of the natural sciences. The whole period from Miiller and Lotze to the close of the century was covered by the life and work of Wilhelm Wundt. Born in 1832, Wundt was trained in the medical sciences and became assistant in physiology to Helmholtz (1857). Between the years 1852 and 1862 he composed his first work, *Beiträge zur Theorie der Sinneswahrnehmungen.* Living in the atmosphere of German philosophy, Wundt was faced with the question of the soul, which became for a time the storm centre of German thought. Wundt decided that the soul was to be defined not as a separate agent but as a particular class of actions. Henceforth he was free to work on the nature and classification of these actions. The merits of Wundt's achievement depend very largely on the attitude which he adopted toward the problems of method. He conceived scientific method as a universal term which became specialized by the nature of the field in which it was employed. He accepted the idea of experience as a distinct object of study and proposed to apply to experience all the methods which would help to explain it. With his own training in physiology and his knowledge of the work done in psychophysics, he attacked the field of experience along both lines. His monumental work, *Grundzüge der Physiologischen Psychologie* (1872), shows in its title the emphasis which is thrown on the relation between anatomy, neurology and psychology. The facts which were to be studied were not taken as abstract movements of the mind but as functions of the organism to be explained in terms of physiological processes correlated with psychological events. The distinction between mind and body was thus subordinated to the view of experience as the actual events which could be analyzed partly in terms of the neural action and partly by a purely psychological analysis. The *Grundriss der Psychologie* (1897) presented the main outline of the system in a form useful as a text-book; which has been widely used and has influenced the teaching of psychology in every country.

To Wundt must be given the credit of two great achievements. He created the modern type of experimental psychology and he devised a method of analysis. Previously the idea of experimental psychology had been confused with the indefinite kind of appeal to experience which was occasionally opposed to the more exaggerated types of metaphysics. Experiment in Wundt's sense means the isolation of a particular problem and the employment of methods for exact observation under conditions which were properly controlled. Work of this kind demanded all the facilities of a well-equipped laboratory and Wundt was a pioneer in this direction. His laboratory was opened in 1879 and was the first of its kind The method of analysis, which determined the greater part of the work done in the laboratory, was based on the view that psychical states as experienced are compounded out of simple elements. The mind can be analysed into three main classes of activities, ideas, feelings and volitions. The ideas are the ways in which we become aware of objects: they are presentations which are immediately known. But the earlier psychologists had considered chiefly the relation between the awareness and its object: they had in fact considered the logical significance of the idea rather than its psychological structure. Wundt turned his attention to the processes which constitute the act itself and distinguished the elements which enter into the complex experience. These elements are the sensations, which are themselves complex in so far as they have both quantity and quality. Though these are inseparable they can be varied under experimental conditions and the quantity or intensity can be measured. A great part of the work done by Wundt, and the numerous workers who gathered around him or copied his methods, was in this field of exact measurement of sensations. It is obvious that the programme could be most easily carried out in the field of sensations and some time elapsed before any similar attack was made on the higher functions. As sensation corresponds to the action of afferent nerves, so volition or willing corresponds to efferent neural currents. Here the simplest pattern is that of the reflex arc. The reception of sensation is followed by the reflex muscular action and in this way a system of responses is established. These responses from the first have a purposive character, and it is therefore possible to explain the whole range of voluntary action as the complex or developed form of elementary reflex acts. It is not possible here to enter into the details of Wundt's experiments. The point which is to be emphasized is the general plan of analysis by which all complex states or activities are broken up into their constituent parts. The psychology which results is described as structural because it works with factors which in themselves are abstract and proceeds by ideas of fusion and complication to build up the total mental states.

Wundt also attempted to apply his methods to the field of anthropology. His *Völkerpsychologie* was a monumental work. Language, religion and custom were the three aspects of primitive tribal life which he studied. To these three he applied the method of analysis, tracing the concrete forms to their origins in gesture and vocal sounds, imagery and habit. But Wundt's excursion into this field was less fruitful than it would have been if he had possessed a direct knowledge of anthropology.

Helmholtz. — The middle of the nineteenth century was a time when a variety of new movements began to influence the course of psychological thought. Before considering them it is necessary to mention the important contributions made by Hermann Helmholtz (1821–94). Helmholtz was professor of physiology in the earlier part of his career and later (1871) became professor of physics. From his early days he was in contact with the idealistic philosophy of Germany and this remained throughout his life an influence which drew him toward the problems of perception. As Helmholtz had a gift for making instruments, he was equipped in a most extraordinary way for the particular work which he undertook. His main contributions were contained in two great works. The work entitled *Die Lehre von den Tonempfindungen: Physiologische Grundlage fur die Theorie der Musik* (1873), was a complete study of sound, both as regards its production, the physiological mechanism of hearing and the character of perceptions. The other work, *Handbuch der physiologischen Optik* (1859), was equally comprehensive in its treatment of vision. In the analysis of sound Helmholtz explained the nature of overtones and the consequent "colour" or distinctive character which different instruments give to the same tone. Physics, physiology and psychology were brought together in the treatment of this subject and the result remains one of the great examples of experimental analysis. In the field of vision Helmholtz was the first to appreciate the work done by Thomas Young. In 1801 Young suggested that sensations of different colours depend on different frequencies of the vibrations and that there were three primary colours, red, yellow and blue. Experiments by Wollaston caused him to change this list, putting violet for blue. The subject seems to have attracted little attention till Helmholtz took it up. A rival theory existed which goes back to the time of Aristotle and rests on the actual description of visual experiences. It had been revived by Goethe in his *Farbenlehre* and was distinguished by the fact that black and white were included in the list of colours. Goethe was interested in the work of J. E. Purkinje (1819) on subjective visual experiences, and also entertained a peculiar dislike for the work of Newton. Purkinje is remembered as the observer of the "Purkinje phenomenon," which is the fact that as the intensity of light decreases the colours with short wave lengths (green, blue) are more visible than the others. The Young-Helmholtz theory was based on the physical analysis of light rather than the immediate experiences and therefore omitted black and white, which may be regarded as degrees of brightness. Since the days of Helmholtz the theories of hearing and vision have been developed in many different directions. In 1879 James expressed doubts about the finality of the explanation of hearing, and work done by Rutherford, Rayleigh, Ewald and others must be taken into consideration in judging its merits. In the case of vision new factors have been introduced. Hering (1874) proposed an explanation which involved the idea of chemical changes in the retina and four primary colours related to four substances in which the changes take place. The explanation of after-images has been a complicating factor and the possibility that the rods and cones of the retina are the most important factors gives the whole question another aspect. The work of Max Schultze (1866), Parinaud (*La Vision,* 1898) and von Kries (1894), together with the suggestions of Wundt, McDougall and the more radical views of Ladd-Franklin, would claim attention in a complete history of this subject. The original work of Helmholtz has been reissued in 3 vols. (Eng. trans. 1924) and this edition contains accounts of later work. But whatever changes may be necessitated by the progress of science, the achievements of Helmholtz will remain immensely significant for the historical development of psychology.

Evolutionism. — The establishment of laboratory methods and experimental ideals was one of the great achievements of the nineteenth century. But viewed in retrospect it is seen to be inadequate by itself to cope with the demands of life. It needs to be supplemented by methods and materials which have a different value. These were supplied by the rise of evolutionary biology which dates from Charles Darwin's *Origin of Species* (1859). Darwin himself made valuable contributions to the literature of psychology, though at the time they were not recognized as belonging in that class. In the *Origin of Species* he discussed the nature of instincts: in the *Descent of Man and Selection in Relation to Sex* he raised the whole question of the development of mental powers in man and animals, with further extension to the more startling probability that moral qualities might have a natural history: still more definitely psychological was the treatment of *The Expression of the Emotions in Man and Animals* (1873). This last work will serve to illustrate the enormous importance of Darwin's work. The first characteristic is the habit and power of observation which makes the theory arise directly out of personal experiences: next comes the belief that every event has an explanation, that an expression is equivalent to the operation of definite muscles, and that the use of the muscles is not a matter of chance but intimately related to the life of the individual. The results of Darwin's work were only partly adequate and the laws he formulated do not go much beyond the limits of works on physiognomy. But the ideas were suggestive and could be applied in other directions: they were destined to leaven the whole mass of psychology. British psychology was already beginning to move in new channels. The man who understood the situation was Alexander Bain and his work forms a bridge between the age of Mill and the rise of evolutionary thought. Bain was a Scotchman, trained in Aberdeen, who at different times lectured on moral philosophy, natural philosophy and logic. He took a practical interest in the problems of education and was well acquainted with the development of physiology at the time when the German School was flourishing under Müller. This factor in Bain's outlook mainly accounts for the character of his work. He was prepared to accept the idea of an innate activity but not to treat it as in any sense a mysterious or spiritual force. In his view it was equivalent to cerebral energy and was a physiological process. Though he was not prepared to deny the reality of the soul, Bain considered that psychology should not go beyond the limits of the natural sciences. His theories are empirical in character and the solidity of his work is largely due to the amount of positive scientific material which he collected: he was a believer in the value of the inductive methods. Bain's chief publications were *The Senses and the Intellect* (1855), *The Emotions and the Will* (1859), *The Study of Character* (1861), *Relation of Mind and Body* (1873) and *Education as a Science* (1881). In scope and importance no one equalled Bain during the days of his productive activity, and the works are still consulted and quoted. But it is significant that Bain's system of the human mind, as he called it, was finished in the year which saw the beginning of Darwin's influence. In this respect Bain was unfortunate. His energy and industry achieved great results, but he remained rooted in the Associationism which could no longer be stretched to cover the whole life of the mind. The age of Alexander Bain passed away in his own lifetime. He belonged to the age of transition which was rounded off by Lewes and ended by Spencer.

Herbert Spencer (1820–1903) was the first writer to make general use of the principle of evolution. At first this was not a form of Darwinism. As Darwin owed something to Malthus, so Spencer was indebted to Lamarck and the Positivists. The idea of development in social life came first and then in 1855 appeared the first edition of the *Principles of Psychology.*

In pure psychology Spencer achieved very little: when he came to the place in the system which should have been filled by that subject, he did no more than adopt the current ideas of the Associationists. But the real service rendered by Spencer was in progressing by gradual steps from the description of organic structure, through neurological specialization of function into the origins of mental life. In this descriptive work he kept constantly in mind the guiding principle of adaptation, which implies that the inner development is controlled by the necessity of responding to the external environment. The term biology is thus given a concrete meaning. As the nervous system develops the inner development takes the form of psychic action. Next to general physiology Spencer proposed to put aesthophysiology. In other words there is a development from purely somatic or bodily action (as in reflex motion) to sense-perception and thence by degrees of refinement and complication to the higher mental functions. This plan contains all the essential elements of a purely objective approach to psychology and is in fact a form of psychobiology. The importance of Spencer was due to the way in which he established the idea of objective psychology and stimulated work in comparative psychology. His article on "The Comparative Psychology of Man" *(Mind,* 1876) may be described as the foundation-stone of that science.

In British psychology the tendency between 1850 and 1880 was toward emphasis on the relation between body and mind, with considerable attention to the abnormal and pathological states. The books most widely known were such as the *Psychological Enquiries* of Sir Benjamin Brodie (1855–62), *Chapters on Mental Physiology* by Sir Henry Holland (1858), *Mind and Brain* by T. Laycock (1860), *Body and Mind* by H. Maudsley (1871), *Principles of Mental Physiology* by W. B. Carpenter (1852 and 1874). George Henry Lewes, Professor of Physiology in London University, wrote a series of volumes on *Problems of Life and Mind.* The third volume, published after his death in 1879, was entitled *The Study of Psychology, Its Object, Scope and Method.* In this work Lewes defined psychology as "the analysis and classification of the sentient functions and faculties, revealed to observation and induction, completed by the reduction of them to their conditions of existence, biological and sociological." This definition represents the view created by the writers of the preceding quarter of a century. It is notable for the fact that it states clearly the necessity of extending the biological treatment to include the activities which are peculiar to man as related to a social environment. This aspect of the subject was soon to have its day.

French School.—While British psychology was passing through its enlightenment, France was beginning to emerge from a period of lethargy. The undisputed leadership in science which France held at the close of the eighteenth century, gradually slipped from its grasp. There was a period of confused and scattered efforts which seemed to show that France had abandoned the methods of Condillac without finding any new inspiration. The only line of thought which was not broken was the medical which, from Pinel onward, seemed to be peculiarly suited to the French genius. Esquirol, Baillarger (1842) and Brierre de Boismont (1845) kept alive a psychology which was more concerned with abnormal than normal states. A special line of investigation which occasioned a long controversy beginning in 1825 was concluded by Broca in 1861. This was the question of a special centre for speech, which Broca declared to be the third frontal convolution of the left hemisphere. The study of aphasia has developed since Broca's time into a much more complex question involving motor aphasia, word-blindness, word-deafness and agraphia (loss of power to write a word otherwise comprehended). Broca's problem was part of the general question of localisation. The pioneer work had been done by Gall and was carried on in a desultory manner until about 1870. Then new methods were employed in experiments on animals and the brain began to be mapped out according to results which showed how the destruction of a particular part of the cortex affected muscular action or sense-perception. The names of Fritzsch, Hitzig, Munk, Goltz, Ferrier, Horsley, Schaefer and many others indicate the activity shown in this branch of research. Though Broca's view has been modified by subsequent research it is historically important. The more general advance of psychology was initiated by Taine's book *De l'Intelligence* (1870). Taine used his literary gifts to interest the French in the empirical English methods. His book was important as an influence in establishing new ideas of method, and in 1888 a professorship of Experimental and Comparative Psychology was created at the Collège de France. The first occupant of the chair was Theodule Ribot (1839–1916). In 1873 Ribot published a book on *L'Hérédité Psyclzologique* which Taine and his party regarded as the beginning of a scientific study of mind. In 1876 Ribot founded the *Revue Philosophique,* rivalling Bain who began the publication of *Mind* in the same year. In 1879 Ribot produced two small but valuable books on the historical development of English and German psychology. In 1888 he published a study of *Attention* and this was followed by other monographs. By his writings Ribot did much to set psychology on the right road, partly by emphasising positive experimental work and partly by suggesting new points of view, such as the relation between emotion and memory. In 1889 a laboratory for psychological work was established at the Sorbonne. Its first director was Henri Beaunis who published in that year his book on *Les Sensations Internes.* Beaunis was a physiologist and his appointment was significant as indicating that psychology was to rank among the sciences. From this time onward there was rapid growth and expansion over the whole field. Richet, Grasset and others followed the more physiological lines. Pierre Janet opened a new era in pathological psychology. The study of character occupied a prominent place and was promoted by Perez (1892) Paulhan (1894) and Fouillée (1895). The psychology of society was treated by Gabriel Tarde in his work Lois de *l'Imitation* with a brilliance which attracted attention beyond the limits of France, and Gustav Le Bon secured an even more extensive reputation by his work on the psychology of crowds. The psychology of religion received attention in 1896 through the work of Recejac, followed by special studies in mysticism (1908, Delacroix), in primitive beliefs (Lévy-Bruhl) and in the psychology of primitive societies (Durkheim). Every topic and every point of view now has a representative in France.

While French psychology is made famous by many brilliant names, the most famous product of the French school is the method of the intelligence tests known as the Binet-Simon test. Alfred Binet (1857–1911) began his active life when psychology had already passed out of the philosophical schools. In 1886 he collaborated with Féré to study animal magnetism and in 1887 he wrote on The Psychic Life of Micro-organisms. The *Psychol-ogie du Raisonnement* (1886) initiated a series of studies on the functions of thought and will, and in 1892 a work on Alterations of Personality showed the tendency to abandon associationism for a more adequate view of mental activity. In 1894 Binet became director of the Laboratory of the Sorbonne. In 1895 he began to develop work in individual psychology. The importance of this event lies in the fact that it involved a new conception of experimental work: the object was not so much to study isolated phenomena in the manner of Wundt as to correlate one aspect of mental life with others. This kind of work was specially useful in the problems of the schoolroom and the factory. In 1900 Binet published the results of long research in a work entitled La *Suggestibilité:* an earlier work (La fatigue *intellectuelle,* 1898) had been produced in collaboration with Victor Henri and these works showed the possibilities latent in the field of education. A laboratory for the study of pedagogical problems was founded in 1905. By good fortune the Government in 1904 decided to investigate the condition oi mentally defective children in the schools. But there was no exact way of determining the status of a child: there was no exact formula by which to define the relations between the normal and the subnormal. The metric scale of intelligence was devised. As a first attempt it was, naturally, imperfect. Various "revisions" have appeared from time to time and variations have been introduced to suit different conditions. But the merit of being the original creator of tests belongs to Binet.

Italian Writers.—In Italy the course of development was similar to that in France. Positivism was influential in Italy before 1870 and found a champion in Roberto Ardigo. Though more a philosopher than a psychologist, Ardigo had a point of view which allied him with Spencer and he used his influence to promote what he regarded as the positive science of the soul. A more experimental line of work was initiated by Giuseppe Sergi at Rome. This type of psychology is predominantly physiological, has reference particularly to problems of physical and mental education, and has become widely known on account of its application in schools under the name of the Montessori method. Important work in the study of the bodily changes in fear and fatigue was done by Angelo Mosso, professor of physiology at Turin (La Paura, 1896; La Fatica, 1903). Francesco de Sarlo represents the influence of Wundt. He founded an Institute for Experimental Psychology at Florence and published among other works I dati *dell'esperienza psichica* (1903). Sancte de Sanctis has made many valuable contributions to psychology beginning with a study of dreams (I *sogni,* 1899). The subject of criminal psychology was made the centre of extensive interest by the work of Lcmbroso (*L'uomo delinquente,* 1876). The idea of criminal types as used by Lombroso has not stood the test of later investigations, but this branch of psychology owes its active progress to the beginning made by Lombroso.

British Writers.—Returning to the situation in England after 1880, we find a distinct type of psychology developed by James Ward (1843–1925). Ward represents a movement sufficiently influenced by German philosophy to reject associationism, but not drawn by that influence into either physiological or experimental psychology. Ward's teaching was developed in a number of articles written between 1875 and 1886, but the first complete statement was presented in the article *Psychology* contributed to the ninth edition of the Encyclopedia *Britannica* in 1886. It is a singular tribute to the worth and vitality of this article that it was reproduced, with no fundamental changes in 1918 as a book entitled Psychological Principles. Ward considered that the task of psychology is "to analyze and trace the development of individual experience as it is for the experiencing individual." Influenced largely by such writers as Leibniz and Lotze, with adequate knowledge of Wundt and the contemporary biologists, Ward developed a psychology which was based on the concepts of a self and the continuity of development. The self as the subject of all experiences accounts for the unity of psychic life: it is active in the form of attention. The gradual development of the sense-organs and the nervous system is accompanied by a development of the primary mental acts, the sensori-motor experiences. There is a succession of higher levels of activity as this original material becomes more complex; perception, memory and thought emerging as products of development. The interaction between subject and object is the general character of the process, but fresh possibilities are created by the forms of interaction between selves. The social factor in psychology was given a particular significance by Ward as the medium by which the process of mental development reaches its highest level. The school to which Ward belongs is known as the "self-psychologists," because the distinctive feature of their method is the assertion of a "self" as subject and the use of introspection as the chief source of information. The origin of this school was in the work of Brentano (Psychologie *vom empirischen Standpunkte,* 1874). Brentano, a neo-scholastic writer, opposed all tendencies toward either physiological theories or the idea of the subconscious. He accepted the view that the "soul" is the same as the acts called psychic phenomena and that these phenomena can be directly observed: observation of others, of children, animals and abnormal types can also be used. The influence of Brentano (and Herbart) is seen in the works of G. F. Stout. namely *Analytic* Psychology (1896), *Manual* of *Psychology* (1898) and Groundwork of Psycltology (1903). As a study of the structure and processes of the mind the *Analytic* Psychology has taken rank among the classics of modern British psychology. The other works have been among the most influential text-books of recent times. There is a strong likeness between the work of Stout and Ward's standpoint. Both present a pure psychology supported chiefly by direct inspection of mental processes, rich in fine distinctions and acute observations. The value of this work is not disparaged by admitting that modern psychology has passed beyond its limitations. In some respects there is a more modern quality in the works of James Sully. In 1874 he published a work on Sensation *and* Intuition: in 1884 the *Outlines* of Psycltology appeared: the Teacher's Handbook (1886) reached a fifth edition in 1909: the most complete exposition was given in The Human *Mind* in 1892. Sully was more like Bain than Ward. He had a gift for accumulating data without much inclination to give them the form of a philosophical system. Separate studies on *Illusions* (1881) and *Laughter* (1902) showed the author's tendency toward the experimental method and the viewpoint of the natural sciences. Sully also felt the importance of making psychology applicable to practice. He followed the example of Herbart and Bain in making psychology a part of the education of teachers. He wrote Studies of Childhood (1895) and founded the British Association for Child Study.

American Writers.—Among the first group of workers in Wundt's laboratory was James McKeen Cattell, whose reports on the work being done were published in *Mind* (1881) and were the first announcements of the new methods to reach English and American readers. The first laboratory for experimental psychology in America was opened in 1883 by Stanley Hall, at that time Professor of Psychology and Pedagogy in the Johns Hopkins University, Cattell was the first professor to occupy a chair exclusively assigned to psychology: this was at the University of Pennsylvania in 1888, where a laboratory was also established. America took the lead in developing experimental psychology, though not without opposition and delays. The progress was in a large measure due to William James (1842–1910), the only man who can be compared with Wundt for the range and influence of his work. James had the interests, abilities and training without which no one could make exactly the contribution which the times demanded. Born in 1842, James graduated in Medicine at Harvard in 1870, became instructor in physiology and later Assistant Professor of Comparative Anatomy and Physiology. From 1879–1889 James was accredited to philosophy, but in 1889 he became Professor of Psychology. In 1899 he became Professor of Philosophy and retained that title until he retired from teaching in 1907. This record is extremely significant, both as showing the variety of interests in the life of James and the complex sources from which his doctrine evolved. *The Principles of Psychology,* published in 1890, stands alone as a monument of scientific skill, comprehensive knowledge and attractive writing. It presented at one and the same time the physiological, the psychophysical, the analytic and the pathological aspects of the subject. James did not allow physiology to obscure the main issues. He did not sympathize with the extremists who treated consciousness as a by-product, the "epiphenomenon" of Huxley. He was inclined to be sceptical about the work of Fechner and to be more interested in the mental pathology studied in France. He had a keen sense for the dynamic aspect and by his famous phrase, "the stream of consciousness," made popular the idea that psychology was more concerned with processes than with static forms or faculties. The chapters on instinct and habit showed an appreciation of the genetic attitude, soon to become developed into a distinct branch of psychology. With the scientific element in the mind of James was united a strain of mysticism, revealed partly in the belief that the powers of the mind were not exhausted in the ordinary phenomena of experience, partly in the interest which led him to study the forms of religious consciousness. James revolutionized thought on the nature of religion by his characteristic treatment of that subject in his *Varieties of Religious Experience* (1902). In this also he was a seminal thinker and the psychology of religion owes an immense debt to the effect produced by this book.

The presence of James and Miinsterberg at Harvard gave that university for a time the first place in American psychology. Hugo Miinsterberg (1863–1916) was an able experimentalist and made valuable contributions reported in his *Beiträge zur experimentellen Psychologie* (1889–1892), and the *Harvard Psychological Studies* (1903–1906). In 1900 he published *Grundzüge der Psychologie,* a discussion of principles. In his later period Munsterberg broadened the field of his work. In 1908 he published a book on *Psychology and Crime.* In 1912 he produced a study of *Psychology and Industrial Efficiency.* In this work he reports a number of investigations, partly made in the laboratory, on such subjects as the qualifications for success in driving street cars. The application of psychological tests to discover the aptitudes of men employed in different industries was then a new departure and this was pioneer work in a field which has since become recognized as a distinct part of psychology.

Edward Bradford Titchener (1867–1927) at Cornell University represented for many years a well-defined type of structural psychology which relied almost exclusively on the experimental laboratory and the principles of Wundt. Granville Stanley Hall (1846–1924) represented a different attitude. Though he had been one of the first students who went from America to Wundt's laboratory, he afterwards became critical of that school and considered its outlook too narrow. The influence of Darwin then became the source of Hall's conception of psychology which was primarily genetic. The evolution of mind in the individual and the race was taken as the focus of a study which had more affinitywith biology than physiology. This programme necessitated a study of child life, for it was based on the "law of recapitulation," that the individual reproduces in the stages of mental growth the mental evolution of the race. This "law" was nothing more than an unprovable dogma, but it did good work as a regulative principle and led to careful studies of individual development. Articles written in 1882–3 on such subjects as "The Contents of Children's Minds on Entering School" are regarded as the beginning of the scientific child-study which now flourishes in America. A work entitled *Adolescence* (2 vols., 1904) was the chief contribution which Hall made to the literature of the subject. James Mark Baldwin was also influenced by the biological doctrine of evolution. His works on *Mental Development in the Child and the Race, Social and Ethical Interpretations in Mental Development* and *The Individual and Society,* were notable contributions to the study of the individual in the social environment, more systematic and logical than Hall's work but also more dialectical and less wide in scope and application.

THE TWENTIETH CENTURY

In Germany another attitude toward the problems of psychology became prominent in 1900. This was due to the influence of Oswald Külpe and the so-called Wiirzburg School. The tradition of the Wundtian school tended to limit individual psychology to the technique of physiological or psychophysical experiments. Kiilpe attacked the problems of judgment and volition with the intention of discovering how far the experience at a given time was influenced by the whole set of the person's mind. The higher mental processes were treated not so much as combinations of elements but as variable functions of the whole mental attitude. The method required the use of introspection and aimed to make an analysis of the higher thought processes in a way which was more concrete and natural than any of the existing methods. The workers in this school included Karl Marbe, H. J. Watt, N. Ach, A. Messer and K. Biihler. Their writings served to shift the emphasis from the concept of psychological elements to the idea of total reactions dependent on such broad conditions as temperament, personality and interests. This effort coincided with a growing interest in the science of the individual as a living unity and materially assisted the development of psychology in this direction. The logical result of this tendency would be a complex method which could produce a complete picture of the mental life of an individual. A programme for this kind of work was outlined by W. Stern who founded an Institute for Applied Psychology in Berlin, and wrote, among other works, a *Psychologie der Individualitat* (1911). The object in view was to make for each individual a complete record of all data, such as environment, education, physical condition and intellectual attainments. In effect this was an attempt to organize ail methods of psychology in a comprehensive scientific survey of the individual. *(See* DIFFERENTIAL PSYCHOLOGY.)

The expansion of psychology in the 20th century has been so rapid and complex that it is impossible to do more than describe its tendencies.

Behaviourism.—In its most extreme form behaviourism excludes everything which cannot be stated in the terms of organic response. This would still be ambiguous if the term organic were not taken to mean exclusively nerves, muscles and glands. In its most general terms the psychology of the behaviourists may be called the study of the stimulus-response situation. But while the terms stimulus and response define the field of observation, they must be limited in their application if behaviourism is to be given its exact significance. In the earlier period, before the theory reached its most extreme form, the main dispute was between the structural and functional views of psychology. The structuralist worked with elements and mental states which were described as complexes of elements. The functionalist did away with elements and substituted processes as forms of organic adjustment to the environment. One party was concerned with saying what the mind is: the other considered only what it does. The functionalist was influenced by the growth of biology and so came to use the term behaviour as the most convenient way of suggesting that the subject of his study was the life of the mind. By these gradual transitions a large number of psychologists became virtually behaviourists even before the school was conscious of its own standing. For example William McDougall in 1912 published a book with the title *Psychology: the study of Behaviour,* and defined psychology "as the positive science of the behaviour of living things." But the mark of this kind of behaviour is "the manifestation of purpose or the striving to achieve an end." In other works McDougall has defended animism *(Body and Mind: A History and Defence of Animism)* and continued to uphold a psychology based on the idea of purposive striving *(Outline of Psychology* 1923). Although the terms soul and mind and consciousness are rejected as unsatisfactory, there is nothing in this form of psychology to offend supporters of the older tradition. But in the year 1913 John B. Watson put out the first statement of a more radical doctrine of which the essential feature was that all reference to consciousness should be condemned as unscientific. In 1914 Watson published the book called *Behavior* and in 1919 another book called *Psychology from the standpoint of a Behaviorist.* These works constituted the manifesto of the new school. It will be useful to note some of the tendencies which explain its appearance. As early as 1887 Carl Georg Lange produced a famous monograph on the emotions *(Über Gemüthsbewegungen).* In 1890 James restated a similar theory of emotions which he had partly outlined in 1884. The peculiarity of the theory consisted in resolving the emotion into the perception of the bodily changes which take place at the same time as the perception of the object said to cause the emotion. The real emotion is the motor and other processes which occur in the body, as in flight or weeping, and qualify the state of cognition. Physiologists had already established the fact that the vasomotor disturbances (dilatation and contraction of blood vessels) were controlled by the sympathetic system and, though not voluntary, were functionally connected with the cerebral centres. The increasing recognition of this involuntary system and its activities encouraged those who were already inclined to write psychology in purely objective language. The most influential work came from Russia where Setschenow began as early as 1863 to say that psychology must take simple reflexes as its basis. The simple reflex would not have enabled psychologists to advance very far, but after the publication of the work of Pavlov on the salivary glands the idea of conditioned reflexes became an important supplement. A reflex is said to be conditioned if a reflex action normally excited by a stimulus of one kind can be excited by another stimulus through association. For example, if the flow of saliva due to the presence of food comes to be produced by ringing a bell, the reflex action of the salivary gland is said to be conditioned, After 1909 this became the stock example of mechanistic theories and supported the doctrine that behaviour is never more than a very complex set of conditioned reflexes. The knowledge of glandular action and particularly the ductless glands (endocrinology) was the new element in physiology and was also accepted as a new chapter in psychology. One of the most influential books of this period was W. M. Cannon's *Bodily Changes in Pain, Hunger, Fear and Rage* (1915), which supplied more detailed facts about the physiological element in emotional behaviour, especially the automatic increase in the production of adrenalin under conditions of emotional excitement. The results seemed so much more scientific and exact than the other views on mental states that Behaviourism was advocated as the only scientific form of psychology. Carried out on rigidly theoretical lines, the principles of Behaviourism require the psychologist to avoid all such terms as sensation, emotion, memory or thought. Sensation is neural response: emotion is glandular or visceral response: memory is neural habit: thought is verbalized response or language behaviour. This theory has the advantage of being apparently simple and using only objective terms. It has the disadvantage of being paradoxical and failing to do more than state the bodily functions in which mental states are objectified. *(See* BEHAVIOURISM.)

Animal Psychology.—The attitude of the behaviourist has been due in large part to the progress of Animal Psychology. This has been compelled to rely on objective data and either ignore or deny any factor called consciousness. Animal behaviour is an ancient study which belongs primarily to zoology. It became a part of psychology after the work of Darwin had shown the importance of studying human and animal behaviour comparatively. A large amount of material had been collected by various writers from Aristotle and Pliny to C. G. Leroy and Reimarus in the eighteenth century. Leroy especially was a good observer and earned commendations from Darwin. Some, like Descartes, classified animals as machines; a view revived and supported by T. H. Huxley. Others retained a more generous view with an inclination to be sentimental and anthropomorphic. The idea of continuity in human and animal life was deeply resented by orthodox thinkers, and the shock of this resentment was largely borne by G. J. Romanes. He wrote on *Mental Evolution* (1878), *Animal Intelligence* (1882), *Mental Evolution in Animals* (1883), *Mental Evolution in Man* (1883). This epoch was mainly descriptive: it passed away when the problems of animal behaviour were taken into the laboratory. In 1890 Jacques Loeb published a work on *Der Heliotropismus der Tiere,* followed by another *Über die Bedeutung der Tropismen fur die Tierpsychologie* and *Studies of General Physiology* (1905). This work was primarilyphysiological. Loeb made popular the term tropism, a form of behaviour which consists in "turning" from one position to another as a result of unequal stimulation. The term was in use in the case of plants (heliotrope) which "turn" to the light in the sense that light stimulates the kind of cell growth which results in that position. Loeb was prepared to explain the behaviour of the moth when it flies into the flame by a similar analysis. The physico-chemical changes would then be the only factors needed to explain animal behaviour. The truth of Loeb's thesis is not open to dispute in particular cases, but it is not possible to make it adequate for all cases without too free use of the imagination. The physiological method requires to be supplemented by the biological. In this direction very important work was done by Lloyd Morgan, *Introduction to Comparative Psychology* (1893), *Instinct and Habit* (1896) and other works. The mechanistic school was represented by Bethe, Uexkiill, Ziegler and others in Germany. In 1904 H. S. Jennings published the results of his experimental work in a volume entitled *Contributions to the study of the Behavior of Lower Organisms.* The phrase "trial and error" was made current by its use in this connection. The experimental work begun by Jennings on lower organisms has been. carried on in a great variety of forms by many workers, especially in America. A pioneer in the work was E. L. Thorndike (*Animal Intelligence,* 1898), followed by Yerkes, Parker, Holmes and others. In France G. Bohn published *La Naissance de l'Intelligence* (1909) and *La Nouvelle Psychologie Animale* (1910). These are only samples of a great variety of contributions which range from the amoeba and ants to the chimpanzee. One of the most important points for the psychologist is the question of learning. The experimental work has largely been devoted to the problems of the learning process. The maze has been most extensively used for this purpose, and other contrivances such as the box with the closed door which the animal must open to get its food. While the progress has been cumulative and valuable, the methods have not been very original or satisfactory. A new possibility was introduced by Wolfgang Kohler when he studied the apes in the German zoological station at Tenerife. Kohler devised problems which could not be solved by the blundering tactics of trial and error: the apes were compelled by the circumstances to use methods which involved more intricate mental processes. Kohler contends that the solution of the problem is reached by an act of insight, a grasp of the logical significance of the whole situation. If this is true the trial and error doctrine needs revision, at least in the case of the higher animals. *(See* PSYCHOLOGY, COMPARATIVE.)

Child Psychology.—Child psychology is the most modern of all departments of the subject. Though animal psychology has a long history, human psychology was consistently limited to the reason of the adult man instead of being treated genetically. It is a curious fact that no distinctive treatise on child-psychology appeared before Dieterich Tiedemann (1748–1803) wrote his *Bookachtungen uber die Entwickelung der Seelenfähigkeiten bei Kinder* (1786). This work was translated for the *Journal Général de l'Instruction* in 1863, quoted by Perez in a book on

Tiedemann in *1881* and translated into English in *1877* as *A Record of an Infant's Life*. In France Perez, Egger and Compayré produced works of some importance. In America F. Tracy's book, *The Psychology of Childhood* (1893), had a wide influence and was later translated into several languages. Other works in the earlier period were produced by Lobisch (*Entwickelungsgeschichte der Seele des Kindes*, 1851), by Sigismund (*Kind und Welt*, 1856) and by Kussmaul (*Untersuchungen ueber das Seelenleben des neugeborenen Menschen (1859)*. The date of the last work coincides with the rise of Darwinism. Here as elsewhere Darwin was a pioneer, setting the example of keeping a daily record of a child's development. Taine imitated this example, but both essays were relatively small contributions, appearing as articles in *Mind, 1877*. A more ambitious attempt was made by Wilhelm Preyer, *Die Seele des Kindes* (1882), which reached a seventh edition in 1908. In *1895* Sully published his *Studies of Childhood.* Stanley I-Iall and Mark Baldwin also made notable contributions. The subject has since expanded into a large literature which is partly child-study, partly a division of genetic psychology and partly a product of educational psychology. In Germany W. Stern published in 1914 a comprehensive work translated into English under the title *Psychology of Early Childhood* (1924). In its latest stage of development child-psychology has become practically a study of human behaviour from birth onwards. The behaviourist is interested in the reactions of the infant, whether they can be defined as mental or not. Behaviour in this sense begins with the earliest reflexes, is observed and described according to the correlation with chronological age, and is explained chiefly in terms of conditioning. In this work John B. Watson has set an example and data are being continually supplied by other students. Educational psychology is concerned with children at the school age and aims to establish norms of achievement with a view to improved methods of training. Here the intelligence-tests play a large part and much experimental work is being done on subjects of instruction, such as reading, writing and arithmetic. The work of E. L. Thorndike in America (*Educational Psychology*, 1903) represents the historical basis of the work belonging to this branch of applied psychology. Among other contributions those of E. Meumann and E. Claparède deserve special mention.

SOCIAL PSYCHOLOGY

Social psychology was the product of the Romantic Age which was initiated by Herder and completed by Hegel (d. 1831). There is nothing before this period which has power and continuity. It is true that Aristotle used the idea of a sense of kinship, that Hobbes made fear dominant in human relations and that Adam Smith partly evaded the individualism of the eighteenth century by a doctrine of sympathy as a primary instinctive response to the actions of other persons. But the justification of a social psychology was lacking so long as there was no conception of a total life in which the individual was merged by the very conditions of his existence. This conception was provided by the historical school which began at the close of the eighteenth century to challenge the individualism of that age. Herder created a new sense for the continuity of racial life and began the movement which was destined to become the science of anthropology. The development of this science was deeply affected by the Hegelian concept of universal mind and of culture as the manifestation of that mind. This interpretation, though wholly speculative in character, had the effect of concentrating attention on the psychic anthropology which the German philosophers first attempted to construct and they called their science by that name. But the defect of the method they employed was its lack of empirical investigation, and the conscipusness of this defect led to different attempts at reconstruction. Auguste Comte's sociology was one of these attempts and, though it does not belong exclusively to the field of psychology, the idea of social forces which it established must be noted as a significant contribution. In Germany at the same time Herbart was leading a reaction from idealism to realism and the Herbartians were responsible for the first attempt to translate the idea of the social mind into definite theories of a psychological type. The work of T. Waitz, *Anthropologie der Naturvolker*, belongs to this school *(1859)*. In *1856* Moritz Lazarus published a work entitled *Das Leben der Seele;* Hermann Steinthal published *Der Ursprung der Sprache* in the same year. In *1860* Lazarus and Steinthal founded the journal called *Zeitung fur Volker-Psychologie und Sprach-Wissenschaft.* This is usually regarded as the historical basis of modern social psychology. In England Comte's influence affected Herbert Spencer who emphasised the relation of psychology to sociology. G. H. Lewes, under the same influences, first defined psychology as including, over and above the functions of the organism, those interactions between individuals which constitute the social nature of man. A further stimulus to the subject was given by the rise of evolutionary biology which gave the required definiteness to the earlier doctrines of progress and development. An original and striking attempt to indicate the positive evolution of the social mind was made by Walter Bagehot *(Physics and Politics, 1873)*. Bagehot was fully conscious of the method which he proposed to use, namely "the applications of the principles of natural selection andinheritance to political society." In carrying out his programme he employed the language of dynamic psychology. The first age of man was called by him the custom-making age, a period in which the ruling force was imitation and of which the product was a "cake of custom." Next follows the period of conflict between customs, a period of disruption and mental agitation, which leads to "the age of discussion" and produces toleration and a respect for intellectual independence. Bagehot gives many acute examples of the spread of customs, as for example the adoption of a particular literary style by writers of a given period. Very little was left for later writers to do in this particular class of work. Gabriel Tarde (1843–1904) achieved a great reputation for a theory which was in essence another statement of Bagehot's theme. Tarde's works, of which the best known is *Les lois de l'Imitation,* were temporarily important. Time has shown that they were not sufficiently emancipated from the historical and sociological romanticism which Comte's ideas of social evolution made popular in France. A similar criticism can be applied to Taine who exploited the suggestive but misleading doctrine of the "milieu." Taine was influenced by the growth in France of psychopathology and the emphasis laid on suggestion. This influence was even stronger in the case of Gustave Le Bon who has popularized a rather uncritical doctrine of the Crowd and its mentality *(La Psychologie des Foules, 1895)*. There is an element of truth in Le Bon's chief contention that crowd-mentality is inferior to the mental level of the same individuals acting separately: there is also undoubted truth in the view that emotional states are in some sense contagious: but Le Bon's method is too purely descriptive to be permanently valuable as psychology. The wide generalizations of Tarde and Le Bon have been in part responsible for a reaction toward a narrowly analytic view of social reactions.

Before stating the principles of this later school it is necessary to trace some other movements. The German school produced a monumental work in the *Volkerpsychologie* of Wilhelm Wundt. The French school which follows Durkheim approaches the psychological questions from the basis of social organization. Durkheim felt that mental contents are not strictly individual. What a man thinks or wills is not merely the product of his neuro-cerebral system: it is equally the product of the social life which he shares. There are collective representations and collective volitions, states and activities of the tribal mind, which owe their character and particularly their compulsive force as beliefs to what can only be described as their super-personal reality. This type of theory is perhaps biassed by excessive pre-occupation with primitive mentality. The difficulties of understanding the nature of primitive thought are very great, and credit is due to Durkheim and his school for the vigorous attack made on the problem. Important work has been done on the psychological aspects of primitive life under the impulse of this movement, for example by Lévy-Bruhl (*Les Fonctions Mentales dans les Sociétés Inférieures,* 1912; and other works). While this type of work was predominantly sociological, there was another line of development which could be regarded as conforming more closely to the definition of social psychology. This was rooted in Darwinism and was an attempt to analyse the whole life of the individual as it developed in a social environment. In this class must be reckoned G. S. Hall and J. M. Baldwin. Hall became dissatisfied with the narrow limits of the psychology which he first expounded and sought to make the science more concrete, vital and comprehensive. His work was mainly descriptive, registering the information obtained from questionnaires and other sources. Such topics as "The Contents of Children's Minds on Entering School" (1882–3) and the major work on *Adolescence* indicate sufficiently the interests which dominated Hall's work. Baldwin aimed to show that individual development was achieved through interaction between the person and the society, the two being at all times coexisting aspects of an organic unity. The growth of animal psychology gave a new direction to thought by bringing into prominence the question of the relation between the native endowment of the human animal and its acquired characters. E. L. Thorndike undertook to define the "original nature of man" and to discover what instinctive tendencies determine human behaviour. A similar aim inspired the work of William McDougall, *An Introduction to Social Psychology* (1908). McDougall's work in experimental and physiological psychology made him a leader among psychologists before he attacked the special questions of social psychology: his work in this field has had exceptional influence among British and American students of the subject. McDougall adopts an attitude which is defined by the concept of purpose. All life and all mental activity has the striving, conative or purposive characteristic: it is not merely response to a stimulus. The elements of social psychology are found in the natural instincts and emotions. A list of instincts is made and to the majority of them a corresponding emotion is assigned. Examples of these pairs are flight and fear, repulsion and disgust, pugnacity and anger, self-assertion and elation. The value of this catalogue of instincts has been disputed by some critics and vigorously denied by others. But the wide acceptance given to McDougall's views is good proof that they harmonized with some general trend of opinion. The popularity of reason was already waning and everyone was ready to turn over the page and begin another story. For the learned reader there was already a model provided by Galton's essay on *Gregarious and Slavish Instincts,* in which he endeavoured "to prove that the slavish aptitudes in man are a direct consequence of his gregarious nature, which itself is a result of the conditions both of his primaeval barbarism and of the forms of subsequent civilization." Galton based his generalizations on the observation of cattle in South Africa and his real topic was the nature of herd instincts. The significance of the gregarious instinct did not at the time receive much attention: the average man was not prepared to see in social institutions the working of impulses which were operative below the levels of reflective thought. But the study of animal societies and the popularity of theories about the Unconscious have united to make attractive any interpretation of human life which throws emphasis on primitive instincts. A further result has emerged from the distinction between natural impulses and social organization. In so far as the impulses must exist in order to maintain the structure and continuity of society. while society at the same time requires their restriction, there will necessarily be forms of conflict both in the life of the individual and in the society. Here psychoanalysis steps in to corroborate the general principles of this social state of transition which involves repression of the most dynamic forces, especially sex-instincts and pugnacity. An adequate treatment of this topic demands an equal knowledge of the medical, psychological and anthropological aspects. Very few men combine these studies in a way that would qualify them to succeed in the task, but W. H. R. Rivers was one of the few and his contributions were exceedingly valuable *(Instinct and the Unconscious,* 1920; *Psychology and Politics,* 1923). The extension of social psychology into the analysis of political organization and the nature of the modern state carries the subject beyond the outlook of this article, and studies of the group-mind must be regarded as belonging to the almost unlimited field of applied psychology.

A reaction in the field of social psychology was produced by the attitude of the behaviourists. With an excess of revolutionary zeal the behaviourists adopted the principle of reducing all mental life to the stimulus-response formula and were led to challenge the traditional views of instinct and emotion. Some rejected instincts entirely, accusing the instinct-psychologists of defending the old faculties under new names. Such lists as that which McDougall created have been specially attacked by adherents of this latest school. In the language of these reformers these are only action-patterns, laid down in the organism as physiological structures, and the stimulus brings into play one or other of these patterns. As modes of action these ara reflexes and the total action can be analysed into component parts which are reflex in character. Language, for example, is acquired by the combination of an auditory stimulus with a vocal response (at first accidental): when the connection is once established the utterances of the parent or teacher operate as an extension of the original "circular reflex," that is, the process in which the child hears the sound which it makes and then imitates the sound which it hears. As a descriptive analysis of elementary behaviour explanations of this kind are valid. The difficulties begin at the later stages when the responses are more varied and their selection seems to depend on such factors as interpretation of meaning. It is then necessary to introduce hypotheses and take refuge in the complexity of brain-structure with the possibility of innumerable cells carrying on activities which as yet cannot be observed.

Present Tendencies.—The dynamic attitude predominates among psychologists who have entered the field since 1900. The majority find the biological approach most congenial: they link up animal and human psychology by this way of regarding them, include child-psychology as a genetic science, and treat the more difficult problems of the nature of intelligence by regarding it as a capacity for the variation of responses in varying situations. But these titles do not apply to all psychologists. Many would disclaim any particular designation and say that for the present psychology is simply concerned with methods and results, not with theories. Specific problems exist in bewildering numbers and it is enough for the worker to solve his chosen problem without attempting to build a system. This agnostic attitude is justifiable, but it is difficult for its exponent to escape from the pre-suppositions of his own technique. This has been shown by two movements which have earned important places in the recent history of the subject. These are the *Gestalt* psychology and the Freudian doctrine. The term *Gestalt* has come into general use for want of an equivalent in the Anglo-Saxon vocabulary. It may be translated "configuration," though the German writers do not consider that this word is exactly adequate. An early tendency in the same direction may be found in the work of Külpe and the Wurzburg School, but the specific origin is found in the writings of Ehrenfels (*Über Gestaltqualitäten, Vierteljahrschr. f. wiss. Philosophie,* xiv. 1890) and Wertheimer (articles in *Zeitschrift fur Psychologie,* 1911–12, reprinted as *Drei Abhandlungen zur Gestalt-theorie,* 1925). The essential feature of the *Gestalt* theory is that it employs "configurations" instead of elements, or it may be said to take as its elements significant groups rather than abstract parts. For example, a tone in a musical sequence is not heard as a tone simply: it is merged in the configuration of the musical phrase in which it occurs. In vision a similar fact is demonstrable either in the grouping of the objects or in the form of movement from one position to another. Five dots arranged in a row have a different "form-quality" from the same dots arranged like the five of hearts. A line presented in the vertical position and then again in the horizontal position will, if the rate of motion is not too slow, produce the impression of one line rotating through an angle. There seems to be a process in these cases which is more than the reception of impressions (peripheral) and may be a reaction originated centrally. The most important work in the development of this theory has been done by W. Kohler. The full significance of the viewpoint can hardly be estimated yet. One of the implications seems to be that in the actual mental experience a relation may be as significant as the data between which the relation holds. Thus an animal may learn to respond to a change from one colour to another though the colours used may be quite different. If this is true, it would imply that the total character of the situation is more significant than the (supposed) elements; in fact the elements as such would exist only for the experimenter who arbitrarily analyzes the situation into those elements. Kurt Koffka has shown how this new outlook would affect problems of education (The *Growth* of the *Mind,* Tr. 1924). Kohler's observations on apes suggested to him that the apes arrived at a solution of a problem when they saw all the factors in the situation as a whole: this he regarded as an intuition, a real comprehension, rather than the trial-and-error process usually attributed to animals. If this line of enquiry leads to more complete results and the Gestalt theory becomes an established doctrine, recent ideas about the learning process will require to be revised in accordance with the new discoveries.

The new psychology of 1880 was the psychology of the laboratory and the experimental method of Wundt. The new psychology of 1900 was the dynamic psychology of Freud. (See PSYCHO-ANALYSIS.) The most significant contribution which Freud has made to general psychology is to demonstrate the sense in which the affective or emotional life of the individual may control the entire psychic life. The keyword of the theory is repression. Though other writers had suggested that forgetting might be as great a problem as memory and that in fact there might be no such thing as complete forgetting, Freud first expounded the processes by which an experience may be thrust into oblivion and kept there as an active but unconscious psychic force. The term "unconscious" thus acquires a positive meaning and the unconscious is the underworld of the mind where the repressed memories live and act. This unconscious area cannot be reached by the normal memory: it is not equivalent to a lapse of memory or a failure of attention, for in those cases the lost idea or impression might return to consciousness through later recollection. The unconscious of which Freud speaks is only to be reached through the technique of psychoanalysis. The reality of the unconscious for the individual consists in the conflict which it creates and in the unrecognized symptoms of that conflict, such as irrational dislikes and fears, inhibitions and peculiar physical disabilities. The particular theory has been generalized in such a way as to become a possible element in general psychology. This is due to the interpretation of the individual's relation to society. It is held that natural instincts (especially those connected with sex) are never perfectly harmonized with the requirements of the social order. Conflict at some stage of life is inevitable and this conflict may lead to repression with consequent harm to the psychic development of the person concerned. It is accordingly probable that every person has some degree of emotional disturbance, if only in the form of mild prejudices. The doctrines of Freud have penetrated into modern psychology and become one of the chief reasons why the emotions are now so much emphasized. The behaviourists, however, are disinclined to give any place to the unconscious and claim that the only distinction necessary is between verbalized and unverbalized behaviour. The Behaviourist would accept most of the facts, particularly the presence of sex-interests in the early life of the child, and explain the subsequent development entirely in terms of conditioning. For the practical psychologist, concerned only with the normal mind, the process of conditioning and reconditioning may be a satisfactory explanation of the personal characteristics which he is called upon to study. If mental pathology demands a different technique, the psychologist may claim that it does not fall within his province. But the psychology of the future will in any case be increasingly concerned with the problems of personality, with the early stages of development and with the growth of the mind, laying stress on the methods of training which will prevent abnormality and promote the development of well-balanced minds.

PSYCHOPHYSICS, the science that deals with the determination of the relation between the mental and physical worlds, or, more specifically, of the relation between sensation and its stimulus. The word is generally used with reference to the quantitative determination of the latter relationship.

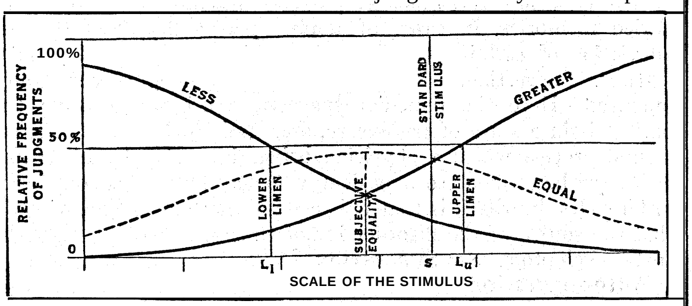
History.—Psychophysics was established by Gustav Theodor Fechner (1801–1887), who coined the word, invented the three fundamental methods, conducted elaborate psychophysical experiments, and began a line of investigation that still persists in experimental psychology to-day. Fechner's classical book, Die *Elemente* der *Psychophysik* (1860), may be looked upon as the beginning, not only of psychophysics, but also of experimental psychology (*q.v.*) itself. Fechner, trained in physics, became interested in his later life in metaphysics, and cast about for a way of relating the spiritual to the material world. He hit upon the notion of measuring sensation in relation to its stimulus. Ernst Heinrich Weber (1795–1878), the physiologist, had discovered that the just noticeable differences between the intensities of sensation always bore, when stated in the increment of stimulus necessary to produce such differences, an approximately constant ratio to the total magnitude of the stimulus. This fact, properly speaking, is Weber's Law: if two weights differ by a just noticeable amount when separated by a given increment, then, when the weights are increased, the increment must be proportionally increased for the difference to remain just noticeable. Fechner chanced upon Weber's Law and undertook to use it for the measurement of sensation. If R be the stimulus (*Reiz*), and S be the resultant sensation, and A signify an increment of either, then Weber's Law becomes $\Delta R/R =$ a constant, for the just noticeable difference. Fechner went further and assumed that all equal increments of sensation must be proportional to the same ratio, $\Delta R/R$, that is to say $AS = c\Delta R/R$, where c is a constant of proportionality. If this equation is integrated, if R be measured in terms of the threshold stimulus (the value of stimulus at which S is zero or just ready to appear), and if the constant be changed to k for common logarithms, we have $S = k \log R$.

This particular formula Fechner named Weber's Law, although it is really Fechner's Law and is thus sometimes called the Fechner-Weber law. It expresses the simple relation that the magnitude of a stimulus must be increased geometrically if the magnitude of sensation is to increase arithmetically. For Fechner it meant that the relation between the spiritual and material worlds is statable, and that there is therefore only one world, the spiritual; but for physiologists and for many philosophers it meant the measuring of sensation in relation to a measured stimulus, and thus the possibility of a scientific quantitative psychology. Fechner got his conception of psychological measurement from Herbart, but he was really refuting Herbart in demonstrating that psychology can be experimental.

Fechner's original work stimulated much research and much controversy. It was argued against him that it is introspectively obvious that sensations do not have magnitude (the quantity objection), that "a scarlet is not just so many pinks." This difficulty was met by the Belgian, J. L. R. Delboeuf (1831–1896), who developed the concept of the sense-distance, holding that sensations, although not complex magnitudes, are separated by variable distances which can be compared as "greater," "equal," or "less," the three categories of judgment which the psychophysical methods require. In Germany, Georg Elias Müller (1850—) undertook an elaborate criticism of Fechner and an extension of his work. In America, E. B. Titchener (1867–1927) made a historical and practical exposition of psychophysics in the second volume of his Experimental Psychology (1905). More recently F. M. Urban, then also in America, improved one of the methods and developed the concept of the psychometric function. Other well known psychophysicists are W. Wirth in Leipzig, and William Brown and G. H. Thomson in England.

Limens.—Psychophysics makes extensive use of the concept of the threshold or limen, of which there are two kinds. (i.) The *stimulus* limen is that value of stimulus which terminates a sensory continuum. The visible spectrum is limited by a stimulus limen in the reds (ca. 800$\mu\mu$ wave-length of light) and another in the violets *(ca.* 400$\mu\mu$). Tones range between the limen for the lowest audible tone (ca. 16 vibrations per sec.) and the limen for the highest audible tone (ca. 20,000 vs./sec.). The stimulus limens for intensities of weights, sounds, brightnesses, and other sense-qualities have been determined, but depend upon so many factors that no simple statement of their values is possible. Stimulus limens have also been determined for size and for duration. In the case of illumination, the size, duration and intensity of the stimulus are interrelated; a very small stimulus has to be more intense to be perceived. (ii.) The *differential* limen is that difference between two stimuli which marks the boundary between sensed difierence and sensed equality. It is often confused with the just noticeable difference, although in fact it is a statistical quantity for the theoretical point between what is just noticeable and what is just not noticeable. In fact both limens are statistical values, for the variability of the conditions of excitation can not be controlled and what is sensed at one time may not be sensed at another. Hence the limens are averages or mathematically determined points where the sensation is as often sensed as it is not.

Methods. — There are three fundamental methods of psychophysics, all of which Fechner invented. (i.) In the method of limits (method of minimal changes, of least perceptible differences) the stimulus is varied serially (usually by discrete steps) until a change is noticed. For example, to determine the stimulus limen of intensity, imperceptible intensities are presented in increasing order until the stimulus is first sensed; then a descending series from perceptible to imperceptible is observed; and finally the results of many such series are averaged. For the differential limen there are always two stimuli, of which one, the standard, is kept constant, and the other, the variable, is altered until a difference between the two appears or disappears, according to the direction of change. Here the limen is the distance from the standard to the average point of change, and there are always both an upper differential limen and a lower, since change can be noticed on either side of the standard. (ii.) In the method of average error (method of production) the experimental subject himself changes, by means of appropriate apparatus, the stimulus continuously, usually until subjective equality with a standard has been reached. Since subjective equality is not physical equality, the results yield an average or constant error for the subject and also a variable error about this average. (iii.) In the constant method the subject is presented at random with a predetermined set of stimuli for which he judges in every case the presence or absence of sensation or of the difference between the sensations. Because of the variability in the conditions of excitation his judgments are not always the same for the same stimulus, but it is found that, as a difference increases, the frequency with which the differenceisperceived increases. When enough judgments have been taken, these relative frequencies can be plotted in a psycho*metric* function. The figure shows the case of the differential limen. Reading from left to right, the frequency with which the variable is judged "less" than the standard decreases, the frequency of the judgments "greater" increases, whereas the remaining cases, the equality judgments, are maximal at the centre. The liminal values of the stimulus are taken as those values where the probability of the judgment "less" or "greater" is as likely as it is not, *i.e.,* the points on the scale of the stimulus corresponding to the points where the abscissa for 50% crosses the psychometric functions. The limens are the distances of these values from the standard stimulus (the distances L_l to S and L_u to S) and one of them may even be negative when subjective equality deviates widely from the standard. Subjective equality is usually taken as the point where the judgments "less" and "greater" are equally likely, *i* e., the intersection of the two psychometric functions. It is customary (as in the figure) to fit to the observed frequencies for the psychometric functions smooth ogives of the normal probability integral, sometimes called the phi-function of gamma; but this curve is only an empirical approximation and has no theoretical significance.



Weber's Law. — The Fechner-Weber Law implies that all differential limens of intensity should bear a constant ratio to the standard stimulus, whatever its value, and for this reason the psychophysical methods have been used most extensively to test the law and to determine these ratios. In general it may be said that the experiments indicate that the law holds approximately, although not exactly, within the middle ranges of intensity, but not for very small or very large intensities. Thus it appears that the liminal ratio for visual brightness is about 1/100, that is to say, illumination must be increased by 1/100 of its amount for a change to be perceived. The liminal ratio for lifting weights with the hand is about 1/40 and for pressure on the skin about 1/20. For tone the value is about 1/10; and for smell it ranges as a rule between 1/4 and 1/3. See DISCRIMINATION, SENSIBLE.

Results. — There is a very large body of quantitative results on liminal determinations. For theoretical purposes the constant method with weights, lifted by the hand, has been most used. The psychophysical methods, however, lie at the basis of nearly all quantitative methods of experimental psychology, especially those that deal with sensation. In its mathematical theory psychophysics is identical with the statistical methods that psychology uses in social measurements and with mental tests, and the boundary between the psychophysical and the statistical methods is thus quite properly becoming dim.

PSYCHOSIS. Strictly speaking, the term psychosis means a state of mind, a concrete psychical process or a mental act; but is now generally used to signify an abnormal state of mind. This definition needs qualification, however, since the technical use of the term in psychiatry is confined to certain forms of mental disorder which can be distinguished from states of congenital mental deficiency on the one hand, and from "borderland" conditions or neuroses on the other. A distinction should be made between "psychosis" and "insanity," which in popular and legal language signifies that an individual, owing to his state of mind, is unable to manage himself or his affairs, is in need of care and control and is not to be held accountable to society for his actions.

Psychosis, on the contrary, is a strictly medical term; it refers to a type of mental illness with certain intrinsic characteristics, assuming various forms, and due to a variety of causes. It does not necessarily lead to serious disturbances of behaviour, and there are many individuals who though not insane in a legal sense are nevertheless the subjects of a psychosis.

Psychological Considerations. — Though it is convenient to divide mental disorders into different categories based upon their causation, clinical characteristics or course and outcome, so many transformations of the clinical syndromes occur that no hard and fast division into separate disease entities is possible.

One broad division is that made between the psychoses proper and the neuroses, a term embracing such morbid conditions as hysteria and obsessional neurosis. One of the essential features of a neurosis is the retention of what may be called the "herd-sense," and a psychosis is marked by its diminution or loss. In a neurosis the patient is oriented to realities and has an intelligence alive to his own needs; his symptoms tend to be provoked by external circumstances, and he is sensitive to changes in the social atmosphere; he sees facts as they are but meets them in a faulty way. He does not seriously offend against the conventions, and however exacting his conduct may be his *entourage* still regard him as akin to themselves—as, indeed, he is, since all persons are apt to exhibit mild neurotic symptoms when life becomes too complex and difficult.

In a psychosis, however, the irruption of images, feelings and cravings into consciousness leads to distorted, views of reality and to falsification of facts; the sentiments and habits of the patient undergo a change, and his conduct becomes inexplicable and (apparently) unmotivated; he becomes indifferent to public opinion and impervious to solicitations from without; briefly, he loses touch with common life and lives in a world of his own.

Two Groups of Psychosis.—The differentiation by Kraepelin of the psychoses into two broad groups—manic-depressive insanity and dementia praecox—has been of inestimable service to psychiatry, though his view that these should be regarded as distinct disease entities has not been established. It is more in accordance with clinical facts to regard them as two reaction types which sometimes occur in pure form but more often as mixed. The manic-depressive reaction is characterized by severe and irregular fluctuations of mood in the directions of excitement and depression with intervals of normality. Dementia praecox tends to pursue an unfavourable course, and is characterized by a peculiar and often complete disorganization of personality with predominant changes in the affective life and will.

As the disease does not always proceed to dementia, and may develop at any age, Bleuler prefers to apply to it the term *schizophrenia* (splitting of mind). Jung has stated that the essence of dementia praecox consists in the fact that the unconscious to a large extent replaces the conscious, and the validity of this formulation is clearly exemplified in those schizophrenics to whom the term *paraphrenia* is given. This psychosis is marked by the exuberant development of fantastic delusions and hallucinations, which appear all the more extraordinary as the personality is so preserved as to enable the patient to make a normal reaction to social life on occasions. The morbid mental products in these cases can properly be regarded as an echo of the ultimate realities of organic life.

Causation and Treatment of Psychoses.—A psychosis is a disorder of behaviour, and represents a failure of function at the psychological level. Psychiatry (*q.v.*) thus differs in its subject-matter from general medicine; the former deals with disturbances in the reactions of the organism as an integrated whole, and the latter with disorders of special systems of organs. Since the behaviour of an individual, whether normal or abnormal, depends upon an infinity of factors—the nature of his life situations, the state of his organism, and the whole of his past history, both personal and ancestral—it is impossible to select one factor as explanatory of the total reaction. The problem of causation in the psychoses is thus dissolved in relativity, and in each case an endeavour is made to seek out, and remove where possible, any factors, either physical or mental, which seem to be exerting an unfavourable influence upon the behaviour.

There is now a general tendency to approach the problems of mental disorder from the standpoints of biology, pathology and general medicine, as it is recognized that the psychoses must be the outcome of a malfunctioning organism. Many psychoses, indeed, have definite relationships to diseases of the nervous system and of the bodily organs, as well as to general disturbances due to infections, exhaustion and drug intoxications. The causal significance of foci of chronic infections from the nose, throat, teeth, uterus or intestines has recently been emphasized and investigations along these lines make it evident that the whole resources of medicine should be utilized in the treatment of mental disorder. Mind cannot be regarded as an entity and detached from the body, and the secrets of disordered personality cannot be discovered by confining researches to the brain. The mind is not merely a function of the brain; it is a function of the whole organism having its roots in the viscera, the endocrine glands, the vegetative nervous system and the musculature.

In contrast to the toxic-exhaustive group of psychoses or an organic psychosis such as general paralysis, which are accidental episodes in the life of normal people, the biogenetic psychoses are the outcome of an hereditary or constitutional predisposition to mental disease. The psychotic episodes may be excited by mental or physical stresses, but the tendency already exists. The different forms assumed by these psychoses are independent of any specific pathogenic agent and dependent upon the personality make-up or inborn psychic constitution. Thus a manic-depressive psychosis is considered to exhibit an exaggeration of a pre-existing cyclothymic or extraverted temperament, and dementia praecox of a pre-existing schizophrenic or introverted temperament. Kretschmer has noted a relationship between certain forms of physique and these psychic types. His work sheds light on the organic foundations of temperament, and has an intimate bearing on the problem of the biogenetic psychoses.

The psychoses do not offer a fertile field for the application of formal psychotherapeutic procedures, such as hypnotism and psychoanalysis; their subjects lack insight and sense of illness, and tend to be non-co-operative and impenetrable. Indirectly, however, psychological treatment plays a large part in the prevention, cure and amelioration of psychoses and psychogenetic factors largely influence for better or worse the reactions of a psychotic.

(H. DEV.; C. S. R.)

PSYCHOTHERAPY, the treatment of disease by psychological means. Throughout the ages the attempted cure of ills through mental influences has been in vogue, but it is only of late that psychotherapy has been placed on a scientific basis and become a recognized branch of medicine. It is in the main employed in the treatment of so-called functional nervous disorders which are now regarded as mental in origin. One of various methods may be used according to the special faith of the physician or the type of case he is dealing with.

Hypnotism and Suggestion.—During hypnosis, suggestions towards the removal of symptoms are made. The common aversion to this means, its unreliability, and the supervention of more satisfactory methods, have led to its progressive disuse in recent years. In treating neurotically disabled soldiers during the World War it was, however, much employed. And for the recovery of buried memories, in cases of double personality, and for the alleviation of certain symptoms, it is of some value. *See* HYPNOTISM. Suggestion, without any hypnotic sleep is commonly practised. Here the remedial suggestions are made while the patient is in a state of passive repose. It is in essence the same mental process which a physician brings into play by his assurances for betterment to a patient who has faith and confidence in him. Its drawback is that it is a blind method of treatment in that the source of the disorder is not thus attacked but only the surface symptom. *See* SUGGESTION.

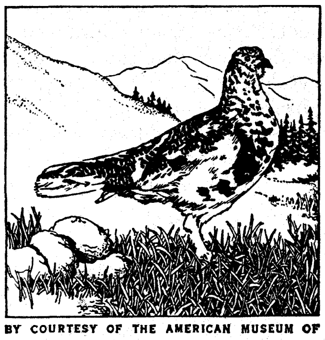
Auto-suggestion and Persuasion.—In the case of auto-suggestion the suggestions are given by the self and not by another. Its great advocates, Coué and Baudouin, believed that all suggestion was of this type and that a second individual was not necessary. It is probable, however, that emotional forces, directly or indirectly, between two persons are needed in most cases.

Persuasion is that method especially associated with Dubois of Berne, in which the patient takes an active share in modifying his mental state. His reason is appealed to, and from the explanations given him he is led to see that there is no logical basis for his symptoms. Though persuasion may benefit certain mild forms of nervous symptoms, it has to be borne in mind that an exaggerated value is given to the reasoning process and that many sufferers are painfully conscious of the absurdity of their fears which reason can in no way modify. The element of suggestion, too, must be a factor in the mental process.

Psychological Analysis endeavours to trace out the root origin of the nervous disorder, and in this respect is therapeutically more scientific than other methods. It involves a frank dissection of all the neurotic symptoms, taking a longitudinal survey of the emotional life history of the patient, noting the circumstances and situations which produced the neurotic reaction, interpreting dreams, giving the individual insight into cause and effect, as well as re-educating him towards a more normal attitude of mind as regards his instinctive desires and impulses. As in all psychotherapy, the personality of the physician counts for much. Unconscious suggestive influence is of course present also to some extent. Such analysis may be carried out by a special technique known as *psycho-analysis* which involves the adoption and application of the psychological theories of Sigmund Freud. In a few types of cases this method is valuable, but the expense and length of time it usually necessitates render its use extremely limited. *See* PSYCHIATRY and PSYCHOANALYSIS Occupational therapy has in late years been developed much for certain types of patients in conjunction with psychotherapeutic treatment. Organized occupational work tends to give an opportunity for the expression of the personality, forms an outlet for energy, and diverts attention from the self. Moral and religious influences, though of no small import, hardly enter into the sphere of scientific medicine.

(C. S. R.)

PTARMIGAN (*Lagopus mutus*), a gallinaceous bird akin to the grouse (*q.v.*). The word in Gaelic is *tarmachan.* It is not found in Scotland below 2,500 ft. and haunts the open moors, where there is no cover. It is the only British bird which turns white in winter. The American form, L. *rupestris,* is scarcely distinguishable. These birds show perhaps better than any of the group the protective coloration of the plumage so characteristic of the grouse.



BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

WHITE-TAILED PTARMIGAN. OR MOUNTAIN GROUSE (LAGOPUS LEUCURUS), SHOWING SUMMER PLUMAGE

PTERIA (mod. *Boghaz Keui),* the ancient capital of the "White Syrians" of Cappadocia, which Croesus of Lydia is stated by Herodotus to have taken, enslaved and ruined, after he had declared war on the rising power of Persia and crossed the Halys (after the middle of the 6th century B.C.). Thereafter he fought a battle near the city, and retired again across the river to his ultimate defeat and doom. Pteria is mentioned by no other ancient authority, but it is of great interest if, as seems highly probable, (1) its "White Syrian" inhabitants were what we call "Hittites" (*q.v.*), or at least, participants in the "Hittite civilization"; (2) its remains are to be seen in the prehistoric city and remarkable rock-sculptures near Boghaz Keui (*q.v.*) in Cappadocia, about 100 m. east of Angora and beyond the Kizil Irmak *(Halys)*. This is the chief "Hittite" site in Asia Minor.

The remains of Boghaz Keui are indubitably pre-Persian and pre-Greek. They consist of a large fortified city on a steep slope enclosed by two deep ravines, and falling to northward over 800 ft. from summit to base. The acropolis was strengthened with a circle of stone redoubts, between which led very narrow gateways, and with internal redoubts as well. Just inside what seems to have been its principal entrance is a rock face inscribed with nine lines of "Hittite" characters, greatly defaced (Nishan Tash), and a similar inscription, equally illegible, can be detected on a neighbouring rock. Below the acropolis on the north-east is a residential quarter, containing large ruins of what seems to have been a palace or temple built round a central court. The whole site is surrounded by a wall, 14 ft. thick, with towers about 100 ft. apart. The monument, however, which earliest rendered Boghaz Keui famous is the sculptured rock grotto, 1 m. to the east, called Yasili Kaya. Here two hypaethral galleries are adorned with reliefs in panels, the larger gallery showing two processions, which, starting on both walls from the entrance, meet at the head of the grotto. On the left wall are 45 figures, headed by a gigantic male figure, erect on the bent necks of two men. On the right wall he is opposed by a female of almost equal stature standing on a leopard or lioness, and followed by a young male with battle-axe, erect on a similar beast. Behind these are some 20 figures of mitred priests, etc. There can be no doubt that the female is the great Nature goddess of western Asia, attended by her spontaneously-generated son, with whose help she creates the world. *(See* GREAT MOTHER OF THE GODS.) Priests or minor divinities follow them. The other procession, according to the analogy of other monuments, should be composed of mortals bearing *sacra* and headed by their king, who makes offering or dedicates his city to, or engages in some mystic union with, the goddess. The figure following him seems to be that of his high priest. "Hittite" symbols are carved above many of the figures. Besides the processions there are five independent reliefs in the small gallery and its approach, one repeating the figure of the high priest.

In 1906, Winckler found a number of tablets in two languages, Babylonian and local, the latter being that of the Arzawa letters found at Tell el-Amarna. Among them was a cuneiform copy of the treaty made by Rameses II. in his 20th year with the king of the Kheta, and inscribed on a wall at Karnak. In 1907 Winckler continued his excavations. From tablets written in Babylonian Winckler has established the fact that Boghaz Keui was the capital of a powerful Hatti dynasty from the middle of the 16th century B.C. to at least 1200 B.C. He claims further that its ancient name was Hatti. At the height of its power it ruled all Asia Minor down to the Aegean and northern Syria to the headwaters of the Orontes, and was also overlord of the Mitanni and the Amurri (Amarru) in hfesopotamia. It had relations with Egypt and Babylonia. The four kings of the Kheta, alluded to by name in Egyptian texts, have been identified with kings of Boghaz Keui. The decline of Hatti power began with the expansion of Assyria after 1100 B.C. and Cappadocia seems to have been inferior to Phrygia after the rise of the Midaean dynasty in the 9th and 8th centuries. It should be added that the identification of Boghaz Keui with the Pteria of Herodotus has not yet been confirmed.

PTERIDOPHYTA, one of the groups comprising the ferns and their allies, of the second great division of plants, the Archegoniatae, the other being the Bryophyta (*q.v.*). The Pteridophyta thus share with the Bryophyta a middle position between the essentially aquatic Thallophytes and the essentially terrestrial Spermatophytes. Much of their special interest centres round that fact. They include plants well represented at the present day; but many already existed in the early land-vegetation of the Devonian period, now known only as fossils; they appeared in greater profusion as fossils of the coal, and many of these early types continued on into the Mesozoic age while their correlatives are included in the flora of the present day. Thus their geological history supports the conclusion that they take a middle position in the evolutionary progression of plant-life, in which a transition from life in water to life on land was a striking incident.

Hofmeister first showed that there is essential similarity underlying the life-histories of mosses and ferns, and that the same scheme, in modified form, extends to the seed-plants also. Since this is so, an account of the Pteridophyta may fitly be introduced by a brief record of the life-history of a fern, as an example of the Archegoniatae generally, and of the Pteridophyta in particular. There are two periods in each normally completed life-cycle of these plants when the individual is represented by a single cell; and these punctuate the limits between two distinct bodily phases, or generations as they are called. One of these is the leafy *fern plant* which every one knows; the other is a small green scale-like body, delicate in texture, called the *prothallus,* which escapes the observation of most people, though actually common enough. The former is sexless, but bears *spores* in large numbers; it is the *sporophyte* generation. The latter is the sexual generation, and, since it produces *gametes,* it is called the *gametophyte.*

Life-history of a Fern.—The fern plant varies in size from a minute herb to a tree-like body, 60 or even 80ft. in height. It consists of a stem bearing characteristic leaves, usually of large size and delicate outline; the shoot thus constituted is attached by roots to the soil, the whole being traversed by conducting tracts. Since the green leaves serve a nutritional function, the plant is able to subsist as a perennial land-plant (fig. 1). On the leaves the *sori* are borne, of various form and position. In the hart's tongue or the common shield fern they appear as dense groups of brown *sporangia* seated on the lower surface, and covered while young by a membranous indusium. Each sporangium is a stalked capsule containing numerous minute, dry and dusty spores, which are violently ejected when ripe, and each is then liable to be carried away individually by the breeze. The spores are unicellular propagative organs.

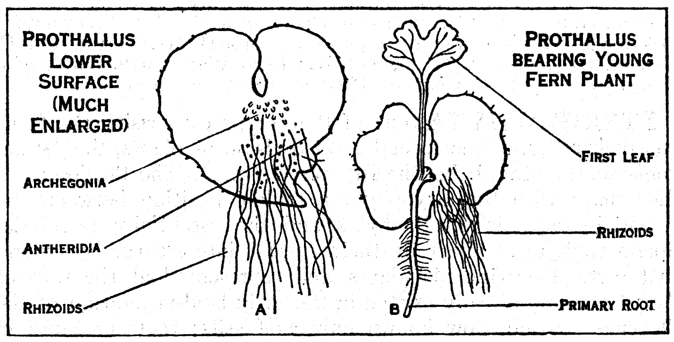
FIG. 1.—HART'S TONGUE (PHYLLITIS SCOLOPENDRIUM)

Each spore germinating on moist soil may grow into a prothallus or gametophyte (fig. 2), which never grows large, though being green it is physiologically independent. It bears the *sexual organs* or *gametangia,* usually on its lower surface (fig. 2, A). Near its base are the male gametangia or *antheridia,* which when ripe consist each of a protective wall of cells surrounding numerous spermatocytes. When bathed by external water (rain or dew) the wall ruptures, and each spermatocyte emits a single spiral *spermatozoid,* which moves in the water by lashing cilia (fig. 3). Near the indented apex of the prothallus the female gametangia or *archegonia* are formed (fig. 2). They are flask-shaped organs, also protected by an external wall; each contains a row of three

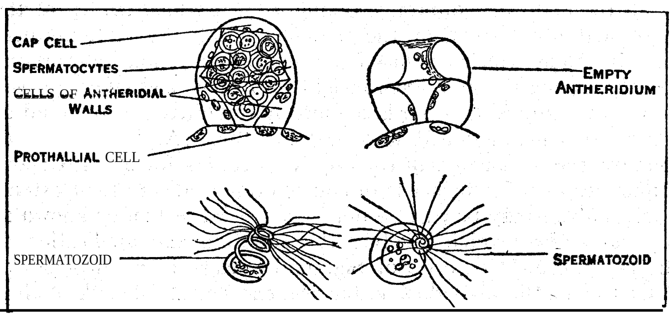


FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 2.—PROTHALLUS OF SHIELD FERN (DRYOPTERIS FILIX-MAS)

cells, of which the lowest and largest is the ovum or egg, sunk in the tissue of the parent (fig. 4). When ripe the archegonium also ruptures on access to external water, the distal cells of the wall parting so that an open channel filled with mucilage leads down to the rounded egg. *Fertilization (syngamy)* consists in the fusion of the spermatozoid with the egg to which it is attracted by soluble substance diffusing from it into the water that bathes the open archegonium. The result of that fusion is the *zygote,* which is the starting point for the development of a new fern plant. This new individual appears first as a spherical mass of delicate cells, nursed in the cavity of the archegonium; but it soon bursts out with its first leaf and root, and its apical bud ready to grow into a new fern, while the prothallus rots away (fig. 2, B).

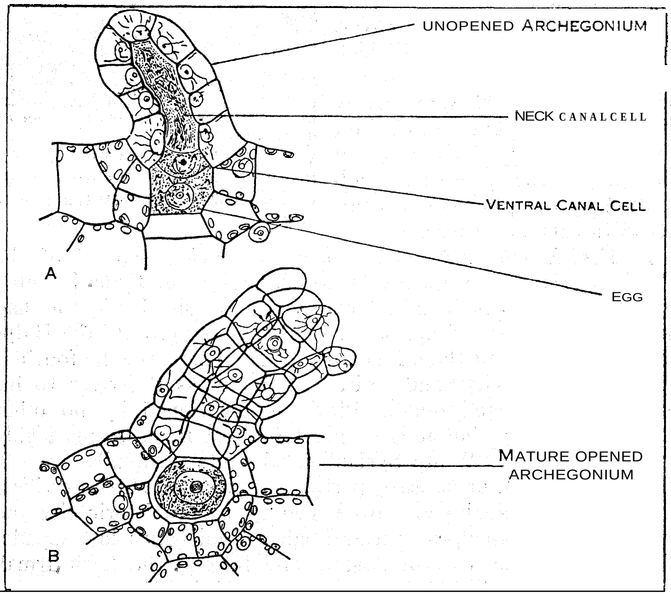
The central feature in syngamy is the *coalescence of the male and female nuclei;* the resulting fusion-nucleus is then *diploid,* with the $2n$ number of chromosomes (*see* CYTOLOGY). That character is then maintained throughout the tissues of the sporophyte. On the other hand, when the fern-plant comes to maturity and forms sporangia, the cells that are to form the spores undergo



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 3.— ANTHERIDIUM OF POLYPODY (POLYPODIUM VULGARE)

a nuclear change, called *reduction* or *meiosis,* by which they resume that simpler, constitution possessed by the nuclei of the prothallus, and described as *haploid* (n). These events normally alternate in regular succession, and they constitute that *nuclear cycle* which underlies all normal life-histories of the Archegoniatae. They stamp structurally the distinction of the two alternating generations. Such alternation, in one form or another, appears in all plants that show sexuality. The Pteridophyta illustrate the cytological cycle with unusual clearness, since the two somatic phases (viz., the haploid prothallus and the diploid fern plant) are so unlike, and so markedly independent the one of the other during their adult existence. It seems probable that in the course of evolution some simple form of alternation present in an algal



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 4—ARCHEGONIUM OF POLYPODY (*POLYPODIUM* VULGARE)

ancestry has been regularized and standardized in the Archegoniatae in accordance with a passage from the relative uniformity of aquatic life to the more varied vicissitudes of life on land. In the Bryophyta the gametophyte was more adaptive, and became the dominant generation; on the other hand, in the Pteridophytes, as also in all the higher land-plants, the sporophyte became specialized as the dominant land-living organism. But the Archegoniatae themselves were never wholly emancipated from dependence on external liquid water. They show their amphibious character by their zoidiogamic fertilization; and this confirms their position as primitive land-plants.

For the most part the Pteridophyta are like the Bryophyta in possessing only one type of spore (*homosporous*); but they produce these in enormous numbers. A common shield fern may ripen over 50,000,000 of them in a season. This is a primitive mode of propagation characteristic of early vegetation.

On the other hand, some few Pteridophyte-types such as Selaginella and Isoetes, and those curious little fern-derivatives styled collectively the Hydropterideae, possess sexually-differentiated spores, and are described as *heterosporous;* numerous smaller spores (*microspores*) bear each a rudimentary male prothallus, while a few larger spores (*megaspores*), or only a single one, produce each a massive female prothallus. In this they show a state of specialized advance along lines that have led to the final success of the flowering plants. The Pteridophytes as a whole present the paradox of a great division of the vegetable kingdom that has achieved success by force of numbers, rather than by the more refined methods of physiological adjustment and of propagation even in the higher plants. These paragraphs, of necessity rather technical, will suffice to introduce the Pteridophyta, Vascular Cryptogams, or fern-allies as they are sometimes called. They are represented by six natural groups or classes of organisms, of which four include forms both living and fossil, but two are known only as extinct and very early fossils. Such facts at once confirm their position as representing a primitive vegetation. They may be arranged in rough sequence according to their complexity of form and structure; but this must not be understood as conveying any definite view as to affinity.

CLASSIFICATION

I. PSILOPHYTALES, comprising only fossil types of simple conformation, from early Devonian rocks.

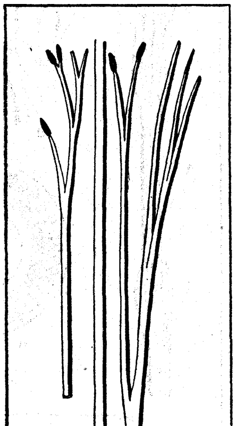
II. PSILOTALES, represented by two genera of living plants, Psilotunz which is intertropical, and *Tmesipteris* which is confined to Australia.

III. SPHENOPHYLLALES, containing extinct Palaeozoic fossils of small size, which hardly extended into the Mesozoic period.

IV. EQUISETALES, including only the single living genus of the horsetails (Equisetum), but largely represented also by Palaeozoic fossils often of dendroid form (Calamariaceae).

V. LYCOPODIALES, or so-called club-mosses, well represented at the present day by the large genera, *Lycopodium* and *Selaginella;* also by Phylloglossum and Isoetes. But in the Palaeozoic period there existed the giant Lepidodendroid trees, as well as allied plants of humbler dimensions.

VI. FILICALES, or ferns; these comprise not only the living ferns, with about 150 genera and over 6,000 species, but also a rich sequence of fossils, from the Palaeozoic Coenopteridaceae to the most recent strata.

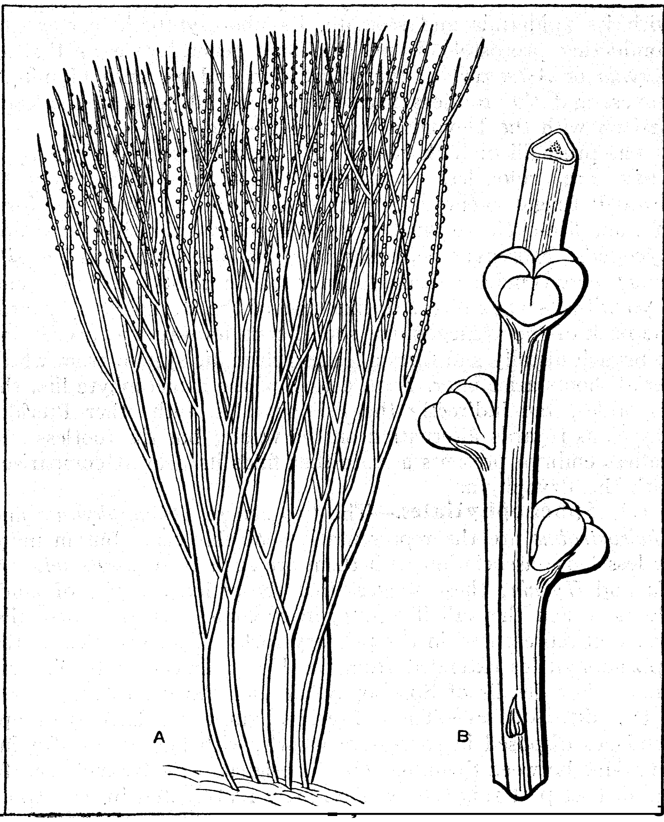


FROM KIDSTON & LANG IN BOWER, "FERNS" (CAMBRIDGE UNIVERSITY PRESS)

FIG. 5—HORNEA LIGNIERI

A newer scheme of classification treats the higher categoriee in a somewhat different manner. The phyla Pteridophyta and Spermatophyta (Seed Plants) are united into one group, the Vascular Plants or TRACHEOPHYTA. This includes four subdivisions: (1) the PSILOPSIDA, including the Psilophytales and Psilotales, (2) the LYCOPSIDA, including the Lycopodiales, (3) the SPHENOPSIDA, including the Equisetales and Sphenophyllales and (4) the PTEROPSIDA, including the Filiciniae, the Filicales of the above treatment, and also the Gymnospermae and Angiospermae, the two large groups of seed plants.

I. **Psilophytales.**—This new class of plants was constituted by Kidston and Lang to receive certain fossils of early Devonian time, discovered by Dr. Mackie at Rhynie in Aberdeenshire. Its name is taken from the old genus *Psilophyton* of Dawson, and the class now comprises a number of other genera of like age, more recently discovered, forming together a very distinctive flora. But of these only the sporophyte is known (fig. 5). The vegetative system consists of upward-growing, forked, aerial shoots that spring from a rhizome sometimes creeping, sometimes tuberous and mycorhizic; sometimes the underground branchlets are rootlike, forking in the substratum (Asteroxylon). The erect shoots are cylindrical, and were evidently green, covered by an epidermis, with stomata, and they are traversed by conducting strands of simple structure. Various superficial growths, often with the appearance of thorns or prickles, are borne upon the larger branches, as in Psilophyton and *Asteroxylon.* The plants



FROM ENGLER & PRANTL. "DIE NATURLICHEN PFLANZENFAMILIEN" (WILHELM ENGELMANN)

FIG. 6.—PSILOTUM TRIQUETRUM. (A) HABIT OF PLANT. SHOWING DICHOTOMOUS BRANCHING (B) PART OF A SHOOT

were of low stature, and growing gregariously"they must have looked rather like grass. The genera Hornea, Rhynia and *Aster*oxylon, described by Kidston and Lang were so well preserved that their structure is as well known as though they were modern plants. The class stands conspicuously apart as leafless and rootless vascular plants.

The most distinctive feature of the class for diagnosis is that the large sporangia, protected by a wall of many layers and containing numerous homosporous spores, are terminal on the vegetative twigs. The early existence thus demonstrated of leafless, and rootless and homosporous vascular plants, with distal sporangia of primitive construction is a fact of the first comparative importance. It is true it does not demonstrate any nearer connection with the Algae, but as regards other relations the new facts are highly suggestive. Long ago it was remarked that the widest gap in the sequence of plants was that between the Bryophytes and Pteridophytes. It is within this gap that the newly discovered fossils take their natural place, acting as synthetic links for the whole sequence of land-living, sporangium-bearing plants.

II. Psilotales.—The Psilotales are represented by two living genera, *Psilotum* and *Tmesipteris,* of which both generations are now known. They form a natural family of the Psilotaceae. By their features they appear remarkably isolated among living plants, and their nearest affinity is to be sought among the Psilophytales and Sphenophyllales, both being classes of plants long extinct. These two genera appear in fact as living fossils.

They live epiphytically, or in soil rich in humus, and are rootless. The green, more or less shrubby shoot is fixed in the substratum by much branched leafless rhizomes, which are infected by a mycorhizic fungus. The saprophytic nutrition by these is supplemented by photosynthesis in the green leafy shoots. In *Psilotum* the aerial stems bifurcate, bearing small and simple scaly leaves, which however pass upwards into bifid "sporophylls," and between the two teeth is seated a large trilocular synangium, containing numerous homosporous spores (fig. 6). *Tmesipteris* resembles it in general character, but branching is infrequent, the leaves and "sporophylls" are larger, and the synagium has only two large loculi. The anatomy of the green stem of *Psilotum,* with its epidermis and stomata, its photosynthetic cortex and conducting protostele, is on the same general plan as that of Rhynia or Asteroxylon; the bifurcation and presence of minute leaves, and the rootless mycorhizic base all support the comparison with the Devonian types of Rhynie.

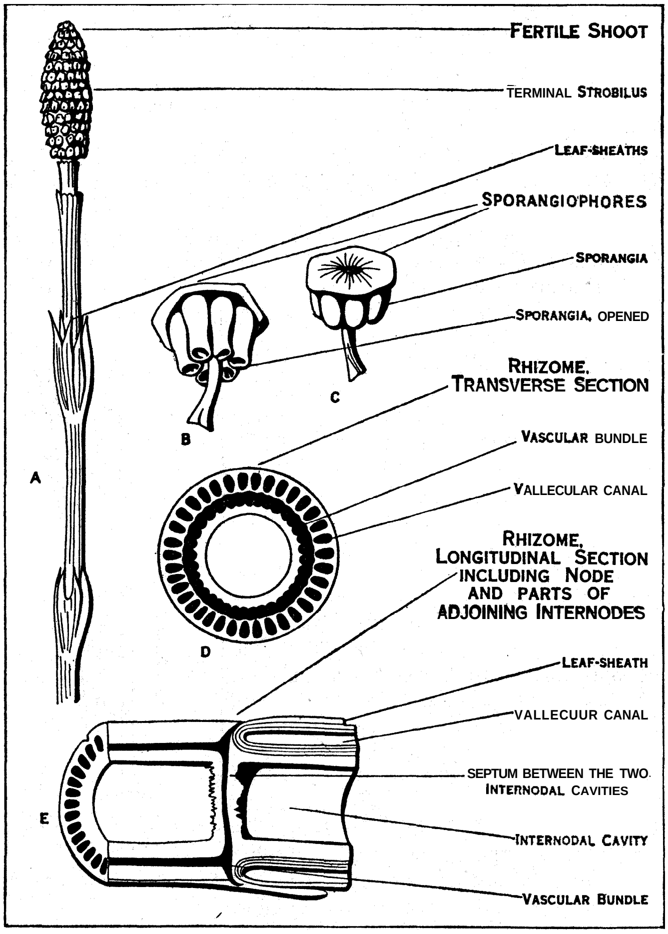
The prothalli of both genera have been discovered since 1914. They are colourless, nourishing themselves saprophytically through fungal agency. In fact these primitive plants conform in their life-cycle to what is seen in many primitive ferns and Lycopods. Moreover, the embryology has been traced in *Tmesipteris;* there is neither suspensor, nor root, nor cotyledon. The embryo with its apex directed, like that of the Bryophytes towards the neck of the archegonium, soon bursts its way out, proceeding to branch distally and form a leafless rhizomic system from which aerial shoots arise later. Such details of the gametophyte link the Psilotales, and indirectly the Psilophytales, with other Pteridophytes as regards alternation on the whole; but the rootless and leafless embryo presents a state that finds its nearest comparison with the Bryophyta.

III. **Sphenophyllales.**—The two genera *Sphenophyllum* and Cheirostrobus are the representatives of this class, but in more or less loose association with them are such types as *Pseudobornia* and Hyenia; these suggest that the articulate type of land-plants, which they all illustrate, in common with the horsetails, was well represented in the primary rocks. The existence of the Sphenophyllales extended from the Upper Devonian to Triassic time. (For details of Sphenophyllales see PALAEOBOTANY.)

IV. **Equisetales.**—Those Pteridophyta which have their appendages disposed in successive whorls, with long internodes intervening between them, have been designated the Articulatae. In the distant past this type was strongly represented by the Sphenophyllales, and by the Calamariaceae and others. But it is familiar to us to-day as it is seen in the horsetails, included in the cosmopolitan genus *Equisetum,* the only species of Equisetaceae, and the only living representatives of the Equisetales. These are semi-aquatic plants; they vary in height from a few inches to 30ft. or more, and are rhizomatous, with erect shoots arising from richly branched, subterranean stems, which are themselves rooted in the soil. The habit of the plants depends upon the method of branching of the shoot rather than upon the foliage, for the leaves are minute (microphyllous), and closely appressed to the stem that bears them. Each whorl of them forms a sheath closely investing the base of the next higher internode, while the teeth projecting upwards from it are all that represent the individual leaves. Their position alternates in successive nodes (fig. 7). The internodes are fluted, the ridges being continuous downwards from the next higher leaves; consequently those of successive internodes alternate. The number of the leaves in a whorl may vary according to the size of the stem, from three to 20 or 30. This is the scheme of the shoot in all species of *Equisetum,* and the shoot is constantly of radial construction. In some species the branching is sparse (E. *limosum*); in others it is profuse (E. *sylvaticum* and maximum), and the branches may themselves branch again repeatedly. Their number and the degree of secondary branching defines the habit, and justifies for the more bushy types the familiar name of horsetails. The branches arise in the axils of the leaf-sheaths, but they alternate with the leaves themselves. Many of those initiated remain dormant. A root is found at the base of each bud, but it also is frequently dormant, especially in aerial shoots. The structure of the underground rhizome is on the same plan as that of the aerial branches that it bears. Thus the whole plant consists of a succession of shoots, each with a dominant axis, whorls of subordinate leaves, and accessory roots.

In the transverse section of an aerial internode the sinuous outline shows the projecting ridges and depressed furrows of its fluted form, though this is less evident in the rhizomes (fig. 7, D). The centre of the section is occupied by a large air-cavity, surrounded by the remains of the pith. A circle of isolated vascular strands, corresponding in number to the leaves in the next whorl above, is in most species enclosed by a sinuous endodermis, which thus delimits the stele (E. arvense, etc.). Outside this lies the cortex, marked by an equal number of large air-cavities, which alternate with the vascular strands, and correspond to the furrows of the fluting. The vascular strands themselves are opposite the projecting ridges, and are extended upwards into the several leaf-teeth. Between the ridges are regions of green chlorophyll-parenchyma, while the whole is invested by a well-marked epidermis, with curiously elaborate stomata: these are ranged along the furrows, and so are opposite the photosynthetic tissue. The anatomy is clearly that of a semi-aquatic plant with its reduced vascular tissue and large air-spaces.

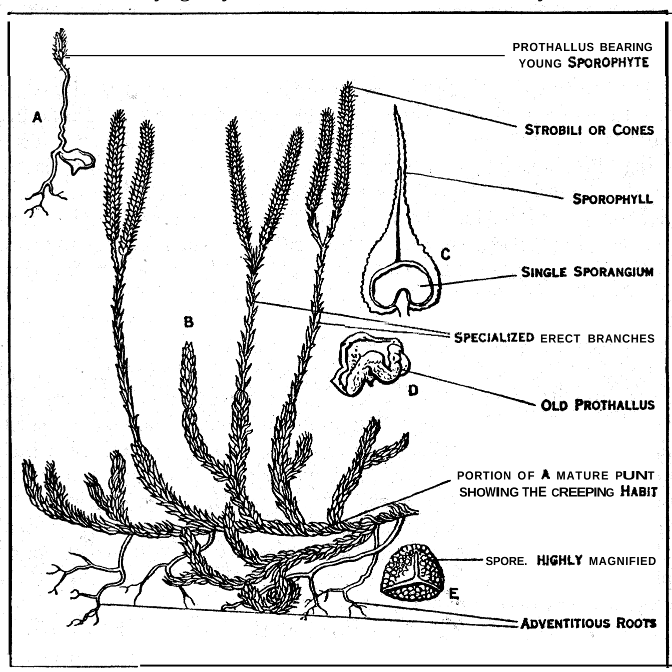
The sporangia of *Equisetum* are borne upon lateral appendages of the axis, sporangiophores, which are disposed in whorls, and are associated in definite strobili or cones, borne distally (fig. 7, A). Each sporangiophore consists of a stalk that expands into a peltate disc, from the inner surface of which some



FROM (A, B, C) STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 7.—LARGER HORSETAIL (EQUISETUM TELEMATEIA)

six to nine large sporangia hang parallel with the stalk (fig. 7, B, C). A single vascular strand passing through the stalk supplies a branchlet to each sporangium. These arise as massive growths from the first, and each produces a large output of homosporous spores (eu-sporangiate). The spores themselves are large; in ripening the outermost layer of the mall of each splits along spiral lines, giving rise to four elaters that straighten out when dry, and close round the spore in damp air. They are effective in forcing open the sporangium, which dehisces by a longitudinal slit: and those of different spores hooking together, the spores are grouped in germination, a matter of importance since the sexes are usually borne on separate prothalli. The spores germinate at once, producing each a green prothallus, which may be filamentous, flattened, or irregularly lobed. The smaller bear sunken antheridia, each with numerous spermatocytes, from which spermatozoids are liberated on access of water. The larger bear archegonia. The conditions of syngamy and formation of the embryo are essen-



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 8.—A CLUB-MOSS (LYCOPODIUM CLAVATUM)

tially as in ferns; but here the embryo has its apex directed to the archegonial neck (exoscopic), and it grows out directly into the apex of the young plant, successive whorls of leaves arising laterally upon it; a root derived from the basal region fixes the young plant in the soil. Notwithstanding the differences of detail, the life-cycle of a horsetail is comparable as a whole with that of a fern.

A greatly added interest in *Equisetum* arises from comparison with allied fossils; for not only were these numerous and of early occurrence, but they attained dendroid proportions, while some were heterosporous. They are grouped as the Calamariaceae, which will be specially treated elsewhere (see PALAEOBOTANY).

The Equisetales, thus comprising the Equisetaceae and the Calamariaceae, form a natural and closely related class, of which the nearest affinity was with the Sphenophyllales, but with some degree of relation also with the Psilotales; all of these being sporangiophoric Pteridophytes.

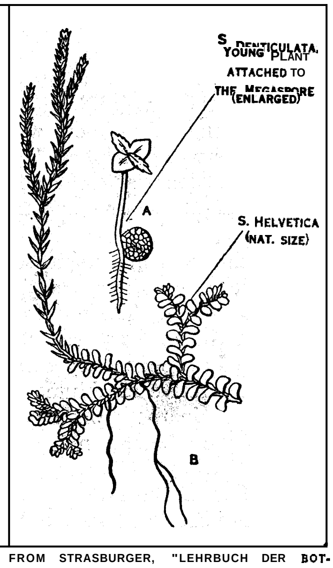
V. **Lycopodiales.**—This class comprises a considerable number of species now living widely distributed upon the earth, and known as *club-mosses;* though they are in fact vascular plants, and quite distinct from the true mosses. They are all relatively small, and indeed insignificant as features in the present flora, compared with the fossil types which, though they may have included a number of relatively small species, comprised also some of the largest plants of the forests of the coal period. It may be that among the lycopods no actual diminution in size took place as time went on, but rather that the types which were always small survived, while the giant members of the group became extinct.

The features which all club mosses have in common are that the leaves are relatively small and simple in form (*microphyllous*), while the sporangia are seated singly, one in the axil of each leaf of the fertile region, or spreading outwards on its base. This marks off the Lycopodiales clearly from the sporangiophoric Pteridophytes on the one hand, and from the Filicales on the other. As in the former, however, the axis is dominant in the adult shoot, and forks equally or unequally. According to the position assumed by the stem the habit of living club mosses is upright or pendent; but frequently, as in the stag's horn moss common on Scottish hills, with its creeping stem rooted in the soil, and bearing upright fruiting branches (fig. 8, B).

The class is divided systematically according to the presence or absence of a ligule, which is a small scale-like body borne on the upper surface of each leaf, near its base. Those in which no ligule is present, the ELIGULATAE, include *Lycopodium* and *Phylloglossum,* together with certain early fossils designated *Lycopodites;* those which possess a ligule, the LIGULATAE, include *Selaginella* and *Isoetes,* and with these are associated the fossil Lepidodendraceae and Sigillariaceae. The distinction is accentuated by the fact that the former are all homosporous, the latter heterosporous.

A, Lycopodiales *Eligulatae.* Lycopodium comprises about 100 species of small plants of varied habit, creeping, shrubby or epiphytic. The construction of the shoot is uniformly microphyllous, the bifurcating stem dominating the conformation of the whole plant. The leaves are simple and small, and in some species uniform throughout the plant. In others the sterile leaves are larger than the membranous sporophylls, the latter being associated in definite strobili, or cones (fig. 8, B). The former probably represent the more primitive type. Each of the isolated sporangia is seated at the base of its sporophyll; it is large, and kidney-shaped, with a short massive stalk, and it dehisces like an oyster-shell, in a plane parallel to that of the leaf. The arrangement of the leaves is sometimes in regular whorls, but frequently it is according to some more or less interrupted spiral scheme. The plant is fixed at its base by roots which spring endogenously from the stem, and show bifurcation.

The stem of *Lycopodium* is seen in transverse section to be surrounded by a bulky and often indurated cortex, and traversed by a stele continued to the apical cone itself, while from each leaf a minute vascular strand passes to its periphery. In the young stem there is a solid woody core, surrounded by phloem and ill-defined sheaths. But in fully-grown stems the core may be invaded by tracts of phloem, moulding it into a cruciform or stellate transverse section, or even separating it into distinct radiating plates, or permeating it to form a sort of woody sponge.



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

FIG. 9.—A CLUB-MOSS (SELAGINELLA)

The sporangia are massive from the first, and vary slightly in spread along the leaf-surface, a point of interest for comparison with the ligulate types. Each produces after the usual tetrad-division a large number of homosporous spores, which germinate slowly. The prothalli produced from them, and the embryology that follows, vary more than is usual in a single genus. The prothallus sometimes grows at soil-level and is green (L. *cernuum*); but often it is underground and wholly saprophytic (*L. clavatum,* fig. 8, D, A). Whatever its form, the sex-organs are massive and deeply sunk, and both are present on the same prothallus. The antheridia produce numerous biciliate spermatozoids; the archegonia vary in length of neck, and sometimes have numerous canal-cells. But the egg is deeply seated, and produces an embryo with a suspensor. This thrusts the embryo deep into the prothallus, where it often develops juvenile characters of importance for comparison. The most striking of these is the swollen "protocorm," a tuberous growth seen in Hornea, and present also in *Phylloglossum.* Bursting out from the prothallus the embryo develops shoot and root, the former in the underground types finding its way upwards to the soil-level (fig. 8, A).

B. Lycopodiales Ligulatae. Selaginella comprises some 500 species, widely spread through the tropics, some native on temperate hill stations. The latter, chiefly of exposed habit, have radial symmetry, but most *Selaginellas* are dorsiventral, and live under shade. The genus shares the leading features of *Lycopodium,* but it differs in the presence of a ligule, and in the fact that all the species are heterosporous. Various *Selaginellas* are favourite greenhouse plants, and the fan-like spread of the delicate branches with their dimorphic leaves is well known (fig. 9, B); also the strange rhizophores springing from points of branching of the shoot, which turning downwards give rise to the true roots, being themselves organs of indeterminate morphological nature. It will be unnecessary to describe the vegetative organs or their anatomy in detail; the chief comparative interest lies in the propagative process

The sporangia are borne on radially-constructed distal cones. A smgle sporangium similar to that of *Lycopodium,* is borne just above the insertion of each sporophyll, with the ligule protecting it from without. The microsporangia are brownish when ripe and the megasporangia pale in colour, and both may be borne on a single cone. They appear all alike up to the stage when the numerous spore-mother-cells are formed. If all the spore-mother-cells undergo tetrad-division numerous microspores resembling those of *Lycopodium* result. But in a rnegasporangium only one, or at most a few of them form tetrads, and the resulting spores are large with a rugged wall; the number matured in a single sporangium may vary from one to four, or sorne multiple of four. On germination each microspore produces a small number of spermatozoids from a very reduced prothallus; but the large megaspore forms a more bulky prothalius, which, projecting from the disrupted wall, bears archegonia. One of these on fertilization develops an embryo with a suspensor The essentials of the process are as in *Lycopodium,* though the details are different. As the sporeiing develops its leafy shoot grows upwards, and its root downwards; with the megaspore attached laterally the whole has the appearance of a seedling of some flowering plant (fig. g, A). This is clearly an advance upon *Lycopodium.*

The other genus *Isoetes* is peculiar in habit and in habitat, yet shares many of the characteristics of *Selaginella* It contains about 50 species of tufted herbs, mostly living at the bottom of fresh-water lakes, though a few are amphibious or terrestrial. The plant consists of a short massive lobed stock, bearing crowded awl-shaped leaves of considerable length. Each bears a ligule on its upper surface, and when fertile as any one of them may be, a large cake-like sporangium lies between this and the axis. Roots with dichotomous branching arise from furrows between its lobes. The sporangia are heterosporous, and propagation is essentially similar to that in *Selaginella;* but there is no suspensor, and the spermatozoids are multi-ciliate.

A chief interest in these Ligulate types lies in their comparison with the Lepidodendraceae and Sigillariaceae, for these are also ligulate and heterosporous (*see* PALAEOBOTANY). These fossils attained dendroid dimensions, and though the primary vascular system was not unlike that of the modern Lycopods, they often differed in having secondary growth with an active cambium. In *Isoetes* there is a sluggish secondary growth in the short stock, which itself shows certain analogies with the Stigmarian rrunks of the gigantic fossils. Since any of the leaves of *Isoetes* may be fertile the whole plant appears as a strobilus of the same nature as *Lepidostrobus,* seated upon a Stigmarian base. In fact *Isoetes* is like a telescoped, but still living, fossil.

VI. **Filicales.**—The Filicales may be held as comprising all the living Megaphyllous Pteridophytes, together with such fossils as show essentially similar characters. But the mere fact that their leaves are relatively large in proportion to the stem that bears them is not a sufficient diagnosis. Some Lycopods (*Isoetes, Sigillaria*) share this character, and megaphylly is possible in any of Pteridophytes. But as a matter of fact, excepting *Isoetes,* none such are now living other than the Filicales. The most distinctive feature of ferns, however, is that *on the relatively large leaves many sporangia are borne, either singly or in groups (sori).*

Ferns are represented at the present day by about 150 genera, and 6,000 species. Some are minute, others attain considerable size as tree ferns; but none can be reckoned among the largest of living plants, nor is there fossil evidence that ferns ever attained extreme dimensions. Their geographical spread is general; some few are arctic, but ferns increase in numbers both of species and of individuals towards the Equator. Most are mesothermal hygrophytes, *i.e.,* they flourish under moist conditions with a moderate temperature; and the majority are shade-loving. Hence their headquarters are in the mountains of the tropics, where they form a considerable part of the undergrowth below the forest canopy. But their habitat is variable; some specialized types are actually aquatic, while others are able to withstand conditions of moderate, some even of extreme drought. Ferns are much richer in genera, species and individuals than any other living Pteridophytes. They present the climax of successful development in homosporous vascular plants. They show also a high degree of variety both in their vegetative and their propagative characters; these provide good diagnostic features for their classification. They have a full and long palaeontological history that stretches back to Palaeozoic times. The geological record can therefore be used as a valid check upon the conclusions drawn from the comparison of living types.

It has been said that the Palaeozoic period was the age of ferns, and it is true that "fern-like" leaves were then common. But it has now been shown that many of these belonged to seed-plants ranked as Pteridosperms, a class long since extinct, which also had fern-like leaves (*see* PALAEOBOTANY). It is not improbable that they represent a stock more distinct from ferns than the similarity of their foliage would suggest, for they had advanced early to seed-formation. It may be left as an open question whether or not both may have had far back in their evolution some common origin.

The life-history already described at the opening of this article holds for ferns generally, so that the grouping and natural classification of the class must depend upon differences of detail other than the life-history itself. A general comparison of them led long ago to the recognition of eight main families, which may here be placed in the reverse order to that first given by Mettenius (1856):—

I. Ophioglossaceae.	V. Gleicheniaceae.
II. Marattiaceae.	VI. Hymenophyllaceae.
III. Osmundaceae.	VII. Cyatheaceae.
IV Schizaeaceae	VIII. Polypodiaceae.

This grouping in linear sequence places the more robust types first, and the more delicate last, while the rest take middle positions. The former have been styled by Von Goebel the *Eusporangiate ferns,* in which the sporangium is from the first a massive body, in the formation of which many cells co-operate; in the latter each sporangium arises from a single cell, and those ferns in which this is so were styled *Leptosporangiate.* Intermediate states exist, and these suggest that the whole series constitutes an evolutionary progression. If this be true the question arises which is the more primitive, and which the more advanced state? The importance of this question is enhanced by the fact that the sporangium is a mere index of a general difference of organization of the two contrasted types. In point of fact *the Eusporangiate ferns are relatively robust in their general constitution, while the Leptosporangiate are relatively delzcate.* Thus the question is whether there has been in the course of evolution a progression from a robust to a delicate state, or the reverse Since the Eusporangiate ferns find their correlatives in the fossils of Palaeozoic time and are relatively few to-day, while the specialized Leptosporangiate ferns are absent from the Palaeozoic rocks and comprise the bulk of living ferns, it is concluded that the general progression has been from a more robust ancestry towards a more delicate and precise constitution.

Having perceived this general scheme of progressive refinement, it cannot be assumed that the 150 genera, and 6,000 species have formed a simple sequence. In testing the question of their relationships it will become necessary to revise the methods in use by systematists, whose aims were primarily classification They worked as a rule upon few criteria of comparison, drawn almost exclusively from the sporophyte generation. A more exact comparison will be necessary not only as regards external form, but also of internal structure and development, both of the vegetative and the propagative organs, and it must be extended to both generations. The larger the number of the criteria used in comparison the more trustworthy will be the conclusions drawn from them. The criteria currently used in the comparison of ferns are these:

1. The external morphology of the shoot.
2. The initial constitution of the plant-body as indicated by segmentation.
3. The architecture and venation of the leaf.
4. The vascular system of the shoot.
5. The dermal appendages.
6. The position and structure of the sorus.
7. The indusial protections.
8. The characters of the sporangium, and the form and markings of the spores.
9. The spore-output.
10. The morphology of the prothallus.
11. The position and structure of the sexual organs.
12. The embryology of the sporophyte.

By the combined use of these criteria it has been possible to revise the natural groupings of ferns, sometimes amending but more often upholding the decisions of the earlier systematists. The main conclusions may be stated as follows: The *Eusporangiatae* include the living Ophioglossaceae, Marattiaceae and Osmundaceae, together with the fossil Coenopteridaceae *(see* PALAEOBOTANY). All these are Palaeozoic types, though they overlapped into the Mesozoic, and some representatives have even survived to the present day. With them are to be associated also the Schizaeaceae, Gleicheniaceae and Matoniaceae, all of which figured prominently in the Mesozoic, and are well represented among living ferns. In addition to many archaic features of the vegetative system they all possess relatively massive sporangia, which originate simultaneously, being produced either singly or in small numbers in the sori. They are collectively styled *Simplices.* Each sporangium has a relatively large spore-output.

The Ophioglossaceae and Marattiaceae appear to have ended blindly and left no further derivatives. But derivative phyla may be traced by comparison from each of the Schizaeaceae, Osmundaceae, and Gleicheniaceae, while to the Matoniaceae so closely allied to the Dipterids, another phylum may be ascribed. The Schizaeaceae with their solitary marginal sporangia lead to the marginal Dicksoniaceae. The Osmundaceae have many features in common with *Plagiogyria,* while the superficial Gleicheniaceae link on to the Cyatheaceae, these being distinguished by their superficial sori from the marginal Dicksoniaceae. In both of these last-named families the sorus has become *"gradate," i.e.,* after the distal sporangia have been formed on the receptacle, a sequence of further sporangia follows *in basipetal sequence,* the effect of which is that the drain of nutrition is spread over a longer period of time. This may well have been a real factor in the success of these families.

A third state of the sorus, which has a like effect to the last, and may either be initiated independently or by transition from the gradate, is the *"mixed"* state, where sporangia of different ages are irregularly *interpolated between those already present.* This is the final condition seen in the evolution of the Leptosporangiate ferns, and is found in all the more advanced types.

From such intermediate stocks as those mentioned some *six derivative phyla of advanced Leptosporangiate ferns* may be distinguished, each centring round some well-known genus. Two of these comparison shows to have been derived from the Dicksoniaceae, viz., the Davallioid ferns centred round *Davallia,* and the Pteroids round *Pteris.* The Gymnogrammoid ferns are naturally grouped round *Gymnogramme,* and may probably be traced from the Osmundaceae, with *Plagiogyria* as a suggestive link. The Cyatheaceae probably gave rise on the other hand to the Blechnoid ferns, with *Blechnum* as a central type; and the Dryopteroids round *Dryopteris.* Lastly, a quite considerable number of genera may be traced as Dipteroid derivatives, from an ancestry suggested by *Matonia* and *Dipteris.* Thus at least six main evolutionary sequences of advanced Leptosporangiate ferns, with more or less pronouncedly "mixed" condition of their sori, may be referred in origin to types already distinct in Palaeozoic, or certainly in Mesozoic time. Each of these will have pursued its own phyletic advance independently of the others. Comparison reveals that most of them. or in some respects all, show parallel features of advance in form, vascular structure, soral characters, and sporangia, and particularly in the reduced spore-output from each sporangium. There is thus wide evidence of independent *homoplastic, and even convergent evolution* in the several phyla. In no respect is this clearer than in the distinctive feature of heterospory: for the Marsileaceae are referable in origin to a Schizaeoid source, while the Salviniaceae, whatever their actual relation, were of distinct origin from the Marsileaceae.

This brief abstract of the present position of the phyletic study of the Filicales can do no more than suggest how the matter stands to-day. Of all the Pteridophyta the ferns yield the most consecutive results. The living representatives of all the rest appear as isolated survivals, illuminated by fossil evidence, often as fragmentary and isolated as theirs. They raise as many evolutionary questions as they solve. It is only in the Filicales that it is possible, by placing together the evidence from palaeontology and that derived from the living flora, to reconstruct a story which, however incomplete, is sufficiently consecutive to serve as a basis for evolutionary opinion. The sum of it is for the ferns, as also for other Pteridophyta, that they have held their own to the present day as a class which has made the best of their amphibious existence by help of profuse production of homosporous spores. But from the point of view of descent, they have led on directly to no further type of land vegetation. The sources of this must be sought elsewhere.

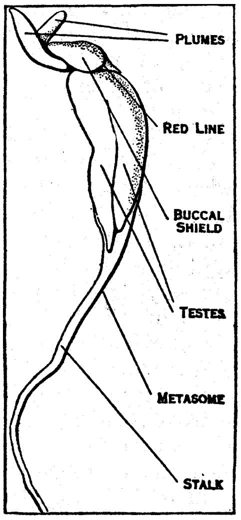
FROM THE CHALLENGER REPORTS (H.M. STATIONERY OFFICE)

FIG. 1A.—CEPHALODISCUS DODECALOPHUS AN ILLUSTRATION OF A FEMALE AS SEEN FROM IN FRONT. (AFTER McINTOSH)

PTEROBRANCHIA. The most strikingly novel discovery of the "Challenger" Expedition was a mysterious animal, dredged from 245 fathoms in the Straits of Magellan. It was described as *Cephalodiscus dodecalophus,* in 1882, and was at first placed in the Polyzoa. In 1903 it was announced that *Cephalodiscus* had been found by the Swedish Antarctic Expedition, from the original locality southwards to the Antarctic sea; and that it had been discovered off Borneo (near low-water mark), Celebes and Korea It was later recorded from new Antarctic or Sub-Antarctic localities, and off New Zealand, South Africa and Ceylon. Forgotten specimens were found in the British Museum from Kerguelen ("Challenger") and from the Antarctic (probably the Ross Expedition, 1839–1843). The study of the anatomy of this surprising animal revealed the unexpected fact that its affinities are with *Balanoglossus* (*q.v.*).

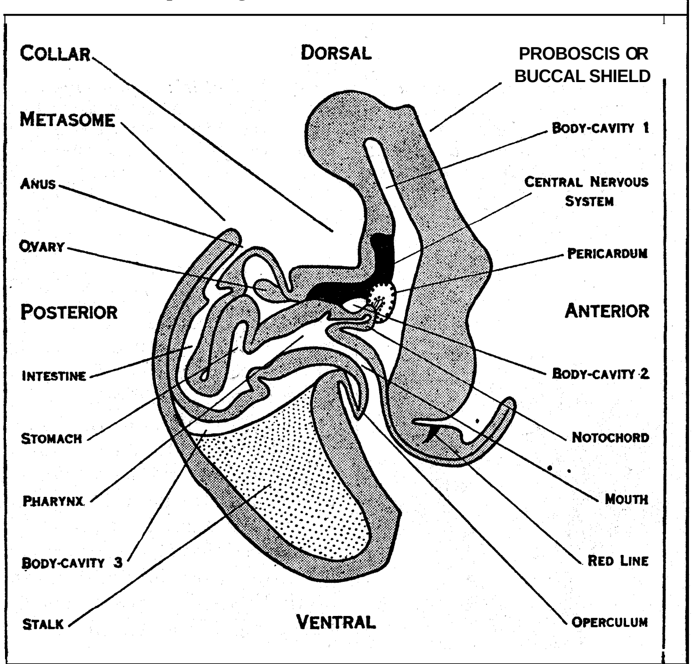
A colony of Cephalodiscus inhabits an orange, gelatinous dwelling (coenoecium), from a foot to half an inch long. The branches, from two inches to one tenth of an inch across, are composed of numerous laminae, including Foraminifera or other bodies, sometimes so numerous as to mask the gelatinous walls. The animals occur in large numbers, and are from 7 to 1mm. in length, without the stalk, which is very extensible. They can wander on the surface of their dwelling, the lower end of the stalk remaining attached to the wall of the tube, to facilitate retraction.



FROM S. F. HARMER, "MONOGRAPH ON THE SIBOGA EXPEDC TION" (MAX WEBER)

FIG. 1B.—A MALE (SIDE VIEW)

The body consists of the three regions characteristic of *Balanoglossus:*—(1) the "proboscis" or "buccal shield" (fig. 2), used as a crawling organ. A crescentic red line, near its lower edge, is distinctive of the genus; (2) the "collar," its front edge produced above into 3–9 pairs of plumes, each with two series of tentacles, and at the sides and below into a large "operculum"; (3) the third segment or "metasome," with the stalk. Each segment has its own body-cavity, unpaired in the proboscis, paired in the other two segments (figs. 2, 3). The first body-cavity opens externally by two "proboscis-pores," on the buccal shield, near its junction with the collar. The second cavities extend into the operculum and the plumes, each opening by a "collar-canal," immediately behind which is a "gill-slit," leading from the pharynx to the exterior (fig. 3). From the upper wall of the pharynx a "notochord" projects into the proboscis-cavity, where there is a "pericardium," corresponding with that of *Balanoglossus.* The central nervous system is in the dorsal region of the collar and of part of the proboscis.



FROM S. P. HARMER, "MONOGRAPH ON THE SIBOGA EXPEDITION" (MAX WEBER)

FIG. 2.— CEPHALODISCUS DODECALOPHUS, MEDIAN SECTION OF AN ADVANCED FEMALE BUD

The third body-cavities contain the alimentary canal and reproductive organs. The anus is on the upper side, the mouth being below, between the proboscis and the operculum. The young alimentary canal (fig. 2) is shortly U-shaped, but in the adult the U is much longer, passing ventrally down the body, the long axis of which is dorso-ventral. The two ovaries or testes open dorsally, in front of the anus, and the oviducts (at first mistaken for eyes) are highly pigmented. The eggs have much yolk, and development commences in the tubes. In certain species the colonies are either male or female, while in others both sexes occur, and an animal may have an ovary on one side and a testis on the other. The males resemble the females except in C. *sibogae* (fig. 1, B), in which they occur with neuter individuals without functional reproductive organs. These males have a single pair of plumes, with no tentacles, the alimentary canal is vestigial and the operculum has been lost. The three segments, their body-cavities, the collar-canals and the central nervous system are normal, but the third segment is mainly occupied by the two testes. The males are probably nourished by vascular connection with the neuters; and blood-vessels have been observed in this and other species. The buds, often in considerable number, remain connected by their stalks with the parent stalk until a late stage, but ultimately become free.

The species of Cephalodiscus are most easily recognized by the form of their coenoecium. The number of plumes is not always quite constant. but is a useful character. About 13 species are known, referable to three sub-genera: — Demiothecia, with a single cavity extending throughout the colony; and *Idiothecia* and *Orthoeczis*, in which each animal, with its system of buds, occupies a separate tube, nearly always isolated from its neighbours. The coenoecium is branched in *Idiothecia,* discoidal or plano-convex in Orthoecus. Rhabdopleura, the only other Pterobranch, resembles *Cephalodiscus* in form and structure, but is almost microscopic. It was first described from Norwegian and British seas (in rather deep water), but it occurs from Greenland to the Antarctic sea, including the Azores, the Malay archipelago, Ceylon, New Zealand, Australia and Tristan da Cunha. Several species have been described, but it is not at all certain how many are valid.

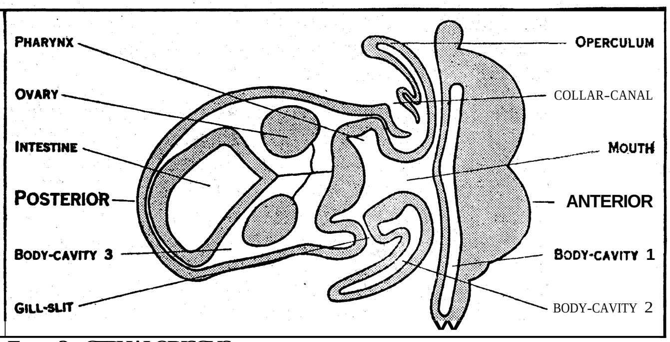


FIG. 3.—CEPHALODISCUS DODECALOPHUS, LONGITUDINAL (FRONTAL) SECTION OF THE FEMALE. SHOWING THE LEFT COLLAR-CANAL AND THE RIGHT GILL-SLIT (AFTER HARMER)

Rhabdopleura has no doubt been simplified, in correlation with its reduction in size. There is only one pair of plumes and gill-slits are not present. In most other respects it agrees with *Cephalodiscus*, to which it is clearly allied. The elongated, cylindrical tubes are about 2–3mm. long and a quarter of a millimetre in diameter. Each arises vertically from a tube closely attached to a solid object; and all the tubes are composed of laminae, which form distinct rings in the erect parts. The budded individuals do not become free, their stalks remaining connected by a cord. Its jet-black colour, in the adherent part, and the ringed tubes are features easily recognized.

PTEROCLIDAE: see SAND-GROUSE.

PTERODACTYL, a term familiarly used for any member of the order Pterosauria, or winged reptiles. The pterodactyls are extinct flying reptiles found in rocks of all ages from the Lower Lias or perhaps the Rhaetic to the Upper Cretaceous. They fall into two great groups distinguished from one another by the presence of a long tail with a horizontal fin at its tip, in the one, and the lack of a tail in the other.

The best known form is *Rhamphorynchus* from the Solenhofen slate of Bavaria and probably the Kimmeridge clay of England. *Rhamphorynchus* has a head about $3\frac{1}{2}$ in. long, with a mouth opening very widely and armed with long, slender, sharp-pointed teeth. The eye, which is placed above the articulation of the lower jaw, is very large, and like that of many birds has a series of bony plates lying in its wall. The paired nostrils lie far back in front of the eyes. The neck, which is some 2 in. long, was flexible, and the head was carried at right angles to the neck. The body is small, about 4 in. in length by $1\frac{1}{4}$ in. in diameter. The tail is enormously long (15 in.) and although built of many joints, is stiffened by ossified tendons so that it must have moved as a whole. The wings are stretched membranes made by folds of skin held out by

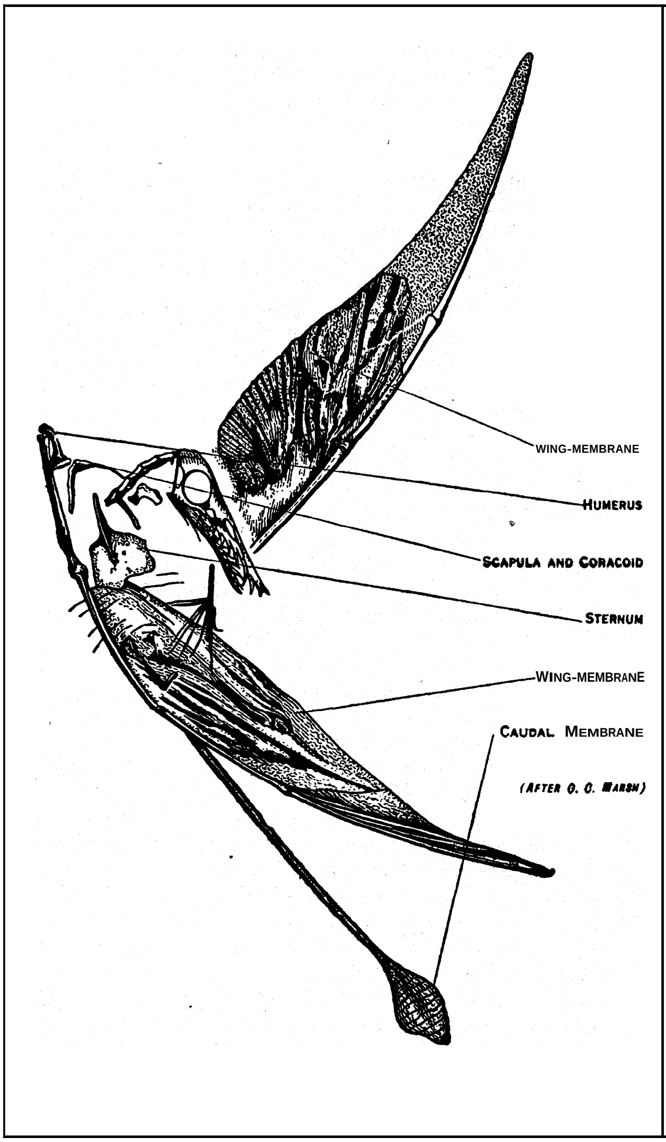

FIG. 1.—RHAMPHORHYNCHUS PHYLLURUS. FROM THE SOLENHOFEN LITHOGRAPHIC STONE, WITH THE GREATER PART OF THE WING MEMBRANE PRESERVED

the greatly elongated fore-limb, and especially by the enormously extended fourth finger, the width across the wings when fully spread is some 25 inches. The bony finger lies practically at the forward edge of the wing, the membrane which forms the rest of the structure being only some 2 in. from front to back, and passing backwards along the side of the body to the hind leg. The extremity of the tail bears a horizontal flap of membrane. The three first fingers of the hand are free and provided with large claws; they stand out in front of the wings and must have been used for holding food or for help in landing. The knees included in the wing membrane stand straight out from the side of the body, the lower leg is long and there are five slender toes, the first being always curiously bent inwards and downwards. The other four toes seem to have been connected by a web.

Rhamphorynchus was covered with a smooth skin usually without scales, but the top of the head bore a tuft of hair-like protuberances. The animal appears to have lived like a sea-gull on fish, and it is exceedingly difficult to understand how it could ever have risen from land or water after alighting.

FROM E. STRONER, "RECKONSTRUKTIONEN DES FLUGSAURIERS RHAMPHORHYNCHUS GEMMINGI" (SCHWEIZERBART, STUTTGART)
FIG. 2.— RECONSTRUCTION OF THE SKELETON AND WING MEMBRANE OF A PTERODACTYL, RHAMPHORYNCHUS, SEEN FROM BELOW

The group of tail-less pterodactyls is best represented by *Pteranodon* from the Kansas chalk. This creature had a wing-spread of 18 ft. and its head (measured from the tip of the snout to the summit of a great crest which rises from the occiput) is nearly 4 ft. in length. It was perhaps the largest flying animal of which we have any knowledge. Despite its great size it was extremely light, the wing-bones consisting of a bony layer no thicker than a visiting card, surrounding an air space which might be more than an inch in diameter; even the bone of an albatross is a crude and heavy structure in comparison. The remains of these giant animals are found in the Kansas and English chalk sufficiently commonly to show that they flew at a distance of some hundreds of miles from land. The brain of these large pterodactyls is extraordinarily like that of a bird, and its characters are such as to suggest that they practically lacked a sense of smell and depended on sight for the capture of their food.

FIG. 3.—PTERANODON GLIDING, AND ABOUT TO COMMENCE A FLIGHT

See REPTILES. (D.M.S.W.)

PTEROMA, in architecture, the colonnade at the side of a classic temple.

PTERON, in architecture, a term used by Pliny the Elder for the peristyle or colonnade of the tomb of Mausolos; loosely and rarely used for any surrounding colonnade or peristyle.

PTOLEMAEUS, of Alexandria, surnamed Chennus, Greek grammarian during the reigns of Trajan and Hadrian. According to Suïdas, he mas the author of an historical drama named *Sphinx*, of an epic, *Anthomeros*, in 24 books (both lost) and a *Strange History*. The last is probably identical with the work of which an abridgment has been preserved in Photius (*cod.* 190).

See editions of Photius's abridgment by J. Roulez (1834); and in A. Westermann, *Mythographi graeci* (1843); R. Hercher, *Über die Glaubwürdigkeit der neuen Geschichte des Ptolemaus Ckennus* (Leipzig, 1856); J. E. Sandys, *Hist. of Classical Scholarship* (2nd ed., 1906).

PTOLEMAIS, an ancient city on the coast of Cyrenaica, 70 m. N.E. of Bengasi, and 28 m. N.E. of Teuchira (Tocra). Its modern name is Tolmeita or Tolmetta. Of the city walls nothing is preserved, excepting a massive gate on the west, with two towers, at the end of the road from Barce (mod. El Merg). At the further extremity of the town is a fine Roman bridge. Little of the town remains but some very large cisterns.

See *Ministero delle Colonie, Notiziario Archeologico,* i. 114–154 (1915).

PTOLEMIES, a dynasty of Macedonian kings who ruled in Egypt from 323 to 30 B.C.

PTOLEMY I. (Πτολεμαῖος), the founder, son of Lagus, a Macedonian nobleman of Eordaea, was one of Alexander the Great's most trusted generals, and among the seven "body-guards" attached to his person. He plays a principal part in the later campaigns of Alexander in Afghanistan and India. At the Susa marriage festival in 324 Alexander caused him to marry the Persian princess Artacama; but there is no further mention of this Asiatic bride in the history of Ptolemy. When Alexander died in 323 the resettlement of the empire at Babylon is said to have been made at Ptolemy's instigation. At any rate he was now appointed satrap of Egypt under the nominal kings Philip Arrhidaeus and the young Alexander. He at once took a high hand in the province by killing Cleomenes, the financial controller appointed by Alexander the Great; he also subjugated Cyrenaïca. He contrived to get possession of Alexander's body which was to be interred with great pomp by the imperial government and placed it temporarily in Memphis. This act led to an open rupture between Ptolemy and the imperial regent Perdiccas. But Perdiccas perished in the attempt to invade Egypt (321). In the long wars between the different Macedonian chiefs which followed, Ptolemy's first object was to hold his position in Egypt securely, and secondly to possess the Cyrenaïca, Cyprus and Palestine (Coele-Syria). His first occupation of Palestine was in 318, and he established at the same time a protectorate over the petty kings of Cyprus. When Antigonus, master of Asia in 315, showed dangerous ambitions, Ptolemy joined the coalition against him, and, on the outbreak of war, evacuated Palestine. In Cyprus he fought the partisans of Antigonus and reconquered the island (313). A revolt of Cyrene was crushed in the same year. In 312 Ptolemy, with Seleucus, the fugitive satrap of Babylonia, invaded Palestine and beat Demetrius, the son of Antigonus, in the great battle of Gaza. Again he occupied Palestine, and again a few months later, after Demetrius had won a battle over his general and Antigonus entered Syria in force, he evacuated it.

In 311 a peace was concluded between the combatants, soon after which the surviving king Alexander was murdered in Macedonia, leaving the satrap of Egypt absolutely his own master. The peace did not last long, and in 309 Ptolemy commanded a fleet in person which detached the coast towns of Lycia and Caria from Antigonus and crossed to Greece, where Ptolemy took possession of Corinth, Sicyon and Megara (308). In 306 a great fleet under Demetrius attacked Cyprus, and Ptolemy's brother, Menelaus, was defeated and captured in the decisive battle of Salamis. The complete loss of Cyprus followed. Antigonus and Demetrius now assumed the title of kings; Ptolemy, as well as Cassander, Lysimachus and Seleucus, answered this challenge by doing the same. In the winter (306–5) Antigonus tried to follow up the victory of Cyprus by invading Egypt, but here Ptolemy was strong, and held the frontier successfully against him. Ptolemy led no further expedition against Antigonus overseas. To the Rhodians, besieged by Demetrius (305–4), he sent such help as won him divine honours in Rhodes and the surname of Soter ("saviour"). When the coalition was renewed against Antigonus in 302, Ptolemy joined it, and invaded Palestine a third time, whilst Antigonus was engaged with Lysimachus in Asia Minor. On a report that Antigonus had won a decisive victory, for a third time he evacuated the cduntry. But when news came that Antigonus had been defeated and slain at Ipsus (301) by Lysimachus and Seleucus, Ptolemy occupied Palestine for the fourth time. The other members of the coalition had assigned Palestine to Seleucus after what they regarded as Ptolemy's desertion, and for the next hundred years the question of its ownership becomes the standing ground of enmity between the Seleucid and Ptolemaïc dynasties. Henceforth, Ptolemy seems to have mingled as little as possible in the broils of Asia Minor and Greece; his possessions in Greece he did not retain, but Cyprus he reconquered in 295–4. Cyrene, after a series of rebellions, was finally subjugated about 300 and placed under his stepson Magas (Beloch, Griech. Gesch. III. [ii.], p. 134 seq.).

In 285 he abdicated in favour of one of his younger sons by Berenice (*q.v.*), who bore his father's name of Ptolemy; his eldest (legitimate) son, Ptolemy Ceraunus, whose mother, Eurydice, the daughter of Antipater, had been repudiated, fled to the court of Lysimachus. Ptolemy I. Soter died in 283 at the age of 84. Shrewd and cautious, he had a compact and well-ordered realm to show at the end of fifty years of wars. His name for bonhomie and liberality attached the floating soldier-class of Macedonians and Greeks to his service. Nor did he neglect conciliation of the natives. He was a ready patron of letters, and the great library, which was Alexandria's glory, owed to him its inception. He wrote himself a history of Alexander's campaigns, distinguished by its straightforward honesty and sobriety.

PTOLEMY II. PHILADELPHUS (309–246) was of a delicate constitution, no Macedonian warrior-chief of the old style. His brother Ptolemy Ceraunus found compensation by becoming king in Macedonia in 281, and perished in the Gallic invasion of 280–79. (See BRENNUS.) Ptolemy II. maintained a splendid court in Alexandria. Not that Egypt held aloof from wars. Magas of Cyrene opened war on his half-brother (274), and Antiochus I., the son of Seleucus, desiring Palestine, attacked soon after. Two or three years of war left Egypt the dominant naval power of the eastern Mediterranean; the Ptolemaïc sphere of power extended over the Cyclades to Samothrace, and the harbours and coast towns of Cilicia Trachea ("Rough Cilicia"), Pamphylia, Lycia and Caria were largely in Ptolemy's hands (Theoc. Idyll. xvii. 86 seq.). The victory won by Antigonus, king of Macedonia, over his fleet at Cos (between 258–56; see Beloch, III. [ii.], p. 428 seq.) did not long interrupt his command of the Aegean. In a second war with the Seleucid kingdom, under Antiochus II. (after 260), Ptolemy sustained losses on the seaboard of Asia Minor and agreed to a peace by which Antiochus married his daughter Berenice (250?). Ptolemy's first wife, Arsinoe (I.), daughter of Lysimachus, was the mother of his legitimate children. After her repudiation he married, probably for political reasons, his full-sister Arsinoe (II.), the widow of Lysimachus, by an Egyptian custom abhorrent to Greek morality. The material and literary splendour of the Alexandrian court was at its height under Ptolemy II. Pomps and gay religions flourished. Ptolemy deified his parents as the θεοὶ ἀδελθοί and his sister-wife, after her death (270), as *Philadelphus*. This surname was used in later generations to distinguish Ptolemy II. himself, but properly it belongs to Arsinoe only, not to the king. Callimachus, made keeper of the library, Theocritus, and a host of lesser poets, glorified the Ptolemaïc family. Ptolemy himself was eager to increase the library and to patronize scientific research. He had the strange beasts of far-off lands sent to Alexandria. But, an enthusiast for Hellenic culture, he seems to have shown but little interest in the native religion. The tradition which connects the Septuagint translation of the Old Testament into Greek with his name is not historical. Ptolemy had many brilliant mistresses, and his court, magnificent and dissolute, intellectual and artificial, has been justly compared with the Versailles of Louis XIV.

PTOLEMY III. EUERGETES I. (reigned 246–221), son of Ptolemy II. and Arsinoe I. At the beginning of his reign he reunited the Cyrenaïca to Egypt by marrying Berenice the daughter and successor of Magas (who had died about 250). At the same time he was obliged to open war on the Seleucid kingdom, where Antiochus II. was dead and his sister Berenice had been murdered, together with her infant son, by Antiochus's former wife, Laodice, who claimed the kingdom for her son Seleucus II. Ptolemy marched triumphantly into the heart of the Seleucid realm, as far at any rate as Babylonia, and received the formal submission of the provinces of Iran, while his fleets in the Aegean recovered what his father had lost upon the seaboard, and made fresh conquests as far as Thrace. This moment marks the zenith of the Ptolemaïc power. After Ptolemy returned home, indeed, Seleucus regained northern Syria and the eastern provinces, but the naval predominance of Egypt in the Aegean remained, although there are traces of its being replaced locally, towards the end of Euergetes' reign, by that of Macedonia—in Amorgos, Naxos, Syros, Nisyros, Cos and parts of Crete. (See Beloch, III. [ii.], p. 463.) After his final peace with Seleucus, Ptolemy no longer engaged actively in war.,

PTOLEMY IV. PHILOPATOR (reigned 221–204), son of the preceding, was a wretched debauchee under whom the decline of the Ptolemaïc kingdom began. His reign was inaugurated by the murder of his mother, and he was always under the dominion of *favourites, male and female, who indulged his vices and conducted the government as they pleased. Self-interest led his ministers to make serious preparations to meet the attacks of Antiochus* III. *(the Great) on Palestine, and the great Egyptian victory of Raphia* (217), at *which Ptolemy himself was present, secured the province till the next reign. The arming of Egyptians in this campaign had a disturbing effect upon the native population of Egypt, so that rebellions were continuous for the next thirty years. Philopator was devoted to orgiastic forms of religion and literary dilettantism. He built a temple to Homer and composed a tragedy, to which his vile favourite Agathocles added a commentary. He married (about* 215) *his sister Arsinoe (III.), but continued to be ruled by his mistress Agathoclea, sister of* Agathocles.

PTOLEMY *V.* EPIPHANES *(reigned* 204–181), *son of Philopator and Arsinoe, was not more than five years old when he came to the throne, and under a series of regents the* kingdom *was paralysed. Antiochus* III. *and Philip V. of Macedonia made a compact to divide the Ptolemai'c possessions overseas. Philip seized several islands and places in Caria and Thrace, whilst the battle of* Panium (198) *definitely* transferred *Palestine frurn* the *Ptolemies to the Seleucids. Antiochus after this concluded peace, giving his own daughter Cleopatra to Epiphanes to wife* (193–192). *Nevertheless, when war broke out between Antiochus and Rome Egypt ranged itself with the latter power. Epiphanes in manhood was chiefly remarkable as a passionate sportsman; he excelled in athletic exercises and the chase.*

PTOLEMY *VI.* PHILOMETOR (181–145), *the elder of his two sons, succeeded as an infant under the regency of his mother Cleopatra. Her death was followed by a rupture between the Ptolemai'c and Seleucid courts, on the old question of Palestine. Antiochus IV. Epiphanes invaded Egypt* (170) *and captured Philometor.*

The Alexandrians then put his younger brother PTOLEMY *VII.* EUERGETES II. *(afterwards nicknamed Physkon, on account of his bloated appearance) upon the throne. Antiochus professed to support Philometor, but, when he withdrew, the brothers agreed to be joint-kings with their sister Cleopatra as queen and wife of Philometor. Antiochus again invaded Egypt* (168), *but was compelled by the Roman intervention to retire. The double kingship led to quarrels between the two brothers in which fresh appeals were* continually *made to Rome. In 163 the Cyrenai'ca was assigned under Roman arbitration to Euergetes as a separate kingdom. As he coveted Cyprus as well, the feud still went on, Rome continuing to interfere diplomatically but not effectively. In* 154 *Euergetes invaded Cyprus but was defeated and captured by Philometor. He found his brother, however, willing to pardon and was allowed to return as king to Cyrene. In* 152 *Philometor joined the coalition against the Seleucid king Demetrius I. and was the main agent in his destruction. The* protégé *of the coalition, Alexander* Balas, *married Philometor's daughter Cleopatra (Thea), and reigned in Syria in practical subservience to him. But in* 147 *Philometor broke with him and transferred his support, together with the person of Cleopatra, to Demetrius II., the young son of Demetrius I. He himself at Antioch was entreated by the people to assume the Seleucid diadem, but he declined and installed Demetrius as king. In 145 in the battle on the* Oenoparas *near Antioch, in which Alexander Balas was finally defeated, Philometor received a mortal wound. Philometor was perhaps the best of the Ptolemies. Kindly* and *reasonable, his good nature seems sometimes to have verged on indolence, but he at any rate took personal part, and that bravely and successfully, in war. Philometor's infant son, Ptolemy Philopator Neos (?)*[1]*, was proclaimed king in Alexandria under the regency of his mother Cleopatra. Euergetes however, swooping from Cyrene, seized the throne and married Cleopatra, making away with his nephew. He has left an odious picture of himself in the historians—a man untouched by benefits or natural affection, delighting in deeds of blood, his body as loathsome in its blown corpulence as his soul. Something must be allowed for the rhetorical habit of our authorities, but that Euergetes was ready enough to shed blood when policy required seems true. He soon found a more agreeable wife than Cleopatra in her daughter Cleopatra, and thenceforth antagonism between the two queens, the "sister" and the "wife," was chronic. In* 130–1 *Cleopatra succeeded in driving Euergetes for a time to Cyprus, when he revenged himself by murdering the son whom she had borne him (surnamed Memphites). Massacres inflicted upon the Alexandrians and the expulsion of the representatives of Hellenic culture are laid to his charge. On the other hand, the monument and papyri show him a liberal patron of the native religion and a considerable administrator. In fact, while hated by the Greeks, he seems to have had the steady support of the native population. But there are also records which show him, not as an enemy, but a friend, like his ancestors, to Greek culture. He himself published the fruit of his studies and travels in a voluminous collection of notebooks, in which he showed a lively eye for the oddities of his fellow kings. The old Ptolemai'c realm was never again a unity after the death of Euergetes* II. *By his will he left the* Cyrenaïca *as a* separate *kingdom to his illegitimate son Ptolemy Apion* (116–96), *whilst Egypt and Cyprus were bequeathed to Cleopatra (Kokke) and whichever of his two sons by her,* PTOLEMY *VIII. Soter* II. *(nicknamed Lathyros) and* PTOLEMY *IX. Alexander I., she might choose as her associate. The result was, of course, a long period of domestic strife. From 116 to* 108 *Soter reigned with his mother, and at enmity with her, in Egypt, whilst her favourite son, Alexander, ruled Cyprus. Cleopatra compelled Soter to divorce his sister-wife Cleopatra and marry another sister, Selene. Cleopatra plunged into the broils of the Seleucid house in Syria and perished. In* 108 *Cleopatra Kokke called Alexander to Egypt, and Soter flying to Cyprus took his brother's place and held the island against his mother's forces. The attempts which Soter and Cleopatra respectively made in* 104–3 *to obtain a predominance in Palestine came to nothing. Alexander now shook off his mother's yoke and married Soter's daughter Berenice. Cleopatra Kokke died in* 101 *and from then till 89 Alexander reigned alone in Egypt. In 89 he was expelled by a popular uprising and perished the following year in a sea-fight with the Alexandrian ships off Cyprus. Soter was recalled (88) and reigned over Egypt and Cyprus, now reunited, in association with his daughter Berenice. This, his second, reign in Egypt* (88–80), *was marked by a native rebellion which issued in the destruction of Thebes.*

PTOLEMY *X.* ALEXANDER II.—*On his death* Berenice *assumed the government, but the son of Alexander I., Ptolemy X., entering Alexandria under Roman patronage, married, and within* 20 *days assassinated, his elderly cousin and stepmother. He was at once killed by the enraged people and with him the Ptolemai'c family in the legitimate male line became extinct. Ptolemy Apion meanwhile, dying in 96, had bequeathed the Cyrenai'ca to Rome.*

The Alexandrian people now chose an illegitimate son of Soter II. *to be their* king, PTOLEMY *XI. Philopator Philadelphus Neos Dionysus* (80–51), *nicknamed Auletes, the flute-player, setting his brother as king in Cyprus. The rights of these kings were doubtful, not only because of their illegitimate birth, but because it was claimed in Rome that Alexander* II. *had bequeathed his kingdom to the Roman people. Two Seleucid princes, children of Soter's sister Selene, appeared in Rome in 73 to urge their claim to the Ptolemai'c throne. Ptolemy Auletes was thus obliged to spend his reign in buying the support of the men in power in Rome. Cyprus was annexed by Rome in* 58, *its king committing suicide. From 58 to* 55 *Auletes was in exile, driven out by popular hatred, and* worked *by bribery and murder in Rome to get himself restored to Roman power. His daughter* Berenice *meanwhile reigned in Alexandria, a husband being found for her in the Pontic prince Archelaus. In 55 Auletes was restored by the proconsul of Syria, Aulus Gabinius. He killed* Berenice *and, dying in* 51, *bequeathed the kingdom to his eldest son, aged ten years, who was to take as wife his sister Cleopatra, aged seventeen.*

In the reign of PTOLEMY *XII. Philopator* (51–47) *and* Cleo*patra Philopator, Egyptian history coalesces with the general*

[1]Or according *to another* view, Eupator. *On the obscure questions* raised *by* these two *surnames. see* L. Pareti, ***Ricerche sui*** *Tolemei Eupatore e* ***Neo Filopatore*** *(Turin,*1908).

history of the Roman world, owing to the murder of Pompey off Pelusium in 48 and the Alexandrine War of Julius Caesar (48–47).

In that war the young king perished and a still younger brother, PTOLEMY XIII. Philopator, was associated with Cleopatra till 44, when he died, probably by Cleopatra's contriving. From then till her death in 30, her son, born in 47, and asserted by Cleopatra to be the child of Julius Caesar, was associated officially with her as PTOLEMY XIV. Philopator Philometor Caesar; he was known popularly as Caesarion. (For the incidents of Cleopatra's reign see CLEOPATRA, ARSINOË.) After her death in 30 and Caesarion's murder Egypt was made a Roman province. Cleopatra's daughter by Antony (Cleopatra Selene) was married in 25 to Juba II. of Mauretania. Their son Ptolemy, who succeeded his father (A.D. 23–40), left no issue[1].

(E. R. B.)

PTOLEMY (CLAUDIUS PTOLEMAEUS), of Alexandria, the celebrated mathematician, astronomer and geographer, was, according to the Byzantine Theodorus Meliteniota (*c.* 1361), born at Ptolemais Hermii, a Grecian city of the Thebaid. All that is known for certain about him is that he observed at Alexandria during the reigns of Hadrian and Antoninus Pius, between the years A.D. 127 and 141 or 151. Olympiodorus, a philosopher of the Neoplatonic school, who lived in the reign of the emperor Justinian, relates in his scholia on the *Phaedo* of Plato that Ptolemy devoted his life to astronomy and lived for 40 years in the so-called Πτερὰ τοῦ Κανώβου, probably elevated terraces of the temple of Serapis at Canopus, near Alexandria, where they raised pillars with the results of his astronomical discoveries engraved upon them. Arabian traditions say that Ptolemy lived to the age of 78 years, and give some details about his personal appearance, to which too much weight must not be attached.

His Work as a Mathematician.—Ptolemy's work as a geographer is discussed below, and an account of the discoveries in astronomy of Hipparchus and Ptolemy is given in the article ASTRONOMY: History. Their contributions to pure mathematics, however, require to be noticed here. Of these the chief is the foundation of trigonometry, plane and spherical, including the formation of a table of chords, which served the same purpose as our table of sines. This branch of mathematics was created by Hipparchus for the use of astronomers, and its exposition was given by Ptolemy in a form so perfect that for 1,400 years it was not surpassed. The doctrine as to the motion of the heavenly bodies known as the Ptolemaic system, was paramount for about the same period of time. The astronomical and trigonometrical systems are contained in the great work of Ptolemy, Ἡ μαθηματικὴ σύνταξις or The Mathematical Collection. Later it came to be known as the μεγάλη σύνταξις or alternatively as Ὁ μέγας ἀστρονόμος, the Great Astronomer, to distinguish it from another collection called Ὁ μικρὸς ἀστρονόμος or ἀστρονομούμενος, the Little Astronomer, comprising some works of Autolycus, Euclid, Aristarchus, Theodosius, Hypsicles and Menelaus. To designate the great work of Ptolemy, the Arabs used the superlative μεγίστη from which, the article *al* being prefixed, the hybrid name *Almagest*, by which it has ever since been known, is derived.

We proceed now to consider the trigonometrical work of Hipparchus and Ptolemy. In the ninth and tenth chapters of the first book of the Almagest Ptolemy shows how to form a table of chords. He supposes the circumference divided into 360 equal parts (τμήματα or degrees). Further, he divides the diameter into 120 equal parts. Then, for the subdivision both of the degrees and of the parts of the diameter, he uses sexagesimal fractions or, as we say, "minutes," "seconds," etc. It must not be supposed, however, that these sexagesimal divisions are due to Ptolemy; Babylonian in origin, they must already have been used by Hipparchus. Nor did the formation of the table of chords originate with Ptolemy; indeed, we know that Hipparchus wrote a treatise in 12 books on straight lines (chords) in a circle, while Menelaus (c. A.D. 100) wrote another in six books. Ptolemy shows how the calculation of chords is based on a few simple theorems in geometry (including the well-known "Ptolemy's theorem" relating to a quadrilateral inscribed in a circle), and these he gives in a form which for conciseness and elegance could not be surpassed; Hipparchus' method was no doubt the same, though his exposition would run to greater length.

As starting-point the values of certain chords in terms of the diameter were already known, or could be easily found by means of the Elements of Euclid. Thus the side of the hexagon, or the chord of 60°, is equal to the radius, and therefore contains 60 parts. The sides of the regular pentagon and decagon inscribed in a circle, which are the chords subtending arcs of 72" and 36" respectively, are found by means of propositions in Euclid's Book xiii.; expressed in terms of the "parts" of the diameter, they are found to be (nearly) $70^p\ 32'\ 3''$ and $37^p\ 4'\ 55''$ respectively. (It should be noted that the ratio of the chord subtending any angle to the diameter of the circle is the same as the ratio of half the chord to the radius; hence, expressed on this system, the chord of any angle is equivalent to the trigonometrical sine of half the angle.)

Now "Ptolemy's Theorem" enables us to deduce from the chords of two angles the chord of their sum or difference; the theorem is equivalent to the formulae $\mathrm{Sin}(A+B)=\mathrm{Sin}A\ \mathrm{Cos}\ B+\mathrm{Cos}\ A\mathrm{Sin}B$. Another proposition which Ptolemy gives, shows how to deduce from the chord of any angle the chord of half the angle; it is equivalent to the formula $\mathrm{Sin}^2\ \frac{1}{2}\theta=\frac{1}{2}(1-\mathrm{Cos}\theta)$. Yet another proposition gives the equivalent of $\mathrm{Sin}^2\theta+\mathrm{Cos}^2\theta=1$. As we know the lengths of (crd. 72°) and (crd. 60°), we deduce (crd. 12°); from this we deduce successively the chords of 6°, 3°, $1\frac{1}{2}°$ and $\frac{3}{4}°$, and again from these (by "Ptolemy's Theorem") the chords of $4\frac{1}{2}°$, $7\frac{1}{2}°$, 9°, $10\frac{1}{2}°$ etc.; we have therefore a table of chords going by gradations of $1\frac{1}{2}°$. It remains to find the chord of 1", and thence the chord of $\frac{1}{2}°$, in order to obtain a table going by gradations of $\frac{1}{2}°$. To find (crd. 1") Ptolemy uses a clever method of "interpolation" based on a proposition already assumed as known by Aristarchus of Samos (*fl.* 280 B.C.) and equivalent to the trigonometrical formula $\mathrm{Sin}\,\alpha/\mathrm{Sin}\beta<\alpha/\beta$ (where $\frac{1}{2}\pi>\alpha>\beta$). It follows from the proposition in question that (crd. 1") : (crd. $\frac{3}{4}°$) $<1 : \frac{3}{4}$ and (crd. $1\frac{1}{2}°$) : (crd. 1°) $<1\frac{1}{2} : 1$, whence $\frac{4}{3}$(crd. $\frac{3}{4}°$) $>$ (crd. 1") $>\frac{2}{3}$ (crd. $1\frac{1}{2}°$). Now Ptolemy has found (crd. $\frac{3}{4}°$) to be $0^p\ 47'\ 8''$ and (crd. $1\frac{1}{2}°$) to be $1^p\ 34'\ 15''$. Thus $\frac{4}{3}$ of the former is $1^p\ 2'\ 50''$ nearly (actually $1^p\ 2'\ 505''$) and $\frac{2}{3}$ of the latter is $1^p\ 2'\ 50''$. Thus (crd. 1"), being both greater and less than $1^p\ 2'\ 50''$, may be taken to be $1^p\ 2'\ 50''$ as nearly as possible. Ptolemy deduces that (crd. $\frac{1}{2}°$) is very nearly $0^p\ 31'\ 25''$; and he is therefore in a position to complete his table going by gradations of $\frac{1}{2}$ a degree. No wonder that De Morgan called this exposition "one of the most beautiful in the Greek writers." Ptolemy further uses the same method of proportional increase ("interpolation") to find the chords of angles containing a number of odd minutes between 0′ and 30′, inserting in the table opposite each chord, in a third column, $\frac{1}{30}$ of the excess of that chord over the one before. One particular result is worth quoting. Since (crd. 1") is found to be $1^p\ 2'\ 50''$, the whole circumference $=360\times(1^p\ 2'\ 50'')$ nearly, and, the length of the diameter being 120^p it follows that $\pi=3\times(1+\frac{2}{60}+\frac{50}{3600})$ or $(3+\frac{8}{60}+\frac{30}{3600})$, which is equivalent to $\pi=3{\cdot}14166$.

Trigonometry, as we have seen, was created by Hipparchus for the use of astronomers. Now, since spherical trigonometry is directly applicable to astronomy, it is not surprising that its development was prior to that of plane trigonometry.

Ptolemy obtains all that he wants in the shape of spherical trigonometry from the one fundamental proposition known as "Menelaus' Theorem" applied to the sphere, a theorem concerning the segments into which the sides of a spherical triangle are cut by a transversal. Menelaus gave the proof in his *Sphaerica*, iii. 1. Ptolemy gives it with two simple propositions on which it depends in the *Syntaxis* i. 13; the proof assumes as known the corre-

[1] The Ptolemies were not in antiquity distinguished by the ordinal numbers affixed to their names by modern scholars and represented according to the usual convention by Roman figures. This is merely done for our convenience. In the case of the later Ptolemies different systems of notation prevail according as the problematic Eupator and Philopator Neos are reckoned in or not.

sponding proposition for a plane triangle. The theorem for the sphere, though called by the name of Menelaus, must certainly have been known to Hipparchus, while the theorem for the plane triangle at least was probably known to Euclid. When Ptolemy requires the equivalent of one of our formulae in the solution of spherical triangles, he does not quote such propositions but proves them afresh each time by means of Menelaus' theorem. These various applications include the equivalent of such formulae for a right-angled spherical triangle as (1) $\text{Sin}\,a = \text{Sin}\,c\ \text{Sin}\,A$, (2) $\text{Tan}\,a = \text{Sin}\,b\ \text{Tan}\,A$, (3) $\text{Cos}\,c = \text{Cos}\,a\ \text{Cos}\,b$, and (4) $\text{Tan}\,b = \text{Tan}\,c\ \text{Cos}\,A$.

We are, above all, indebted to Ptolemy for very full particulars of observations and investigations by Hipparchus as well as of the earlier observations which Hipparchus recorded, *e.g.*, that of a lunar eclipse in 721 B.C. The work of Ptolemy is, in general, evidently based upon Hipparchus to a degree that makes it far from easy to identify Ptolemy's own contributions to the subject, except where he propounds a definite theory of the motions of the five planets, for which Hipparchus had only collected material in the shape of observations made before his time or by himself.

The **"Syntaxis."**—The contents of the *Syntaxis* can here be only very briefly indicated. Book i. contains the indispensable preliminaries to the study of the Ptolemaic system, treating of the earth, its spherical shape and its position in the centre of the universe, the circular movements of the heavenly bodies, the propositions required for the preparation of the Table of Chords, this table itself, the angle of obliquity of the ecliptic and Ptolemy's own method of determining it, and, lastly, so much of spherical geometry and trigonometry as is necessary for the determination of the connection between a star's right ascension, declination, latitude and longitude, and for the formulation of a table of declinations to each degree of longitude. Book ii. contains matter similar to that of Autolycus' On the Moving Sphere, *i.e.*, problems on the sphere, with special reference to the difference between various latitudes, the length of the longest day at any degree of latitude, and the like. Book iii. treats of the length of the year and the motion of the sun on the eccentric and epicycle hypothesis. Ptolemy observes that, to understand the difficulties of the question, we should read the treatises of the ancients, and especially those of Hipparchus, "that enthusiastic worker and lover of truth." He mentions here Hipparchus' discovery of the precession of the equinoxes (a subject to which he returns in viii. 2). In chapter 1, Ptolemy also lays down some general principles which are worth quoting, namely, (1) that, in seeking to explain phenomena, we should adopt the simplest possible hypothesis, provided that it is not contradicted in any important respect by the observations; (2) that in investigations depending on observations in which great delicacy is required, we should select those made at long intervals of time in order that the error due to the imperfection of our instruments may be lessened by being distributed over a large number of years. Book iv. deals with the length of the months and the motions of the moon, and Book v. with the same subject continued, the construction of the astrolabe, the diameters of the sun, the moon and the earth's shadow, the distance of the sun, and the dimensions of the sun, moon and earth. Book vi. is on the conjunctions and oppositions of the sun and moon, solar and lunar eclipses and the periods of their recurrence. Books vii. and viii. treat of the fixed stars, including precession. Book vii. ends with the catalogue (arranged under constellations) of the stars in the northern hemisphere, in which are entered the latitudes, longitudes and magnitudes; Book viii. begins with a similar catalogue for the southern hemisphere; the two catalogues include 1,022 separate stars as compared with the 850 or more included in Hipparchus' catalogue. Book viii. also describes the Milky Way and the construction of a celestial globe. Books ix. to xiii. are devoted to the planets. Book ix. begins with general remarks on the order of the planets, the difficulties in the way of framing a theory of the subject, the periods of revolution of the five planets, the different hypotheses that are possible; then (ch. 7) Ptolemy passes to the separate case of Mercury. Book x. treats of Venus; Book xi. of Jupiter and Saturn; Book xii. deals with the stationary points and retrogradations of each of the planets, and with the greatest elongations of Mercury and Venus; Book xiii. considers the motions of the planets in latitude, the inclination of their orbits and its magnitude.

The *Syntaxis* early became the subject of commentaries. For Book vi. and part of Book v. the commentary of Pappius is extant in Greek. Theon of Alexandria's commentary in 11 books was first published by Joachim Camerarius of Basle in 1538; the first two books were appended by Halma to his edition of Ptolemy. The *Syntaxis* was translated into Arabic for the Caliph al-Ma'mūn, himself an astronomer, by a translator unnamed, in 827; later it was translated by al-Hajjāj, the translator of Euclid, and again by Isḥāq b. Hunain (or perhaps his father Hunain b. Isḥāq), whose translation was revised by Thābit b. Qurra (d. 901). The first Latin translation was made from the Arabic by Gherard of Cremona; this translation, finished in 1175, was first published by P. Liechtenstein at Venice in 1515, but without the author's name. George of Trebizond made the first Latin translation from the Greek in 1451; this was revised and published by Lucas Gauricus at Venice in 1528. The editio *princeps* of the Greek text was brought out by Simon Grynaeus at Basle in 1538. The next complete edition was Halma's (1813–16). All former Greek texts are now superseded by Heiberg's edition of the astronomical works of Ptolemy (1899–1907) to which, so far as the *Syntaxis* is concerned, a German translation by Manitius has been added (1912–13).

Other Mathematical Works.—Of the other works of Ptolemy the following should be mentioned: (1) the Analemma, the object of which is to explain a method of representing on one plane the different points and arcs of the heavenly sphere by orthogonal projection on three planes mutually, at right angles, the meridian, the horizon and the "prime vertical." The problem is to find the position of the sun at a given hour of the day. Only a few fragments remain of the Greek text, but we have a Latin translation by William of Moerbeke from an Arabic version. This translation was edited with a valuable commentary by Commandinus (1562); and Heiberg has included it, with the Greek fragments alongside (where extant), in vol. ii. of his edition of the astronomical works. (2) The *Planisphaerium* survives in a Latin translation from the Arabic, which was edited by Commandinus in 1558 and is likewise included in Heiberg's vol. ii. The book is an explanation of a system of projection known as "stereographic," by which points on the heavenly sphere are represented in the plane of the equator by projection from one point, a pole. The pole taken by Ptolemy is the south pole. (3) *Φάσεις ἀπλανῶν ἀστέρων*. This is a calendar of the sort which the Greeks called *parapegma*, or a table of the risings and settings of stars in morning and evening twilight, with weather-indications (*ἐπισημασίαι*). (4) *Ὑποθέσεις τῶν πλανωμένων*, Planetary Hypotheses, in two books, the first of which is extant in Greek, the second in Arabic only. These works are also included in Heiberg's vol. ii.

Two separate geometrical works are mentioned by ancient commentators, (1) a single book *Περὶ διαστάσεως*, On Dimension, in which Ptolemy apparently tried to prove that there are only three dimensions in space; (2) a tract containing an attempt to prove Euclid's Parallel Postulate. The gist of the latter tract is given by Proclus in his Commentary on Euclid, Book i. (ed. Friedlein, 1873). Simplicius mentions a mechanical work *Περὶ ῥοπῶν*, On *Balancings*, while Suidas credits Ptolemy with three books on Mechanics.

The Optics of Ptolemy exists (save for Book i. and the end of Book v. which are lost) in a Latin translation made by a certain Admiral Eugenius Siculus from the Arabic in the 12th century. It was in five books, the last of which is interesting because it contains what is apparently the first recorded attempt at a theory of refraction of luminous rays through media of different densities; it deals also with astronomical refraction, of which it gives a better account than that of any astronomer before Cassini.

Lastly, Ptolemy wrote Harmonica in three books, a treatise on music. This was edited in Greek and Latin by John Wallis (1682); it appeared also with Porphyry's commentary, in *Johannis Wallis* Opera *Mathematica* (1699), vol. iii.

For further particulars the reader may refer to the article on Ptolemy in Smith's *Dictionary of Greek and Roman Biography*, vol. iii. (by De Morgan); Delambre's *Histoire de l'astronomie ancienne* (1817–21) vol. ii.; Rud-Wolf, *Geschichte der Astronomie* (1877); A. Berry, *A Short History of Astronomy* (1898); and for the mathematics to A. von Braunmühl, *Geschichte der Trigonometrie* (1900); Gino Loria, *Le scienze esatte nell' antica Grecia* (1914); and Sir T. L. Heath, *History of Greek Mathematics* (1921) vol. ii.

His **Work** as a Geographer.—Ptolemy is hardly less celebrated as a geographer than as an astronomer, and his **Γεωγραφικὴ ὑφήγησις** (or Guide to Geography) exercised as great an influence on geographical progress (especially during the period of the Classical Renaissance), as did his *Almagest* on astronomical. Its exceptional position was largely due to its scientific form, which rendered it convenient and easy of reference; but, apart from this, it was really the most considerable attempt of the ancient world to place the study of geography on a scientific basis. The astronomer Hipparchus had indeed pointed out, three centuries before Ptolemy, that the only way to construct a trustworthy map of the inhabited world would be by observations of the latitude and longitude of all the principal points on its surface. But the materials for such a map were almost wholly wanting, and, though Hipparchus made some approach to a correct division of the known world into zones of latitude, "climates" or *klimata,* as he termed them, trustworthy observations of latitude were then very few, while the means of determining longitudes hardly existed. Hence probably it arose that no attempt was made to follow up the suggestion of Hipparchus until Marinus of Tyre, who lived shortly before Ptolemy, and whose work is known to us only through the latter. Marinus' scientific materials being inadequate, he contented himself mostly with determinations derived from itineraries and other rough methods, such as are still employed where more accurate means of determination are not available. The greater part of Marinus' treatise was occupied with the discussion of his authorities, and it is impossible, in the absence of the original work, to decide how far his results attained a scientific form. But Ptolemy himself considered them, on the whole, so satisfactory that he made his predecessor's work the basis of his own in regard to all the Mediterranean countries, that is, in regard to almost all those regions of which he had definite knowledge. In the more remote regions of the world, Ptolemy availed himself of Marinus' information, but with reserve, and he explains the reasons that induced him sometimes to depart from his predecessor's conclusions. Among other things Ptolemy's work shows the increased knowledge of Asia and Africa acquired since Strabo and Pliny.

As an astronomer, Ptolemy was, of course, better qualified to explain the mathematical conditions of the earth and its relations to the celestial bodies than most preceding geographers. His general views had much in common with those of Eratosthenes and Strabo. He adopted from Hipparchus the division of the equatorial circle into 360 parts (our degrees), and supposed other circles (meridians) to be drawn through this, from the equator to the pole. Another set of circles was the series of parallels of latitude, and within the network of parallels of latitude and meridians of longitude it was Ptolemy's task to place the outline of the world, so far as known to him.

But at the very outset of his attempt he fell into an error vitiating all his conclusions. Eratosthenes (c. 276–196 B.C.) was the first who had attempted scientifically to determine the earth's circumference, and his result of 250,000 (or 252,000) stadia, *i.e.,* 25,000 (25,200) geographical miles, was generally adopted by subsequent geographers, including Strabo. Posidonius, however (*c.* 135–50 B.C.), reduced this to 180,000, and the latter computation was inexplicably adopted by Marinus and Ptolemy. This error made every degree of latitude or longitude (measured at the equator) equal to only 500 stadia (50 geographical miles), instead of its true equivalent of 600 stadia. The mistake would have been somewhat neutralized had there existed a sufficient number of points of which the position was fixed by observation; but we learn from Ptolemy himself that such observations for latitude were very few, while the means of determining longitudes were almost wholly wanting. Hence the positions laid down by him were, with few exceptions, the result of computations from itineraries and the statements of travellers, which, owing to the want of instruments, etc., were liable to much greater error in ancient times than at the present day. But, great as were the errors resulting from such imperfect means of calculation, they were increased by the permanent error arising from Ptolemy's system of graduation. Thus, if he concluded (from itineraries) that two places were 5,000 stadia distant, he would place them 10° apart, and thus in fact separate them by 6,000 stadia.

Ptolemy followed Marinus in taking, as his prime meridian from which to measure longitudes, a line drawn through the supposed position of the Fortunate islands (vaguely answering to the Canaries *plus* the Madeira group) which they placed $2\frac{1}{2}°$ (instead of 9° 20') west of the Sacred promontory (*i.e.,* Cape St. Vincent, regarded by Marinus and Ptolemy, as by previous geographers, as the westernmost point of Europe). Hence all Ptolemy's longitudes, reckoned eastwards, were about 7" less than they would have been if really measured from the meridian of Ferro, which continued so long in use.

The problem that had especially attracted the attention of geographers from Dicaearchus to Ptolemy was to determine the length and breadth of the inhabited world. This question had been fully discussed by Marinus, who had arrived at conclusions widely different from his predecessors. Towards the north, indeed, there was no great difference of opinion, the latitude of Thule being generally recognized as that of the highest northern land, and this was placed both by Marinus and Ptolemy in 63" N., not far beyond the true position of the Shetland islands, which had come to be generally identified with the mysterious Thule of Pytheas. The western extremity, as already mentioned, had been in like manner determined by the prime meridian drawn through the supposed position of the outermost of the Fortunate islands. But towards the south and east Marinus gave an enormous extension to Africa and Asia, beyond what had been known to or suspected to exist by earlier geographers, and, though Ptolemy reduced Marinus' calculations, he retained an exaggerated estimate of their results.

Contents **of the** "Guide to Geography."—In Book i., after general explanations (cc. 1–6), Ptolemy applies himself to a correction of Marinus' results, taking account (1) of the observed (astronomical) phenomena, (2) of the various recorded itineraries of travel (a) by land and (b) by sea. Marinus had assumed as the limit of knowledge to the south a region in Africa called Agisymba, inhabited by Ethiopians and abounding in rhinoceroses, which had been reached by Julius Maternus. Modifying the data regarding this journey, Marinus placed Agisymba on the southern tropic. This made the "breadth" of the inhabited world from Thule to Agisymba $63°+24°=87°$. Ptolemy, on the other hand, placed Agisymba and a certain promontory called Prason on a parallel as far south as Meroe is north of the equator; taking, then, the southern limit to be 16" 25' S., he finds the "breadth" of the inhabited earth to be $63°+16°\ 25'=79°\ 25'$, in round figures 80°, or 40,000 stades.

Marinus' estimate of the "length" of the inhabited earth overland (from west to east) may be stated in three parts, (1) from the "Fortunate islands" to Hierapolis on the Euphrates 28,800 stades, (2) from Hierapolis to the "Stone Tower" (near the Pamir?) 26,280, and (3) from the "Stone Tower" to Sera, the capital of the Serae (? inland China), 36,200 stades, making 91,280 stades in all. Ptolemy reduced the last two estimates to 24,000 and 18,100 respectively, thus arriving at a total of 70,900 stades. Reckoning 400 stades as the proper length of a degree of longitude measured at the latitude of Rhodes (36°), we have as the "length" according to Marinus 228°, which he rounded down to 225°, and as Ptolemy's estimate 177° 15', in round figures 180°. The measurement by Marinus of the distance by sea gave 125° from the Fortunate islands to Kory, a promontory in India opposite the northern point of Ceylon, and 61" more to the "Golden Chersonese"; the distances from the Golden Chersonese eastwards to Zaba and thence nearly south to Kattigara Marinus only gave in days of sailing. Ptolemy reduced the figure of 61° to 34° 48′, and the difference in longitude between the Golden Chersonese and Kattigara he made 17° 10′. Thus Ptolemy's total became 125° + 34° 48′ + 17° 10′ = 176° 58′ say 177°, to which he added 3° for the difference in longitude between Kattigara and the capital of the Sinae (sea-coast of China), making 180° as before.

But in thus estimating the length and breadth of the known world, Ptolemy attached a very different sense to these terms from that which they had generally borne. Most earlier Greek geographers and "cosmographers" supposed the inhabited world to be surrounded on all sides by sea, and to form a vast island in the midst of a circumfluous ocean. This notion (perhaps derived from the Homeric "ocean stream," and certainly not based upon direct observation) was nevertheless in accordance with truth, great as was the misconception involved of the continents included. But Ptolemy in this respect went back to Hipparchus, and assumed that the land extended indefinitely north in the case of eastern Europe, east, south-east and north in that of Asia, and south, south-west and south-east in that of Africa. His boundary line was in each of these cases an arbitrary limit, beyond which lay the Unknown Land, as he calls it. But in Africa he was not content with this extension southward; he also prolonged the continent eastward from its southernmost known point, so as to form a connection with south-east Asia. In Asia he took the line of coast from the Golden Chersonese as making a great bay towards the Sinae, and then proceeding southwards to Kattigara. The effect was to enclose the Indian ocean as one vast lake surrounded by Unknown Land. It must be noticed that Ptolemy's extension of Asia eastwards, so as to diminish by 50° of longitude the interval between easternmost Asia and westernmost Europe, fostered Columbus' belief that it was possible to reach the former from the latter by direct navigation, crossing the Atlantic.

Ptolemy proceeds (i. 19 sq.) to consider the question of maps and methods of constructing them. He first describes (i. 24) a method of conical projection in which the meridian circles are represented as straight lines all meeting in a certain point (a kind of north pole) and the parallels of latitude (in particular those passing through Thule, Rhodes, Meroe and Agisymba) as circles with that point as centre. (The fixed "pole," or centre of projection is as nearly as possible the vertex of the cone passing through the actual parallel circle of Thule and the equator.) A more elaborate system, in which the meridians are represented as actual arcs of circle and not straight lines, is then described (s. 10 sqq.).

Books ii. to vii. contain Ptolemy's systematic tabular location of places and features in terms of latitude and longitude for all countries. He deals in order with Europe and the Mediterranean, then Africa, then Asia, beginning with Asia Minor and passing to Palestine, Mesopotamia, Arabia, India, etc. Under Europe, the first countries dealt with are the "Britannic islands," Ireland and Albion; then comes Spain in three divisions, then Gaul in four divisions, then Germany, and so on. The arrangement of the subject-matter in tabular form, instead of being at once embodied in a map, suggests that Ptolemy's object was to enable the student to construct his maps for himself. Nevertheless, the work was from the time of its first publication accompanied by maps, which are regularly referred to in Book viii. How far the maps which are appended to the extant mss. represent the original series is a moot point. It is possible, however, that they have been transmitted by uninterrupted tradition from the time of Ptolemy.

In spite of the merits of Ptolemy's geographical work it cannot be regarded as a complete or satisfactory treatise upon the subject. It was the work of an astronomer rather than a geographer. Not only did its plan exclude all description of the countries with which it dealt, their climate, natural productions, inhabitants and peculiar features, but even its physical geography proper is treated in an irregular and perfunctory manner. While Strabo was fully alive to the importance of the rivers and mountain chains which (in his own phrase) "geographize" a country, Ptolemy deals with this part of his subject in so careless a manner as to be often worse than useless. In Gaul, for instance, the few notices he gives of the rivers that play so important a part in its geography are disfigured by some astounding errors; while he does not notice any of the great tributaries of the Rhine, though mentioning an obscure streamlet, otherwise unknown, because it happened to be the boundary between two Roman provinces.

Bibliography.—Ptolemy's Geographia was printed for the first time in a Latin translation, accompanied with maps, in 1462 (?), and numerous other editions followed in the latter part of the 15th and earlier half of the 16th centuries, but the Greek text did not make its appearance till 1533, when it was published at Basle in quarto, edited by Erasmus. All these early editions, however, swarm with textual errors, and are critically worthless. The same may be said of the edition of P. Bertius (Gr. and Lat., Leyden, 1618, typ. Elzevir), which was long the standard library edition. The first attempt at a really critical edition was made by F. G. Wilberg, and C. H. F. Grashof (Essen, 1838–45), but this only covered the first six books of the entire eight. The edition of C. F. A. Nobbe (3 vols., Leipzig, 1843), presents the best Greek text of the whole work, and has a useful index. The best edition, so far as completed, is that published in A. F. Didot's Bibliotheca graecorum scriptorum (Claudii Ptolemaei geographia; 2 vols., 1883 and 1901), originally edited by Carl Müller and continued by C. T. Fischer, with a Latin translation and a copious commentary, geographical as well as critical. See also H. Bradley, "Ptolemy's Geography of the British Isles," in *Archaeologia*, vol. xlviii. (1885); T. G. Rylands, Geography of Ptolemy Elucidated (1893); and a Polish study of Ptolemy's Germany and Sarmatia, in the Historical-Philosophical Series (2) of the Cracow University (1902), vol. xvi. (E. H. B.; C. R. B.; T. L. H.)

PTOMAINE POISONING, a phrase now popularized in the sense of a certain class of food-poisoning. The word "ptomaine" was invented by the Italian chemist Selmi for the basic substances produced in putrefaction. They belong to several classes of chemical compounds. (See Enteritis; Medical Jurisprudence.)

PUBLICAN: see Licensed Victualler.

PUBLICANI, the name given in ancient Rome to a body of men who either hired state property or monopolies to farm for their own profit or bought for a fixed sum the right to farm the taxes due to the treasury from the public land in Italy, or the land held by Roman subjects in the provinces. In early times the senate entrusted to officials the control of the sale of salt (Livy iii. 9), and it was a development from this that the state, instead of appointing officials to manage its monopolies, let out those monopolies to individuals. A regular system was established by which the censors who held office every fifth year, placed the sources of public revenue in the hands of individuals or companies, who on payment of a fixed sum into the treasury, or on giving adequate security for such payment, received the right to make what profit they could out of the revenues during the five years elapsing before the next censorship. The assignment was made to the highest bidder at a public auction. The same system was applied to the public works, the publicanus in this case being paid a certain sum, in return for which he took entire charge of a certain department of the public works. That this system was well established at the time of the Second Punic War is assumed in Livy's account of the various offers made by the wealthier class of citizens to relieve the exhausted treasury after the battle of Cannae (216 B.C.). On the one hand we have companies offering for branches of the revenue a price which was calculated rather to meet the needs of the state than to ensure any profit for themselves (Livy xxiii. 49). On the other hand individuals are represented as undertaking the management of public works on the understanding that they would expect no payment until the conclusion of the war (ibid. xxiv. 18).

Since wealth was a necessary qualification for the post, and wealth at Rome became more and more confined to the commercial class, the publicani became identical with the class of capitalists and traders. This was distinct at Rome from the senatorial class, which was excluded from it by definite enactment (see Senate), and, except in face of common danger, was often hostile to it. It was in their capacity of publicani in the wealthiest provinces that the capitalist or equestrian *iudices* (see Equites) became a menace to the provincial governors who represented the senatorial power. When the demands of the equestrian party determined the policy of the state we can trace the interests of the *publicani* as the motive of its action. Thus the fate of the Roman business men in Cirta led to the Jugurthine War in 112 B.C.; the disorganization of Asiatic commerce by the pirates led the *equites* to support the proposal to confer extraordinary powers on Pompey in 67 B.C.; and the quarrel over the contracts for the taxes of Asia in 60 B.C. led to the downfall of the senatorial party.

Under the empire the *publicani* were subject to close supervision. The name appears as "publicans" in the New Testament.

BIBLIOGRAPHY.—A. H. J. Greenidge, Roman Public Life (1901); J. E. Sandys, Companion to Latin Studies (1921).

PUBLIC AUTHORITIES PROTECTION ACT. This British statute was enacted in 1893 and represents, to some extent, a consolidation of previous statutes limiting the time within which actions may be brought against "public authorities," including thereunder local government authorities, justices of the peace and, it has recently been held, Crown servants also. It goes, however, far beyond the particular statutes which it proposed to "generalize and amend" in that it imposes new and most ihvidious restrictions on any plaintiff who seeks to sue a "public authority" for a wrongful act. These are dealt with in the article Petition of Right. The statute which requires all such actions to be brought within six months does not, however, extend to actions for breach of contract, as distinct from tort by public authorities. Such actions are subject to the ordinary period of limitation prevailing in actions between subject and subject, *i.e.,* private persons, namely six years. The Act has been described as "intended to protect public bodies from expense when they are unsuccessfully sued in respect of acts done or omitted to be done in the exercise of statutory powers or duties" (Lindley M.R. in Fielding v. Morley Corporation, 1899, 1 Ch. at. p. 4). The description is inadequate, however. As is shown elsewhere (see PETITION OF RIGHT), the statute operates in practice to deter persons wronged from suing at all, and penalizes them on technical grounds with special costs for suing even where they would have had an undoubted cause of action had the action been brought within the prescribed period of time. The "protection" afforded by the statute extends not only to any wrongful acts done "in pursuance or execution or intended execution" of a statutory duty but also in pursuance of any "public" duty or authority. All these terms, as also the question whether the act complained of arises out of a constructual relation or not, whether it occurred in the execution of a "duty" or merely in the exercise of a "power," as also the relation between a "continuing" act and "continuous" damage, have been the subject of endless litigation. The "protection," in other words the privilege, conferred by the statute extends not only to a public authority but also to all officers and servants acting under its orders. (J. H. Mo.)

PUBLIC HEALTH. The term as used in Great Britain connotes in the broad sense principles and measures which aim at promoting and safeguarding the health of the community in contra-distinction to those which are concerned in the main with the treatment of declared disease in the individual. For public health in the United States see Section II.

I. GREAT BRITAIN

The original conception of public health requirements in Great Britain was fairly simple—the improvement of drainage and sewerage, the provision of adequate and satisfactory water supplies, scavenging, the isolation of cases of infectious disease. Then came the supervision of housing conditions, the clearance of slum areas, the provision of open spaces and the efforts to provide a cleaner atmosphere. More attention is now paid to food supply as in provision for the analysis of food-stuffs, in the supervision of the production and distribution of milk, the elimination of tuberculosis from dairy cattle, the control of slaughtering and inspection of meat, the inspection of premises used for the preparation or storage of food. Action regarding infectious disease has passed beyond isolation of the individual attacked and disinfection of premises to the supervision of contacts and careful investigation of possible sources of infection, and the system of port sanitary control has been placed on a scientific basis and all these matters, as they develop, are referred to and accepted as public health measures.

The present century has witnessed public health development in other directions. There has been the growth of activities which aim at the conservation of young life, the early treatment of physical defects, the inculcation of healthy nurture with the object of ensuring healthy citizens. These have found expression in the Maternity and Infant Welfare (*q.v.*) and the School Medical Services. Public provision has been made for the treatment of certain diseases which, from their economic or social importance, can best be countered by organization on a communal rather than an individual basis, such as tuberculosis, venereal disease, and the crippling effects of infantile paralysis.

The statutory authority for this work is furnished by various Acts of Parliament. The charter of public health administration is the Public Health Act of 1875 which has been amended by the Acts of 1890, 1904, 1907 and 1925. Other important health enactments are the Public Health (Water) Act, 1878, the Infectious Disease (Notification) Act, 1889, the Infectious Disease (Prevention) Act, 1890, the Open Spaces Act, 1906, the Milk and Dairies (Consolidation) Act, 1915, the Public Health (Smoke Abatement) Act, 1926, and various provisions in the Housing Acts. The later developments of public health have their basis among other enactments, in the Education (Administrative Provisions) Act, 1907, the Education Act 1921, the National Insurance Act 1911, the Venereal Disease Act, 1917, the Maternity and Child Welfare Act, 1918, the Public Health (Tuberculosis) Act, 1921, and in various regulations framed by the Ministry of Health.

The foregoing refers to legislation for England and Wales. The Scottish and Irish Acts, though similar in objects and results are usually different in form and adjusted to the national conditions of those countries.

Central Authorities.—The authorities concerned in the administration of public health are central and local. In England and Wales the chief central authority is the Ministry of Health. This department had its origin in certain movements which can be traced back to the beginning of the 19th century. Interest of the State in the physical health of its citizens is a comparatively modern development, and may be traced broadly to four chief causes; first, to reaction against the anarchy of the Industrial Revolution; secondly, to the gradual development in the latter part of the 18th century of a humanitarian spirit, as evidenced by the work of John Howard in the reform of prison life, the movement for the abolition of the slave trade, and the efforts of Sir Samuel Romilly and others to infuse a spirit of humanity and common-sense into our penal laws; thirdly, and probably the most important, to the appearance for the first time of Asiatic cholera in Europe and the threat of its invasion of England; and fourthly, to the establishment of the central Poor Law Commission in 1834.

The first Secretary of this Commission was Mr. Edwin Chadwick, one of the great public health pioneers of the 19th century. He forced upon public notice the importance of sickness and ill-health in the production of poverty, and insisted that the prevention of disease was one of the first duties of the State. Largely as a result of his efforts the first Central Health Department, the General Board of Health, was established, prematurely as it afterwards proved, in 1848. Ten years later this board was dissolved and its duties distributed amongst other offices, but in 1871 they were gathered together again and, with those of the Poor Law Commission, transferred by Act of Parliament to a newly-created department, the Local Government Board. This board remained for nearly 50 years the principal central authority for public health, until in 1919 its functions, together with other health functions, such as health insurance and the medical inspection of school children, which had come to be entrusted to separate central authorities, were transferred to the Ministry of Health. The Ministry of Health Act, 1919, by which the Ministry of Health was established, had as its purpose the prevention of oveflapping and competition between certain of the central departments by bringing the health services which they administered into a single department under a Minister of Health.

Among other central authorities concerned with questions of public health are the Medical Research Council, a Committee of the Privy Council, which co-ordinates research on medical subjects, the Board of Trade, which is responsible for the health services of the mercantile marine under the Merchant Shipping Acts, the Ministry of Agriculture and Fisheries which has certain powers and duties relating to the production of food and milk, the Ministry of Pensions which has the care of disabled officers and men after they have left the naval, military and air services, and the Home Office, in respect of industrial hygiene control under the Dangerous Drugs Acts, etc.

Local Authorities. — The local authorities charged with the administration of public health services are the Rural and Urban District Councils, the latter including the Metropolitan, Municipal and County Borough Councils. These bodies are assisted in the discharge of their duties by a technical staff consisting of the Medical Officer of Health and the chief Sanitary Inspector, whom they are required by law to appoint, together with what additional assistance may be necessary. In the smaller districts the duties are sometimes performed by a part-time Medical Officer of Health who is also engaged in general practice, and by a whole-time Sanitary Inspector. In the larger cities the staff of the Public Health Department may number several hundred persons. The Poor Law Guardians have important health functions in relation to the medical care of the poor, and are also responsible for the administration of the Vaccination Acts.

County Councils other than County Borough Councils are not health authorities within the meaning of the Public Health Acts, but they have been given important duties under the Isolation Hospitals Act, under the Tuberculosis Regulations, the Maternity and Child Welfare Act, the Venereal Diseases Regulations, and also in regard to school medical inspection, and the tendency of present-day policy is gradually to shift much of the responsibility for these and similar personal health services from the smaller urban and rural authorities to the County Councils, and thus, by increasing the strength and efficiency of local administration, to diminish the need for detailed control and interference by the central departments.

Public Health Personnel. — The first local authority to appoint a salaried Medical Officer of Health in Great Britain was Liverpool in 1847. In 1848 the Corporation of the City of London appointed Dr. (afterwards Sir) John Simon to be its Medical Officer of Health. The larger cities followed and in 1872 the practice had become so general that the Public Health Act of that year made it obligatory on every urban sanitary authority to appoint a Medical Officer of Health. The Public Health Act of 1875 extended this obligation to all local authorities, both urban and rural.

At first no special qualification was prescribed, but in the Local Government Act of 1888 a clause was inserted requiring that after the 1st of January 1892 every Medical Officer of Health of a County or of a district containing a population of 50,000 or more inhabitants should be not only legally qualified in medicine, but also be the registered holder of a Diploma in Sanitary Science, Public Health or State Medicine. By an Order issued by the Ministry of Health in 1922, this requirement was extended to all Medical Officers of Health, so that to-day no candidate is eligible for such an appointment unless he holds a Diploma in Public Health, except by special dispensation of the Minister of Health. The Sanitary Officers Order of 1922 also laid it down that every Sanitary Inspector appointed by a local authority should possess a recognized qualification in Sanitary Science.

In the brief survey which follows reference is made to some of the more important matters dealt with by local public health authorities.

Vital Statistics. — Vital statistics furnish a measure of the influence of various conditions and occupations on the health of the population and a means by which the value and efficacy of the ameliorative and preventive action taken by local health authorities can be assessed. Every Medical Officer of Health is required to furnish each week to the Registrar General a return of all cases of infectio'us disease notified in his district. These returns, together with those supplied by the local registrars of births and deaths, are the material on which the Registrar General bases his Weekly Report, and also his Quarterly and Annual Statistical Surveys. This information is supplemented by Annual and special reports of Medical Officers of Health and from the results of investigations by Medical Officers of the Ministry of Health and by other departments and voluntary bodies interested in the physical, industrial and social welfare of the people.

Environmental Hygiene. — Long before the discovery of bacteria and their relation to disease, sanitarians recognized the close association of dirt and pestilence and the importance of cleanliness in the prevention of infection. It is difficult to believe that elementary health services such as the provision of a public water supply, drainage, sewerage and sewage disposal, the regular removal of house refuse and the cleansing of streets, which are to-day accepted as indispensable to civilized life, were practically unknown through the greater part of England and Wales less than a century ago. These services are now regularly undertaken by all local sanitary authorities. Control is exercised over building to ensure freedom from dampness, adequate lighting, ventilation, drainage, closet accommodation in houses intended for human habitation. Many of the larger towns have long since reached out beyond these elementary objectives, undertaking other services which have, directly or indirectly, a beneficial effect on the welfare of the community — the provision of cheap transport which has helped to overcome the housing difficulty, the provision of gas and electricity which has lessened labour in the homes and contributed to a cleaner and more wholesome atmosphere, the provision of parks and pleasure grounds where the people may recruit from their labour and the children play in safety.

Infectious Disease. — Local health authorities have been entrusted with important duties in regard to the prevention and control of infectious disease and have developed elaborate machinery for this purpose. The Infectious Diseases Notification Acts of 1889 and 1899 made certain of the commoner infectious diseases notifiable to the Medical Officer of Health and gave local authorities power to add to their number where it seemed necessary and expedient to do so. Since then other diseases have appeared in epidemic form, such as cerebrospinal fever, anterior poliomyelitis (infantile paralysis), encephalitis lethargica (sleepy sickness), and the central department, acting under authority of the Public Health Act 1875, has made these diseases notifiable by regulation and prescribed the measures which should be taken for their prevention and control.

The measures adopted by a local authority to control the spread of an epidemic disease are briefly, — isolation of the patient, either in the home or, where this is not practicable, in hospital; search for the source of infection; observation of the contacts; disinfection; and, where an efficacious vaccine is available, vaccination.

Under the authority either of the Public Health Act 1875 or of the Isolation Hospitals Act 1893, most local authorities have provided hospital accommodation for cases of infectious disease occurring in their districts.

Diphtheria, Tuberculosis, etc. — It is obvious that infectious diseases which are indirectly transmitted through the agency of some medium such as water, milk, food, flies, etc. are more easily prevented than those which are spread directly from person to person, and the measures that are applicable to the one do not always prove successful in the case of the other. For this reason typhoid, cholera, and other intestinal infections which formerly exacted such a heavy toll of life, no longer cause health authorities serious anxiety. In the same category one may place malaria, typhus and other insect-borne diseases. The diseases which are conveyed by personal infection, such as scarlet fever, diphtheria and the various epidemic nervous diseases, are much more difficult to control. The infection of many of these maladies is very widely spread throughout the community and many persons contract the disease in what may be called a sub-clinical form without being conscious of it. The occasional clinical cases are often merely the apex of a considerable pyramid of infection, the greater part of which is submerged and unrecognized. One of the great problems of preventive medicine is to elicit the factors which determine these periodic clinical or epidemic manifestations of an infectious disease. Various theories have been propounded, but none of them is entirely satisfactory. Other diseases, such as tuberculosis, have a dual character, *i.e.*, they may be transmitted directly from person to person or may be conveyed through the medium of some food such as milk or infected meat. Tuberculosis is a disease of great economic importance because the chief burden of mortality falls on the middle or productive years of life. It is for this reason that special measures have been taken to combat it in the form of notification, dispensaries, sanatoria and the other machinery established under the Tuberculosis Regulations. Somewhat similar measures, suitably modified, have been devised for the prevention and treatment of venereal diseases.

Food Inspection. — The most important measures dealing with food inspection are the various Sale of Food and Drugs Acts 1875–1907, the Public Health (Regulations as to Food) Act 1907 and the Milk and Dairies (Consolidation) Act 1915. Under these powers regulations have been made by the Central Authority dealing with such subjects as milk and cream, meat, shellfish, imported food, preservatives and the prevention of tuberculosis. To a country which imports a large proportion of its meat from abroad it is very important to have some means of supervising production at the source. Agreements have been entered into with the chief producing countries by which these countries undertake to inspect and stamp all meat intended for export to England. This reduces the inspection necessary on arrival. A certain amount of inspection is carried on both at the ports and at the chief distribution centres in order to ensure that the producing country fulfils its undertaking. The results of this method of control have been extremely satisfactory and every opportunity is taken to extend the system.

The local sanitary authority exercises supervision over the quality of the food distributed in its district and the conditions under which it is stored and sold to the public. For this purpose officers are appointed for the inspection of slaughterhouses and dairies, and samples of food are regularly submitted for analysis.

School Medical Service — The introduction of compulsory education made it apparent that many children were unable, through ill-health, to benefit from the education facilities provided. This led to the establishment of the medical inspection of school children in 1907 and the gradual evolution of the present School Medical Service. The most important statute dealing with this subject is the Education Act of 1921 which re-enacts and amplifies previous powers and imposes on local education authorities the duty of making adequate and suitable arrangements for the medical inspection and treatment of children attending public elementary schools and also the medical inspection of scholars attending secondary schools. Education authorities are also required to make special provision for blind, deaf, defective or epileptic children.

This systematic inspection has revealed a vast amount of unsuspected disease and minor defects which, if left uncorrected, lead in time to serious crippling. It is estimated that out of a total school population of some 7 millions, over a million children require medical treatment, apart from uncleanliness and dental diseases. The seeds of much of this ill-health are sown before the children enter school, a fact which emphasizes the importance of the pre-school welfare work which has already been referred to. On the other hand, the full fruition of school medical inspection can only be assured by continuation of the supervision during the critical transition years of early industrial life. Here the advantages secured by the National Health Insurance Acts of 1911–1924 are becoming apparent. With certain exceptions these provided for compulsory insurance against sickness of all employed persons between the ages of 16 and 70. (For further industrial welfare measures see INDUSTRIAL WELFARE AND MEDICINE and LABOUR LAW.)

Port Sanitary Administration. — Port sanitary authorities are constituted by order of the Ministry of Health. They carry out duties imposed by the regulations relating to cholera, plague and yellow fever and other "quarantine" work according to the system of International Sanitary Conventions to which this country is party; the Aliens Order 1920, the Port Sanitary Authorities (Infectious Diseases) Regulations 1920, and the Public Health (Imported Food) Regulations 1925. The sanitary staff of a port sanitary authority consists of the Port Medical Officer of Health and such assistants as the volume of work demands. In recognition of the national importance of this work, half the approved expenditure of a port sanitary authority is defrayed out of Central Governments funds.

International Health. — Many public health problems are international in character and there is evident need for some organization which will enable the nations to pool their experience and, where necessary, to co-operate in the application of such measures as are practicable for the prevention and control of disease. The first attempt to secure international uniformity in matters of quarantine was made in Paris in 1851 when a Convention embodying the precautions against infectious diseases which were then regarded as appropriate was signed by the participating countries. Modifications have been introduced into this Convention from time to time and in the Rome Agreement of 1907 an office or bureau called the International Office of Public Health was established in Paris to consider how best the convention could be amended and kept abreast with medical science. England, by reason of its vast international traffic, has been very directly interested in these conventions and has long been at pains to introduce a spirit of reasonableness into their requirements. The last convention, which was signed in Paris in 1926 by the representatives of 70 different nations, embodies most of the views that have long been held and practised in this country. This convention aims at securing what is necessary for the prevention of the introduction of disease with the minimum of interference to commerce and travel.

In the Peace Covenant a clause was introduced providing for the establishment of a health organisation at Geneva under the aegis of the League of Nations. The functions of this organisation cover practically the whole field of preventive medicine wherever co-operation between the nations is desirable or essential. By arrangements with the international office in Paris it undertakes the collection and dissemination of current information on epidemic disease: it gives assistance in times of national emergency as during the great epidemic of typhus in Russia in 1919, during the epidemic of malaria in Southern Russia, in Greece during the influx of refugees from Asia Minor and other parts of Turkey, and during the recent outbreak of dengue in Athens. It has done much to secure the standardization of various medical preparations, such as insulin, pituitrin and certain of the antitoxins. It has promoted inquiry into cancer, certain aspects of maternity and child welfare and tuberculosis.

Public Health Finance. — The expenses of the public health services are defrayed for the most part out of local rates (general district rate or special rate), but assistance is given by the Central Government in respect of what are known as the "grant aided services." Thus half the approved expenditure on school medical inspection, maternity and child welfare work, tuberculosis and port sanitary services, and three-quarters of the expenditure on venereal diseases is defrayed from funds provided by the Treasury. With the exception of certain of the larger boroughs, half the salaries of the medical officers of health and of the sanitary inspectors is refunded out of Exchequer contribution grant.

The question of the substitution of a block grant covering all health services for these special grants-in-aid is at present under consideration by Parliament. (G. BUC.)

II. THE UNITED STATES

A definition which expresses admirably the social and scientific conception of public health in America is that of Winslow, "Public health is the science and art of preventing disease and promoting physical health and efficiency through organized community efforts for the sanitation of the environment, the control of community infections, the education of the individual in principles of personal hygiene, the organization of medical and nursing services for the early diagnosis and preventive treatment of disease, and the development of social machinery which will ensure to every individual a standard of living adequate for the maintenance of

[7]All forms.
[8]Includes deaths from all causes not otherwise indicated.

health." Progress in public health is shown by the following facts.

Increase in the Average Length of Life.—The health of the people of the United States has been improving consistently for the past 50 years as is revealed by the official morbidity and mortality rates and estimates of life expectancy. Even as late as 1880 the average length of life in the New England States and New York city probably did not exceed 40 years. By the beginning of the present century this had increased to 49 years for the original Registration States and in 1920 to 56 years for at least the 85% of the population in the registration area. Latest studies (1940) show the average duration of life for the white population is beyond 60 years. It is entirely possible, without any additions to the present knowledge of the causes and means of prevention of disease, that an average duration of life of 70 years may be attained by 1970.

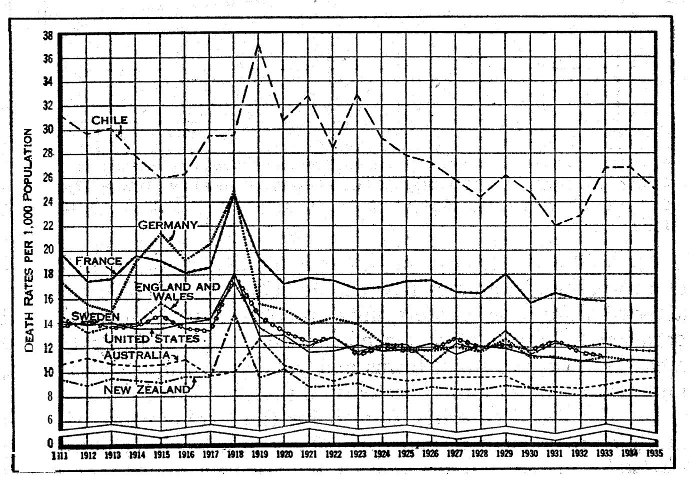
FROM ANNUAL REPORT, CHIEF MEDICAL OFFICER. MINISTRY OF HEALTH, 1937: BUREAU OF THE CENSUS AND U.S.P.H.S. REPORTS, 1938

Decrease in Death Rate.—In 1870 there were 30 deaths from all causes for each 1,000 of the total population of New York city; in 1937 there were 11·4. Similar changes have occurred in other large cities and in the rural populations, although the city rates were higher in the beginning and have fallen at a more rapid rate than have those of rural communities. In some instances the city rates have been, for recent years, lower than the rural. Since 1900 the general death rate for the registration area of the United States has fallen from 17 to 11·4 per 1,000 of the population.



BY COURTESY OF BUREAU OF MEDICAL ECONOMICS OF AMERICAN MEDICAL ASSOCIATION

GENERAL DEATH RATES OF THE UNITED STATES REGISTRATION AREA AND CERTAIN FOREIGN COUNTRIES FOR EACH OF THE YEARS FROM 1911 TO 1935 — FROM MORTALITY STATISTICS, U.S. BUREAU OF THE CENSUS

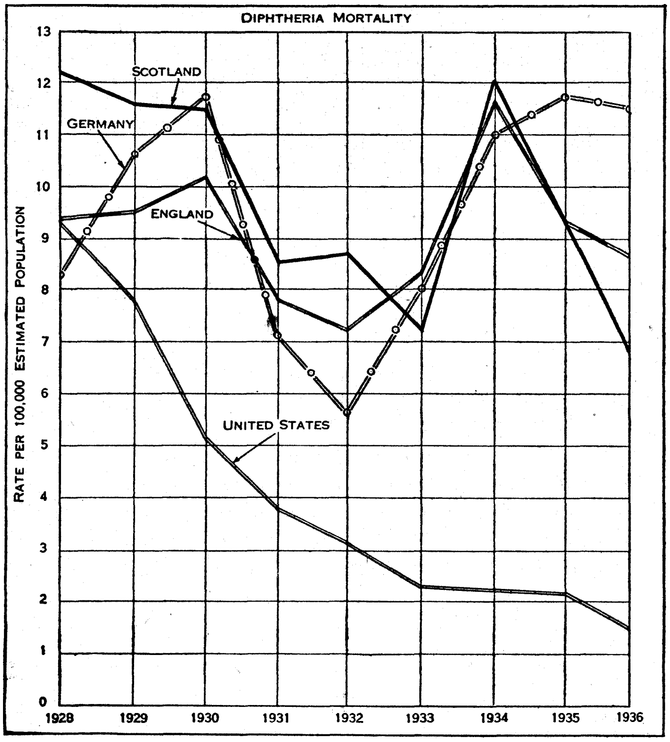
The past quarter century—1910–35—during which an increasing shift of the population took place from rural to urban residence (55% urban in 1927), was characterized by a greater improvement in general health conditions in both city and rural regions than in any previous similar period of time.

The advantage of the rural dweller over the city dweller is found in each decade of life. at least up to the age of 50, and this applies to both sexes.

Changes in Specific Death Rates.—More indicative than are general death rates, of the success of sanitation, personal hygiene and the application of administrative government and social resources for disease prevention, are the changes in the death rates from tuberculosis, typhoid fever, diarrhoea and enteritis among children, diphtheria and the infant mortality. All of these have fallen without exception in those States and cities where reliable records are available.

Typical experience is expressed in the following:

The greatest reduction in the death rate from tuberculosis has been in children under ten. The highest tuberculosis death rates for the country as a whole are those of women from 20 to 30 years of age and for men from 45 to 60.



BY COURTESY OF BUREAU OF MEDICAL ECONOMICS OF AMERICAN MEDICAL ASSOCIATION
FROM ANNUAL EPIDEMIOLOGICAL REPORTS. HEALTH ORGANIZATION. LEAGUE OF NATIONS. 1931-36: SPECIAL ARTICLE, *J.A.M.A.*, JUNE 26, 1937

Typhoid fever, from being an endemic disease of cities, chiefly due to polluted water, is now characterized by its epidemic character resulting from carriers, milk products, oysters and accidental occasional failures of water purification. The endemic typhoid areas are now the small towns and villages of rural States where unprotected water and unpasteurized milk are used.

Diarrhoea and enteritis, from being the leading cause of death in children under five, and particularly among city children and especially in the summer months, now plays a minor rôle, is less prevalent in cities than in rural areas and is hardly more frequent in summer than in winter.

Diphtheria. Now that means of permanent and universal protection of children against diphtheria by active immunization are available, in addition to the resources for specific therapy and determination of susceptibility, the practical disappearance of diphtheria as a frequent cause of death in children under five years of age is within sight.

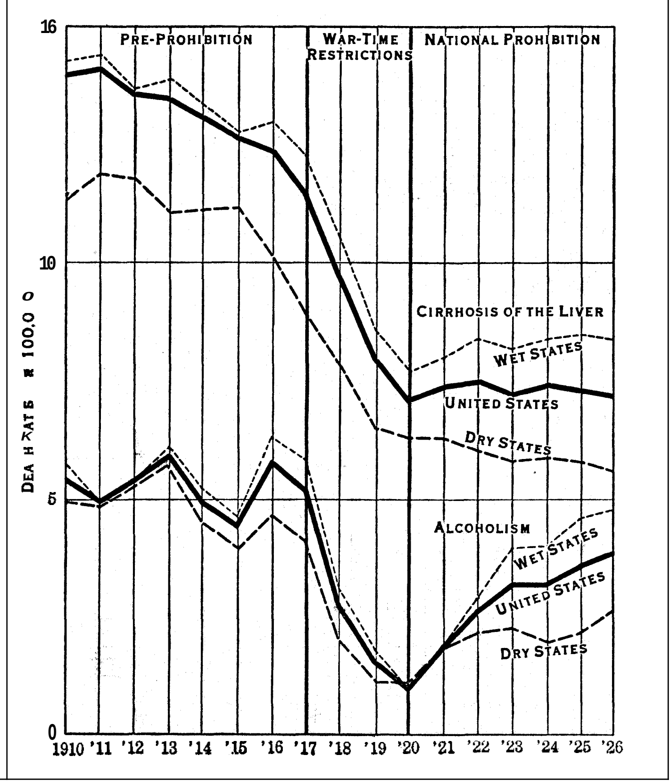
Infant Mortality. While 50 years ago one out of every four babies born alive died within the first year of life, now only one in 20 is so sacrificed. This saving in child life has occurred wherever education of the mother has been provided by doctors and nurses, and water and milk supplies have been safeguarded. It is common to find infant mortality rates lower in the cities than in rural communities, a reversal of the conditions 50 or even 25 years ago.

Increasing Death Rates.—The saving of life in the early years of childhood, particularly from diseases peculiar to infancy and from communicable diseases affecting chiefly children under five, and from tuberculosis in persons from 15 to 30 years of age, since about 1900, has, together with the limitation of immigration altered the age composition of the population to a degree affecting the rates from such causes of death as affect persons over 45 years of age. Of these the most important are heart diseases, cancer and diabetes

The increases in the death rates from heart diseases, cancer and diabetes are in part due to the higher age grouping of the population as a whole, but in addition to this, the death rates for each decade over 45 show increases for each of these diseases.

Deaths from violence and accidents, particularly those due to automobiles, and from appendicitis have increased sharply in recent years. Deaths from causes connected with childbirth have not declined greatly, and those in the United States are above those of other countries with reliable records.

While in 1866 in New York city one death out of every 2,400 was due to diabetes, now (1940) one in 40 is from this cause. The increase, while greater in the cities, is found also in rural populations and among the coloured as among the white races, but everywhere especially among women over 35 years of age.



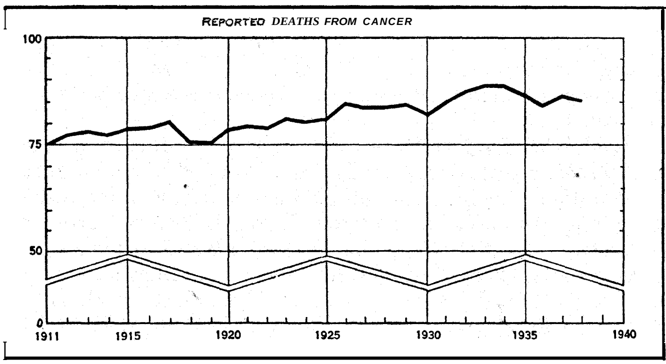
MORTALITY DUE TO ALCOHOLISM AND CIRRHOSIS OF THE LIVER IN THE UNITED STATES (1910-1926)

The shift in proportion of deaths occurring in the various decades of life is a striking evidence of the effective control of the communicable diseases of childhood and early maturity.

Drop in the Birth Rate.—With the reduction in loss of infant life has come a lowering of the birth rate in the United States as a whole and for each State and racial group. Within the past 50 years the birth rate has dropped from approximately 40 per 1,000 population per annum to 16·7. From 1921–25 the birth rate was 22·5 in the birth registration area and in 1936 it was 16·7.

The Three Eras of Public Health.—For the first 125 years of the life of the nation, public health work was limited to control or improvement of man's physical environment and enforcement of quarantine by the exercise of the authority of the official health agencies, the boards and departments of health acting under the police powers which are reserved to the States under the federal constitution. This may be called the era of sanitation, the great accomplishment of which was the reduction of communicable diseases transmitted largely, if not exclusively, through drinking water polluted by human wastes. Sanitary disposal of sewage, the protection and purification of water supplies, the control of nuisances and the improvement of housing constituted the first effective attack on environmental hygiene and saved the cities from destruction. At the beginning of this era death rates in the large cities equalled or exceeded the birth rates. The health officer relied upon legal rather than scientific authority, upon the force of police powers rather than the power of education and authority, upon his individual or departmental services rather than upon the technical assistance and popular influence of volunteer co-operating agencies and associate professional groups.

Not until Lemuel Shattuck in Massachusetts in 1848 and Dr. Stephen Smith and his associates in New York city in 1865 had disclosed by careful surveys of the health of the population the



BY COURTESY OF BUREAU OF MEDICAL ECONOMICS OF AMERICAN MEDICAL ASSOCIATION

STANDARDIZED DEATH RATE PER 100,000 INDUSTRIAL POLICY-HOLDERS, AGES 1-74 YEARS. THE 1938 RATE IS PROVISIONAL.— SOURCE: "TWENTY-FIVE YEARS OF LIFE CONSERVATION," AND STATISTICAL BULLETINS, METROPOLITAN LIFE INSURANCE COMPANY

true extent of preventable disease and death, and the fact that the death rates in the cities were higher than the birth rates did the public demand something approaching qualified direction and consistent scientific operation of a well-organized department of health. The first State department of health was organized in Louisiana in 1853.

In 1900 there began the movement for public education in health which has been a factor of tremendous importance ever since, not only in the widespread dissemination of popular information about preventable disease, but in bringing to the support of the official health department or health officer interest, knowledge, financial assistance and public opinion through the influence of volunteer or unofficial health agencies.

The initial movement of this educational or public informational era of public health was that of the tuberculosis committees and societies and national, State, and local associations, now operating with undiminished vigour and sustained interest and financial strength as the National Tuberculosis Association. The three simple facts with which the public was approached were the communicability, curability and preventability of tuberculosis. Once accepted, it was inevitable that knowledge of these facts should lead to appropriate communal action. The National Tuberculosis Association, its 48 State societies and 1,300 other local societies have been the exciting, if not the driving, force which has brought 600 tuberculosis clinics, 60,000 sanatorium beds for tuberculous patients (1922), a tuberculosis division in all important State and local health departments and a scientific program of prevention uniformly accepted as an essential part of the work of the public health officer and department of every community.

The most important features of the program of the National, State and local tuberculosis associations since the beginning of the movement in 1904, have been those measures which have brought about "notification and supervision of persons afflicted with tuberculosis; the construction and maintenance by cities, counties and States, of institutions for the care and treatment of tuberculous patients of all types; institutions for the prevention of tuberculosis, such as preventoria, open-air schools and camps; the instruction of the public in the methods of avoiding and curing tuberculosis; and finally the intensive scientific study of methods to be used in the prevention and treatment of tuberculosis."

Following the leadership and example of the tuberculosis associations, there were developed similar private health agencies first as local societies and later on a national scale to carry a lesson of prevention and of health on the subject of infant mortality and child hygiene, on pre-natal care of the expectant mother, on social hygiene, a synonym in the United States for venereal disease control, on mental hygiene, cancer, blindness, heart diseases, etc., until the country was swept with successive waves of specialist health propaganda to stimulate appropriate public and official action. It is not unusual to find that twice as much money is spent for public health through the private agencies as is invested by the taxpayers in their official health department.

The third era of public health which was just emerging in 1928 as a definite new phase, out of that of public information or health education, had its inception in the World War experience from which the conviction developed that only by the systematic use of the periodic health examination could all the potential benefits of preventive medicine be made effective for the individual.

With the common action of the American Medical Association and the unofficial and official health agencies through the National Health Council in 1922 an agreement was reached which has been followed with much success. The objective of the present era of public health is to obtain from the prenatal stage until old age for each individual the benefits of personal medical guidance in a healthy way of life, in addition to medical services for the care of sickness. The supervision of the expectant mother, the guidance of the infant's growth, the supervision of the development of the runabout child of two to five, the protection of the health of young people and adults of middle age until their years of work are over in old age all depend for their effectiveness upon individual application of the principles of personal hygiene according to the requirements of age, sex, work, personality and the limitations of inheritance and of economic and social status.

The policy has been to inform the public through official and volunteer health agencies of the benefits to be obtained from a periodic medical examination and to train physicians to carry out the technical service required. Personal interest in and responsibility for individual health is essential if the present knowledge is to be effectively applied through the mechanism of medical examinations and health conferences.

In all health matters pertaining to interstate and foreign comnierce the responsibility rests with the Federal Government through the United States Public Health Service of the Treasury Department. In addition to large functions in medical relief, particularly for merchant seamen, the Public Health Service maintains active consulting and co-operative relations with State and local health authorities, carries on widespread attack upon the venereal diseases through a variety of channels, supervises and controls the standards and production of biological products used for diagnosis and treatment of disease, maintains an effective information and education service of national scope, and carries on researches in sanitation, preventable diseases and vital statistics.

Health activities of various kinds are carried out under six other Cabinet departments and many more independent establishments of the executive branch of the Government.

Local health organizations may not set up standards or enforce local ordinances inconsistent with those established by the competent State authority.

Not only cities, towns and incorporated villages, but counties and rural districts to an increasing degree maintain self-contained health departments adequately performing the essential functions.

A minimum provision for any unit of population of 50,000 persons or over as conceived by the professional public health workers of the United States is as follows: a full time health officer, qualified by training and experience, free from partisan political interference in tenure of office, and paid a salary in proportion to the responsibility of the position; a board of health or advisory health council; trained personnel, including public health nurses to the number of one to every 3,000 of the population, capable of carrying on the seven functions previously described, and a budget based upon an appropriation from public funds of $1.00 to $2.00 per capita for health purposes.

Adequate provision for the organized care of sickness in any community of 50,000 persons or more includes at least:

A general hospital with a capacity of five beds for each 1,000 of the population for the use of general medical and surgical patients, and for maternity cases, and space for the cubicle isolation of acute communicable diseases (one bed for each 2,000 of the population). Beds for diagnosis and observation of tuberculosis, venereal disease and mental patients should be included.

A tuberculosis sanatorium with accommodations for one patient for every 1,000 of the population.

Hospital facilities for three mental patients for each 1,000 of the population. Institutional provision for chronic invalids and convalescent patients according to the social, economic and industrial status of the people.

While all local health departments do not have direct responsibility for the care of the indigent and other sick of the community, the hospital care of the acute communicable diseases and often of tuberculosis and venereal diseases is commonly under the health officer and in a number of large cities, *e.g.*, Philadelphia and Detroit, public hospitals for general medical, surgical and maternity care and district or city physicians to visit the sick poor are under the health department.

Interest in treatment and prevention of all sickness is within the proper province of the health officer and unless the institutional and private physician facilities for the diagnosis and care of sickness are adequate, a community cannot have a wholly satisfactory service for health.

ORGANIZED HEALTH WORK

In the United States the problem of the proper or desirable division of public health authority between Federal, State, and local agencies is one as yet unsettled. By the Federal Constitution, the State is the ultimate authority and each State jealously guards its autonomy in matters pertaining to public health.

In the same way the local authorities demand ultimate power in relationship to certain health functions which relate wholly to the health problems of the local community. The development of many non-governmental health agencies is also to be considered in the evaluation of public health work in the United States.

The chief questions of recent years have related to the inequality of the distribution of the benefits of modern public health and medical science. Thus recent years have seen the conduct of a National Health Survey to determine the amount of chronic disabling illness and the extent of medical service available for its care. Innumerable surveys have also been made of local, State, and national health services. As a result there has been proposed a National Health program, involving the appropriation of vast funds to be distributed to the individual States as grants-in-aid for specific health purposes. Moreover, under the Social Security Act of 1934 extensive funds have been appropriated to the United States Public Health Service and the Bureau of Maternal and Child Welfare in the Department of Labor to carry on extensive preventive, medical, and educational services in the individual States. Under this system, the States must match the appropriation of the national Government and must submit plans for the approval of national bureaus before grants are made.

There is also widespread agitation for compulsory sickness insurance in some of the individual States and by certain agencies which would ask the Federal Government to provide funds for establishing such systems in the individual States. (*See* also HEALTH VISITOR).

PUBLIC HOUSE, in its general English acceptation, a house in respect of which a licence has been obtained for the consumption of intoxicating liquors. Public houses are frequently distinguished as "tied" and "free." A tied house is one rented from a person or firm from whom the tenant is compelled to purchase liquors or other commodities to be consumed therein. A free house has no such covenant. (See INN; LIQUOR LAWS; TEMPERANCE; PROHIBITION.)

PUBLIC SCHOOLS. In the United States this term is used to describe free, tax-supported, public controlled and directed, non-sectarian schools. The term public school in England includes not only the schools of ancient foundation like Eton, Harrow and Winchester (see SCHOOLS), but also schools of comparatively recent creation like Clifton, Cheltenham and Marlborough. As forming part of the secondary school system of England (see SECONDARY EDUCATION) they are included in the official statistics as non-aided schools.

PUBLIC SERVICE CORPORATION OF NEW JERSEY, a holding company carrying on its activities through subsidiaries, was incorporated in 1903, and thereupon acquired the ownership of the principal electric, gas and street railway companies of New Jersey. It was one of the first great aggregations of public utility properties in the United States. Its principal subsidiaries, Public Service Electric and Gas Company and Public Service Co-ordinated Transport, operated (1939) in 426 New Jersey municipalities, providing gas, electric, street-car and motor-bus service. The territory served reaches from the Hudson to the Delaware river, and includes the cities of Newark, Jersey City, Paterson, Trenton, Camden, Hoboken, Passaic and Bayonne—in all of these services, and the cities of Elizabeth and Perth Amboy in all except gas service. This territory contains 95% of the State's population and 90% of its industrial activity.

The Public Service electric system, interconnected for exchange of power with large systems in New York and Pennsylvania, included five large steam operated power plants and some 80 substations. The system of gas mains extends across the State and is all interconnected; the motor-bus and the street railway systems are among the largest in the United States.

Upwards of $415,000,000 of new capital has been expended in the last 36 years, in extending and developing the plants of the subsidiaries of the corporation. The securities of the corporation and its underlying companies are distributed among approximately 104,000 owners, the number of individual stockholders of the corporation itself being in the neighbourhood of 85,000. The operating revenues of the Public Service Corporation of New Jersey for the year 1938 approximated $127,000,000. (T. N. McC.)

PUBLIC UTILITIES,[1] a designation for a special grouping of industries. These industries should be distinguished from State services or public works, which are administered as public functions and hence supported by taxation, and from that variety of industrial, commercial and agricultural undertakings which are usually comprehended under the term "private business." Public utilities, properly so-called, need not be privately owned. In

[1]The writer is indebted to the Macmillan Company for permission to adapt from his recent work, *Outlines of Public Utility Economics,* certain summaries for substantial portions of this article.

almost every country a varying number of them are owned and operated by the State. But these publicly managed enterprises, instead of looking to the State for financial support, sell their services to the general public. Both publicly and privately owned utilities sell their services at prices which are not fixed in the open market but are governmentally fixed. This is the most important aspect of the process known as public utility regulation. Although economic and technical evolution is continually changing the character of these industries besides creating new ones, public utilities may be classified according to the generalized function which they perform in economic life.

The following have been treated as and classified into groups of public utilities: (1) Services of transportation (common carriers); (2) Services incidental to transportation; (3) Services facilitating communication; (4) Facilities providing power, light, heat and refrigeration; (5) Facilities providing water and sanitation in urban communities; (6) Facilities regulating water-supply for agricultural purposes.

HISTORICAL SURVEY

Public utilities are closely associated with our developing civilization, supplying wants so fundamental for communal living that Government has at all times subjected them to some measure of control. With the growth of trade in ancient empires facilities providing transport and communication were set up. The governmentally maintained highway system of the Roman empire and its many aqueduct systems are celebrated ancient public works. The need of some system of public communication was so great that even our letter post has its ancient parallel. In the more populous ancient cities systems of sanitation also became a necessity. Along with this came the recognition that services used collectively should be supplied by the State. Public utilities thus began as State functions. By the middle ages most of the ancient public utilities had declined or virtually disappeared. By slow stages, upon the manors and in the mediaeval cities, these public facilities again appeared. Of great importance in British and American legal history, is the fact that out of the economic and legal relationships of feudalism there arose the concept of a "public calling" upon which is based the present-day policy of public utility regulation.

The modern national State gradually supplanted the elements of the feudal system of social control. The expanding domestic system of manufacture was displacing the gild and manorial system of production; foreign trade was growing. National systems of transport involving highways and canals were undertaken and the regulation of utilities became national rather than local.

Effects of the Industrial Revolution. — The greatest impetus in the expansion of public utilities came with the industrial revolution. The factory system so stimulated production that the need for ever-expanding markets became the limiting factor in economic evolution. Cities grew as never before, creating a new municipal need for systems of water-supply, sanitation, transport, communication, illumination and finally of power.

But the philosophy of laissez *faire* was not fertile ground for extending public functions. Hence, although the rapid industrial changes intensified needs, the tendency was to give greater scope to private enterprise.

However, the evils of a system which left the supply of basic economic wants to private industry insufficiently regulated by government became too flagrant to be overlooked. Beginning about 1840 the revolt against laissez *faire* doctrines caused an enlargement of the scope of governmental action. The older public utility services were continued for the most part as public enterprises, while the newer services were supplied by private initiative under some form of public supervision and assistance. Thus emerged the modern notion of a public utility, distinct from strictly governmental services and strictly private business.

Need **for** New **Utilities.**—The beginnings of the modern postal system date back to the 15th century. In the 18th century England was covered with improved roads built by public authority or by private turnpike companies. The first canal in a new era of canal building was completed in 1761. The first steam railroad was built in 1825 and the first regular steamboat began operation in 1812. The steam railway has developed into the backbone of land transportation, yet canals and inland-waterways continue to serve as important arteries of commerce. With the coming of the automobile, in the United States as elsewhere, highway systems are being reorganized upon an unprecedented scale. The motor-bus and the motor-truck are making use of this development and are rapidly cutting into the short-distance traffic of steam railroads. Since 1850, systems of rapid, world-wide communication have been perfected. The commercial electric telegraph and the telephone are now of tremendous importance. (See TELEPHONE; TELEGRAPH.) After 1900 radio-telegraphy and since 1907 radio-telephony have increased the varieties of means of communication. The ancient art of irrigation is undergoing a rebirth.

In the field of municipal public utilities local transportation was supplied, at first, by fleets of omnibuses in the '20s of the 19th century. The horse-car came in the '30s. Artificial gas for illumination was introduced commercially in London in 1812 and was widely in use for lighting by 1840. A new development in water-supply systems appears to have been introduced by the municipality of London in 1583, followed by Plymouth in 1585 and by Oxford in 1610. Boston in 1652 installed the first modern central water-supply system of the gravity type in America. Central water-supply systems became general in the large cities by 1820. Growing out of experiences in the cholera epidemic, British sanitary authorities put forward the trilogy of public hygiene—street paving, canalization and water-supply. As a final achievement in the development of municipal sociology came a new city-planning movement, begun in Paris about 1850. (See TOWN PLANNING and related articles.)

New public utilities centring in cities have developed out of the industrial applications of electric power. In 1882 the first central station for electric lighting began operation in the United States. By 1885, electric power was applied to street-railways. The first hydro-electric plant began operation in 1882, the precursor of a new movement in power production.

In this historical survey it is important to note that public utilities were not definitely segregated from public functions until the laissez fake philosophy of the 18th century restricted the scope of governmental activity and created institutions and processes whereby the supplying of these changing public needs could be left to private initiative. Industrial interdependence now prevails. Thus public utilities, although privately owned, must be subjected to governmental regulation. The term socialization has been chosen to describe this latest phase of utility development because it implies that government may actively promote these enterprises through public ownership or arrive at the same result by creating private agencies and controlling them through well-conceived policies of regulation.

ECONOMIC CHARACTERISTICS

Developments in the engineering arts bring changes in economic organization. For instance, lighting of the home has been transformed first from a self-sufficient household industry (as the making of candles) to a commercial competitive industry (the supply of candles, lamps, whale-oil and petroleum), and then to monopolistic industry (as in electric lighting and the various forms of gas illumination), where central sources of supply satisfy all demands. Perhaps the most significant economic conclusion founded upon these changes is that the social value of public utility services is increased and the economic cost of rendering them is reduced by a consolidation of enterprises. The individual user of water in our urban centres no longer depends for his supply upon his own well, nor does he buy from one of several competing sources. He resorts to a single common source of supply along with other users. This has been found to be more convenient, economical and, indeed, the only practical solution. But this process of integration of supply has been a long process. In some public service industries it is not even yet completely realized. There are still competing gas, electric, transportation and telephone utilities. This tendency toward monopoly, whether the result of a competitive struggle or brought about by legislation, is a fundamental characteristic of public utility business.

Every public utility must be in possession of the natural resource upon which that industry is based. A gas or electric company must have possession of sites for the location of its works; a transportation company must have rights of way and terminal sites. These properties must have strategic locations. Limitation in the choice of this agent of production tends to make the cost of acquiring or leasing these facilities greater than it would be if the industry had a wider range of choice. Furthermore, utilities must make allowances in advance for probable increase in the required capacity. For these reasons utilities are provided with the governmental power of *eminent domain* which makes possible the compulsory sale of private property. Thus the law recognizes that, socially considered, these properties are being put to the highest uses of which they are capable.

Fixed Capital Characteristics. — In constructing public utility plants we meet all the varying stages of transmutation of capital. The so-called free or liquid capital is changed into durable and specialized types of buildings, structures and equipment, capable of use in only one industry. The roadway and track of a railway, for instance, is so completely "specialized" that only the rails and rail-fastenings can be salvaged. These characteristics of specialization, durability and immobility are included in the definition of "fixed capital." It is also well to bear in mind the specialized managerial and engineering talent required in constructing and operating these enterprises.

A utility which has assembled its plant and thereby incurred heavy construction costs of a "fixed" character anticipates that the product can be sold at a profit. If expectations are not realized the utility will suffer a pecuniary loss because the government has not generally undertaken to secure the utility against such risks. It is therefore highly important that each enterprise take into account the economic principle of proportionality which requires that enterprises be so planned that the maximum of physical output may be secured at the lowest possible money cost and that this maximum supply does not exceed the reasonable, long-run demand for service.

But there is another aspect of the matter. Technical improvements involving much fixed investment of capital are also more economical. A double-track railway has more than twice the efficiency of a single track railway. Electrical generators of large capacity cost less per kilowatt than do generators of small capacity. The cost of operating large plants thus tends to be less than for small plants. Public utilities are therefore anxious to increase the volume of business. Economical operation is also secured by "interconnection" of power sources into so-called super-power systems. A super-power system consists of two elements: the utilization of highly economical generating stations, steam or hydro, and the interconnection of power stations by transmission lines. Not only is the fuel consumption per unit of output reduced by using only large steam plants but the investment cost per unit of capacity is also lowered. By interconnecting such power systems the reciprocal sale of power from one system to another is made possible and a common reserve is made to serve for a large area. Co-operative action thus ensures the utilization of surplus power, safeguards the service from interruptions and secures the advantages of long hour use of investment by building up the diversity of use. This movement for interconnection is growing particularly in the instance of gas and electric utilities.

Availability of Utility Services. — There are also peculiarities arising out of the time when the demand of customers comes and these have a special influence upon cost of production. All public utilities must stand ready to supply their services when demanded and from this point of view utilities may be divided into two classes according to the ease or difficulty with which they meet this situation.

The first class comprises the utilities which must adjust themselves to demand variations by having constantly ready a productive capacity equal to or exceeding the maximum demand for service. Thus utility plants will have spare capacity for service at other times in the shape of idle equipment and reserves of employees. This class of utilities has been called the "service type" and is exemplified by electric utilities, telephone and telegraph utilities, the different kinds of transportation utilities and the postal service. Here the nature of the service is such as not to permit of delay if it is to be performed efficiently. Technical development has not been successful in making available for instant use surplus service which existing equipment might have produced at times of low demand. Changes in the volume of business can not be met by a policy of meeting peak requirements in part by stored supplies of the past. This has a tendency, therefore, to increase the cost of operation.

The second class consists of those utilities where the inequalities in customers' requirements may be met, at least in part, by a policy of production and storage of surplus to meet future deficiencies. This class has been called the "product type." It is exemplified by water and gas utilities which may produce at a uniform rate, impounding the water and storing the gas not required to meet the immediate demands against the excess demands of the future. Storage facilities thus enable the "product type" to operate at a uniform output within the productive limits for which the plant was designed. Utilities of the second class need have a producing capacity equated only to meet an average demand but they must provide storage capacity.

We must, therefore, compare the operating efficiency of the product-type utility, based upon a constant output with costs enhanced by an added investment in storage facilities, with the operating efficiency of the service-type with its lessened efficiency resulting from a variable output and with costs enhanced by "standby" losses and the carrying charges for idle equipment. The services of public utilities are thus conditioned by factors which tend to differentiate them from other business enterprises. They minister to wants which are regarded as basic. From a social point of view they are necessary economic functions because they are the basis for the specialization of occupations and the interdependence which exist in modern economic society.

SOCIAL CONTROL OF PUBLIC UTILITIES

Public service enterprises are regulated by governments throughout the civilized world. It is impossible in this article to trace this development or to outline the present structure of regulation. Those desiring a detailed presentation are referred to the bibliography. In this summary is mainly given a discussion of the development of social control of public utilities in Anglo-American countries. The regulation of national systems of transportation and communication is also excluded except in so far as their prior development has influenced the course of regulation of local utilities.

Munn v. Illinois Decision. — The legal basis of public utility regulation may best be disclosed by considering the famous decision of the U.S. Supreme Court in *Munn* v. *Illinois* (94 U.S. 113 [1876]). In this decision is focused the common historico-legal background of public utility regulation in both the United States and Great Britain. *Munn* v. *Illinois* involved the validity of an Illinois statute fixing maximum rates for storing grain in elevators at Chicago. Munn had been engaged in the elevator business since 1862, long before the enactment of the statute, and had been in the habit of charging rates fixed by agreement among the elevator owners in Chicago and had continued to charge these rates although they were in excess of those fixed by the act. Munn was convicted and fined in the State courts but appealed to the U.S. Supreme Court upon the ground that the act violated the 14th amendment in that it deprived him of his property without due process of law.

Chief Justice Waite, in upholding the validity of the statute, said in substance that under the circumstances in which the elevators were being operated in Chicago, that is, standing in "the very gateway of commerce and taking toll from all who pass," they had become business "affected with a public interest and had ceased to be *juris* private only." This was not his own language but was quoted from Lord Chief Justice Hale who had penned it some 200 years ago in England. This legal doctrine, he said, had been a rule of the law of property ever since; that under this rule and in exercising the police power of the State, "it had been customary in England from time immemorial and in America from its first colonization to regulate ferries, common carriers, hackmen, bakers, millers, wharfingers, innkeepers, and so forth," and to fix maximum charges. In further explanation of this "public interest" doctrine, the court said that private property is being used "in a manner to make it of public consequence, and affecting the community at large. When, therefore, one devotes his property to a use in which the public has an interest, he, in effect, grants to the public an interest in that use, and must submit to be controlled by the public for the common good, to the extent of the interest he has thus created. He may withdraw his grant by discontinuing the use; but, so long as he maintains the use, he must submit to the control."

In a recent case *(Charles Wolff Packing Co.* v. *Court of Industrial Relations of the State of Kansas,* 262 U.S. 522 [1923]), Chief Justice Taft of the U.S. Supreme Court gave further precision to this "public interest" doctrine by saying: "In a sense, the public is concerned about all lawful business because it contributes to the prosperity and well-being of the people. The public may suffer from high prices or strikes in many trades, but the expression 'clothed with a public interest' as applied to a business means more than that the public welfare is affected by continuity or by the price at which a commodity is sold or a service rendered. The circumstances which clothe a particular kind of business with a public interest, in the sense of *Munn* v. *Illinois* and other cases, must be such as to create a peculiarly close relation between the public and those engaged in it, and raise implications of an affirmative obligation on their part to be reasonable in dealing with the public."

Obligations of Public Utilities. — The affirmative obligations upon public utilities arising out of their peculiarly close relation to the public are usually spoken of as that system of rights and duties which constitutes the law of public service undertakings. Briefly, this law places upon a public utility the extraordinary duty to render reasonably adequate service to all who apply. It is required to serve them up to the limit of its capacity, with capacity being defined as the limit of profitableness. It may not let customers' wants go unsatisfied. Nor may it attach unreasonable conditions to contracts for service so as in effect to negative its duty "to serve all comers." Furthermore, it must serve without discrimination all customers similarly circumstanced. Finally, a public utility must observe more than ordinary care in the rendition of service in view of the dependence of the public. On the other hand, the law concedes a public utility the right to collect a reasonable price, to render service subject to reasonable rules and regulations, and to withdraw service under prescribed conditions after giving notice to customers. While customers are given the right to demand that a public utility live up to its duties, they are, on the other hand, required to accept recip rocal obligations.

In determining whether a given industry is subject to this coercive law of public utility the courts have adopted certain practical tests of both a legal and an economic nature. The economic tests look to the presence of elements of natural monopoly in such number and strength that competition can not work successfully. Under these conditions fair prices, in the sense of competitive prices, are not realized. The power of the State will be used either to regulate industries so as to restore equality of bargaining power by maintaining competition and controlling competitive practices, or used to promote the inherent trend toward monopolistic organization by conferring upon such industries legal monopolies and then controlling their economic relations by means of the system of rights and duties just outlined.

From an economic point of view it is clear, therefore, that the notion of a public utility is made up of two ideas: *(a)* the idea of monopoly and (b) the idea of common necessity. Both must be present in order that an industry may become a public utility. Neither alone will suffice. The supply of housing facilities is a necessary economic function, and when it is furnished upon a competitive basis the customer is not coerced. But when, in emergencies such as the acute housing shortage *(see* HOUSING) during the World War, the consumer is forced to bargain for a necessity under conditions of temporary monopoly, the courts will uphold the regulation of rents. Yet the character of regulation will be attuned to the normal condition. The emergency having passed, as building operations are resumed, competition again sets in, and the reason for regulation disappears. The housing industry therefore represents a border line case which, nevertheless, ought not to be classed as a public utility under normal conditions.

Legal Conception of a Utility. — When freedom of choice is seriously restricted — that is, when the coercion residing in private property makes itself felt as a monopolistic power — public interest arises in proportion as equality of opportunity to choose is restricted, provided that the wants supplied are recognized as a common necessity. Monopolization of a luxury will not call forth regulation, for public opinion is the arbiter in the selection of those common economic needs whose monopolization engenders regulation. The concept of public utility thus becomes a legal instrumentality to achieve an improvement of the standard of life. In a society which is accustomed to look to governmental initiative for the supply of common needs, the facility will be supplied as a public function On the other hand, a society which is distrustful of the State will leave the supplying of such common needs to a private agency under a franchise privilege, not as a matter of common right, but as an agency of the State.

Since the law has long recognized the rights and duties of public utilities, this legal conception has attained a certain fixity in the form of legal rules. But the number and kind of industries that may be subjected to these rules is not fixed. It may be said that the legal notion of public utility is that of a fixed concept with a changing content. The industries at any time recognized as "clothed with a public interest" are not necessarily the industries which may legally be classified as public utilities at another time. The industrial and political situation as mirrored in public opinion will determine: (a) the number and kind of industries classified as public utilities; (b) the elaboration of the system of rights and duties which make up the institution; (c) the regulating agencies and instrumentalities employed (whether the legal rules and decrees of courts or the charters, special franchises and statutes of legislatures); and (d) the subordinate administrative standards which are evolved in practice. The trend in the development and application of the institution will be a resultant of the amount of social inertia, of the pressure of the economic environment and of the influence of intellectual progress. Special attention should be directed to these dynamic factors: *(a)* the growth and extension of monopoly; (b) war and other conditions creating special emergencies; (c) the movement for conservation of natural resources; (d) the movement for public ownership.

Regulation in the United States is accomplished in three distinct ways (1) judicialiy by means of suits at law where the common law duties and rights of public utilities are applied in specific cases; (2) legislatively by means of corporate charters or special franchises; (3) legislatively by means of the police power of the States or its Federal equivalent, the power of Congress over interstate and foreign commerce. Judicial regulation is the oldest and constituted almost the only form of control during the first half of the 19th century. Legislative regulation has now largely supplanted judicial regulation, but the latter remains in the background as a potential agency which may become active again if legislative regulation should disappear. The function of the judiciary by 1928 had been restricted to the review of legislative and administrative acts.

Legislative regulation by means of the charter or special franchise was the next to be tried. The special franchise is now generally conferred under constitutional or statutory authority by local governments. The method of special franchise regulation is applied to so-called local public utilities, furnishing telephone, gas, electric, water and transportation services in local communities.

The weakness of legislative regulation by charter was that the maximum rates therein provided were largely in excess of those actually charged by the companies. Competition of carriers with each other, the decreasing unit cost of operation on account of increased utilization of plant capacity, the decline in the level of prices after the Civil War, continuous improvements in technique, made necessary and possible the rendition of service at rates below those fixed in the charters. The failure to provide adequately for financial and accounting control enabled the issuance of more stock and the padding of investment accounts, thus vitiating the control based upon net income. Special franchise regulation followed the procedure applied in the case of carriers. Maximum rates were fixed in the local franchise of telephone, gas, electric and water undertakings. These maximum rates soon became obsolete because the growing business of the companies required more complex and flexible rate schedules. Moreover, the companies began to appreciate that increased earnings, both gross and net, could be secured by means of rate reductions.

When State legislatures in the case of national carriers and local councils in the case of local utilities attempted to adjust these rates downward, they were met by the objection that the change would violate a contractual obligation and confiscate the property of the companies. Only when the franchise was silent on rate questions or when the power to alter, amend or repeal the terms of franchises was reserved, could the power to regulate rates or service be exercised by State or local legislatures. Another evil that had crept into the administration of public utilities due to the ineffectiveness of rate control was discrimination in rates. This was also induced by the fact that competition had never been entirely eliminated. Added to this, in the case of the limited term franchises of local utilities, was the growing insecurity of tenure. Failing to obtain a renewal the properties would be worth only their scrap value. Often there were no provisions for public purchase or for purchase by some other grantee at the end of the franchise period. The inducement was too great, therefore, to manipulate operations so as to enable investors to recoup their capital out of earnings.

Thus the fundamental drawbacks of charter and special franchise regulation were: that such regulation proved inadequate when communities grew rapidly; or when, as during the period of the World War, underlying economic conditions changed rapidly, so that the administrative machinery for the execution of franchise terms proved inadequate.

About 1870–80 a policy was adopted of fixing rates by direct legislation. Legislatures realized that statutory regulation should be general rather than specific; that the rate and service problems require continuous attention; that the subject matter of statutes should be the laying down of principles and standards; that the new policy of continuous regulation required an effective agency, sufficiently "informed by experience" to carry legislative standards and principles into effect. This agency is the modern administrative commission, acting as an agent of the legislature. All States except Delaware now have regulatory commissions with varying jurisdictions. The Interstate Commerce Commission (1887), the Maritime Commission (1938), the Federal Power Commission (1920) and the Securities and Exchange Commission (1935), are Federal commissions regulating the interstate operations of national utilities. The administrative commission applies the common law rule of reasonableness to the concrete facts in each case and names the particular rate or service regulation reasonable under the circumstances. Practically all States prohibit discrimination in rates for service. This legislative injunction has been made operative in connection with another one calling for publicity of rates and providing that only those rates and regulations which are on file and have been approved by the administrative authority are the lawful rates. In some States designated local utilities continue to be controlled by means of franchises. One form of these local franchises, the so-called service-at-cost franchise, deserves special mention. In general, service-at-cost franchises seek to protect invested capital by giving the company an exclusive right to conduct the particular utility, the right being terminable upon purchase of the property at a stipulated price. See also **UNITED STATES**.

REGULATION IN EUROPE

On the continent of Europe practically all of the telephone and telegraph systems and so many of the railroad systems are nationally owned and operated that there is little opportunity for the development of anything approaching the American system of public utility control. This also holds true in a large measure of local utilities. Where local utilities are privately owned they are operated under franchise contracts with the municipalities.

In Great Britain, however, all of the railroads and so many of the local utilities are in private hands that there has been considerable development in policies of social control. Restricting ourselves again in the main to local utilities we find that here also these undertakings have been put in a position of special privilege, and have had conferred upon them special powers with a corresponding measure of special restriction in the public interest. The rendering of water, gas, electric and tramway services is by private corporations, municipal corporations, urban and rural district councils, and also occasionally by joint boards with a distinct corporate existence. Some public utility undertakings were originated by royal charter but this has been supplanted by parliamentary action.

Regulation of public utilities in England is accomplished by the method of "private bill legislation," which is a special act of parliament for each undertaking and which performs the double function of conferring a franchise and of laying down regulatory standards. Usually certain applicable general laws are by reference made a part of the special act, such as the legislation controlling the acquisition of land by condemnation as set forth in the Lands Clauses Consolidation Act of 1845.

Other important general legislation is contained in the following: Railways Clauses Consol. Act, 1845; Companies Clauses Consol. Act, 1845; Watenvorks Clauses Act, 1847; Gasworks Clauses Act, 1847; Harbours, Docks and Piers Clauses Act, 1847; Tramways Act, 1870; Electric Lighting (Clauses) Act, 3899.

In certain cases of common occurrence special legislation by parliament establishing public service undertakings is made unnecessary by permitting some appropriate department of the Government to issue "provisional orders" under general legislation after due inquiry. But full parliamentary control is retained by requiring confirmation of provisional orders, either by parliament itself or, in some cases, by an agency such as the Board of Trade, made effective by resolution of each house of parliament.

The English system of regulation is, accordingly, comparable to the charter or special franchise system in the United States. The most recent legislation of this type is the Gas Regulation Act of 1920, the Electricity Supply Acts of 1919, 1922 and 1926 and the Railways Act of 1921. The focal point of control is the regulation of rates. In the case of private gas companies the first method of control, after a brief preliminary period of competition, was the so-called "Official Revision System." Maximum rates and maximum dividends were fixed in special acts but the power to reduce rates was given to the court of quarter sessions.

Later another method, the system of sliding scales, was used, the adoption of which was optional. There was established a standard selling price for gas and a standard maximum rate of dividend. Then it was provided that the dividend rate might vary in inverse ratio to the rate of charge. Since the maximum dividend method, even when accompanied by official revisions of rates, failed to bring about reductions in charges, the sliding scale method was proposed as a means of automatic regulation and as a stimulus to more efficient management. In 1920 the Board of Trade was empowered temporarily to relieve private gas companies, operating under either method of rate control, of specified rate limitations by reason of changes in economic conditions since 1914.

In order to bring about mergers and reorganizations in the electrical industry which would make possible the generation of electricity in large units and the attainment of greater economy and efficiency, the Electricity Act of 1919 created a board of "Electricity Commissioners" of five members, appointed by the minister of Transport with the approval of the Board of Trade. Most of the regulatory powers over electric undertakings vested in governmental departments were transferred to this body.

Although the world-wide movement toward concentration in electricity supply was apparent in England as elsewhere, it had not progressed as far as in the United States. In order to bring about a more rapid concentration of generation by means of interconnected super-power systems, the commissioners were authorized to define provisional electricity districts, the area of which was to be grouped in a manner "as to be most conducive to efficiency and economy of supply and to convenience of administration." Interested parties comprised within each district, chiefly public and private distributors of energy, might then suggest a "scheme" for the reorganization of the district, or the commission might itself formulate one. On the whole the act failed to achieve its end because many public and private authorities refused to co-operate.

Accordingly the Electricity Act of 1926 created a "Central Electricity Board" with power to carry the "scheme" prepared by the electricity commissioners into effect. For this purpose the Central Electricity Board, operating as a limited company, was authorized to sell stock to the public not exceeding £33,500,000, principal and interest of these loans being guaranteed by the National Treasury. The funds are to be used for the construction of high-tension transmission lines, together with transforming equipment, which will interconnect the power stations selected by the electricity cominissioners in the particular district. The board is to purchase electrical energy from these plants at cost and such other surplus energy as is available in the district, and sell it again at wholesale to the authorized distributing utilities in the district. It is contemplated that the loans will ultimately be paid off out of profits.

Continental Europe. — Similar movements to bring about the large scale generation of electrical energy are being pushed in Italy, France, Germany and elsewhere. In Germany public joint-stock companies are being created, similar to the German Railways Company, with the shares in the hands of the cities co-operating under the plan. In this way it is planned to separate the technical administration and financial management from the political arm of the government, at the same time providing for flexibility in the economic area within which service is supplied.

PUBLIC WELFARE LAW: see POOR LAW.

PUBLILIUS (less correctly PUBLIUS) **SYRUS,** a Latin writer of mimes, flourished in the 1st century B.C. He was a native of Syria and was brought as a slave to Italy, but by his wit and talent he won the favour of his master, who freed and educated him. His mimes, in which he acted himself, had a great success; he was perhaps even more famous as an improvisatore, and received from Caesar himself the prize in a contest in which he vanquished all his competitors, including the celebrated Decimus Laberius. All that remains of his works is a collection of Sentences (*Sententiae*), a series of moral maxims in iambic and trochaic verse, which has been much interpolated with later extracts.

The best texts of the *Sentences* are those of E. Wölfflin (1869), A. Spengel (1874) and W. Meyer (1880), with complete critical apparatus and index verborum; recent editions with notes by O. Friedrich (1880), R. A. H. Bickford-Smith (1895), with full bibliography; *see* also W. Meyer, *Die Sammlungen der Spruchverse des Publilius Syrus* (1877).

PUBLISHING. The modern publisher, as we understand the term, is one who produces printed books and puts them on the market. Of recent years, and especially since the World War, there have been some instances of English and United States publishers conjoining the business of the printer, and in a less degree of the bookseller, with their ordinary function. But it is not the usual practice.

The first problem of the publishing profession is naturally the relation between authors and publishers. The diatribes of authors against publishers are familiar to every one; and publishers, on their side, have some hard things to say about authors, though their sentiments are less piquantly expressed.

However, within the last half century, especially in Great Britain many new developments have taken place, which have helped to bring about a better understanding of the conditions affecting author and publisher, on both sides. The Society of Authors was established in London in 1883, with Tennyson as its first president. It offered useful assistance to authors ignorant of business in the way of examining contracts, checking publishers' accounts, revising their sometimes too liberal estimates of costs of production, and giving advice as to the publishers to be applied to or avoided in any given case. It has, no doubt, been of great service in checking the abuses of the publishing trade, and in compelling the less scrupulous among the publishers to conform more or less exactly to the practice of the more honourable.

In 1896, with a similar aim of co-operation and self-protection, was formed the Publishers' Association, which has undoubtedly tended to raise the standard of their efficiency all round. One of the first questions they had to deal with was the market price of books. Many attempts have been made in the past to destroy free trade in books. In July 1850, 1,200 booksellers within 12 m. of the London General Post Office signed a stringent agreement not to sell below a certain price This agreement was broken almost immediately. Another attempt was made in 1852; but at a meeting of distinguished men of letters resolutions were adopted declaring that the principles of the Booksellers' Association of that period were opposed to free trade, and were tyrannical and vexatious in their operations. *The Times* took an active part in defending and enforcing the conclusions which they sanctioned. The question was eventually referred to a commission, consisting of Lord Campbell, Dean Milman and George Grote, which decided that the regulations were unreasonable and inexpedient, and contrary to the freedom which ought to prevail in commercial transactions. An attempt was also made in 1869 to impose restrictions upon the retail bookseller; but that also failed, mainly by reason of the ineffective organization which the publishers then had at command.

Feeling their hands greatly strengthened by the establishment of their association, the publishers were emboldened to make another effort to put an end to reductions in the selling price of books. After much discussion between authors, publishers and booksellers, a new scheme was launched on Jan. 1, 1900. Books began to be issued at net prices, from which no bookseller was permitted to make any deduction whatever. This decree was enforced by the refusal of all the publishers included in the association to supply books to any bookseller who should dare to infringe it in the case of a book published by any one of them.

The **"Net** System."—With the question of the "net system" of publishing books is connected that of their fixed price, and both have been hotly contested. An earlier encyclopaedist, writing on the matter, put the case strongly against the fixed price. "The cast-iron retail price," he said, "is economically wrong. A bookseller with a large turn-over in the midst of a dense population can afford to sell at a small profit. He finds his reward in increased sales. His action is good for the public, for the author, and for the publisher himself, were he enlightened enough to see it. But a small bookseller in a remote country town cannot afford to sell at an equally low profit, because he has not access to a public large enough to yield correspondingly increased sales. Yet both are arbitrarily compelled to sell only at a uniform price fixed by the publisher. What makes the matter worse is that there is no cast-iron wholesale price. The small bookseller has to pay more for his books than the large one who buys in dozens of copies. Carriage on his small parcels often eats up what profit is left to him. As he is not allowed to have books 'on sale or return,' he has no chance whatever; and as a distributing agency the small bookseller has become negligible." It has-been said, on the other hand, that, "whatever one may think of the Net Book agreement, its function is not to protect the publisher against the bookseller, but to protect the retail trade by forcing the public to pay high prices for books. It is exactly on a par with any other industrial protection; by solidarity the trade is able to exact what it considers its fair prices from the community, and this reacts in favour of all engaged in the trade — authors, publishers, printers, paper-makers, booksellers." The booksellers, we may add, admit that they gained materially by the net system, in bringing which about two publishers, the late J. M. Dent and Sir Frederick Macmillan, were the active pioneers.

In estimating the market value of books, considered as publishers' wares, we have to note that, despite the huge popular vogue of the novel, which enables it to be maintained at a fixed price, above its real value, literature and the classics of literature are now often priced relatively low. This is in spite of the greatly increased cost of production since the World War.

There are certain classes of books which must always be relatively expensive, because they appeal only to students of some particular branch of science or of art or of literature, whose number is not great. But these are books of enduring value. Their price is justified not only by their prolonged service, but by the erudition or the exceptional qualities which go to the writing of them, as well as by the frequently exceptional cost of producing them. But as regards the vast output of books which merely amuse an idle hour, the existence of a large body of readers is the only excuse for their appearance, and if they cannot be produced at a low price, ensuring an extensive sale, they ought not to be produced at all. Thus there is more than a mere money question involved in the contention about price. An artificial system of prices leads to the printing of a vast quantity of trash, which demoralizes the reading public and is a serious obstacle to the success of the better books. Such a system operates, in fact, as a protective duty in favour of mediocrity, and even of something worse.

Then there is the troublesome system of "remainders," that is to say, the unsaleable copies of thousands of books published every year. The editions are small enough—probably not more than 1,000 copies—yet, in spite of circulating libraries, a third or a half of that modest number remains in the warehouses of the publishers. They are often sold for about the cost of their covers; sometimes they simply go to be reduced to their original pulp at the paper mills.

Book Production.—Half a publisher's business, it is said, is taken up with the intricate details of book production. To produce a book well and in a comely or durable form, the publisher needs the eye of a craftsman, and stands to gain if he has had experience in printing, book-binding and all the allied processes of the craft. He must be learned in type, paper, illustrations; in the book cloths, "jackets" and end-papers. It has been calculated that the whole time taken in the production of an ordinary book of about 100,000 words, from the "casting off" and the composition to the machinery and binding, and from the first despatch of the "copy" to the printers, to the return of the completed books, is about 12 weeks in all. Even then, the business of actual publication has not been counted in the estimate. The actual selling is another intricate matter, because of the extent and varied demands of the market. The "publishers' traveller" is in this respect an indispensable assistant. In London, the "town traveller" usually takes a week to a fortnight for his rounds; while the "country traveller," who maps out the whole country in his area, may take six or seven weeks.

Publicity.—This brings us to the other means of making the published book known and creating a demand for copies, by means of advertisement and of press notices. "About the advertising of books," confessed an American publisher (the late Walter H. Page, United States minister to Great Britain), "nobody knows anything. The most that can be said is that some publishers are making very interesting experiments." To this may be added the still more recent comment of an English publisher, who says, "Does any author think his book has been adequately or properly advertised? The answer to that question will explain how dangerous it is for a publisher to mention, or even to suggest, that there are any limitations to what can be accomplished by advertising. Should a publisher ever be rash enough to do so, it is at once assumed that he does not believe in advertising, and he is dismissed as a bad publisher."

As to the cost of advertising, no English figures are available, but for a German publisher 3 to 4% on the cost of production is given by Kliemann as the average amount. He adds that, in addition, German retail booksellers spend about 3% of their turnover on advertising. George H. Doran, the American publisher, claims to spend 10% of his gross income on "promotion." In England the publisher's expenses on advertising are given as about 6% of the turnover.

American and Continental Methods.—Towards the end of the 19th century came a large influx into England of American literature, especially fiction. Not only was there a growing appreciation of many American writers, but the attractive "get-up" of American books made its influence felt upon the British market. Some of the American methods of distribution were also introduced into Great Britain, but at first with only partial success. The most successful effort was the sale of important expensive works through the medium of newspapers.

The methods of publishing in America are in many ways similar to those in Great Britain, but the discount to the booksellers is generally given *pro rata* according to the number purchased. It is, however, in respect of the means of distribution that the systems of the two countries differ most. In America the big stores to a large extent take the place of the English bookseller, and by their energy and extensive advertising a wider public is served. In the distribution of fiction the American plan of "booming" a book by copious advertising, although expensive, is often the means of inducing a large sale, and of bringing an author's name before the public. In 1901 the net system, as adopted in Great Britain, was partially introduced into America.

The Continental methods of publishing and distributing, especially in Germany, differ, in many respects very materially, from those of Great Britain. In even the smallest German towns there is a bookseller who receives on sale, immediately upon publication, a supply of such new books as he or the publisher may think suitable to his class of book-buyers. The bookseller submits these books to his customers, and by this method most books issued are at once placed at the disposal of any buyer interested in the particular subject. The large sums spent in other countries upon advertisements are thus saved. At the book fairs held in Leipzig at Easter and Michaelmas the accounts for books sent on sale are made up and paid. In France all books have to be licensed before publication, but the methods of publication differ little from those of other Continental countries, in all of which book prices are much lower than in England.

In bringing the record down to the last decade, we have to count in the passing of a crisis with the World War. The period 1910–25 saw first a brief time of prosperity, then, during and following the war, a time of extreme disorganization in book publishing. The year 1910 was a prosperous one in the book market, as publishers are apt to remember. New books and reprints were in good demand and were readily supplied under normal conditions. Four years later those conditions were violently disarranged.

Effects of the War.—The World War, which raised the cost and the market value of many staple commodities, had a specifically stringent effect on book production and the book market all the world over. The book, of all manufactured articles, is most subject to the caprices of popular taste and one of the most sensitive to any change in the normal economic conditions or the ratio of supply and demand. It is not, like food and clothes, an absolute necessity, nor is it to the idle rich what a great sybarite called an "essential luxury." The process of recovery after a war does not affect books, any more than works of art, with the economic certainty that we observe in boots and shoes, for instance, or in the cotton trade. At the same time certain forms of literature, which offer an escape from actuality and the newspaper, are bound, after a war, to be in growing favour. It is interesting to examine on both counts the post-war returns of books published in Great Britain.

In 1918, when the war ended, the number of new books printed and published was 6,750, the number of reprints 966, which together give us a total of 7,716. In 1924, six years later, the new books had risen to over 9,500, while the reprints, which had suffered badly during the war because of the cost of production and the impossibility of supplying cheap books at a profit, showed a startling recovery. They had increased to over 3,190, actually 255 volumes more than the number of reprints in the year that immediately preceded the war—1913. The total number of new books was not quite so large as in the earlier year, whose October output—a test month in book publishing because of its nearness to the Christmas season—had established a record, namely 1,699 volumes, new books and reprints included. The October return in 1924, it is significant to note, was only 180 behind that figure.

The increasing vogue of the reprint is remarkable. During the war a new taste for reading grew up among the soldiers who had leisure days to pass in hospital or at the base. Some millions of volumes were collected and sent over to the army huts under the auspices of various societies organized for the purpose, or under the seal of the Red Triangle. The editor of one popular series supervised the collection in London and the dispatch to France of over 2,000,000 volumes, new and old, obtained from a house-to-house canvass of the metropolis. This popularizing of literature at large helped to increase the available reading public. But certain classes of books did not maintain their hold on the public when peace came again. In technology, for instance, whose manuals were specially required while the ex-soldiers were seeking work in the skilled trades, the demand fell off noticeably in the succeeding years. The analysis of books in *The English Catalogue* for 1923–24 marks a decrease in the latter year of over 100 published works in technology. In science the decrease was not very far short of that figure. History, medicine and geography also showed a decrease; on the other hand, fiction—easily first—biography, travel and guide books, including what we may call picturesque topography, poetry and the drama, religious books, sports and games and sociology all showed an increase of circulation.

A Ten-year Survey.—If we take a ten years' survey, we discover some curious fluctuations in the returns. In 1914 fiction came first, religion second and science third. Sociology and technology followed close. Poetry, juvenile literature, travel and topography, literature and criticism, history, biography and finally naval and military books, complete the list of a dozen sections, named in the order of their relative popularity. In 1924 fiction was still at the head. Juvenile literature had advanced from the seventh to the second place in the list. Religion was third. Science had fallen from the third to the seventh place. Poetry had advanced while technology had lost a point. Biography, thanks in part to the interest in characters and personalities who had come into prominence during the war, or because of some new reaction to its sharp stimulus, had gained markedly. It is harder to explain why, in that case, history books should have dropped in the comparative scale. Books of travel and books dealing directly or indirectly with literature had also declined slightly.

It would be easy to make too much of these differences. As between one year, or one publishing season, to another, it is necessary to allow a margin for accidental delays owing to strikes, as in the winter season of 1925–26, when the packers caused a serious break in the ordinary supply of books and periodicals, or for diversions of the public interest, as at the time of political excitement or of general elections. On the whole the yearly average in every class of book offers a very fair test of popularity. But as we note the startling preponderance of the first of those classes—fiction, especially the novel—we are driven to consider again how deceptive are the signs of success, and to recognize the notorious discrepancy between the seasonal and the permanent result.

The Publishing of Novels.—We have it on the authority of one large firm of London publishers, that nine out of every ten novels published are comparative failures; that is, they show no decided profit to author or publisher. Another firm put the percentage of failures still higher, and it has been estimated that the average life of a market novel is no more than a month, and that very few survive the year of their birth. In an essay written by Andrew Lang on "The Last Fashionable Novel," he lamented that the type of story in which lords and ladies were favourite characters as during the Victorian vogue, has ceased to exist. That fall from favour serves to remind us that the novel, whether viewed as one of a group or as a single product, is the most perishable of all quasi-literary commodities, and that the producers of such books are tempted to inflate their selling value artificially. It was so when the three-volume novel was given the absurd price of 31s. 6d. It is so when the novel is put upon the market at a net price of 7s. 6d.

Two comments by a successful American fiction publisher, on the market success of the novel may be added:—"To sell a novel that has the mysterious quality of popularity in it is not difficult. Properly launched, it sells itself. To sell a novel that lacks the inherent quality of popularity—that is almost impossible. Apparently it has sometimes been done, but nobody can be sure whether the result after all was due to the book or the salesman. Every publisher has proved, over and over again, to his disgust, that he cannot make the people buy a novel that they do not want; and when a novel appears (no better novel) that they do want, the novel readers find it out by some free-masonry and would buy it if the publishers tried to prevent them.

"Nobody has discovered a rule—to say nothing of a principle—whereby the popularity of a novel by a new writer may be determined. If it be a really great, strong book, of course it is easy to understand that it will sell; but whether it will sell 10,000 copies or 100,000 nobody knows. If it be a slap-dash dime novel, full of action, it is easy to guess that it will sell, but whether 5,000 or 500,000 nobody knows. Sometimes a book of the sheerest commonplace happens to hit the public mood at the happy angle and sells beyond all expectation. The truth is, every new novel by an unknown writer presents a problem peculiar to itself; and in advertising it and offering it for sale, every book's peculiar problem must be studied by itself."

Great Britain **and** the United States: a Comparison.—The trade organ in New York that corresponds to *The Publishers' Circular* in London, namely, *The Publishers' Weekly*, does a like service in collecting annually the returns of new books and reprints that are issued from the press. In 1924 the number of new books published in the United States—or "new titles," as the register more precisely terms them—written by American authors, was 6,380. In addition, over 600 English and foreign works were printed and manufactured in America, and over 1,700 were imported. Roughly summarized, the American production, that is so far as it is comprised in the New York returns for the whole book trade, is compared with that of Great Britain in the ratio of eight to six. More to our present purpose is the comparison instituted in the *Publishers' Weekly* between the book returns for 1923–24 in America with a further recast to the year 1910. There was effectively a 2% increase in 1924 over 1923, but the new titles registered in 1924 were only on a par with those of 20 years before—1904. Six years later, in 1910, the number of new titles was 11,671, or nearly double that of 1924.

As regards the comparative popularity in America of the different classes of books, in 1924 fiction was at the head of the list, but not with anything like the preponderance it showed in the British book trade. Religion came second, poetry and the drama together came third, with a total of 13 new titles more than those registered in Great Britain. Science stood relatively low in the scale and showed a decrease from the figures of the preceding year. Juvenile books, too, lost a point or two; but biography, as in the London book market at the same period, marked a distinct rise. Business books, which are rather an American speciality, also had appreciated in the scale.

Conditions in Other Countries.—Certain wider questions which affect book production and the writers, publishers and sellers of books can only be treated summarily. We must turn to the *Bibliographie de la France* if we would estimate the signs of recovery in the French book market since the war. In 1923 the returns give a total of 8,784 books, a pro rata advance since 1918, steadily maintained year by year, but not so marked in recent seasons. At the same rate of progression, the returns for 1924 should give a total of books registered slightly ahead of that for the year when the war broke out—1914.

In Germany the returns are noticeably higher than in any other country, displaying a total for 1923 of over 35,000 publications. But that includes miscellaneous publications which are not counted as books in the returns for other book-producing countries. In the Italian census furnished by the *Bolletino delle Publicazioni Italiane,* the lists for 1921 and 1922 are relatively encouraging, and in the international scale show an unusually high percentage of educational text-books and manuals. In the former year, for example, the number of works of fiction issued from the press was 580, while in social science the number was 660, and students' manuals are little behind that high figure. Poetry and the drama together number 477 volumes, religion only 206. Philology, surprising to say, stands higher than history. Philosophy is well placed, but cannot compete with the science of words. In the returns for the following year these classes preserve very much the same comparative position, but fiction and religion lose ground; history and biography gain. So do volumes dealing with the fine arts, and also those with military and naval science. Among other European returns may be noted those for Norway, Spain and Switzerland, as marking a slight advance in 1922 from the figures of the year previous.

In the republic of books all the world over the signs are in the main encouraging, and disclose a healthy state of recovery from the war years of stagnation. In a 25 years' review and retrospect, the publishers' organ in New York pointed to several notable factors in the increased power of the book and the widening of its market since the opening of the 20th century. The better ordering and specializing of the bookshops, the greater intelligence of the booksellers and the national development of children's libraries, have all contributed to that advance.

England might learn some practical lessons from America in these things. By the forming of such associations as the National Book Council and the Society of Bookmen she has, however, shown herself of late years newly alive to the cordial co-operation of publishers, booksellers and authors. A recent writer, alluding to the book fairs in Florence, Frankfurt and Paris, advocated a similar yearly event in London itself. Paris had two book fairs in 1925, one at the Universal Exposition, the other, a smaller, more specialized bibliophilic festival, was held in connection with the time honoured Fair of Saint Germain. Either of these might be imitated, with an English or American difference, in London or New York, with good effect in stimulating the interest of the public and the activities of the book producers and publishers.

PUCCINI, GIACOMO (1858–1924), Italian operatic composer, was born at Lucca on June 22, 1858, of a family already distinguished in music: his great-great-grandfather Giacomo, great-grandfather Antonio, grandfather Domenico, and father Michele, having all been professional musicians. He was educated at the Milan Conservatoire where he studied under Ponchielli. In 1889, *Edgar* was performed at La Scala, and in 1893 his *Manon Lescaut* in Turin. The former, based on *La Coupe et les lèvres* of Alfred de Musset, was a failure, but the latter, founded on the well-known story of the Abbé Prévost (which had been previously treated by three other composers, Halévy, Auber and Massenet) was favourably received, and still holds the stage. Its success was as nothing compared with that of the work which followed it, the sparkling *La Bohème* (Turin, Feb. 1, 1896). The libretto is based on Murger's novel from which four scenes are taken, and the skill and resource and effectiveness with which they are treated leave no room for doubt as to the merits of the work. In *La Tosca* (Rome: Jan. 14, 1900), based on Sardou's tragedy, Puccini had an altogether different task, of which, however, he acquitted himself no less successfully. The work contains indeed some of the strongest and most genuinely dramatic music which he ever wrote, and like *La Bohème* has enjoyed unlimited popularity at the hands of the general public from the first.

Madame Butterfly, on its first performance at La Scala on Feb. 17, 1904, was pronounced an absolute failure. Probably the libretto of the opera, with its unusual setting in Japan, had at least as much to do with this result as its music, but in any event the Milan public's unfavourable verdict was speedily reversed when the work was heard again at Brescia three months later, and since then its popularity has been prodigious and world-wide. If equal success did not attend its successor *La Fanciulla del West* (The Girl of the Golden West), this was easily accounted for, not only by the unsatisfactory character of its "book," but also by the undoubted inferiority of its music, so that the work, though favourably received when first performed in New York (Dec. 10, 1910), has never found general favour. Of the one-act operas *Il Tabarro, Suor Angelica,* and *Gianni Schicchi,* which followed, all contain clever and characteristic music, but only the third, based on a most amusing libretto, has kept its place in the general repertory. As regards *Turandot,* the composer's last work, which he had not quite finished at the time of his death, and which was completed by Alfano, and produced at La Scala on April 25, 1926, critical opinion has been sharply divided. While some condemn it severely, others reckon it the composer's finest achievement. Puccini died at Brussels on Nov. 29, 1924.

See A. Weissmann, *Giacomo Puccini* (Munich, 1922); A. Fraccarroli, *La vita di G. Puccini* (Milan, 1925); and Wakeling Dry, *Giacomo Puccini (Living Masters of Music)* (London, 1906).

PUDDINGS. The word pudding denotes a sweet dish; it is also used in connection with meat, but then its use is restricted to meat boiled or steamed inside a case of suet pastry *(see* **COOKERY** and PASTRY: *Home-made).*

The following recipes are for typical British puddings: *Milk Puddings:* Allow 4oz. of rice (Carolina), sago or tapioca to one quart of milk, 1 tablespoonful of sugar or more to taste and a pinch of salt. Grease a pie dish. Put into it the cereal, add salt, sugar and milk and, if liked, a grate of nutmeg, or keep a piece of stick vanilla in the sugar jar and so obtain a flavour of vanilla. Stir well, and then occasionally for the first hour. If a dessert-spoonful of butter or a little cream is stirred in after the first hour the pudding will be better. Cool oven. Time 3 hours.

Variations of milk puddings which are cooked on the hot plate and served cold are: *Creamed Rice, Tapioca or Sago* (cold): 2oz. of rice, tapioca or sago, cream, 1 pint of milk, powdered chocolate or other garnish. Cook the cereal in the milk in a double pan until quite soft and thick, sweeten and flavour to taste. Spread in a glass dish: when cold cover with cream or custard and garnish with powdered chocolate, hundreds and thousands, or cherries and angelica.

General Directions for Steamed Puddings: Grease the basin, allow room for the mixture to swell, and cover with a greased paper; the reason for this covering is that steam condenses on the inner side of the lid of the pan, and would drip into the pudding and make it heavy if it were not protected. The water must be boiling in the outer pan or steamer when the pudding is put in and must be kept boiling steadily. Be sure the water does not boil away, and add more boiling water if necessary.

Suet **Puddings:** *Plain Suet Pudding:* 6 oz. dry sifted flour, ½ teaspoonful baking powder, pinch of salt, 2½oz. suet, cold water. Mix flour, baking powder and salt well together, then with clean floured hands rub into it the suet, finely shred, using the finger tips. Mix in by degrees a small teacupful of cold water, using a knife for the mixing. Finish according to general directions.

Plain Suet Pudding (with bread crumbs): Use recipe No. 1 but allow 4oz. flour and 2 to 3oz. fine stale bread crumbs.

Richer Suet Pudding: Proceed as in No. 2 but allow 3 to 4oz. suet and add 1 egg and milk instead of water. Beat egg into the milk.

Roly-Poly, Treacle, Jam or Sultana: Mixture for suet pudding

1 or 2; treacle, bread crumbs, lemon. When the dough is mixed roll it out on a floured board in a long thin strip. Spread with syrup thickened with bread crumbs and flavoured with lemon. Roll up, seal the ends well, tie in a scalded floured cloth, and put into a pan of boiling water. Boil steadily for about 3 hours. Untie the cloth and put the pudding on a hot dish Slice it and dust it with castor sugar. For *jam* roll proceed as above but use jam and omit bread crumbs as the jam does not need thickening. For *sultana roll* add 3oz clean, dry, floured sultanas to the pudding mixture.

Boiled Fruit Pudding (hot): Suet crust (*see* **PASTRY**, HOME-MADE) fruit, sugar. Roll out the crust two or three times and let it stand a little after rolling. Line a greased basin with it, fill with prepared fruit and sugar (if the fruit is dry add a little water) put on a cover of paste and press the edges together. Tie in a scalded floured cloth and boil for 1½ hours, or steam for 3 to 3½ hours with a greased paper tied over the top.

Christmas Puddings: The "king's *empire recipe*" for Christmas pudding contains the following ingredients, the proportions of which may be taken as standard: 2½lb. currants, 2½lb sultanas, 2½lb. stoned raisins, ⅝lb. minced apple, 2½lb. bread crumbs, 2½lb. beef suet, 1lb. cut candied peel, 1¼lb. flour, 1¼lb. Demarara sugar, 10 eggs, 1oz ground cinnamon, ¾oz. ground cloves, ¾oz. ground nutmeg, ½ teaspoonful pudding spice, ½ gill brandy, 1 gill rum, 1 quart old beer

Chop suet very finely, add flour and bread crumbs, fruit (washed, picked, dried and floured), candied peel chopped fine, spice, lemon rind, sugar and eggs Over all pour the liquids, stir well and put all aside to swell and blend until next day, then put mixture into a basin, filling it quite full, tie a scalded floured cloth over it, making a pleat in the cloth to allow for the pudding swelling, put into a pan of boiling water and boil for 6 hours at least. The pudding should then be hung up in a cool dry place and re-boiled for 2 hours when needed.

To scald a cloth, dip it into boiling water and squeeze it dry and then dredge flour over it.

Sunday Plum Pudding (hot) : ½lb. flour, 1 teaspoonful baking powder, 6oz. suet, ½lb. sultanas, 2 eggs, ½ teacupful golden syrup, a little milk. Mix according to directions, but steam at once for 4 hours in a greased basin. This pudding is a deep golden brown, light and crumbly when well made.

Sponge *Pudding:* 4oz. flour, 3oz. sugar, 2oz. butter, 2 eggs, 1 teaspoonful baking powder, milk. Cream butter and sugar together, add each egg, separately. Beat well, stir in flour and baking powder iigbtly, add milk until mixture drops easily from the spoon. Pour into greased mould, steam for about 1 hour and serve with jam or custard sauce. (D. C. PE.)

PUDDING-WIFE. A tropical American fish of the wrasse family (Labridae), called also doncella. It has a deep, compressed body, which is covered with large scales except on the head, has strong canine teeth in the front part of the jaw, and attains a lengrh of 18 inches. In colom the pudding-wife is a vivid blue-green tinged with bronze or soft orange, though varying somewhat with sex and age. Spots and streaks of blue, especially on the head, fins and through the eye, add to its attractive appearance.

THE PUDDING-WIFE (IRIDIO RADIATUS), A

PUDSEY, a municipal borough in the Pudsey and Otley parliamentary division of the West Riding of Yorkshire, England, served by the L.N.E.R. Pop. (est. 1938) 27,880. Area, 8.3 sq.mi. It has an important woollen trade and dyeing and fulling mills. It was incorporated in 1900 and considerably enlarged in 1937.

PUDUKKOTTAI, a state of southern India, lying between the British districts of Tanjore and Madura. Area, 1,179 sq.mi. Pop. (1931), 400,694. The state consists mainly of an undulating plain, largely barren; it is interspersed with rocky hills, especially in the south-west. Rice is the chief crop. There are no large industries. The chief, whose title is tondaman, is of the Kallan or robber caste. His ancestors received a grant of territory for loyal services to the British during the wars in the Carnatic at the end of the 18th century.

The town of Pudukkottai had a population in 1931 of 28,776. It is well laid out and contains several fine public buildings, a college and a training school.

PUEBLA, a State of Mexico, occupying the south-east angle of the great central plateau, or that part of it known as the Anáhuac table-land with an elevation of from 5,000 to 8,000 feet. Area, 13,125 sq. miles Pop. (1930) 1,150,425, largely civilized Indians and mestizos. Lofty mountains overlook the plateau from the north-east and west, three of the highest peaks, Orizaba, Popocatépetl and Ixtaccihuatl rising above the permanent snow-line, while another, Malinche, lifts its isolated mass nearly to that limit. In the south the table-land breaks away and long fertile valleys lead downward toward the warm southern plains. The central table-land forms part of the watershed between the eastern and western drainage systems, some of the streams in the north and south-east emptying into the Gulf of Mexico, while the Atoyac, which has its source in Tlaxcala, crosses the State and discharges into the Pacific through the Rio Balsas or Mescala. Puebla has a temperate, healthy climate, one of the best in Mexico. The soil is generally fertile and the rainfall moderate (36 in.). Agriculture is the principal industry. The Mexican, Interoceanic and Mexican Southern railways, cross the State.

PUEBLA (full title *La Puebla de* lor *Angeles,* and more recently, *Puebla de* Zaragoza), a city of Mexico and capital of the State of the same name, on the banks of the Atoyac river, 130 m. S.E. of the city of Mexico. Pop. (1930) 114,793, including a large percentage of Indians. Its railway connections put it in daily communication with the national capital, Vera Cruz, Pachuca, Oaxaca and the terminal ports of the Tehuantepec railway — Puerto Mexico and Salina Cruz. The city is built on a broad healthy plain, about 7,200 ft. above sea-level. It is well provided with street railways, electric and gas illumination, water and drainage. The great Doric cathedral, about 165×320 ft., is perhaps the finest ecclesiastical building in Latin America. It was begun about 1552, but not completed until 1649. Among other churches, famous for their lavish decorations, are those of San José, San Cristóbal, Santa Catalina and Santo Domingo. The "Teatro Principal," built in 1790, is said to be the oldest existing theatre on the continent. There are several other theatres, and an immense bull-ring. In 1911 a terrible massacre of revolutionary forces by the Federal troops took place within and around this bull-ring. Among the more conspicuous public buildings are the palace of justice, the building of the State legislature, a school of medicine to which is attached the Palafoxiana library of over 100,000 volumes, an academy of fine arts, and the national college. At Ft. Guadalupe, near the city, there are several hot sulphur springs, which are used for medicinal baths. Puebla is one of the busiest manuiacturing cities in Mexico, and among its products are cotton and woollen textiles, soap, glass, straw hats, pottery and leather goods. There are also some large foundries.

Puebla was founded in 1532 by Sebastián Ramirez de Fuenleal, archbishop of Santo Domingo and the celebrated Franciscan friar Toribio Motolinia. In 1550 it became the see of the bishopric originally created in 1526 at Tlaxcala. The appellation "de los Angeles," which is now practically dropped, originated in a popular belief that during the building of the cathedral two angels every night added as much to the height of the walls as the workmen had completed on the preceding day. Its present title was given in honour of Gen. Ignacio Zaragoza (1829–62), who successfully defended the city against the first French attack in 1862.

PUEBLO. The agricultural, town-dwelling Indians of the semi-desert south-western United States. They are of four distinct linguistic groups: (1) Shoshonean, comprising the seven Hopi (*q.v.*) villages in Arizona; (2) Zuñi (*q.v.*), one town in western New Mexico; (3) Keres. comprising Acoma (*q* v.), Laguna, Sia, Cochiti, Santa Ana, Santo Domingo, San Felipe, all but the first two in the Rio Grande valley; (4) Tano, consisting of three divisions, all near the Rio Grande: (a) Tiwa, five towns, of which Taos is the most northerly and best known; (b) Tewa, six pueblos (including Hano among the Hopi); (c) Jemez. The aggregate population is not far from 10,000, stationary or slowly decreasing, and approximately equally divided between the four speech groups. At the discovery in 1540 the Hopi, Zuñi and Keres may have been twice, the Tano three or four times, as numerous as to-day; the number of towns has also decreased, though some new ones have been founded. The Pueblos live on ancestral lands and cultivate these much as in the prehistoric period, though they have added wheat to maize and acquired some sheep, cattle, horses and asses; their houses, though larger, are of the old type; their religion has been successfully maintained by the Hopi and Zuiii and partly preserved alongside Roman Catholicism by the Keres and Tano. They are peaceable, gentle, unenterprising. quietly industrious and conservative. Physically they are fairly uniform; below average in stature, generally brachycephalic, with the skull somewhat flattened occipitally from the cradle-board.

Of all the tribes of the United States the Pueblos are most similar to the advanced native peoples of southern Mexico, and the bases of their culture — maize-beans-squash agriculture, cotton growing and weaving, turkey rearing, painted pottery, masonry architecture, ritualism — are no doubt derived from these Mexican civilizations. They lack, however, a number of accomplishments characteristic of the Aztec, Toltec and Maya, such as metallurgy, political organization, calendrical system, ideographic writing, temples and pyramidal substructures. Since some of these traits have an age of about 2,000 years, the main influences emanating from Mexico are likely to have reached the Pueblos perhaps as much as three millennia ago.

South-western archaeology reveals a development through several stages: (1) Basket maker, possessing maize but apparently no other cultivated plants; no pottery or stone houses; spear thrower, but no bow; the physical type was long-headed. (2) Post-basket-maker, with crude pottery, slab-lined pit houses, the bow and arrow. (3) Proto-Pueblo, with the short-headed type which has persisted to the present; masonry, painted and neck-corrugated pottery, cotton, the turkey, the essentials of historic Pueblo culture, are already present. (4) Early Pueblo, in small house clusters; black-on-white and body-corrugated pottery; this is the era of most of the cliff dwellings and of the greatest geographical extension of Pueblo culture, ruins in Nevada and well north in Utah belonging to this period. (5) Great Pueblo period, with large towns like Pueblo Bonito and Aztec, centring in the San Juan drainage; the northernmost area had been given up, but the ruins in Chihuahua, like Casas Grandes, seem to be of this epoch. (6) Late Prehistoric Pueblo, with glaze-painted pottery; the San Juan area and Chihuahua extension had been given up, but there were still Pueblos on the middle Rio Grande near El Paso. The Spanish discovery of 1540 falls in this period, which may be assumed to have continued until the influence of the missions became strong in the early 17th century, or until the general Pueblo rebellion of 1680. (7) Historic Pueblo, after the unsettlement caused by the rebellion; pottery is again painted instead of glazed, but both black-on-white and corrugated ware are long since forgotten; domesticated mammals have been introduced and sheep's wool tends to take the place of cotton for clothing.

In general, the Pueblos did not irrigate, although they knew how to choose farmlands containing sub-soil water. They are matrilineal and matrilocal, women owning the houses; but men order all public and religious matters. On the Rio Grande the clans weaken and moieties appear, until in the extreme northern towns clans are, to-day at least, lacking. The religious edifice is the kiva, Spanish estufa, a small semi-underground structure for the performance of esoteric rites. Temporary altars are erected in these, often with ritualistic sand or meal paintings; feathers are "planted" as offerings at outdoor shrines; and for all religious organizations, offices and clans there are fetish bundles. The mythology is characterized by tales of emergence from the lower world and long tribal wandering. Cults take three chief aspects: (1) Youths are initiated into a communal men's society performing masked dances representative of gods and ancestors — kachinas. (2) Men and women are initiated individually into "fraternal" societies whose main function is curing, although there are also war and hunt societies; masks are little used. (3) Hereditary priests fast, entreat and pray for rain for the crops and communal welfare, and ultimately direct not only all religious affairs but the civil officials. Ritual symbolism is rich, especially as regards the idea of fertilization and number-colour-direction symbol patterns.

P. E. Goddard, *Indians of the South-west* (1921) and A. V. Kidder, *South-western Archaeology* (1924), summarize the ethnology and archaeology and list the principal monographic works. (A. L. K.)

PUEBLO, a city of Colorado, U.S.A., on the Arkansas river at the mouth of Fountain creek, 120 m. S. by E. of Denver; the county-seat of Pueblo county and the second city of the State in size. It is on Federal highways 50 and 85; has airmail service; and is served by the Colorado and Southern, the Colorado-Kansas, the Denver and Rio Grande Western, the Missouri Pacific and the Santa Fe railways. The population was 43,050 in 1920 (79% native white) and 52,162 in 1940 by federal census. It lies at an altitude of 4,690 ft., near the coalfields of the state and many of the metal deposits, in an irrigated region of 50,000 ac., which produces 65% of all the cucumber seed grown in the U.S. and great quantities of red clover, cantaloupe, squash and onion seed. San Isabel national forest (600,000 ac.) is 20 mi. to the south and west. Pueblo is an important manufacturing centre, "the Pittsburgh of the west." The industrial pay roll for the city and its suburbs amounts to about $20,000,000 annually. At Minnequa, on the mesa south of the city, is the plant of the Colorado Fuel and Iron corporation, employing 5,000 men in mining and 5,000 more in the Pueblo mills in the manufacture of iron and steel. There are plants for meat packing, brooms, brick, tile, tents, awnings; also foundries and machine shops. The debits to individual accounts in the city's banks totalled $35,558,367 in 1940. The assessed valuation of property for 1940 was $27,507,-522. Since 1911 the city has had a commission form of government. It is the seat of the State hospital for the insane (established 1879). In 1806 Lieut. Pike and his exploring party camped at the confluence of Fountain creek with the Arkansas ("The Forks," he called it), and the spot was visited by Major Long in 1820. A band of Mormons settled here temporarily in 1846–47 on their way to Utah. In 1850 a trading post was established. In 1858 a settlement (Fountain City) was made on the east side of Fountain creek, and the following winter (1859–60) the townsite of Pueblo was laid out and the first house was built on the site of the present city. Regular stage service to Denver began in 1862, but development was slow until the Denver and Rio Grande Railroad reached the Arkansas in 1872. The two pioneer settlements were consolidated and chartered in 1870, when the population was about 500.

By 1880 this had grown to 3,217. Other railroads reached the city in 1875, 1887 and 1888; the Colorado Coal and Iron Company had its steel works in operation in 1881; and in 1890 the population of the city was 24,558.

PUENTE GENIL, a town of southern Spain, in the province of Cordova; on the right bank of the river Genil or Jenil, a tributary of the Guadalquivir. Pop. (1930), 23,410. Puente Genil is on the Cordova-Malaga railway, and is the starting-point of the line to Linares. A bridge across the Genil, from which the name of the town is derived, joins the lower part of Puente Genil with the higher. The principal industry is the manufacture of olive oil. There are also flour-mills and linen factories.

PUERPERAL FEVER. A medical term implying a general blood-poisoning of the same nature as that arising from an infected wound (see SEPSIS), its specific name indicating merely its origin from childbirth or miscarriage. The area becoming the seat of infection is usually the raw surface inside the womb left after separation of the afterbirth, though lacerations at the mouth of the womb and elsewhere in the genital passages may also provide an avenue for the entry of organisms.

The infecting organisms are the pus-producing cocci, of which the streptococcus pyogenes is the commonest and its haemolytic forms the most serious. Other pyogenic cocci (*e.g.,* staphylococcus, gonococcus, pneumococcus) and bacteria from the bowel (*e.g.,* colon bacillus and the gas-forming B. Welchii) are occasional infecting agents.

Infection may either be *exogenous, i.e.,* introduced from without by those attending the woman, or *autogenous, i.e.,* due to further spread of organisms already present in the patient's genital tract (cervix or vagina) or from septic foci elsewhere in her body {mouth, tonsils, etc.). It is generally accepted that the majority of puerperal infections are exogenous, but the autogenous infections are held by some to be more frequent than is commonly supposed. Rarely cases of puerperal fever arise in patients who have delivered themselves naturally and without any internal examination being made, and streptococci are not infrequently discovered before labour in the neck of the womb or vagina, especially in women who have suffered from gonorrhoea or have had previous labours or abortions, but they are very rarely of a haemolytic or virulent type.

Some idea of the frequency and seriousness of the disease may be gathered from the fact that over 1,000 women die from it every year in England and Wales, and a much larger number recover, many of them being left with some permanent invalidity or disability. The Registrar General's returns show that the death-rate from puerperal fever is about 1·5 mothers per 1,000 live births registered. It forms about 40% of the total maternal mortality in childbearing.

Symptoms commonly arise about the third day after delivery, the first sign being fever with quickening of the pulse. If the temperature exceeds 103° F rigors may occur and heavy sweats with remissions of the fever. The womb remains enlarged, the discharges from it may be profuse and foul-smelling or more rarely scanty and free from odour. Serious symptoms are persistent high fever and pulse-rate, repeated rigors, presence of streptococci in the blood, especially if haemolytic, sleeplessness, delirium and diarrhoea. Lung and abdominal complications are of evil omen. The disease has always grave possibilities but the case-mortality is under 10%.

Prevention on antiseptic principles has not succeeded to a like degree to that accompanying the prevention of sepsis after surgical operations, and the reasons therefor are not fully understood. The more natural the labour and the less the interference, the less is the incidence of fever. Conversely, the more prolonged and extensive (*i.e.,* the higher up the genital canal) the interference and the greater the trauma caused, the greater the risk of infection. Cleansing of the external genitals, disinfection of instruments and dressings, wearing of sterilized gloves, lessen the risk but will not wholly eliminate infection, because it is impossible to render the external genitals, anus and surrounding skin absolutely germ-free. Hence the introduction of hands and instruments within the genital passage carries with it the risk of conveying organisms. Manual removal of the afterbirth retained in the womb is specially liable to be followed by fever and this time-saving manoeuvre must be avoided to the greatest extent possible.

Infection is readily carried from other puerperal patients and from septic wounds and may be spread by the coughing or breathing of those with septic tonsils over instruments and dressings. The readiness with which the infection may be carried by doctors, nurses and instruments from patient to patient accounts for the appalling mortality that used to obtain in lying-in hospitals and institutions. Such mortality is now a thing of the past.

The severity of the disease depends not only on the virulence and dose of the infecting agent but also on the power of resistance of the patient. Ill-health, especially kidney disease, diabetes, loss of blood and exhaustion, lower resistance generally. The local resistance of the tissues of the generative tract is lowered by bruising and injury.

Treatment is first of all preventive; the most urgent measures are to adopt the same antiseptic and aseptic precautions in labour as for a major surgical operation; and further by antenatal care to maintain the vitality at its best, avoiding all foreseeable complications in labour, and generally to secure natural delivery without interference. Complete emptying of and free drainage from, the womb are likewise essential, and these also must be carried out under the strictest antiseptic and aseptic conditions.

Curative treatment of puerperal sepsis depends on good nursing and attention to every detail of the patient's comfort. Fresh air and sunshine increase the powers of resistance, and artificial methods of increasing tissue-resistance by antitoxic sera and vaccines are also adopted. Antiseptic injections intravenously are tried but are not very successful. Local treatment of the infected uterus has the danger of spreading the infection and is now restricted to such simple measures as the injection of glycerine to promote a free flow of lymph. Pelvic abscesses and other complications must be looked for and treated surgically. Recognition of the fact that puerperal fever must be a preventable condition in the large majority of cases has led to the formation of a strong departmental committee of the British Ministry of Health to enquire into the conditions of its occurrence and devise means for its better prevention and treatment. There is reason to believe that the condition is more common in certain districts (*e.g.,* the low-lying Thames valley) than in others but the establishment of this as a fact together with its explanation, if true, await elucidation. (J. S. FA.)

PUERTO CABELLO, a city and port of Venezuela, in the State of Carabobo, 34 m. N. by W. of Valencia, the capital of the State. Pop. (1936), 20,622. Puerto Cabello has railway and motor road connections with Valencia and thence with Caracas. It stands on a small peninsula which partly shelters a large bay. After La Guayra the harbour is the principal port of Venezuela, and is provided with mole, wharves, and other facilities for the handling of merchandise and produce. The protected area is small but easily accessible to the largest vessels calling at Venezuelan ports.

Puerto Cabello ranks first as a port of export for hides and skins, second for coffee and third for cacao. Of additional importance to the port has been the establishment there of the national dry dock and navy yard, which has two floating docks in operation for the repair of coasting vessels and small steamers, a large machine shop and building facilities for small vessels. The town and harbour were strongly fortified in colonial times. Among the exports are coffee, cacao, dyewoods, hides, skins and copper ores. Puerto Cabello suffered much in the War of Independence, changing hands several times and remaining in the possession of Spain down to 1823.

PUERTO DE SANTA MARIA, a seaport of southern Spain, in the province of Cádiz, on the right bank of the river Guadalete, with a station on the railway from Cádiz to Seville. Pop. (1930), 19,714. Puerto de Santa Maria, commonly called "El Puerto," is probably the *Menesthei Portus* of Ptolemy. Its most important industry is the wine trade; there are also glass. liqueur, alcohol, starch and soap manufactures.

PUERTOLLANO, a town of central Spain in the province of Ciudad Real, on the Madrid-Ciudad Real-Mérida railway and at the north-east of the Valle de la Alcudia. Puertollano is 2,345 feet above sea-level and possesses mineral baths. Its population (19,275 in 1930) more than doubled in the 20th century.

PUERTO MONTT, a city and port of Chile, capital of the province of Chiloé. It is located at the northern end of the gulf of Reloncavi, about 670 mi. S.W. of Santiago. Population (1940) 21,552. It is the southern terminal of the southern section of the Chilean state railways and is served by the air line from Santiago to Magallanes. Its chief importance lies in its geographical location, which makes it the logical point of contact between the northern and southern sections of Chile.

Puerto Montt is built on a plain surrounded by wooded hills and by grazing land. Its principal industry is lumber. The city was founded in 1853 by a group of German emigrants led by Vicente Pérez Rosales, and was named for Manuel Montt, then president of Chile.

PUERTO PRÍNCIPE: *see* CAMAGÜEY.

PUERTO REAL, a seaport of southern Spain, on the Bay of Cádiz and on the Seville-Cádiz railway. Pop. (1930) 11,185. Puerto Real (Port Royal) is the *Portus Gaditanus* of the Romans, and is probably the most ancient trading-station on the Bay of Cádiz. It owes its modern name to the fact that it was rebuilt in 1488 by Ferdinand and Isabella. The port has good quays, a dry dock and deep water for large steamers.

PUERTO RICO: *see* PORTO RICO.

PUFENDORF, SAMUEL (1632–1694), German jurist, was born at Chemnitz, Saxony, on Jan. 8, 1632, the son of a Lutheran pastor. He was educated at Grimma and the University of Leipzig, and then at Jena. Pufendorf quitted Jena in 1657 and became a tutor in the family of Petrus Julius Coyet, one of the resident ministers of Charles Gustavus, king of Sweden, at Copenhagen. As a result of Danish resentment of Gustavus' conduct in suddenly declaring war, Pufendorf with the rest of the suite was imprisoned. He occupied himself during this time in meditating upon what he had read in the works of Grotius and Hobbes. He mentally constructed a system of universal law; and when, at the end of his captivity, he accompanied his pupils to the University of Leyden, he was enabled to publish, in 1661, the fruits of his reflections under the title of *Elementa jurisprudentiae universalis.* The work was dedicated to Charles Louis, elector palatine, who created for Pufendorf at Heidelberg a new chair, that of the law of nature and nations, the first of the kind in the world. In 1667 he wrote, with the assent of the elector palatine, a tract, *De statu imperii germanici, liber unus.* Published under the cover of a pseudonym at Geneva in 1667, it was supposed to be addressed by a gentleman of Verona, Severinus de Monzambano, to his brother Laelius. The pamphlet made a great sensation. It was a direct attack on the Holy Roman Empire and the house of Austria. In 1670 Pufendorf was called to the University of Lund, where he published in 1672 the *De jure naturae et gentium, libri octo,* and in 1675 a résumé of it as *De officio hominis et civis.*

In the *De jure naturae et gentium* Pufendorf took up in great measure the theories of Grotius and sought to complete them by means of the doctrines of Hobbes and of his own ideas. His first important point was that natural law does not extend beyond the limits of this life and that it confines itself to regulating external acts. He combated Hobbes's conception of the state of nature and concluded that the state of nature is not one of war but of peace. But this peace is feeble and insecure, and if something else does not come to its aid it can do very little for the preservation of mankind. As regards public law Puiendorf, while recognizing in the state *(civitas)* a moral person *(persona moralis),* teaches that the will of the state is but the sum of the individual wills that constitute it, thus showing himself a precursor of J. J. Rousseau and of the *Contrat social.* Pufendorf powerfully defends the idea that international law is not restricted to Christendom, but constitutes a common bond between all nations.

In 1677 Pufendorf was called to Stockholm as historiographer-royal. To this new period belong *Einleitung zur Historie der vornehmsten Reiche und Staaten,* also the *Commentarium de rebus suecicis,* and *De rebus a Carolo Gustavo gestis.* In his *De habitu religionis christianae ad vitam civilem* he traces the limits between ecclesiastical and civil power. This work propounded for the first time the so-called "collegial" theory of church government (*Kollegialsystem*), which, developed later by Pfaff (1686–1760), was the basis of the relations of church and state in Germany.

This theory makes a fundamental distinction between the supreme jurisdiction in ecclesiastical matters (*Kirchenhohheit* or *jus circa sacra),* which it conceives as inherent in the power of the state in respect of every religious communion, and the ecclesiastical power *(Kirchengewalt* or *jus in sacra)* inherent in the church, but in some cases vested in the state by tacit or expressed consent of the ecclesiastical body. The theory helped towards the principle of toleration.

It was put into practice to a certain extent in Prussia in the 18th century. The theory, of course, has found no acceptance in the Roman Catholic Church, but it none the less made it possible for the Protestant governments to make a working compromise with Rome.

In 1688 Pufendorf took service under Frederick William, elector of Brandenburg, but he had no sooner arrived than the elector died. His son, Frederick III, fulfilled the promises of his father; and Pufendorf, historiographer and privy councillor, was instructed to write a history of the Elector Frederick William (De *rebus gestis Frederici Wilhelmi Magni*). Pufendorf was also created baron.

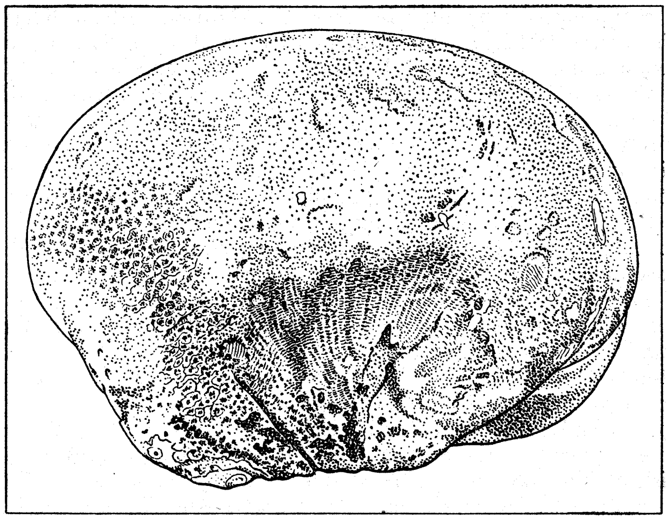
Pufendorf died at Berlin on Oct. 26, 1694.

The value of Pufendorf's work was much underestimated by posterity. Much of the responsibility for this injustice rested with Leibnitz, who would never recognize the incontestable greatness of one who was constantly his adversary, and whom he dismissed as "vir parum jurisconsultus et minime philosophus." His *Jurisprudence* is the standard one for the 17th and 18th centuries.

Franklin, *Das deutsche Reich nach Severino von Monzambano* (1874).

PUFF ADDER: *see* ADDER; VIPERS; SNAKES.

PUFF-BALL, the popular name of a group of fungi belonging to the Basidiomycetes *(see* FUNGI), and so called because of the cloud of brown dust-like spores which is emitted when the mature plant bursts or is struck a blow. They are common in meadows and woods and on heaths or lawns, and when young



COURTESY OF THE DOMINION BOTANIST, DEPARTMENT OF AGRICULTURE, OTTAWA
Puff-ball. A medium sized specimen of the giant puff-ball (approximately 8½ in. wide)

resemble white balls, sometimes with a short stalk, and are fleshy in texture. While white and fleshy they are edible.

The giant puff-ball, *Calvatia maxima,* may sometimes attain a weight of 15 pounds or more and measure up to 4 to 5 ft. or more in circumference. It has been estimated that a specimen measuring 15.7 x 11.0 x 7.8 in. will produce approximately 7,000,000,000,000 spores.

PUFF-BIRD, the name given to a group of birds forming the family *Bucconidae,* of the order Piciformes, which also includes the woodpeckers (*q.v.*). The *Bucconidae* are confined to the neotropical region, in the middle parts of which, and especially in its sub-Andean subregion, they are, as regards species, abundant; while only two seem to reach Guatemala and but one Paraguay. *Chelidoptera* breeds in holes in banks, and lays white eggs. The *Bucconidae* are plainly coloured, and the majority have a spotted or mottled plumage suggestive of immaturity.

PUFFIN, a sea-bird *(Fratercula arctica*), known also as bottle-nose, coulterneb, pope, sea-parrot and tammy-norie. Of old time, puffins were a valuable commodity to the owners of their breeding-places, for the young were taken from the holes in which they were hatched, and were "kept salted and reputed for fish." Puffins resort in vast numbers to certain stations on the coast, reaching' them in spring with remarkable punctuality. They lay their single egg (white, with a few grey markings at first, but which speedily becomes begrimed by the soil) in a shallow burrow, which they either dig for themselves or appropriate from a rabbit.

The plumage of both sexes is glossy black above—the cheeks grey, encircled by a black band—and white beneath; the feet are of a bright reddish orange. The most remarkable feature of these birds is their huge bill. In the breeding season this is very deep, laterally flattened, parti-coloured—blue, yellow and red—and curiously grooved and embossed in places. The puffin's bill undergoes an annual moult, some of its most remarkable appendages, dropping off at the end of the breeding season. The puffin, when feeding its young, manages to arrange crosswise in its bill, a number of fish at a time. In the north Pacific we find the horned (*F. corniculata*) and the crested puffin (*Lunda cirrhata*).

TUFTED PUFFIN (LUNDA CIRRHATA)

A blackish brown bird, with a white cheek, and a yellow plume over the eye

PUGACHEV, EMEL'YAN IVANOVICH (1741?–1775), Russian pretender, the date of whose birth is uncertain, was the son of a small Cossack landowner. He married a Cossack girl Sofia Nedyuzheva, in 1758, and the same year was sent with his fellow Cossacks to Prussia, under the lead of Count Zachary Chernuishev. In the first Turkish War (1769–74) of Catherine II. Pugachev, now a Cossack ensign, served under Count Peter Panin and was present at the siege of Bender. Invalided home, he led for the next few years a wandering life; was more than once arrested and imprisoned as a deserter; and finally, after frequenting the monasteries of the "Old Believers," who exercised considerable influence over him, suddenly proclaimed himself (1773) to be Peter III. Pugachev asserted that he and his friends had escaped from Catherine, and were resolved to redress grievances, give liberty to the Cossacks and put Catherine in a monastery. He held a mimic court at which one Cossack impersonated Nikita Panin, another Zachary Chernuishev and so on. At the beginning of Oct. 1773 500 roubles was considered a sufficient reward for the head of the troublesome Cossack. At the end of November 28,000 roubles were promised. Still, Catherine, in her correspondence with Voltaire, affected to treat *"l'affaire du Marquis de Pugachev"* as a mere joke. By the beginning of 1774 the forts on the Volga and Ural were in the hands of the rebels; the Bashkirs had joined them; and the governor of Moscow reported great restlessness in central Russia. Pugachev captured Kazan, reduced most of the churches and monasteries there to ashes and massacred those who refused to join him. Panin, the conqueror of Bender, was sent against the rebels with a large army, but the innumerable and ubiquitous bands of Pugachev were victorious in nearly every engagement. Not till August 1774 did General Mikhelson inflict a crushing defeat upon the rebels near Tsaritsyn, when they lost ten thousand in killed and prisoners. Suvorov completed their discomfiture. Pugachev was delivered up by his own Cossacks on attempting to fly to the Urals (Sept. 14), and was brought in an iron cage to Moscow, where he was executed on Jan. 11, 1775.

See N. Dubrovin, ***Pugachev and his Associates*** (Rus.; Petersburg, 1884); *Catherine II., Political Correspondence* (Rus. Fr. Ger.; Petersburg, 1885, &.); S. I. Gnyedich, ***Emilian Pugachev*** (Rus.; Petersburg, 1902); also the literature quoted *s.v.* CATHERINE II.

PUGACHEVSK (formerly NIKOLAYEVSK), a Russian town in the Samara province, in 52° 1' N., 48° 48' E., on the Irgiz river. Pop. (1926) 17,460. It is a collecting point for agricultural produce. Under the name of Mechetnoye, Nikolayevsk was founded in 1762 by Raskolniks who had fled to Poland and returned when Catherine II. undertook to grant them religious freedom. In 1828 serious persecutions began, with the result that the monasteries were closed with the exception of three, which were handed over in 1829 and 1836 to the United Greek Church. In 1835 the name of the town was changed to Nikolayevsk.

PUGET, PIERRE (1622–1694), French painter, sculptor, architect and engineer, was born at Marseille, on Oct. 31, 1622. He travelled in Italy as a young man, and was employed by Pietro di Cortona on the ceilings of the Barberini palace. On his return to Marseille in 1643, he painted portraits and carved the colossal figure-heads of men-of-war; he also painted numerous pictures for Aix, Toulon, Cuers and La Ciotat; his caryatides for the hôtel de ville of Toulon were executed between 1655 and 1657. Fouquet employed him to sculpture a "Hercules" for his château in Vaux. In 1655, owing to a serious illness, he was forced to give up painting. In 1660 he was in Genoa, where he executed his French Hercules (Louvre) and the statues of St. Sebastian and of Alexandre Sauli in the church of Carignano (*c.* 1664). In 1669, at the summons of Colbert, he returned to France, and took up his old work in the dockyards of Toulon, until in 1685, disheartened by the destruction by fire of an arsenal he was constructing, he returned to Marseille. Here he continued the series of sculptures on which he had been employed by Colbert. His statues of Milo (1682), Perseus and Andromeda (1684), and the bas-relief, Alexander and Diogenes (1685) are in the Louvre. In 1688 he visited Paris, but court intrigues obliged him to abandon the project of an equestrian statue of Louis XIV., and he retired to Marseille, where he died on Dec. 2, 1694. His best work, the St. Sebastian at Genoa, shows energy and life. In the museum of Aix in Provence is the bust of a long-haired young man, believed to be Louis XIV., made by Puget in 1660.

See L. Lagrange, ***Pierre Puget*** (1868, with a catalogue of works); C. Ginoux, ***Annales de la vie de P. Puget*** (1894); P. Auquier, ***Pierre Puget . . . biographie critique*** (1903).

PUGILISM, the practice or sport of fighting with the fists (from Lat. *pugil*, boxer, Gr. πύξ, with clenched fist). The first mention of such fighting in literature is found in the 23rd book of the Iliad; another full description is in Virgil, Aeneid.

Although fist-fighting was supposed by the Greeks of the classic period to have been a feature of the mythological games at Olympia, it was not actually introduced into the historic Olympic contests until the 23rd Olympiad after the re-establishment of the famous games by Iphitus about 880 B.C. Onomastos was the first Olympic victor. Wearing no belt, or ζῶμα, the contestants, except for the cestus, fought entirely naked, since the custom had been introduced in the 15th Olympiad, and was copied by the contestants at the Pythian, Nemean, Isthmian and Panathenaic games (see GAMES, CLASSICAL). At Olympia the boxers were rubbed with oil to make them supple and limit the flow of perspiration, a precaution the more necessary as the Olympic games were held during the hottest part of the year. The cesti, of which there were several varieties, were bound on the boxers' hands and wrists by attendants or teachers acting as seconds. On account of the weight of the gloves worn, the style of boxing differed from that now in vogue (see BOXING), the modern straight-from-the-shoulder blow having been little used. Both Homer and Virgil speak of "falling blows," and this was the common method of attack, consisting more in swinging and hammering than in punching. The statue of a Greek boxer in the Louvre shows the right foot forward, the left hand raised as if to ward off a blow from above, and the right hand held opposite the breast, the whole attitude more resembling that of a warrior than of a modern boxer. The Greek champions trained for months before the games, but encounters between athletes armed with such terrible weapons as the loaded cestus were bound to result in very serious bruises and even disfigurement. Pluck was as highly thought of as at the present day, and it was related of a certain Eurydamas, that, when his teeth were battered in, he swallowed them rather than show that he was hurt, whereupon his antagonist, in despair at seeing his most furious blows devoid of effect, gave up the battle. As, on account of the swinging style of blows, the ears were particularly liable to injury ear-protectors (ἀμφωτίδες) were generally used in practice, though not in serious combats. The so-called "pancratist's ear," swollen and mis-shapen, was a characteristic feature of the Greek boxer.

The rules of Greek boxing were strict. No wrestling, grappling, kicking nor biting were allowed, and the contest ended when one combatant owned himself beaten. On this account pugilism and the *pancratium* (see pp. 758) were forbidden by Lycurgus, lest the Spartans should become accustomed to an acknowledgment of defeat (Plutarch, *Lycurgus*). Moreover, it was strictly forbidden to kill an adversary, on pain of losing the prize. Rhodes, Aegina, Arcadia and Elis produced most of the Olympic victors in boxing, which was considered an excellent training for war.

The Greek athletic contest called pancratium (παγκράτιον, complete or all-in, contest), which was introduced into the Olympic games in the 38th Olympiad. was a combination of boxing and wrestling in which the contestants, who fought naked, not wearing even the cestus, were allowed to employ any means except biting to wring from each other the acknowledgment of defeat. Boxing, wrestling, kicking, dislocation of joints, breaking of bones, pulling of hair and strangling were freely indulged in. The fight began with sparring for openings and was continued on the ground when the contestants bit the dust. Sudden attacks were also taught, reminding one of the Japanese *jiu-jitsu.* The pancratium was considered by the Greeks the greatest of all athletic contests. It became popular in Rome during the empire and remained so until the time of Justinian. Diagoras of Rhodes, his three sons ahd many grandsons, who were sung by Pindar (Olymp. 7), were the most celebrated of the Olympic boxing champions. A celebrated fighter and wrestler was Milo of Crotona (520 B.C.).

Boxing was evidently in vogue in very ancient times in Italy, imported, in all probability, from Greece, for Livy (i. 35) relates that, at the first celebration of the great Roman games (ludi, *Romani magnique varie appellati*) by Tarquinius Priscus (6th century B.c.), boxers were brought from outlying provinces; and there was an old tradition that a school of pugilism flourished in Etruria in heroic times. During the republic boxing was cultivated as a gentlemanly exercise, and we find Cato the Elder giving his son instruction in the art (Plutarch, Cato Major). Tacitus (Ann. xvi. 3) says that the emperor Caligula imported the best Campanian and African pugilists for the gladiatorial games, and Strabo (iii. 3) records that the Lusitanians and also the Indians, who gave virgins as prizes, boxed. The art remained popular in Italy down to a late period of the empire.

Pugilism in England. — From the fall of the Roman empire to the beginning of the 19th century pugilism seems to have been unknown among civilized nations with the single exception of the English. The first references to boxing in England as a sport occur towards the end of the 17th century, but little mention is made of it before the time of George I., when "prize-fighters" engaged in public encounters for money, with the backsword, falchion, foil, quarter-staff and single-stick, and, to a less extent, with bare fists, the last gradually gaining in popularity with the decline of fencing. The most celebrated of these fighters and the one who is generally considered to have been the first champion of England, fighting with the bare fists, was James Figg, who was supreme from 1719 to 1730. Figg was succeeded by Pipes and Gretting, both of whom made way in 1734 for Jack Broughton, who built the amphitheatre for public displays near Tottenham Court road and who was undisputed champion until 1750. Broughton seems to have been a man of intelligence, and to him is ascribed the scientific development of the art of boxing. During his time the sport became truly national and the prize-fighter the companion of the greatest in the land. Among Broughton's successors were Slack, "Big Ben" Brain, Daniel Mendoza (a Jew who flourished about 1790 and was the proprietor of the Lyceum in the Strand), J. Jackson, Tom Cribb, Jern Belcher, Pearce (called the "Game Chicken"), and John Gully, who afterwards represented Pontefract in parliament.

To Broughton is ascribed the invention of boxing-gloves for use in practice. All prize-fights, however, took place with bare knuckles in roped-off spaces called rings, usually in the open air. Pugilists toughened their hands by "pickling" them in a powerful astringent solution. A fight ended when one of the "bruisers," as they were called, was unable to "come to the scratch," *i.e.,* the middle of the ring, at the call of the referee at the beginning of a new round. Each round ended when one fighter fell or was knocked or thrown to the ground, but a pugilist "going down to avoid punishment," *i.e.,* without being struck by the opponent, was liable to forfeit the fight. Wrestling played an important rôle in the old prize-ring, and a favourite method of weakening an adversary was to throw him heavily and then fall upon him. seemingly by accident, as the manoeuvre, if done intentionally, was foul. The fighting was of the roughest description, low tricks of all kinds being practised when the referee's attention was diverted, gouging out an adversary's eye being by no means unknown. Until 1795 pugilists wore long hair, but during a fight in that year Jackson caught Mendoza by his long locks and held him down helpless while he hit him. This was adjudged fair by the referee, with the result that prize-fighters have ever since cropped their heads. Nevertheless, there were rules which no fighter dared to overstep, such as those against kicking, hitting below the belt, and striking a man when he had fallen.

From the time of Cribb the English champions were Tom Spring (1824), Jern Ward (1825), Jern Burke (1833), W. Thompson, called "Bendigo" (1839–4j), Ben Caunt (1841), W. Perry the "Tipton Slasher" (1850), Harry Broome (1851), Tom Sayers (1857–60), Jern Mace (1861–63), Tom King (1863), and again Mace, until 1872. In America boxing began to be popular about the beginning of the 19th century. The first recognized national champion was Tom Hyer (1841–48), who was followed by James Ambrose (born in Ireland), called "Yankee Sullivan"; John Morrissey (afterwards elected to the United States Congress); John C. Heenan; Tom Allen (of England); Jern Mace (of England); J. Kilrain; John L. Sullivan (1880–91). Sullivan was the last of these to fight with the bare fists. Pugilism (*i.e.,* fighting with the bare fists) was driven out in favour of boxing (*i.e.,* fighting with the glove) by public opinion and by the general adoption after 1866 of the Marquis of Queensberry rules. The last championship fight under the old prize ring rules was fought between Frank Slavin and Jern Smith in Belgium, the latter retaining the championship. The old prize ring being illegal and extinct no champion can succeed him. See BOXING.

See Egan, *Boxiana* (1818–1824) ; *Fistiana* (1868) ; *American Fistiana* (1876).

PUGIN, AUGUSTUS WELBY NORTHMORE (1812–1852), English architect, son of Augustus Charles Pugin (1762–1832), a Frenchman who settled in London as an architectural draughtsman, was born in Store Street, Bedford Square, on Mar. 1, 1812, and died on Sept. 14, 1852, at Ramsgate. He was educated at Christ's Hospital and in his father's office, where he helped to prepare a large series of works on the Gothic buildings of England. All through his life he made numerous drawings and sketches, in pen and ink or with sepia monochrome, perfect in their delicacy and precision of touch. After his reception into the Roman Catholic Church in 1833, he became a leader in the English Gothic revival. In 1837–43 he assisted Sir Charles Barry by working out the details of the designs for the new Houses of Parliament at Westminster; and though his exact share was the subject of bitter controversy after both he and Barry were dead, there is no doubt that the excellence of the details was partly due to him and to his training of the masons and carvers. Many of his executed works suffered from the fact that his designs were altered, both by cutting down their proportions and by introducing shams, such as plaster groining and even cast-iron carving. The cathedral of St. George at Southwark, and the church in Farm Street, Berkeley Square, London, are melancholy instances of this. The cathedral of Killarney and the chapel of the Benedictine monastery of Douai best express the original conception. Pugin was very broad in his love for the mediaeval styles, but on the whole preferred the Perpendicular of the 15th century as being best suited to modern requirements. He used this with success in his own house at Ramsgate and in the stately Adare Hall in Ireland built for Lord Dunraven.

In 1836 Pugin published his Contrasts; or *a* Parallel between the Architecture of the *15th* and *19th* centuries; *True* Principles of *Christian Architecture* (1841); Glossary of Ecclesiastical *Ornament* (1844); and Treatise *on Chancel* Screens *and* Rood Lofts (1851) He was a skilful etcher.

See B. Ferrez, *Recollections* of *A. W. Pugin and his Father* (1861); Paul Waterhouse, "The Life and Work of Welby Pugin" in the *Architectural Review,* iii., iv. (1898).

PUINAVIAN, a tribe of South American Indians, which appear to constitute by itself alone an independent linguistic stock. The Puinavis live or lived on the border between Venezuela and Colombia, on the Inirida river, just south of 4° N. lat.

See A. F. Chamberlain, *Sur quelques familles linguistiques . . . de l'Amérique du Sud* (J. Soc. Americanistes de Paris [n.s.], vol. vii., pp. 179–202).

PUISNE, a term in law meaning "inferior in rank." It is pronounced "puny" and the word, so spelt, has become an ordinary adjective meaning undersized. By the Supreme Court of Judicature act, 1877, a "puisne judge" is defined as a judge of the High Court other than the lord chancellor, the lord chief justice of England, the master of the rolls, the lord chief justice of the common pleas, and the lord chief baron, and their successors respectively; but the last two offices have since been abolished.

PUJA, Hindu "worship": whence *pujāri,* "priest." Colloquially the word is used for any rite; and "pujah of the Rag" is the sepoy term for trooping the colours.

PUKET, sometimes spelled BHUKET (the Chinese name is *Tongkah*), leading Thai port on the west coast of the Malay peninsula, on Junk Ceylon island (also called Puket) in 7° 50′ N. and 98° 24′ E. The island constitutes one of the 70 changvads (districts) of Thailand; pop. (1937) 41,827, nearly half Chinese. Rich tin deposits have been worked by Chinese from ancient times. A European company commenced modern dredging operations in 1907. The 1938–39 tin ore production was 4,256 tons. Exports of ore from the Puket customs area (the Thai west coast) amounted to 31,873,287 bhat (about $14,000,000) in 1939–40. Rubber stood second among exports, followed by betelnuts, oriental equivalent of chewing tobacco. European merchants began trading at Puket in the 16th century. It was besieged by the Burmese during the 18th century wars between Burma and Thailand, but was relieved by troops from the mainland.

PULASKI, CASIMIR, COUNT (1748–1779), Polish soldier. was born in Podolia in 1748, and took a prominent share, under his father Count Joseph Pulaski, in the formation of the confederation of Bar and in the military operations which followed, becoming ultimately commander-in-chief of the Polish patriot forces. Driven into exile about 1772, Pulaski went to America and joined the army of Washington in 1777. He distinguished himself at Brandywine, was made a brigadier-general and chief of cavalry by Congress, and fought at Germantown, and in the battles of the winter 1777–78, after which he raised a mixed corps called the Pulaski legion, with which he defended Charleston in May 1779. He was mortally wounded at Savannah, dying on Oct. 11th.

PULASKI, a town of Virginia, U.S.A., county seat of Pulaski Co.; 50 mi. S.W. of Roanoke, on federal highway 11 and Norfolk and Western Ry. Pop. (1940) 8,792. It is in a region of beautiful scenery and of coal, lead and iron mines, between the Blue Ridge and Allegheny mountains. It is a summer resort.

PULCI, LUIGI (1432–1484?), Italian poet, was born at Florence on Dec. 3, 1432, of a well-connected family. His elder brother Luca (d. 1470) was also a poet, and the share of each of the two brothers in the poems *Pistole, Driadeo d'amore,* and *Ciriffo Calvaneo* is not easily distinguishable. Luigi was patronized by Cosimo, Piero, and Lorenzo de' Medici. He used to find an object for his mockery in the long romances of chivalry recited in the streets and in public places. He chose for his semi-burlesque poem, *Morgante,* generally known as *Morgante Maggiore* (complete ed. Venice 1482; critical ed. Milan 1875), the epic of Charlemagne. The story centres in Ganelon's hatred of Roland and the Christian Paladins. Pulci's *Letters* were edited at Lucca 1886.

See L. Einstein: *L. Pulchi and the Morgante Maggiore* (Berlin 1902) A. Momigliano: *L'Indole e il Riso di Pulci* (1907); E. Walser: "Die Religion des L. Pulci" in *Die Neueren Sprachen* 10 Beiheft (1926).

PULICAT, a town of British India, in Chingleput district, Madras, 25 m. N. of Madras city. Pop. (1931), 4,164. The Dutch built a fort here as early as 1609, and it was for a long time their chief settlement on the Coromandel coast. Repeatedly captured, it did not finally become British until 1825. It gives its name to the Pulicat lake, a shallow lagoon stretching for about 37 m. along the coast. The seaward side is formed by the island of Sriharikota, which supplies firewood to Madras city.

PULITZER, JOSEPH (1847–1911), American editor and newspaper proprietor, was born in Mako, Hungary, April 10, 1847. His father, a grain-merchant, was Magyar-Jewish; his mother Austro-German. Pulitzer was educated privately in Budapest. Excluded from the army as a result of physical defects, and failing in an attempt to join the French Foreign Legion, he was induced by an American agent to emigrate to the United States as a prospective recruit for the Union army. He enrolled in Company L, 1st New York Lincoln cavalry, for a term of one year. Discharged on July 7, 1865, in New York city, he looked in vain for work there. In the autumn he started west for St. Louis, where he arrived penniless.

In St. Louis, with its large German population, Pulitzer's progress was rapid. While making his living by odd employments, he studied for the bar and was admitted in 1867. On March 6 he was naturalized, and in 1868 he became a reporter on the *Westliche-Post* staff; in Dec. 1869 he was elected to the lower house of the legislature. Here he led a successful movement to reform the corrupt county government of St. Louis. When the revolt against Grant led to the Liberal Republican movement in 1871–72, Pulitzer helped to organize this party in Missouri and was one of the secretaries of the Cincinnati convention which nominated Greeley.

Pulitzer then became a newpaper proprietor. Some owners of the *Westliche-Post* sold him a share on liberal terms. This he soon resold for $30,000, using part of the proceeds for an extended tour of Europe. On his return he purchased a moribund German daily, the St. Louis *Staats-Zeitung,* for a song, and sold its Associated Press franchise to the *Globe* for $20,000. In 1876 he took an active share in the presidential campaign, breaking loose from all his Republican associates.

On June 19, 1878, he married Miss Kate Davis, a distant relative of Jefferson Davis. On Dec. 9 of the same year he laid the foundation of his fortune by purchasing at auction the worn-out St. Louis *Dispatch,* paying $2,500 cash and giving a $30,000 lien. This newspaper he merged with the *Post,* owned by John A. Dillon, as the *Post-Dispatch,* which immediately began to pay and soon dominated the St. Louis evening field. It was independent in politics and devoted to "hard money" and tariff reform. In 1880 Pulitzer became sole owner. He laboured with unremitting energy, and the profits were soon running from $40,000 to $85,000 a year. Unfortunately in Oct. 1882 his chief editorial aid, Col. John A. Cockerill, shot and killed a lawyer, Col. Alonzo W. Slayback, in a bitter quarrel of political origin. The case did not come before the courts, but public reprobation was so great that the *Post-Dispatch* lost revenue and Pulitzer thereafter felt unwelcome in St. Louis. He departed for the East in the spring of 1883, and bought the New York *World* for $346,000, taking possession on May 10.

In 1884 he was elected to Congress from the Ninth District, a position he resigned before his term expired. Under its new management the *World* won an immediate prosperity. It was aided by a quarrel in which its rival, the *Herald,* became engaged with the newsdealers, and by the *Sun's* disastrous decision in 1884 to support Benjamin F. Butler for the presidency. By 1886 the annual earnings of the *World* were more than $500,000. With these resources Pulitzer in 1887 established the *Evening World,* which lost $100,000 the first year, but by 1890 was highly profitable. William R. Hearst's purchase of the New York *Journal* in 1895 brought the *World* a powerful competitor, and it met the challenge on Feb. 10, 1896, by reducing its price from two cents to one. The daily circulation of the *World* quickly rose to 300,000 and its Sunday circulation before the end of 1896 reached 623,000 copies. To the *World,* as to the *Post-Dispatch,* Pulitzer gave a tone of aggressive editorial independence. The paper earnestly supported Cleveland in his contests for the presidency in 1884, 1888 and 1892. It was sympathetic to labour, and in 1892 took the side of the striking steel workers at Homestead. Pennsylvania. It opposed Bryan for the presidency in 1896. A year later the *World* became an advocate of war with Spain, for Pulitzer sympathized with the Cuban struggle for liberty. Meanwhile Pulitzer's health, including his eyesight, compelled him to live the secluded existence of an invalid, but he kept in intimate touch with the *World* until within a few weeks of his death in Charleston (S.C.), Oct. 29, 1911.

During his lifetime Pulitzer had given liberally. In 1903 he endowed the School of Journalism of Columbia university, opened in 1912. In his will he established a series of prizes, known as the Pulitzer prizes, to be awarded annually, for letters, the drama, music and newspaper work.

PULKOVO (Pulkowa), the most important meteorological observatory in Russia, 10 m. S. of Leningrad in 59° 47' N., 30° 18' E., altitude 248 ft. and built 1833–9. Russian longitude is usually indicated from Pulkovo, though some recent Russian atlases and maps give longitude east of Greenwich, the difference having been fixed by wireless.

War conditions (1914–21) made a considerable break in international exchanges with Pulkovo. Yudenich captured Pulkovo in his march against Leningrad in 1919, and its re-capture by Soviet troops was the beginning of the collapse of his army.

PULLEY, a wheel, either fixed to a turning axle or carried freely on a stationary one, the periphery of which is adapted to receive some form of wrapping connector. A pulley carried on a rotating shaft and connected to another pulley on a second shaft by an endless band consisting of a flat belt, rope, chain or similar connector serves for the transmission of power from the one shaft to the other and is known as a driving pulley; while combinations of pulleys or "sheaves" mounted in fixed or movable frames or "blocks" facilitate the raising of heavy weights.

Driving Pulleys.—These are usually constructed of cast iron, and are of circular form, having a central nave by which they are secured to the shaft by keys or other fastenings, and straight or curved arms connecting the nave to the rim, which latter is of a form adapted to the connector. Pulleys are usually cast in one piece, and the proportions of the various parts are designed to resist the unknown stresses due to contraction of the casting in cooling. The rim is slightly wider than the belt, and is of such a section as will suffice to resist the stress due to the pull of the belt, which is commonly taken as 80lb. per inch of width for single belting and 140lb. per inch of width for double belting. The rim is also subject to a centrifugal tension of amount wv^2/g pounds per square inch of section, where w is the weight in pounds of a length of one foot of the pulley rim one square inch in section, and v is the velocity of the rim in feet per second. This stress amounts to 1,043lb. per square inch, if the velocity is 100 ft. per second. The combination of these stresses generally limits the rim velocity of cast-iron pulleys to 80 or 100ft. per second. The arms, preferably straight, are elliptical in cross-section, diminishing from the nave to the rim, and are usually designed as equally loaded cantilevers, fixed at the nave and free at the rim. The statical experiments of C. H. Benjamin (American Machinist, 1898) showed that the rim is usually not sufficiently rigid to load the arms equally, and that the ends of the arms are subjected to bending movements of opposite sign, that at the nave being almost invariably the greater.

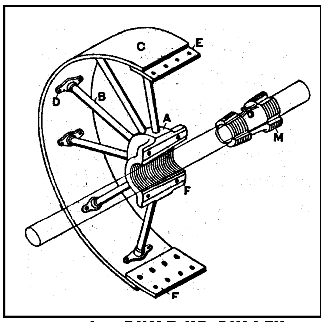

FIG. 1.—BUILT-UP PULLEY

Pulleys are also built up of wrought iron and steel, and can then be constructed entirely free from internal stress; they are thus much lighter and stronger, and are not liable to fly to pieces like cast iron if they break. Fig. 1 shows a built-up pulley having a cast-iron nave A, straight wrought-iron arms B, screwed therein and connected to a steel plate-rim C by riveted ends, and also by screwed flanges D riveted on each side to the rim. The pulley is in halves to facilitate fixing, and when in place the sections C are joined by plates E bolted or riveted to the rim. The two halves of the nave are secured by bolts or rivets passing through the flanges F, and the pulley is connected to the shaft by a sunk key or by conical keys driven in between the shaft and the boss, which latter is bored to suit. A modified form of this arrangement of cone keys is shown in the figure, in which a screwed conical bush M, divided into several parts longitudinally, is clamped round the shaft, and screwed into the corresponding part of the nave until the grip is sufficient. The parts of the bush are glued to a sheet of emery paper, so that its rough side may give a better grip on the shaft.

Pulleys are also made of paper, wood and other materials. Wooden pulleys are preferably made of maple, the rim being formed of small sections morticed, pinned and glued together, with the grain set in such directions that any warping of the material will leave the cylindrical form practically unaltered. Wooden pulleys are generally made in two halves, bolted together at the rim and nave, and are provided with wooden spokes dovetailed into the rim and secured by keys.

If the centre of gravity of a pulley is on the axis of rotation, and the whole mass is distributed so that the axis of inertia coincides with the axis of rotation, there can be no unbalanced force or unbalanced couple as the pulley revolves. The magnitude of the unbalanced force, for a mass of w pounds at a radius of r feet and a velocity of v feet per second, is expressed by wv^2/gr lb.; and, since the force varies as the square of the velocity, it is necessary carefully to balance a pulley running at a high speed to prevent injurious vibrations. This can be accomplished by attaching balance-weights to the pulley until it will remain stationary in all positions, when its shaft rests on two horizontal knife-edges in the same horizontal plane, or, preferably, the pulley and shaft may be supported on bearings resting on springs, and balanced by attached masses until there is no perceptible vibration of the springs at the highest speed of rotation.

The rims of pulleys, round which flat bands are wrapped, may be truly cylindrical, in which case the belt will run indifferently at any part of the pulley, or the rim may be swelled towards the centre, when the central line of the band will tend to run in the diametral plane of the pulley. This self-guiding property may be explained by the tendency which a flat band has, when running upon a conical pulley in a direction normal to its axis, to describe a spiral path as it wraps on to the surface because of the lateral stiffness of the material; the advancing side therefore tends to rise towards the highest part of the cone. In practice the pulley rim is curved to a radius of from three to five times its breadth.

Parallel Shafts.—Parallel shafts may be driven by flexible bands or connectors passing over pulleys, the central planes of which coincide, without any guiding arrangements for the belting. The shafts revolve in the same or opposite directions, according as the belt is open or crossed. Means of changing the relative speeds of rotation are furnished by pulleys of continuously varying diameter, or by speed cones (see MECHANICS: *Applied*). A common arrangement for driving a lathe spindle, in either direction at several definite speeds, is to provide a countershaft on which are mounted two fixed pulleys and two loose pulleys to accommodate two driving belts from the main shaft, one of which is open and the other crossed. The belts are moved laterally by the forks of a striking gear pressing on the advancing sides of the belts, and the pulleys are arranged so that the belts either wrap round the loose pulleys, or can be shifted so that one wraps round a fixed pulley, while the other still remains on its loose pulley. Motion in either direction is thereby obtained and a considerable variation in the speed of rotation can be obtained by providing a cone pulley on the countershaft, which drives the cone pulley secured to the lathe spindle by a separate band. The dimensions of the pulleys are generally so arranged that the return motion of the lathe spindle is faster than the forward motion.

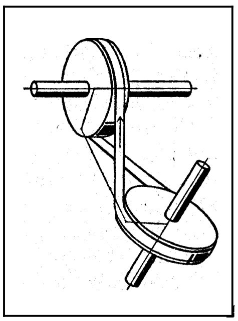

FIG. 2

When pulleys are mounted on shafts which are parallel to one another, the band will retain its position, provided that its central line advances towards each pulley in the diametral plane of this latter. This condition is fulfilled in the example shown by fig. 2, in which the central planes of each pulley pass through the points of delivery of the other pulley for the given direction of motion. If the motion is reversed the condition is no longer satisfied and the belt will leave the pulleys. In more complicated cases guide pulleys must be used. In the most general case for inclined pulleys, any two points may be chosen on the line of intersection of the diametral planes, and tangents drawn to the pitch circles of the pulleys. Guide pulleys are set with their diametrical planes in the planes containing corresponding pairs of tangents, and a continuous belt wrapped round these pulleys in due order can then be run in either direction.

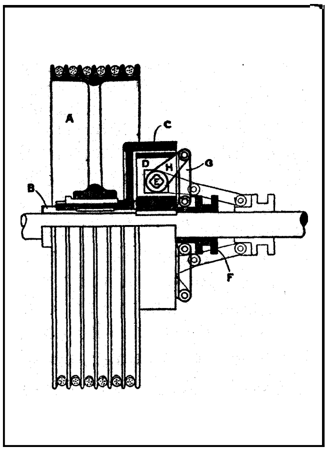

FIG. 3.—FRICTION CLUTCH FOR ROPE-PULLEY

The rims of pulleys for hemp or other ropes or cords are grooved, and the sides are usually either inclined at 45° or curved to give a sharper angle at the outside than at the bottom of the groove; in the latter case, as the rope wears it engages in a groove of greater angle and less effective grip. Wire ropes are injured by the lateral crushing of the material, and in this case the grooves are wide enough to allow the rope to rest on the rounded bottom, which is lined with leather or wood to diminish the wear and increase the friction. In English practice there are as many separate endless ropes as there are pairs of grooves in the two pulleys to be connected, but in cases of American practice the rope is continuously wound round the two pulleys, and the free end passes over a pulley mounted on a'movable weighted carriage to adjust the tension.

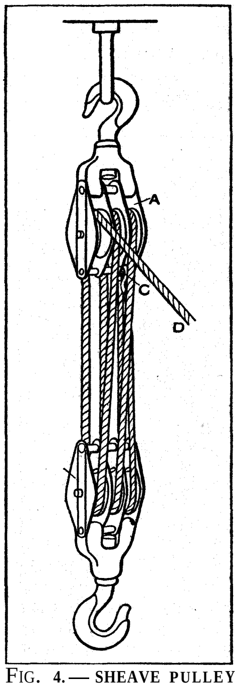

FIG. 4.— SHEAVE PULLEY BLOCK

Pulleys may be detachably connected to a shaft by friction clutches, so that they may be thrown in and out of engagement at will. The section, fig. 3, shows a clutch for a rope-driven pulley A, which runs freely on a bush B on the shaft, and is provided with an enlarged cylindrical nave or clutch box C. A split ring D, carried by the clutch and turning with it, can be thrust against the clutch box by right- and left-handed screws E, so that a sufficient grip is obtained to cause the clutch and the pulley to turn as one piece. The engagement of the pulley and clutch is determined by a hand-controlled block F sliding on the shaft, the movement of which is communicated to the right- and left-handed screw shafts by links G connected to the levers H.

Pulley Blocks.—Frames or blocks containing pulleys or sheaves are used in combination for lifting heavy weights. There are usually two blocks, of which one A (fig. 4) is fixed, and the other B is movable, and a rope or chain, with one end secured to one of the blocks at C, passes round the sheaves in a continuous coil, leaving a free end D at which the effort is applied. In the arrangement shown there are three equal sheaves in each block, and each set turns on a pin secured in the framing. The load, supported by the lower hook, is raised by hauling on the free end and, neglecting any slight obliquity of the plies of rope, the free end moves six times as fast as the lower block carrying the weight, and in the absence of friction and other resistances the mechanical advantage will be in the same ratio of the effort to the resistance. In practice the full advantage of this or any other similar combination is not realized, because of the friction of the sheaves against the pin or shaft, and more important stilt is the stiffness of the rope, which requires work to be done upon it to bend it round the sheave and straighten it again.

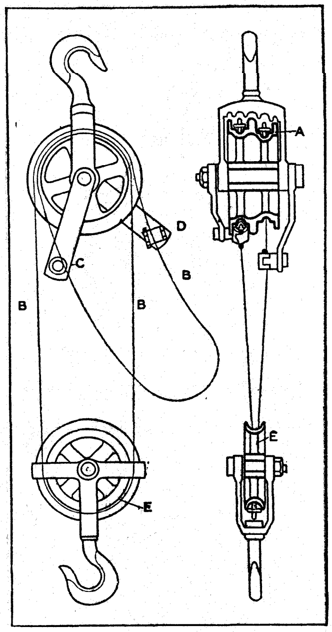

FIG. 5.—WESTON DIFFERENTIAL PULLEY BLOCK

Differential Pulley Block.—To obtain a greater ratio of resistance to effort, without using a large number of sheaves, various arrangements are used, of which the Weston differential pulley block is a typical example. The upper block carries a pair of chain pulleys A (fig. 5), strongly secured together and of slightly different effective diameters. An endless chain B, passing through guides C and D, encircles these pulleys and the single loose pulley E of the lower block, as indicated. If a greater difference of effort from resistance is required, a further mechanical advantage can be obtained by employing a separate hand-wheel and chain, or by forming the upper sheave with an annular spur-wheel gearing with a pinion driven by a hand-wheel and chain, as in the Tangye form of Weston pulley-block. The efficiency of the Weston pulley-block is less than 50%, and it does not therefore overhaul. An objection to this form of block is the great length of the endless chain, which may drag on the ground and pick up dirt and grit, and thereby interfere with the smooth working of the mechanism. Other forms, which do not require so lengthy a chain, sometimes employ an epicyclic train to obtain the reduced velocity of the load.

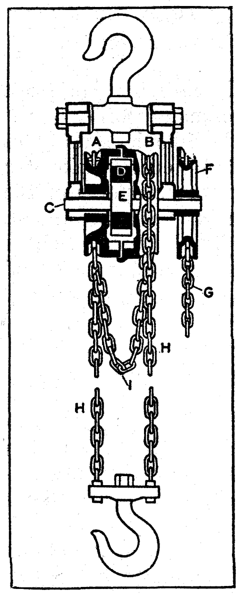

FIG. 6.—MOORE AND HEAD PULLEY BLOCK

The Moore and Head block has two equal chain-wheels A, B, fig. 6, loosely mounted on an axle C, and provided with annular toothed gear-wheels which usually differ by one tooth. A spur pinion D, gearing with both wheels, is carried loosely upon an eccentric E forming part of the central pin, so that when this latter is turned by the hand-wheel F and chain G the axis of the pinion describes a circle the diameter of which equals the throw of the eccentric, and a small relative motion of the two sheaves takes place, depending on the number of the teeth of the annular wheels. The motion obtained is divided between the two vertical parts of the chain H, which is wrapped round each sheave in opposite directions, with a free loop I between, while the ends are attached to the lifting hook. This form is self-sustaining at all loads.

Worm Gear Pulley.—To obtain a self-sustaining pulley tackle, which will have an efficiency of more than 50%, various arrangements are adopted, which during lifting automatically throw out of action a brake and cause it to come into action again when the effort is removed. A worm-gear tackle of this description is shown in fig. 7, in which a worm A, operated by a hand-wheel B and chain C, drives the worm-wheel D, thereby coiling up a chain E, one end F of which is secured to the upper block, and the other end hangs loosely, after passing round the sprocket-wheel. The worm is of great pitch, so that if the effort were removed the weight would descend, did not the axial end thrust of the worm shaft throw into action a friction brake H, the resistance of which prevents motion downwards. In the brake shown, the cone I is pressed against a corresponding recess in the ratchet-wheel J, which latter turns loosely in the casing and is provided with a pawl not shown in the figure; this pawl allows freedom of motion when the load is being raised. The frictional grip between the two surfaces prevents return motion of the worm shaft and the load remains suspended, but it may be lowered by turning the hand-wheel so as to overcome the friction brake. Various other arrangements of friction brakes have been devised to give a resistance proportional to the load.

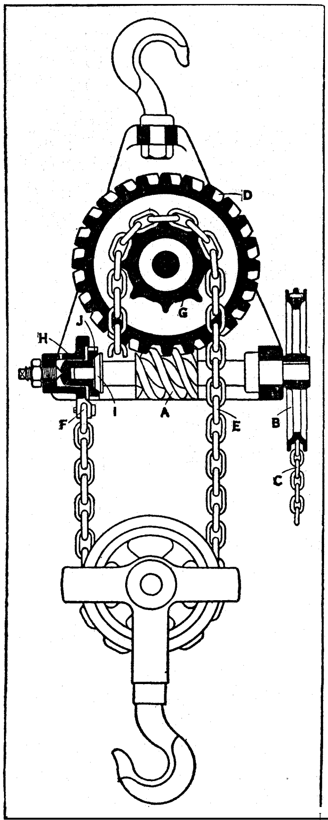

FIG. 7.—WORM-GEAR PULLEY BLOCK WITH AUTOMATIC BRAKE

Blocks, for lifting very heavy weights, are sometimes provided with an electric motor for driving the worm. The worm-wheel shaft then sometimes carries a spur-pinion gearing, with a spur-wheel on the lifting shaft, whereby a much greater advantage is obtained with a small loss by friction of the spur gearing.

PULLMAN, now a part of the city of Chicago. The place was founded in 1880 by George Mortimer Pullman (1831–97), the inventor of the Pullman sleeping car, and the founder (1867) of the Pullman Palace Car Company, who attempted to make it a "model town." Even the public works were the property of the Pullman Company and were managed as a business investment. Popular discontent with the conditions led to the annexation of Pullman to Chicago in 1889, but until 1910 the corporation held most of the property. In June and July 1894 a bitter railway strike developed in the Pullman works.

PULLMAN, a city of Whitman county, Washington, U.S.A., 75 mi. S. of Spokane, in the Palouse river valley, at an altitude of 2,750 feet. It is on federal highway 195, and is served by the Northern Pacific and the Union Pacific railways. Pop. (1940) 4,417. The State college of Washington (established 1890) had in 1940-41 an enrolment of 4,100. The campus and agricultural experiment station occupy 910 acres. Pullman was settled about 1884 and incorporated as a city in 1889.

PULLMAN INCORPORATED (DELAWARE), a holding company formed in 1927, has three important subsidiaries: The Pullman Company (Chicago)—originally incorporated in 1867 as Pullman's Palace Car Company, with a capital of $100,000—is the largest operator of sleeping and other super-comfort railway cars in the world, controlling practically all the business in the United States and Mexico and part of that in Canada; Pullman-Standard Car Manufacturing Company (Chicago), the world's largest car building unit, and the Pullman-Standard Car Export Corporation (New York). At the beginning of 1940 The Pullman Company owned some 7,000 cars of which about 6,000 were sleeping cars. Over zoo of these were of the new light-weight and streamlined type. There were 750 parlour cars of different combinations, 143 composite cars, including baggage-club and other variations, and 15 private cars for special parties. In the year 1939, 15,655,135 revenue passengers were carried in Pullman cars, equal to a daily average of 42,890 in 5,100 cars. The passenger mileage was 8,485,-399,123mi., or an average distance of 542 miles. Pullman-Standard Car Manufacturing Company in 1940 had 9 plants and 3 wheel foundries with these annual capacities: 2,370 passenger, 74,700 freight cars; 49,000 tons forgings, 287,500 wheels. Pullman-Standard Car Export Corporation's capacity is 1,500 freight and 150 passenger cars annually. (G. A. K.)

PULP: see PAPER MATERIALS.

PULPIT, a raised platform with enclosed front, whence sermons are delivered. Pulpits were probably derived from the *ambones* in the early Christian Church. (See AMBO.) There are many old pulpits of stone, though the majority are of wood. Those in churches are generally hexagonal or octagonal; and some stand on stone bases, and others on slender wooden stems, like columns. The designs vary according to the periods in which they were erected, having panelling, tracing, cuspings, crockets and other ornaments. Some are extremely rich, and ornamented with colour and gilding. A few also have rich canopies or sounding-boards. Their usual place is in the nave, mostly on the north side, against the second pier from the chancel arch. Out-door pulpits were common in the mediaeval period, and stood near a road or cross. Pulpits, for reading during the meals of the monks, are found in refectories.

Shortly after the Reformation the canons ordered pulpits to be erected in all churches. Many of the time of Elizabeth and James are beautifully carved, and are of Flemish workmanship. The pulpits in mosques, known as "mimbars," are canopied and approached by a straight flight of steps. These have a doorway at the foot, with an enriched lintel and boldly moulded head; the work is of wood, often inlaid, gorgeously painted and gilt.

PULQUE or **PULQUE FUERTE,** the national beverage of the Mexican natives. It is prepared by fermenting the juice of a number of species of the agave (Agave *americana,* etc.). The cultivation of the agave for purposes of pulque manufacture constitutes a considerable local industry. The juice of the agave termed aguamiel is allowed to ferment naturally for about ten days, and the product is termed *madre* pulque (mother of pulque). A small quantity is added to fresh aguamiel, and a rapid fermentation is induced, the pulque being ready in a day or two. It has a heavy flavour, resembling sour milk, but it is esteemed by the natives on account of its cooling and, according to them, nutritious properties.

GATHERING SAP OF THE AGAVE ON THE PLATEAU NEAR MEXICO CITY
In the making of pulque, the favourite drink of the Mexican people, the sap is sucked out of the plant into a tube, and from there poured into a pail or skin bag and allowed to ferment for about ten days

PULSE, throbbing or beating; in physiology the rhythmical beating due to the changes of blood-tension in the arteries consequent on the contractions of their elastic tissues (see VASCULAR SYSTEM). In botany, a collective term for beans, peas, lentils and other members of the family Leguminosa (*q.v.*).

PULSOMETER: *see* VACUUM PUMP.

PULTUSK, a town of Poland, on the Narew. Pop. 15,510. The town was entirely destroyed by fire in 1875, but was rebuilt on a more modern scale. In 1703 Charles XII of Sweden defeated and captured a Saxon army here, and in 1806 Napoleon defeated the Russians. The town was occupied by the Germans in 1915 and again in 1939. It was formerly part of the large estate of the bishops of Plock, whose former palace, dating from 1319, was destroyed in the fire.

PULVERIZED FUEL. The use of coal in the form of dust for raising steam has been known from isolated experiments for about the last forty years, but the fact that it was one of the most difficult methods of burning coal long delayed the development of the practice.

The theoretical advantages of burning crushed coal become obvious when one considers that if a cubic inch of coal, which has an exposed surface of six square inches, is crushed into cubes each of which has a side one-hundredth of an inch in length, the area of the exposed surface is multiplied one hundred times, and a more intimate mixing of the coal and air is rendered possible, and this without using a large excess of air. It is considered good practice under normal conditions with an average boiler furnace under conditions of mechanical stoking if 150 to 200 per cent of excess air is being admitted to the furnace. Under pulverized coal conditions of firing no difficulty is experienced in working regularly with not more than 20 to 30 per cent of excess air.

Inasmuch as coal-dust cannot be burnt in the ordinary way, special burners have to be provided. These differ in design, but the principles underlying all of them are the same. The coal is dried, pulverized, and the dust passing to the furnace is conveyed to a burner, mixed with air and burnt in the form of a jet. A point common to all the systems is that of the fineness to which it is necessary to reduce the coal. It has to be so fine that all of it will pass through a 100 mesh screen (that is to say a screen containing $100 \times 100 = 10{,}000$ apertures to the square inch) and 85 per cent of it through a 200 mesh screen.

There are a number of different forms of burners, the dust being driven into the fire-box by means of either fans or compressed air. In one system the air pressure is exerted in the tank, which is connected with the furnace by means of a pipe* and the dust forced in a stream, unmixed with air, through the pipe to the furnace. In another it is drawn as required from the storage bin, mixed with air, and carried in suspension through pipes to the furnace at a high velocity. In yet another system the dust from the feed worm is blown into the fire-box.

Whilst the chief use of powdered fuel is in its application for raising steam, it is also largely used in cement works and in steel furnaces.

The economies claimed in respect of the use of coal in the powdered form over the lump coal are: —

(1) A reduction (by reason of the more complete combustion) in the amount of fuel necessary to secure a given heat result.

(2) Ability to use low-grade fuel.

(3) Saving in labour as stoking is rendered unnecessary.

(4) Flexibility of the operation, coal dust firing in this respect being almost equal to oil firing.

(5) Elimination of "banking" and easier disposal of ashes.

(6) Ease of control of furnace conditions in the case of metallurgical furnaces.

Of late years oil has been taking the place of coal in the generation of power in the movement of ships. Thus of the ships under construction in the year 1927 only about 31 per cent were those in which coal will be used, 69 per cent being driven by oil either to raise steam or used in internal combustion (Diesel) engines. The relative comparative efficiencies and costs of oil versus coal driven ships may be expressed as follows: —

The high efficiency of oil engines gives 1 S.H.P. for $& lb. of oil and 1 lb. of oil costs $\frac{43}{100}$ of a penny, so that 1 S.H.P. in a Diesel engine costs $\frac{17}{100}$ of a penny. In an ordinary marine steam engine and boiler, 1 S.H.P. requires 1·7 lb. of coal, which (with coal at 24/– per ton) costs $\frac{13}{100}$ of a penny, and one coal produced S.H.P. costs $\frac{22}{100}$ of a penny. In the particular case of "King George V.," built in 1926 and using high pressure steam, this has been reduced to $\frac{14}{100}$ of a penny, so that it has been demonstrated that coal is a cheaper fuel than oil for ship propulsion where high pressure steam is used, *i.e.,* 500 to 600 lb. per square inch. With pulverized fuel still further economies would be secured.

In America the development in the use of pulverized coal since 1920 has been exceptionally rapid and probably the world's consumption of pulverized fuel at the present time exceeds 150 million tons annually. In the United States of America the use of pulverized coal per annum has been estimated as follows: —

Cement kilns	50 million tons
Metallurgical furnaces	20 " "
Steam boilers	30 " "

On the Brazilian, Central Railway some locomotives are being worked with pulverized coal derived from local deposits of inferior quality in place of using high-grade imported lump coal. In England also a system for locomotive use has been successfully developed.

PUMA, a name for one of the largest cats (*Felis concolor*) of the New World. It is called "couguar" by the French and "panther" by hunters of the United States (*see* CARNIVORA).

BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY

THE PUMA OR MOUNTAIN LION, (FELIS CONCOLOR)

Though often spoken of as the mountain lion, on account of the tawny colour of its upper parts, it rather resembles the leopard of the Old World in size and habits: measuring from nose to root of tail about 40in., the tail being rather more than half that length. The head is small and has no mane. The ears are large and rounded. The tail is cylindrical, with some bushy hairs near the end, but no distinct tuft. The lower parts, inner surface of the limbs, throat, chin, and upper lip are dirty white; the outside of the ears, and a patch on each side of the muzzle black; the end of the tail dusky. The young are born spotted a dusky brown and with the tail ringed.

The puma has a wide range, extending from Canada in the north to Patagonia in the south, and formerly was generally distributed in suitable localities from the Atlantic to the Pacific Ocean. In Central America it is still common in the dense forests which clothe the mountain ranges. Though an expert climber, it is by no means confined to wooded districts, being also found in scrub and reeds along the banks of rivers and in the open pampas and prairies. Its habits resemble those of the rest of the group to which it belongs. It rarely attacks man.

PUMICE, a very porous, froth-like, volcanic glass. It is an igneous rock which was almost completely liquid at the moment of effusion and was so rapidly cooled that there was no time for it to crystallize. When it solidified the vapours dissolved in it were suddenly released and the whole mass swelled up into a froth which immediately consolidated. Had it cooled under more pressure it would have formed a solid glass or obsidian (*q.v.*);

in fact if we take fragments of obsidian and heat them in a crucible till they fuse they will suddenly change to pumice when their dissolved gases are set free. Hence it can be understood that pumice is found only in recent volcanic countries. Any type of lava, if the conditions are favourable, may assume the pumiceous state; but basalts and andesites do not so often occur in this form as do trachytes and rhyolites. Pumices are most abundant and most typically developed from acid rocks; for which reason they usually accompany obsidians, in fact in Lipari and elsewhere the base of a lava flow may be black obsidian while the upper portion is a snow white pumice.

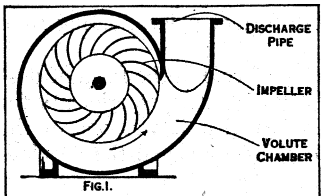
Small crystals of various minerals occur in many pumices; the commonest are felspar, augite, hornblende and zircon. If they are abundant they greatly diminish the economic value of the rock, as they are hard and wear down more slowly than the glassy material; consequently they produce scratches. The cavities of pumice are sometimes rounded, but may also be elongated or tubular owing to the flowing movement of the solidifying lava. The glass itself forms threads, fibres and thin partitions between the vesicles. Rhyolite and trachyte pumices are white, contain 60 to 75% of silica and the specific gravity of the glass is 2.3 to 2·4; andesite pumices are often yellow or brown; while pumiceous basalts, such as occur in the Sandwich islands, are pitch black when perfectly fresh.

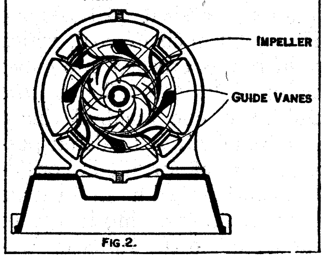
Good pumice is found in Iceland, Hungary, Nevada, Teneriffe, New Zealand, Pantellaria and the Lipari islands. The last-named are the chief sources of pumice for the arts and manufactures. At Campo Bianco in Lipari there is an extinct volcanic cone with a breached crater from which a dark stream of obsidian has flowed. For industrial purposes the best varieties are obtained from Monte Pelato and Monte Chirica. The pumice is extracted by shafts and tunnels driven through the soft incoherent stone.

Among the older volcanic rocks pumice occurs, but usually has its cavities filled up by deposits of secondary minerals introduced by percolating water; hence it is of no value for industrial purposes. Pumice, in minute fragments, has been shown to have an exceedingly wide distribution over the earth's surface at the present day. It occurs in all the deposits which cover the floor of the deepest portion of the oceans, and is especially abundant in the abysmal red clay. In some measure this pumice has been derived from submarine volcanic eruptions, but its presence is also accounted for by the fact that pumice will float on water for months, and is thus distributed over the sea by winds and currents. After a long time it becomes waterlogged and sinks to the bottom, where it gradually disintegrates and is incorporated in the muds and oozes which are gathering there. After the great eruption of Krakatoa in 1883 banks of pumice covered the surface of the sea for many miles and rose in some cases for four or five feet above the water level. In addition much finely broken pumice was thrown into the air to a great height and was borne away by the winds, ultimately settling down in the most distant parts of the continents and oceans. Pumice stone has been satisfactorily used as a packing material for vinegar generators, its porous nature affording large oxidation surfaces, which are favourable to the development of dilute alcoholic liquids (washes) into vinegar. (J. S. F.)

PUMP, a machine to raise or move fluids. The method to be adopted in raising the elevation or the pressure of a fluid depends largely on the volume to be handled and the magnitude of the lift. For large volumes the centrifugal pump is almost universally used. In its modern forms this type is capable of pumping against any pressure up to about 1,500 lb. per sq.in. Where small volumes are to be handled, under high heads, the reciprocating pump is more suitable, while where corrosive liquids are to be pumped, other types of air-lift pumps often offer advantages. *(See* VACUUM-PUMP.)

Centrifugal Pump.—In its simplest form the Centrifugal *Pump* consists of an impeller fitted with vanes and rotating in a closed casing. Water is supplied to the centre of the impeller. Due to its rotating in the impeller its pressure is increased by centrifugal force, and it is delivered at the periphery with an increased pressure and a high velocity. The kinetic energy involved in this exit velocity would be wasted if no means were available for converting it into pressure energy before leaving the pump, and various means are adopted for affecting this conversion. In the majority of pumps the impeller is surrounded by a spiral volute chamber (fig. 1) whose area gradually increases in the direction of flow, so that the velocity is gradually reduced before the water leaves the pump. Such a device is capable of converting at most about 40% of the kinetic energy into pressure energy. Where higher efficiencies are required a ring of guide vanes is used, surrounding the impeller (fig. 2). These vanes are so designed as to receive the water without shock on leaving the wheel and to direct it through passages having gradually diverging walls into the collecting volute from which it is fed to the discharge pipe. In these passages the pressure increases as the velocity is gradually reduced, and under favourable circumstances such an arrangement is capable of converting some 75% of the kinetic energy into pressure energy.





FROM BIGSON, "HYDRAULICS AND ITS APPLICATIONS" (CONSTABLE & CO.)

FIG. 1.—CENTRIFUGAL PUMP WITH VOLUTE CHAMBER

FIG. 2.— CENTRIFUGALPUMP WITH GUIDE VANES SURROUNDING IMPELLER

The necessary peripheral speed of a centrifugal pump increases with the working head, and since fluid frictional losses increase rapidly with the speed, the efficiency begins to fall off appreciably if the working head per impeller is more than about 150 feet. Where very high heads have to be handled, multi-stage pumps are used in which the water passes through one impeller after another in series. Pumps of this type are extensively used for boiler feed work and for hydraulic power pumping stations.

The characteristics of a centrifugal pump depend essentially on the vane angles of its impeller, and under suitable conditions its overall efficiency may attain a value as high as 85%. At the inner periphery the vane angle β (fig. 3) should be such that the water enters the impeller without shock. This condition is satisfied if $\tan \beta = f_2/u_2$ where f_2 is the radial component of the velocity of the water, and u_2 is the peripheral velocity of the impeller at this point. At the point of discharge the vanes may either be radial, or may be curved forwards, or backwards from the direction of rotation depending upon the duty for which the pump is designed. If γ be the vane angle at this point, and if u_3 be the peripheral velocity and f_3 the radial component of velocity of the water, the gain of pressure head in the impeller is, neglecting frictional losses, equal to

$$\frac{u_3^2 - f_3^2 \operatorname{cosec}^2 \gamma + f_2^2}{2g} \text{ feet}$$

while if K represents the proportion of the kinetic energy of discharge which is converted into pressure energy in the volute chamber or guide vanes, the total gain of pressure in the pump is given by

$$u_3^2(K+1) + f_3^2 \operatorname{cosec}^2 \gamma (K-1) - 2Ku_3 f_3 \cot \gamma \text{ feet.}$$

In the majority of pumps the angle γ is between 30° and 75°, the value increasing with the height of lift.

Reciprocating Pumps.—These may be either of the single acting or double acting type. In the former, water is drawn into the pump through a suction valve on one stroke, and is forced out through the delivery valve on the return stroke. By fitting suction and delivery valves on both sides of the plunger, the pump becomes double acting.

The acceleration and retardation of the plunger at the ends of the stroke causes corresponding retardations and accelerations in the supply and delivery columns, and if these are long considerable momentum effects may be experienced. If the speed is

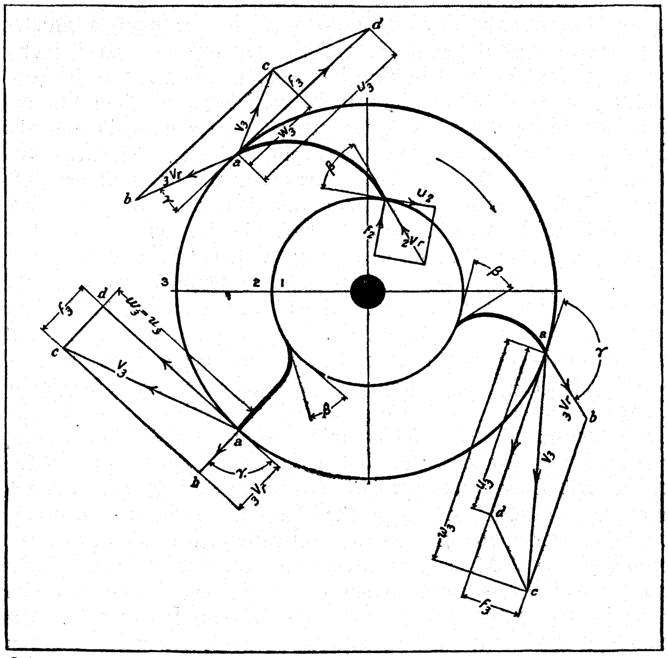
VARIOUS TYPES OF PUMPS

1. Rotary displacement pump
2. Section of a two-stage turbine pump
3. A 330 h.p. Diesel engine, connected to an 80-in. drainage pump, to the right
4. High pressure Diesel pump set, showing multi-stage pump to the left
5. A 200 h.p. Diesel engine, direct connected to a high-pressure plunger pump serving an oil pipe line
6. A 4-cycle air injection engine used in petroleum pipe line stations

sufficiently high the columns may be unable to maintain contact with the plunger and "cavitation" is set up, which gives rise to considerable shock in the pump. To avoid this an air vessel should always be fitted on the suction side of the pump, and often on the delivery side. This equalizes the flow along the pipe lines.

For low speed pumps, disc valves of rubber or metal, which are returned to their seat either by the action of a spring or by their



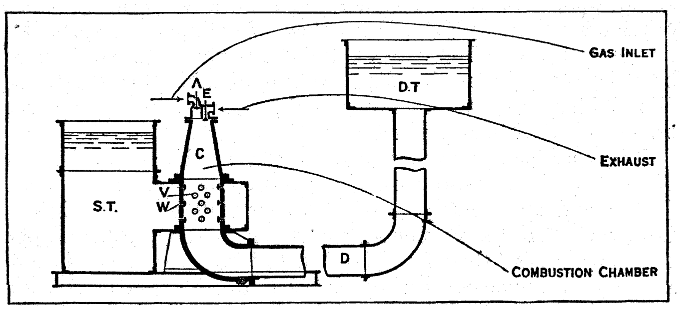
FROM GIBSON. "HYDRAULICS AND ITS APPLICATIONS" (CONSTABLE & CO.)

FIG. 3.— VELOCITY DIAGRAMS FOR VANES OF CENTRIFUGAL PUMP. HAVING DIFFERENT DEGREES OF BACKWARD CURVATURE

own elasticity, are usually used. For high speed pumps mechanically operated valves are often used.

Rotary Pumps.—Pumps of the rotary type are well adapted for working over a wide range of speeds with comparatively low head and with widely varying discharges. They have the advantage over the reciprocating pump that the discharge is practically continuous, while the efficiency does not fall off nearly so quickly with discharge variations as the centrifugal pump.

There are two main types of rotary pump. In one a drum mounted eccentrically in its casing carries one or more sliding diaphragms which make contact with the interior of the casing.



FROM GIBSON, "HYDRAULICS AND ITS APPLICATIONS" (CONSTABLE & CO.)

FIG. 4.— HUMPHREY GAS PUMP

In the other type two rotating drums are used mounted on parallel axes and coupled together by two equal gear wheels mounted on the shafts outside the casing.

Humphrey Gas Pump.—In the Humphrey Gas Pump water is raised by the direct action of the pressure accompanying the explosion and expansion of a gas-air mixture. At the beginning of the power stroke a compressed charge of air and gas in the combustion chamber C (fig. 4) is ignited by an electric spark and expands forcing the column of water D between the combustion chamber and the delivery tank D T towards the tank and discharging part of it in the process. Due to the momentum of this column, expansion continues until the pressure at the lower part of the water column falls to atmospheric, when the suction valves V, communicating with the suction tank ST, open and water is drawn through them into the pipe. At the same time the exhaust valve is opened. When the momentum of the water column is exhausted it oscillates back, driving the products of combustion out of the combustion chamber until it reaches the exhaust valve, which it closes by impact; on the next rebound of the water column the gas inlet valve opens and a fresh charge is drawn in; at the end of the outward oscillation the gas inlet valve is closed and the returning oscillation compresses the charge which is fired as the column comes to rest.

The **Air Lift** Pump.—This consists of an open ended vertical lift pipe, of which the lower end is submerged in the liquid to be raised, and the upper end delivers into a discharge tank at the height which is required. Air is supplied from an air compressor through an air pipe to the lower end of the lift pipe, and rising in the form of small bubbles through the liquid in this pipe forms a mixture having a specific gravity lower than that of the liquid itself. The pressure of the liquid surrounding the pipe then raises the lighter mixture above the supply level and out of the top of the lift pipe. The possible lift depends upon the amount of air supplied and upon the depth of submersion of the bottom of the lift pipe. For best results the depth of submersion should be approximately 1·5 times the height of the lift. For high efficiency the air should be supplied to the lift pipe through a foot-piece having a series of small openings so arranged as to distribute the air in a series of small bubbles through the liquid. If well designed such a pump is capable of converting some 60% of the energy in the compressed air at the foot-piece into useful work in lifting water. Air lift pumps have been constructed for lifting against heads of upwards of 400 ft., and with lift pipe diameters up to about 1 j inches.

Jet Pump.—In the jet pump a high pressure water supply is conducted to a small nozzle, whence it issues into a suction chamber as a jet having a high velocity and a relatively low pressure. The suction chamber surrounding the jet is connected to the suction reservoir. If the pressure at the jet is sufficiently low, water is lifted into this chamber and is forced by the impact of the high velocity jet into a discharge pipe, whose suction gradually increases in the direction of flow. There the kinetic energy is partially converted into pressure energy, enabling the pump to discharge against a head considerably higher than that of the suction reservoir. Owing to the loss due to eddy formation accompanying the admixture of the high and low velocity water, the efficiency of such a pump is low and does not usually exceed about 20%. When the fluid used for the high pressure jet is steam. the pump becomes the boiler feed injector so largely used in locomotive work.

The Hydraulic Ram.—This is an apparatus devised to utilize the energy of a water supply at a low head, to pump up part of this water to a height greater than that of the supply head. It consists of an inclined supply pipe leading straight into a valve-box which is fitted with a waste valve opening inwards, and a delivery valve opening outwards. This valve discharges the water into an air vessel from which it is delivered in a steady stream to the discharge pipe.

The action of the ram is as follows: The waste valve being opened, water is free to escape, and flow is set up along the supply pipe. The velocity of flow increases under the influence of the supply head until the dynamic pressure on the under side of the valve becomes sufficiently great to overcome its weight. The valve now closes rapidly and the sudden check to the momentum of the supply column causes a rapid increase of pressure in the valve-box until this pressure becomes sufficiently great to open the delivery valve. Water then escapes through this valve into the air vessel, compresses the air, and flows away along the rising main. As soon as the momentum of the supply column is destroyed the delivery valve closes, the water below the valve partaking of the backward motion thus instituted. This motion, once set up, can only be checked by a reduction of pressure in the valve-box below that corresponding to the statical head of the supply, and consequently the pressure in the valve-box is reduced rapidly until at some instant the waste valve reopens, and the whole cycle of operations is repeated. The efficiency of the hydraulic ram falls off as the ratio of the delivery head to the supply head is increased. When this ratio does not exceed about 4 : 1, the efficiency may be high as 75%. If the ratio is increased to 20 : 1 the efficiency does not exceed about 25%.

A pumping device known as the "Hydrotomat" has been recently introduced which also utilizes a large quantity of water under a low head to raise a portion of itself to some greater height. This works by alternately compressing and exhausting air in a series of containers.

PUMPKIN, the fruit of certain varieties of Cucurbita pepo or of C. moschata, members of the family Cucurbitaceae. The names pumpkin and squash, especially in America, are applied rather inconsistently to certain varieties of both these species. The quick-growing, small-fruited bush or non-trailing varieties of C. pepo, (see SQUASH and VEGETABLE MARROW) are called squash in America, while the long-season, long-trailing, large-fruited varieties are called pumpkin. The fruits are large, generally 10–20 lb. or more, yellowish to orange in colour and vary from oblate through globular to oblong. The rind is smooth and usually lightly furrowed or ribbed, the fruit stem is hard and woody, ridged or angled, and in C. *pepo* not flared at its point of attachment to the fruit. The very largest varieties of "pumpkin" are more properly designated as winter squash, C. *maxima,* and may weigh 75 lb. or more. Varieties cross-pollinate very readily within each of the three species mentioned, but the species do not cross naturally. A few inter-specific crosses have been recorded but the hybrids were highly self-sterile and set no fruit with their own pollen. Neither pumpkins nor squash will cross with cucumbers or with melons.

Pumpkins are commonly grown in Great Britain, Europe and North America for human food and also for livestock feed. The varieties commonly called pumpkin produce very long vines and are usually planted in hills of 2–3 plants each, about 8x8 ft. apart. They are also planted at wide intervals in fields of corn Pumpkins mature in early fall and can be stored a few months in a dry place well above freezing. They are prepared for food in a wide variety of ways. (V. R. B.)

PUNANS, a nomad, hunting, and forest-people of Borneo, without agriculture, and owning neither houses nor boats, but relying on their jungle-lore and the use of the blow-pipe for the supply of their daily needs. In their purity they are found almost exclusively in the interior, where there are also kindred tribes, such as the Ukits and Sians; but in certain parts of Sarawak "modified Punans," such as the Penans and Milanos are found. The Punans are closely akin to the Sakais of the Malay Peninsula and the Kubus of Sumatra. Physically they are of short stature, with a proportionately long body, their complexions are of a pale yellow, shading off into a greenish hue, a circumstance due, no doubt, to the fact that they never expose themselves to direct sunlight, but live perpetually in the half-light of the forest. See BORNEO.

PUNCH, the abbreviated form of Punchinello (Ital. *Policinella*, Pulcinella), the most popular of the puppets or marionettes (*q.v.*), and the chief figure in the "Punch and Judy" show. It is of Italian origin, though its history is by no means free from obscurity. The earlier etymologists sought to trace the name to various mythical individuals, by whom, it was alleged, the type was first furnished. F. Galiani adopts the theory which derives it from the name of Puccio d'Aniello, a vintager of Acerra near Naples, who, having by his wit and grotesque appearance vanquished some strolling comedians in their own sphere, was induced to join the troop, and whose place, by reason of his popularity, was supplied after his death by a masked actor who imitated his dress and manner. The claims of other individuals — Paolo Cinella, Polliceno and Pulcinella, a Neapolitan dealer in fowls — have also found supporters, and the derivation of the name and character from some old mystery representing Pontius (O. Eng. Pownce; Fr. *Ponce*) Pilate and Judas, or the Jews, was formerly popular. It has even been suggested that the title is a modification of πολὺ κινέω (I move much) as expressive of the restlessness which is characteristic of the puppet; and the assumption that the character was invariably of diminutive size has given rise to its reference to the word *pollice,* the thumb (cf. *Däumling,* Tom Thumb). The most plausible theory, however, regards the name in its Italian form as a diminutive of *pulcino,* fem. *pulcina,* a chicken. It is sometimes stated that, in consequence of the habit of using the word "chicken" as a term of endearment, it came to mean "a little child," and hence "a puppet" (W. Skeat). The choice, however, seems to lie between the theory of Quadrio, that it was applied on account of the resemblance of the hooked nose to a beak, and that of J. Baretti, which ascribes its employment to the nasal squeak and timorous impotence of the original character. With respect to the development of the modern type, it has been assumed that the whole family of Italian *maschere* (Arlecchino, Brighella and the like) are modified survivals of the principal Oscan characters of the Atellanae, and that Punchinello is the representative of Maccus, the fool or clown. In proof of this it is urged that Acerra, the supposed residence of Puccio d'Aniello and the traditional source of the character, is in the neighbourhood of Aversa, the old Atella; and reference is also made to a bronze statue of Maccus, discovered at Rome in 1727, an engraving of which has been preserved in Ficoroni's Le Maschere *sceniche e le figure comiche* d'antichi Romani. But the resemblance of the statue to the puppet is scarcely a striking one, and the large nose and deformed figure are somewhat hazardous ground on which to base a theory.

Andrea Perrucci (1699) and Gimma assert with some show of authority that Silvio Fiorillo, a comedian named after his principal part, Captain Matamoros (the Italian Miles *Gloriosus*), invented the Neapolitan Pulcinella. It was afterwards improved by Andrea Calcese, surnamed Ciuccio, who died of the plague in 1656, and who, according to Gimma, imitated in the character the peasants of Acerra. This would place the origin of the Italian Pulcinella somewhere about the commencement of the 17th century, the original character appearing to have been that of a country clown, hook-nosed, shrill-voiced, cowardly, boastful and often stupid, yet given at times to knavish tricks and shrewd sayings. In thorough accordance with this date, we find that the earliest known appearance of Polichinelle in France is at the beginning of the reign of Louis XIV., in the show of the puppet-playing dentist Jean Brioché. The date of its introduction into England has been disputed, J. Payne Collier being of opinion that Punch and King William came together, a second theory suggesting an earlier origin with the Huguenot refugees.

It is more than probable that it crossed the channel in the wake of the Royalists. Apart from the general references by S. Pepys (1662) and by J. Evelyn (1667) to an Italian puppet-show at Covent Garden, the former makes 'mention (1669) of some poor people who called their fat child Punch, "that word being become a word of common use for all that is thick and short." An allusion to "Punchinellos" is also to be found in Butler's satire on English imitation of the French, and Aubrey speaks of "a Punchinello holding a dial" as one of the ornaments of Sir Samuel Lely's house at Whitehall. But, though the puppet did not travel in the train of William of Orange, allusions to it became far rnore frequent after the Revolution of 1688, and the skill of the Dutch in their treatment of puppet mechanism may have enhanced its attractiveness. In 1703 it was introduced at Bartholomew Fair into a puppet play of the creation of the world; in 1709 (*Tatler,* No. 16) it was to be found in a representation of the Deluge, though in a different part from that of the Momus Polichinelle of Alexis Piron's *Arlequin-Deucalion* (1722); and in 1710 (Spectator No. 14) it is mentioned as a leading figure in Powell's puppet-show at Covent Garden. The alleged satire on Robert Walpole, entitled *A Second Tale of a Tub, or the History of Robert Powell, the Puppet-Showenan* (1715), furnishes some details of Punch performances, and has an interesting frontispiece representing Powell with Punch and his wife. The Judy (or Joan, as she appears to have been sometimes called) is not of a specially grotesque order, but the Punch is easily recognizable in all but the features, which are of the normal puppet type.

The older Punchinello was far less restricted in his actions and circumstances than his modern successor. He fought with allegorical figures representing want and weariness as well as with his wife and with the police, was on intimate terms with the patriarchs and the seven champions of Christendom, sat on the lap of the queen of Sheba, had kings and dukes for his companions. Powell seems to have introduced a trained pig which danced a minuet with Punch, and the French (among whom Punch is now usually styled Guignol, originally a puppet hailing from Lyons) occasionally employed a cat in the place of the dog Toby, whose origin is somewhat uncertain. A typical version of the modern play, with illustrations, was published by Payne Collier and Cruikshank in 1828 (3rd ed.. 1844). (R. M. WH.)

PUNCHING AND SHEARING MACHINES. The quickest method of making holes in, or severing, materials is by punching or shearing, and there are few forms of manufacture that do not utilize machines for these operations. Paper, card, leather, cotton, cloth, slate, tin, brass, iron and steel all undergo such treatment. Circular and other shaped holes are made, pieces are punched out to give various outlines, and various shapes are sheared off. The most striking examples are in steel works, where blades of 12 feet in length will shear through 2 in. cold steel plate, or hot slabs 43 in. by 20 in. thick are cut through. Many industries are suited by hand-worked machines, others require belt, electric motor or steam-engine drive, while the largest punches and shears are worked hydraulically. Hand machines are employed by tinsmiths and other light metalworkers, also by boxmakers, and these machines rest on the bench. Larger punches or shears are actuated by treadle, the latter machines having blades up to about 4 feet in length. Some have blades formed to cut curves in tinplate or iron plate, instead of using a die to stamp the outlines, and corrugated blades are used for shearing corrugated iron. Blacksmiths and others make use of a combined type of machine, with a single lever moving the punch and the shear blade. This principle is also applied in many big machines of the engineering works, but using power drive.

Punching and shearing are alike in action which amounts to a rather violent separation of the fibres of the material. In soft substances there is little injury, because the cutting edges can be

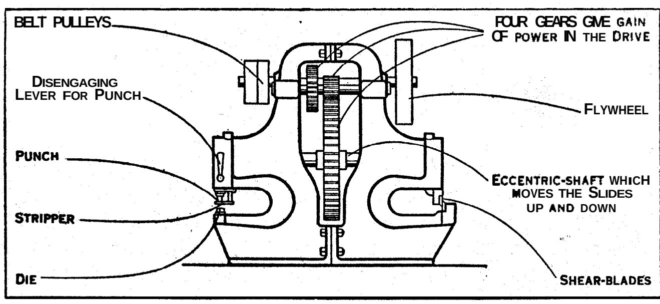

DIAGRAM OF A PUNCHING AND SHEARING MACHINE, WHICH PUNCHES AT ONE END AND SHEARS AT THE OTHER

made of a keen angle, but iron and steel become more or less torn unless very thin, and the edge reveals minute cracks. For certain purposes these would be undesirable, as tending to increase under stress; consequently plates and strips for steam-boilers are not punched, but drilled for reasons of safety. And where structures are subject to heavy loads of a fluctuating nature, the best plan is undoubtedly to ream punched holes, the reamer taking away the cracked and torn walls and leaving a smooth and whole surface. Shorn plates for boilers and certain other constructions are also machined on the edges, by turning, planing or milling, until a clean faultless metal is left. Obviously in order to ensure neat punching or shearing, as well as to minimize cracks and damaged edges, the tools should be kept ground up sharp, and set so that the material is well supported at the moment of impact. In a great many cases a slotted finger, termed a *stripper,* is fixed a fraction of an inch above the material, so that as the punch rises after the stroke the material cannot be pulled up with it, but is automatically stripped off. Some substances, especially when laid in piles for simultaneous treatment, must be clamped down firmly to prevent faulty results, while the thicker steel plates are held immovably by a mechanically-operated clamping device which comes into play just before the descent of the slide. Hydraulic vice rams perform this function in the large hydraulic shears of the steel-works. In rolling-mills, plates and slabs are transported under the shear on sets of power-driven rollers.

Types of Punching and Shearing Machines. — The power-driven punching machines vary in design according to whether the material is thin or thick. For the general run of tinware and similar thin stock the crank-driven power-presses are used, being of much the same or identical design as for other operations on sheetmetal parts. The machine frame must be stiff, and if necessary braced with tie-rods to prevent spring, otherwise the act of penetration will cause the punch and die to come out of alignment, and they will be injured, and poor work will result. The slide which moves the punch up and down must be well fitted, as any slackness will have a similar effect. The fit of the punch in the die, through which it pushes the punching, must be fairly close to ensure getting a sharp impression around the edges. The fit is closer in very thin metal than it need be in thick stuff. Many special mandrels or supports are attached to presses to carry the lower die when the object is of a difficult outline, such as a pipe.

For engineering manufactures, including all sorts of steel construction (boilers excepted), ships, agricultural machinery, tanks, cisterns, piping, fencing, railway carriage and wagon frames and so on, the punching machines are either single or multiple, or are combined in one frame with a shearing machine, so that one drive actuates each slide (see the sketch). The punch slide has a disengaging device, rendering the punch inoperative until the attendant has accurately located the plate beneath it, whereupon he pulls a little lever and the punch descends. The purpose of the flywheel is to give a reserve of energy to carry the punch or shear through the metal. The larger machines possess self-contained jib cranes, enabling heavy plates to be slung and moved along as necessary without keeping the shop crane engaged. Punching-machines only have an eccentric action to the slide (similar in principle to that of the diagram) and are often double-ended, using a differently sized punch in each slide. Instead of eccentric motion, powerful levers are often utilized in collaboration with a central eccentric which rocks them and so moves each slide. Sometimes a third slide is included in a double-ended punching and shearing machine to cut angle-iron, which requires a special shape of blade. Provision for shearing off angles, tees, channels, girders or H-irons is incorporated in some machines, there being apertures of corresponding section through which the shapes are pushed and sheared by a knife behind. The framings of such machines are frequently made in either cast-steel or steel plates riveted together, to afford extra strength without such weight as is necessary for cast-iron framings.

Multiple punching is greatly in favour because of the economy of production. The regular machines may have an attachment to take two or three punches, but otherwise a special machine has to be used, with a wider slide than usual. The punches are either adjustable as to distance apart, or fixed in this respect. Plates and bars for tanks, agricultural machines, carriages and wagons and various machinery may have any number up to roo holes pierced at a stroke. If several rows must be put through a sheet (as for mine screens) the sheet can be handled rapidly on an automatic spacing table, which feeds it accurately to the successive positions past the punches. Alternatively the plate may remain stationary and the punching head travel intermittently to the successive positions.

The massive shears required in steel works and those making big boilers are actuated by powerful gearing and eccentrics, or by hydraulic cylinders. The parts must be extremely strong in order to withstand the enormous force exerted at the moment of shearing and powerful spring buffers are often provided to take the shock as the blade goes through the plate. In these, as in most other shears, the blade is set at an angle so that it only shears progressively from one end to the other.

Hydraulic action furnishes a simpler mode of actuating a punch or shear slide than gearing in some of the shipyards, for punching big holes necessary in some of the plates. Portable machines for either punching or shearing are often used in the yards, being either carried about or transported on wheels. The working of a lever operates the pump and sends water to the actuating cylinder. Small machines are termed punching bears.

Rotary shears are so named because bevel-edged discs are used for the shearing. Some cut straight, others in circles, the plate being rotated on a central stud. Both circles and rings are sheared thus in large numbers for the tinware industry and other branches requiring these forms to build up shapes, or to stamp to further outline in dies. Some are built as slitting shears, that is suitably to make a long straight cut to divide a plate in two, or shear it up into strips, and there are also scroll *shears* which will cut intricate outlines between the discs, the attendant suitably manoeuvering the sheet as he feeds it along. (F. H.)

PUNCTUATION, the art of "pointing" a literary composition so as to divide it into sentences and portions of sentences, which the "points" mark at their close, thus indicating what would in speech be pauses or changes of expression (Lat. *punctum,* a point). The uses of the chief "points" are thus explained in the "Rules for Compositors" at the Oxford University Press, compiled by Mr. Horace Hart:—

The "full stop" or "period" (.) marks the end of a sentence. The "colon" (:) is at the transition point of the sentence. The "semicolon" (;) separates different statements. The "comma" (,) separates clauses, phrases and particles. (The terms "period," "colon," "comma," were borrowed from the Greek grammarians, who originally described either the whole sentence or a part of it in this way.) The "dash" (—) marks abruptness or irregularity. The "exclamation" (!) marks surprise. The "interrogation" or "query" (?) asks a question. The apostrophe (') marks elisions or the possessive case. "Quotes," quotation-marks or "inverted commas" (" ") define quoted words. Interpolations in a sentence are marked by various forms of bracket () or parenthesis. Usage and practice vary however. The subject may be studied in such works as H. Beadnell's Spelling and Punctuation, P. Allardyce's ,Stops: or how to punctuate, and T. L. de Vinne's Correct *Composition.* In the earlier forms of writing the letters ran on continuously in lines; only by degrees were words divided up by spacing within the line; later came the distribution into sentences by points, and the introduction by Aldus Manutius (16th century) of a regular system for these. The chief signs were derived from the dots of the Greek grammarians, but these have often changed meanings; thus the Greek interrogation mark (;) becomes the semicolon. (See PALAEOGRAPHY and TYPOGRAPHY.)

PUNIC WARS, a name specially appropriated to the wars between Rome and Carthage in the 3rd and 2nd centuries B.C. The origin of these conflicts is to be sought in the position which Rome acquired about 275 B.C. as suzerain and protector of all Italy. Her new obligation to safeguard the peninsula against foreign interference made it necessary that she should not allow the neighbouring island of Sicily to fall into the hands of a strong and expansive power. Carthage, on the other hand, had long been anxious to conquer Sicily and so to complete the chain of island posts by which she controlled the western Mediterranean.

First Punic War (264–241 B.C.[1]).—The proximate cause of the first outbreak was a crisis in the city of Messana, commanding the straits between Italy and Sicily. A band of Campanian mercenaries, which had forcibly established itself within the town and was being hard pressed in 264 by Hiero II. of Syracuse, applied for help both to Rome and Carthage and thus brought a force from either power upon the scene. The Carthaginians, arriving first, occupied Messana and effected a reconciliation with Hiero. The Roman commander nevertheless persisted in throwing troops into the city, and by seizing the person of the Carthaginian admiral during a parley induced him to withdraw. The Romans thus won an important strategic post, but their aggression met a declaration of war from Carthage and Syracuse.

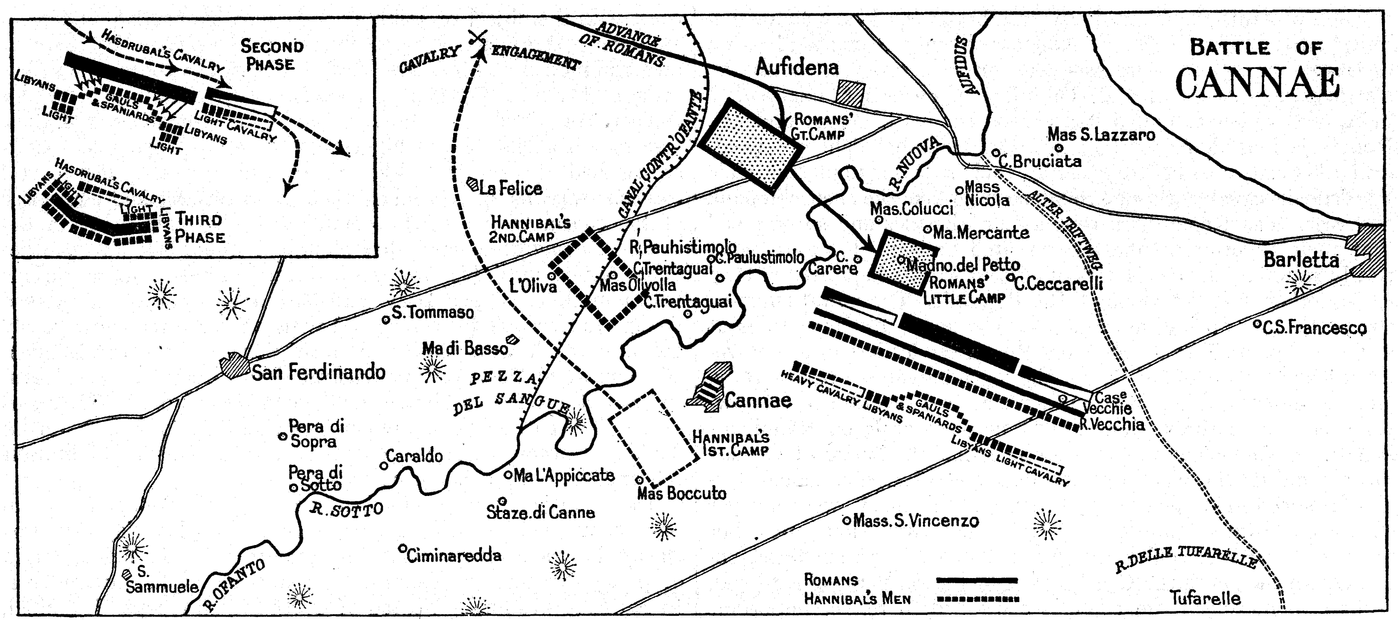
Operations began with a joint attack upon Messana, which the Romans easily repelled. In 263 they advanced with a considerable force into Hiero's territory and induced him to seek peace and alliance with them. Having thus secured their foothold on the island they set themselves to wrest it completely from Carthage. In 262 they besieged and captured the enemy's base at Agrigentum, and proved that Punic mercenary troops could not stand before the infantry of the legions. But they made little impression upon the Carthaginian fortresses in the west of the island and upon the towns of the interior which mostly sided against them. Thus in the following campaigns their army was practically brought to a standstill.

In 260 the war entered upon a new phase. Convinced that they could gain no serious advantage so long as the Carthaginians controlled the sea and communicated freely with their island possessions, the Romans built their first large fleet of standard battleships. At Mylae, off the north Sicilian coast, their admiral C. Duilius defeated a Carthaginian squadron of superior manoeuvring capacity by a novel application of grappling and boarding tactics. This victory left Rome free to land a force on Corsica and expel the Carthaginians (259), but did not suffice to loosen their grasp on Sicily.

After two more years of desultory warfare the Romans decided to carry the war into the enemy's home territory. A large armament sailed out in 256, repelled a vigorous attack by the entire Carthaginian fleet off Cape Ecnomus (near Agrigentum) and established a fortified camp on African soil at Clypea. The Carthaginians, whose citizen levy was utterly disorganized, could neither keep the field against the invaders nor prevent their subjects from revolting. A single campaign compelled them to sue for Peace, but the terms which the Roman commander Atilius Regulus offered were intolerably harsh. Accordingly they equipped a new army in which, by the advice of a Greek captain of mercenaries named Xanthippus, cavalry and elephants formed the strongest arm. In 255, under Xanthippus's command, they offered battle to Regulus, who had taken up position with an inadequate force near Tunis, outmanoeuvred him and destroyed the bulk of his army. A second Roman armament, which subsequently reached Africa after defeating the full Carthaginian fleet off Cape Hermaeum, did not venture to reopen the campaign, but withdrew all the remaining troops.

The Romans now directed their efforts once more against Sicily. In 254 they carried the important fortress of Panormus (Palermo) by an attack from the sea; but when Carthage threw reinforcements into the island the war again came to a standstill. In 251 at last the Roman general L. Metellus brought about a pitched battle near Panormus in which the enemy's force was effectively crippled. This victory was followed by an investment of the chief Punic base at Lilybaeum by land and sea. The besiegers met with a gallant resistance, and in 249 were compelled to withdraw b~ the loss of their fleet in a surprise attack upon the neighbouring harbour of Drepanum (Trapani), in which the admiral Claudius Pulcher was repulsed with a loss of 93 ships. Meanwhile other losses in storms on the high seas so reduced the Roman fleet that the attack upon Sicily had to be suspended. At the same time the Carthaginians, who felt no less severely the financial strain of the prolonged struggle and had a war in Africa on their hands, reduced their armaments and made no attempt to deliver a counter-attack. The only noteworthy feature of the ensuing campaigns is the skilful guerrilla war waged by a new Carthaginian commander, Hamilcar Barca, from his strong positions on Mt. Ercte (247–244) and Mt. Eryx (244–242) in western Sicily, by which he effectually screened Lilybaeum from the Roman land army.

[1] The chronology here given is the traditional one, but recent researches tend to show that many events have been antedated by one year.



PLAN OF THE BATTLE OF CANNAE, AN ENCOUNTER OF THE SECOND PUNIC WAR, WHERE THE ROMANS WERE PRACTICALLY ANNIHILATED BY HANNIBAL IN 216 B.C.

In 242 Rome resumed operations on sea. By a magnificent effort on the part of private citizens a fleet of zoo warships was equipped and sent out to renew the blockade of Lilybaeum. The Carthaginians hastily collected a relief force, but in a battle fought off the Aegates or Aegusae islands (west of Drepana) their fleet was caught at a disadvantage and mostly sunk or captured (March 10, 241). This victory, by giving the Romans undisputed command of the sea, rendered certain the ultimate fall of the Punic strongholds in Sicily. The Carthaginians accordingly opened negotiations and consented to a peace by which they ceded Sicily and the Lipari islands to Rome and paid an indemnity of 3,200 talents (about £800,000).

The Interval Between the First and Second Wars (241–218 B.C.).—The loss of naval supremacy not only deprived Carthage of her predominance in the western Mediterranean, but exposed her oversea empire to disintegration under renewed attacks by Rome. The temper of the Roman people was soon made manifest during a conflict which broke out between the Carthaginians and their discontented mercenaries. Italian traders were allowed to traffic in munitions of war with the mutineers, and a gross breach of the treaty was perpetrated when a Roman force was sent to occupy Sardinia, whose insurgent garrison had offered to surrender the island (239). To the remonstrances of Carthage the Romans replied with a direct declaration of war, and only withheld their attack upon the formal cession of Sardinia and Corsica and the payment of a further indemnity.

From this episode it became clear that Rome intended to use her victory to the utmost. To avoid complete humiliation Carthage had no resource but to humiliate her adversary. The recent complications of foreign and internal strife had indeed so weakened the Punic power that the prospect of renewing the war under favourable circumstances seemed remote enough. But the scheme of preparing for a fresh conflict found a worthy champion in Hamilcar Barca, who sought to compensate for the loss of Sicily by acquiring a dominion in Spain where Carthage might gain new wealth and form a fresh base of operations against Rome. Invested with an unrestricted foreign command, he spent the rest of his life in founding a Spanish empire (236–228). His work was continued by his son-in-law Hasdrubal and his son Hannibal, who was placed at the head of the army in 220. These conquests aroused the suspicions of Rome, which in a treaty with Hasdrubal confined the Carthaginians to the south of the Ebro, and also guaranteed the independence of Saguntum, a town on the east coast which pretended to a Greek origin. In 219 Hannibal laid siege to Saguntum and carried the town in spite of a stubborn defence. It has always been a debatable point whether his attack contravened the new treaty. The Romans certainly took this view and sent to Carthage to demand Hannibal's surrender. But his defiant policy was too popular to be disavowed; the Carthaginian council upheld Hannibal's action, and drew upon itself a declaration of war.

Second Punic War (218–201 B.C.).—It seemed as though the superiority of the Romans at sea must enable them to choose the field of battle. They decided to embark one army for Spain and another for Sicily and Africa. But before their preparations were complete Hannibal began that series of operations by which he dictated the course of the war for the greater part of its duration. Realizing that so long as Rome commanded the resources of an undivided Italian confederacy no foreign attack could beat her down beyond recovery, he conceived the plan of cutting off her supply of strength at the source by carrying the war into Italy and causing a disruption of the League. His chances of ever reaching Italy seemed small, for the sea was guarded by the Roman fleets and the land route was long and arduous. But the very boldness of his enterprise contributed to its success; after a six months' march through Spain and Gaul and over the Alps, which the Romans were nowhere in time to oppose, Hannibal arrived in the plain of the Po with 20,000 foot and 6,000 horse, the pick of his African and Spanish levies (autumn 218: for details *see* HANNIBAL).

His further advance was here disputed by some Roman troops which had been recalled from the Spanish expedition. But the superiority of the Carthaginian cavalry and the spread of insurrection among the Gaulish inhabitants forced the defenders to fall back upon the Apennines. At the end of the year the Roman army was reinforced by the division from Sicily and led out to battle on the banks of the Trebia (*q.v.*). Hannibal, by superior tactics, repelled the assailants with heavy loss, and thus made his position in north Italy secure.

In 217 the campaign opened in Etruria, into which the invading army, largely reinforced by Gauls, penetrated by an unguarded pass. A rash pursuit by the Roman field force led to its being entrapped on the shore of Lake Trasimene (*q.v.*) and destroyed with a loss of 40.000 men. This catastrophe left Rome completely uncovered; but Hannibal, having resolved not to attack the capital before he could collect a more overwhelming force, directed his march towards the south of Italy, where he hoped to stir up the peoples who had formerly been Rome's most stubborn enemies. The natives, however, were everywhere slow to join the Carthaginians, and a new Roman army under the dictator Q. Fabius Maximus ("Cunctator"), which, without ever daring to close with Hannibal, dogged his steps on his forays through Apulia and Campania, prevented his acquiring a permanent base of operations.

The eventful campaign of 216 was begun by a new aggressive move on the part of Rome. An exceptionally strong field army, estimated at 85,000 men, was sent forth in order to crush the Carthaginians in open battle. On a level plain near Cannae (*q.v.*) in Apulia, which Hannibal had chosen for his battle-ground, the Roman legions delivered their attack. Hannibal deliberately allowed his centre to be driven in by their superior numbers, while Hasdrubal's cavalry wheeled round so as to take the enemy in flank and rear. The Romans, surrounded on all sides and so cramped that their superior numbers aggravated their plight, were practically annihilated, and the loss of citizens was perhaps greater than in any other defeat that befell the Republic. The moral effect of the battle was no less momentous. The south Italian nations at last found courage to secede from Rome, the leaders of the movement being the people of Capua, the second greatest town of Italy. Reinforcements were sent from Carthage, and several neutral powers prepared to throw their weight into the scale on Hannibal's behalf. At first sight it seems strange that the battle of Cannae did not decide the war. But the resources of Rome, though terribly reduced in respect both of men and of money, were not yet exhausted. In north and central Italy the insurrection spread but little, and could be sufficiently guarded against with small detachments. In the south the Greek towns of the coast remained loyal, and the numerous Latin colonies continued to render important service by interrupting free communication between the rebels and detaining part of their forces. In Rome itself the quarrels between the nobles and commons, which had previously unsettled her policy, gave way to a unanimity unparalleled in the annals of the Republic. The guidance of operations was henceforth left to the senate, which by maintaining a persistent policy until the conflict was brought to a successful end earned its greatest title to fame.

The subsequent campaigns of the Italian War assume a new character. Though the Romans contrived at times to raise 200,000 men, they could only spare a moderate force for field operations. Their generals, among whom the veterans Fabius and M. Claudius Marcellus frequently held the most important commands, rarely ventured to engage Hannibal in the open, and contented themselves with observing him or skirmishing against his detachments. Hannibal, whose recent accessions of strength were largely discounted by the necessity of assigning troops to protect his new allies or secure their wavering loyalty, was still too weak to undertake a vigorous offensive. In the ensuing years the war resolved itself into a multiplicity of minor engagements which need not be followed out in detail. In 216 and 215 the chief seat of war was Campania, where Hannibal vainly attempted to establish himself on the coast but experienced a severe repulse at Nola. In 214 the main Carthaginian force was transferred to Apulia in hopes of capturing Tarentum. Though Croton and Locri on the Calabrian coast had fallen into his hands, Hannibal still lacked a suitable harbour by which he might have secured his oversea communications. For two years he watched in vain for an opportunity of surprising the town, while the Romans narrowed down the sphere of revolt in Campania and defeated other Carthaginian commanders. In 212 the greater part of Tarentum and other cities of the southern seaboard at last came into Hannibal's power. But in the same year the Romans found themselves strong enough to place Capua under blockade. They severely defeated a Carthaginian relief force, and could not be permanently dislodged even by Hannibal himself. In 211 Hannibal made a last effort to relieve his allies by a feint upon Rome itself, but the besiegers refused to be drawn away from their entrenchments, and eventually Capua was starved into surrender. Its fall was a sign that no power could in the long run uphold a rival Italian coalition against Rome. After a year of desultory fighting the Romans in 209 gained a further important success by recovering Tarentum. Though Hannibal still won isolated engagements, he was being slowly driven back into the extreme south of the peninsula.

In 207 the arrival of a fresh invading force produced a new crisis. Hasdrubal, who in 209–208 had marched overland from Spain, appeared in north Italy with a force scarcely inferior to the army which his brother had brought in 218. After levying contingents of Gauls and Ligurians he marched down the east coast with the object of joining hands with his brother in central Italy for a direct attack upon Rome. By this time the drain of men and money was telling so severely upon her confederacy that some of her most loyal allies protested their inability to render further help. Yet by a supreme effort the Romans raised their war establishment to the highest total yet attained and sent a strong field army against either Carthaginian leader. The danger to Rome was chiefly averted by the prompt insight and enterprise of the consul C. Nero, who commanded the main army in the south. Having discovered that Hannibal would not advance beyond Apulia until his brother had established communications with him, Nero slipped away with part of his troops and arrived in time to reinforce his colleague Livius, whose force had recently got into touch with Hasdrubal near Sena Gallica (Sinigaglia). The combined Roman army frustrated an attempt of Hasdrubal to elude it and forced him to fight on the banks of the Metaurus (*q.v.*). The battle was evenly contested until Nero by a dexterous flanking movement cut the enemy's retreat. Hasdrubal himself fell and the bulk of his army was destroyed.

The campaign of 207 decided the war in Italy. Though Hannibal still maintained himself for some years in Calabria, this was chiefly due to the exhaustion of Rome after the prodigious strain of past years and the consequent reduction of her armaments. In 203 Italy was finally cleared of Carthaginian troops. Hannibal, in accordance with orders from home, sailed back to Africa, and another expedition under his brother Mago, which had sailed to Liguria in 205 and endeavoured to rouse the slumbering discontent in Cisalpine Gaul and Etruria, was driven back on the coast and withdrawn about the same time.

Campaigns in Sicily and Spain.—Concurrently with the great struggle in Italy the Second Punic War was fought out on several other fields. It will suffice merely to allude to the First Macedonian War (214–205) which King Philip V. commenced when the Roman power seemed to be breaking up after Cannae. The diversions which Roman diplomacy provided for Philip in Greece and the maintenance of a patrol squadron in the Adriatic prevented any effective co-operation on his part with Hannibal.

In view of the complete stagnation of agriculture in Italy the Romans had to look to Sardinia and Sicily for their food supply. Sardinia was attacked by a Carthaginian armament in 215, but a small Roman force sufficed to repel the invasion. In Sicily a more serious conflict broke out. Some isolated attacks by Punic squadrons were easily frustrated by the strong Roman fleet. But in 215 internal complications arose. The death of Hiero II., Rome's steadfast friend, left the kingdom of Syracuse to his inexperienced grandson Hieronymus. Flattered by the promises of Carthaginian emissaries the young prince abruptly broke with the Romans, but before hostilities commenced he was assassinated. The Syracusan people now repudiated the monarchy and resumed their republican constitution, but they were misled by false threats of terrible punishment at the hands of Rome to play into the hands of the Carthaginians. The attacks of a Roman army and fleet under Marcellus which speedily appeared before the town were completely baffled by the mechanical contrivances of the Syracusan mathematician Archimedes (213). Meantime the revolt against Rome spread in the interior, and a Carthaginian fleet established itself in the towns of the south coast. In 212 Marcellus at last broke through the defence of Syracuse and in spite of the arrival of a Carthaginian relief force mastered the town by slow degrees. A guerilla warfare succeeded in which the Carthaginians maintained the upper hand until in 210 they lost their base at Agrigentum. They were dislodged from their remaining positions, and by the end of the year Sicily was wholly under the power of Rome.

The conflict in Spain was second in importance to the Italian war alone. From this country the Carthaginians drew large supplies of troops and money which might serve to reinforce Hannibal; hence it was in the interest of the Romans to challenge their enemy within his Spanish domain. Though the force which Rome at first spared for this war was small in numbers and rested entirely upon its own resources, the generals Publius and Gnaeus Scipio by skilful strategy and diplomacy not only won over the peoples north of the Ebro and defeated the Carthaginian leader Hasdrubal

Barca in his attempts to restore communication with Italy, but carried their arms along the east coast into the heart of the enemy's domain. But eventually their successes were nullified by a rash advance Deserted by their native contingents and cut off by Carthaginian cavalry, among which the Numidian prince Massinissa rendered conspicuous service, the Roman generals were slain and their troops were destroyed in detail (212 or 211).

Disturbances in Africa prevented the Punic commanders from reaping the full fruit of their success. Before long the fall of Capua enabled Rome to transfer troops from Italy to Spain, and in 209 the best Roman general of the day, the young son and namesake of the recently slain P. Scipio, was placed in command. The new leader signalized his arrival by a bold and successful *coup-de-main* upon the great arsenal of Carthago Nova (*see* CARTAGENA). Though he was unable to prevent Hasdrubal Barca from marching away to Italy, Scipio profited by his departure to push back the remaining hostile forces the more rapidly A last effort by the Carthaginians to retrieve their losses with a fresh army was frustrated by a great victory at Ilipa (*q.v.*), near Corduba, and by the end of 206 they were driven out of Spain

The War in Africa.--In 205 Scipio, who had returned to Rome to hold the consulship, proposed to follow up his victories by an attack upon the home territory of Carthage. Though the presence of Hannibal in Italy at first deterred the senate from sanctioning this policy, the general popularity of the scheme overbore all resistance. Scipio was granted a force which he organized and supplemented in Sicily, and in 204 sailed across to Africa. He was here met by a combined levy of Carthage and King Syphax of Numidia, and for a time penned to the shore near Utica But in the winter he extricated himself by a surprise attack upon the enemy's camp, which resulted in the total loss of the allied force by sword or flame. In the campaign of 203 a new Carthaginian force was destroyed by Scipio on the Great Plains not far from Utica, their ally Syphax was captured, and the renegade Massinissa (*q.v.*) reinstated in the kingdom from which Syphax had recently expelled him. These disasters induced the Carthaginians to sue for peace, but before the very moderate terms which Scipio offered could be definitely accepted a sudden reversal of opinion caused them to recall Hannibal's army for a final trial of war, and to break off negotiations. In 202 Hannibal assumed command of a composite force of citizen and mercenary levies stiffened with a corps of his veteran Italian troops. After an abortive conference with Scipio he prepared for a decisive battle at Zama (*q.v.*), an inland site not yet identified with certainty Scipio's force was smaller in numbers, but well trained throughout and greatly superior in cavalry. His infantry, after evading an attack by the Carthaginian elephants, cut through the first two lines of the enemy, but was unable to break the reserve corps of veterans. The battle was ultimately decided by the cavalry of the Romans and their new ally Massinissa, which by a manoeuvre recalling the tactics of Cannae took Hannibal's line in the rear and completely destroyed it. The Carthaginians having thus lost their last army again applied for peace and accepted tht terms which Scipio offered. They were compelled to cede Spain and the Mediterranean islands still in their hands, to surrender their warships, to pay an indemnity of 10,000 talents (about £2,400,000) within 50 years and to forfeit their independence in affairs of war and foreign policy.

The Second Punic War, by far the greatest struggle in which either power engaged, had thus ended in the complete triumph of Rome. This triumph is not to be explained in the main by any faultiness in the Carthaginians' method of attack. The history of the First Punic War, and that of the Second outside of Italy, prove that the Romans were irresistible on neutral or Carthaginian ground Carthage could only hope to win by invading Italy and using the enemy's home resources against him. The failure of Hannibal's brilliant endeavour to realize these conditions was not due to any strategica! mistakes on his part. It was caused by the indomitable strength of will of the Romans, whose character during this period appears at its best, and to the compactness of their Italian confederacy, which no shock of defeat or strain of war could entirely disintegrate. It is this spectacle of individual genius overborne by corporate and persevering effort which lends to the Second Punic War its peculiar interest.

The Third Punic War (149–146 B.C.).—The political power of Carthage henceforth remained quite insignificant, but its commerce and material resources revived in the 2nd century with such rapidity as to excite the jealousy of the growing mercantile population of Rome and the alarm of its more timid statesmen. Under the influence of these feelings the conviction—sedulously fostered by Cato the Elder, the Censor—that "Carthage must be destroyed" overbore the scruples of more clear-sighted statesmen. A *casus belli* was readily found in a formal breach of the treaty, committed by the Carthaginians in 154, when they resisted Massinissa's aggressions by force of arms. A Roman army was despatched to Africa, and although the Carthaginians consented to make reparation by giving hostages and surrendering their arms, they were goaded into revolt by the further stipulation that they must emigrate to some inland site where they would be debarred from commerce. By a desperate effort they created a new war equipment and prepared their city for a siege (149). The Roman attack for two years completely miscarried, until in 147 the command was given to a young officer who had distinguished himself in the early operations of the war—Scipio Aemilianus, the adoptive grandson of the former conqueror of Carthage. Scipio made the blockade stringent by walling off the isthmus on which the town lay and by cutting off its sources of supplies from oversea. His main attack was delivered on the harbour side, where he effected an entrance in the face of a determined and ingenious resistance The struggle did not cease until he had carried house by house the streets that led up to the citadel. Of a population probably exceeding half a million only 50,000 remained at the final surrender. The survivors were sold into slavery; the city was razed to the ground and its site condemned by solemn imprecations to lie desolate for ever. The territory of Carthage, which had recently been much narrowed by Massinissa's encroachments, was converted into a Roman province under the name of "Africa."

BIBLIOGRAPHY.—1. *Ancient Authorities.* For the First Punic War Polybius, bk. 1, provides a trustworthy and impartial account, but owing to his conciseness leaves many problems of chronology and strategy unexplained. For the Second War bks. 2 and 3 of Polybius present a complete and detailed record down to Cannae; bks. 7–15 contain fragmentary notices of which the most continuous deal with the campaigns of Scipio. Livy (bks. 23–30) gives a continuous and detailed narrative, partly based upon Polybius and other good authorities, partly upon untrustworthy Roman annalists. The Third War is described in Appian's *Res Libycae,* chs. 67 *sqq.*, and the fragments of Polybius, bks. 36–39

The subsidiary authorities are. Diodorus, bks. 20–27, 32; Appian, *Res libycae, hispanicae, hannibalicae;* Zonaras' epitome of Dio Cassius, frs. 43, 54, 57; Plutarch's *Lives of Fabius'and Marcellus;* Cornelius Nepos's *Lives of Hamilcar and Hannibal,* and short references in Justin, Eutropius, Aurelius Victor and Orosius. The sources and methods of composition of these authors have been discussed in numerous articles and dissertations, mostly German, of which the most important are mentioned in Niese's work (quoted below). These essays have brought out few certain results, but they tend to show that the narratives, so far as they are not based on Polybius or earlier authorities, are of little value.

2. *Modern Works. a.* For general accounts *see* the respective passages in the general histories of Rome, especially Mommsen (Eng. trans., 1894, vol. ii.), Ihne (Eng. trans., vol ii.) and de Sancti's; also C. Neumann, *Das Zeitalter der punischen Kriegs* (breslau, 1883), and R. B. Smith, *Rome and Carthage* (1881) The battles are methodically evamined in J. Kromager, *Antike Schlachtfelder* (1912 *et seq.),* and in Kromager-Veith, *Schlachten-Atlas zur antiken Kriegsgeschichte* (Leipzig, 1922). *See* also H. PUNISHMENT, the infliction of some kind of pain or loss upon a person for a misdeed, *i.e.,* the transgression of a law or command. See CRIMINAL LAW; CRIMINOLOGY; CAPITAL PUNISHMENT; PRISON, etc.

PUNJAB, province, British India, named from the "five rivers" by which it is watered: the Jhelum, Chenab, Ravi, Beas and Sutlej, all tributaries of the Indus. It is primarily the triangular country of which the Indus and the Sutlej to their confluence form the two sides, the base being the lower Himalaya hills between those two rivers; but the British province now includes a large tract outside those boundaries. On the other hand certain areas once included in the administrative province are now excluded, the Frontier Province having been cut off in 1902 and the Delhi Enclave in 1912.

The Punjab includes two classes of territory, that belonging to the British Crown, and that in possession of 34 feudatory chiefs, Of the latter the 13 more important have direct relations with the Government of India, the rest being under the Punjab Government. The total area of the province is 136,261 sq.m., of which 99,200 sq m. are British territory and the remainder belongs to the native states. The British territory is divided into 29 districts, grouped under the five divisions of Amballa, Lahore, Jullundur, Rawalpindi and Multan; while the states vary in size from Bahawalpur, with an area of 15,003 sq.m., to the tiny state of Darkoti, with an area of 8 sq.m. and a total population of 531 souls.

Physical Features. — The mountain regions of the Punjab fall under four separate groups. To the north-east of the province lies the Himalayan system, with the fringing range of the Siwaliks at its foot. In the south-eastern corner the Aravalli system sends out insignificant outliers, which run across Gurgaon and Delhi districts and strike the Jumna at Delhi. The lower portion of the western frontier is constituted by the great Suliman chain; while the north-western districts of the province are traversed by the hill system known as the Salt range.

The "five rivers" of the Punjab are each of large volume; but, on account of the great width of sandy channel in their passage through the plains, their changing courses, and shifting shoals, they are of no value for steam navigation, though they all support a considerable boat-traffic. Of recent years they have been utilized for purposes of irrigation, and have turned the sandy desert of the Punjab into a great wheat-growing area.

South of the Himalayas stretch the great alluvial plains. From the Jumna on the east to the Sulimans in the west, one vast level, unbroken save by the wide eroded channels within which the great rivers ever shift their beds, by the insignificant spurs of the Aravalli range in the south-eastern corner, and the low hills of Chiniot and Kirana in Jhang.

Geology. — By far the greater part of the Punjab is covered by alluvial and wind-blown deposits of the plain of the Indus. The Salt range hills form a plateau with a steeply scarped face to the south, along which there is an axis of abrupt folding, accompanied by faulting. The rocks found in the Salt range belong to the Cambrian, Carboniferous, Permian, Triassic and Jurassic systems, while Tertiary beds cover the plateau behind. The extensive and valuable deposits of salt, from which the range takes its name, occur near the base of the Cambrian beds. Gypsum, kieserite and other salts are also found. Between the Cambrian and the Carboniferous beds there is an unconformity, which, however, is not very strongly marked, in spite of the lapse of time which it indicates. At the bottom of the Carboniferous series there is usually a boulder bed, the boulders in which have been brought from a distance and are scratched and striated as if by ice. It is generally admitted that this deposit, together with contemporaneous boulder beds in tbe peninsula of India, in Australia and in South Africa, indicate a southern glacial period in late Carboniferous times. Above the sandstone series at the base of which the boulder bed lies, come the Productus and Ceratite limestones. The former is believed to belong to the Upper Carboniferous and Permian, the latter to the Trias. Jurassic beds are found only in the western portion of the range.

Climate. — Owing to its sub-tropical position, scanty rainfall and cloudless skies, and the wide expanse of untilled plains, the climate of the Punjab presents greater extremes of both heat and cold than any other part of India. From the middle of April to the middle of September it is extremely hot, while from the beginning of October to the end of March there is a magnificent cool season, resembling that of the Riviera, with warm bright days and cool nights. Frosts are frequent in January. In the first three months of the hot season, from April till the end of June, a dry heat is experienced, with a temperature rising to 120° F in the shade. At the end of June the monsoon arrives, the rains break in the East of the Province, and though the heat is less intense the air is moist, and from the middle of August the temperature gradually falls. This is the most unhealthy period of the year, being exceedingly malarious. The Punjab enjoys two well-marked seasons of rainfall; the monsoon period, lasting from the middle of June till the end of September, on which the autumn crops and spring sowings depend; and the winter rains, which fall early in January, and though often insignificant in amount materially affect the prosperity of the spring harvest. Excepting in the Himalayas the rainfall is greatest in the east of the province, as the Bombay monsoon is exhausted in its passage over the great plains of Sind and Rajputana, while the west winds from Baluchistan pass over an arid tract and leave such moisture as they may have collected on the western slopes of the Suliman range; so that the Punjab depends for its rain very largely on the south-east winds from the Bay of Bengal. The submontane tract has an annual average of 36 to 32 in., the eastern plains vary from 20 to 14 in., and the western plains from 10 to 5 in.

Minerals.—Besides rock-salt, the mineral products of the Punjab are not many. Limestone, good for building, is obtained at Chiniot on the Chenab and at a few other places. There are extensive alum-beds at Kalabagh on the Indus. A small quantity of coal is found in the Salt range in disconnected beds, the Dandot colliery in the Jhelum district being worked by the North-Western railway. Petroleum is found in small quantities at a number of places in Rawalpindi, and there is an oil company extracting oil by modern methods. In almost all parts of the Punjab there is kankar, rough nodular limestone, commonly found in thick beds, a few feet below the surface of the ground, used for road metal and burned for lime.

Agriculture. — As in other parts of India, there are commonly two harvests in the year. The spring crops are wheat, barley, gram, various vegetables, oil-seeds and tobacco; the autumn crops are rice, millets, maize, pulses, cotton, indigo and sugar-cane. Wheat has become the most important export of the province. In the spring of 1938 an area of 11½ million acres was harvested, producing 4½ million tons. Tea is cultivated in Kangra district. Potatoes are grown extensively on cleared areas on the hills. The Punjab produces freely many of the Indian fruits. Grapes are grown in many of the Himalayan valleys where the rain is not excessive; but they are inferior to those brought from Kabul.

Forests. — The forest area of the Punjab consists of 6,251 sq.m., of which 1,682 sq.m. are preserved and 3,270 sq.m. protected. The principal reserved forests are the deodar (*Cedrus* Deodara) and chil (*Pinus longifolia*) tracts in the hills, the plantations of shisham (*Dalbergia* Sissu) and sal (*Shorea robusta*) in the plains, and the fuel rakhs or preserves (Acacia, Prosopis, etc.).

Manufactures and Trade. — Most of the native manufactures of the Punjab are those common to most other parts of India. Among other manufactures, not so general, yet not peculiar to the Punjab, are woollen fabrics, carpets and shawls, silk cloths and embroidery, jewellery, ornamental metal-work, wood and ivory carving, turned and lacquered woodwork, glazed pottery, arms and armour and musical instruments. But some of these classes of manufacture are represented by work of special kinds or special excellence in particular parts of the Punjab, notably the silk fabrics of Multan and Bahawalpur; the carpets of Lahore and Amritsar; the *kashi* or glazed tilework (an ancient art still practised in a few places); koft-kari, inlaid metal-work (gold wire on steel), chiefly made at Gujrat and Sialkot; shawls and other fine woollen fabrics, made by Kashmiri work-people at Ludhiana and Nurpur, as well as in Kashmir; silk embroidery for shawls, scarfs and turbans, at Delhi, Lahore and Multan; embroidery on cloth for elephant-trappings, bed and table covers, etc., at Lahore and Multan; enamelled ornaments, in Kangra and Multan; quill embroidery on leather, in Kangra and Simla; lacquered woodwork, at Pak Pattan. Cotton-weaving gives employment to about a million persons, but the most flourishing industry is the woollen factories of Amritsar, Gurdaspur and elsewhere.

Trade.—The trade of the Punjab is almost wholly dependent upon agriculture. In a normal year the principal feature of the trade is the movement of wheat to Karachi, which is the chief port for the province. But in a bad season, when the rains fail, this movement is at once checked, the wheat is held up in reserve and an eastward movement in cheaper grains begins. The other chief articles of export are pulse and raw cotton. The Punjab has a trans-frontier trade with Kashmir, Ladakh, Yarkand and Tibet on the north, and with Afghanistan on the west.

Irrigation and Railways.—Irrigation for large areas is from canals and from reservoirs, and for smaller areas from wells. The canals are of two kinds: those carrying a permanent stream throughout the year, and those which fill only on the periodical rising of the rivers, the latter being known as "inundation canals." There are only a few parts of the country presenting facilities for forming reservoirs, by closing the narrow outlets of small valleys and storing the accumulated rainfall. The present canal system is probably the finest in the world. The old canals made by the Mohammedan rulers, of which the principal are Feroz's Canal from the Jumna and the Hasli Canal from the Ravi, have been improved or reconstructed by the British government and are now represented by the Western Jumna and Bari Doab Canal. They were followed by the Sirhind Canal (1883) and by the two great Colony Canals, the Lower Chenab and Lower Jhelum (1892–1901). Then succeeded the so-called Triple Canal Scheme (1912–15) comprising the Upper Jhelum, Upper Chenab and Lower Bari Doab Canals. And these again were followed by the Sutlej Valley Canals completed in 1933. The canals irrigated 12½ million acres in 1936–37 and produced a net return of some £3½ million, representing about 14½% on capital.

Railways.—The Punjab is well supplied with railways, and Lahore, the headquarters of the North-Western Railway system has a very large railway population. One main line of the North-Western runs from Umballa through Lahore and Rawalpindi towards Peshawar; another main line runs from Lahore to Multan, and thence to the sea at Karachi; while a third runs along the left bank of the Indus, from Attock southwards. From Delhi to Umballa there are two lines, one of the North-Western through Meerut and Saharanpur in the United Provinces, and a more direct one, which is continued to Kalka and Simla. The south-east of the province is served by three branches of the Rajputana system, which have their termini at Delhi Hissar and Ferozepore; and also by the Southern Punjab, from Delhi to Bahawalpur.

Population and Administration.—The total population of the Punjab (including states) according to the census of 1931 was 28,490,857. The Jats, who number some six millions, form the backbone of the cultivating community. Large numbers of them have become Sikhs or Mohammedans in the tracts where those religions predominate. The Rajputs, with a total of two million and three-quarters, comprise tribes of different religions, races and social systems. By religion they are mostly Mohammedan, only about one million being Hindus and half a million Sikhs. The Gujars are an important agricultural and pastoral tribe. Baluchis and Pathans are strongly represented in the south-west and nest. The distinctive religion of the Punjab is Sikhism (*q.v.*), though Sikhs form only 14·3% of the total population. The Mohammedans represent 52% of the population. The people bear a martial character and entered with enthusiasm into the War of 1914–18. Nearly half a million of men were mobilized and the Punjab supplied more than 40% of the combatants from India.

Language.—Of the 28,490,857 people in the Punjab about 21,893,342 speak the provincial language, Punjabi, which varies in character in different parts of the province. About 3,988,000 speak Hindustani (see HINDOSTANI), this number including those whose ordinary vernacular is Hindi, but who understand and are gradually adopting the more comprehensive Hindustani. These two languages are the most generally used throughout the province, but not equally in all parts. The other languages in use are more or less local. The hill dialects, known as Pahari, are akin to the language spoken in Rajputana. Hindustani is the language of the law courts and of all ordinary official and other communications with chiefs and people.

Administration.—The administration is conducted by a Governor, a premier and five ministers of developments. Two Financial Commissioners take the place of the board of revenue in most of the provinces and each of the five Divisions is under a Commissioner. A survival of the "non-regulation" system is to be found in the title of deputy-commissioner for the district officer elsewhere called collector. The highest judicial authority is the high court, consisting of a Chief Justice and ten puisne judges. A legislative council, first created in 1897, was enlarged in 1909 to 26 members, and in 1921 to 94. Under the reform scheme of 1935 a legislation assembly was constituted with 175 members.

Education.—The Punjab University, which was founded in 1882 serves the Kashmir State and the Frontier Province as well as the Punjab. In the Province there were in 1938 34 arts colleges and 10 professional colleges, 397 high schools, 3,336 middle schools and 7,730 primary schools. The number of enrolled pupils, which in 1921 was 556,989 had risen in 1938 to 1,302,461. (E. D. MACL.)

HISTORY

Proofs of a remarkable prehistoric culture (about 2500 B.C) have been found at Harappa; seals unearthed there, almost identical with Sumerian seals discovered in Babylonia, suggest an art connection between Babylonia and India at that time, but racial affinity cannot be deduced. For early history to the fall of the Mogul dynasty see INDIA: History. From the time of Alexander onwards Greek settlers remained in the Punjab and Greek artists gave their services for Buddhist work, introducing new features into Indian architecture. The most conspicuous and distinctive Buddhist buildings are the topes (stupa), plain hemispheres on platforms of two or more stages. One of the largest is at Manikiala, 14 m. east of Rawalpindi. These buildings and sculptures date probably from zoo B.C. to A.D. 400.

The early colonists formed clans (not identical with castes, but often joining them), which generally preserved distinct characteristics and followed certain classes of occupation. Some existing Punjab tribes are traced to these settlers, as the Bhattis of Bhattiana south of the Sutlej, who have also in the village of Pindi Bhattian a record of early occupation of the left bank of the Chenab. The Dogras, another Aryan clan, belong to the lower hills between the Chenab and the Ravi. So with others. To the earlier settlers—the dark race (Dasyu, commonly called aborigines), whom the Aryans found in the country, may have belonged the old Takka tribe, whose name is found in Takshasila or Taxila. From the later foreigners, the Indo-Scythians, are probably descended the Jat cultivators, the Gujars and others.

During the events which brought Babar to the throne, the sect of the Sikhs was founded by Nanak (born 1469) and under the persecution of Aurangzeb they were raised into a nation of warriors by Govind Singh (1675–1708), the tenth and last Guru. (See SIKHISM.) Upon the break-up of the Mogul Empire in the 18th century the Sikhs formed confederacies on both banks of the Sutlej. After long internecine warfare one of their chieftains secured a position of authority over the rest. This was Ranjit Singh, born in 1780, who acquired Lahore as his capital in 1799. When he tried to include within his jurisdiction Sirhind and Malva, the Sikh States south of the Sutlej, their chiefs sought British protection. The British desired an alliance with Lahore as well as Kabul against supposed French designs on

India. A British envoy, Charles Metcalfe, was received by Ranjit at Kasur in 1809 and the alliance was formed.

In 1809 Ranjit secured Kangra which the Nepalese were besieging, and in 1813 the fort of Attock on the other side of the Punjab; in that year he obtained from Shah Shuja, then a refugee in Lahore, the celebrated Koh-i-Nur diamond carried off by Nadir Shah from Delhi. In 1818 he captured Multan; Kashmir and the southern part of the country between the Indus and the hills were annexed in the following year. He added the Peshawar valley four years later, but placed an Afghan governor in charge. These trans-Indus and other outlying tracts were left very much to themselves and received a military visit only when revenue was wanted. Peshawar was never really ruled till Avitabile went there in later years. While Ranjit was raising his powerful army, French and other foreign officers drilled his troops and improved his artillery. He relied on them for military and sometimes administrative services, but he drew round him able Indian ministers of whom the brothers Gulab Singh and Dhian Singh of Jammu were the most influential. He always remained friendly with the British and before his death gave tacit approval to the scheme for placing Shah Shuja on the throne of Kabul.

Wars Against British, **1845–49.**—Ranjit's death in 1839 was followed by six years of anarchy, princes and ministers being murdered in quick succession, while all real power passed to the army of 120,000 trained troops who, unpaid and discontented, demanded to be led into British territory. They crossed the Sutlej in Dec. 1845. The battles of Mudki, Firozshah and Aliwal were followed by the rout of the Sikh army at Sobraon, Feb. 10, 1846; the British advanced to Lahore and a treaty was made on March 9 with the chiefs and ministers who were to hold the government on behalf of the young maharaja, Dalip Singh (b. 1837, d. 1893). The Jullunder Doab, Kangra and the maharaja's possessions on the left bank of the Sutlej were ceded to the British. In addition a payment of £1,500,000 was agreed upon. Gulab Singh, raja of Jammu, for his services to the Lahore state in restoring friendly relations was granted independent sovereignty in such lands as might be made over to him. The Sikh government ceded, as equivalent for two-thirds of the stipulated amount, the hill country between the Beas and the Indus, including Kashmir and Hazara. Gulab Singh received Kashmir, March 1846, in return for a sum of money. At the durbar's request a British force was left at Lahore to protect the maharaja and preserve peace. A British resident was appointed to guide the council of regency, and assistants were stationed in different places. Peace was soon broken. The governor of Multan, Diwan Mulraj, resigned. Two British officers, sent to take charge of the fort, were murdered, April 19, 1848, and their escort went over to the diwan. One of the assistants to the resident, Lt. Herbert Edwardes, then in the Derajat, west of the Indus, collected a force and attacked the Multan army with signal success, but had not sufficient troops to take the city. Sikh and British forces again took the field and Multan fell.

Annexation to British India.—The severe battle of Chilianwalla, Jan. 13, 1849, left the Sikhs as persistent as ever, and the war ended only after the defeat of Gujrat, Feb. 21, 1849. The Punjab was annexed on April 2, 1849.

To govern the new province, including the Jullunder Doab, previously annexed, and the cis-Sutlej states, an administration board was appointed, consisting of three members, replaced in 1853 by a chief commissioner aided by a judicial commissioner and a financial commissioner. British troops, European and Indian, were stationed in the chief cities, including Peshawar, and other places. For the rest of the trans-Indus territory a special body of Indian troops, called the Punjab frontier force, was raised. During the Mutiny of 1857 Sir John Lawrence as chief commissioner sent important aid to the force besieging Delhi and dealt with disturbances in the Punjab itself. In 1858 the Delhi territory, as it was called, west of the Jumna, was transferred to the Punjab, and on Jan. 1, 1859 the chief commissioner became lieutenant-governor. In 1901 the districts beyond the Indus were made into a separate province called the North-West Frontier Province and in Oct. 1912 Delhi, the new capital, with the country round it became a separate district under a chief commissioner.

The races of the Punjab are full of vigour and virility in both war and religion. They show this sometimes by striking loyalty and sometimes by an inclination to turbulence. Thus the Punjab is the birthplace or stronghold of religious bodies like the Sikhs, the Arya Samaj, the Ahmadiyyas and others. During the Great War, 1914–8, it made a splendid response to the call of the Empire, yet there were sporadic internal troubles in 1915, grave disorders in 1919 and excitement among the Sikhs from 1922 to 1924 in connection with the Akalis. However the feeling of toleration and mutual assistance increased and in 1928 the Simon Commission received a general, though quiet, welcome. In 1920 the province was raised in rank and the Lieutenant-governor was given the title of Governor. (T. G. Ba.)

PUNKTMENGEN: *see* Aggregates, Theory of.

PUNO, a south-eastern department of Peru. It includes the shores of Lake Titicaca, the high plateau on which the lake is situated, together with the mountains west, north and east enclosing the plateau. It also includes the headwaters of several tributaries of the Madre de Dios river east of the eastern cordillera and draining into the Amazon, but the greater part of the northern provinces were taken in 1912 to form part of the new department of Madre de Dios (*q.v.*). Puno has an area of 26,133 sq.mi.; population (1940) 646,385. Connection is by the Southern railway with Cusco, 200 mi. to the north, also with the Pacific port of Mollendo and by steamer (across Lake Titicaca) and railway to La Paz, Bolivia. A projected section of the Pan American highuay will eventually traverse the department.

Around the shores of the lake (12,466 ft. above sea-level) the plateau is cultivated and well settled, but the altitude is so great that only potatoes, barley and a few other cereals will mature. The department of Puno produces about 70% of all the gold of Peru. It comes chiefly from the mountain provinces of Sandia and Carabaya. Coal, salt, copper, antimony, tin, quicksilver, zinc, marble and cobalt are also found. The manufacturing of woollen goods is important and in the Province of Lampa there is a considerable manufacture of pottery.

Puno, the town, capital of the department of Puno and also of the Province of Puno, is located on the shore of Lake Titicaca. Pop. (1940) 15,999. It is the lake terminus of the railway.

PUNTARENAS or **PUNTA ARENAS,** a seaport and capital of the province of Puntarenas, Costa Rica; on the Gull of Nicoya, an inlet of the Pacific ocean, and at the western terminus of the interoceanic railway from Limón. Pop. (1940) town. 7,722; province, 41,517. Puntarenas is the principal harbour of Costa Rica on the Pacific, and a port of call for the United States liners which ply between San Francisco and Panamá. It has a growing export trade in coffee and bananas. The district of Puntarenas comprises the entire littoral from Burica point to the Rio de las Lajas, an effluent of the Gulf of Nicoya.

PUNXSUTAWNEY, a borough of Jefferson county, Pennsylvania, U.S.A., 70 mi. N.E. of Pittsburgh; served by the Buffalo, Rochester and Pittsburgh and the Pennsylvania railways. Pop. (1930), 9,266; 1940 it was 9,482. The bank clearance for 1940 was $39,000,000. It is a trading centre for agriculture, surrounded by coal operations and gas fields. Punxsutawney was founded about 1812 and incorporated in 1845.

PUPIN, MICHAEL IDVORSKY (1858–1935), American inventor, aas born in Idvor, Hungary (now in Jugoslavia), Oct. 4. 1858. He went to America, 1874, graduating from Columbia university, 1883. The first to hold the John Tyndall fellowship (1886–88), he later studied physics and mathematics at Cambridge university and under Von Helmholtz at the University of Berlin (Ph.D., 1889). He was instructor in mathematical physics at Columbia, 1890; and was appointed adjunct professor of mechanics, 1892, becoming professor of electro-mechanics there in 1901 and later director of the Phoenix research laboratories.

By means of inductance coils placed at predetermined intervals of the transmitting wire, he greatly extended the range of long-distance telephony, particularly over telephone cables. The patent for this invention was acquired in 1901 by the Bell Telephone company and by German telephone interests. He has made several other inventions in electrical wave propagation, electrical resonance and multiplex telegraphy. He discovered secondary X-ray radiation in 1896 and invented in the same year means for short exposure X-ray photography by the interposition of a fluorescent screen. He was active during the World War aiding Serbia and the United States. He wrote *From Immigrant to Inventor.*

PUPPIS, one of the three southern constellations into which the large Ptolemaic constellation Argo (*q.v.*) was subdivided (*puppis:* poop).

PUQUINAN, a group of tribes of South American Indians, doubtfully constituting an independent linguistic stock. Their identity with the modern Uros (*q.v.*) has been much discussed. The area occupied (if this identity be accepted) would include the whole basin of lakes Titicaca and Poopo, and the Salar de Uyuni in the Bolivian plateau, together with the Peruvian-Chilean coast from about 16° to 22° S. lat. Within this area they lived in scattered small groups, amongst the Aymaran (*q.v.*) tribes. Rivet thinks that the Puquinan language (together with the Uro) is in reality a member of the Arawakan (*q.v.*) stock, and that this whole group of Puquinan and Uran tribes represent a very ancient intrusion westward of the Arawakan peoples.

See G. de Crequi-Montfort and P. Rivet, "La Langue Uru ou Puquina" (*J. Soc. Américanistes de Paris* [n.s.] vol. xvii., 211–244; vol. xviii., 111–139, with bibliography).

PURCELL, HENRY (1659–1695), English composer, was born in Westminster. His recent biographer, Dennis Arundell, points out that the statement *aet. suae. 24* on the printed edition of his *Sonatas* in June 1683 places his birth between June and November 1659, Nov. 20, 1695 being the date of his death in his thirty-seventh year. His father Henry Purcell, or Pursell, was a gentleman of the Chapel Royal, whose eldest son Edward (1653–1717) became gentleman usher to Charles II., and afterwards distinguished himself in the army, while Henry and Daniel, the two younger sons, became musicians. On his father's death in 1664, Henry Purcell was placed under the guardianship of his uncle Thomas Purcell (d. 1682), also a gentleman of the Chapel and a man of extraordinary probity and kindness. Both he and Henry Purcell the elder sang at the coronation of Charles II. Through his uncle's interest Purcell was admitted as a chorister of the Chapel and was placed under Captain Henry Cooke (d. 1672), "master of the children," an excellent teacher and a composer of anthems, to whom Pepys makes a number of references in his *Diary.* On Cooke's death Pelham Humfrey (1647–1674) became "master," and he again mas an excellent teacher as well as a musician of genius; but as a pupil of Lully he naturally stood for the French school, and in this respect failed to influence Purcell, who took the Italian masters for his models.

Purcell's third and last master was the distinguished composer and organist Dr. John Blow (1648–1708), to whom Purcell's great indebtedness is not always sufficiently realized. In 1673, when his voice broke, Purcell was dismissed with an ex-chorister's salary of £30 a year and presented with certain articles of dress. He was also given the appointment of (unpaid) assistant to John Kingston, keeper of the king's instruments, together with a promise to succeed him. In 1677 he was appointed "composer in ordinary for the violin" in succession to Matthew Lock. Purcell had been copyist at Westminster abbey since 1677, and in 1680 he succeeded Dr. Blow as organist.

The year 1680 was the beginning of a period of great productivity. In it he wrote the music to Lee's *Theodosius,* the first of a long series of dramas for which he provided incidental music, and one in which an introductory ritual scene gave him unusual scope; this was followed by D'Urfey's *Virtuous Wife.* He also produced the first of his court odes or "Welcome Songs" at this date and wrote several anthems. many of which were composed especially for the prodigious basso profondo of the Rev. John Gostling (or Gosling), a singer at Canterbury and later at the Chapel Royal, to whom Evelyn alludes as "that stupendous bass." Either in 1680 or the following year he married Frances Peters, and in 1682 his eldest son was born. From 1682 he held the post of organist to the Chapel conjointly with his appointment at the Abbey. His first printed composition was the 12 *Sonnatas of III. Parts: two violins and basse: to the organ or harpsichord.* These, though avowedly based on Italian models, show great power and originality. Purcell had now become "composer in ordinary to the king" and his official life was a very full one. For each public event he composed an ode or an anthem: some of the finest of these are the ode, "Swifter, Isis, swifter flow" (1681); the "St. Cecilia" odes; the "Fly, bold Rebellion" (in celebration of the suppression of the Rye House Plot, 1683); two anthems written for James II.'s coronation: "O I was glad" and "My heart is inditing." The *Te Deum* and *Jubilate,* written for St. Cecilia's Day 1694, was notable as being the first English anthem with orchestral accompaniment. It was performed annually at St. Paul's cathedral until 1712 and in alternate years with Handel's Utrecht *Te Deum* until 1743. In all his anthems there is a large proportion of instrumental music.

The opera *Dido and Aeneas,* which above all Purcell's works inspires admiration and affection in an equal degree, was written to a libretto furnished by Nahum Tate at the request of Josiah Priest, a dancing-master who also kept a boarding-school for young gentlewomen, first in Leicester Fields and afterwards at Chelsea. The date of its composition and original performance at the school has been fixed by W. Barclay Squire of the British Museum as about the year 1689. In this work there is no spoken dialogue, but only recitative, and it is characterized from beginning to end by the dramatic directness which Purcell possessed in so high a degree. Dido's exquisite song of farewell is one of the flawless things in music, classical in form and in its dignified restraint, and yet of rare emotional quality. As is so often the case when he has some poignant emotion to express, Purcell chooses here to build up the song on a "ground," and the relentless reiteration of the bass contributes greatly to the dramatic effect. Graceful dance choruses, lumbering sailor dances and witches' incantations relieve the tragedy, and, avoiding an anti-climax after Dido's farewell, the composer ends with a soft and tenderly expressive chorus, "With drooping wings, ye Cupids, come," in which music and words achieve perfect union.

Although *Dido and Aeneas* stands out to-day as an isolated phenomenon in the age in which it is written, it was rather the peak of a movement in which Purcell's predecessors did valuable experimental work; and here, again, Dr. Blow's influence is seen, for in his only known dramatic work, *Venus and Adonis,* he sets the example of having every word sung and none spoken. He is no doubt also partly responsible for Purcell's skill in the use of a ground, and he probably encouraged, rather than discouraged, his pupil's audacities of harmony, since he himself was a notorious offender. Among the peculiarities of Purcell's idiom are the constant false relations and the use of the descending melodic minor in ascending passages, and vice versa. He had a marked preference for the flat minor keys. His fine feeling for rhythm, form and climax invests even his smaller pieces with a quality that is unmistakable. In judging Purcell's scores it should be remembered that he was practically restricted to oboes and trumpets as regards wind instruments, since even the modern flute had not come into use in his time.

In 1690 Purcell wrote the music to Betterton's *Dioclesian,* which includes a masque. He was associated with Dryden in *Tyrannic Love* (1687), *Amphitryon* (1690) and *King Arthur* (1691), in all of which the music consists of separate numbers which form no integral part of the drama. In *King Arthur,* Josiah Priest was responsible for the dances. This play, which contains the famous song, "Fairest Isle," had a great success and was revived on various occasions up to 1803, and once in 1842. It was first published in 1843 by the Musical Antiquarian Society. The score of Purcell's songs and music to *The Fairy Queen* (an adaptation of Shakespeare's *The Tempest)* written in 1693, was discovered in 1901 and edited for the Purcell Society by J. S. Shedlock in 1903.

Purcell suffered much at the hands of his editors until, in 1876, the Purcell Society was founded for the purpose of bringing out a complete and authoritative edition of his works, the majority of which were still in manuscript. There are signs of the beginning of a great Purcell revival, not only in England, but also on the Continent, where recent performances of *Dido and Aeneas* in Vienna, Miinster and Basle aroused enthusiasm and interest.

Purcell died at his house in Dean's Yard, Westminster, on Nov. 21, 1695, and was buried in Westminster abbey on Nov. 26. He left a widow and three children, three others having died before him. His widow died in 1706. In 1682 and 1702 she published *Orpheus Britannicus,* a collection of his works, in two parts. A famous portrait of the composer is that by Kneller, bequeathed to the National Portrait Gallery, London, by Barclay Squire. There is also an engraved portrait by R. 'White on the first edition of his Sonatas (1683).

Other dramatic works by Purcell were *Don Quixote, The Indian Queen,* and *Bon duca* (all in 1695), and many earlier works. Smaller works are the Fantasias and Sonatas for three or more parts, the Suites and many miscellaneous pieces for harpsichord, and songs. For a complete list, *see* Grove's *Dictionary* and the publications of the Purcell Society, now nearly complete. Recent publications include the *Chacony* for string quartet (Chester Ltd. 1926) ; *Dido and Aeneas* with Eng. and German text, ed. by E. J. Dent; and Dennis Arundell's life, *Henry Purcell* (both by the Oxford University Press, 1928) ; Henri Dupré, *Purcell* (Eng. trans., Knopf, New York and London, 1929) ; the life by Dr. W. Cummings in the *Great Musicians* series (1903) remains a standard work.

PURCHAS, SAMUEL (1575?–1626), English compiler of works on travel and discovery, was born at Thaxted, Essex, and studied at St. John's college, Cambridge, and at Oxford. In 1604 he was presented by James I. to the vicarage of Eastwood, Essex, and in 1614 became chaplain to Archbishop Abbot and rector of St. Martin's, Ludgate, London. Purchas died in Sept. or Oct. 1626, according to some in a debtors' prison. As an editor and compiler he was often injudicious, careless and even unfaithful; but his collections are often the only sources of information upon questions affecting the history of exploration. His works include: *Purchas, his Pilgrimage; or, Relations of the World and the Religions observed in all Ages* (1616); *Purchas, his Pilgrim. Microcosmus, or the histories of Man. Relating the wonders of his Generation, vanities in his Degeneration, Necessity of his Regeneration* (1619); *Hakluytus Posthumus or Purchas his Pilgrimes, contayning a History of the World in Sea Voyages and Lande Travells, by Englishmen and others (4* vols., 1625).

PURCHASE, in its common sense, that which is acquired by the payment of money or its equivalent. The term was early used by the lawyers (*e.g.,* Britton, in 1292) for the acquirement of property by means other than inheritance or mere act of law, including acquirement by escheat, prescription, occupancy, alienation and forfeiture; more generally, purchase in law means acquisition of land by bargain or sale, according to the law of "vendor and purchaser." *(See* CONVEYANCING.) A later meaning is the mechanical contrivance by which power can be used, a hold or fulcrum. This first appears (16th century) in the nautical use of the verb, to haul up a rope or cable, that is, to "gain" advantage over the rope bit by bit.

PURDAH, the curtain which screens women from the sight of men in Eastern countries; a *purdah-nashin* is a woman who sits behind the curtain (Pers. *parda).* In Anglo-Indian usage, to "lift the purdah" means to reveal a secret.

PURE LINE. A pure line consists of a self-fertilized individual and its progeny; it is a group of individuals all possessing the same hereditary constitution, in which all the factors are present in duplicate. Until Johannsen studied the effects of selection on the weights of individual seeds of the Princess bean there was no general explanation of the manner in which this process operates *(see* BREEDS AND BREEDING; INBREEDING; ANIMAL BREEDING; GENETICS ; HEREDITY ; MENDELISM and SELECTION, *Artificial Selection).*

See W. Johannsen, *Ueber Erblichkeit in Populationen und in reinen Linien* (1903).

PURGATORY, according to Roman Catholic faith, a state of suffering after death in which the souls of those who die in venial sin, and of those who still owe some debt of temporal punishment for mortal sin, are rendered fit to enter heaven. It is believed that such souls continue to be members of the Church of Christ; that they are helped by the suffrages of the living — that is, by prayers, alms and other good works, and more especially by the sacrifice of the Mass; and that, although delayed until "the last farthing is paid," their salvation is assured. Catholics support this doctrine chiefly by reference to the Jewish belief in the efficacy of prayer for the dead (2 Macc. xii. 42 *seq.),* the tradition of the early Christians, and the authority of the Church.

The state of Purgatory is usually thought of as having some position in space, and as being distinct from heaven and hell; but any theory as to its exact latitude and longitude, such as underlies Dante's description, must be regarded as imaginative. Most theologians since Thomas Aquinas and Bonaventura have taught that the souls in purgatory are tormented by material fire, but the Greeks have never accepted this opinion. It must be inferred from the whole practice of indulgences as at present authorized that the pains of purgatory are measurable by years and days; but here also everything is indefinite. The Council of Trent, while it commands all bishops to teach "the sound doctrine of purgatory handed down by the venerable fathers and sacred councils," bids them exclude from popular addresses all the "more difficult and subtle questions relating to the subject which do not tend to edification."

The Eastern Church affirms belief in an intermediate state after death, but the belief is otherwise as vague as the expressions of the pre-Nicene fathers on the subject. The Longer Catechism of the Orthodox Church (Q. 376) states: —

"Such souls as have departed with faith but without having had time to bring forth fruits meet for repentance may be aided towards the attainment of a blessed resurrection by prayers offered in their behalf, especially such as are offered in union with the oblation of the bloodless sacrifice of the Body and Blood of Christ, and by works of mercy done in faith for their memory."

The efficacy of prayers for the dead, and indirectly the doctrine of purgatory, were denied by early Gnostic sects, by Aëtius in the 4th century, and by the Waldenses, Cathari, Albigenses and Lollards in the middle ages. Protestants, with the exception of a small minority in the Anglican communion, unanimously reject the doctrine of purgatory, and affirm that "the souls of believers are at their death made perfect in holiness and do immediately pass into glory." Rejection of an intermediate state after death follows the Protestant idea of justification by faith as logically as the doctrine of purgatory results from the Catholic idea of justification by works.

An analogy to purgatory can be traced in most religions. Zoroaster conducts souls through twelve stages before they are sufficiently purified to enter heaven; and the Stoics conceived of a middle place of enlightenment which they called ἐμπύρωσις.

BIBLIOGRAPHY.—The principal authoritative statements of the Catholic Church on the doctrine of purgatory were made at the Council of Florence *(Decret. unionis),* and at that of Trent (Sess. vi. can. 30; Sess. xxii., c. a, can. 3; Sess. xxv.). *See* H. J. D. Denziger's *Enchiridion;* J. Bautz, *Das Fegfeuer* (Mainz, 1883) ; and L. Redner, *Das Fegfeuer* (Regensburg, 1856). A very elaborate treatise from the Catholic standpoint is that of Cardinal Bellarmine, *De purgatorio.* The subject is discussed, moreover, in all major works on dogmatic theology. There is a representative Catholic statement in the *Catholic Encyclopaedia,* and *a* Protestant presentation by Rud. Hoffmann in Herzog-Hauck's *Realencyklopädie,* 3rd ed. vol. v. pp. 788–792.

PURI or **JAGANNATH,** a town and district of British India, in the Orissa division of Bihar and Orissa. The town is on the seacoast, and has a railway station. Pop. (1931) 37,568. As containing the world-famous shrine of Jagannath *(see* JUGGERNAUT), Puri is perhaps the most frequented of all Hindu places of pilgrimage; of recent years also it has won some popularity as a seaside health resort. The great temple of Jagannath was built in the 12th century by Choda Ganga, the greatest of the Eastern Ganga kings of Kalinganagara (Ganjam).

The DISTRICT OF PURI has an area of 2,492 sq.m. and a population (1931) of 1,035,154. Most of the country is flat. The middle and eastern divisions of the district, forming the southwestern part of the Mahanadi delta, consist entirely of alluvial plains, watered by a network of channels through which the most southerly branch of that river, the Koyakhai, finds its way into the sea. The other rivers are the Bhargavi, the Daya and the Nun, all of which flow into the Chilka lake. During the rainy season the rivers come down in floods, sometimes bursting their banks and carrying everything before them. The Chilka lake is one of the largest in India; its length is 44 m., and its mean breadth 13 m. in the north and 5 m. in the south. It is separated from the sea only by a narrow strip of sand. The lake is saline and everywhere very shallow, its mean depth ranging from 3 to 5 feet.

Puri first came under the British in 1803. Later events were the rebellion of the maharaja of Khurda in 1804 and the rising of the paiks or peasant militia in 1817–18. In the Orissa famine of 1866 more than one-third of the population is said to have perished. The district is served by the Bengal Nagpur railway which was opened throughout from Calcutta to Madras in 1891, with a branch to Puri town.

Puri district is rich in historical remains, from rock-hewn caves to the magnificent mediaeval shrines at Bhubaneswar and Konarak. On a hill at Dhauli, 4 m. S.W. of Bhubaneswar, are rocks with edicts inscribed by Asoka in the 3rd century B.C. and an elephant carved out of the solid rock, the oldest carving of an elephant known in India. In the hills of Udayagiri and Khandagiri are Jaina caves hewn out of the rock, and some (such as the Rani Gumpha or queen's palace) profusely carved, between the 3rd and 1st centuries B.C. The greatest architectural glory of the district is its collection of temples built between the 8th and 13th centuries A.D. Bhubaneswar is crowded with Saiva shrines of which the largest is the Lingaraj, while the Raja Rani temple has been described by Fergusson as one of the gems of Orissa art. More magnificent, even in its ruin, is the sun-god's temple of Konarak, of which Sir John Marshall writes: "There is no monument of Hinduism, I think, that is at once so stupendous and so perfectly proportioned."

PURIFICATION. Purification denotes the processes employed to prepare individuals or communities for contact with persons or things otherwise dangerous, or to prevent the consequences of contact with such persons or things. To deal first with the latter aspect, a man may unwittingly violate a tabu and such is the sense of social solidarity that the whole community feels itself menaced with calamity. He must be purified. The society must be protected. All conditions of diminished social activity on the part of an individual are dangerous. (*Andaman Islanders*, p. 303.) Thus, "among most or all African tribes a sin, wrong doing or breach of custom is not merely a matter demanding punishment or redress but it imparts a bane or evil influence which remains unless the necessary purification follows. The point to be emphasized is that this mysterious force affects not the evildoer but the person injured, so that it is he who must be purified. For instance, a man who is wounded is purified by the one who wounded him." (C. Dundas, Kilimanjaro and its People, 1924, p. 155.) Contact with persons and things possessing this dangerous potency is often essential. In this sense cleanliness is very close to godliness. In general food is regarded as something that may only be approached with ritual precautions. (*Andaman Islanders,* p. 273.) The savage must come to his meals clean. Primitive communities insist on the purification of the successful warrior. (*Andaman Islanders,* p. 133; *Ila* Speaking Peoples, I., 179; Akamba 198, see note; *The* Sema *Nagas,* p. 175; and *42nd Annual* Report, Bureau of American Ethnology, p. 423.) The sacrificial priest must be purified before he touches the holy object. He must be purified again when the rite is over.

It is evident that the dangerous qualities whose effect has to be neutralized are in one aspect of a spiritual nature and that intention, motive, purpose are not essential elements. The automatic effect of a breach of the law gives strength to the social order since, where the results of sin may affect all or any of the members of the society it is the business and interest of each man to keep the law and to see that his neighbour keeps it.

Whenever and wherever sin has come to be viewed as a breach of a divine order, punished by the Divinity, a judge of the heart of man, a just judge, motives and purposes assume importance. Purification is here directed to the conscience. The preventive action of the rites of purification comes in course of time to include deep, permanent modifications of the personality of the sinner, so that he sins no more. Coercion comes from within and is self-determined. See Bibliography to article ANTHROPOLOGY.

PURIM, a Jewish festival on Adar 14 and 15, to commemorate the deliverance of the Jews from Haman, the minister of Ahasuerus (Artaxerxes?), as related in the book of Esther (lit. lots, Heb. פור, Esther iii. 7; ix. 24, 26, possibly from Assyrian *puru,* stone or Vedic *pûrti,* portion): so called from the lots cast by Haman to determine an auspicious day for the massacre. The origin of the festival is much disputed: some hold that it developed from a primitive spring festival because (a) it is celebrated just before the advent of the New Year in *Niṣṣan* and that the preliminary fasting was actually ordained in Esther iii. 7; iv. 16 for *Niṣṣan.* But the fasting is a later institution (on this see Jew. *Enc.,* x. 278); (b) the feast is secular rather than religious: it has all the characteristics of a spring carnival including the ironical crowning of the buffoon-king or vegetation-god who was put to death after mockery (*cf.* Frazer, *Golden* Bough, ed. ii., vol. iii, pp. 154). S. Langdon (Bab. Epic of Creation, 1923, pp. 28, 33, etc.) traces a similar festival to Marduk (cf. Mordecai; Ishtar-Esther?) during *Niṣṣan,* with the mystic ceremony of the death and resurrection of *Bêl,* from primitive times in Babylonia. Zimmern (see refs. in Langdon) drew a parallel with the leading features in the scourging and death of Jesus. But the Jewish beating of Haman or burning of his effigy is late and clearly borrowed from mediaeval carnival customs, probably in the 13th century. On the contrary, during the synagogal reading of the book of Esther the reader hurries over the execution of the ten sons of Haman (Esther ix. 7–10), pronouncing them in one breath. This goes back to the Talmud (Neg. 16 b) and is ordained (1) to denote their simultaneous death and (2) to avoid gloating over a fallen foe. If Purim were purely a Babylonian feast, the Jews of Palestine and Egypt would hardly have accepted or retained it long after their connection with the Persian Empire ceased, whereas Purim has always been most popular. (c) On the other hand, there are features in the Jewish liturgy which strongly suggest a secular origin and it is most likely that this festival, first secular and national, ultimately became sanctified and was made a religious occasion. The growth of this process may be traced in the service. The name of God is absent from the *Megillah* and various devices of the scribe make good the deficiency, *e.g.,* when the letters of the Tetragrammaton occur close together they are crowned or written large: in iv. 14 "another place" is interpreted of God because "place" (*Maqōm*) is used in this way. The only religious allusions in the book are iv. 16 and ix. 31. The scroll is called *'Iggereth* or letter (ix. 26 and 29) and the reader folds the scroll so as to make it resemble a letter and holds it aloft when he recites the word "letter" in the verses just named. This tends to mark the lower or secular category of the book, *i.e.,* it is classed as an "Epistle" rather than as a "Gospel." For the service itself see Singer's *Authorized* Daily Prayer Book, p. 276 (and p. ccvi. of annotated ed.), where the alphabetical poem (אֲשֶׁר הֵנִיא) may be noted.

A characteristic of Purim and the book of Esther often overlooked is its similarity to the Euripidean drama. A cardinal feature is the punishment of ὕβρις. Purim plays are frequent, by Christian (*e.g.,* Racine) as well as by Jewish authors.

PURINES. The purines comprise a large group of nitrogenous compounds, a few of which occur widely distributed throughout nature. They derive their name from the fact that they can be regarded as derived from one substance, purine itself. This name was coined by the German chemist, Emil Fischer, from the two Latin words *purum* and *uricum,* the latter being chosen because the best known purine at that time, uric acid, occurs in urine. Fischer named this compound and pointed out its relation to known purines about 14 years before he actually prepared it in the laboratory.

Of the several hundred purines known, only 12 have been isolated from natural sources. All other purines are synthetic products and are only of academic interest. The following discussion will be limited almost entirely to eight of these purines which occur widely distributed throughout nature, namely, uric acid, guanine, adenine, xanthine, hypoxanthine, caffeine, theobromine and theophylline.

THE INDIVIDUAL PURINES

Uric Acid.—This was the first purine known, being discovered in human urinary calculi by the Swedish chemist Scheele in 1776. Scheele made careful investigations of its reactions and properties, these results being still used to identify uric acid. Thirty years later it was found that uric acid occurred in guano, and still later it was found that birds' excrement consisted largely of uric acid. Guano consists of the excrement of certain South American sea birds, which, with the help of a dry climate, has been accumulating for untold years. By far the best source of uric acid, however, is the excrement of serpents, which consists of over 95% of uric acid combined with small amounts of potassium and ammonia. It is only necessary to dissolve snakes' excrement in dilute alkali, filter, and reprecipitate with mineral acid.

Uric acid, however, occurs in other ways. As the mono-sodium salt it is the substance precipitated in body tissues in cases of gout, and is responsible for the formation of the gouty nodules with the subsequent inflammation and irritation which characterize this disease. Uric acid also occurs normally in the blood of man and other animals. In man the blood normally contains less than 0·1 mg. per cu. cm. Uric acid confines itself to the animal kingdom, although other purines are common as plant products.

The following table (Givens and Hunter) shows the variation in the relative amounts of allantoin, uric acid and bases (other purines) excreted in the urines of different species of mammals.

Order and Species.	*Allantoin*	*Uric acid*	*Nitrogen (%) present as Bases*
Marsupialia:			
Opossum	76·0	19·0	6·0
Rodentia:			
Guinea-pig	91·0	6·0	3·0
Rat	93·7	3·7	2·7
Ungulata:			
Sheep	64·0	16·0	20·0
Goat	81·0	7·0	12·0
Cow	92·1	7·3	0·7
Horse	88·0	12·0	0·5
Pig	92·3	1·8	5·8
Carnivora:			
Raccoon	92·6	5·4	2·0
Badger	96·9	1·9	1·2
Dog	97·1	1·9	1·3
Coyote	95·6	2·6	1·8
Primates:			
Monkey	66·0	8·0	26·0
Man	2·0	90·0	8·0

Man stands out as eliminating 90% of his purine-allantoin nitrogen in the form of uric acid, this proportion being 11 times as much as the monkey, which is biologically his closest relative. Too much importance must not be attached to the biological significance of this, however, as the ratio is known to vary considerably, even within a species.

The origin of uric acid as an excretory product has long been a matter of interest. According to A. P. Mathews (*Physiological Chemistry*, New York, 1915), the reason for the excretion of protein nitrogen in the form of uric acid rather than urea by birds and reptiles, is to be ascribed to their environment during evolution. The birds were evolved from the reptiles, and the reptiles were probably evolved in a dry, arid region, as indicated by other body characteristics. Urea is very soluble in water, and has a great affinity for it, whereas uric acid is insoluble, with no affinity for water, so that the excretion of nitrogen as uric acid rather than urea, saves much water for the organism, and would be an important adaptation in a region comparatively devoid of water.

In man the excreted uric acid may be divided into two varieties, the endogenous and the exogenous uric acid. The endogenous uric acid, about 0.4 grams a day, is very nearly constant for a given individual, but varies slightly in amount in different persons. It represents the uric acid which is formed in the body by synthesis and by the breakdown of nuclear tissue. On a diet which is free from purines, it is independent of the amount of fat, carbohydrate, protein or number of calories ingested. It is thought to originate from the oxidation of the hypoxanthine constantly formed in muscle and other tissues.

The exogenous uric acid is that formed by the oxidation of purines taken in as part of the food, chiefly in meat. All meat. and particularly glandular meat such as liver and sweetbreads, contains varying amounts of nucleic acid, which contains about 20% of the purines guanine and adenine. In the body these two substances are changed, by means of enzymes, into two other purines, xanthine and hypoxanthine, which are both oxidized to uric acid. The amount of exogenous uric acid depends, then, on the purine intake. Furthermore, it has repeatedly been shown that uric acid and other purines, injected hypodermically into the body, can be recovered nearly quantitatively in the urine.

Man excretes ingested purines almost entirely as uric acid, although other mammals excrete theirs almost entirely as allantoin, because the human body is lacking in a specific enzyme, uricase. which oxidizes uric acid to allantoin. The small amount of allantoin excreted by the human is probably preformed in the food. In the livers and other organs of animals which excrete allantoin, we find varying amounts of uricase, and if these organs are ground up and digested with uric acid, it is oxidized to allantoin. Different animals apparently differ in the efficiency with which this reaction is performed.

When the uric acid metabolism is disturbed, for reasons which are not as yet understood, the uric acid output in the urine is lowered. As the individual constantly ingests more purine, the result is that it is stored up. At first this storage takes place in the blood, but owing to the very low solubility of uric acid and its mono-sodium salt, only a limited amount can be held in this way. The excess crystallizes out, mainly in the cartilages and joints, as acid sodium urate, and the irritation resulting from these deposits is known as gout. It is evident that a gouty person should avoid foods which contain purines, such as meat, and confine his protein diet to such foods as milk and eggs, which are virtually purine free.

Guanine and Nucleic Acid.—Guanine, one of the two amino-purines occurring in nature, takes its name from the fact that it was discovered in guano, by B. Unger in 1845. Since that time, however, it has been found widely distributed throughout the animal and plant world. It occurs in the scales and skin of the bony fishes, and in the swim bladders, to which it gives their characteristic pearly appearance. It also is the chief constituent of the excrement of spiders. Human and pig urine contain small amounts of guanine. By far its most important occurrence, however, is in organs rich in cells, such as the pancreas, liver, spleen, testicles, etc., in animals, and in the germ cells of plants. It occurs here as a constant constituent of nucleic acid, of which it constitutes about 10%.

Nucleic acid, a compound occurring in the nuclei of all cells, is built up from four molecules of phosphoric acid, four of sugar. two of pyrimidines, and one each of guanine and adenine. When taken into the body as food, the guanine and adenine are eventually excreted as uric acid. These changes are brought about by the action of enzymes, which eventually break the nucleic acid up into its component molecules. The guanine is then changed by an enzyme, guanase, into its corresponding oxygen derivative, xanthine, which is then oxidized by an enzyme, xanthine oxidase, to uric acid.

It is an extremely interesting fact that in the pig the organs are entirely lacking in guanase; it is thus impossible for it to change guanine into allantoin, and consequently the pig frequently suffers from a form of gout, similar in all respects to that in humans, except that the deposit in the joints consists of crystalline guanine instead of acid sodium urate.

Adenine. — Adenine and guanine are the only two amino-purines, and differ from one another by only one atom of oxygen, guanine being an oxidized adenine.

Adenine, discovered by A. Rossel in 1884 among the hydrolytic products of pancreatic nucleic acid, is found in all glandular tissues, which are rich in nucleins. In addition, it occurs free in the leaves of plants, for example tea leaves and alfalfa leaves. It has also been found combined with sugar in the blood stream.

Adenine, like guanine, is one of the chief contributors to the uric acid and allantoin output of mammals. After the enzymic cleavage of the nucleic acid there are two special enzymes to take care of the adenine. One of these, adenase, replaces the amino-group by an hydroxyl, giving hypoxanthine. Another enzyme, an oxidase, oxidizes the hypoxanthine to xanthine, which is further metabolized as in the case of guanine.

Xanthine.—This purine, first discovered by Marcet, in 1817, in a urinary stone, derives its name from the Greek word, *xanthos*, meaning yeiiow. when it is evaporated in a dish with HNO_3, a yellow spot remains. Xanthine occurs widely distributed in animal and plant matter, wherever guanine is found, being probably derived from guanine by enzymic and putrefactive processes.

Hypoxanthine **(Sarcine).**—Hypoxanthine is a reduced xanthine, which was discovered by Scherer in 1850 in an extract of spleen. In general, it may be found in all nuclear tissues, and is probably there as a decomposition product of adenine, from which it is derived by the substitution of an hydroxyl by an amino-group. This change is brought about by the enzyme, adenase, as a result of either normal degradation or putrefactive processes. It is also found in small amounts in bone marrow.

Caffeine or **Theine.**—These two names are applied to a well-known purine discovered in 1820 in tea leaves by Ferdinand Runge. Caffeine is found only in vegetable matter, occurring to the extent of 0·8–1·7% in coffee beans, 0·1–0·8% in cocoa beans, 1–2% in Kola nuts, 2–5% in tea leaves, and 2·5–5% in guarana, the roasted fruit of *Paullinia,* which is eaten in South America. It is this purine, along with theobromine and theophylline, which gives the stimulating effects to drinks made from the above sources.

Caffeine has the notable effect of stimulating the central nervous system. In addition it is a cardiac tonic, and, in common with nearly all purines, has a strong diuretic action. In the body it is oxidized to uric acid and excreted as such. There is a tendency among many medical practitioners to warn patients to do without tea and coffee. In certain cases there are undoubtedly very good reasons why caffeine is harmful. For example, in the case of a person suffering with gout, everything must be done to lower purine ingestion, and thus to lessen the load on the already over-burdened kidneys. Specially prepared brands of tea or coffee are available from which caffeine has been removed without any alteration of taste. In the case of tea this is done by extracting the leaves with light petroleum to remove the volatile oils which are responsible for the flavour. The caffeine is then removed by extraction with chloroform, after which the original petroleum extract is added to the leaves and the solvent allowed to evaporate, thus restoring to the tea its original flavour. Green coffee beans are treated with live steam and ammonia gas to swell them, the caffeineis then chloroform processed, and the beans subsequently roasted.

Theobromine.—This purine is unfortunately named, for it is devoid of bromine. It was noted first by A. Woskresensky, in 1842, in an extract of cocoa beans, where it occurs to the extent of 1·5–2·4%. This bean is the seed of the plant *Theobroma Cacao* hence the name theobromine. As in the case of caffeine and theophylline, it occurs only in plant matter, being present in the kola nut and in tea leaves, but not in coffee beans. It is a powerful diuretic, and in the body is oxidized to and excreted as uric acid.

Theophylline.—In 1888 A. Kossel discovered very small traces of this purine in tea extract.

Paraxanthine, Heteroxanthine, **1-Methylxanthine** and Epiguanine have all at one time or another been isolated from human urine. They are regarded as secondary products, arising from the action of the body on caffeine (*see* p. 780).

THE CHEMISTRY OF THE PURINES

Purine has the empirical formula, $C_5H_4N_4$, the atoms being joined together according to one or other of the following structural schemes:

I.  II.

In order to endow the many purines with names which may at once be distinctive and descriptive, each atom in the purine ring is given a number, as indicated in formula I.

It will be noted that, as the arrows indicate, purine is a mixture of two substances which readily pass from one to another. This mutation is known as tautomerism (*q.v.*). In purine, one of the hydrogen atoms is labile and can pass from the nitrogen atom at 7 to the nitrogen at 9, and vice versa. Any of the four hydrogen atoms in purine may be substituted by any of a large number of groups, the most important being the hydroxyl group (OH), amino- (NH_2), chlorine (Cl), and methyl (CH_3) groups.

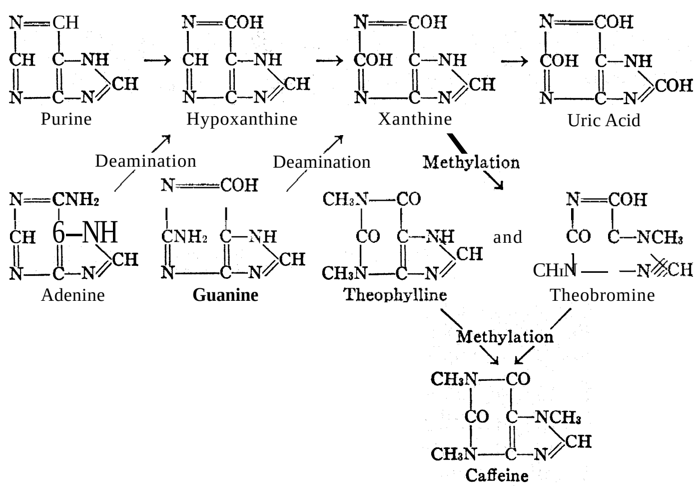
A substitution on nitrogen in either the 1 or 3 position is only possible when the hydrogen at either or both of the 2 and 6 positions is substituted by an hydroxyl. For instance, uric acid (2:6:8-trihydroxypurine) is a tautomeric substance, existing

III.  IV.

either in the lactim form (III.) or the lactam form (IV.). As a lactim uric acid yields salts with metals, the hydrogen on oxygen being replaceable. The lactam form explains why substitution occurs on the 1 and 3 nitrogen atoms.

The following diagram explains the relationships existing between the purines. Starting with purine, and successively substituting hydroxyl groups for the hydrogen atoms attached to carbon, hypoxanthine, xanthine and uric acid are obtained, these being the mono-, di- and tri-hydroxypurines respectively. Similarly, adenine is a mono-aminopurine and guanine is a mono-aminohypoxanthine.

Uric Acid. — This dibasic acid is a white, finely crystalline substance, insoluble in water and all organic solvents. Alkaline salts of weak acids, such as potassium phosphate, sodium acetate, and particularly lithium carbonate, increase the solubility in water owing to the fact that these salts all form alkaline solutions, and the sodium salt of uric acid is much more soluble than the free acid. (Lithium salts have been used in the treatment of gout on the erroneous assumption that, lithium urate being more soluble



than sodium urate, the uric acid would be eliminated more quickly.) Uric acid, when heated, decomposes into ammonia, carbon dioxide, urea and cyanuric acid. It is unstable and decomposes if left in moderately strong alkali for any length of time. Uric acid is identified by the "murexide" reaction. The suspected substance is evaporated to dryness with nitric acid; if uric acid is present this leaves a yellow spot which when moistened by ammonia turns purple, due to ammonium purpurate formed.

Although uric acid was discovered in 1776, its structural formula was not investigated until 1875, when L. Medicus proposed the formula which has since been established by numerous syntheses.

Guanine is a white amorphous powder, insoluble in water and organic solvents. It is a much weaker acid and stronger base than uric acid. It is, however, such a weak base that ammonia will precipitate it from solution. Owing to the hydroxyl group on carbon, it will dissolve in strong bases, such as sodium hydroxide. The amino-group present in its structure makes it soluble in acids, and thus separable from uric acid. Silver nitrate precipitates guanine in either neutral or alkaline solution, and forms double salts with guanine nitrate. The nitrate is insoluble in strong nitric acid. If treated with nitrous acid, or digested with the enzyme guanase, the amino-group is replaced by hydroxyl giving xanthine.

Adenine crystallizes from water in clusters of leaflets which contain $3H_2O$. When anhydrous it melts at 360–365° F; it is a stronger base than guanine, and hence is not precipitated by ammonia, this difference affording a separation of the two bases. Like guanine, it is precipitated by phosphotungstic or picric acid, the picrate forming beautiful silky yellow needles. Nitrous acid, or the enzyme adenase, decomposes adenine, the resulting replacement of amino- by hydroxyl giving hypoxanthine. Adenine is stable to weak oxidizing agents, but unstable to even mild reducing agents. At 200° F hydrochloric acid decomposes it completely to carbon dioxide, ammonium formate and glycine acid.

Xanthine, a white crystalline substance forming salts with both strong acids and bases, occurs in nature but is best prepared by the action of nitrous acid upon guano. When heated dry it decomposes into carbon dioxide, ammonia and hydrocyanic acid.

Hypoxanthine occurs as small colourless needles, soluble in both acids and bases. Its hydrochloride crystallizes with one molecule of water. The picrate is very insoluble, and can be used to remove hypoxanthine from solution. This purine is not precipitated by ammonia and is a strong enough acid to decompose carbonates. Hypoxanthine is obtained from adenine by deamination with nitrous acid or adenase.

Theophylline, like theobromine, is a weakly basic substance. Upon oxidation with hydrochloric acid and potassium chlorate it gives dimethylalloxan, in contrast to xanthine, hypoxanthine and uric acid, which give alloxan. When methylated, theophylline and theobromine give caffeine.

Theobromine, an isomeride of theophylline, occurs as colourless needles having a very bitter taste. It is prepared by the methylation of the lead salt of xanthine. Oxidation with hydrochloric acid and potassium chlorate gives methylalloxan and methylurea, whilst boiling with baryta produces methylamine, ammonia, carbon dioxide, formic acid and methylglycine.

Caffeine crystallizes with one molecule of water in beautiful, glistening needles, having a slightly bitter taste. They are sparingly soluble in cold water and alcohol, and soluble in chloroform. It is most conveniently prepared by the extraction of tea. Upon oxidation with hydrochloric acid and potassium chlorate it gives dimethylalloxan, methylurea and carbon dioxide. In the body, caffeine undergoes a number of changes, being excreted as uric acid and four other purine bases mentioned earlier.

PURITANISM. The name Puritan, "would-be purifier," was applied in England about 1564 to groups who disapproved of Queen Elizabeth's choice of a middle path between Rome and Geneva, and sought further purification of the Church of England. Originally scornful, Puritan has become, particularly in New England, a term of honor.

The initial principles of Puritanism were brought to England from Zurich or Geneva by English Protestant refugees. There was frequent objection to the surplice as not expressly authorized in Scripture; to this "vestiarian controversy," succeeded in 1570–72 the second stage of Puritan agitation, the strife over Church polity. Thomas Cartwright, spokesman of the party which wished to reform the Church of England from within, on the Presbyterian model, found no warrant in the Bible for prelacy. Archbishop Whitgift vigorously opposed this movement, as he did the Separatist movement led by Robert Browne.

James I rejected the Millenary Petition, a syllabus of Puritan requests, and demanded that the Puritans conform or be harried out of the land. By 1610 most of the opponents of the growing Stuart tendency toward autacracy found in political Puritanism a rallying-point against tyranny. A generation later the Grand Remonstrance accused the party of Charles I and Archbishop Laud of plotting to expel the Puritans. Civil war ensued.

The Solemn League and Covenant (1643) led to the attempt to reform the Church of England on the Scottish model; but Cromwell successfully opposed the plan. Charles II's Act of Uniformity (1662) threw nearly two thousand Puritan clergymen out of their benefices.

The Restoration reopened the theatres and took many a fling at the Puritans, the classical attack being Butler's *Hudibras:* low-born, sour-faced hypocrites, jealously disapproving the pleasures of their superiors. Puritanism, however, was never a mere class movement: many great noblemen and statesmen were Puritans as were most of the wealthy merchants. London and the University of Cambridge were strongholds of Puritanism. The ethical standards of later Puritanism, seen in Perkins and in Baxter, were deduced from the detailed injunctions of Scripture. The economic life on both sides of the Atlantic has been deeply influenced by Puritan discussions.

Seventeenth-century Puritanism diverged at a number of points from continental Calvinism, particularly because of the publication in 1595 of Robert Bounde's treatise on Sabbath observance. Puritanism influenced Pietism in Holland and in the Empire; and many emphases survived in the Methodist and in the Evangelical movement. New England gave the first opportunity for putting the Puritan theories into practice; there an earnest effort was made to model legislation on Scripture.

Posterity tends to misrepresent Puritan standards. Very few Puritans were total abstainers from alcoholic beverages. They did not hate art, and when they had power, as in 1644, did not smash all "images," but spared effigies of statesmen and others not likely to be worshipped. Cromwell himself patronized painters, and loved athletic games, fast horses, and music.

PURLIN, in architecture, the longitudinal timbers of a roof, carried by the principal rafters or trusses and the end walls, and supporting the common rafters.

PURNEA, a town and district of British India, in the Bhagalpur division of Behar and Orissa. The town is on the little river Saura, with a railway station. Pop. (1931) 15,474.

The DISTRICT OF PURNEA has an area of 4,972 sq.m. and a population (1931) of 2,186,543, extending from the Ganges northwards to the frontier of Nepal. It is a level tract of country, traversed by several rivers flowing from the Himalayas, the greatest of which is the Kosi, which has been known to move 20 m. in 25 years, leaving behind it a trail of sterile sand. The principal crops are rice, pulses and oilseeds. The cultivation of indigo has declined, but that of jute has greatly increased. Branches of Eastern Bengal State railway join the Bengal and North-Western railway at Katihar, which is a rapidly growing town with 15,864 inhabitants. Kishanganj (pop. 5,939) is the centre of the jute trade and is a branch terminus of the Darjeeling-Himalayan railway.

PURPLE, a shade varying between crimson and violet. Formerly it was used of the deep crimson colour called in Latin purpura, from the name of the shellfish (Purpura) which yielded the famous Tyrian dye. Tyrian purple during many ages was the most celebrated of all dyed colours, and possibly the first to be permanently fixed on wool or linen. Being extremely costly, robes of this colour were worn as a mark of imperial or royal rank, whence the phrase "born in the purple." In the Roman Catholic church "promotion to the purple" is promotion to the rank of cardinal.

The ancients derived their purple from the mollusc, Purpura *haemastoma,* known to Pliny as "Buccinum," and Murex bran*daris,* termed by Pliny "Purpura," the shells of which have been found adjacent to ancient dyeworks at Athens and Pompeii. The colour-producing secretion is contained in a small cyst adjacent to the head of the animal, and this pus-like matter when spread on textile material in presence of sunlight develops a purple-red colour. According to Pliny these receptacles after being laid in salt were boiled with water for several days, the liquor being tested from time to time as to its dyeing properties. Before dyeing the wool could be grounded with a second colouring matter. for which purpose alkanet root (*Anchusa tinctoria*) and "orchil" were employed. Friedländer has shown that the dye developed from the molluscs is 6:6′-dibromoindigotin. (A. G. P.)

PURPURA, a pathological condition in which blood leaves the smaller blood-vessels and is deposited in the tissues in patches, which, if minute, are termed "petechiae," if large, "ecchymoses." The condition depends upon an alteration of the blood itself, particularly the blood-platelets; coagulation time is prolonged and the plasma often contains haemoglobin that has left the red blood corpuscles owing to disturbance of their normal relations. Probably these modifications act on the endothelial walls of the capillaries and venules and lead to changes in them also. In the main the haemorrhages constituting purpura occur beneath free surfaces such as skin, mucous and serous membranes and are there most visible but they also occur in the substance of organs and bleeding may occur in dangerous quantity from nose, mouth, bowel, kidney, etc. Blood effused into the tissues undergoes subsequent changes like those seen in a receding bruise.

The clinical causes of purpura are various. Following snakebite, or the administration of such drugs as copaiba and belladonna, or the onset of jaundice, it seems to be caused by the action of a chemical poison and probably the same is true when it accompanies acute infectious fevers (*e.g.,* severe forms of scarlet fever and small-pox), heart disease, especially ulcerative endocarditis, and some forms of Bright's disease. It is a short step from this to invoking a chemical poison of microbial origin in those forms of purpura which are associated with articular or rheumatic pain or even constitute apparently the substantive disease, but of this there is, as yet, no proof. From the fact that haemorrhage is present in both instances purpura has many clinical resemblances to haemophilia (*q.v.*) and the two morbid conditions may often have been confused. Probably similar blood changes occur in both, but they appear to be distinct diseases.

Treatment is that of any underlying condition, but astringents (such as iron, gallic acid), may be required in severe cases. Sir A. Wright holds that in all cases of purpura the coagulation time should be determined and if prolonged, calcium should be given internally. In severe haemorrhage adrenalin is often useful.

See H. L. Tidy, "The Haemorrhagic Diathesis," *Brit. Med. Jn.* 1928; 583. (W. S. L.-B.)

PURRAH, PURROH or **PORO,** a secret society of Sierra Leone, West Africa. Only males are admitted to its ranks while the Bundu is strictly reserved to women.

The Purrah had its special ritual and language, markings and symbols and exercised authority by the imposition of tabus which were enforced by various methods. In 1897 the British local government was compelled to pass a special ordinance absolutely forbidding the imposition of the tabu on all indigenous products.

See T. J. Alldridge, *The Sherbro and its Hinterland* (1901); N. W. Thomas, *Anthropological Report on Sierra Leone,* Part I. (*Law* and *Custom* of *the* Timne and other tribes).

PURSH, FREDERICK (1774–1820), American botanist, was born at Tobolsk, Siberia, in 1774. He received his education in Dresden, Germany. In 1799 he went to the United States where he devoted 12 years to botanical exploration and the scientific study of North American plants. In 1811 he visited England and in 1814 he brought out in London his important Flora *Americae* Septentrionalis. He then returned to the United States and resumed his botanical investigations. On one of his solitary tours afoot he discovered the hart's-tongue (*q.v.*), one of the rarest of the ferns found in North America. Pursh's original contributions regarding the plants of the north-eastern United States, rank among the most valuable made by early American botanists. While collecting materials for a flora of Canada he died suddenly at Montreal on June 11, 1820. (See BITTERROOT.)

PURSLANE, the common name for a small fleshy annual with prostrate stems, entire leaves and small yellow flowers, known botanically as Portulaca *oleracea* (family Portulacaceae). It is a native of India, which was introduced into Europe as a salad plant, and in some countries has spread so as to become a noxious weed; it is found in England but is rare. In certain parts of the United States the evil qualities of "pussly" have become proverbial. The persistence of purslane plants is due to their ability to retain moisture and thus blossom and ripen seeds long after they have been removed from the soil. The capsules opening by a lid produce many small seeds of great longevity. Besides the common purslane, some 10 other species occur in North America, chiefly in the southern United States. Some of the species of the same genus, such as P. *grandiflora* and its varieties, are grown in gardens on rockwork.

PURSUIVANT, a member of the third and lowest rank of heraldic officers, formerly an attendant on the heralds.

PURVEYANCE was a prerogative of purchasing goods for the royal household, enjoyed by all English kings up to Charles II. Certain officers attached to the king's court were charged with the duties of buying and arranging for the cartage of goods where necessary, the ancient prerogative of the King entitling him to demand carriage services from his subjects. The possibilities of abuse were obvious. Magna Carta (*q.v.*) ordered that goods should be paid for at once, and that horses and carts should not be taken for carriage duty, nor timber taken for castles without the consent of the owner. These stringent regulations were considerably modified to the King's advantage in later issues of the charter.

Many early statutes were passed against purveyance. People particularly resented the exercise of this right by royal officials and ministers for their own benefit. Statutes therefore limited its use to the immediate households of the king and queen. The name purveyor was so much hated that it was provided by statute that it should be changed to *achatour* (buyer). But statutes had little effect. In Elizabeth's reign complaints against purveyance were particularly bitter. In her early years the queen seems to have made use of her rights of purveyance to victual her navy. Later an arrangement was made by which some, if not all, counties agreed to furnish definite provisions at a fixed rate in order to get rid of the uncertainty which made the burden so much heavier. These compositions were arranged between the officers of the Board of Green Cloth and the Justices of Peace for each county at fixed prices. These fixed prices were very much lower than the market value of the goods and the difference was met by an assessment on the county. Cattle supplied in this way were kept in certain royal pastures. The parliaments of James I. determined to get rid of the abuses of purveyance, and Sir Francis Bacon made a famous speech against the purveyors in the first parliament of the reign. It was held that only the abolition of the right would put an end to its abuse. The purveyors made a practice of demanding far more goods than were necessary and sold the surplus for their own advantage. They ordered goods to be taken to remote places that people might buy from them exemption from coming with their portions. There were innumerable ways in which purveyors could make dishonest profit. Despite complaints, the right of purveyance went on until it fell into disuse during the Commonwealth. Its abolition was part of the Restoration Settlement, though till the end of the century it was sometimes partially revived during royal progresses.

An elaborate treatise on the subject was written by the ardent royalist Fabian Philipps, The Antiquity, legality, reason, *duty* and necessity of preemption and *pourveyance for the king* (1663). *See also* W. Money, *A Royal Purveyance* (Newbury, 1901). (D. M. S.)

PURVITS, VILHELMS (1872–), famous Latvian landscape painter, one of the first artists to introduce the contemporary tendencies of Western art, not only into Latvian art but also into the whole of eastern Europe. During his travels he studied French Impressionist art and reached a standard of perfection in this branch. He did not, however, stop at this stage, but, following closely the movements of international art, he ceaselessly varied and perfected his powers of expression. Starting from pure Impressionism he gradually developed a style of landscape painting, methodical linear construction, into a conscious composition. He paints numerous and varied pictures of the landscape of his own country. Purvits is undoubtedly the most important of the first two generations of Latvian artists. He may be considered as being the founder of Baltic landscape painting and of a special school of art. He is director of the Latvian Academy of Arts in Riga.

PUSA, a village of British India, in Darbhanga district, Bihar and Orissa, near the right bank of the Burh Gandak river; and 6 m. from the Pusa Road station on the Bengal and North-Western railway. The Government acquired an estate here in 1796, long used as a stud depot and afterwards as a tobacco farm. The estate, which covers 1,280 ac. was made over in 1904 to the Imperial Agricultural Department (of the Government of India), of which it is the headquarters. The Research Institute here comprises, in addition to a farm, an agricultural college, at which officers are trained for the higher posts in the Agricultural Department, and a research laboratory bearing the name of Mr. Phipps, an American gentleman, who contributed £30,000 towards its cost. The institute, which owed its inception to Lord Curzon, has, within the comparatively short period of its existence, done magnificent service to Indian agriculture by producing improved varieties of crops. In particular, it has achieved remarkable success by evolving strains of wheat which give a high yield, have powers of resistance to rust, are able to mature with less water than the generality of Indian wheats, and give good results under diverse conditions of soil and climate. The Pusa varieties are now grown on over 1½ million acres of the United Provinces, the Punjab and the North-Western Frontier province. The institute has also produced a heavy-yielding variety of bearded wheat suitable for areas where the crop is liable to damage by birds. The institute has introduced berseem, or Egyptian clover. It has been proved that a small irrigated area of poor land, in which berseem is followed by early maize, can provide a large herd with all the bulky green food it requires—a discovery of immense importance in a country depending so largely on cattle, where the pasture lands are for a large part of the year parched and bare. Further, valuable results have been obtained by selective breeding of cattle, *e.g.,* by doubling the milk yield of a pure herd in ten years. In order to improve both the quality and quantity of sugar production, a Sugar Bureau has been established, which gives advice to cultivators, manufacturers, etc. The institute studies soil improvement and the use of phosphates found in India.

PUSEY, EDWARD BOUVERIE (1800–1882), English divine, was born at Pusey near Oxford on Aug. 22, 1800, the son of Philip Bouverie, who took the name of Pusey on succeeding to the manor of that name. Edward Pusey was educated at Eton and at Christ Church, Oxford, and became a fellow of Oriel in 1824. He thus became a member of a society which included J. H. Newman and John Keble. Between 1825 and 1827 he studied Oriental languages and German theology at Göttingen. In 1828 the duke of Wellington appointed him to the regius professorship of Hebrew with the canonry of Christ Church.

By the end of 1833 he showed a disposition to make common cause with those who had already begun to issue the *Tracts* for the Times. "He was not, however, fully associated in the movement till 1835 and 1836, when he published his tract on baptism and started the Library of the Fathers" (Newman's *Apologia,* p. 136). He became a close student of the fathers and of that school of Anglican divines who had continued, or revived, in the 17th century the main traditions of pre-Reformation teaching. A sermon which he preached before the university in 1843, *The* Holy *Eucharist, a Comfort* to the Penitent, so startled the authorities that he was suspended for two years from preaching. The effect of his suspension was the sale of 18,000 copies of the condemned sermon and Pusey at once became an influence in the Anglican Church.

The movement, in the actual origination of which he had had no share, came to bear his name: it was popularly known as Puseyism (sometimes as Newmania) and its adherents as Puseyites. His activity, both public and private, as leader of the movement was enormous. He was not only on the stage but also behind the scenes of every important controversy, whether theological or academical. In the Gorham controversy of 1850, in the question of Oxford reform in 1854, in the prosecution of some of the writers of *Essays and Reviews,* especially of Benjamin Jowett, in 1863, in the question as to the reform of the marriage laws from 1849 to the end of his life, in the Farrar controversy as to the meaning of everlasting punishment in 1877, he was always busy with articles, letters, treatises and sermons. Some of his sermons before the university marked distinct stages in the history of the High Church party which he led.

The revival of confession in the Church of England practically dates from his two sermons on *The Entire Absolution of the Penitent,* in 1846. The sermon on *The Presence of Christ in the* Holy *Eucharist,* in 1853, first formulated the doctrine round which almost all the subsequent theology of his followers revolved, and which revolutionized the practices of Anglican worship. Of his larger works the most important are: his two books on the Eucharist—*The Doctrine of the Real Presence* (1855) and *The Real Presence* . . . the *Doctrine* of the *English Church* (1857); *Daniel the Prophet* in which he endeavours to maintain the traditional date of that book; *The Minor Prophets, with* Commentary, his chief contribution to the study of which he was the professor; and the *Eirenicon,* in which he endeavoured to find a basis of union between the Church of England and the Church of Rome.

In private life Pusey's habits were simple almost to austerity. He had few personal friends, and rarely mingled in general society; though bitter to opponents, he was gentle to those who knew him, and his munificent charities gave him a warm place in the hearts of many to whom he was personally unknown. The deaths of his wife (1839) and of his only son (1880) saddened his life. He died on Sept. 16, 1882, and was buried at Oxford in the cathedral of which he had been for fifty-four years a canon. In his memory his friends purchased his library, and endowed for it a house in Oxford, known as Pusey House.

See B. W. Savile, Dr. Pusey, an Historic Sketch, with Some Account of the Oxford Movement (1883); the Life by Canon Liddon, completed b~ J. C. Johnston and R. J. Wilson (5 vols., 1893–99); Newman's Apologia, and other literature of the Oxford Movement.

Pusey's elder brother, Philip Pusey (1799–1855), was a member of parliament and a friend and follower of Sir Robert Peel. He was one of the founders of the Royal Agricultural Society, and was chairman of the implement department of the great exhibition of 1851. He was a fellow of the Royal Society, a writer on varied topics for the reviews and the author of the hymn "Lord of our Life and God of our Salvation."

PUSHBALL, a game played by two sides on a field usualiy 140yds. long and 50yds. wide, with a ball 6ft. in diameter and 50lb. in weight. The sides usually number 11 each, there being five forwards, two left wings, two right wings and two goalkeepers. The goal consists of two upright posts 18ft. high and 20ft. apart with a crossbar 7ft. from the ground. The game lasts for two periods with an intermission. Pushing the ball under the bar counts five points; lifting or throwing it over the bar counts eight. A touch-down behind the goal for safety counts two to the attacking side. The game was invented by M. G. Crane of Newton, Massachusetts, in 1894, and was taken up at Harvard University the next year, but has never attained any considerable vogue. In Great Britain the first regular game was played at the Crystal Palace in 1902 by teams of eight. The English rules are somewhat different from those obtaining in the United States. Pushball was one of the games frequently played by teams of military men at the training camps during the World War. It is usually considered one of the feature events at American circuses when played by teams of Indians and cowboys on horseback. It is also played by mounted organizations of the U.S. army at various military posts. Pushball on horseback was introduced in 1902 at Durland's riding academy in New York, and has been played in England at the Military 'Tournament.

PUSHKIN, ALEXANDER (1799–1837), Russian poet, was born at Moscow on June 6, 1799. He belonged to an ancient family of boyars; his maternal great-grandfather was an Abyssinian general in the Russian service, ennobled by Peter the Great. In 1811 the future poet entered the newly founded lyceum of Tsarkoe Selo, situated near St. Petersburg. On quitting the lyceum in 1817 he was attached to the ministry of foreign affairs, and in this year he began to write his *Ruslan and Ly'udmila,* a romantic epic in six cantos, which was completed in 1820. Meanwhile Pushkin mixed in all the gayest society of the capital, and it seemed as if he would turn out a mere man of fashion instead of a poet. Rut a very daring *Ode to Liberty* written by him and circulated in manuscript in St. Petersburg came to the notice of the governor, and the young author was exiled to the south of Russia where he held official positions at Ekaterinoslav and at Kishinev.

In company with General Rayevsky he visited the baths of the Caucasus for the re-establishment of his health in 1820. The Rayeyskys introduced him to the poetry of Lord Byron, and the magnificent scenery of the Caucasus kindled his own poetic genius. The first fruit of the Caucasian visit was *The Captive of the Caucasus* (1822), narrating the story of the love of a Circassian girl for a Russian officer. This was followed by the *Fountain of Bakhchisarai* (1827) which tells of the detention of a young Polish captive in the palace of the khans of the Crimea. About the same time he composed the lines on Ovid, whose place of banishment, Tomi, was not far distant, and the *Ode to Napoleon.* The next long poem was the *Gipsies* (Tsygany) (1827). During his stay in southern Russia he mixed with the secret societies then rife throughout the country. In 1823 he was allowed to leave Kichinev, where the life was hateful to him, and was transferred to Odessa where he was once more on real Russian soil, and on the coast of the sea which delighted him. But he came into conflict with his official superior, and was dismissed from the service, because of an intercepted letter in which he spoke favourably of atheism. He was ordered to reside at Mikhailovskoe, near Pskov, where he soon involved himself in trouble on all sides. In his retirement he studied old Russian popular poetry. Recollections of Byron and André Chenier gave the inspiration to some fine lines consecrated to the latter, in which Pushkin appeared more conservative than was his wont. In 1825 he wrote his tragedy *Boris Godunov,* not published till 1831, a bold effort to imitate the style of Shakespeare, thus breaking with the French traditions.

In 1825 the conspiracy of the Dekabrists broke out. Many of the conspirators were personal friends of Pushkin, especially Kiichelbecker and Pustchin. The poet himself was to a certain extent compromised, but he succeeded in getting to his house at Mikhailovskoe and burning all the papers which might have been prejudicial to him. The emperor, to whom he was presented at Moscow soon after his coronation, summoned him to Moscow and assured him of pardon and "protection." The story goes that Nicholas said to Count Bludov on the same evening, "I have just been conversing with the most intelligent man in Russia." In 1829 appeared *Poltava,* a spirited narrative poem, in which the expedition of Charles XII. against Peter and the treachery of the hetman Mazeppa were described. In 1829 Pushkin again visited the Caucasus on this occasion accompanying the expedilion of General Paskevich, which is described in *A Voyage to Arzrum* (pr. 1836). The lyrics are delightful. In 1831 Pushkin married Natalia Goncharov, and in the following year was again attached to the ministry of foreign affairs, with a salary of 5,000 roubles. He now began his *History of the Revolt of Pugachev of 1773* (pr. 1834) an admirable piece of historical writing. While engaged upon this he wrote The *Captain's Daughter* (1836), one of the best of his prose works. In 1832 was completed the poem *Evgeni Onegin* (1825–33), again influenced by Byron.

In 1837 the poet, who had been long growing in literary reputation, fell mortally wounded in a duel (Feb. 8) with Baron George Heckeren d'Anthès, the adopted son of the Dutch minister who had married a sister of the poet's wife. Pushkin died on Feb. 10. D'Anthès was tried by court-martial and expelled from the country. In 1880 a statue of the poet was erected at the Tver Barrier at Moscow. He left four children; his widow married an officer named Lanskoi; she died in 1863.

Pushkin's poetical tales are full of drama. *Boris Godunov* and *Evgeni Onegin* are the basis of operas by Mussorgsky and Tschaikowsky respectively. Pushkin's lyrical pieces are the finest in the language. Interspersed among his minor works will be found many epigrams. He was one of the earliest Russian novelists. Indeed most of his work after 1831 was done in prose. In 1831 he published a small volume of tales under the pen name of Ivan Belkin. These all show great narrative powers. The one long novel finished is *The Captain's Daughter,* a tale of the times of Catherine II., which exercised a great influence on later Russian novelists. The most famous of all his short stories is *The Queen of Spades* (1834). In the *History of the Manor of Goryukhino* (1857), Pushkin parodied Polevoy's *History of the Russian People,* and presented an amusing picture of the fictitious author of his own Tales, Ivan Petrovich Belkin.

See Prince *D. S.* Mirsky, *Pushkin* (1926), which contains a bibliography; and the bibliography in the editions of Gennadi (7 vols., St. Petersburg, 1861), and Annenkov (6 vols. St. Petersburg, 18jj).

PUSHTU, PAKHSTO, PAKKHTO (PASHTO), the language of the Afghans, belongs to the Eastern Iranian group, the oldest form of which is probably found in the Zend. Numerous terms are traceable to the Avesta. *(See* Paul Horn's *Grundriss der Neupersischen Etymologie*). The remainder of its vocabulary cames from Arabic, Persian and from the Indian Prakrits. Among the last, Sindhi takes first place. It has thus considerable claims to antiquity.

About 10% of the Afghans are able to read and write, and education is making rapid progress.

Structure. — There are nine declensions. The accusative is the same as the nominative. The agent and oblique forms are identical. The genitive, dative and locative are formed by adding suffixes to the oblique form. Most adjectives form the feminine by adding a. Pronominal suffixes are used as well as definite, personal, demonstrative and reflexive pronouns. The regular verb has two main tenses, the imperfect and the present. There are 37 classes of verbs, 13 intransitive and 24 transitive.

PUT AND CALL: *see* OPTIONS.

PUTEOLI, an ancient town of Campania (mod. *Pozzuoli, q.v.*), Italy, on the northern shore of the Bay of Puteoli, a portion of the Bay of Naples, from which it is 6 m. W. The city was probably founded under the name of Dicaearchia by a colony of Samians from Cumae about 520 B.C., before which Misenum was the original port. In 21j the Romans introduced a garrison of 6,000 men and Hannibal besieged it in vain in 214. In 194 a Roman colony of 300 men was established. Puteoli belonged to the tribus Palatina, thus breaking the rule (the only other exception is Turris Libisonis [*q.v.*] which belonged to the Colluia) that *municipia* and *coloniae* were not enrolled in the four urban tribes. The *lex parieti faciundo,* 105 B.C., relating to building works in front of the temple of Serapis, shows that Puteoli had considerable administrative independence. Sulla retired to Puteoli after his resignation of the dictatorship in 79. Cicero had a house in Puteoli itself, and a villa on the edge of the Lucrine lake (*q.v.*), and many other prominent men of the republic possessed country houses near by. *(See* BAIAE; AVERNUS: LUCRINUS LACUS; and MISENUM.) In A.D. 61 St. Paul landed here, and spent seven days before leaving for Rome (Acts xxviii. 13). Vespasian gave the town part of the territory of Capua, and installed more colonists

—whence it took the title Colonia Flavia.

The remains of Hadrian, who died at the neighbouring town of Baiae, were at first deposited at Puteoli, and Antoninus Pius erected a temple to his memory on the site of Cicero's villa. It was mainly, however, as a great commercial port that Puteoli was famous in ancient times. It exported iron from Elba, mosaics, pottery, perfumes, pozzolana earth (taking its name from the place), glass cups engraved with views of Puteoli, mineral dyes, etc., but its imports were considerably greater. During the Punic Wars it was a naval port, but in the latter part of the 2nd century B.C. it became the greatest commercial harbour of Italy and we find Lucilius about 125 B.C. placing it next in importance to Delos, then the greatest harbour of the ancient world.

The corn supply of Rome came partly through Puteoli, partly through Ostia. Seneca (*Epist.* 77) describes the joy of the inhabitants in the spring when the fleet of corn vessels from Alexandria was seen approaching, and Statius tells us that the crew of the ship which arrived first made libations to Minerva when passing the promontory which bore her name (the Punta Campanella at Sorrento).

Claudius established here, as at Ostia, a cohort of *vigiles* as a fire-brigade. Brundisium was similarly protected. There was also a station of the imperial post, sailors of the imperial fleet at Misenum being apparently employed as couriers. The artificial mole was probably of earlier date than the reign of Augustus; and by that time at any rate there were docks large enough to contain the vessels employed in bringing the obelisks from Egypt. Alaric (410), Genseric (455) and Totila (54j) devastated Puteoli.

The original town of Puteoli stood on the narrow hill of the Castello. The streets of the old town preserve the ancient alinement. There are also traces of the division of lands near the town into squares by parallel paths (*decumani* and cardines) at regular intervals of $1,111\frac{1}{9}$ Roman feet, postulating as the basis af the division a square with a side of 10,000 Roman feet, divided into 81 smaller squares. The market hall (*macellum*), generally known as the temple of Serapis, from a statue of that deity found there, was excavated in 1750. In the centre of the ancient city was a round colonnade with sixteen columns of Numidian marble (giallo antico) now in the theatre of the palace at Caserta. In the amphitheatre there were exceedingly interesting arrangements for flooding the arena, but these can only have been in use before the construction of the greater part of the subterranean portion with its cages, etc. The whole amphitheatre is 489×381 ft.; the arena 24j×138 ft. Inscriptions record that it was built by the Colonia *Flavia, i.e.,* not before Vespasian. In the older amphitheatre (426×312 feet), which was found in excavations for the new railway to Naples, Nero fought in games given in honour of Tiridates, king of Armenia. Remains of thermae also exist in various places. The cathedral of S. Proculus (containing the tomb of the musician Pergolesi, d. 1736) is built into a temple of Augustus, 6 columns of which, with their Corinthian capitals, still exist. Other ruins--of a circus, of tombs, villas, etc., exist.

Puteoli was supplied with water by two aqueducts, both subterranean, one of which, bringing water from springs in the immediate neighbourhood, is still in constant use. Puteoli was reached direct by a road from Capua traversing the hills to the north by a cutting (the Montagna Spaccata), which went on to Neapolis, and by the Via Domitiana from Rome and Cumae. There was also a short cut from Puteoli to Neapolis by the tunnel of Pausilipon, made under Augustus. In 305, S. Januaris (S. Gennaro, the patron saint of Naples), bishop of Beneventum, S. Proculus, patron of Puteoli. and others, were martyrs at Puteoli,

See the study of C. Dubois, *Pouzzoles* antique (Paris, 1907) (Bibliothèque des écoles françaises d'Athènes et de Rome, fasc. 98). (T. A)

PUTNAM, GEORGE HAVEN (1844–1930), dean of American publishers, at eighty-five (1929) the active head of one of the oldest publishing houses in the country, the house that gave to American literature such names as Washington Irving and Fenimore Cooper; with sixty-five years of publishing experience behind him, he had time to win honors as a soldier, a writer, and a man of public affairs.

This sterling American citizen, whose forefathers fought for George Washington, and who himself languished in Libby prison, upholding the Union cause, was born in England on April 2, 1844. His father, George Palmer Putnam, had founded the American publishing concern in 1837, and after that date had found it important for his publishing business to make annual trips to England. In 1841, he brought into organization the London publishing house, being the first American publisher to invade England. He was a resident of England for seven years, and it was in this way that his son came to be born in London.

It was not until 1848, that young George Haven Putnam was brought to America. Among his early memories are such outstanding figures as Washington Irving, Charles Dickens, Thackeray, Louis XVII. ("Eleazar Williams"), and Lincoln.

The major's father was a member of the Committee that invited Lincoln to New York in 1860, and the younger Putnam sat on the platform during the delivery of the Cooper Union address. After the address, he was introduced by Bryant to Lincoln.

His boyhood education was completed at Columbia grammar school, followed by studies abroad at the Sorbonne and the University of Gottingen, studies which were cut short by the beginning of the Civil War. Mr. Putnam hastened home from Europe in 1862 to enlist in the Union Army. He was taken prisoner at Cedar Creek, and sent to Libby Prison and later to Danville.

Major Putnam's outstanding contribution to publishing history was his championship of international copyright, which resulted, in 1891, in the present copyright relations between the United States and Europe. He died in New York city on Feb. 27, 1930.

PUTNAM, HERBERT (1861–), American librarian, was born in New York city on Sept. 20, 1861. He graduated from Harvard college in 1883 and thereafter studied law at Columbia university, being admitted to the bar in 1886. His calling, however, proved to be that of librarian. He was librarian of the Minneapolis Athenaeum in 1884–87, of the Minneapolis Public library in 1887–91 and, after a few years spent in the practice of law, of the Boston Public library in 1895–99. Thence he was called in 1899 to the librarianship of the Library of Congress, in Washington. He was president of the American Library association in 1898 and 1904 and wrote on library science.

PUTNAM, ISRAEL (1718–1790), American soldier, was born in Salem Village (now Danvers), Mass. on Jan. 7, 1718, and in 1740 removed to a farm in the vicinity of Pomfret, Conn. He was active in the French and Indian War, rising to the rank of major in 1758. News of the fighting at Lexington and Concord reached him while he was ploughing on his farm; he instantly left the plough in the furrow and hastened to Cambridge; and he was later made second brigadier of the Connecticut forces. He was with the force, commanded by Col. William Prescott. which on the night of June 16, 1775, fortified Breed's Hill, and on the next day he took a conspicuous part in resisting the British attack (see BUNKER HILL). After the evacuation of Boston he was in command of New York city till Washington's arrival (April 13, 1776), and then was put in general charge of the city's fortifications. Immediately before the battle of Long Island he succeeded Gen. John Sullivan in command of the troops on Brooklyn Heights, and in the battle of Long Island (of Aug. 27) he was in immediate command of the American side. In the retreat from New York city he took part in the battle of Harlem Heights (Sept. 16). In May, 1777, he took command of the Hudson highlands at Peekskill, which with Forts Montgomery and Clinton he abandoned in October, being out-manoeuvred by the British. After a few months' recruiting service in Connecticut he returned to the main army at White Plains. In the winter of 1778–79 he commanded the troops quartered near Redding, Conn. In May, 1779, he took command of the right wing on the west side of the Hudson. An attack of paralysis in Dec. 1779 terminated his active service in the war. He spent his last years on his farm in Brooklyn, Conn, where he died May 29, 1790. A bronze equestrian statue by Karl Gerhardt, over a sarcophagus, was erected at Brooklyn, Conn., by the State in 1888, and there is another statue (1874) in Bushnell park, Hartford, by J. Q. A. Ward.

Putnam was a brave, intrepid and very industrious soldier rather than a great general. His bluff heartiness has made him one of the popular heroes in American history.

See W. F. Livingston, *Israel Putnam, Pioneer, Ranger and Major-General* (1901) in the "American Men of Energy" series; I. N. Tarbox, *Life of Israel Putnam* (Boston, 1876); and *Essay on the Life of the Honorable Major-General Israel Putnam* (Hartford, 1788; enlarged ed., Boston, 1818), by David Humphreys, for a time Putnam's aide-de-camp.

PUTNAM, RUFUS (1738–1824), American soldier and pioneer, was born in Sutton, Mass., on April g, 1738 (O.S.). He served in the French and Indian War in 1757–60; was a millwright in New Braintree in 1761–68, during which time he studied surveying; and from 1769 until the American Revolution was a farmer and surveyor. He became lieutenant colonel in one of the first regiments raised after the battle of Lexington, and served before Boston. In 1777 he served in the Northern army under Gen. Horatio Gates, commanding two regiments in the second battle of Saratoga. In 1778 he laid out fortifications, including Ft. Putnam, at West Point, and in 1779 he served under Gen. Anthony Wayne after the capture of Stony Point. After the war he returned to Rutland, Mass., where he had bought a confiscated farm in 1780. In March, 1786, he founded, with other officers of the American Revolution, the Ohio Company of Associates for the purchase and settlement of Western lands. In Nov. 1787, he was appointed by the company superintendent of its proposed settlement on the Ohio, and in 1788 he led the small party which founded Marietta, Ohio. He was a brigadier-general in the army and a commissioner to treat with the Indians in 1792–93; was surveyor general of the United States in 1796–1803; and in 1802 was a member of the Ohio State Constitutional convention. He died, in Marietta, May 4, 1824. He has been called "the father of Ohio," and greatly contributed to its development.

See John W. Campbell, *Biographical Sketches* (Columbus, O., 1838); Sidney Crawford, "Rufus Putnam, and his Pioneer Life in the North-West," vol. xii., new series, pp. 431–454, *Proceedings of the American Antiquarian Society* (Worcester, 1899), and Rowena Buell (ed.), *The Memoirs of Rufus Putnam* (Boston, 1903), in which his autobiography, his journal and other papers, now in the library of Marietta College, are reprinted. His *Journal, 1757–1760,* dealing with his experiences in the French and Indian War, was edited with notes by E. C. Dawes (Albany, N.Y., 1886).

PUTNAM, a city of north-eastern Connecticut, U.S A , on the Quinebaug river, at the mouth of the Mill; the county seat of Windham county. It is served by the New York, New Maven and Hartford railroad. Population (1930) 7,318; (1940) 7,775. It manufactures cotton, woollen and silk goods, steam heaters and castings. The town of Putnam was formed in 1855 and named after Gen. Israel Putnam. The city was chartered in 1895.

PUTNIK, RADOMIR (1847–1917), Serbian general, was born on Jan. 25, 1847, at Kraguyevats. After serving against Turkey in 1876 and 1877, and against Bulgaria in 1889, he was made deputy-chief of the general staff, and professor at the military academy in Belgrade. The intrigues and favouritism introduced by the kings, Milan and Alexander, caused him to be placed on the retired list, but in the autumn following the military revolution of 1903 he was appointed general and chief of the general staff. In 1906 he succeeded General Gruič as minister of war, and again held that office in 1912, during the period when the military convention with Bulgaria was negotiated.

On the outbreak of war with Turkey Putnik was made *voivode* or marshal (being the first holder of that title) and commander-in-chief, and was responsible for the rapid success of the Serbian arms at Kumanovo, Prilep and Monastir. It was largely owing to his vigilance and foresight that the treacherous night attack by which the Bulgarians opened the second Balkan War (June 29, 1913) failed as it did. When the World War broke out, he was undergoing a cure at an Austrian watering place, and was at first placed under arrest, being later released by special order of the emperor Francis Joseph and conveyed to the Rumanian frontier. Despite impaired health he resumed the position of Serbian generalissimo and inflicted upon the forces of General Potiorek three successive defeats—on the Yadar (Aug. 16–20), the Drina (Sept. 8–19) and at Rudnik, which ended on Dec. 14, 1914 with an Austrian rout and the complete evacuation of Serbia. Putnik retained the supreme command during the triple invasion of Serbia in Nov. 1915, and shared the retreat of the Serbs through Albania. When, however, the exiled Government established itself at Corfu, he and most of his staff were placed on the retired list. He himself withdrew to France. He died on May 17, 1917, at Nice.

PUTTEE or **PUTTIE.** The name adapted from the Hindu *patti,* bandage (Skr. *patta,* strip of cloth), for a covering from the ankle to the knee, consisting of a long narrow piece of cloth wound spirally, and fastened by a tape, though straps may be used. For infantrymen, the winding commences at the ankle, but mounted men reverse the process as the rubbing against the horse causes the tape to come undone. Their advantages over leggings are that they are not "hard" on the legs, can be used as bandages or slings in case of need, and occupy less space when not in wear. Worn by most armies except the German in 1918, they have gradually disappeared in favour of short leggings.

PUTTENHAM, GEORGE (d. 1590), the reputed author of *The Arte of English Poesie* (1589). The book was entered at Stationers' Hall in 1588, and published in the following year. The writer of *The Arte of English Poesie* was educated at Oxford, and at the age of 18 he addressed an eclogue entitled *Elpine* to Edward VI. In his youth he had visited Spain, France and Italy, and was better acquainted with foreign courts than with his own. In 1579 he presented to Queen Elizabeth his *Partheniades* (printed in a collection of ms. *Ballads* by F. J. Furnivall), and he wrote the treatise in question especially for the delectation of the queen and her ladies. He mentions nine other works of his, none of which are extant. There is no direct evidence beyond Bolton's ascription to identify the author with George or Richard Puttenham, the sons of Robert Puttenham and his wife Margaret, the sister of Sir Thomas Elyot, who dedicated his treatise on the *Education or Bringing up of Children* to her for the benefit of her sons. Both made unhappy marriages, were constantly engaged in litigation, and were frequently in disgrace.

Many later "poetics" are indebted to this book. The original edition is very rare. Professor Edu-ard Arber's reprint (1869) contains a clear summary of the various documents with regard to the authorship of this treatise. The history of the Puttenhams is discussed in H. H. S. Croft's edition of Elyot's *Boke called the Governour. A* careful investigation brought him to the conclusion that the evidence was in favour of Richard. There are other modern editions of the book, notably one in J. Haslewood's *Ancient Critical Essays* (1811–15).

PUTTING THE SHOT, the modern form of stone putting, practised at the Irish Tailteann Games, began 1829 B.C. The adoption of a shot in preference to a heavy stone was suggested by the use of such a missile at military sports meetings which had access to an assortment of cannon-balls. The weight of the shot was first stabilized at 16 lb. at Dublin university sports in 1860, but a 14 lb. missile continued in use. The 16 lb. implement was known as a "weight," and the 14 lb. implement as a "stone." It is an event at which Irish athletes for many years were supreme, and in which the big man has an advantage Ralph Rose, U.S. whose 1909 world's record of 51 ft. stood until 1928, stood 6 ft. $5\frac{1}{2}$ in. and weighed 280 lb. J. Torrance, U S.A., holding the world's record of 57 ft. 1 in., is as tall and weighs about 330 lb. Other records are: Olympic, H. Woellke, Germany, 53 ft. $1\frac{1}{4}$ in., U.S.A., J. Torrance, 55 ft. 5 in.; English, R. L. Howland, 47 ft. $8\frac{1}{2}$ in.

For many years this event was practised from a 7ft square, the distance being measured from the first pitch of the shot to the front line of the square, or that line produced. Latterly, however, the square has been replaced by a 7ft. ring with a stop-board on the front half, the distance being measured from the pitch of the shot to the nearest point on the circle. The shot must be put from the shoulder with one hand only, without ever being brought behind the shoulder, and in which no part of the person of the competitor touches the top of the stop-board, the circle, or the ground outside the circle until the shot has touched the ground. The competitor rnay not leave the circle until his put has been marked, and he must then, from a standing position, leave the circle from the rear half.

The athlete, preparatory to making an attempt, takes up his position at the back of the circle. His weight is borne by his right leg: The shot is held on the centre joints of the fingers. The weight resting mainly upon the base of the middle two fingers;

the thumb and little finger support the shot at either side. The shot is held close to the neck in the hollow of the shoulder, with the elbow turned outward; the left foot, pointed forward, with toes resting on the ground, is separated from the right by some 18in. to 24in. The left foot is raised, the left leg is swung behind the right and is then kicked forward and up. At the same time the athlete hops, or glides, forward on his right foot so that it lands at the centre of the circle a fraction of a second before the left foot reaches the ground. During the glide the body is bent from the hips to the side of the hand holding the shot. As the feet take the ground the action is continued without any pause, but the body being fully extended. The drive comes from both legs, and the final effort is continued by the putting arm, and the wrist and fingers impart a final "flick" to the shot. The left leg provides a point of resistance. There must be a good follow through. After the shot has left the hand the position of the feet is quickly reversed, to help the athlete to retain his balance.

See F. A. M. Webster, *Athletes in Action* (1931); *Why—The Science of Athletics* (1936); Lawson Robertson, *Modern Athletics* (1932); Webster and Heys. *Exercises for Athletes* (1932); *Athletic Training for Men and Boys* (1933). (F. A. M. W.)

PUTTKAMER, ROBERT VON (1828–1900), Prussian statesman, was born at Frankfort-on-the-Oder on May 5, 1828. Puttkamer was the chosen instrument of the Clerical Conservative policy initiated by Bismarck when the growth of the socialist movement made it expedient to conciliate the Catholic Centre. As *Oberpräsident* of Silesia he had mitigated the rigour of the application of the "May laws," and as minister of public worship and of the interior he continued this policy. He was also the author of the ordinance of Jan. 2, 1880 on the simplification of German orthography. As minister of the interior Puttkamer's temper was in harmony with the view of Bismarck and the emperor William, and with their support he tried to re-establish the old Prussian system of rigid discipline from above. On his initiative, on Jan. 4, 1882, a royal ordinance required all officials to give the government their unconditional support at political elections. He also interfered with the liberty of public meetings, and attempted to suppress strike movements by force. This "Puttkamer régime" was intensely unpopular, and when the emperor Frederick III. succeeded to the throne Puttkamer was forced to resign (June 8, 1888). He was largely rehabilitated under William. He died at Karzin, in Pomerania, on March 15, 1900.

PUTTY. Originally tin oxide in a state of fine division used for polishing glass, granite, etc., now known as "putty powder" or "polisher's putty." The term is applied to cement composed of fine powdered chalk (whiting) or oxide of lead (white lead) mixed with linseed oil, either boiled or raw. It is used for fixing sheets of glass in frames, and for filling up nail-holes, etc., in woodwork. The oxidation of the oil hardens the putty and when it is required to dry quickly, boiled oil and sometimes litharge and other driers are used. Putty is also a fine lime cement employed by masons.

PUVIS DE CHAVANNES, PIERRE CÉCILE (1824–1898), French painter, was born at, Lyons or Dec. 14, 1824. His father was a mining engineer, the descendant of an old family of Burgundy. Pierre Puvis was educated at the Lyons College and at the Lycée Henri IV. in Paris, and was intended to follow his father's profession when a serious illness interrupted his studies. A journey to Italy opened his mind to fresh ideas, and on his return to France he went to study painting first under Henri Scheffer, and then under Couture. In 1852 he established himself in a studio in the Place Pigalle (which he did not give up till 1897), and there organized a sort of academy for a group of fellow students who wished to work from the living model. Puvis first exhibited in the Salon of 1850 a "Pietà." In 1852 and in the following years Puvis's pictures were rejected by the Salon, but the young painter was none the less warmly defended by Théophile Gautier and Théodore de Banville. His compositions at this early period show great variety, reflecting the influence of the Italian masters as well as of Delacroix and Couture. In 1859 Puvis reappeared in the Salon with the "Return from Hunting" (now in the Marseilles Gallery). But not till he produced "Peace" and "War" did he really impress his critics, inaugurating a vast series of decorative paintings. For these two works a second-class medal was awarded to him. In 1864 he exhibited "Autumn" and "Sleep." One of these pictures is now in the Lyons Museum, and the other at Lille. "Peace" and "War" were placed in the great gallery of the museum at Amiens, where Puvis completed their effect by painting four panels—a "Standard-Bearer," "Woman Weeping over the Ruins of her Home," a "Reaper," and a "Woman Spinning." Further decorations were ordered for the same building, and the artist presented to the city of Amiens "Labour" and "Repose." In 1865 a composition entitled "Ave Picardia Nutrix," allegorical of the fertility of the province, was added to the collection. In 1879 the city wished to complete the decoration of the building, and the painter executed the cartoon of "Ludus pro patria," exhibited in the Salon of 1881 and purchased by the state, which at the same time gave him a commission for the finished work. Meanwhile Puvis de Chavannes also painted easel pictures. To the Salon of 1870 he had sent a picture called "Harvest"; the "Beheading of John the Baptist" figured in the Great Exhibition of 1889; then followed "Hope" (1872), the "Family of Fisher-Folk" (1875), and "Women on the Seashore" (1879). Two paintings in the Palais Longchamp at Marseilles, ordered in 1867, represent "Marseilles as a Greek Colony" and "Marseilles, the Emporium of the East." After these, Puvis executed for the town-hall of Poitiers two decorative paintings of historical subjects: "Radegund," and "Charles Martel." The Pantheon in Paris also possesses a decorative work of great interest by this painter: "The Life of Saint Geneviève," treated in three panels. In 1876 the Department of Fine Arts in Paris gave the artist a commission to paint "Saint Geneviève giving Food to Paris" and "Saint Geneviève watching over Sleeping Paris," in which he gave to the saint the features of Princess Cantacuzene, his wife. At the time of his death—on Oct. 24, 1898—the work was almost finished. After completing the first paintings in the Pantheon, which occupied him for three years and eight months, Puvis de Chavannes undertook to paint the staircase leading to the gallery of fine arts in the Lyons Museum, and took for his subjects the "Vision of the Antique," a procession of youths on horseback, which a female figure standing on a knoll points out to Pheidias; the "Sacred Grove"; and two allegorical figures of "The Rhône" and "The Saône." It was in the same mood of inspiration by the antique that he painted the hemicycle at the Sorbonne, an allegory of "Science, Art, and Letters." At the Hôtel de Ville in Paris, Puvis decorated the grand staircase and the first reception-room These works occupied him from 1889 till 1893. In the reception-room he painted two panels, "Winter" and "Summer." The pictures in the Rouen Museum (1890–1892) show the artist's power of conceiving a scheme to decorate a public building with beautiful human figures and the lines of landscape. Puvis, as a rule, adhered to the presentment of the nude; here, however, in response to some critical remarks, he has clad his figures in modern dress. After prolonged negotiations, begun so early as in 1891, with the trustees of the Boston Library, U.S.A., Puvis de Chavannes accepted a commission to paint nine large panels for that building. These pictures, begun in 1895, were finished in 1898. In these works of his latest period Puvis de Chavannes soars boldly above realism. Puvis de Chavannes was president of the National Society of Fine Arts (the New Salon). His principal pupils are Ary Renan (d. 1900), Baudouin, J. F. Auburtin and Cottet.

See Marius Vachon, **Puvis** *de Chavannes* (1900); J. Buisson, "Puvis de Chavannes, Souvenirs Intimes," *Gazette des beaux-arts* (1899); L. Riotor, *Les Arts et les Lettres* (1901); A. Michel, *Puvis de Chavannes* (London 1912). (H. Fr.; X.)

PUY, a geological term used locally in Auvergne for a volcanic hill. Most of the puys of central France are small cinder-cones, with or without associated lava, whilst others are domes of trachytic rock, like the domite of the Puy-de-DBme. The puys may be scattered as isolated hills, or, as is more usual, clustered together, sometimes in lines. They probably became extinct in late prehistoric time. Puys are also found in the Eifel, on the Bay of

Naples, in the Swabian Alps of Wiirttemberg, and, as Sir A. Geikie has shown, in Scotland.

PUYALLUP, a city of Washington, U.S.A. It is served by the Chicago, Milwaukee, St. Paul and Pacific, the Great Northern, the Northern Pacific and the Union Pacific railways. Pop. (1920) 6,323 (87% native white); (1940) 7,889 by the federal census. It is famous for its berries and bulbs, and has three large fruit-canning and pre-cooling plants, besides several saw and shingle mills and veneer plants. It is the seat of the Western Washington agricultural experiment station of the state college and the annual Western Washington fair (attendance 264,000, 1940). A tablet across the river marks the site of the first blockhouse built in the valley. Puyallup was founded in 1853 by Ezra Meeker, and was incorporated in 1890, with Meeker as first mayor.

PUY-DE-DÔME, a department of central France, four-fifths of which belonged to Basse-Auvergne, one-sixth to Bourbonnais, and the remainder to Forez (Lyonnais). Area, 3,095 sq. miles. Pop. (1936), 486,103. It is bounded north by Allier, east by Loire, south by Haute-Loire and Cantal, and west by Corrkze and Creuse. The famous plain of the Limagne, watered by the Allier and its tributary, the Dore, has on its western flank the volcanic Puys and Monts Dore, while on its eastern side rises the largely granitic heights of the Forez (5,380 ft.). The Puys include a number of craters, now dead and often filled by lakes, which also occur behind lava dams in the valleys. The Puy de Sancy (6.188 ft.) is the highest crater, but the Puy de Dôme (4,806 ft.) gives its name to the department and has a meteorological observatory on its summit, once crowned by a Roman temple, the ruins of which still exist.

The climate of Puy-de-DBme is usually very severe, owing to its high level and its distance from the sea; the mildest air is found in the northern valleys, where the elevation is least. During summer the hills about Clermont-Ferrand, exposed to the sun, become all the hotter because their black volcanic soil absorbs its rays. On the average 25 or 26 in. of rain fall in the year; in the Limagne, around which the mountains arrest the clouds, rainfall is less. Nevertheless the soil of this plain, consisting of alluvial deposits of volcanic origin, and watered by torrents and streams from the mountains, makes it one of the richest regions of France. In the highest altitudes the rainfall attains 64 inches.

About two-thirds of the inhabitants of the Puy-de-Dôme are engaged in agriculture. The Limagne yields a variety of products and the vine flourishes on its hill-sides. The high mountains provide pasture for large flocks of cows and sheep, and cheese-making is an important industry. The intermediate region is cultivated mainly for cereals, the chief of which are wheat, rye, oats and barley. Potatoes are largely grown, and peas, beans, beetroot, colza and tobacco. The Limagne produces fruit of all kinds—apricots cherries. pears, walnuts and apples, yielding considerable quantities of cider. The department possesses considerable mineral wealth. There are important coal-mines at Brassac on the Allier, on the borders of Haute-Loire, at St. Eloy near the department of Allier, and at Bourg-Lastic on the borders of Corrèze. Peat, asphalt, bituminous schists, antimony, mispickel and argentiferous lead are also worked. Of the last named there are mines and foundries at Pontgibaud on the Sioule. Amethysts and other rare minerals are found, and there are numerous stone-quarries. Mont Dore, Royat and La Bourboule are watering places. The springs of St. Nectaire contain sodium and iron chlorides and bicarbonates. The waters of Châteauneuf (on the Sioule), also known to the Romans, contain iron bicarbonates; those of Châtelguyon, like the waters of Carlsbad and Marienbad, are also widely known, and there are many other mineral springs of varied character. Manufactures are grouped around Thiers, which produces a large amount of cheap cutlery, and Clermont-Ferrand, the capital The textile industry includes uool-carding and making of linen cloths, bunting, clothing manufactories for lace and for rubber (Clermont-Ferrand), sugar-works, manufactures of edible pastes and of fruit-preserves. The department exports grain, fruits, cattle, wines, cheese, wood, mineral waters, cutlery. etc. It is served by the Orléans and P.L.M. railways. Many thousands of the inhabitants, chiefly of the district of Ambert, leave it during winter and find work elsewhere.

The department comprises 4 arrondissements—Clermont-Ferrand, Issoire, Riom, Thiers—50 cantons and 473 communes. Clermont-Ferrand is the seat of the bishopric and the *académie* (educational division); court appeals are heard at Riom.

The chief towns are Clermont-Ferrand, Issoire, Thiers, Riom, Ambert, Mont-Dore-les-Bains, La Bourboule and Royat. Near Clermont-Ferrand is Mt. Gergovie (see GERGOVIA), the scene of the victory of Vercingetorix over Julius Caesar. Billom, Chamalières, Courpière, Orcival, St. Nectaire and St. Saturnin possess churches in the Romanesque style of Auvergne. There are interesting ruined feudal strongholds at Murols and Tournoël (near Volvic). Vic-le-Comte has a beautiful sainte-chapelle, and Aigueperse has a Gothic church of the 13th to the 15th century. Near Pontgibaud are the ruins (13th century) of the Carthusian abbey of Port St Marie.

PWLLHELI ("salt pit," or "pool"), a municipal borough, seaport and market town of Caernarvonshire, north Wales, 21 mi. S.W. of Caernarvon with station on the G.W.R. Pop. (1938) 3,578. Area 1.8 sq.mi. It has a sandy beach on the north side of Cardigan bay, on the shore of Tremadoc bay. The town was incorporated by Edward the Black Prince. Pwllheli commands a good view of the Merionethshire and Snowdon mountains.

PYANEPSIA, an ancient festival in honour of Apollo, held at Athens on the 7th of the month Pyanepsion (October). A hodge-podge of pulse was offered to Apollo. Another offering was the *eiresiōnē,* a branch of olive or laurel, bound with purple or white wool, round which were hung fruits of the season, pastries, and small jars of honey, oil and wine. Both are old pieces of rustic magic, for which many analogies can be found elsewhere. It was carried in procession to the temple of Apollo where it was suspended on the gate by a boy whose parents were both alive. The doors of private houses were similarly adorned. The branch was allowed to hang for a year, when it was replaced by a new one, since by that time it was supposed to have lost its virtue. During the procession a chant (also called *eiresiōnē*) was sung, the text of which has been preserved in Plutarch (*Theseus,* 22).

Aetiologists connected both offerings with the Cretan expedition of Theseus, who, when driven ashore at Delos, vowed a thank-offering to Apollo if he slew the Minotaur, which afterwards took the form of the *eiresiōnē* and Pyanepsia. His comrades on landing in Attica gathered up the scraps of their provisions which explains the origin of the hodge-podge.

See W. Mannhardt, *Wald- und Feldkulte,* ii., 214, for an exhaustive account of the *eiresiōnē* and its analogies; Sir J. G. Frazer, *Golden Bough,* vol. ii., pp. 48, 71; A. Mommsen, *Feste d. Stadt Athen,* p. 278. et seq.; J. E. Harrison, *Prolegomena to Greek Religion,* ch. iii.; L. R. Farnell, *Cults of the Greek States,* iv. 286.

PYAPON, a town in Burma, on the Pyapon river. Pop. (1931) 12,338. The district, formed in 1903, lies within the delta of the Irrawaddy. It is intersected by creeks and liable to inundation at high spring tides. The jungle is being reclaimed for rice, which is the sole crop. Area, 2,148 sq m.; pop. (1921) 288,994, showing an increase of 32,779 in the decade. The district has no railways and few roads, communication being by water. Other urban centres, which ship the rice to Rangoon, are Kyaiklat (9,224 in 1921), and Dedayè (5,568 in 1921).

PYAT, FELIX (1810–1889), French communard, was born at Vierzon (Cher) on Oct. 4, 1810, the son of a Legitimist lawyer. Called to the bar in Paris in 1831, he threw his whole energies into journalism. The violent personalities of a pamphlet entitled *Marie Joseph Chénier et le prince des critiques* (1844), in reply to Jules Janin, brought him a six months' sojourn in La Pélagie, in the cell quitted by Lamennais. In 1848 George Sand, whom he had introduced in 1830 to the staff of the *Figaro,* now asked Ledru-Rollin to make him commissary-general of the Cher. After three months' tenure of this office he was returned by the department to the Constituent Assembly, where he voted with the Mountain, and brought forward a motion for the abolition of the presidential office. About this time he fought a duel with Proudhon, who had called him the "aristocrat of the democracy." He joined Ledru-Rollin in the attempt of June 13, 1849, after which he sought refuge in Switzerland. Belgium, and finally in England. For a glorification of regicide at the time the Orsini attempt against Napoleon III. he was brought before an English court, but acquitted, and the general amnesty of 1869 permitted his return to France, but further outbursts against the authorities compelled his return to England. The revolution of Sept. 4 brought him back to Paris, and it was he who in his paper *Le* Combat displayed a black-edged announcement of the *pourparlers* for the surrender of Metz. After the insurrection of Oct. 31, he was imprisoned for a short time. In Jan. 1871, *Le Combat* was suppressed, only to be followed by an equally virulent *Vengeur*. Elected to the National Assembly, he retired from Bordeaux with Henri Rochefort and others until such time as the "parricidal" vote for peace should be annulled. He returned to Paris to join the committee of public safety, and, in Hanotaux's words, was the *âme ulcérée* of the Commune, but was blamed for the loss of the fort of Issy. He was superseded there by Delescluze, but he continued to direct the violent acts of the Commune, the overthrow of the Vendôme column, the destruction of Thiers's residence and of the expiatory chapel built to the memory of Louis XVI. He escaped across the frontier, and, though condemned to death in 1873, the amnesty of July 1880 permitted his return. He was elected to the Chamber of Deputies in 1888, but died at Saint-Gratien on Aug. 3, 1889.

PYATIGORSK, a town of Russia in the North Caucasus on the Podkoumok river and on a plateau 1,680 ft. above sea-level, hence its name ("five mountains"). Its sulphur springs, about 15 in number, vary from 75° to 96° F and are used for drinking and bathing and are bottled for export. The first buildings were erected in 1812 and a great impetus was given to the town when it was linked with the Rostov-on-Don to Baku railway. Its population in 1933 was 60,000. Its springs had long been known to the Circassians of the district who addressed a petition to Ivan the Terrible in 1551 asking for protection against the Crimean Tatars. The poet M. Y. Lermontov (1814–41) was killed here in a duel. In 1918 a skeleton, apparently Neanderthal, was reported.

PYCNOGONIDA, also known as Pantopoda or Podosomata, a small group of marine Arthropoda characterized by a very small body and disproportionately long legs. The facts that there are usually four pairs of legs and, typically, a pair of chelate or pincer-like appendages in front of the mouth, have led to the Pycnogonida being associated with the Arachnida in most systems of classification, but the relationship is not close.

The body is composed of an unsegmented anterior head region followed by three, rarely four, somites which may be free or more or less coalesced, and a minute terminal piece which bears the anus. The legs, as a rule, are exactly alike, and are attached, the first pair to the head region and the others to the following three (or four) somites. The triangular mouth-opening is at the end of a proboscis which may be as long or longer than the rest of the body. In the more typical genera, such as *Nymphon,* the head-region carries, in front of the first legs, three pairs of appendages, the chelate chelophores above and in front of the proboscis, followed by a pair of sensory palps and a pair of leg-like ovigers which get their name from the fact that they are nearly always used, in the male, to carry the eggs received from the female. Some or all of the appendages of the first three pairs may be reduced or absent in the adult, although they are probably always present in the young.

The internal structure is simple, with some peculiarities due to the reduced size of the body compared with the legs. The proboscis contains a suctorial pharynx, but the greater part of the digestive cavity is formed by the immensely long diverticula which extend from the alimentary canal into each of the legs. There is a tubular dorsal heart with two or three pairs of lateral ostia hut no definite blood-vessels. The nervous system consists of a supra-oesophageal ganglion or "brain" and a ventral chain of six to eight ganglia. The eyes, when present, are four in number, simple in structure, and elevated on a tubercle on the dorsal surface of the head. The gonads lie, to begin with, in the body, but send long diverticula into the legs, and the ripening eggs are lodged in the swollen fourth segments of these appendages. The genital apertures are on the second segments of the legs.

It is very characteristic of the Pycnogonida that the males take charge of the eggs as they are extruded by the females and carry them, cemented together in packets, on the ovigers. In a few genera, however, the egg-packets have never been seen and the mode of oviposition is unknown.

Not much is known of the habits of Pycnogonida. Most species are found clambering in ungainly fashion among the branches of hydroids or other coelenterates. Some are known to swim by beating the water with their long legs. Many species, perhaps all, feed upon the soft tissues of coelenterates which they suck into the mouth by dilating the pharynx. The distribution of the Pycnogonida extends to all seas, and in arctic and antarctic waters they sometimes occur in vast numbers. The affinities of the Pycnogonida are very obscure. (W. T. C.)

PYCNOSTYLE, the architectural term given by Vitruvius to the inter-columniation (*q.v.*) of a temple, when the distance between these columns was equal to 1½ times their diameter.

PYDNA, BATTLE OF (168 B.C.). The Roman operations in Greece having lingered on for some time, Lucius Aemilius Paullus, "one of the few Romans of that age to whom one could not offer money," was sent to hasten a decision. Arriving at Heracleum he at once seined the pass of Pythium, which compelled Perseus king of Macedonia to fall back on Pydna.

The serried ranks of the Macedonian phalanx astonished and terrified Paullus, who, however, disguised his anxiety from his men, and advanced towards his enemy. The Roman vanguard was dispersed and one cohort almost annihilated. Once again the sarissa (pike) carried all before it, the Roman legions being forced back until they reached the hill upon which stood their camp. Here, on account of the broken nature of the ground, the phalanx became somewhat disorganized. Paullus at once sizing up the situation "commanded his men, that wherever they should see the line of the enemy present openings, they should individually rush to these spots, and insinuating themselves like a wedge into such spaces, however narrow their extent, they should fight with impetuosity" (Livy). These tactics resulted in complete success, the phalanx being disjointed and broken up into a number of separated bodies. The II. legion then charged the disorganized mass of pikemen and routed it. Perseus and his cavalry fled the field leaving the infantry to be slaughtered—20,000 were killed and 11,000 made prisoners. This battle was the last fought by the phalanx. The whole campaign was only fifteen days. Thus perished the empire of Alexander the Great 144 years after his death.

PYE, HENRY JAMES (1745–1813), English poet laureate, was born in London on Feb. 20, 1745, and educated at Magdalen college, Oxford. Of all he wrote his prose *Summary* of *the Duties* of *a Justice* of *the Peace out of Sessions* (1808) is most worthy of record; it is based on his own experience as a magistrate at Westminster. He was made poet laureate in 1790, perhaps as a reward for his faithful support of Pitt in the House of Commons. The appointment was looked on as ridiculous, and his birthday odes were a continual source of contempt. His most elaborate poem was an epic, *Alfred* (1801). He was the first poet laureate to receive a fixed salary of £27 instead of the historic tierce of Canary wine. He died at Pinner. Middlesex, on Aug. 11, 1813.

PYGMALION, (1) son of Cilix, and grandson of Agenor, king of Cyprus. He fell in love with an ivory statue he had made; Aphrodite granted life to the image, which he married (Ovid. *Metam.* x. 243). There is no ancient authority for the introduction of the name Galatea. (2) Brother of Dido (*q.v.*).

PYGMY, a term for a diminutive human being. Homer, in the *Iliad* (iii. 6) uses it of a race of tiny folk dwelling in a far southern land, whither the cranes fly when inclement winters and piercing frosts visit the northern shores. Fierce battles were often mentioned by later writers as occurring between the pygmies and cranes, and were even represented on their vases. On these the pygmies were depicted as dwarfs with large heads, negro features. close, curly hair, and sometimes armed with lances. Aristotle firmly believed in the existence of these pygmies, whom he characterized as a race of men of small stature inhabiting the marshes of upper Egypt towards the sources of the Nile. Herodotus (ii. 32), describes how five Nasamonians, while journeying through the African desert, came at last to a plain where fruit-trees grew. While gathering the fruit they were seized by some dwarfish men of strange speech, who led them to a town, where dwelt people of a similar appearance, and near which a great river flowed from west to east containing crocodiles. This river was probably the Niger, and the people referred to were no doubt the ancestors of the existing pygmies of equatorial Africa. Representations of pygmies are sculptured on the tombs at Sakkarah, the Vth Dynasty, *c.* 2500 B.C. They faithfully reproduce the racial characteristics of the present race of pygmies inhabiting the Ituri and Central forests.

BY COURTESY OF THE FIELD MUSEUM OF NATURAL HISTORY
BATAK PYGMY MAN AND WOMAN OF THE ISLAND OF PALAWAN, P.I.

Pliny mentions dwarfed races in both Asia and Africa, of the Catizi dwarfs in Thrace, and a similar race in Caria. Ctesias, a century after Herodotus, described a race of pygmies in the heart of India, as black and ugly, and only two *pygmai* in height. The Chinese author, Chao Fu-Kua, in the beginning of the 13th century, described a tribe of black pygmies dwelling in the Philippine Islands, called Hai-tan, small in size, with round, yellow eyes, curly hair, and with the teeth showing through their lips, no doubt the ancestors of the present Aetas. The existing pygmy races are divided into two groups: (a) the African pygmies, Negrillos, (b) the Asiatic pygmies, Negritos (*q.v.*).

PYLE, HOWARD (1853–1911), American artist and writer, was born at Wilmington (Del.), on March 5, 1853, He was a pupil of the Art Students' league, New York, and first attracted attention by his line drawings after the manner of Albrecht Diirer. His brilliant work as an illustrator made him one of the foremost of American artists, his drawings to illustrate American colonial life, particularly in New England and New Amsterdam, being especially noteworthy; and he published a number of books of fiction, written and illustrated by himself. He also became prominent in decorative painting, his works including "The Battle of Nashville" for the capitol at St. Paul (Minn.), and "The Landing of Carteret" for the Essex county court house, Newark (N.J.). At his home in Wilmington (Del.), he established a school of art, instruction being gratuitous, and many successful American illustrators were educated there. In 1907 Howard Pyle was elected a member of the National Academy of Design. He died in Florence on Nov. 9, 1911.

PYLOME, in zoology, is the name which is given to the principal opening (or openings) of the shell (theca, test) of various Protozoa. See FORAMINIFERA; RADIOLARIA.

PYLON, in architecture, originally a gate, but in modern usage reserved to the huge truncated pyramidal forms, crowned with cornices, that flanked the entrances to Egyptian temples. The term is also applied to any similar large masses of masonry, often decorated with sculpture or architectural forms, used to flank the entrance to an avenue, a plaza or a bridge—especially a suspension bridge. (See BRIDGES; EGYPTIAN ARCHITECTURE.)

PYLOS (mod. Navarino), a town and bay on the west coast of Messenia, noted chiefly for the part it played in the Peloponnesian War. The bay, roughly semicircular, is protected by the island of Sphacteria (mod. Sphagia), over $2\frac{1}{2}$ m. long. To the north lies the lagoon of Osman Aga. North of Sphagia is the rocky headland of Pylos or Coryphasium, called in modern times Palaea-Navarino or Palaeokastro, from the Venetian ruins on its summit. Most scholars have identified this with the Homeric Pylos, the home of Neleus and Nestor, and a cave on the north slope of Coryphasium is pointed out as that in which Hermes hid the stolen cattle of Apollo. But this view presents considerable difficulties, and Strabo (viii. 348, *sqq.*) argued that the Pylos of Nestor must be the place of that name in Triphylia, now known to have been an important prehistoric site. After the Dorian migration Pylos declined, and it is referred to by Thucydides (iv. 3) as a deserted headland in 425 B.C. In May of that year, the seventh of the Peloponnesian War, the Athenians sent an expedition to Sicily under command of Eurymedon and Sophocles. With them was the general, Demosthenes, who landed at Coryphasium with a body of Athenian troops and hastily fortified it. The Spartans, who were then invading Attica, withdrew their forces and attacked Pylos vigorously by sea and land, but were repulsed, and the Athenians were enabled by the arrival and victory of their fleet to blockade on the island of Sphacteria a body of 420 Spartiates with helots. Their resistance was overcome by a rear attack directed by a Messenian, who led a body of men by a difficult path along the cliffs on the east, and the 292 Spartan survivors laid down their arms 72 days after the beginning of the blockade. Their surrender made a deep impression on the whole Greek world, which had learned to regard a Spartan surrender as inconceivable. Though Pylos should have been ceded to Sparta under the peace of Nicias (421 B.C.) it was retained by the Athenians until the Spartans recaptured it early in 409 B.C. (Diodorus xiii. 64).

In the middle ages the name Pylos was replaced by that of Avarino (Ἀβαρῖνος) or Navarino, derived from a body of Avars who settled there; the current derivation from the Navarrese company, who entered Greece in 1381 and built a castle at this spot, cannot now be maintained (*Eng. Hist.* Review, xx. 307, xxi. 106; *Hermathena,* xxxi. 430 sqq.). From 1498 to 1821 Navarino was in the hands of the Turks, save at two periods when it was held by the Venetians, who named it Zonklon. (See NAVARINO, THE BATTLE OF.)

PYM, JOHN (1584–1643), English statesman, son and heir of Alexander Pym, of Brymore, Somersetshire, a member of an ancient family which had held this seat in direct male descent from the time of Henry III. He matriculated as a commoner at Broadgates Hall (now Pembroke College), Oxford, in 1599, and entered the Middle Temple in 1602. He became receiver-general of the king's revenue for Wilts., and was returned to parliament as member for Calne in 1614 and again in 1621. To the committee appointed to consider the state of religion he made his first great speech on Nov. 28, 1621; he spoke in defence of maintaining the disabilities of Roman Catholics on political grounds, and moved for a special commission for the suppression of recusancy. Pym was a chief promoter of the petition which incurred James's violent displeasure, and of the Commons' answer defending their privileges, which was afterwards torn from the records by the king's own hand. On the dissolution of parliament which immediately followed, Pym, with other "ill-tempered spirits," was arrested in Jan. 1622, and was confined first to his house in London, and then to Brymore. He associated himself with the party of Francis, 4th earl of Bedford, mas returned for Tavistock in 1624, and represented this borough in all the ensuing parliaments.

On May 8, Pyrn was manager of Buckingham's impeachment. In the third parliament of Charles I., in 1628, Pyrn overruled Eliot in deciding that Buckingham's impeachment should now be subordinated to the struggle on general grievances. He zealously pushed on the Petition of Right, resisting the clause added by the Lords to safeguard the king's "sovereign power," declaring that "he knew not what it was." He carried up to the Lords the impeachment of Roger Manwaring, and delivered a famous speech (June 9) in which he expounded the fundamental principles which guided his policy.

His name is not mentioned as actively resisting Charles's arbitrary government during the eleven years which followed the dissolution of 1629. It has not been proved that Pym, with Hampden and Cromwell, actually embarked for New England and was prevented from sailing by orders from the government. Pyrn himself was directly interested in the colonies, being patentee of Connecticut and Providence, and of the latter company also treasurer, and there can be little doubt that like other leaders of the opposition, he regarded America as a possible refuge.

Short Parliament.--On the assembly of the Short Parliament on April 13, 1640, Pym was the acknowledged leader. "Whilst men gazed upon each other," says Clarendon (*Hist.* ii. 68), "looking who should begin (much the greater part having never before sat in parliament), Mr. Pym, a man of good reputation . . . who had been as long in these assemblies as any man there living, broke the ice." On April 17 he spoke for nearly two hours on the national grievances, pointed out the practical injury inflicted on commerce and every sort of enterprise including colonial expansion by illegal and arbitrary taxation, and concluded by asking the Lords to join in finding out causes and remedies. His words made a deep impression. On April 27 he resisted the grant of supply, and when the Lords passed a resolution that supply should precede the discussion of grievances, Pym, as manager of the Commons on May 1, read them a severe lecture on the breach of privilege they had committed. Finally, on the 4th, it was resolved that Pyrn should next day petition the king to make terms with the Scots, to avoid which Charles summarily dissolved the parliament.

All the energies of Pyrn were now concentrated on obliging Charles to summon another parliament. He was the author of the petition of the twelve peers to the king for redress of grievances and for calling a new parliament, and he was the promoter of the petition signed by 10,000 citizens of London. In company with Hampden he rode through the provinces, rousing and organizing public opinion. Meanwhile Charles's attempt to implicate Pym in treasonable communications with the Scots failed.

Long Parliament.—When the king was forced to call the Long Parliament (Nov. 3), Pyrn was its acknowledged author and leader. On Nov. 7 he moved for a sub-committee to examine into Strafford's conduct in Ireland. The latter's sudden arrival at London on the 9th with the intention of instantly impeaching the popular leaders of treason was met by Pyrn with corresponding quickness and resolution. On the 11th, after a debate of four hours in the Commons, by his directions with locked doors, he carried up Strafford's impeachment to the Lords, and rendered him at once powerless.

On Dec. 6 he moved the impeachment of Laud. He was the chief promoter of the case against Strafford, while the attempts of the queen to gain him over were without result, and Jan. 28, 1641 he brought up to the Lords the list of charges. To the attainder, which was at this stage resolved upon, he was opposed (since he clung to the more judicial procedure by impeachment), but when overruled he supported it, at the same time procuring that the legal arguments should not be interrupted. He delivered his final speech on April 13, a great oratorical performance, when he again appealed to the Elizabethan political faith and to that of Bacon, who had so severely censured any action which divided the king from the nation. The man who violated this union was guilty of the blackest treason. "Shall it be treason," he asked, "to embase the King's coin though but a piece . . . of sixpence . . . and not to embase the spirits of his subjects: to set a stamp and character of servitude upon them?" Towards the end of his tremendous indictment of Strafford, Pyrn broke down, fumbled among his papers, and lost the thread of his argument. But his temporary failure did not diminish the force and effect of his words, all the more impressive because actually spoken in the presence of the sovereign. "I believe," wrote Baillie (Letters, i. 348) "the king never heard a lecture of so free language against his idolized prerogative."

Attempts were now once more made to gain over Pyrn to the administration. He had two interviews with the king, but without result, and Charles again determined to resort to force. On May 2 he endeavoured to get possession of the Tower. On the 3rd the Protestation, on Pym's motion, was taken by the Commons within closed doors, and afterwards circulated in the country, and on the 5th Pyrn disclosed the army plot. These incidents decided the struggle and Strafford's fate. Pyrn also took the lead in the religious controversy. During the dispute between the two houses on this question on Feb. 8–9, 1641, while supporting the London petition for the abolition of the bishops, he had declared his opinion that "it was not the intention of the House to abolish episcopacy or the Book of Common Prayer, but to reform both wherein offence was given to the people." This, no doubt, expressed his real intentions and policy. When, however, it became clear that the bishops were merely the nominees of the king to carry out "innovations in religion" and preach arbitrary government, Pyrn was easily persuaded to support their abolition, and voted in opposition to the moderate party for the Root and Branch Bill of May 1641, and again for taking away their votes in October. But in his "Vindication," published in March 1643, he especially states that his action with regard to the bishops in "no way concluded me guilty of revolt from the orthodox doctrine of the Church of England."

The first act in the great political struggle had ended in the complete triumph of Pym. His chief care now was to defend the parliament from violence, since this was the only method of retaliation left at the king's disposal, and on Nov. 22 he made a great speech on the Grand Remonstrance, of which he was the chief promoter, when he referred to plots "very near the king, all driven home to the court and popish party."

Charles returned on the 25th. He immediately substituted a force commanded by Dorset for the guard already placed at Westminster, but was compelled to withdraw it, and on Pym's motion the house appointed its own watch. Charles appointed Lunsford to the Tower, rejected the Grand Remonstrance and the Impressment Bill, and began to assemble an armed force. In consequence Pyrn urged, but unsuccessfully, on Dec. 30 the summoning of the train-bands to guard the parliament, and moved the impeachment of the bishops, who had declared the proceedings of the parliament to be sinful and illegal. At the critical moment, however, Charles wavered. He renewed his offer to Pyrn of the exchequer on Jan. 1, 1642, and on his refusal, he determined on the impeachment of the five members on Jan. 3. But these had been forewarned of the king's plans, and when on the 5th he entered the House of Commons with an armed band to seize them, they had removed themselves in safety. (See LENTHAL, WILLIAM.) Charles's first look on entering was for his great opponent, and he was greatly disconcerted at not finding him in his usual place. To his question "Is Mr. Pyrn here?" there was no answer, and nothing remained but to retreat with his mission completely unachieved. The second act in the great national drama had thus, as the first, ended in a victory for Pym. On the 11th, with the other members, he was escorted in triumph back to Westminster, and while the other four stood uncovered, Pym returned thanks from his place to the citizens.

Civil War.—When war broke out, Pym remained at headquarters in control of the parliament and executive, and on July 4 was appointed to the committee of safety which directed the movements of the parliamentary forces. His attitude was firm but moderate. He opposed the attempt to prevent Colepepper giving the king's message to the house on Aug. 27 when Charles declined to receive the petition of parliament and advanced on London Pym proposed (Oct. 20) the parliamentary covenant, and that those who refused it should be "cast out of the House." He succeeded in overcoming the opposition in the city to the heavy taxation now imposed. After repeated efforts to secure peace had failed, he proposed in order to carry on the war an excise, hitherto unknown in England, which met with the same violent hostility afterwards aroused by Walpole's scheme. In March he published a "Declaration and Vindication" of his public conduct, in which he threw the whole blame of the appeal to arms on the opposite party, and expressed his fidelity to the Church and constitution. In May he entered, together with the other leaders, into resultless negotiations with the queen, and on the 23rd he took up her impeachment to the Lords. In June he reported on Waller's plot, which exposed the insincerity of Charles's negotiations, and on June 26 wrote a "sharp letter" to Essex on his inaction. In July, after the defeat at Adwalton Moor, he prevented the house from again initiating negotiations for peace, which he declared "full of hazard and full of danger," and on Aug. 3, after having visited Essex at Kingston, persuaded him to separate himself from the peace propositions of the Lords and to march to relieve Gloucester. He thus incurred the hatred of the peace party, and on Aug. g a mob of women surrounded the house calling for Pym's destruction, and were not dispersed without some bloodshed.

Pym had already proposed (Jan. 3) to the house an alliance with the Scots, and the Royalist victories now induced parliament to consent to what had before been rejected. The establishment of Presbyterianism was accepted by Pym as a disagreeable necessity, and he was one of the first to take the covenant (Sept. 25). This alliance, which was afterwards destined to have so decisive an influence on the military campaign, and was the first occasion on which the two nations had united in public action, closes Pym's career. He was made master of the ordnance on Nov. 8, but died Dec. 8 at Derby House. He received a public funeral in Westminster Abbey, whence his body was ejected at the Restoration. A sum of £10,000 was voted by the parliament to pay Pym's debts and provide for his family. About 1614 Pym married Anne Hooke, or Hooker (d. 1620), by whom he had five children, including two sons, Alexander, who died unmarried, and Charles, who was created a baronet; this title, together with Pym's male line, became extinct in the person of Pym's grandson Charles in 1688, Brymore then passing to his sister Mary, wife of Sir Thomas Hales, Bart.

Character.—Pym had little of the Puritan in his character or demeanour. His good humour, humanity and cheerfulness in all circumstances, "his pleasant countenance and sweet behaviour," were marked characteristics; the aspersions, however, on his morals, as well as the accusations of bribery, are completely unsubstantiated and discredited. Pym's eloquence lay rather in the clearness of his expression and in the depth and solidity of his ideas than in the more showy arts of oratory.

The article on Pym by S. R. Gardiner, in the *Dict. Nat. Biog.* with its references to authorities, must be supplemented by the same author's *Hist. of England and of the Civil War*. Pym's life has also been ivritten at length by J. Forster in Lardner's *Cabinet Cyclopaedia, Eminent British Statesmen*, vol. iii., and by Wood in *Ath. oxon* iii. 72, who adds a list of Pym's printed speeches. His character, drawn by Clarendon, *Hist.* iii. 30 and vii. 409, is inaccurate and obviously prejudiced. See also J. Fosster's *Grand Remonstrance, Arrest of the Five Members, Life of Sir J. Eliot;* Verney's *Notes of the Long Parliament;* Whitelocke's *Memorials* (needing corroboration of other authorities); R. Baillie's *Letters; Eng. Hist. Rev.* xvii. 736; Rushworth's *Collections; Thomason Tracts, E* 153 (10), 63 (8), 172 (14), 164 (3), 200 (13) (26) (37) (49) (65), 199 (24) (49), 78 (13); *Somers Tracts* iv. 217, 355, 461, 466; *Affaniae* and *Death's Sermon*, by C. Fitzgeffrey; *Add. MSS*. Brit. Mus. 14,827; 11,692; *Lords and Commons Journals*. There are a large number of references to Pym in *Calendars of State Papers Dom.* 1619–1643, and *Colonial Series* 1574–1660, and in the *Hist. MSS. Comm. Series*; but the supposed notebook of Pym mentioned in *Rep.* x. app. vi. 82, has been shown by Gardiner to be that of another person (*Eng. Hist. Rev.*, Jan. 1895, p. 105).

PYORRHOEA is a term used to designate any one of a group of diseases (periodontoclasia or pyorrhoea alveolaris) which attack the gums and bone around the teeth. They include ulatrophia (recession of the gums), gingivitis (inflammation of the gums), alveolar resorption (wasting of the bony socket), pericementoclasia (pus pocket formation). Vincent's gingivitis, erroneously called Vincent's angina, also trench mouth, is an acute gingivitis caused by the fusiform bacillus and spirochaete of Vincent. It is the only type of periodontoclasia which is communicable. These diseases have a direct sequential relationship, although they do not always occur in the same order. A typical case may begin as recession associated with slight alveolar resorption: later it merges into gingivitis with advancing alveolar resorption; finally it develops a pus pocket (pericementoclasia), due to the detachment of the gum from the root, and still more advanced alveolar resorption. Unless checked by correct treatment this results in the loss of the tooth.

Knowledge as to the cause of periodontoclasia, while still incomplete, has advanced so far that rational treatment is now possible, and, in skilful hands, success is obtainable in nearly all cases. While infection plays a prominent part, the important factor is some influence which depresses the resistance of the tissues, thereby making infection possible. In a large percentage of cases the important depressant is an inequality of the biting surfaces of the teeth known as traumatic occlusion, resulting in unequal distribution of pressure when the jaws are brought together. Deposits of tartar, long regarded as the important factor, now only share the responsibility. Improper diet is regarded as important in the causation of periodontoclasia. This is apparently due to a failure to develop strong, resistant, supporting tissues for the teeth, because of dietary deficiencies. After the disease has become established dietary improvement is relatively ineffective.

Treatment includes the following, given in the order of their usual importance: equalizing functional stresses; raising local resistance by massage of the gums; removal of deposits of tartar, etc.; maintaining cleanliness; and building up general resistance by attention to nutrition. Preventive treatment follows the same lines, with special emphasis on stimulating the blood supply by tooth-brush massage. Orthodontic treatment, by helping to equalize functional stresses, helps in treatment and prevention.

Foci of infection may develop in the later stages of the disease, owing to the absorption of toxic material from the pus-pockets into the circulation. Also when the pocket extends to the end of the root, a typical abscess is produced. Advanced pyorrhoea or periodontal disease may usually be detected in the X-ray film, which registers the resorption of alveolar bone accompanying this disease. (J. O. McC.; P. R. S.)

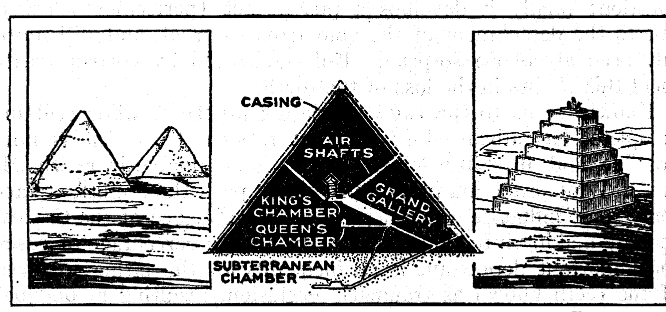
PYRAMID, the name for a class of buildings, first taken from a part of the structure,[1] and mistakenly applied to the whole of it by the Greeks, which has now so far acquired a more definite meaning in its geometrical sense, that it is desirable to employ it in that sense alone. A pyramid therefore should be understood as meaning a building bounded by a polygonal base and plane triangular sides which meet in an apex. (For figures of geometrical pyramids see CRYSTALLOGRAPHY, and for their mensuration see MENSURATION.) Such a form in architecture is best known in Middle Egypt, during the period from the IVth to the XIIth Dynasty (before 3000 B.C.)—having square bases and angles of about 50°. In other countries various modifications of the tumulus, barrow or burial-heap have arisen which have come near to this type; but these when formed of earth are usually circular, or if square have a flat top, and when built of stone are always in steps or terraces.

The origin of the pyramid type has been entirely explained by the discovery of the various stages of development of the tomb. In prehistoric times a square chamber was sunk in the ground, the dead placed in it, and a roof of poles and brushwood overlaid with sand covered the top. The Ist Dynasty kings developed a wooden lining to the chamber; then a wooden chamber free-standing in the pit, with a beam roof, then a stairway at the side to descend; then a pile of earth held in by a dwarf wall over it. By the IIIrd Dynasty this dwarf wall had

[1]The vertical height was named by the Egyptians *pir-em-us* (*see* E. Revillout, *Rev. Ég.*, 2nd year, 305–309), hence the Greek form *pyramis*, pl. *pyramides* (Herod.), used unaltered in the English of Sandys (1615), from which the singular *pyramid* was formed.

expanded into a solid mass of brickwork, about 280 by 150 ft. and **33** ft. high. This was the *ntastaba* type of tomb, with a long, sloping passage descending to the chamber far below it. This pile of brickwork was then copied in stonework early in the IIIrd Dynasty (Saqqara). It was then enlarged by repeated heightening and successive coats of masonry. And lastly a smooth casing was put over the whole, and the first pyramid appeared (Medum).

The pyramids were each begun with a definite design for their size and arrangement; this is plainly seen in the two largest, where continuous accretion (such as Lepsius and his followers propound) would be most likely to be met. Any section of these buildings shows how impossible it would have been for the passages to have belonged to a smaller structure (Petrie, 165). The supposition that the designs were enlarged so long as the builder's life permitted, was drawn from the compound mastabas of Saqqara and Medum; these are, however, quite distinct architecturally from true pyramids.



PYRAMID. LEFT: TWO AT GIZEH; CENTRE: SECTION, GREAT PYRAMID OF KHUFU, GIZEH, C. 3000 B.C.; RIGHT. ASSYRIAN

Around many of the pyramids peribolus walls may be seen, and it is probable that some enclosure originally existed around each of them. At the pyramids of Gizeh the temples attached to these mausolea may be still seen. As in the private tomb, the false door which represented the exit of the deceased person from this world, and towards which the offerings were made, was always on the west wall in the chamber, so the pyramid was placed on the west of the temple in which the deceased king was worshipped. The temple being entered from the east (as in the Jewish temples), the worshippers faced the west, looking towards the pyramid in which the king was buried.

The pyramid was never a family monument, but belonged—like all other Egyptian tombs—to one person, members of the royal family having sometimes lesser pyramids adjoining the king's (as at Khufu's); the essential idea of the sole use of a tomb was so strong that the hill of Gizeh is riddled with deep tomb-shafts for separate burials, often running side by side 60 or 80 ft. deep, with only a thin wall of rock between; and in one place a previous shaft has been partially blocked with masonry, so that a later shaft could be cut partly into it.

The usual construction of pyramids is a mass of masonry composed of horizontal layers of rough-hewn blocks, with a small amount of mortar; and this mass in the later forms became more and more rubbly, until in the VIth Dynasty it was merely a system of retaining walls of rough stones and mud, filled up with loose chips, and in the XIIth Dynasty the bulk was of mud bricks. There was always on the outside a casing of fine stone, elaborately finished, and very well jointed; and the inner chambers were of similarly good work. Indeed, the construction was in all cases so far sound that, had it not been for the spite of enemies and the greed of later builders, it is probable that every pyramid would have been standing in good order at this day. The casings were of massive blocks, usually greater in thickness than in height. Inside each pyramid, always low down, and usually below the ground level, was built a sepulchral chamber; this was reached in all cases by a passage from the north, sometimes beginning in the pyramid face, sometimes descending into the rock on which the pyramid was built in front of the north side. This chamber, if not cut in the rock altogether (as in Menkaura's), or a pit in the rock roofed with stone (as in Khafra's), was built between two immense walls which served for the east and west sides, and between which the north and south sides and roofing stood merely in contact, but unbonded. The gable roofing of the chambers was formed by great sloping slabs of stone, projecting from the north and south walls, on which they rested without pressing on each other along the central ridge; thus there was no thrust, though it had been provided for in the sloping form of the roof, so as to delay as long as possible the collapse of the chamber. This is best seen in the pyramid of Pepi (Petrie). opened from the top right through the roof. The roofing is sometimes of more than one layer; in Pepi's pyramid it is of three layers of stone beams, each deeper than their breadth, resting one on another, the thirty stones weighing more than 30 tons each. In the king's chamber (Gizeh) successive horizontal roofs were interposed between the chamber and the final gable roof, and such may have been the case at Abu Roash (Howard Vyse).

The passages which led into the central chambers have usually some lesser chamber in their course, and are blocked once or oftener with massive stones. In all cases some part, and generally the greater part, of the passages slopes downwards, usually at an angle of about 26°, *or* 1 in 2. These passages appear to have been closed externally with stone doors turning on a horizontal pivot, as may be seen at South Dahshur. This suggests that the interiors of the pyramids were accessible to the priests, probably for making offerings.

The pyramid of Medum was the first true pyramid. It was begun as a mastaba. This mastaba was then enlarged by heightening it and adding a coating, and this process, repeated seven times, resulted in a high stepped mass of masonry. Such had been made before, at the step pyramid of Saqqara; but for the first time it was now covered with one uniform slope of masonry from base to top, and a pyramid was the result. The chamber is peculiar for being entered by a vertical shaft in the floor. The great pyramid of Gizeh (Khufu's) is very different in its internal arrangements from any other. The pyramid covers upwards of 13 ac. and is about 150 ft. higher than St. Paul's cathedral. The greater number of passages and chambers, the high finish of parts of the work and the accuracy of construction all distinguish it. The chamber which is most normal in its situation is the subterranean chamber; but this is quite unfinished. The upper chambers, called the "king's" and "queen's," were completely hidden, the ascending passage to them having been closed by plugging blocks, which concealed the point where it branched upwards out of the roof of the long descending passage. Another passage, which in its turn branches from the ascending passage to the queen's chamber, was also completely blocked up. The object of having two highly-finished chambers in the mass may have been to receive the king and his co-regent (of whom there is some historical evidence) and there is very credible testimony to a sarcophagus having existed in the queen's as well as in the king's chamber. The accuracy of work is such that the four sides of the base have only a mean error of $\frac{6}{10}$ in. in length and 12" in angle from a perfect square.'

The second pyramid of Gizeh, that of Khafra, has two separate entrances (one in the side, the other in the pavement) and two chambers (one roofed with slabs, the other all rock-hewn); these chambers, however, do not run into the masonry, the whole bulk of which is solid so far as is known. This pyramid has a part of the original casing on the top; and it is also interesting as having the workmen's barracks still remaining at a short distance on the west side, long chambers capable of housing about 4,000 men. The third pyramid, that of Menkaura, was cased around the base with red granite for the 16 lowest courses. Its design has been enlarged at one bound from a small pyramid (such as those of the family of Khufu) to one eight times the size, as it is at present, the passages needed therefore to be altered. But there is no sign of gradual steps of enlargement: the change was sudden. The basalt

'With respect to the construction of this and other pyramids, *see* Howard Vyse; on measurements of the inside of the great pyramid and descriptions, *see* Piazzi Smyth; and on measurements in general mechanical means, and theories, *see* Petrie.

Place	King	Date B.C.	Base	Error	Angle	Height	Azimuth

sarcophagus of this pyramid was ornamented with the panel decoration found on early tombs, unlike the granite sarcophagi of the two previous pyramids, which are plain. Unhappily it was lost at sea in 1838.

Farther south are the pyramids of Abusir, described in the work of Col. Howard Vyse, and since excavated by the Germans. Next come those of Saqqara. The construction of the step pyramid or cumulative mastaba has been noticed above; its passages are very peculiar and intricate, winding around the principal chamber, which is in the centre, cut in the rock, very high, and with a tomb-chamber built in the bottom of it, which is closed with a great plug of red granite. A doorway faced with glazed tiles bearing the name of Ring Neter-khet of the IIIrd Dynasty existed here; the tiles were taken to Berlin by Lepsius. Beyond these come the pyramids of Dahshur, which are in a simple and massive style, much like those of Gizeh. The north pyramid of Dahshur has chambers roofed like the gallery in the great pyramid by successive overlappings of stone, the roof rising to a great height, with no less than 11 projections on each side. The south pyramid of Dahshur has still the greater part of its casing remaining, and is remarkable for being built at two different angles, the lower part being at the usual pyramid angle, while the upper part is but 43°. Beyond the Memphitic group are the scattered pyramids of Lisht (Senusert I.), Illahun (Senusert II.) and Howara (Amenemhat III.), and the earliest pyramid of Medum (Sneferu). Illahun is built with a framework of stone filled up with mud bricks, and Howara is built entirely of mud bricks, though cased with fine stone like the other pyramids.

The dimensions of the pyramids that are accurately known (as shown in table above) are in inches.

The first two closely agree to the proportion of 7 high on 11 base, approximately the ratio of a radius to its circle. And on dividing the base at Medum by 11 the modulus is 515·64, and the base of Khufu÷11 is 824·44. These moduli are 25 cubits of 20·625 and 40 cubits of 20·611; so it appears that the form was of the same type, but with moduli of 25 and 40 cubits respectively.

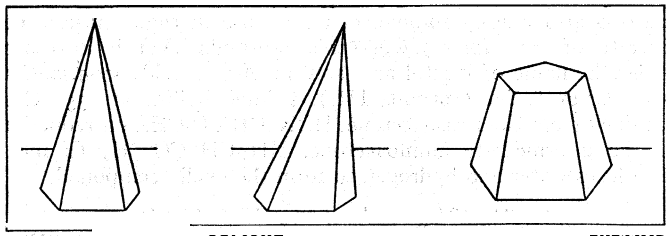
Beyond these already described there are no true pyramids, but we will briefly notice those later forms derived from the pyramid. At Thebes some small pyramids belong to the kings of the XIth Dynasty; the tomb-chamber is in the rock below. The size is under 50 ft. square. These are not oriented, and have a horizontal entrance, quite unlike the narrow pipe-like passages sloping down into the regular pyramids. (*See* Mariette, in *Bib. arch. trans.* iv. 193.) In Ethiopia, at Gebel Barkal, are other so-called pyramids of a very late date. They nearly all have porches; their simplicity is lost amid very dubious decorations; and they are not oriented. They are all very acute, and have flat tops as if to support some ornament. The sizes are very small, varying from 23 to 88 ft. square at Gebel Barkal and 17 to 63 ft. square at Meroe. The interior is solid throughout, the windows which appear on the sides being useless architectural members. (*See* Hoskin's *Ethiopia,* 148, etc.) The structures sometimes called pyramids at Biahmu in the Fayum have no possible claim to such a name; they were two great enclosed courts with sloping sides, in the centres of which were two seated statues raised on pedestals high enough to be seen over the walls of the courts.

Not one fragment of early inscription is known on the casing of any pyramid, either *in situ* or broken in pieces. Large quantities of travellers' "graffiti" doubtless existed, and some have been found on the casing of the great pyramid; these probably gave rise to the accounts of inscriptions, which are expressly said to have been in many different languages.

The mechanical means employed by the pyramid-builders have been partly ascertained. The hard stones, granite, diorite and basalt were in all fine work sawn into shape by bronze saws set with jewels (either corundum or diamond), hollows were made (as in sarcophagi) by tubular drilling with tools like our modern diamond rock-drills. (W. M. F. P.)

See Colonel Howard Vyse, *Operations at the Pyramids* (1840); Prof. C. Piazzi Smyth, *Life and Work at the Great Pyramid* (1867); W. M. Flinders Petrie, *Pyramids and Temples of Gizeh* (1883); M. D. Fraser, *The Pyramids* (Glasgow, 1894); H Borchardt, *Die Pyramiden* (1911); M. Edgar, *The Great Pyramid* (Glasgow, 1924).

PYRAMID, in geometry, a polyhedron of which one face, called the base, is any polygon and the other faces (the lateral faces) are triangles with one vertex in common. The intersections of the lateral faces are called the lateral edges of the pyramid, and their common vertex is called the vertex of the pyramid. The perpendicular distance from the vertex to the plane of the base is called the height or altitude of the pyramid. If the base is a regular polygon the centre of which coincides with the foot of the perpendicular from the vertex to the base, the pyramid is called a regular pyramid. As in the case of prisms (*q.v.*), pyramids are classified according to their bases. The portion of a



REGULAR PYRAMID, OBLIQUE PYRAMID, AND FRUSTUM OF PYRAMID

pyramid and a plane cutting all the lateral edges is called a truncated pyramid; and if the cutting plane is parallel to the base, the truncated pyramid becomes a frustum of a pyramid. The volume of a pyramid with base B and altitude a is $\frac{1}{3}aB$. The volume of a frustum of a pyramid with bases B and B' and altitude a is $\frac{1}{3}a(B+B'+\sqrt{BB'})$. *See* SOLIDS: *Geometric.*

PYRAMIDION (diminutive of "pyramid"), an architectural term for the copper-gilt casing covering the apex of an obelisk; also its upper termination of pyramidal form.

PYRAMUS AND THISBE, the hero and heroine of a Babylonian love story told by Ovid (*Metam.* iv. 55–465). Their parents refused to consent to their union, and the lovers used to converse through a chink in the wall separating their houses. At last they resolved to flee together, and agreed to meet under a mulberry tree near the tomb of Ninus. Thisbe was the first to arrive, but, terrified by the roar of a lion, took to flight. In her haste she dropped her veil, which the lion tore to pieces with jaws stained with the blood of an ox. Pyramus, believing that she had been devoured by the lion, stabbed himself. Thisbe returned to the rendezvous, and finding her lover mortally wounded, put an end to her own life. From that time the fruit of the mulberry, previously white, was always black.

See G. Hart, *Die Ursprung und Verbreitung der Pyramus- und-Thisbesage* (1889–92).

PYRARGYRITE, a mineral consisting of silver sulphantimonite, Ag_3SbS_3, known also as dark red silver ore, an important source of the metal. It is closely allied to, and isomorphous with, the corresponding sulpharsenite known as proustite (*q.v.*) or light red silver ore. "Ruby silver" or red silver ore (Ger. *Rotgültigerz*) was mentioned by G. Agricola in 1546, but the two species were completely distinguished by J. L. Proust in 1804.

The colour of pyrargyrite is usually greyish-black and the lustre metallic-adamantine; large crystals are opaque, but small ones and thin splinters are deep ruby-red by transmitted light, hence the name, from Gr. πῦρ (fire) and ἄργυρος (silver). The streak is purplish-red, thus differing markedly from the scarlet streak of proustite and affording a ready means of distinguishing the two minerals. The mineral occurs in metalliferous veins with calcite, argentiferous galena, native silver, native arsenic, etc. The best crystallized specimens are from St. Andreasberg in the Harz, Freiberg in Saxony and Guanajuato in Mexico. It is not uncommon in many silver mines in the United States, but rarely as distinct crystals; and it has been found in Cornish mines.

PYRAZINES, Piazines or Paradiazines, in organic chemistry, nitrogenous compounds containing a ring composed of four carbon atoms and two nitrogen atoms, the latter being at opposite ends of the ring in the so-called "para-position."

Pyrazine (formula I.) crystallises from water in

(I.)  (II.)

colourless prisms having a heliotrope odour; it melts at 55° C and boils at 115° C. In general the pyrazines are obtained by eliminating water and hydrogen from α-aminoaldehydes or α-aminoketones (2 molecular proportions in each case).

Piperazine (formula II.), the reduction product of pyrazine, is employed medicinally in gout and rheumatism. It is best prepared by condensing aniline and ethylene dibromide to diphenyldiethylenediamine, the dinitroso-compound of which hydrolyses to *p*-nitrosophenol and piperazine. It is a strongly basic compound melting at 104° C, boiling at 145° C, and soluble in water. Its urate is also readily soluble, hence its use in therapeutics. The tartrate of *$\alpha\gamma$-dimethylpiperazine* (formula IV.) is also used under the name of lycetol as a solvent of uric acid *$\alpha\gamma$-dimethylpyrazine* or *ketine* (formula III.), a liquid boiling at 153° C, is obtained from isonitrosoacetone, $HON:CH\cdot CO\cdot CH_3$, on reduction, as the intermediate aminoacetone, $NH_2\cdot CH_2\cdot CO\cdot CH_3$ (2 mol.) then loses water and hydrogen to form the cyclic compound.

(III.)  (IV).

A methyldiketopiperazine has been isolated from the hydrolysis of silk fibroin and shown to be identical with the synthetic compound from glycine and d-alanine.

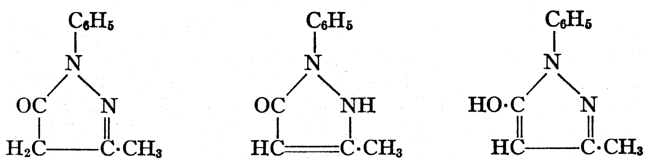
PYRAZOLES, in organic chemistry a series of compounds containing a five-membered ring with three carbon atoms united to two adjacent nitrogen atoms arranged as in formula (I.), which represents the structure of pyrazole itself.

(I.)  (II.)

The application in medicine of such pyrazole derivatives as antipyrine (*q.v.*) and pyramidone, and the production of synthetic dyes (*q.v.*) of the pyrazolone type, lends a special interest to this chapter of organic chemistry.

The simplest synthesis of pyrazole is effected by heating together acetylene and diazomethane (H. von Pechmann, 1897), this process corresponding with the synthesis of pyrrole (*q.v.*) from acetylene and ammonia. The earliest synthesis of pyrazole was accomplished by E. Buchner in 1889, who condensed ethyl diazoacetate with diethyl acetylenedicarboxylate, thus obtaining triethylpyrazole-3:4:5-tricarboxylate. The free pyrazoletricarboxylic acid on prolonged heating lost carbon dioxide and yielded pyrazole, which crystallises in colourless needles melting at 70° C (boiling point, 185° C), and giving well-defined salts with acids. Pyrazole has certain chemical properties in common with pyridine and benzene; it exhibits an aromatic character and can be sulphonated or nitrated. Its 4-nitro-compound can be reduced to 4-aminopyrazole, which resembles the aromatic bases; it gives a colour reaction with bleaching powder solution and its hydrochloride is readily diazotised. Pyrazole-4-diazonium chloride couples with phenols and naphthols to form azo-dyes after the manner of benzenoid diazo-compounds.

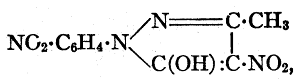
Pyrazoline or 4:5-dihydropyrazole (formula II.), is formed from acrolein and hydrazine hydrate and has also been obtained by the interaction of diazomethane and ethylene. It is a colourless liquid boiling at 144° C. The pyrazolines are unstable oxidisable substances resembling dihydrobenzene and its homologues; they are generally prepared by reducing the corresponding pyrazoles with sodium in alcoholic solution. On further reduction they yield pyrazolidines or tetrahydropyrazoles and when oxidised they develop blue or red colorations. This reaction, described by L. Knorr as the "pyrazoline reaction," is used for the detection of pyrazole and pyrazoline bases derived from phenylhydrazine. The *pyrazolones* (ketodihydropyrazoles), first prepared by Knorr in 1883, result from the elimination of the elements of alcohol from the hydrazones of β-ketonic acids. The most important member of this group is *1-phenyl-3-methyl-5-pyrazolone,* the parent substance of antipyrine and an intermediate in the manufacture of certain pyrazolone dyes (Eriochrome Red, etc.). 1-Phenyl-3-methyl-5-pyrazolone, prepared by condensing together phenylhydrazine and ethyl acetoacetate, crystallises in colourless prisms melting at 127° C, and although it is only known in this form, nevertheless it exhibits twofold tautomerism (see ISOMERISM) and behaves as if it had one or another of the three following structures



Methylene form — Imino-form — Phenolic form

When condensed with aldehydes, water is eliminated between aldehydic oxygen and the two hydrogens of the methylene group, thus indicating the mcthylene form. When methylated with methyl iodide in methyl alcohol to form the hydriodide of antipyrine (1-phenyl-2:3-dimethyl*iso*pyrazolone), the pyrazolone reacts in its imino form, the methyl group replacing the hydrogen of the imino group. Antipyrine (*q.v.*) and its therapeutically important derivatives and analogues are all constituted on the imino type. When in the production of synthetic dyes the pyrazolone is coupled with diazonium salts, it reacts in its third phenolic form, the diazo-group replacing the hydrogen of the CH residue adjacent to the hydroxyl-group.

Picrolonic acid,



or 4-nitro-1-*p*-nitrophenyl-3-methyl-5-hydroxypyrazole, is also a pyrazolone of phenolic type. It closely resembles picric acid and is used to identify alkaloids and other bases owing to the formation of very sparingly soluble *picrolonates.* For benzopyrazoles, see INDAZOLES.

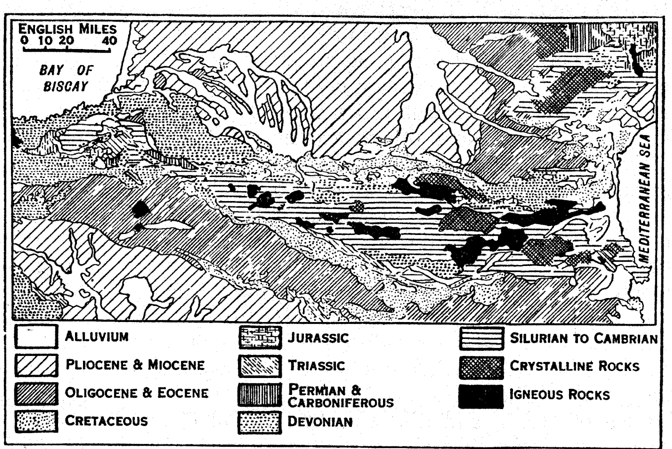
PYRENE, an aromatic hydrocarbon found with chrysene (*q.v.*) in the coal-tar distillate boiling above 360° C and also in "Stubb" fat, a by-product from the working up of mercury ores in Idria. It crystallises in pale yellow leaflets, melts at 148–149° and boils at 360° C. Chromic acid oxidises it successively to pyrenequinone and pyrenic acid; permanganate oxidises the latter substance to naphthalene-1:4:5:8-tetracarboxylic acid, which confirms the constitutional formula ascribed to pyrene $C_{16}H_{10}$.

BIBLIOGRAPHY.—A. E. Everest, *The* Higher Coal Tar Hydrocarbons (1927).

PYRENEES, a range of mountains in south-west Europe (Span. *Pirinéos,* Fr. *Pyrénées*), separating the Iberian Peninsula from France, and extending for about 240 m., from the Bay of Biscay to Cape Creus, or, if only the main crest of the range be considered, to Cape Cerbère, on the Mediterranean Sea. The main crest constitutes the Franco-Spanish frontier; except in the case of the valley of Aran, which belongs orographically to France but



GEOLOGICAL MAP OF THE PYRENEES

politically to Spain. The Pyrenees are conventionally divided into three sections, the central, the Atlantic or western, and the Mediterranean or eastern. The central Pyrenees extend eastward from Canfranc to the valley of Aran, and include the highest summits of the whole chain, Aneto or Pic de Néthou (11,168 ft.), in the Maladetta ridge, Posets (11,047 ft.), and Mont Perdu or Monte Perdido (10,997 ft.). In the Atlantic Pyrenees the average altitude gradually diminishes westward; while in the eastern Pyrenees, except for one break at the eastern end of the Pyrénées Ariégeoises, the mean elevation is maintained, till a rather sudden decline occurs in the extreme eastern portion, the Albères. This threefold division is only valid so far as the elevation of the Pyrenean chain is concerned, and does not represent its geological structure or general configuration. The southern versant of the mountains is the more important. It is recognized that the range must be regarded as an elevated part of the earth's crust, the culminating portion of which is composed of a series of chains, which do not coincide with the watershed, but cross it obliquely. Maps by Schrader and de Margerie (*Ann. du Club Alpin français,* 1891 and 1892) show the orderly arrangement of these chains. The primitive formations of the range are shown to be almost all continued diagonally on the Spanish side, and the central ridge thus presents the appearance of a series of wrinkles with an inclination (from north-west to south-east) greater than that of the chain as a whole. Other less pronounced wrinkles run from south-west to north-east and intersect the former series at certain points, so that it is by alternate digressions from one to the other series that the irregular crest of the Pyrenees acquires its general direction. Far from having impressed its own direction on the orientation of the chain at large, this crest is merely the resultant of secondary agencies by which the primitive mass has been eroded and lessened in bulk, and though its importance from a hydrographic point of view is still considerable, its geological significance is practically nil.

Geology.—The Pyrenees are divided into a number of longitudinal zones. The central zone (Central Massifs) consists of Primary rocks, Archaean, Cambrian, Ordovician, Silurian, Devonian and Lower Carboniferous (Dinantian) together with great masses of granite. It forms most of the higher summits, but west of the Pic d'Anie it disappears beneath an unconformable covering of Cretaceous deposits. On the French side the central zone is followed by (1) the zone of Ariège, consisting of Lower Cretaceous and Jurassic beds, together with granitic masses; (2) the zone of the Petites Pyrénées, Upper Cretaceous and Eocene; a thin outcrop of Jurassic; (2) the zone of Aragon, Eocene; and Primary rocks. On the Spanish side, from north to south, are (1) the zone of Mont Perdu, Upper Cretaceous and Eocene with a thin outcrop of Jurassic; (2) the zone of Aragon, Eocene; and (3) the zone of the Sierras, Trias, Cretaceous and Eocene. Although the number of zones is the same on the two flanks, they do not correspond. The zone of the Corbières has no equivalent in Spain, while in France there is no definite zone of Eocene like that of Aragon. The zone of the Petites Pyrénées, however, is clearly homologous with that of the Sierras. On the northern side granitic masses occur in the zone of Ariège amongst the Jurassic and Lower Cretaceous beds. On the southern side they are not found except in the axial zone, and the Jurassic and Lower Cretaceous deposits are reduced to a narrow band. In spite of these differences between the two flanks, the structure is to some extent symmetrical.

The tectonics of the Pyrenees are still only imperfectly understood. Some authorities consider the structure to be that of a "fan," whilst others have shown that the phenomena of *recouvrement* play an important part here. Large masses of rock have been brought forward upon thrust-planes over the edges of other beds with which they originally had no connection. Several cases have been described; but denudation has been carried further than in the Alps, and accordingly the masses overlying the thrust-planes have been more completely removed.

The Pyrenean axis was outlined by the Hercynian movement and folding took place along it at the close of the Dinantian epoch and again before the Permian. Later the chain was completely submerged until early Cretaceous times, when the earth movements which raised the present mountains commenced and continued into the Oligocene period. The uplift of the Pyrenees was therefore completed before that of the Alps.

The arrangement of the Pyrenees in chains gently inclined near the centre but longitudinal everywhere else, is illustrated by the courses of the streams which flow down towards Spain. On the French side most of the longitudinal valleys have disappeared, except at the eastern end. On the south the principal streams, after cutting their way through the highest zone at right angles to the general direction of the range, become involved half-way to the plains in great longitudinal folds, from which they make their escape only after traversing long distances.

The total area of the Pyrenees is estimated at 21,044 sq.m., two thirds of which is on the southern versant. The mean elevation is placed at 3,930 ft., whilst the highest summit Pic de Néthou, is 11,168 ft. above sea level. The passes show a greater altitude than those of the Alps.

Gaves.—Four features of Pyrenean scenery are the absence of great lakes, as in the Alps; the rarity and great elevation of passes; the large number of the mountain torrents locally called *gaves,* which often form lofty waterfalls, surpassed in Europe only by those of Scandinavia; and the frequency with which the upper end of a valley assumes the form of a *cirque.* The highest waterfall is that of Gavarnie (1,515 ft.), at the head of the Gave de Pau; the Cirque de Gavarnie, in the same valley, is perhaps the most famous example of the cirque formation. Low passes only occur at the two extremities of the range, where the principal highroads and railways run between France and Spain; a third railway (Pau to Jaca via the pass of Somport) was opened in 1928. In the mountains themselves there are only five passes practicable for motors—the Col de la Perche, Col du Pourtalet, Col de Somport, Roncevalles road and the road through the Baztan valley.

Projects for further railway construction, including the building of tunnels on a vast scale, have been approved by the French and Spanish governments (*see* SPAIN: *Communications*).

The metallic ores of the Pyrenees are not important. There are considerable iron mines at Vicdessos in Ariège and at the foot of Canigou in Pyrénées-Orientales. Coal deposits capable of being profitably worked are situated chiefly on the Spanish slopes and the French side has numerous beds of lignite. Mineral springs are abundant and specially noteworthy are the hot springs. The latter, among which those of Bagnères de Luchon and Eaux-Chaudes may be mentioned, are sulphurous and mostly situated high, near the margin of the granite. The lower springs, such as those of Bagnères de Bigorre (Hautes-Pyrénées,), Rennes (Aude) and Campagne (Aude), are mostly selenitic and not very warm. The use of hydro-electric power has been developed in recent years.

The amount of the precipitation, including rain and snow, is much greater in the western than in the eastern Pyrenees, causing a marked contrast between these sections of the chain in more than one respect. In the first place, the eastern Pyrenees are without glaciers, the quantity of snow falling there being insufficient. The glaciers are confined to the northern slopes of the central Pyrenees, and do not descend far down in the valleys, but have their greatest length in the direction of the chain. They form, in fact, a narrow zone near the crest of the highest mountains. Here, as elsewhere in Europe, there are evidences of a much wider extension of the glaciers during the Ice Age. The best known glacier is that in the valley of Argelks. The snow-line varies in different parts of the Pyrenees from 8,800 to 9,200 ft. above sea-level.

A more marked effect of the high rainfall in the west is seen in the vegetation. The lower mountains in the extreme west are very well wooded, but the extent of forest declines eastwards, and the eastern Pyrenees are peculiarly wild and naked, more so because here the granite massifs occur. There is a change, moreover, in the type of flora in passing from west to east. In the west the flora, at least in the north, resembles that of central Europe, while in the east it is distinctly Mediterranean in character. The Pyrenees are relatively as rich in endemic species as the Alps, and among the most remarkable instances of this is the occurrence of the sole European species of Dioscorea (yam), the D. pyrenaica, on a single high station in the central Pyrenees, and that of the monotypic genus Xatardia, only on a high pass between the Val d'Eynes and Catalonia. The genus most abundantly represented in the range is that of the saxifrages, several species of which are here endemic.

In their fauna also the Pyrenees present some striking instances of endemism. There is a distinct species of ibex (*Capra* pyrenaica) confined to the range, while the Pyrenean desman or water-mole (*Mygale* pyrenaica) is found only in some of the streams of the northern slopes of these mountains, the only other member of this genus being confined to the rivers of southern Russia. Among the other peculiarities of the Pyrenean fauna are blind insects in the caverns of Arihge, the principal genera of which are *Anophthalmus* and *Adelops.*

The ethnology, folk-lore, institutions and history of the Pyrenean region form an interesting study: see ANDORRA; ARAGON; BASQUE PROVINCES; BÉARN; CATALONIA; NAVARRE.

PYRÉNÉES-ORIENTALES, a department of south-western France, bordering on the Mediterranean and the Spanish frontier, formed in 1790 of the old province of Roussillon and of small portions of Languedoc and of Cerdagne. Population (1936) 233,347, including many Spaniards. Area, 1,600 sq.mi. The department is bounded north by Arihge and Aude, east by the Mediterranean, south by Catalonia and west by the republic of Andorra. Its borders are marked by mountain peaks, on the north by the Corbières, on the north-west and south-west by the eastern Pyrenees, on the extreme south-east by the Albères, which end in the sea at Cape Cerbera. The coast is low-lying, with large lagoons. In the lowlands the climate is Mediterranean, with mild winters, dry summers and short and sudden rain-storms. Amélie-les-Bains is much frequented on account of its mild climate and sheltered position. The temperature ranges from 85° to 95° F in summer, and in winter only occasionally falls as low as 26" or 27°. The mean rainfall is 27 in. on the coast, but increases towards the hills. The most common wind is the *tramontane* from N.N.W., as violent as the mistral of Provence and extremely parching. The *marinada* blows from the S.S.E.

On the Canigou massif to a height of 1,400 ft. are found the orange, the aloe, the oleander, the pomegranate and the olive; the vine grows to a height of 1,800 ft.; next come the chestnut (2,625 ft.), the rhododendron (from 4,330 to 8,330 ft.), pine (6,400), and birch (6,560); while stunted junipers grow to the summit. The cultivated land in Pyrénées-Orientales is devoted to wine-growing, market-gardening and fruit culture, the production of cereals being comparatively unimportant. The main source of wealth to the department is its wine, of which some kinds are strongly alcoholic and others are in request as liqueur wines (Rivesaltes, Banyuls). Early vegetables are grown in the irrigated lowlands, and fruit-growing is chiefly carried on in the river valleys. In iron Pyrénées-Orientales is one of the richest departments in France, the greater part of the ore being transported to the interior. Lignite and various kinds of stone are worked. The mineral waters are popular. Amélie-les-Bains has hot springs, chalybeate or sulphurous. In the arrondissement of Céret there are also the establishments of La-Preste-les-Bains, near Prats de Mollo, with hot sulphurous springs, and of Le Boulou, the Vichy of the Pyrenees. Near Prades are the hot sulphurous springs of Molitg, and a little north of Mont Canigou are the hot springs of Vernet, containing sodium and sulphur. In the valley of the Tet the sulphurous and alkaline springs of Thuès reach a temperature of 172° F.

The baths of Les Escaldas, near Montlouis, are hot, sulphurous and alkaline.

The chief route (Southern Railway) across the Pyrenees is from Perpignan through Montlouis, a fortified place, to Puigcerda, in the Spanish province of Gerona, through the pass of La Perche, skirting in the French department an enclave of Spanish territory. Three other roads run from Perpignan to Figueras through the passes of Perthus (defended by the fort of Bellegarde), Banyuls and Balistres, the last-named being traversed by a railway. The chief towns of the three arrondissements are Perpignan, Céret and Prades: there are 18 cantons and 234 communes.

The department constitutes the diocese of Perpignan under the archbishop of Albi, and is attached to the appeal court and the *académie* (educational division) of Montpellier and to the region of the XVI. army corps.

Perpignan, the capital town and a fortress of the first class, Amélie-les-Bains and Elne (*qq.v.*) are the chief towns.

Rivesaltes ([1936] 4,793) is the most populous town after Perpignan (64,100).

PYRETHRUM. The pyrethrum (family Compositae), now regarded as a section of the genus Chrysanthemum, flowers in the early summer months, and is remarkable for the great variety of colour which it presents.

The type form is the Caucasian species C. coccineum, a hardy perennial, with finely cut leaves and large flower heads, having a ray of deep rose-coloured ligulate florets surrounding the yellow centre or disk. They bloom during the months of May and June, as well as later, and are always most welcome ornaments for the flower borders, and useful for cutting for decorative purposes.

The powdered flower heads of *C.* coccineum and C. *anethifolium* are the source of Persian insect powder, and C. *cinerariaefolium* yields Dalmatian insect powder. Both are important insecticide ingredients, commonly called pyrethrum.

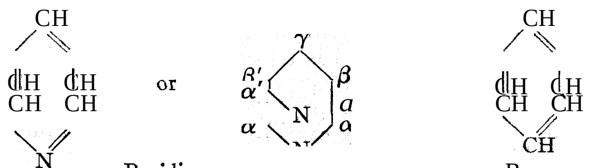
PYRGI, an ancient town of Etruria, Italy, on the southwest coast, g mi. W.N.W. of Caere. The name is Greek (πύργοι towers), and the place of considerable antiquity. Remains of its defensive walls exist in polygonal blocks of limestone and sandstone, neatly jointed. They enclosed a rectangular area some 200 yd. in width and at least 220 yd. in length, and there was a small harbour.

A rich temple of Leucothea here was plundered by Dionysius in 384 B.C. Later it became dependent on Caere, though it was not originally its harbour, for Alsium (*q.v.*) is a good deal nearer (5 mi. south). The Romans planted a colony here about 200 B.C.

PYRGOS, a town of Greece, in the province of Elis and Achaea, 43 mi. S.S.W. of Patras. It is connected with its harbour, Katakolon, $7\frac{1}{2}$ mi. distant. with Patras, Olympia and Kalamata by rail. It has frequently been injured by earthquakes. Pop. 22,500. Axis troops occupied it during World War II.

PYRIDINE, C_5H_5N, is a liquid organic base formed during the destructive distillation of a great variety of nitrogenous organic substances such as bone, coal, shale and lignite. It has been detected in crude petroleum and fusel oil, and is also a characteristic decomposition product of various alkaloids (*q.v.*) either heated alone or with zinc dust. Pyridine was discovered and isolated in a pure state by T. Anderson (1851) from bone oil, which, together with coal tar, is its chief commercial source, and which is obtained in the preparation of bone black or animal charcoal by distilling bones in a closed retort. For the extraction from coal tar or bone oil, the light oil boiling up to 120° C is taken and the basic constituents are extracted by washing with dilute sulphuric acid and removing the acid layer. The bases, which have dissolved in the acid, are liberated by the addition of excess of caustic soda and separate as a dark oily layer at the surface of the liquid After drying they are fractionally distilled in order to separate pyridine from its higher homologues which inevitably accompany it when obtained from these sources. Synthetically pyridine may be prepared by distilling allylethylamine over lead oxide; by passing acetylene and hydrocyanic acid through a red-hot tube; by heating pyrrole with sodium methoxide and methylene iodide; also by heating *iso*amyl nitrate with phosphoric oxide. These methods are of theoretical interest only. When required very pure, it is made by distilling nicotinic acid with lime.

Properties. — Pyridine is a colourless liquid with a penetrating sickly odour. It boils at 115° C, has a specific gravity of 0.9855 and a high refractive index. It is hygroscopic and miscible with water in all proportions, but is not soluble in strong caustic alkali or salt solutions. It is very stable towards the common chemical reagents. Nitric and chromic acids are without action upon it, whilst chlorine and bromine yield substitution products with difficulty. If bromine is added to a hydrochloric acid solution of pyridine, a crystalline unstable dibromide, C_5H_5N,Br_2, is precipitated, which can be used as a delicate reagent to brominate other compounds. It is because pyridine possesses this property of forming loose additive compounds on the nitrogen atom that it is a useful "carrier" in the halogenation of various materials. At high temperatures it reacts with sulphuric acid to form a sulphonic acid. As a base it combines with acids to form crystalline salts, such as the hydrochloride, which is very soluble in water. With many inorganic salts such as mercuric, auric and platinic chlorides, it forms double salts or addition compounds, many of which are highly crystalline and sparingly soluble in cold water. Pyridine combines with alkyl iodides to form pyridinium alkyliodides which are often highly crystalline and have definite melting points. Nascent hydrogen reduces pyridine to piperidine, $C_5H_{11}N$ (*see* p. 798), whilst hydriodic acid reduces it to n-pentane. Pyridine is a strong base; its aqueous solution turns red litmus blue. It is a tertiary amine possessing a ring structure that is expressed symbolically by the following formulae:



Pyridine Benzene

The resemblance in chemical behaviour found between the derivatives of benzene and pyridine indicates that these two substances must have a similar ring constitution, The above formulae also allow for the existence of all the known isomeric substitution products. Thus, when substituent groups are identical, six di-derivatives, six tri-, three tetra-, and one penta-derivative have been isolated. The five hydrogen atoms which can be replaced by a substituting group are represented by the Greek letters α, β, γ, β', and α', the positions α and α', β and β', being equivalent.

Uses.—Pyridine is used for asthma, and certain of its iodine derivatives for antiseptic purposes as well as for some protozoal diseases. In some countries pyridine is used as a denaturant for alcohol. As a catalyst it is applied in specific chemical reactions. Pyridine is one of the best organic solvents, readily dissolving a large number of technical products such as fats, mineral oils and rubber. It has also the remarkable property of dissolving many metallic salts such as silver nitrate and mercuric acetate. In the dye industry it is used as a solvent in the extraction of carbazole from crude anthracene. Pure pyridine is mainly used for the production of piperidine.

Derivatives.—Chloropyridines can all be obtained under varying conditions by the action of phosphorus pentachloride on pyridine or upon hydroxypyridines. The β-derivative is best prepared by the action of chloroform on potassium pyrrole. By heating with alcoholic ammonia, several of the higher chlorinated pyridines can be converted into amino-chloropyridines.

β-Pyridinesulphonic acid, $C_5H_4(SO_3H)N$, is formed when pyridine is treated with fuming sulphuric acid. The sodium salt on distillation with potassium cyanide yields β-cyanopyridine, which on hydrolysis gives nicotinic acid. On fusing the sulphonic acid with potash, β-hydroxypyridine is formed.

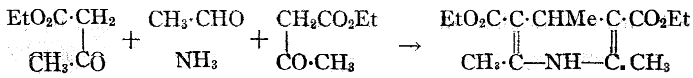
Nitration of the pyridine nucleus is only possible when amino-, hydroxy- or similar groups are present. Aminopyridines are obtainable by the action of ammonia upon the corresponding chloropyridine. The α-amino- and $\alpha\alpha'$-diamino-derivatives are formed by the action of sodamide on pyridine and subsequent treatment with water. The aminopyridines can be diazotised in the same way as aniline and can form azo-dyes.

Hydroxypyridines correspond to aminophenols in that they form salts with strong bases and acids. They are feebly basic in character and are readily soluble in water. They also exhibit keto-enol tautomerism (*q.v.*), derivatives of keto-dihydropyridine, or pyridone, being obtainable.

The carboxylic acids of pyridine are usually prepared by oxidizing the homologues of the base with potassium permanganate. Many of the alkaloids yield these acids upon energetic oxidation. When heated with strong hydrochloric acid the higher polycarboxylic acids give rise to the lower acids by loss of carbon dioxide. By heating with lime all the carboxyl groups are eliminated and pyridine is formed. The most important pyridine carboxylic acids are described in the following table:

Name	Formula	Position of substituent	Remarks
Picolinic acid	$C_5H_4N(CO_2H)$	α	M.p. 137° C. Easily soluble in water.
Nicotinic acid	$C_5H_4N(CO_2H)$	β	M. p. 228° C. An oxidation product of nicotine and berberine.
Quinolinic acid	$C_5H_3N(CO_2H)_2$	$\alpha\beta$	M.p. 190° C with decomposition into nicotinic acid. Formed on oxidation of quinoline.
n o meronic acid	$C_5H_3N(CO_2H)_2$	$\beta\gamma$	M.p. 266° C. Formed on oxidation of quinine, cinchonine and iso-quinoline.

Homologues.—The homologues of pyridine constitute that fraction of the crude bases from bone or coal-tar oil boiling between 120–230° C. They can be synthesized in various ways. One of the most important is A. Hantzsch's "collidine" synthesis, which consists in the condensation of two molecules of acetoacetic ester with one of aldehyde and one of ammonia:



The resulting dihydro-compound is oxidized with nitrous acid, the ester hydrolysed, and the acid heated with lime, when the trimethylpyridine is obtained. The α- and γ-alkyl-pyridines are also produced by heating the pyridinium alkyl iodides, a molecular rearrangement taking place. These homologues are of importance because of their relation to the alkaloids. A simple alkyl-pyridine is often the main product of distillation of an alkaloid with zinc dust or lime. They are liquids of an unpleasant odour resembling pyridine. The chief alkyl-pyridines are summarized in the following table:

Name	Formula	Position of substituent	Remarks
Picolines	$C_5H_4N(CH_3)$	a	Liquid, b. p. 129° C. Oxidizes to picolinic acid.
		β	Liquid, b. p. 142° C. Oxidizes to nicotinic acid.
		γ	Liquid, b. p. 143° C.
Lutidines	$C_5H_3N(CH_3)_2$	aa', αβ', ay , ββ', βγ	Six isomerides, all liquids, b. p. 140–165° C (approx.)
Collidines	$C_5H_2N(CH_3)_3$	aya'	Liquid, b. p. 171° C. Five other isomerides.

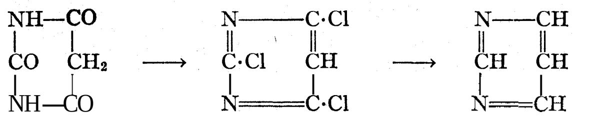
Piperidine, or hexahydropyridine, $C_5H_{11}N$, is a colourless liquid of peculiar odour slightly resembling that of pepper. It dissolves readily in water and alcohol, boils at 106° C, and has strongly basic properties. It occurs in pepper in combination with piperic acid as the alkaloid piperine. It is prepared by the reduction of pyridine with metallic sodium and alcohol. Upon oxidation it yields pyridine. Piperidine is a secondary amine and its imino-hydrogen atom is therefore replaceable by alkyl and acyl radicals. Benzoylpiperidine when heated with phosphorus pentachloride in sealed tubes yields benzonitrile and pentamethylene dichloride, showing that the piperidine ring is readily opened. When heated with fuming hydriodic acid it yields n-pentane and ammonia.

Piperidine is often used as a catalyst in synthetic organic chemistry. It was one of the first organic accelerators used in the vulcanisation of both synthetic and natural rubber, and certain of its derivatives are still used for this purpose. The hydrogen tartrate and other salts have been employed in medicine for urinary calculi and as uric acid solvents, of doubtful efficacy.

(J. RD.)

PYRIMIDINES, METADIAZINES or MIAZINES, a series of nitrogenous organic substances which play an important part in physiological processes. They possess a cyclic structure as shown in the formula (III.) of pyrimidine itself, and the group includes cyclic urea derivatives (ureides) and also compounds of the uric acid or purine group.

Pyrimidine is best prepared from barbituric acid (malonyl urea, formula I.) by the action of phosphorus oxychloride and by reduction of the resulting 2:4:6-trichloropyrimidine (formula II.).

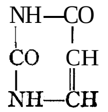


(I.) (II.) (III.)

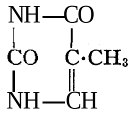
Pyrimidine is a crystalline base of narcotic odour and dissolves readily in water; it melts at 21° C and boils at 124° C. Derivatives of pyrimidine are of great physiological importance and take part in many fundamental life processes. They have been shown by Kossel (1893) to be present in the cell nucleus where synthetic changes associated with the growth of the cell are taking place.

Uracil (2:6-dioxypyrimidine, formula IV.), a white crystalline powder, sparingly soluble in cold but more readily soluble in hot water, melts with evolution of gas at 338° C. It was recognised as a hydrolytic product of nucleic acids from yeast in 1900 by A. Ascoli and was synthesised by E. Fischer and Roeder in 1901 by heating urea with acrylic acid. This condensation gave dihydrouracil which was successively converted into monobromo-derivative and uracil.

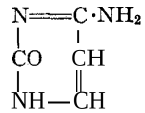
Thymine or 5-methyl-a:6-dioxypyrimidine (formula V.) is obtainable in large amount from animal and vegetable nucleins; it has also been synthesised by E. Fischer; it crystallises from water in colourless leaflets melting at 318–321° C.



(IV.)



(V.)



(VI.)

Cytosin (2-oxy-6-aminopyrimidine, formula VI.) was synthesised by H. Wheeler and Treat B. Johnson in 1903 and identified by Kossel and Neumann in 1894 as a hydrolytic product of thymonucleic acid. It crystallises from water in colourless, nacreous plates decomposing at 320–325° C. It is converted by nitrous acid into uracil (v. supra) and is oxidised by barium permanganate into oxalic acid and biuret. (See UREA.)

For methods of preparation and properties of numerous pyrimidine derivatives see T. B. Johnson, *Jour. Biol. Chem.*, 1906; Amer. *Chem. Journ.*, 1906; *Journ.* Amer. *Chem. Soc.*, 1911 et seq.

BIBLIOGRAPHY.—C. Oppenheimer, Handbuch der Biochemie, vol. i. (1924); E. Abderhalden, Biochemisches Handlexikon, vol. iv. (1911); vol. ix., Supplement, 1915; V. Meyer and P. Jacobson, *Lehrbuch der* Organischen Chemie, vol. ii. (1920).

PYRITE or **PYRITES,** a term applied to iron disulphide when crystallized in the cubic system. The original word pyrites (from Gr. πῦρ, fire) had reference to the fact that sparks might be elicited on striking the mineral violently, as with flint, so that πυρίτης λίθος meant a stone which struck fire. Hence the name seems to have been applied also to flint, and perhaps to emery and other hard stones. Nodules of pyrite have been found in prehistoric barrows and elsewhere under conditions suggesting their use as a primitive means of producing fire. Even in late historic time it was employed in some of the old wheel-lock guns. The compound FeS_2 is dimorphous, and the modern practice is to distinguish the cubic form as pyrite and the orthorhombic as marcasite (*q.v.*).

Iron pyrites, or pyrite, belongs crystallographically to the parallel-faced hemihedral class of the cubic system. Its common forms are the cube, the octahedron, and the pentagonal dodecahedron, or various combinations of them. It has a conchoidal fracture, and a very indistinct cubic cleavage. Its hardness is about 6, and its specific gravity 4.9 to 5.2, being rather more than that of marcasite. Moreover, the colour of pyrite is brass-yellow, whilst that of marcasite when untarnished may be almost tin-white. From copper-pyrites (chalcopyrite) pyrite is distinguished by its superior hardness and by its paler colour. On exposure to meteoric influences pyrite commonly becomes brown, by formation of ferric hydrate. Such a change is very common on the outcrop of mineral veins, forming what miners call "gozzan."

According to the formula FeS_2, pyrite contains theoretically 46.67% of iron and 53.33% of sulphur. Practically, however, it frequently contains other metals, such as copper, cobalt and nickel. Gold is often present, and in many gold-mining districts the precious metal is obtained mainly from auriferous pyrite. As pyrite, from its brass-yellow colour, is sometimes mistaken for gold, it has been vulgarly called "fool's gold." Traces of thallium, which are present in some pyrite, may be detected in the flues of the furnaces where the metal is roasted. Arsenic is an impurity which may be of serious consequence in some of the purposes to which pyrite is applied. The presence of copper, nickel and arsenic is possibly due in many cases to traces of kindred minerals, like chalcopyrite, pentlandite and mispickel.

DISTRIBUTION AND USES

Pyrite is a mineral of very wide distribution, occurring under varied conditions and probably originating in various ways. It is common in mineral-veins, usually associated with quartz, and is often known to miners as "mundic." It occurs crystallized, commonly in cubes, in schistose and slaty rocks, and less abundantly in the younger sedimentary deposits. In coal it not infrequently forms bands and nodules known as "brasses," and may also be finely disseminated through the coal as "black pyrites"; but much of the so-called pyrite of coal is really marcasite. Films of pyrite sometimes coat the joint-planes of coal. Pyritous shales have been largely used in the manufacture of alum, and are therefore known as "alum shales." Many fossils are mineralized with pyrite, which has evidently been reduced by the action of decomposing organic matter on a solution of ferrous sulphate, or perhaps less directly on ferrous carbonate dissolved in water containing carbonic acid, in the presence of certain sulphates. A similar action probably explains the origin of pyrite and marcasite in coal and lignite, in clay and shales, and in limestone like chalk.

Pyrite is largely worked for the sake of the sulphur that it contains, and has displaced sulphur in the manufacture of sulphuric acid. For this purpose its value depends on the proportion of sulphur present. Pyrite low in sulphur is incapable of sustaining its own combustion without the aid of an external source of heat, and 45% of sulphur is, for economic reasons, usually regarded as the lowest percentage admissible for sulphuric acid manufacture. It is also important for this purpose that the ore should be as free as possible from arsenic (see SULPHURIC ACID).

An extremely important variety of pyrite is that which is more or less cupriferous, and is commonly known commercially as "copper-pyrites" (*q.v.*), though distinct mineralogically from that mineral. It consists, indeed, mainly of pyrite, with a notable but variable proportion of copper, sometimes with silver and gold, and not infrequently associated with lead and zinc sulphides. The copper probably exists as disseminated chalcopyrite. Deposits of such cupriferous pyrite are widely distributed and are often of great magnitude. They are generally of lenticular form, and usually occur in or near the contact of eruptive rocks with schists or slates; the presence of the igneous rock being probably connected genetically with their origin.

The world's annual production of iron-pyrite is about 4,500,000 tons. The largest producer is Spain, with upwards of 2,000,000 tons, including the cupriferous pyrite. France yields about 200,000 tons, largely from the Sain Bel mines, department of the Rhône. Then follows Portugal, with its important output of cupriferous pyrites. In the United States the production of pyrite now reaches about 170,000 tons per annum. The State of Virginia is the chief producer, followed successively by Georgia, North Carolina, Colorado, Massachusetts, California, Missouri, New York, etc. From Indiana and Ohio a quantity of pyrite is obtained as a by-product in coal-mining. The United Kingdom yields but little pyrite, the annual output being not more than about 5,000 tons. Large quantities of "sulphur ore" were, however, formerly worked in the Vale of Avoca, County Wicklow, Ireland. Finely crystallized specimens of pyrite are obtained from many other localities, especially from Cornwall, Elba and Traversella, near Ivrea, in Piedmont.

PYRITZ, a town in the Prussian province of Pomerania, Germany, 16 mi. S.W. of Stargard by the railway to Cüstrin. Pop. (1939) 11,200. It became a town in 1150 and is still surrounded by walls with towers. Near the town was the spring in which Otto, bishop of Bamberg, baptized the first Pomeranian converts to Christianity in 1124.

PYROCATECHIN or **PYROCATECHOL:** *see* CATECHOL.

PYROGALLOL or PYROGALLIC ACID, a trihydroxybenzene, $C_6H_3(OH)_3=1:2:3$, first prepared by Scheele in 1786 by heating gallic acid. It is used as a photographic developer and also as an oxygen absorbent in gas analysis. It has antiseptic properties and is employed medicinally in the treatment of psoriasis. The process of manufacture is still based on Scheele's procedure. Gallic acid with half its weight of water is heated in an autoclave until the pressure reaches 12 atmospheres and the temperature registered is 175° C. Steam and carbon dioxide are then allowed to escape, leaving in sufficient water to keep the pyrogallol liquid. The cooled solution is decolorised with animal charcoal and evaporated down until the volatile pyrogallol has distilled over into flat iron receivers. The solidified material is purified by repeated distillation or sublimation. Pyrogallol crystallises in colourless leaflets or needles, melts at 133° C and is easily sublimed; it distils at 293° C under the ordinary pressure with partial decomposition. It dissolves in $2\frac{1}{4}$ parts of water at 13° C, and its aqueous solution develops a blue colour with ferrous sulphate containing a little ferric salt. Its alkaline solution, when exposed to air, rapidly becomes black, owing to the absorption of oxygen with the production of complex coloured substances. (G. T. M.)

PYROLUSITE, a mineral consisting essentially of manganese dioxide (MnO_2), of importance as an ore of manganese. It is a soft, black, amorphous mineral, often with a granular, fibrous or columnar structure, and sometimes forming reniform crusts. It has a metallic lustre, and a black or bluish-black streak, and readily soils the fingers. The specific gravity is about 4.8.

Supposed crystals of pyrolusite have been proved to be pseudomorphs after manganite; in fact the mineral often results by the dehydration and oxidation of manganite ($Mn_2O_3{\cdot}H_2O$), and for this reason it frequently contains a little water. True crystals of manganese dioxide are referred to the rare species polianite: they are tetragonal and isomorphous with cassiterite. Pyrolusite is an alteration product of other manganese minerals—manganite, rhodochrosite, rhodonite, etc. It occurs as irregular masses and nodules in the residual clayey materials resulting from the decomposition of various rocks, for example, limestone. That it is readily deposited from solution is shown by the frequent occurrence of black dendritic markings in the crevices of rocks, excellent examples of which are seen in mocha stone (*q.v.*) and in the lithographic stone of Solenhofen, Bavaria. It is deposited by some springs and manganiferous nodules are dredged from the floor of the deep sea.

As an ore pyrolusite is extensively mined at Ilmenau and other places in Thuringia, in North Wales, at several places in the United States (Vermont, Virginia, Arkansas, etc.), Nova Scotia, Brazil, India, etc. Together with the rather less important ore, psilomelane, it has various economic applications: it is extensively used for the manufacture of spiegeleisen and ferromanganese, and of various alloys, such as manganese-bronze; as an oxidizing agent it is used in the preparation of chlorine and disinfectants (permanganates); and when mixed with molten glass it oxidizes the ferrous iron to ferric iron, and so discharges the green and brown tints, hence the name pyrolusite, from Gr. πῦρ (fire) and λύειν (to wash). As a colouring material, it is used in calico printing and dyeing; for imparting violet, amber and black colours to glass, pottery and bricks; and in the manufacture of green and violet paints.

PYROMETER, an instrument for measuring high temperatures (Gr. πῦρ, fire, μέτρον, a measure). The term was first used by Musschenbroek to denote an instrument wherein the expansion of a metal rod measured the temperature. Discontinuous thermoscopes, depending on the fusion of a metal or salt, have also been employed. Prinsep prepared a series of alloys of silver and gold, and of gold and platinum, whose melting points, as determined by accurate instruments, covered a range of temperature from 954° to 1,775°, at intervals of from 25° to 30°. By placing ingots in a furnace and observing which one melted a fair idea of the temperature was obtained Carnelley and Williams employed certain salts of known melting point; whilst the Seger's cones, employed in porcelain manufacture, depend on the softening of small cones made of clay. The instruments employed today depend either on electrical effects produced in wires inserted in the furnace and so raised to its temperature, or upon measurements made on the radiation emitted by the furnace. (See also THERMOMETRY for scientific forms.)

PYROMORPHITE, a mineral species composed of lead chloro-phosphate $(PbCl)Pb_4(PO_4)_3$, sometimes occurring in sufficient abundance to be mined as an ore of lead.

Crystals are common, and have the form of a hexagonal prism terminated by the basal planes, often with a barrel-like curvature, globular and reniform masses also being found. Between pyromorphite and the corresponding chloro-arsenate (mimetite, *q.v.*) the resemblance in external characters is so close that, as a rule, it is only possible to distinguish them by chemical tests, and they were formerly confused under the names "green lead ore" and "brown lead ore." The phosphate was first distinguished chemically in 1784, and it was named pyromorphite from Gr. πῦρ (fire) and μορφή (form), because when a fragment is fused the globule assumes a faceted form on solidifying. The colour is usually some bright shade of green, yellow or brown, and the lustre is resinous. The hardness is 3.5 and specific gravity 6·5–7·1. Pyromorphite has resulted from the alteration of galena in the oxidized portions of metalliferous veins, and is frequently met with in the upper levels of lead mines.

PYROMUCIC ACID (Furoic Acid): see FURFURAN.

PYRONES, in chemistry a group of heterocyclic compounds containing a six-membered ring composed of five carbon atoms and one oxygen atom. Substances containing the pyrone nucleus occur in nature; for example, coumarin, the odoriferous principle of the tonka bean, contains a pyrone, residue and so also do meconic acid, present in opium, and chelidonic acid, found in the celandine and white hellebore.

Two types of pyrones may be distinguished, the α-pyrones (I.), in which the oxygen atom is adjacent to a carbonyl group, and the y-pyrones (II.), where the oxygen atom and the carbonyl group are at opposite ends of the ring structure.

(I.) 
 (II.)

a-Pyrone or coumalin (I.) is derived from malic acid (*q.v.*). This acid on heating with strong sulphuric acid yields coumalic acid (α-pyrone-5-carboxylic acid) and on distilling the mecury salt of this intermediate acid in hydrogen, carbon dioxide is eliminated and α-pyrone is obtained as an oily liquid boiling at 206–209° C.

Phenylcoumalin or α'-phenyl-α-pyrone, colourless crystals melting at 68" C, is found in coto-bark. On heating with alkalis it yields benzoic acid and acetophenone. $\alpha'\beta'$-Benzo-α-pyrone is discussed under its other name, coumarin (*q.v.*). Like y-pyrone and dimethyl-y-pyrone (*v. infra*), coumarin has the property of forming salts with the acids (aurichloric, cobalticyanic, hydriodic and platinichloric acids). y-Pyrone or pyrocomane (II.) crystallises in colourless prisms melting at 32" C and boiling at 210–215° C. It is prepared from chelidonic acid γ-pyrone-2-6-dicarboxylic acid, m.p. 262° C. This acid on being heated loses carbon dioxide in two stages to form comanic acid, γ-pyrone-2-carboxylic acid, and finally y-pyrone. The elimination of carbon dioxide is facilitated by the addition of copper powder. Chelidonic acid can either be obtained from natural sources (v. *supra*) or prepared synthetically by condensing acetone with ethyl oxalate in presence of sodium ethoxide, when ethyl acetonedioxalate is produced, and this substance on boiling in alcoholic solution loses water to form ethyl chelidonate.

$\alpha\alpha'$-Dimethylpyrone (III.) is prepared by condensing carbonyl chloride with the copper derivative of ethyl acetoacetate, or by the action of concentrated hydrochloric acid on dehydracetic acid. It forms white monoclinic plates, melting at 132° C and boiling at 248° C/713 mm. It is readily soluble in water or alcohol to neutral solutions which have a bitter after-taste. Dimethylpyrone has the noteworthy property of giving well-defined crystallisable salts with hydrochloric, platinochloric and tartaric acids.

(III.) 
 (IV.)

The salts, which are considerably hydrolysed in aqueous solution, arise from a combination between one of the oxygen atoms (possibly the carbonyl one) and the hydrion of the acid. On the electronic theory of chemical combination either of these oxygens can furnish a pair of electrons to co-ordinate with the hydrion which has already given its single electron to the anion of the acid. Formula IV. represents the dimethylpyrone hydrochloride as having the hydrogen co-ordinated with the carbonyl oxygen. Dimethylpyrone was shown by A. Werner to combine in a similar way with cupric chloride to form the compound $C_7H_8O_2,CuCl_2$, the existence of which supports the hypothesis that the oxonium salts of the pyrones are co-ordination compounds arising from the operation of the subsidiary valencies of the oxidic or ketonic oxygen atoms. (G. T. M.)

PYROPHONE, the name of a curious kind of musical instrument invented by Georges Frederick Eugen Kastner (1852–82), son of the German composer and musical theorist, Jean Georges Kastner (1810–67). It consists of a set of tubes, from which the sound is produced, not by wind, but by jets of gas, picturesquely described by the author in a book which he published on the subject as "flammes chantantes."

PYROPHORIC ALLOYS, alloys which when filed or scratched give off bright sparks. Alloys containing about 15% iron and mixtures of rare-earth metals with small amounts of antimony, bismuth, copper and silicon are used in various lighters.

PYROPHORUS, a material which inflames spontaneously on contact with air. Homberg's pyrophorus (Gr. πῦρ, fire; *φέρειν*, to bear), one of the earliest known, was prepared by heating alum with finely divided carbon or organic material (lampblack, starch or flour) in a closed tube. The product, a mixture of potassium sulphide, aluminium sulphate and carbon, is spontaneously inflammable. The oxides of iron, cobalt or nickel when reduced by hydrogen at low red heat leave the metal in a state of such fine division that it becomes incandescent on exposure to air. Lead tartrate heated in a closed tube leaves a pyrophoric residue of finely divided lead. Liquid phosphine, P_2H_4, and organo-metallic compounds such as cacodyl, zinc diethyl, trimethylstibine, etc., are spontaneously inflammable liquids.

PYROPHYLLITE, a mineral species composed of hydrous aluminium silicate, $HAl(SiO_3)_2$. It occurs in two more or less distinct varieties, namely. as crystalline folia and as compact masses; distinct crystals are not known.

The folia have a pronounced pearly lustre, owing to the presence of a perfect cleavage parallel to their surfaces: they are flexible but not elastic, and are usually arranged radially in fanlike or spherical groups. This variety, when heated before the blowpipe, exfoliates and swells up to many times its original volume, hence the name pyrophyllite, from the Greek πῦρ (fire) and φύλλον (a leaf), given by R. Hermann in 1829. The colour of both varieties is white, pale green, greyish or yellowish; they are very soft (H.=1–2) and are greasy to the touch. The specific gravity is 2·8–2·9. The two varieties are thus very similar respectively to talc (*q.v.*) and its compact variety steatite, which is, however, a hydrous magnesium silicate. The compact variety of pyrophyllite is used for slate pencils and tailors' chalk ("French chalk"), and is carved by the Chinese into small images and ornaments of various kinds. Other soft compact minerals (steatite and pinite) used for these Chinese carvings are included with pyrophyllite under the terms agalmatolite and pagodite.

Pyrophyllite occurs in schistose rocks, often associated with kyanite, of which it is an alteration product. Pale green foliated masses, very like talc in appearance, are found at Beresovsk near Ekaterinburg in the Urals, and at Zermatt in Switzerland. The most extensive deposits are in the Deep River region of North Carolina, where the compact variety is mined, and in South Carolina and Georgia.

PYROTECHNY: see FIREWORKS.

PYROXENE, in mineralogy, an important group of rock-forming minerals very similar in chemical composition and general characters to the amphiboles (q v.). The name (from Gr. πῦρ, fire, and *ξένος*, stranger) was originally given by Haüy in 1796 to the augite (*q.v.*) of the lavas of Vesuvius, in the belief that the crystals had been caught up by the lavas that contained them; but next to the felspars the pyroxenes are the commonest constituents of igneous rocks, being especially characteristic of those of basic composition (basalt, gabbro, pyroxenite, etc.). Though crystallizing in three different systems, the pyroxenes all possess distinct prismatic cleavages, with an angle of about 87° between them. Usually the habit of these minerals is that of short prisms, but in the alkaline varieties long slender prisms are often characteristic, e g, acmite.

The pyroxenes are conveniently subdivided into three series according to the symmetry of their crystals. Chemically they are essentially metasilicates. The principal species are indicated in the table on p. 801.

Rhombic Series	
Enstatite	$Mg\,SiO_3$
Bronzite	$(Mg, Fe)\,SiO_3$
Hypersthene	$(Fe, Mg)\,SiO_3$
Monoclinic Series	
Clinoenstatite	$Mg\,SiO_3$
Diopside	$Ca\,Mg\,(SiO_3)_2$
Hedenbergite	$Ca\,(Mg, Fe)\,(SiO_3)_2$
Enstatite — Diopside or Magnesium Diopside	$m(Mg,Fe)SiO_3.\ nCa(Mg,Fe)(SiO_3)_2$
Augite	$Ca(Mg,Fe)(SiO_3)_2$ with $(Mg,Fe)SiO_3$ and $(Al,Fe''')_2O_3$
Acmite	$NaFe'''(SiO_3)_2$
Jadeite	$NaAl(SiO_3)_2$
Spodumene	$LiAl(SiO_3)_2$
Wollastonite	$CaSiO_3$
Pectolite	$HNaCa_2(SiO_3)_3$
Rosenbuschite	$Na_2Ca_3[(Si,Zr,Ti)O_3]_4$
Triclinic Series	
Rhodonite	$MnSiO_3$
Pyroxmangite	$(FeMn)\,SiO_3$
Bustamite	$(Ca,Mn)\,SiO_3$
Babingtonite	$Ca(Fe,Mn)\,(SiO_3)_2$ with Fe_2O_3 and SiO_2
Sobralite	$CaMgFe_2Mn_4\,(SiO_3)_8$
Hiortdahlite	$4Ca(Si, Zr)O_3.\ Na_2ZrO_2F_2$

Many of these species are described under their respective headings, to which reference should be made. Others not so treated are briefly mentioned below. *Clinoenstatite,* the monoclinic magnesium metasilicate, occurs in meteorites. It is the only stable metasilicate of magnesium prepared in the laboratory. It melts incongruently at 1,557° C with separation of forsterite. *Enstatite-diopside* or *magnesium diopside* is an isomorphous mixture of diopside with clinoenstatite, and as such is a characteristic pyroxene of the quartz-dolerite group of igneous rocks. *Hedenbergite* is a black or dark green pyroxene characteristic of metasomatically metamorphosed limestones or skams, and is often associated with andradite garnet. A fluorine-bearing diopside known as *mansjöite,* occurs at Mansjö Mt. in Sweden. The manganese and zinc-bearing monoclinic pyroxenes include *schefferite* $Ca(Mg,Fe,Mn)(SiO_3)_2$, and *jeffersonite,*

$$Ca(Mg,Fe,Mn,Zn),(SiO_3)_2,$$

both occurring at Franklin Furnace, New Jersey.

Jadeite is a white to grey pyroxene occurring in dense fibrous masses in association with serpentine, glaucophane schists or eclogites in Turkistan, Tibet, Burma and other places. It possesses a distinct ethnographic interest owing to its use by prehistoric man in the manufacture of images and utensils. *Pectolite* occurs as a secondary mineral in the form of radiating fibrous crystals in druses and veins of basic igneous rocks of the triclinic series of minerals classified as pyroxenes, *bustamite, fowlerite* and *pyroxmangite* are closely related to *rhodonite.* The two former occur at Franklin Furnace, New Jersey. *Sobralite* occurs with manganese-garnet in an eulysite from Sodermanland in Sweden. According to the most recent analyses, *babingtonite* contains alkalis and water as essential constituents. The mineral occurs in black crystals on felspar in the granite of Baveno, Italy, and also as a product of contact metamorphism in Japan and elsewhere. The rare zirconium-bearing silicates, *hiortdahlite* and the monoclinic *rosenbuschite,* occur in the nepheline-rich rocks of southern Norway and of the Los archipelago (Guinea). (C. E. T.)

PYROXENITE, a rock consisting essentially of minerals of the pyroxene group, such as augite and diallage, hypersthene, bronzite or enstatite. Names have been given to members of this group according to their component minerals, *e.g.,* pyroxenite (augite), diallagite (diallage), hypersthenite (hypersthene), bronzitite (bronzite), websterite (diallage and hypersthene). Closely allied to this group are the hornblendites, consisting essentially of hornblende. The term perknite (Gr. περκνός, dark) has also been used to designate the whole series.

PYRRHB OF ELHS (c. 360–270 B.C.), a Greek sceptic philosopher and founder of the school known as Pyrrhonism. Diogenes Laertius (ix. 61), quoting from Apollodorus, says that he was at first a painter, and that pictures by him were in existence in the gymnasium at Elis. Later he was diverted to philosophy by the works of Democritus. He studied in India under the Gymnosophists (*q.v.*) and under the Magi in Persia. Returning to Elis, he lived in poor circumstances, but highly honoured by the Elians and also by the Athenians, who gave him the rights of citizenship. His doctrines are known mainly through the satiric writings (Σίλλοι) of his pupil Timon of Phlius (the Sillographer). The main principle of his thought is expressed in the word *acatalepsia,* which implies the impossibility of knowing things in their own nature. Pyrrho concludes that, since nothing can be known, the only proper attitude is imperturbability *(ataraxia).* The impossibility of knowledge, even in regard to our own ignorance or doubt, should induce the wise man to withdraw into himself, avoiding the stress and emotion which belong to the contest of vain imaginings. *(See* PHILOSOPHY, HISTORY *OF.)*

PYRRHOTITE, a mineral species consisting of iron sulphide and crystallizing in the hexagonal system. The formula is Fe_nS_{n+1}, in which n may vary from 5 to 16; such a composition being explained by the "solid solution" of sulphur in ferrous sulphide (troilite). Small amounts of nickel and cobalt are often present; the mineral is of some importance as an ore of gold, and the nickeliferous pyrrhotite of Sudbury, Ontario, is by far the most important source of nickel.

Crystals have the form of hexagonal plates bounded at their edges by faces of a hexagonal prism and pyramids, which are deeply striated horizontally. More frequently, however, the mineral is massive, with a laminar or granular structure. It is magnetic, sometimes with polarity, and is therefore often called "magnetic pyrites." The colour is bronze yellow, the lustre metallic and the streak greyish black. The hardness is 4 and the specific gravity 4·58–4·64.

Pyrrhotite occurs in metalliferous veins, and as grains and plates disseminated through various rocks.

PYRRHUS *(c.* 318–272 B.C.), king of Epirus, son of Aeacides, and a member of the royal family of the Molossians. He claimed descent from Pyrrhus, the son of Achilles, and was also connected with the royal family of Macedonia through Olympias, the mother of Alexander the Great. He became king when still a boy, and fought for Demetrius Poliorcetes at Ipsus in 301. He was sent to the court of Ptolemy as a hostage by Demetrius, married Ptolemy's step-daughter Antigone, and became in his turn a thorn in Demetrius' side. For some time he occupied most of Macedonia under the terms of a truce, but in 286 Lysimachus defeated him at Edessa and drove him back into Epirus.

In 281 Tarentum, in southern Italy, asked his assistance against Rome. Pyrrhus went with some 25,000 men, and might, with more whole-hearted assistance from the Greek cities, have been a fatal obstacle to the growth of Rome, faced with Etruscans and Gauls in the north as well as this reinforced opposition in the south. Greeks and Romans met at Heraclea, and Pyrrhus, with the advantage gained by his cavalry and elephants, completely defeated the consul M. Valerius Laevinus, but at the cost of very heavy losses. This battle is the origin of the phrase "a Pyrrhic victory." He advanced on Rome through Latium, but the towns were all garrisoned, and though the senate were inclined to agree to terms, the speech of Appius Claudius the censor decided them against it. Cineas, Pyrrhus' minister, was sent back with a refusal to negotiate as long as Pyrrhus' troops were in Italy.

In 279 Pyrrhus won another victory at Asculum in Apulia. He then went to Sicily with the idea of driving the Carthaginians out; his military operations were successful, and Rome and Carthage united in an alliance against him, while his despotic methods alienated the Sicilian cities. He stayed three years in Sicily, and then returned to Italy, but the Greek cities now entirely failed to support him, and he was completely defeated at Beneventum in 275. He left Italy, saying "what a battlefield I am leaving to Rome and Carthage"—a remark of some insight. The rest of his life was passed in wars at home, including a victory over Antigonus Gonatas, and an unsuccessful expedition into Sparta at the invitation of Cleonymus in 273. He was killed in 272 in a night skirmish in a street in Argos. Pyrrhus wrote a history of the art of war, which is praised by Cicero, and quoted by Dionysius of Halicarnassus and Plutarch.

The chief ancient authority for the life of Pyrrhus is Plutarch; *see* also Polybius xviii. 11, and elsewhere; Dion. Halic. xviii. 1, xix. 6–9; Pausanias i. 13; Justin xviii. 1, 2, xxiii. 3, xxv. 4, 5. Modern monographs by G. F Hertzberg, "Rom und König Pyrrhus" (popular: in O. Jäger's *Darstellungen aus der römischen Geschichte,* 1870); R. von Scala, *Der Pyrrhische Krieg* (1884), with map of Roman garrison system in 281; R. Schubert, *Geschichte des Pyrrhus* (1894), with full list of authorities; also ROME: *History.*

PYRROLE, in chemistry a comparatively simple organic base containing four carbon atoms and one nitrogen atom, united to form a five-membered ring C_4H_5N (formula I.). Its tetrahydro-compound, *pyrrolidine,* has a similar cyclic structure (formula II.) but with four additional hydrogen atoms. Pyrrole and pyrrolidine are of great significance in connection with the chemistry of many complex substances found in living organisms both vegetable and animal. These two five-membered rings are patterns frequently

(I.) 
 (II.)

employed in the molecular structure of products arising from the vital activities of plants and animals. The tobacco alkaloids, nicotine and nicoteine contain pyrrole nuclei, whereas pyrrolidine residues are present in other alkaloids such as stachydrine, betonicine, hygrine and the solanaceous and coca alkaloids. Hydrolysis of protein materials often leads to the production of proline (pyrrolidine-2-carboxylic acid) or of hydroxyproline (4-hydroxypyrrolidine-2-carboxylic acid). Moreover, the researches of Willstatter and other investigators have shown that the pyrrole pattern is manifolded in chlorophyll (*q.v.*) and haemoglobin (*q.v.*), thus revealing an interesting relationship between the colouring matters of leaves and blood.

Pyrrole is a colourless liquid which becomes brown on exposure and smells like chloroform. It boils at 130–131° C/761 mm.; its specific gravity is 0·9752/12·5° C. Although readily soluble in ether or alcohol, it dissolves only sparingly in water. It is insoluble in aqueous alkalis and dissolves but slowly in acids. On keeping or on warming its acid solution a red precipitate known as pyrrole red separates, this characteristic reaction being accompanied by liberation of ammonia.

Pyrrole is present to a small amount in coal tar but is most readily obtained from bone oil (Dippel's oil) when the fraction boiling between 98° and 150° C is heated with solid caustic soda. The solid product, a sodium pyrrole, C_4H_4NNa, is hydrolysed by water and distilled in steam, when pyrrole passes over and is purified from its homologous methylated pyrroles by fractional distillation. It can be prepared synthetically by heating ammonium mucate (see MUCIC ACID) with glycerin, the mixture being then saturated with ammonia and distilled at 320–330° C. In pyrrole vapour a pine-wood splinter moistened with hydrochloric acid develops an intense carmine-red coloration, this reaction being employed as a delicate test for pyrrole.

Pyrrole has been obtained by passing acetylene and ammonia through a heated tube containing ferric oxide; it is also produced on heating succinimide (see SUCCINIC ACID) with zinc dust containing zinc hydroxide.

With zinc dust and mineral acid, pyrrole is reduced to its dihydro-derivative, *pyrroline,* a colourless liquid boiling at 90° C/748 mm., fuming in air and having a strongly alkaline reaction.

Pyrrolidine (formula II.) is obtained by reduction of either pyrrole or pyrroline with hydriodic acid and phosphonium iodide at 240–260° C, or with hydrogen at this temperature over a nickel catalyst. The reduction of ethylene cyanide leads to pyrrolidine together with tetramethylenediamine (putrescine, a ptomaine alkaloid). Pyrrolidine is a constituent of the tobacco alkaloids.

Although pyrrole itself has had no technical application, its iodo-derivative is an antiseptic. Iodine acts on potassium pyrrole to yield tetraiodo-pyrrole or *Iodole,* $C_4I_4{:}NH$, which crystallises in yellowish-brown prisms and decomposes at 140° C. This compound acts antiseptically like iodoform but has the advantage of being odourless.

Angeli 1913; C. Hollins, *The Synthesis of Nitrogen Ring Compounds* (1924). (G. T. M.)

PYRUVIC ACID or **PYRORACEMIC ACID,** an extremely reactive organic acid employed in the synthesis of derivatives of aryl-cinchonic acids including phenylcinchonic acid (Acidum Phenylcinchonicum, U.S. Pharmacopoeia), which is also known as Phenoquin or Atophan, used in neuralgia, sciatica or for the elimination of uric acid in gout and rheumatic affections.

Pyruvic acid, $CH_3{\cdot}CO{\cdot}CO_2H$, is best prepared by heating together an intimate mixture of 6 parts of fused potassium hydrogen sulphate and 4 parts of tartaric acid at 210–220° C. The distillate is fractionated under reduced pressure when a 50–55% yield of the acid is obtained (O. Kamm, Organic Syntheses, J. Wiley and Sons, 1925, vol. v., p. 63). Pyruvic acid was first obtained by Berzelius in 1855 by the dry distillation of tartaric or racemic acid. Methods of academic interest are: (1) the acid hydrolysis of acetyl cyanide, $CH_3{\cdot}CO{\cdot}CN$, or of ethyl oxaloacetate, $Et{\cdot}O_2C{\cdot}CO{\cdot}CH_2{\cdot}CO_2{\cdot}Et$; (2) boiling $\alpha\alpha'$-dichloropropionic acid with moist silver oxide. As prepared by any of the foregoing methods pyruvic acid is a liquid boiling at 75–80°/25 mm. and at 165° C/760 mm. with partial decomposition; it may be solidified and then melts at 13·6° C. With phenylhydrazine it yields a well defined crystalline phenylhydrazone and it combines additively with prussic acid and with alkali bisulphites. It forms mercaptols with the mercaptans and is reduced successively to lactic and propionic acids. Its most characteristic reaction with aldehydes and aromatic amines (Doebner's reaction) leads to the production of aryl-cinchonic acids. With benzaldehyde and aniline it furnishes phenylcinchonic acid and with other aldehydes and β-naphthylamine it yields β-naphthylcinchonic acids of definite melting points which on heating lose carbon dioxide and give well-defined bases. The reactions serve to identify aldehydes (*q.v.*).

PYTHAGORAS (6th century B.C.), Greek philosopher, was a native of Samos and flourished about 532 B.C. He is said to have been a pupil of Pherecydes (*q.v.*). He left in Ionia the reputation of a learned and universally informed man. "Of all men," says Heracleitus, "Pythagoras, the son of Mnesarchus, was the most assiduous enquirer." The extensive travels attributed to Pythagoras are no doubt mostly apocryphal, but there is no intrinsic improbability in the statement of Isocrates (Laud. *Busir.* 28, p. 227 Steph.) that he visited Egypt and other countries of the Mediterranean. The historically important part of the career of Pythagoras begins with his migration to Croton, a Dorian colony in southern Italy, about the year 529. According to tradition, he was driven from Samos by the tyranny of Polycrates. At Croton Pythagoras became the centre of a widespread organization, which was, in its origin, a religious brotherhood or an association for the moral reformation of society rather than a philosophical school. The Pythagorean brotherhood had much in common with the Orphic communities which sought by rites and abstinence to purify the believer's soul and enable it to escape from the "wheel of birth." Its aims were those of a religious order rather than a political league. The new order did indeed establish for a time its supremacy over a considerable part of Magna Graecia, but this entanglement with politics led in the end to the dismemberment and suppression of the society. The first reaction against the Pythagoreans, led by Cylon, seems to have taken place in the lifetime of Pythagoras in connection with the victory gained by Croton over Sybaris in 510. Cylon was able to bring about the retirement of Pythagoras to Metapontium, where he remained until his death at the end of the 6th or the beginning of the 5th century. The order appears to have continued powerful in Magna Graecia till the middle of the 5th century when it was violently trampled out. The meeting-houses of the Pythagoreans were everywhere sacked and burned; mention is made in particular of "the house of Milo" in Croton, where 50 or 60 Pythagoreans were surprised and slain. Those who survived took refuge at Thebes and other places. Lysis went to Thebes, where he became the instructor of Epaminondas. Philolaus, too, who according to tradition wrote the first exposition of the Pythagorean system, lived at Thebes at the end of the 5th century. Philolaus, however, and some others were afterwards able to return to Italy, and thenceforth Taras (Tarentum) became the chief seat of the school. Here Archytas, the friend of Plato, lived; he ruled Taras for years and was never defeated in battle. As a philosophic school the Pythagoreans became extinct about the middle of the 4th century.

Aristotle in his accounts of Pythagorean doctrines never refers to Pythagoras but always to "the Pythagoreans" or "the so-called Pythagoreans" (*οἱ καλούμενοι*). Nevertheless certain doctrines may be traced to the founder. Foremost among these is the theory of the immortality and transmigration of the soul (*see* METEMPSYCHOSIS). Pythagoras's teaching on this point is connected with the primitive belief in the kinship of men and beasts, a view which Pythagoras also held. The Pythagorean rule of abstinence from flesh is thus, in its origin, a taboo resting on the blood-brotherhood of men and beasts; and a number of the Pythagorean rules of life which we find embodied in the different traditions appear likewise to be genuine taboos belonging to a similar level of primitive thought. The moral and religious application which Pythagoras gave to the doctrine of transmigration continued to be the teaching of the school. The view of the body (*σῶμα*) as the tomb (*σῆμα*) of the soul and the account of philosophy in the Phaedo as a meditation of death are expressly connected by Plato with the teaching of Philolaus; and the strain of asceticism and other-worldliness which meets us here and elsewhere in Plato is usually traced to Pythagorean influence.

Theory of Numbers.—The scientific doctrines of the Pythagorean school have no apparent connection with the religious mysticism of the society or their rules of living. Their discourses and speculations all connect themselves with the idea of number, and the school holds an important place in the history of mathematical and astronomical science. Aristotle tells us that the Pythagoreans "applied themselves to the study of mathematics and were the first to advance that science; insomuch that, having been brought up in it, they thought that its principles must be the principles of all existing things." Pythagoras is said to have attached supreme importance to arithmetic, which he advanced and took out of the region of commercial utility. He also made geometry a part of a liberal education, examining the principles of the science and treating the theorems from an immaterial and intellectual standpoint.

Pythagoras's greatest discovery was, perhaps, that of the dependence of the musical intervals on certain arithmetical ratios of lengths of string at the same tension, 2:1 giving the octave, 3:2 the fifth and 4:3 the fourth. This discovery could not but have powerfully contributed to the idea that "all things are numbers." According to Aristotle, the-theory in its original form regarded numbers, not as relations predicable of things, but as actually constituting their essence or substance. Numbers, he says, seemed to the Pythagoreans to be the first things in the whole of nature, and they supposed the elements of numbers to be the elements of all things, and the whole heaven to be a musical scale and a number (*Metaph.* A. 986 a). Later, *e.g.*, in the fragments of "Philolaus," things are spoken of, not as *being* numbers, but as having number and thereby becoming knowable.

The development of these ideas into a comprehensive metaphysical system was probably the work of Philolaus. The "elements of numbers" referred to by Aristotle were, according to the Pythagoreans, the Odd and the Even, which they identified with the Limit and the Unlimited. The Unlimited, and therefore the Limit also, was conceived as spatial. Numbers were thus spatially regarded, and "one" was identified with the point, which was thus a unit having position and magnitude; "two" was similarly identified with the line, "three" with surface, and "four" with solid. The Odd and Even and the Limit and Unlimited were the first two of a set of ten fundamental oppositions postulated by the Pythagoreans, the remaining eight being: one and many, right and left, male and female, rest and motion, straight and curved, light and darkness, good and evil, square and oblong. To the Pythagoreans the Universe was in a sense the realization of these opposites. The further speculations of the Pythagoreans on the subject of number rest mainly on fanciful analogies. Thus "seven" is called *πάρθενος* and *Ἀθήνη* because within the decade it has neither factors nor products; "five," on the other hand, is marriage because it is the union of the first masculine and the first feminine number (3+2, unity not being considered a number); "one" is identified with reason because it is unchangeable; "two" with opinion because it is unlimited and indeterminate; "four" with justice because it is the first square number, the product of equals.

Aristotle has the interesting remark that Eurytus, who was a disciple of Philolaus, used to assign numbers to all sorts of things such as horses or men, and imitated their shapes by arranging pebbles after the manner of those who bring numbers into the forms of triangles or squares (*Metaph.* N. 5, 1092 b 10). This brings us to figured numbers and the connection between numbers and geometry. The "holy tetractys," by which the later Pythagoreans used to swear, was a figure of this kind  representing the "triangular" number 10 and showing at a glance its composition as 1+2+3+4. To add a row of five dots gives the next "triangular" number with 5 as the side, and so on, showing that the sum of any number of the series of natural numbers beginning with 1 is a triangular number. The sum of any number of the series of odd numbers beginning with 1 is similarly seen to be a square; thus 3 and 5 added successively to 1 give a figure of this kind , and so on. If we take the series of even numbers, we see that the sum of any number of them beginning with 2 makes an "oblong" number .

The successive odd numbers after 1 were called "gnomons" because the addition of each of them to the sum of the preceding ones (beginning with 1) makes a square number into the next larger square. If the "gnomon" added to a square is itself a square number, *e.g.*, g, we have a square number which is the sum of two squares; thus $1+3+5+7=16$ or 4^2, and the addition of g $(=3^2)$ gives 25 or 5^2, that is, $3^2+4^2=j^2$. Pythagoras himself is credited with a general formula for finding two square numbers the sum of which is also a square, namely (if m is any odd number), $m^2+\left\{\tfrac{1}{2}(m^2-1)\right\}^2=\left\{\tfrac{1}{2}(m^2+1)\right\}^2$. This connects itself with the theorem of the square on the hypotenuse of a right-angled triangle, which tradition universally associates with the name of Pythagoras. This being a property of all right-angled triangles, consideration would show that, while some such triangles have their sides in the ratio of rational numbers, some, and in particular the isosceles, have not. In the case of the isosceles right-angled triangle the ratio of the hypotenuse to either of the other sides is what we write as V2, which is "irrational" in the sense that its value cannot be expressed exactly as a ratio between numbers. It was the Pythagoreans who discovered the irrationality of V2, and not only so, but they discovered the law of formation of the series of "side"?—and "diagonal" numbers (as they were called), which satisfy the equations $2x^2-y^2=+1$ and so enable us to find, as x and y increase, closer and closer approximations to the value of V2. The law depends on the proposition in Eucl. ii. 10 to the effect that $(2x+y)^2-2(x+y)^2=2x^2-y^2$, whence it follows that if x, y satisfy one of the above equations, then $2x+y$, $x+y$ is a solution in higher numbers of the other equation. From this we derive $\frac{1}{1}, \frac{3}{2}, \frac{7}{5}, \frac{17}{12}, \frac{41}{29}$ and so on ad *infinitum* as approximations to V2.

Contributions to Geometry.—Other contributions to geometry by the Pythagoreans comprise the following: (1) Pythagoras, we are told, himself formulated definitions in geometry. (2) The Pythagoreans proved that the sum of the three angles of any triangle is equal to two right angles; we have their proof, which, like Euclid's, uses the property of parallels; hence they knew the theory of parallels. (3) They discovered the powerful method in geometry of the "application of areas" (cf. Eucl. i. 44, 45), including application with "excess" and "defect" (*cf.* Eucl. vi. 28, 29) which amounts to the geometrical solution of any quadratic equation in algebra having real roots. (4) Pythagoras himself is said to have discovered the theory of proportion (for when Proclus says that he discovered the theory of irrationals, τῶν ἀλόγων, the reading should almost certainly be τῶν ἀνάλογον, of proportionab) and of the three means, arithmetic, geometric and harmonic. The arithmetic and harmonic means are shown in the middle terms of the proportion $a:\frac{a+b}{2}=\frac{2ab}{a+b}:b$, a particular case being $12:9=8:6$, from the terms of which the three musical intervals can be obtained. The Pythagorean theory of proportion was arithmetical (after the manner of Euclid, Book vii.) and did not apply to incommensurable magnitudes; it must not therefore be confused with the general theory due to Eudoxus which is expounded in Euclid < (5) Proclus also says that Pythagoras discovered the construction of the five regular solids. It was more probably Theaetetus who (as another scholium says) discovered the octahedron and the icosahedron; but the Pythagoreans were clearly acquainted with the pyramid or tetrahedron and the dodecahedron. The construction of the dodecahedron requires that of a regular pentagon, which again depends (as in Eucl. iv., 10, 11) on the problem of Eucl, ii. 11. about the division of a line "in extreme and mean ratio," a particular case of the "application of areas." The assumption that the Pythagoreans could construct a regular pentagon is confirmed by the fact that the "pentagram," the "triple interwoven triangle," or the star-pentagon, was used by the Pythagoreans as a symbol of recognition between the members of the school and was called by them Health. (6) The Pythagoreans discovered how to construct a rectilineal figure equal to one and similar to another rectilineal figure.

Summing up the Pythagorean geometry, we may say that it covered the bulk of the subject matter of Euclid's Books i., ii., iv., vi. (and probably iii.), with the qualification that the Pythagorean theory of proportion was inadequate in that it did not apply to incommensurable magnitudes.

Pythagorean **Astronomy.**—It remains to speak of the Pythagorean astronomy. Pythagoras was one of the first to hold that the earth and the universe are spherical in shape. He realized that the sun, moon and planets have a motion of their own independent of the daily rotation and in the opposite sense. It is improbable that Pythagoras himself was responsible for the astronomical system known as Pythagorean, which deposed the earth from its place in the centre and made it a "planet" like the sun, the moon and the other planets; for Pythagoras apparently the earth was still at the centre. The later Pythagorean system is attributed alternatively to Philolaus and to Hicetas, a native of Syracuse. The system may be thus described. The universe is spherical in shape and finite in size. Outside it is infinite void which enables the universe to breathe, as it were. At the centre is the central fire, called the Hearth of the Universe (among other names), wherein is situated the governing principle, the force which directs the movement and activity of the universe. In the universe there revolve round the central fire the following bodies: nearest to the central fire is the "counter-earth" which always accompanies the earth; next in order (reckoning from the centre outwards) is the earth, then the moon, then the sun, then the five planets and then, last of all, the sphere of the fixed stars. The counter-earth, revolving in a smaller orbit than the earth, is not seen by us because the hemisphere in which we live is always turned away from the counter-earth (the analogy of the moon which always turns the same side to us may have suggested this). This part of the theory involves the assumption that the earth rotates about its own axis in the same time as it takes to complete its orbit round the central fire; and, as the latter revolution was held to produce day and night, it is a fair inference that the earth was thought to revolve round the central fire in a day and a night, or in 24 hours.

The system amounts to a first step towards an anticipation of the Copernican hypothesis, and Copernicus himself referred to it as such. The curious thing in the system is the introduction of the counter-earth. Aristotle in one place says that its object was to bring the number of the revolving "bodies" up to ten, the perfect number according to the Pythagoreans; but elsewhere he hints at the truer explanation, when he says that eclipses of the moon were considered to be due sometimes to the interposition of the earth, sometimes to the interposition of the counter-earth, whence it would appear that the counter-earth was invented in order to explain the frequency of lunar eclipses as compared with solar.

For accounts of the sources and for further details reference may be made to the following works in addition to Zeller, *Die Philosophie der Griechen* (4th ed. 1892, etc.); Diels, *Doxographi Graeci* (1879) and *Die Fragmente der Vorzokratiker* (4th ed., 1922); A. (1921); Eva Sachs, *Die fünf Platonischen Körper* (1917). (T. L. H.)

PYTHAGORAS, of Rhegium, a noted Greek sculptor of the 5th century B.C., a contemporary of Myron and Polyclitus, and their rival in making statues of athletes. One of these, that of the boxer Euthymus of Locri, can be dated at 472 B.C. He was born at Samos and migrated in his youth to Rhegium in Italy. He made a statue of Philoctetes notable for the physical expression of pain, an Apollo shooting the Python at Delphi, and a man singing to the lyre. His technical improvements went far to ending archaic stiffness. No existing work can be certainly attributed to him, but the "Apollo on the Omphalos" at Athens and the "Choiseul-Gouffier" Apollo in the British Museum have been identified as copies of his statue of Euthymus.

See Waldstein in *J.H.S.* i., 168; E. A. Gardner, *Handbook of Greek Sculpture* (London, 1915).

PYTHEAS, of Marseille (Massilia), Greek navigator and geographer, was probably contemporary with Alexander the Great; his work is lost, and we are left in the dark as to its form and character, but the various titles under which it is quoted (*e.g.,* Γῆς περίοδος, or Τὰ περὶ τοῦ Ὠκεανοῦ) point to a geographical treatise, in which Pytheas had embodied the results of his observations, rather than to a continuous narrative of his voyage.

Some modern writers supposed Pytheas to have been sent out, at public expense, by the republic of Massilia; but there is no ancient authority for this, and Polybius states that he had undertaken the voyage in a private capacity and with limited means. All that we know concerning the voyage of Pytheas is contained in a brief passage of Polybius cited by Strabo, according to which Pytheas had not only visited Britain, but had "travelled all over it on foot," and estimated its circumference at more than 40,000 stadia (4,000 geographical miles). To this he added the account of Thule (which he placed six days' voyage north of Britain) and the adjoining regions. After this he visited "the whole of the coasts of Europe" (*i.e.,* those bordering on the ocean) as far as the *Tanais.* Some modern writers suppose that he made two different voyages; but this is improbable; the expressions of Polybius imply that his explorations in both directions, first towards the north and afterwards towards the east, formed part of the same voyage.

The countries visited by Pytheas, were previously unknown to the Greeks and were not visited again for two centuries. Hence some of the later Greek geographers altogether disregarded his statements, and treated his voyage as a fiction. In modern times a critical examination has been more favourable and the tendency of modern critics has been to exaggerate the value of Pytheas's work. Speculation has dealt chiefly with his "Thule," believed differently to be Norway, Iceland, or the Shetlands; and "Cassiterides" (Tin islands, perhaps St. Michael's mount in Cornwall).

Pytheas had one special merit; he was a good astronomer, and was one of the first to fix latitudes. His calculations of the length of the longest day at four different points in the neighbourhood of Britain are probably based on native reports. If these figures (16, 17, 18 and 19 hours) are to be pressed, they would refer to, say, Ushant (48° N.), Flamborough Head (54°), Tarbet Ness in Ross (58°) and the northernmost Shetlands (61°). Pytheas was also the first among the Greeks to arrive at any correct notion of the tides, and to note their connection with the moon, and their periodical fluctuations. Other observations concerning the manners and customs of the inhabitants of remote northern regions prove that he had himself visited them. Among these are the gradual disappearance of various kinds of grain as one advanced northward; the use of fermented liquors made from corn and honey; and the habit of threshing out corn in barns, instead sf on open threshing-floors as in Greece and Italy.

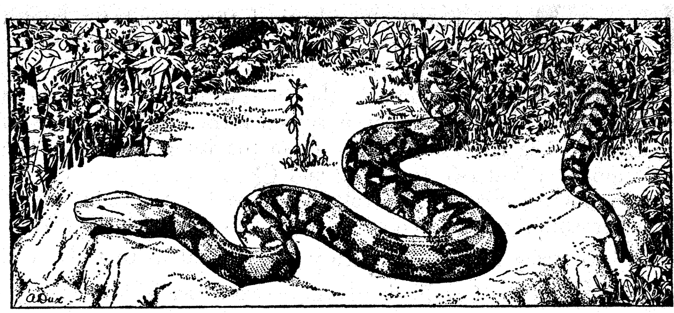
The fragments of Pytheas have been collected by Arvedson (Uppsala, 1824), and by Fuhr (*De Pythea massiliensi*, Darmstadt, 1835). Of the numerous treatises on the subject, *see* Ukert, "Bemerkungen über Pytheas," in vol. i. of his *Geog. d. Griechen u. Romer*, pp. 298–309, which contains an excellent summary of all that is known concerning Pytheas; Sir George C. Lewis, *Historical Survey of the Astronomy of the Ancients*, pp. 466–480 (London, 1862); Sir Edward H. Bunbury, *History of Ancient Geography*, vol. i. ch. xv. § 2 (1883); C. I. Elton, *Origins of English History*, *cf.* especially app. i. pp. 400, etc. (1882); Hugo Berger, *Geschichte der wissenschaftlichen Erdkunde der Griechen*, pt. 3 (2nd ed., Leipzig, 1903). An elaborate investigation of the subject will be found in Mullenhoff, *Deutsche Alterthumskunde*, i. 211–497 (1870). *See* also Sir Clements Markham's paper, "Pytheas, the Discoverer of Britain," in the *Geographical Journal* (June 1893); and H. F. Tozer, *History of Ancient Geography*, pp. 152–164 (Cambridge, 1897).

PYTMIAS, KNIGHTS OF, a fraternal and benevolent order of secret character, founded in Washington, D. C. Feb. 19, 1864 and chartered by a special act of Congress. In 1939 the order maintained j6 grand lodges or grand domains in the States of the United States and in provinces of Canada. There were also,about 5,000 local or subordinate lodges. Most of these (49 grand lodges and approximately 4.800 local lodges) are in the United States; in the Dominion of Canada there were in 1939 seven grand lodges and about 200 local lodges. The governing body is the Supreme Lodge. The organization supports 22 homes in as many States to take care of its dependent members and maintains a military department. There are three recognized auxiliary bodies, the Dramatic Order Knights of Khorassan, the Junior Order Princes of Syracuse, and the Order of the Pythian Sisters which, founded in 1888, is open to all women relatives of members of the Knights of Pythias.

PYTHIS or **PYTHIUS,** one of the most noted Greek architects of the later age. He cultivated the Ionic style, in which he constructed the temple of Athena at Priene. The dedicatory inscription, which is in the British Museum, records that the founder was Alexander the Great. Pythis also made a great marble quadriga which surmounted the Mausoleum.

PYTHON, a genus of snakes of the family Boidae. The snakes of this genus are very large and are found throughout the tropical regions of the Old World; they are distinguishable from the boas, with which they are often confused, by the presence of an extra bone in the skull above the eye, the supra-orbital. All the members of the genus possess long powerful teeth, but there is no poison apparatus. Killing is effected by constriction; coil after coil is thrown round the victim and these are slowly tightened. All snakes of whatever size are extraordinarily muscular so that the pressure exerted by a large python when constricting must be terrific; usually all the bones of the prey are broken and the whole animal is crushed into the shape of a sausage. This is then swallowed, head first, the head and body of the snake being literally drawn over the victim's body by the alternate forward motions of the right and left halves of the jaws; it is during this swallowing process that the large teeth are called into play, those of one side being dug in and giving a grip whilst the other side is pushed forwards. During the swallowing process much saliva is secreted and should the prey be disgorged, as it sometimes is if the snake is disturbed or frightened, it will be found to be covered with this secretion; this probably accounts for the origin of the fable that pythons cover their prey with saliva before swallowing it.

There is little doubt that a large python would be physically strong enough to kill almost any large mammal, but the stories of their killing and eating cattle and horses cannot be credited;



BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY

RETICULATED PYTHON (P. RETICULATUS)

the prey must be swallowed whole and the mouth of even the largest specimens, wonderfully distensible though it is, could not be stretched to accommodate anything much larger than a small pig. Most species are semi-arboreal and prefer the neighbourhood of water, in which they often lie and soak. Reproduction is by means of leathery-shelled, oval eggs, of which there may be a hundred or more in a clutch; they are laid in a heap round which the mother coils herself and it has been found that the temperature of a female under such circumstances rises above that of the surrounding air so that there is, apparently, true incubation.

The largest species is the reticulated python (*P. reticulatus*) of the Indo-Chinese and Malayan regions; which may attain a length of 30 ft. Other well-known species are the Indian python (P. *molurus*) of India and Ceylon, the rock python (P. sebae) of tropical and South Africa, the West African python (P. regius) and the Australian carpet snake (*P. spilotes*). (H. W. P.)

PYTHQN, a huge serpent, nameless and female in the earliest account (Hymn. Homer iii. 300 et seq.), which was killed by Apollo at Delphi (older name Pytho), either because it would not let him come near the oracle,—in one version (Hyginus, *fab.* 140), it used itself to give oracles,—or because it persecuted his mother Leto during her pregnancy. It is generally said to be the child of Earth (Hyg., l.c.), and in all probability is to be connected with the reliable tradition (*e.g.*, Aesch., *Eumen.* 1–8) that there was an oracle of Earth at Delphi before Apollo came.

In Hellenistic belief, a python was a spirit which possessed certain persons and prophesied unknown to them through their mouths (Hesychius, *q.v.*).

See Farnell, *Cults of the Greek States*, iii. 9; iv. 180; also Preller-Robert, I., 239.

PYTNONOMORPHA, a group of large extinct, aquatic reptiles of Upper Cretaceous age. (See REPTILES.)

PYX, a term for various forms of receptacles (Gr. πυξίς, a box or chest). In ecclesiastical usage it is the sacred vase or tabernacle in which the Host is reserved. In the English Mint the pyx is the chest in which are placed one coin from every 15 lb. of newly coined gold and one from every 60 lb. of newly coined silver to await the "trial of the pyx" (see MINT). This chest was formerly kept in the Chapel of the Pyx in Westminster abbey.

Q This letter corresponds to Semitic φ (*koph*) and Greek ϙ (*koppa*). The form of the majuscule has been practically identical throughout its known history. In the form found on the Moabite Stone the vertical stroke extended to the top of the loop and the same is the case with an early form φ from the island of Thera. The Etruscan form was identical with the Greek. The letter did not occur in the Ionic alphabet. The Latin alphabet had two forms ϙ and Q.

In the minuscle form the stroke has moved to the right side of the letter owing to the speed of writing. This produced the cursive form q occurring in the 6th century A.D. Uncial writing also had the form q and the Carolingian form was practically identical.

In Semitic the sound represented by the letter was an unvoiced guttural pronounced further back than that represented by the letter *kaph*. In Greek the letter was largely redundant, and in the eastern alphabet was entirely superseded by *kappa*.

Name of Form	Approximate Date	Form of Letter
PHOENICIAN	B.C. 1.200	φ
CRETAN	1,100-900	φ
THERAEAN	700-600	φ
ARCHAIC LATIN	700-500	ϙ
ATTIC	600	9
CORINTHIAN	600	ϙ
CHALCIDIAN	600	Q
IONIC	403	Q
ROMAN COLONIAL	PRE-CLASSICAL AND CLASSICAL TIMES	Q
URBAN ROMAN		Q
FALISCAN		V 3
OSCAN		? 3
UMBRIAN		? Ɔ
CLASSICAL LATIN AND ONWARDS		Q

THE DEVELOPMENT OF THE LETTER "Q" FROM THE EARLIEST TIMES

In the Chalcidic alphabet it lingered and was taken over from this into Latin, where it became stereotyped for use only before the letter U in words in which the unvoiced labio-velar occurred, represented by the combination of these letters. The combination of these two letters holds to the present day, and in modern English Q is not used unless followed by U, even if, in words such as oblique, the sound is a simple velar and not a labio-velar. The most usual position of the sound is initial in words such as queen, *quick*. Q is used apart from U only very rarely in words of foreign origin, especially to represent a Semitic guttural, as in Qabala, 'Iraq. (B. F. C. A.)

QABES: see GABES.

QAIN is the administrative headquarters of the very extensive district of Qainat, the south-eastern portion of the province of Khurasan in Persia. This district has the province of Kerman on the south and extends eastwards to the frontier of Afghanistan The region in which Qain is situated consists mainly of a complicated system of hill ranges of mean elevation 4,000 ft. running north to south and sinking down in the south to the Seistan basin. It is without perennial rivers, the drainage flowing westward to the Dasht-i-Lut. The rainfall is greater than that of Kerman province, which has an average fall of 4.7 inches, and the population depend largely on deimi crops, *i.e.*, those which are not artificially watered. Great numbers of camels are reared and the principal products are grain, saffron, wool and opium; the assafoetida plant also grows very profusely.

The town of Qain is situated some 200 m. south of Meshed on the main road (passible for motors) to Duzdab, in a broad valley, in 33° 42′ N., 59° 8′ E., at an elevation of 4,500 feet. The population is variously estimated at 5,000–15,000; the town, surrounded by a mud wall with bastions in disrepair, appears to have considerably increased in size and importance in recent years, so that the houses of the wealthier inhabitants are found without the walls. The cultivation of saffron is a speciality of the immediate neighbourhood which supplies nearly the whole of Persia with this commodity. The chief industries are the making of felts and carpets, but the best Qaini carpets are made at Darakhsh north-east of Birjand. South-east of the town, on the summit of two hills rising 500 ft. above the valley, are the ruins of a great fort some 600 yards in length. Qain is undoubtedly a place of great antiquity and chequered history. The present town was built by Shah Rukh to replace an older town which he is said to have destroyed. After a time the Uzbegs took possession of and held the place until Shah Abbas I. (1587–1629) expelled them. In the 18th century it fell under the sway of the Afghans and was a dependency of Herat until 1851.

See P. M. Sykes, "A fourth journey in Persia, 1897–1901," *Geogr. J.* (1902) XIX., pp. 119–73; see also KHURASAN. (P. Z. C.)

QAIRWĀN, the sacred city of Tunisia, 36 m. south by west by rail from Susa, and about 80 m. due south from the capital. Qairwān is built in an open plain a little west of a stream which flows south to the Sidi-el-Hani lake. Qairwān, in shape an irregular oblong, is surrounded by a crenellated brick wall with towers and bastions and five gates. The city, however, spreads beyond the walls, chiefly to the south and west. Some of the finest treasures of Saracenic art in Tunisia are in Qairwān. The chief buildings are the mosques, which are open to Christians, Qairwān being the only town where this privilege is granted.

In the northern quarter stands the great mosque founded by Sidi Okba ibn Nafi, containing his shrine and the tombs of many Tunisian rulers. It was several times rebuilt; that which subsists dates from the period of the Aghlabites (3rd century of the Hegira, 9th century of the Christian era). Like the primitive mosques of Islam, it consists of a rectangular hypostylar hall preceded by a courtyard surrounded by porticoes on all sides. It is reached through numerous gateways; that on the N.E., named the gate of Lella Rejana, is preceded by a beautiful square porch, decorated with ancient columns. In the middle of the northern side of the courtyard rises a massive square minaret.

The mosque of Sidi Okba is the prototype of many other notable mosques. (See MOSQUE.) Of greater external beauty than that of Sidi Okba is the mosque of the Three Gates. Cufic inscriptions on the façade record its erection in the 9th and its restoration in the 15th century A.D. Internally the mosque is a single chamber supported by sixteen Roman columns. One of the finest specimens of Moorish architecture in Qairwān is the *zawia* of Sidi Abid-el-Ghariani (d. c. A.D. 1400), one of the

Almoravides, in whose family is the hereditary governorship of the city. The entrance, a door in a false arcade of black and white marble, leads into a court whose arches support an upper colonnade. The town contains many other notable buildings, but none oi such importance as the mosque of the Companion (*i.e.,* of the Prophet), outside the walls to the north-west. This mosque is specially sacred as possessing what are said to be three hairs of the Prophet's beard, buried with the saint, who was one of the companions of Mohammed. (This legend gave rise to the report that the tomb contained the remains of Mohammed's barber.) The mosque consists of several courts and chambers, and contains some beautiful stained glass.

The suks of Qairwiin are interesting but less important than those of Tunis The town is the centre of fairly active trade and industry, especially in leather goods and carpets. The town has a population of (1936) 23,000.

The legend says that Okba in A.D. 671 (A.H. 50) determined to found a city as a rallying-point for the followers of Mohammed in Africa. He led his companions into the desert, and having exhorted the serpents and wild beasts, in the name of the Prophet, to retire, he struck his spear into the ground exclaiming "Here is your Qairwiin" (resting-place), so naming the city. In the 8th century Qairwān was the capital of the province of Ifrikia governed by amirs appointed by the caliphs. Later it became the capital of the Aghlabite princes, thereafter following the fortunes of the successive rulers of the country. (See TUNISIA: History.) After Mecca and Medina Qairwān is the most sacred city in the eyes of the Mohammedans of Africa, and constant pilgrimages are made to its shrines.

See Murray's Handbook to Algeria end Tunis, by Sir R. L. Playfair (1895); H. Saladin, Tunis et *Kairouan* (1908); Georges Marcais, *Manuel d'art Mussulman,* Tome I. (1926).

QAIS, an island in the Persian gulf lying about 10 m. off the mainland of Persia in 54° E ; it is the site of a trade emporium of great importance in former times. The island measuring 10 m. by 5 m., rises 120 ft. above sea level to a plateau and is bare of vegetation except for small patches of cultivation and a few date groves and stunted herbage. It is surrounded by a reef and pearl banks. The normal population is estimated at about 2,000 chiefly Arabs of the Al Ali tribe, who largely engage in pearl fishing.

Qais is an arabicized form of the Persian Kish; and is the Kataia of Arrian. In the Mohammedan period it formed a part of the province of Fars, but it was only in the later middle ages that the place attained importance, when a prince of South Arabian origin obtained possession of it, built a fleet there, and gradually extended his power. He captured Siraf (modern Tahiri 27° 40' N., 52° 20' E.) which was then the principal emporium of the Persian-Indian-Chinese trade. Siraf gradually—in the first half of the 11th century—became more and more deserted under the suzerainty of the princes of Qais, as they diverted the very considerable trade from the captured Persian sea-port to their own island, and finally Qais supplanted Siraf.

At its period of greatest power, the dynasty of Qais also ruled over the district of Oman on the opposite Arabian shore. The Rabbi Benjamin of Tudela visited Qais between A.D. 1164–73, and noted the rich market of the island whose chief business was the exchange of Persian, Mesopotamian, Arabian and Indian manufactures and produce. The site of the old city is marked by the ruins known as Harira on the north coast. Qais in turn lost its importance—for what reason is not precisely known—somewhere in the 14th century, and its trade passed to Hormuz.

See W. Ouseley, Travels in various *countries* of the East, vol. i. (1819); A. W. Stiffe, "Ancient trading centres of the Persian Gulf. Kais." *Geogr.* J., 1896, VII.; A. T. Wilson, The Persian Gulf (1928). (P. Z. C.)

QARAITES or **KARAITES** (Hebr. Bend *Miqrā',* sons of the Scripture), a mediaeval Jewish sect claiming to return to primitive Judaism by restoring the Scriptures to their rightful place now usurped by tradition (the Oral Law). Neither historically nor spiritually have they any connection with the Sadducees, the Samaritans or with Schechter's Jewish Sectaries of Damascus. Karaism was an anti-Rabbinic religious innovation prompted by politics, but the Raraites have always endeavoured to prove their antiquity and to trace their origin to former sects that had existed and decayed before Karaism arose. The founder, Anan ben David of Baghdad, in 760 claimed to succeed Isaac Iskawi his uncle as Exilarch, but the *Geōnim* (see GĀON) ultimately chose Anan's younger brother Josiah, whose appointment was confirmed by the Caliph al-Manṣūr. Anan proclaimed himself as anti-exilarch and succeeded in enlisting the support of various sects such as the Isawites, the Yudganites and the Shadganites. This act on the part of a *dhimmi* in Islam was treasonable. In 767 Anan was arrested but saved from execution by the advice of a fellow-prisoner, the famous Abu Hanifa. Anan pleaded that his was a new religion which venerated Islam and followed Muslim law in many ways, *e.g.,* in fixing the calendar by observation instead of by calculation. In 770 he published his code (*Ṣēfer ham-Miçwōth*). Ultimately he led his followers to Jerusalem, whence they spread over Egypt, Syria and S. Russia. They have never been numerous and now number about 14,000.

The chief points of difference with the Rabbanites were the calendar, Sabbath and marriage laws. Karaism had a great effect on the body of Judaism. polemics stimulated learning. Sa'adya of Fayyum was one of the notable scholars who challenged Karaite exegesis. The Karaites possessed a number of scholars of considerable distinction, especially in the direction of Hebrew philology, biblical exegesis (*e.g.,* Yepheth ibn 'Ali) and philosophy of religion (*e.g.,* Isaac b. Abraham Troki, 1533–1594, author of the Hizzziq *'emūnah*). Their liturgy is jejune, being composed almost entirely of scriptural excerpts and possessing practically no hymns. Nevertheless this constitutes no general reflection on Karaite intellectualism. No movement can be considered barren from the literary standpoint that has produced writers such as Benjamin Nahawandi (c. 850), Abu Yusuf al-Qirqisani (tenth cent.) and his contemporaries Sahl ibn Maçliaḥ, Solomon ibn Yeroham, Yusuf ibn Nuh, Aaron ben Elijah of Nicomedia (b. 1300), Elijah ben Moses Bashyazi (1420–90), Caleb Afendopouio (end of 15 cent.) and, latterly, Abraham Firkovitch (1786–1874). The latter dimmed his splendid reputation for scholarship and lowered the value of his enormous archaeological activity by partisan conduct. He discovered in the Crimea very many mss. and tombstones of considerable antiquity but he tampered with the dates and colophons to prove the age of the Karaites and their claims to represent true Judaism. Largely owing to his efforts, the Karaites were exempt from the religious persecution from which the Russian Jews (Rabbanites) suffered. A notable controversy arose in consequence of his discoveries, which were more or less categorically impugned by H. L. Strack and A. Harkavy (lit. *s.v.* Firkovitch in Jew. *Enc.*) but upheld (with reservations) by D. Chwolson (*Corp. Inscrip.* Hebr., St. Petersburg, 1882). The recent Masoretic researches of Paul Kahle (e.g., Masoreten d. *Westens,* Stuttgart, 1927: Hebr. *Bibelhand*-schriften *aus* Babylonien, Giessen, 1928) incline to the latter view.

QARO (or CARO), **JOSEPH BEN EPHRAIM** (1488–1575), codifier of Jewish law, whose code is still authoritative with the mass of Jews, was born in 1488. As a child he shared in the expulsion from Spain (1492), and like most prominent Jews of the period was forced to migrate from place to place. In 1535 he settled in Safed, Palestine, where he spent the rest of his life. Safed was then the headquarters of Jewish mysticism. Qaro's mysticism did not take the form of a'revolt against authority, but was rather the spiritual flower of pietism. It is, however, as a legalist that Qaro is best known. In learning and critical power he was second only to Maimonides in the realm of Jewish law. He was the author of two great works. In the earlier and greater book, in the form of a commentary (entitled Beth Yoseph) on the *Turim* (see 'ASKER BEN YEHIEL) designed exclusively for specialists, Qaro shows an astounding mastery over the Talmud and the legalistic literature of the middle ages. He felt called upon to systematize the laws and customs of Judaism in face of the disintegration caused by the Spanish expulsion. But the Beth *Yoseph* is by no means systematic. Qaro's real aim was effected by his second work, the *Shulḥan 'Arukh* ("Table Prepared"). Finished in 1555, this code was published in four parts in 1565. The work gradually became the almost unquestioned authority of the whole Jewish world. Its influence was to some extent evil. It "put Judaism into a strait-jacket." Independence of judgment was inhibited, and the code stood in the way of progressive adaptation of Jewish life to the life of Europe. But its good effects far outweighed the bad. It was a bond of union, a bar to latitudinarianism, an accessible guide to ritual, ethics and law. It sanctified the home, it dignified common pursuits. When, however, the era of reform dawned in the 19th century, the new Judaism assumed an attitude of hostility to Qaro's code.

QENA, a town of Upper Egypt on a canal about a mile E. of the Nile and 380 mi. S.S.E. of Cairo by rail. Pop. (1937) 34,431. Qena, the capital of a province of the same name, was called by the Greeks Caene in distinction from Coptos, 15 m. S., to whose trade it eventually succeeded. That its modern name should be derived from a purely Greek word seems to point to Qena having originated in a foreign settlement in connection with the Red Sea trade. It is a flourishing town, specially noted for the manufacture of the porous water jars and bottles used throughout Egypt. Its trade in grain and dates with Arabia is all that is left of the extensive commerce formerly maintained between Upper Egypt and India and Arabia.

QISHM, styled by the Arabs as *Jazirat-at-Tawilah* or Long Island, the Oarakta of the ancients, the largest island in the Persian gulf, is situated in the Strait of Ormuz and separated from the mainland of Persia by Clarence strait, 2 to 15 m. in width. The island has an extreme length of 68 m. and average breadth of 10 m. and is composed of table-topped hills rising to 560 ft. with one peak attaining 1,300 ft. The range on the south is largely composed of rock-salt, which is quarried at Namakdan and other places and forms one of the main products. In general aspect the island is parched and barren, but there are fertile patches of cultivation near the villages, producing grain, grapes, dates and melons. The climate is trying to Europeans from May to October.

The total population, mainly of Arab origin, is estimated at 15,000. The chief town is Qishm (pop. 3,000) on the north-eastern point, a well-built Arab village which was partially destroyed by earthquake in 1898. It carries on a small coasting trade which (including that of Hanjam island) amounted to 6,300 tons in 1925–26, mainly in fish, fruit and salt. Borings for oil were made by the Anglo-Persian Oil Company during the years 1914–1922 but without result. A light buoy with a flashing light is moored about a mile east of the Portuguese fort, now in ruins. The administration is in the hands of a *shaikh,* an Arab of the Bani Ma'in, who has executive powers under the Persian authorities.

Basidu, known to British sailors as "Bassadore" is on the north-western extremity of Qishm, exposed to all winds. The site was ceded to the British Crown in 1817, having been selected, after the suppression of piracy, as a base for the naval squadron responsible for keeping order in the Persian gulf and protecting trade. The station was abandoned in 1823.

QOSEIR, EL, a port on the west coast of the Red sea, just north of latitude 26° north. Not only is this place opposite the region in which the Nile comes nearest to the Red sea but between the Nile and El Qoseir is the Wadi Hammamat, with more water than have the valleys farther south. This district (anciently Rohanu) is rich in diorite, which was quarried for building the great monuments of ancient Egypt and, at least from the days of the 18th dynasty, a caravan route (about 120 m.) left the Nile at Qubti (Coptos), afterwards superseded by Qus and then by Qena, north of Thebes, making for the Red sea where the port of Tuâu (the old El Qoseir) was in use at first, but was later superseded by Sav (El Qoseir) 3 m. to the south-east. It was thence that Egypt sent its ships to Punt for spices, perfumes, gold, incense, ivory, skins, scented woods and precious stones. The town stands on a beach with a coral reef in front giving shelter to small craft; larger ships have to anchor outside.

QUACKERY, the pretensions or practice of a boastful pretender to skill which he does not possess, especially medical skill. Although this dictionary definition does not attach the condition that the quack practises for gain, such is usually the fact.

The existence of quackery pre-supposes four factors (1) an evil, usually an obstinate disease, (2) a sufferer from such an evil, (3) a person—the quack—who claims special knowledge or power to cure the particular evil, (4) a person—the orthodox medical practitioner—who holds out little or no hope of cure. Inasmuch as the sufferer has no knowledge whether the quack or the orthodox practitioner is more justified in his statement and is anxious to leave no stone unturned to be rid of his trouble, there is small cause for wonder that the quack has a great following. Other factors play a part, the desire for cheapness, for the quack medicine or treatment can be obtained—at all events in the first instance—at a relatively low price; rebellion against authority especially when authority gives an unpleasant decision; the hope which, as in the old fable, lies at the bottom of Pandora's box of human ills; the element of mystery which the quack usually employs; the natural repugnance to surgical operation when such is the only remedy recognized by the orthodox practitioner; the desire for secrecy particularly in respect of venereal disorders. It may be imagined from the foregoing that such diseases as cancer, venereal diseases, kidney and bladder complaints, diseases of the skin and respiratory tract, chronic rheumatism, chronic indigestion supply the largest proportion of the quack's clientèle; still, no common disease is free from a fringe of quackery.

The agents employed by quacks in various ages repeat themselves. In the case of cancer, the same chemical substances, the same corrosives have been employed, the same articles of diet have been inculpated over and over again. And though the agents have been shown repeatedly to be useless—even injurious—they come daily under the notice of those whose duty it is to investigate suggested cures and causes of cancer. Other agents are vegetable substances often derived from distant and little occupied parts of the world, called by local names, and for the most part unrecognizable by botanists. The tendency to repetition is unjustifiably taken by the public as a sign of their efficacy in the face of medical antagonism, whereas the truth is that the agents lend themselves to the secrecy which is one of the characteristics of the cancer curer and to the production of a medicine or ointment which can be sold at a price. It is a common story that the "cure" has been handed down from parent to child through many generations and often that it has been imparted to the present owner in return for some remarkable service.

Besides the use of chemical and vegetable substances the quack often turns to profitable account the current scientific tendency of the day. With the advance in knowledge of electricity he builds up what he terms a special form of electrical treatment and though his apparatus may be of the crudest kind and unable to generate electricity in appreciable quantity, the mystery attaching to his method of treatment and the pseudo-scientific language which he employs are not without effect upon the mind of the patient who is already more than half convinced in his favour. Similarly, with the discovery of radium, so-called radium treatments were devised for many complaints in which the amount of radium concerned was in the region of the limit of detectability. In the case of chronic rheumatism "magnetic belts," which give no more than a barely detectable electric current, have been recommended widely, as well as radium plasters which in all contained perhaps a thousandth of a milligram of radium. When it is recognized that the commercial value of such an amount of radium at current prices would be under twopence, the profitable side of such a variety of treatment becomes obvious.

The quack relies largely upon advertisement in newspapers and magazines and most publications of repute exercise scrupulous care in the admission or total exclusion of such advertisements. He is aided, too, by the reluctance of those who have consulted him with disadvantage to acknowledge their action and by the magnification of his successes or apparent successes. Moreover, his powers of diagnosis are negligible and upon strict examination a case of cancer, for example, reported to have been cured always fails because there is no evidence, either that the case was truly cancer or else that it was truly cured. The one requires microscopical evidence, the other the lapse, according to medical standards, of a period of years — three, five or more.

Quackery flourishes in certain parts more than others. In respect of cancer the mining districts of Northumberland, Durham and South Wales, South Africa, Australia and to a less extent Canada are the source of the greater number of so-called "cancer cures" met with in England, but the proportion is trivial compared with what occurs in Prussia, where it is said that there is one quack to every three orthodox medical practitioners. Recourse to quackery is not the foible of any particular class of society and is compatible with a high level of general intellect. In the case of the wealthy and intelligent it is difficult to feel sympathy for the sufferer in his action, but for the poor and ill-educated who often waste time and money only to find themselves at the end in a hopeless condition, sympathy is great. Yet it is difficult to see how they can be safeguarded. Legislation with regard to quacks and their medicines varies in different countries. In England they are liable if they hold themselves out to be recognized medical practitioners or if death occurs in a person whom they are treating. On the other hand the law considers that a person consults a quack at his own risk; it does not actually forbid the quack from giving advice though he cannot charge for that advice; as a result the financial side is represented by the sale of ointments, apparatus, etc. Elsewhere (*e.g.* in Prussia) legislation has been tried and has failed. The real remedy lies in advancement of medical knowledge and in education.

A word may be said on patent medicines the sale of which is great in all countries. In England they pay a duty but otherwise their sale is unrestricted though limits are imposed upon their composition. The British Medical Association for years has made a practice of analysing patent medicines and attaching to the report of their composition a statement as to the cost of the ingredients; all return to the proprietor a very large margin of profit. Copies of the reports issued from time to time are published under the authority of the Association. Many of these patent medicines are harmless, some are useful; actual fraud, as a rule, is absent. This cannot be said for the quack and his wares. (W. S. L.-B.)

In the United States the outstanding quacks are located in the large cities; mail-order quackery, like the mail-order house has grown tremendously and it requires a large staff of agents of the post office to make even the slightest inroads on this form of fraud. After some four years of battling in the courts the post office may issue a fraud order against such concerns denying them the use of mails, whereupon they dispose of their wares over the counters of drug stores, and promote them through advertising in the press. Although leading newspapers refuse to carry fraudulent advertisements of cancer and tuberculosis cures, they still carry all sorts of nostrum advertising for coughs, colds, rheumatism and similar complaints.

The use of the testimonial is fundamental to quackery and its advertising. Testimonials, obtainable at a price, have become a current feature in the trade.

In the headquarters of the American Medical Association is a bureau of investigation which carefully investigates the claims made for all new methods of medical treatment. Here is a card index containing 125,000 cards cross-indexing the various forms of quackery practised in the United States. In each of the 48 States there are different laws regulating the practice of medicine; hence quackery varies in each State according to the limits permitted by law. In some States quackery is limited almost entirely to the sale of medicines of secret composition and with claims not justified by the content. In other States quackery is rampant, including not only the sale of patent medicines but the operation of healing institutions conducted by quack doctors, all of the 40 or 50 forms of religious and faith healing, healing by conjuring and by charms, the practice of systems of healing such as chiropractic, naturopathy, naprapathy and similar methods. (M. Fi)

QUACK-GRASS (*Agropyron repens*), a perennial grass of the barley tribe (Hordeae), called also couch-grass or quitch-grass. It is native to Europe, common in northern Europe and widely naturalized in North America. Quack-grass has bright-green, smooth, stiffly erect stems, 1 to 4 ft. high; leaves with flat or inrolled blades; and terminal flowering spikes, 2 to 6 in. long, composed of numerous, usually five-flowered spikelets, which often bear short awns. Sometimes it is grown for forage, but it is better known as a troublesome weed in cultivated fields, especially on rich soil, spreading rapidly by its extensively creeping greenish-yellow rootstocks. The best method to eradicate it is to plow the land, after it has been left in sod two or more years, just after the flowers appear and harrow at weekly intervals for about 6 weeks.

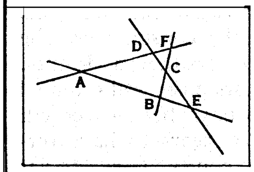
BY COURTESY OF THE IOWA GEOLOGICAL SURVEY

QUACK-GRASS (AGROPYRON REPENS)

QUADRATRIX: see CURVES, SPECIAL.

QUADRATURE (from Lat. *quadratura*, a making square), in astronomy, that aspect of a heavenly body in which it makes a right angle with the direction of the sun; applied especially to the apparent position of a planet, or of the moon at first and last quarters. In mathematics, quadrature is the determination of a square equal to the area of a curve or other figure. Integration by quadratures means calculation by a step-by-step process when no analytical expression for the integral is available.

QUADRILATERAL, in geometry, a figure formed by four straight lines. It is said to be plane or skew according as the four lines do or do not lie in one plane. Quadrilateral is also a military term applied to a combination of four fortresses mutually supporting each other. The most famous military quadrilateral was that of the four fortified towns of north Italy — Mantua and Peschiera on the Mincio, and Verona and Legnago on the Adige. This quadrilateral gave Austria a firm hold on Lombardy.



Let us consider the plane figure bounded by four lines terminated at the vertices. A line joining a pair of opposite vertices is called a diagonal. The area of such a quadrilateral is half the product of the length of one diagonal by the sum of the perpendiculars drawn to this diagonal from the other two angular points. The sum of the squares of the four sides of such a quadrilateral is equal to the sum of the squares of its diagonals increased by four times the square of the line joining the midpoints of the diagonals. If the vertices of such a quadrilateral lie on a circle, the product of the diagonals is equal to the sum of the products of the opposite sides.

It is in projective geometry that the quadrilateral plays its most interesting rôle. If A, B, C, D are four points in a plane no three of which are collinear, then the lines AB, BC, CD, DA, each taken to be of indefinite extent, form a quadrilateral. These sides intersect in pairs not only in the four given points (called vertices) but also in a point E on both AB and CD, and in a point F on both BC and AD. The points E and F are also called vertices. Then each side of the quadrilateral contains three vertices. Two vertices not on the same side are called opposite. A line joining two opposite vertices is called a diagonal. The configuration so described is called a complete quadrilateral. The dual figure is called a complete quadrangle. These figures are of fundamental importance in projective geometry (*q.v.*).

QUADRILLE, the name of a game of cards and of a dance. The game, played by four persons with a pack of forty cards, was a variation of the Spanish game of ombre and superseded it in popularity about 1725, to give way in turn to whist. The dance is of French origin and is usually danced by four couples in square. In the 18th century the *contredanse* was introduced into the ballet, and groups of four, eight or twelve dancers dressed alike performed different figures; these were first called *quadrilles* des *contre-danses,* later shortened to *quadrilles.* Later the dance became popular outside the ballet, and its figures, five in number, with a finale, bore the names of the different contredanses, Le *Pantalon, l'Été,* La *Poule,* La *Trénitz,* La *Pastourelle.*

QUAESTOR (Lat. quaerere, to investigate), a Roman magistrate whose functions, in the later times of the republic, were principally financial, although he was originally concerned with criminal jurisdiction. The quaestorship was probably instituted in 509 B.C. simultaneously with the consulship. The number of quaestors, originally two, was successively increased until Julius Caesar raised it to 40 (45 B.C.); Augustus reduced it to 20, which remained the regular number under the empire. When the number was raised from two to four in 421 B.C., the office was thrown open to the plebeians.

The quaestorship was the lowest of the great offices of State, and hence it was the first sought by aspirants to a political career (*cursus honorum*). The candidate was bound to have completed his 30th year before he entered office, but Augustus lowered the age to 25. Quaestors were elected by the comitia tributa (see COMITIA) under the presidency of a consul or another of the higher magistrates. They held office for one year, but, like the consuls and praetors, they were often continued in office. Indeed, it was a rule that the quaestor attached to a higher magistrate should hold office as long as his superior; hence, when a consul presided over the city for one year and afterwards as proconsul governed a province for another year, his quaestor also held office for two years. A peculiar burden laid on the quaestors, as a sort of fee exacted from all who entered on the political career, was the paving of the high roads, for which the Emperor Claudius substituted the exhibition of gladiatorial games.

Various classes of quaestors may be distinguished:—

The Urban **Quaestors.**—Originally the duties of the quaestors, like those of the consuls, were undefined; the consuls were the superior magistrates of the republic, the quaestors their assistants. From a very early time, however, the quaestors possessed criminal jurisdiction; political crimes only seem to have been excepted. The criminal jurisdiction of the quaestors appears to have terminated only when trial by permanent courts (*quaestiones perpetuae*) was extended to criminal cases.

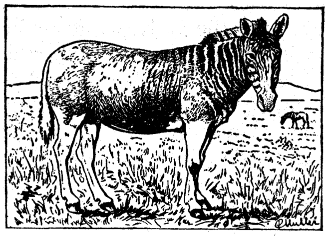
The quaestors had also charge of the public Treasury (*aerarium,* q.v.) in the temple of Saturn, and this was in later times their most important function. They kept the keys of the Treasury and had charge of its contents, the coin and bullion, the military standards, and a large number of public documents, which comprised all the laws as well as the decrees of the senate. Their functions as keepers of the Treasury were withdrawn from urban quaestors by Augustus and transferred to other magistrates.

The Military **Quaestors.**—These were instituted in 421 B.C. and were clearly distinguished from the urban quaestors by the fact that a non-urban quaestor was assigned as an assistant or adjutant to every general in command, whose name or title the quaestor usually added to his own. Originally they were the adjutants of the consuls only, afterwards of the provincial praetors, and still later of the proconsuls and propraetors. The governor of Sicily had two quaestors; all other governors and commanders had but one. Between the quaestor and his superior, a close personal relation existed, and was not severed when their official connexion ceased. The duties of the military quaestor, like those of the Treasury quaestor, were primarily financial. Moneys due to a provincial governor from the State Treasury were often, perhaps regularly, received and disbursed by the quaestor; the magazines seem to have been under his charge; he coined money, on which not infrequently his name appears alone. But, though his duties were primarily financial, the quaestor was the chief assistant or adjutant of his superior in command, and invested with a certain degree of military power. When the general left his province before the arrival of his successor, he usually committed it to the care of his quaestor, and, if he died or was incapacitated from naming his successor, the quaestor acted as his representative.

The Italian **Quaestors.**—The subjugation of Italy occasioned the institution (267 B.C.) of four new quaestors, who appear to have been called quaestores classici because they were originally intended to superintend the building of the fleet (classis); their functions, however, are very imperfectly known.

See Mommsen, Staatsrecht; A. H. J. Greenidge, Roman Public *Life* (1901); J. E. Sandys, *Companion to* Latin *Studies* (1921); W. E. Heitland, *The Roman Republic* (1923).

QUAGGA, an animal of the genus *Equus* (E. Quagga), allied to Burchell's zebra, formerly met with in vast herds on the great plains of South Africa between the Cape Colony and the Vaal river, but now extinct. The colour of the head, neck and upper parts of the body was reddish-brown, irregularly banded and marked with dark brown stripes, stronger on the head and neck, and gradually becoming fainter until lost behind the shoulder. There was a broad dark median dorsal stripe. The under surface of the body, the legs, and tail were nearly white, without stripes. The crest was high, surmounted by a standing mane, banded brown and white. The name is an imitation of the shrill barking neigh of the animal. (See HORSE and ZEBRA.)



THE QUAGGA (EQUUS QUAGGA), OF SOUTH AFRICA CLOSELY ALLIED TO THE ZEBRA; NOW EXTINCT

QUAHOG: see CLAM.

QUAIL, a bird well known throughout Europe, Asia and Africa. The common quail (*Coturnix coturnix*) is variable in colour, but in general is reddish-brown above, marked with dark brown and buff and pale buff below, passing into white on the belly. Essentially migratory, quails breed on the ground, laying 9 to 15 yellowish white eggs, spotted with dark brown. They are very good table birds and immense numbers are netted during the autumn migration across the Mediterranean. Quail is now very rare in Britain, but the numbers fluctuate. It is much the smallest British game bird. It feeds largely on weed seeds, but also eats insects, and is decidedly a beneficial species. Allied species include the rain-quail (*C. coromandelica*) of India; the Australian stubble-quail (C. *pectoralis*); the North American "Bob White" (*Colinus virginianus*); and the Californian tufted quail (Lophortyx *californica*).

The button-quails (*Turnix*) are a somewhat different group, lacking the hind toe in most species. One, T. *sylvatica*, inhabits Barbary and southern Spain; all are confined to the Old World.

QUAIN, SIR RICHARD, BART (1816–1898), Irish physician was born at Mallow-on-the-Blackwater, Co. Cork, on Oct. 30, 1816. After a brilliant career as a student at University college, London, he became assistant physician at the Brompton hospital for diseases of the chest. He served this hospital until his death (March 13, 1898) as full physician (1855–75), and then as consultant. He became physician-extraordinary to Queen Victoria in 1890, and was created a baronet in the following year. Quain's name is remembered by the Dictionary of Medicine, the preparation of which occupied him from 1875 to 1882 (3rd ed., 1902).

QUAKERS, originally a cant name applied in derision to the members of the Society of Friends, but now used without any contemptuous significance. It was used as early as 1647, and arose from the physical manifestations of religious emotion characteristic of many early Friends. (See FRIENDS, SOCIETY OF.)

QUAKERTOWN, a borough of Bucks county, Pennsylvania, U.S.A., 38 m. N. of Philadelphia; served by the Quakertown and Bethlehem and the Reading railway,. Pop. (1930) 4.883 and 5,150 in 1940. It is in an agricultural region, and has a number of factories making stoves, hosiery, silk, clothing, church organs.

QUALITIES. Primary qualities of matter are, mainly, the spatio-temporal ones, such as shape or motion; secondary ones are the sensible qualities, such as colour or smell. "Tertiary qualities" is a new and convenient term, introduced by Bosanquet, among others, to designate what are commonly called the ultimate values, beauty, goodness, truth.

Primary and Secondary Qualities.—The distinction between primary and secondary qualities is given officially for

British philosophy by Locke (*Essay*, Bk. ii., ch. viii. secs. g, 10). "Qualities thus considered in bodies are First, such as are utterly inseparable from the body in what estate soever it be; such as, in all the alterations and changes it suffers, all the force can be used on it, it constantly keeps; and such as sense constantly finds in every particle of matter which has bulk enough to be perceived, and the mind finds inseparable from every particle of matter, though less than to make itself singly be perceived by our senses." Locke enumerates: "solidity, extension, figure, motion or rest and number." Secondly, "Such qualities, which in truth are nothing in the objects themselves, but powers to produce various sensations in us by their primary qualities, *i.e.*, the bulk, figure, texture and motion of their insensible parts, as colours, sounds, tastes, etc., these I call secondary qualities." Locke adds that there is a third set of qualities, which are powers to produce changes in other bodies, not merely sensations in us. The distinction of primary and secondary qualities does not originate with Locke. It occurs in Greek philosophy in the doctrine of Democritus: "Sweet and bitter exist by law or convention" (that is, are relative to us); "what exists in reality are the atoms and the void." The atoms, which possess shape and other "primary" qualities, themselves by their density account for such qualities as heavy or hard; but other qualities are the effect upon us of the atoms. Aristotle makes the distinction on a quite different basis, and probably the more valuable one. He distinguishes (De *Anima*, ii., 5) the special sensibles, like colour or taste, which are apprehended by only one sense, from the common sensibles, apprehended by all the senses alike, motion, rest, etc. For modern philosophy, the distinction of primary qualities from secondary ones, in much the same form as Locke's, begins with Galileo, who goes so far even as to say that secondary qualities are but names which we give to things because they excite certain sensations in us (Hoeffding, *Hist. Phil.*, vol. i., p. 183). Locke derived his statement of the distinction from Descartes who, in a famous passage of the *Meditations*, points out how a piece of melting wax changes its colour but always retains extension. Extension he therefore regarded as an essential quality of matter, the sensible qualities being due to us or subjective. Locke puts the matter naïvely in the form, that ideas of figure or motion exactly resemble their original in real things, whereas colour and taste have nothing like themselves in things, and are the work of the mind. As thus drawn, the distinction corresponds to the practice of science and the tradition of the so-called mechanical theory of the world, which has been of such enormous practical value for scientific procedure.

Locke's statement implies that the primary qualities are real and the secondary ones subjective or mental, that is, have no existence apart from the mind; and secondly that the primary qualities are prior in the order of importance and fact to the secondary ones, for the secondary qualities are due to the impingement, however indirect, upon our sense-organs of the primary qualities of the microscopic constituents of matter. Two fundamental questions are therefore raised for philosophy: the relation of the two sets of qualities in respect of reality; are they unequally real, the one independent of the mind and the other dependent on the mind; and secondly their relative status, which of the two is prior in rank in the world of ideas to which they both belong. It is not strange, therefore, that the formulation of the difference between them raises vital questions of philosophy as a whole.

The first question was the immediate interest of Locke's successor, Berkeley, who declared them both to be upon the same level of reality, both being dependent on the mind, or being ideas, that is mental objects. Berkeley had little difficulty in showing first of all that the primary qualities are as much subject to variation with the condition of the observer as the secondary ones; and secondly that the primary ones cannot be experienced apart from the secondary ones—extension must be seen or touched to be experienced. If, then, the secondary ones are mental, so also are the primary ones Berkeley's contention that both sets are on the same level of reality has been generally accepted by all who have been content to regard both of them as sensible objects. When, as with Kant, a distinction has been readmitted it has been on the ground that extension, for instance, is not a sensible but an a *priori* form of all external sensibles. Granted, however, that they are both on the same level of reality, the primary qualities may still be the more important. But the significance of Berkeley's result for present philosophy lies in this that it leads directly to the question, are the two sets of qualities alike because both are dependent on mind, or because both are equally independent of mind? Now suppose, as simple realism supposes, that what the mind directly experiences is not its ideas but real objects themselves; that instead of holding its objects to be ideas we hold the so-called ideas to be objects themselves; it is still true that primary and secondary qualities are equally real, this time because both are equally independent of mind.

The general metaphysical difficulties of such an idealism as Berkeley's cannot be fully discussed here. But the idealism which has replaced his still declares that reality is experience and even sentient experience (Bradley); and accordingly there is some impatience expressed in either camp when it is asked if secondary qualities are not real. The question still remains whether they are both dependent on mind, or both independent of it. That secondaries are still dependent upon us is maintained even by those realists who urge that, at any rate, they depend if not upon our minds at least upon our bodies, that there would not be colours except there were eyes. The answer made by those realists who maintain that secondaries are as much as primaries independent of mind, is that the bodily organs are instrumental to perception, but are not constitutive, even in part, of the perceived. It is one thing to hold that objects cannot be known without a mind to know them, and another to hold that they owe their existence to mind. The doctrine of behaviourism, which has acquired such strength in American psychology, rests upon the belief that what are called mental acts are nothing but bodily reactions of certain specific sorts to stimulation from objects, and are thus instances of the wider field of organic vital reactions. And some, like the present writer, have expressed the situation for philosophy by saying that in sensation a bodily reaction which is conscious takes place in response to a physical object and that in such action an object or sensum, *e.g.*, a colour, is revealed to the mind. What the exact character of the object in question is may for the moment be deferred.

According to this, secondary and primary qualities alike are independent of mind. An entirely different complexion is put upon the matter in the theory of "neutral monism" advocated by several present philosophers both American (*e.g.*, Holt) and English (*e.g.*, Bertrand Russell). Upon this view the stuff of things is neither material nor mental but neutral; as Bertrand Russell puts it, the mental is more like matter and the material more like mind than is commonly supposed. This doctrine descends from William James who said that physical objects and the ideas of them are but the same thing considered in different relations as, for instance, the same fire may physically destroy a house and mentally suggest the danger of its inhabitants. It is plain that secondary qualities are real on such a view, and that there is no point in asking if they are subjective or objective. Into the grounds of this doctrine there is no space to enter. We may note, however, that it is far closer in its general tendency to idealism as represented by Bradley than it is to any realism which declares that we apprehend objects directly and that we discover what they are in virtue of the specific reactions which the body-mind makes towards them. Without examining neutral monism further we may observe that it stands or falls with its initial statement of experience. When we see a patch of red, it is held that the experience is completely described in the words, a red patch occurs. Is this exact, or must we rather say, I am aware, or there is awareness, of a red patch?

This question must be left, in order to turn to the second question of the order of priority between primary and secondary qualities. No one has ever suggested that the two sets of qualities are upon the same level in this respect. But it is noticeable that in the more recent English philosophy the old priority of the primaries seems to give way to the priority of the secondaries.

Granted that both are equally real, different ways have been adopted of stating their difference. One way is that of G. F. Stout (Proceedings of the Aristotelian Society, N.S. vol. iv., 1903–4, p. 153) that "the difference lies in their respective relation to the interaction of material things." The executive order of the material world can be expressed only in terms of the primary and not in terms of the secondary properties of matter. In Bergson's doctrine (Matter and Memory, ch. iv.) red differs from the corresponding vibrations in the tempo at which the experience is taken by the mind: what at a slower rhythm of *durée* may be apprehended as mechanical vibrations at a faster rhythm is condensed into colour.

But in the important recent philosophy of A. N. Whitehead, although the relative position of the two sets is not discussed as such, the traditional priority of the primaries would seem almost to be reversed in favour of the secondaries. The secondaries are, of course, real. In a happy phrase Whitehead has effectually destroyed the "representationism" inherited from Locke and Descartes by "protesting against the bifurcation of nature into two systems of reality," the one physical, which is not directly known, and the other "which is the byplay of the mind" (Concept of Nature, 1920). The world in this philosophy is a world of events, and the simplest events into which the total event which is "the passage of nature" can be resolved are described as "situations" into which "eternal objects," like red or sweet, which are not events, make "ingression." The perception of sense-objects implies a multiple relation into which enter the "percipient event" which is a bodily state, the "situation," the "eternal object" and the surrounding conditions (p. 152). (Compare his Science and the Modern World, pp. 99–102.)

The reality of secondary qualities is here not in doubt. The relative position of the primaries and secondaries is not so clear. For space and time on this doctrine are relational, relations between events as thus fully qualified by ingression of eternal objects; and accordingly constructions are framed to describe in terms of concrete events such conceptions as points, areas, volumes, etc.; and the great merit of this procedure is that it starts from concrete events instead of from conceptual entities like points. It is possible thus to define a point by means of all the sets of concrete extensions (*e.g.,* red patches) by which we can approach it. Now, to come to the present question, since space and time are relations between events, they are logically posterior in rank to the events themselves; and it would seem to follow that primary qualities such as geometrical figures, which are enumerated under the head of eternal objects (Science and *the* Modern World, p. 146), are posterior to the secondary qualities which are situated in the events. At least the two sets of qualities appear to be on a different footing.. This is, however, not the author's statement but an inference of the writer's, which may be mistaken. We may add that the omission of any analysis or explanation of the vague conception of "relation" makes the whole subject obscure.

A different though allied doctrine, that of the writer (Space, *Time* and Deity), leaves the primary qualities with their traditional priority, while at the same time raising difficulties of its own. According to this view the stuff of the world is space-time itself, that is, pure events, and the qualities or objects, which on Whitehead's doctrine are ingredient into events from the beginning, are said to emerge historically as the web of events within the whole space-time assumes certain complexities of configuration. Primary qualities, such as shapes or numbers, arise within space-time at the earliest level of existence. Subsequently these spatio-temporal configurations assume a certain complexity and we have matter or at least sub-matter. At a higher level of complexity there "emerge" certain material or submaterial configurations, complexes in the end of space-time, which are those conditions of bodies of which we have become aware as colour or taste. The notion of Emergence (*q.v.*) indicates the fact that at certain critical points in the development of the spatio-temporal world, new qualities appear, which are based upon the lower level of existence, and while also equivalent to the lower-level complex are qualified by a new character. So, to take an example from a higher stage of history, a certain complex of chemical and mechanical processes is endowed with the quality life; in the same way as a certain complex of purely spatio-temporal configurations becomes submaterial. Emergence is a term applied by this writer to the large critical novelties only; by Lloyd Morgan it is applied more freely to any change that can be called a change of character. (Whitehead uses the term differently. Since events from the outset are characterized by qualities through the ingression of objects, he speaks naturally of the emergence not of a new quality or "eternal object" but of a new thing through the ingression of a fresh complex of eternal objects.) On this second view, then, secondary qualities emerge from primary ones when those primary qualities, as in material or submaterial things, reach a certain degree and kind of complexity—*e.g.,* when certain motions occur in the body which are propagated in the form of light waves. The grave difficulties, which need not be concealed, in this general doctrine lie in its basis, in its use of the notion of pure event without quality, and its assumption without investigation of geometrical ideas such as point and line.

The Tertiary Qualities or Values raise similar problems, but it may well be doubted whether it is altogether happy to suggest, as the name does, that values belong to things in the same sense as the primary and secondary qualities do. Beauty is the only one of them which belongs directly to things; for truth attaches to propositions, and goodness to actions; and it will be convenient to speak principally of it. It has been held that beauty belongs to the beautiful object itself, a statement which, plausible enough when made of works of art, seems at first only the obvious one to make of a beautiful sunset or any form of natural beauty. Beauty, according to this view, is real and objective like shape or colour. In like manner goodness is held by some to belong to the person or act which is good; and it may be noted that even a writer like Kant treats good as objective though belonging to the intelligible or supra-phenomenal world. The statement that beautiful things have beauty apart from mind is, however, difficult to accept, because in a work of art beauty depends so largely on characters imputed to the work by the artist or the spectator. Thus dead marble looks alive and full of character, or in a picture stable forms are seen, aesthetically, to be in motion, for instance, to be dancing; and in a poem, the words are chosen not merely to describe but to endow: "two voices are there, one is of the sea, one of the mountains," though neither sea nor mountains have voices. There is so far always an element of illusion in art, a character being imputed to the material which it does not possess of itself. Even in natural beauty, the beauty may be seen to depend on selection on our part, or it may be addition; for instance, we may select in the sunset the shades which harmonize, or in the landscape the features which suit our own mood.

It would seem to follow that beauty is really dependent on the mind, and would not exist either in art or nature except for our interference. And it is not difficult to carry this line of reflection further and maintain that goodness and truth are human constructions, as, with respect to goodness, was held by Spinoza. Truth is not so obviously a human invention, but it is, in fact, different from reality itself, though it is guided and controlled by reality. Truth as in science is really a semi-artistic product in which the seeker blends himself with reality and does so by selection. His difference from the artist is that, though he imputes and interprets, he imputes nothing that he cannot verify in the reality. The artist introduces himself into his art giving the work characters which it only has so far as seen with the aesthetic eye. The enquirer who attains truth possesses reality for himself, but he keeps his human imputations out of the product.

The same thing may be concluded from observing that beauty satisfies a specially human impulse which has to make the object which is to satisfy it. Animals, including men, live by using the food which they find; but the impulse to beauty is a creative impulse, which the present writer (Art and Instinct, 1927) identifies as the impulse of constructiveness (such as animals and bees or ants also have) but used without regard to a practical purpose. In the same way truth appeals to an impulse of curiosity, and goodness to a social impulse. The values accordingly possess value because they satisfy these special impulses, and bring a peculiar satisfaction.

Such a conception of beauty and the other values has been held by some critics to be incbnsistent with the view that the secondary qualities are independent of mind. If beauty is so dependent, why not colour? The question is really irrelevant, for the same explanation does not necessarily apply to situations which may seem superficially similar. And, as has been indicated, the action in virtue of which we discover colour is entirely different from the creative action by which we become aware of beauty and goodness and truth.

The values therefore rest on a different basis from primary and secondary qualities. Men produce works of art and good societies and true knowledge. But these products have these qualities only on sufferance from their makers. Remove men, and beauty would disappear. But red would remain; though, unless there are creatures with the appropriate organs, it would not be perceived.

At the same time in declaring the values to be qualities only of the new realities which are held upon human tenure, we do not declare them to be mere figments of men. On the contrary, goodness belongs, in the sense described, to acts which bring out what is best in human nature, and true knowledge, being controlled throughout by reality, admits us to the secrets of that reality. And art embodies, in stone or sound, the constructive visions of men and reveals the deeper relations between us and nature.

The separation of tertiary qualities from those which do not depend on human interference helps us to set in a clearer light the quality of things which is their "worshipfulness" and becomes, when considered as abiding in them, the object of religion. It is commonly spoken of as a value along with beauty, goodness, and truth, and may consistently be so regarded, if value is thought to be inherent in what is valuable. If, however, the above considerations are valid, it would be treated, whether under the name of deity, or worshipfulness, or as Otto calls it (in *The Idea of the Holy*, Eng. trans., 1923), "numinousness," not as a value or tertiary quality at all, but, just because it belongs to its possessor intrinsically, without need of human intervention, as a quality, on the line of the primary and secondary qualities, independent of man and actually belonging to the world of things, which world includes, of course, man and man-made values. This topic is, however, raised here only for completeness, and it falls beyond the scope of this article to examine further the nature of deity and its possessor. (S. A.)

QUANTICS, the study of homogeneous algebraic functions of two or more variables which generally contain only positive integral powers of the variables. *See* ALGEBRAIC FORMS.

QUANTITY THEORY OF MONEY. A summary form of expression for two allied but distinct propositions relating to the causes of changes in the value of money. The broader proposition referred to is that, other things being equal, changes in the value of money are dependent upon changes in the quantity of money. The narrower proposition is that changes in the value of money, other things being equal, are *directly* proportional to changes in the quantity of money: so that, if, say, the quantity of money is either halved or doubled, all other things remaining the same, the value of money will be doubled or halved; that is (since the price level is an expression of changes in the value of money) prices will rise or fall in strict proportion to a given change in the quantity of money, all other things being supposed to remain unchanged. It will be clear from what has been said that the narrower proposition cannot be true if the broader proposition is not, but that it by no means follows that the untruth of the broader proposition can be proved by disproving the truth of the narrower.

The controversies to which these propositions have given rise are amongst the most celebrated in political economy. Before approaching them, it must be pointed out that the issues involved are irrelevant for any theory of money which asserts that money is only a symbol *expressing* values, but itself incapable of *possessing* value. Any such theory must reject not only the quantity theory in any form, but also the view (which historically is very important) that the value of money is based upon the cost of production of the precious metals. It must reject the latter alternative by arguing that, though the given form of money may be made from gold or silver, which may possess value, it is not *this* fact which is relevant in deciding whether the coin so made is money or not; the important fact is the denomination of units of value expressed and these are independent of the material out of which money is made. But. though some "symbolistic" theories of money reject the quantity theory, others are so worded as to admit of some form of it; and, in any case, the "quantity theory" and the "cost of production theory" are capable of reconciliation; for it may be argued, as, for example, by J. S. Mill, that "cost of production would have no effect on value if it could have none on supply." Thus a lowering of the cost of production of gold lowers the value of gold and therefore raises prices, because under these circumstances more gold will be produced.

It must be pointed out, further, that the truth of any form of the quantity theory cannot be established purely by an appeal to facts. This is so, not merely because, in practice, other things never are equal—so that, in the real world, changes in the quantity of money are always accompanied by changes, not only in the price level, but in other things—but also because mathematical or statistical equivalences between quantities are incapable of throwing any light upon causal sequence. In other words, assuming that changes in the price level always do accompany changes in the quantity of money, this fact, if it is a fact, does not tell us which change depends upon which. It must be shown, if any form of the quantity theory is true, why changes in the price level are dependent upon changes in the quantity of money. Otherwise it might be argued that changes in the quantity of money are dependent upon changes in the price level, or that changes in the price level and changes in the quantity of money are co-effects of remoter causes.

Though the truth of the quantity theory is not denied by a majority of economists, the formulation of the theory has undergone profound modifications. A distinction must be drawn between the "older" and the "newer" quantity theories. In what follows we shall deal first with the older and traditional theory, and then with its formulation in recent years.

The Older Theory.—The older view, which received its most complete expression at the hands of Irving Fisher in his *Purchasing Power of Money* before the World War (1911), ultimately rests upon the following assumptions. The dynamic consequences of the theory flow from the fact that additional supplies of money *constitute an incentive to additional spending.* Additional supplies of money drive prices up, because (the supply of goods being assumed constant) there will be more to spend and competition among spenders is a cause of rising prices. The additional supplies of money, secondly, *will be spent* because money possesses no intrinsic power of yielding satisfactions; the satisfactions arising from the possession of money can be realized only by acquiring goods and services which possess a direct power of satisfying wants. Now, given these two assumptions, it follows almost as a matter of course not only that prices will rise as the quantity of money rises, but that the price-rise will be in proportion to the increase in the quantity of money. For, given a certain increase in the volume of money and a *disproportionate* alteration of prices, disequilibrium will prevail until the price level is in direct relation to the new total quantity of money. If prices have risen less than in proportion to money, goods will seem unusually cheap to consumers and this will stimulate further consumption of them. If prices have risen more than in proportion to the increased quantity of money, consumers will, in spite of additional quantities of money, find prices unusually high and will check their consumption, with the result that prices will fall. If, but only if, prices alter in exact correspondence to changes in the quantity of money, everyone will find himself in the same position as formerly, with the same real income of satisfaction, but with higher prices on the one hand, and larger money supplies available on the other.

The quantity theory, in the course of its evolution, gradually acquired complexity of exposition. Three separate points have to be noted in this connection. The first is the modification introduced when changes in the volume of goods are taken into account. Changes in production may be increasing the supply of goods contemporaneously with the increased monetary supply and the latter may even exert some stimulating effect upon production. Other things in this case will not be equal, so that the price level will be forced upwards or downwards according as the influence of increased supplies of money or of goods exerts the preponderating influence; so that the quantity theory is usually expressed in the form that prices move directly with the supply of money and inversely with the supply of goods. Further, it is not the volume of physical goods but the volume of goods *and services* which must be contrasted with the supply of money: an increase in the number of *separate transactions* associated with production works, in this connection, as a price reducing factor, because, in fact, transactions represent services rendered in connection with physical supply. Next, the theory has to take account of the fact that, during a given period of time, each unit of money, passing from hand to hand, necessarily plays a part in the number of transactions, the number depending upon the rapidity of its circulation. Given a certain number of monetary units, an increase in their *velocity of circulation* is equivalent in effect to increasing the supply of units acting as money during the period of time considered, so that an increase in the velocity of circulation, other things being equal, raises prices, whilst a decrease in the velocity reduces prices. Lastly, the quantity theory has to take account of credit instruments of various kinds. Here two solutions are possible. One is to treat these instruments as *additional* to the supply of metallic money and bank and government notes, so that an increase in the supply of credit instruments raises prices in exactly the same way as an increase of money would have done. The second alternative is to regard credit instruments as a *substitute* for ordinary forms of money, which are replaced in a certain number of transactions by credit instruments, so that, *in relation to transactions,* the supply of money rises and prices rise in correspondence.

The **New** Formulation of the Quantity Theory.—The theory fashionable in pre-war days had two great defects. By contrasting money as a whole with transactions as a whole, it was unable adequately to take account of the individual process of revaluation which is implied in a change in the price level. Secondly, the facts of inflation during the war threw grave doubt on the view that prices were altered proportionately to changes in the quantity of money, the fact being that prices rose much more rapidly in the later stages of inflation, and appreciably less rapidly in the early stages of inflation, than the theory warranted. The new formulations have no difficulty in dealing with these points.

The modern quantity theory starts from the fact that each independent individual or other economic unit requires to keep on hand at all times a certain stock of money. At any moment, of course, money may be passing out of one stock into another, but this does not invalidate the fact that considerations of convenience and habit dictate the keeping of a certain stock on hand. This stock of money on hand or, as Hawtrey calls it, "The unspent margin," is as much required as a stock of clothes or a stock of food, if the economic system is to function adequately. The aggregate demand for money, then, is derived from the sum of individual demands for stocks, just as the demand for houses is derived from the individual demands of those who desire to occupy them. An increase in demand for money is equivalent to an unwillingness to reduce the stock actually held and a desire to add to it. If the supply of money is fixed, this must mean that money acquires a higher value, that is, prices will fall, because people can add to their stocks only by parting with goods or services in order to increase the stock they hold and, since the total stock of money is assumed to be fixed, this can only be at the expense of other stocks held by other individuals. If there is a general desire to decrease stocks on hand, prices must rise, in spite of the total supply of money being fixed, because if there is a general alteration in the desire to hold money, holders can only get rid of what they have by offering it more cheaply, that is, at a lower price in goods to the taker. But this is equivalent to a rise of prices.

When the supply of money alters, the effect produced upon prices depends upon the effect alterations in the supply have upon the willingness to hold stocks. At first the effects of increasing supplies upon the price level, when spent by the issuer, are not in any case likely to be very great. If, at such a time, people's willingness to increase their stocks extends, the rise in the price level will not be in proportion to the increase in the output of money. But if this output increases continuously, the rise in the price level will tend to be more and more rapid and to outstrip the increase in the quantity of money, and that for two reasons. The larger the stock already held, the lower must be the price at which additional amounts must be offered to holders in order to induce them to take more. It may be argued that, as prices rise, individual holders need to hold more, because otherwise the stock held will be inconveniently small in view of the new price level. This is so, but it by no means follows that in the course of the process of adaptation, individuals have not altered their ideas as to what a convenient stock is; in fact, the rise of prices shows that they must have done so. In any case, if the supply of money goes on increasing and prices go on rising, anticipation of the future value of money begins to play an important part. Just as individuals will refuse to add to their stocks of cotton at a time when they believe that cotton will continue to fall in value, so they will refuse to add to their stocks of money at a time when that is falling in value, and unwillingness to add to their stocks is in itself a cause why the fall in the value of money should proceed more rapidly.

It makes no essential difference to the new formulation whether credit is regarded as a form of money or not. If it is so regarded, then the demand for stocks must be regarded as a demand for so much cash plus so much credit. It is thus that the position is treated by Keynes and Hawtrey. If credit is regarded as a substitute for cash, as it is by Cannan, then the demand for cash will fall off if credit arrangements are regarded as more convenient, and in the absence of appropriate arrangements for withdrawing superfluous cash, prices will rise, since part of the stock of cash will have become redundant.

QUANTUM THEORY, THE. As recently as the opening years of the present century the vast majority of physicists still regarded Newton's dynamical laws as something established for all time. And they were not without solid grounds for this faith. Many phenomena were indeed known, chiefly those which may be classed under the heading radiation, *e.g.,* black body radiation and line spectra, which refused to accommodate themselves to any sort of theory founded on Newtonian principles; but it was generally believed that such phenomena would, sooner or later, be completely accounted for without any departure from the classical principles of physics. Even the theory of relativity developed by Lorentz, Einstein, Minkowski and their successors was regarded only as a widening or generalization of the Newtonian basis of physics. It was the culmination of classical physical theory. These phenomena we now believe, cannot be accounted for on the basis of the classical physical theory, whether Newtonian or Einsteinian. The first act of sacrilege was committed by Max Planck, until recently professor of theoretical physics in the University of Berlin, about the end of the year 1900, when he initiated the quantum theory. One of the problems engaging the attention of physicists during the closing years of last century was that of the radiation from a blackbody; a body, the surface of which absorbs all the radiation of any wave-length whatever that may fall on it. The radiation emitted by a black body at some definite temperature is like that inside a vacuous enclosure the walls of which are at this definite temperature. (The terms *vacuous* and *empty* as used in this article mean *not containing atoms or molecules.)* The character of black body radiation is determined solely by the temperature of the walls of

FIG. 1.—THE FULL LINE REPRESENTS THE WAY IN WHICH THE ENERGY E, IS DISTRIBUTED AMONG THE VARIOUS WAVE-LENGTHS, λ; THE BROKEN LINE REPRESENTS THE LAW OF DISTRIBUTION ACCORDING TO RAYLEIGH'S FORMULA

the enclosure, and is independent of the nature of the materials of which they are made. Now the feature of this type of radiation which puzzled the physicists of the period immediately preceding the present century was the way in which the radiant energy was distributed among the different wave-lengths. The actual law of distribution is illustrated by the full line in fig. 1. The distribution deduced from Lord Rayleigh's formula is shown by the broken line in fig. 1. The figure illustrates the wide divergence of the theoretical from the actual distribution in the region of very short waves.

Planck convinced himself that Rayleigh's deduction, confirmed by J. H, Jeans, was sound, and he therefore drew the inference that the premises on which it was based, *i.e.*, Newtonian dynamical principles, were faulty. In the year 1896, W. Wien, then a professor in Wurzburg, found a formula which represented the observational data very well for small values of the product of wave-length and absolute temperature. Planck had for his guidance the formulae of Rayleigh and Wien, and also the ideas of Ludwig Boltzmann about the relation between entropy and probability. His first success was the discovery by a method of trial and error, of a formula which interpolated between those of Rayleigh and Wien, and which represents the facts of black body radiation exceedingly well for all ranges of wave-lengths and temperatures over which observations have been made. A little later he succeeded in giving this formula a theoretical basis and it is here where the first mention of the quantum theory appears.

FIG. 2.—THE RELATION BETWEEN THE DISPLACEMENT OF THE BOB OF A PENDULUM AND THE CORRESPONDING MOMENTUM

The essential feature of the innovation which Planck introduced may be described with the aid of a simple illustration. Let us consider a pendulum, the bob of which is vibrating in a vertical plane, with not too large an amplitude. The centre of gravity of the bob will move backwards and forwards along a short arc of a circle. Represent its distance at any instant from the central position by the letter q and the momentum of the bob, *i.e.*, the product of its mass and velocity, by the letter p. If we exhibit the relation between p and q graphically (fig. 2) we obtain a closed curve, on account of the periodicity of the motion. Newton's laws of motion require the shape of this curve to be an ellipse, and further, that the energy of the pendulum bob shall be equal to the product of the area of the ellipse and the frequency, *i.e.*, the number of complete oscillations made by the pendulum in the unit time. Therefore

$$E=A\nu \tag{1}$$

where E is the energy, A is the area of the ellipse and ν is the frequency. We are assuming, of course, that the pendulum is not subjected to damping influences and after being set in motion is not further interfered with. The constant A is called the *action* of the pendulum corresponding to its period of motion and has the dimensions of the product of energy and time. It seems self-evident that, provided we keep within a certain upper limit, the action A may have any value whatever. It merely depends on the energy with which the motion is initiated, and Newton's laws of motion impose no restrictions on the values of the constant A.

Planck's Theory.—It is just here where the theory of Planck steps in. According to Planck, a vibrating system, like the pendulum with a small amplitude of oscillation, will normally behave as if it were not interfered with and will obey the classical laws, *but the constant A is restricted to be an integral multiple of a small universal constant h called the Quantum of Action.* The energy is therefore expressed by

$$E=nh\nu \tag{2}$$

where n is a positive integer or zero. While this normal behaviour continues, the system is said to be in one of its *stationary states,* and the corresponding value of the energy is termed an *energy level.* Energy can only be gained or lost by a transition from one stationary state to another. Such transitions do not conform to classical laws and their nature is still obscure. In the case of a simple harmonic vibration, of which the motion of the pendulum described above is an instance, the integer n can only change by unity in a single transition. The reason for this will be explained later. The universal constant h turns out to be very small, being equal to

$$6\cdot55\times10^{-27}\ \text{ergs}\times\text{seconds},$$

so that, when applied to a thing on as big a scale as an ordinary pendulum, Planck's theory makes no practical or observable difference. But it makes a profound difference when applied to things on the scale of atoms. The classical theory (if under this term we include the theory of relativity) is quite competent to deal with microscopic phenomena, and it has always been, in fact, a guiding principle in the development of the quantum theory to make it coalesce with the classical theory when applied to large scale phenomena.

In his later work Planck modified his earlier hypothesis. Possibly he may have felt that he had laid hands on the doctrines of Newton with more violence than was necessary, since the later modifications conceded that a vibrating system might absorb energy after the classical fashion

Black Body Radiation.—The following description of the theory of black body radiation (*see* **BLACK BODY**), or full radiation as it is now more usually termed, while embodying the essentials of Planck's theory, differs from it in immaterial details. The radiant energy in a vacuous enclosure is associated with aether vibrations of all wave-lengths from zero upwards. The sort of picture we must form of a vibration of a definite frequency (or wave-length) is very like that of the vibration of the column of air in a cylindrical resonance tube or, better still, the transverse vibration of a stretched cord (Melde's experiment). Let us consider such a stretched cord, fixed at both ends. Its possible states of vibration will be such that it is divided into a number of intervals, each of the length of half a wave, terminated by nodes, or points where the cord is not in motion. In such a case we have the relation

$$l=n\frac{\lambda}{2}, \tag{3}$$

where l is the length of the cord, λ is the length of the wave torresponding to the frequency of the vibration and n is the number of intervals. If v represents the velocity with which transverse waves of frequency ν travel along the cord, we have the well known relation,

$$v=\lambda\nu, \tag{4}$$

so that equation (3) becomes

$$l=\frac{nv}{2\nu},\ \text{or}\ n=\frac{2l\nu}{v}. \tag{5}$$

It is clear, therefore, that the total number of possible vibrations of all frequencies from the lowest possible one up to ν will be represented by n in equation (5), and, therefore, the number corresponding to the narrow range of frequencies between ν and $\nu+d\nu$ will be represented by

$$\frac{22}{v}\,d\nu. \tag{6}$$

Strictly speaking this represents the number of vibrations when the motions of the cord are all parallel to one another, or all in one plane. The most general sort of motion of a point on the cord can be regarded as made up of two independent motions in directions at right angles to one another, and, therefore, the expression (6) should be multiplied by 2 to give the number of independent vibrations. We are concerned, however, with a slightly more complicated problem than that of the vibrations of a stretched cord. We wish to find an expression for the number of aether vibrations in unit volume of the enclosure and in the range of frequencies between ν and $\nu+d\nu$. The same sort of method as that just described leads to the result

$$\frac{4\pi\nu^2d\nu}{C^3}, \tag{7}$$

where C is the velocity of aether waves (light waves) in empty space. Or when we take account of the fact that aether waves are transverse like those along the cord, and that therefore, the displacements in such waves can be regarded as compounded of two independent motions at right angles to one another, we must multiply the expression (7) by 2, so that we get the final result

$$\frac{8\pi\nu^2 d\nu}{C^3}. \tag{8}$$

We shall get a formula for the energy per unit volume associated with the vibrations of this range of frequencies if we multiply formula (8) by the average energy of a vibration. The classical kinetic theory of matter requires that the average energy of a vibration shall be two-thirds of the average kinetic energy of translation of a molecule of a gas at the temperature in question. It must therefore be equal to

$$kT, \tag{9}$$

where T is the absolute temperature and k is the "gas constant" reckoned for one molecule. If, however, we adopt Planck's hypothesis and make use, as he did, of Boltzmann's notions of the relation between entropy and probability, we get the expression

$$\frac{h\nu}{\epsilon^{h\nu/kT}-1}, \tag{10}$$

where h is the universal constant already described and ϵ is the base of natural logarithms. Combining (8) and (9) we have Rayleigh's formula,

$$\frac{8\pi\nu^2 kT}{C^3}d\nu, \tag{11}$$

and from (8) and (10) we get Planck's formula,

$$\frac{8\pi h\nu^3}{C^3(\epsilon^{h\nu/kT}-1)}d\nu. \tag{12}$$

The expressions (11) and (12) represent, according to the classical theory and the quantum theory respectively, the energy of full radiation per unit volume and within the range of frequencies between ν and $\nu+d\nu$. If we remember that the product of wave-length and frequency is equal to the velocity of the waves, in this case

$$\lambda\nu = C$$

it is easy to see that these expressions are equivalent to

$$\frac{8\pi kT}{\lambda^4}d\lambda \tag{11a}$$

and

$$\frac{8\pi Ch}{\lambda^5(\epsilon^{Ch/k\lambda T}-1)}d\lambda \tag{12a}$$

respectively, either of which represents the energy per unit volume associated with the range of wave-lengths between λ and $\lambda+d\lambda$, the former according to Rayleigh and the latter according to Planck. Planck's formula fits the observed facts of black body radiation extraordinarily well (see HEAT), and it is easily verified that it approaches Rayleigh's formula in the limiting case of large values of the product λT.

Law of Dulong and Petit.—It is well known that the product of specific heat and atomic weight is very nearly the same, about 6 in the usual units, for many solid elements, *e.g.*, copper, iron, zinc, etc. This is the law of Dulong and Petit. There are many exceptions to the law, notably among elements of low atomic weight, such as boron and carbon (graphite, diamond). (See HEAT.) It should be pointed out that the specific heat of a solid is usually measured under the condition of constant pressure and that we are concerned here with the specific heat measured under the condition of constant volume. The latter is nearly always less than the former, and never greater. Let us examine the law from the point of view of the classical theory. We should expect the heat energy, expressed in mechanical units (ergs), in a gram atom of a solid element to be

$$3NkT, \tag{13}$$

where N is the number of atoms in a gram atom (or the number of molecules in a gram molecule), since the energy of a single atom in a solid element may be regarded as associated with three independent vibrations in mutually perpendicular directions and must therefore be equal to 3kT according to the classical theory. The atomic heat at constant volume, *i.e.*, the amount of heat required to raise the temperature of a gram atom one degree will be therefore

$$3Nk \text{ ergs per degree.} \tag{14}$$

To express it in the usual units, we divide by the mechanical equivalent of heat, *i.e.*, by $4{\cdot}2\times10^7$ ergs per calorie, and so we get

$$\frac{3Nk}{4\cdot2\times10^7} = \frac{3R}{4\cdot2\times10^7}, \tag{15}$$

where $R=8{\cdot}315\times10^7$ ergs per degree is the gas constant for one gram molecule of a gas. It is easily verified that the quantity (15) is very nearly equal to 6. The elements which deviate from the law of Dulong and Petit at ordinary temperatures conform to it more and more closely as the temperature is raised, and conversely, those which agree with the law at ordinary temperatures deviate from it more and more the lower the temperature at which the measurements are taken. We have here an illustration of the competence of the classical theory to deal with phenomena on a sufficiently macroscopic scale.

Planck's theory was first applied to the problem of atomic heats or specific heats by Einstein, and later and more completely by Debye. Debye assumed that the heat energy of a solid element is the energy of elastic vibrations of all frequencies from very low values to a certain upper limit which was fixed by the consideration that, as we have already seen, the theory must asymptotically approach the classical theory when the energy involved is very great (or the temperature very high). This upper limit is low enough (or the corresponding lengths of the elastic waves big enough) to justify us in regarding the material as uniform and to ignore in the calculation the fact that it is made of atoms and therefore granular in structure. The problem is closely analogous to that of black body radiation. The difference lies mainly in the fact that here we are dealing with the vibrations of a material and not with aether vibrations only. The number of vibrations in the frequency range from ν to $\nu+d\nu$ will now be

$$\frac{8\pi\nu^2 d\nu}{v_t^3}+\frac{4\pi\nu^2 d\nu}{v_l^3} \tag{16}$$

per unit volume, where v_t is the velocity of transverse waves in the solid and v_l that of longitudinal waves. This formula is based on the fact that we may have both transverse and longitudinal waves in a solid material and it should be compared with formula (8) above. Each of these vibrations has the average energy expressed by formula (10), so that we get for the total energy in the unit volume the expression

$$\int_0^{\nu m} 4\pi\left\{\frac{2}{v_t^3}+\frac{1}{v_l^3}\right\}\frac{h\nu^3}{(\epsilon^{h\nu/kT}-1)}d\nu, \tag{17}$$

the upper limit being fixed in accordance with the principle referred to above. Strictly speaking we ought to take into account the aether vibrations as well as those of the material; but the additional energy is negligible by comparison with that given by (17). The reason for this is that the velocities v_t and v_l are very small compared with C the velocity of aether waves. Since formula (17) must reduce to the corresponding classical one at high temperatures, we must fix ν_m so that the total number of vibrations is equal to 3N where N is the number of molecules in the unit volume, or

$$3N = 4\pi\left(\frac{2}{v_t^3}+\frac{1}{v_l^3}\right)\int_0^{\nu m}\nu^2 d\nu,$$

and therefore

$$4\pi=\left(\frac{2}{v_t^3}+\frac{1}{v_l^3}\right)=\frac{9N}{\nu_m^3}. \tag{18}$$

When we substitute this result in (17) we get for the energy in the unit volume of the material,

$$\frac{9N}{\nu_m^3}\int_0^{\nu m}\frac{h\nu d\nu}{(\epsilon^{h\nu/kT}-1)}. \tag{19}$$

If we agree that N in formula (19) shall represent the number of atoms in a gram atom of the element, instead of the number in the unit volume, then (19) will give the heat energy in a gram atom at the temperature T.

Since ν_m can be calculated from the velocities of transverse and longitudinal waves in the solid element (equation 18), it follows that the heat energy in a gram molecule and therefore also the atomic heat (the heat required to raise the temperature of a gram atom by unity) can be found from a knowledge of the elastic moduli, Young's modulus and the modulus of rigidity of the material.

If we use the letter E for the energy of a gram atom, and abbreviate by representing $h\nu/kT$ by β, which amounts to replacing v by $\frac{kT\beta}{h}$, formula (19) will take the shape

$$E=T\cdot\frac{9Nk}{\beta_m^3}\int_0^{\beta_m}\frac{\beta^3d\beta}{(e^\beta-1)};\tag{20}$$

or, expressed in words, the energy is equal to the product of the absolute temperature and a certain function (the same for all elements) of the quantity β_m. This may be written concisely,

$$E=Tf(\beta_m).\tag{21}$$

The atomic heat is, of course, $\frac{dE}{dT}$, and when we differentiate $Tf(\beta_m)$ with respect to T and write $f'(\beta_m)$ for $\frac{df(\beta_m)}{dT}$, we get since

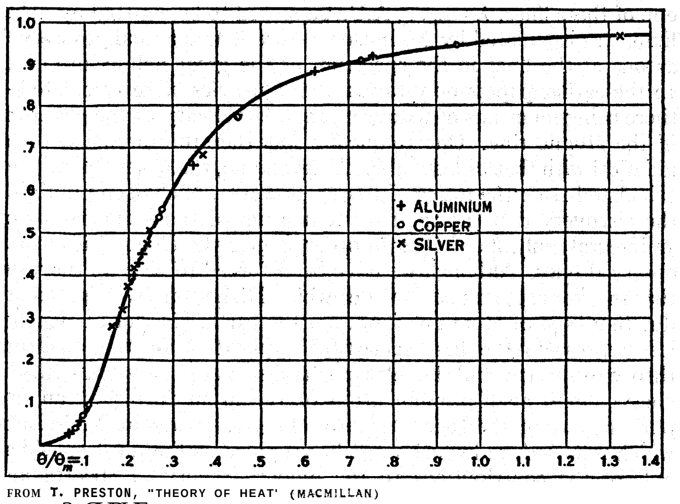
$$\frac{d\beta_m}{dT}=-\frac{\beta_m}{T},$$

$$\frac{dE}{dT}=f(\beta_m)-\beta_m f'(\beta_m),\tag{22}$$

The significance of (22) is that the atomic heat (as usually measured, *i.e.*, in terms of the centigrade degree) is the same function of β_m for all solid elements. Now $\beta_m=\frac{h\nu_m}{kT}$, or

$$\frac{1}{\beta_m}=\frac{T}{\frac{h\nu_m}{k}}=\frac{T}{\theta},\tag{23}$$

and therefore $\frac{1}{\beta_m}$ is the temperature of the element expressed in terms of the unit θ, which is called its characteristic temperature. We may say then finally, that the atomic heat of a solid element (measured in terms of the centigrade degree, or in terms of the same unit for all elements) is the same function of the temperature (now measured in terms of the characteristic temperature of the particular element as a unit) for all solid elements.



FROM T. PRESTON, "THEORY OF HEAT" (MACMILLAN)

FIG. 3—CURVE SHOWING THE VARIATION OF ATOMIC HEAT WITH TEMPERATURE

Reference to fig. 3 will show how well this theoretical result is supported by the facts. The atomic heats are given in terms of $3NK$, *i.e.*, to get the actual atomic heats the ordinates must be multiplied by 5.96. Debye's theory has been improved and extended by Born and Kármán, who have taken the crystalline structure of the solid into account.

The Constants of Planck and **Boltzmann.**—The universal constants h and k which have appeared in the formulae of the theories of full radiation and the specific heats of solid elements are appropriately named after Planck and Boltzmann. The data provided by investigators of full radiation enable us to assign to them the values,

$$h=6\cdot55\times10^{-27}\text{ erg seconds}$$

$$k=1\cdot37\times10^{-16}\text{ ergs per °C.}$$

These values do not differ materially from those originally computed by Planck.

The question now arises: What are the physical meanings of these constants? There is no difficulty in answering the question so far as k is concerned. It enters the theory of radiation as a factor correlating the entropy associated with the state of a thermodynamical system and the probability of that state, and is, therefore, sometimes termed the entropy constant. It appeared, more or less disguised in the kinetic theories of Maxwell and Boltzmann and in the statistical mechanics of Willard-Gibbs long before Planck began his investigations, and it happens to be identical with the quotient of the gas constant,

$$R=\frac{pv}{T}$$

of an ideal gas by the number of molecules in the gas; *i.e.*,

$$k=\frac{R}{N}.$$

Now R has the value $8\cdot315\times10^7$ ergs per degree centigrade for a gram molecule, therefore we get for N, the number of molecules in a gram molecule, $6\cdot06\times10^{23}$. This result, which differs only very slightly from that obtained by Planck, is in good agreement with the number obtained by later and quite different methods and it is very remarkable that it can be arrived at in this way. The quantity of electricity carried by a gram atom of hydrogen or other univalent element in electrolysis is found to be $2\cdot895\times10^{14}$ e.s.u., and when we divide by $6\cdot06\times10^{23}$, the number of atoms in a gram atom, we get for the charge on an ion $4\cdot77\times10^{-10}$ e.s.u. Planck arrived at the result $4\cdot67\times10^{-10}$ e.s.u., which may be said to be the earliest reasonably accurate estimate of the elementary ionic charge.

In the early days of the quantum theory, the question: What is the physical meaning of the constant h? was often asked. The question then really meant: What is the interpretation in terms of more familiar physical concepts of the type of atomicity symbolized by h? If the question is put in this way the answer is that h has no physical meaning. The fact is that the weird type of atomicity which finds its expression in Planck's constant is itself a ***new*** physical fact, first disclosed in the early development of the quantum theory and is something which can no more be expressed solely in terms of the older concepts of physics than can the dimensions of, say, a dielectric constant be expressed in terms of those of length, mass and time.

Photo-electricity.—The phenomena of photo-electricity exhibit two main features. (See article PHOTO-ELECTRICITY.) (1) No emission of electricity from the illuminated body occurs at all unless the frequency of the incident radiation reaches or exceeds a certain lowest value (the threshold frequency), and (2) the maximum kinetic energy of the ejected electrons depends only on the frequency of the incident radiation and not on its intensity. If a metal plate is exposed to homogeneous X-rays, *i.e.*, X-rays of one definite frequency; then, provided there is no electric field or other circumstance to affect the energy of the electrons, experiment shows that the maximum kinetic energy of the individual electrons emitted is quite independent of the distance of the plate from the source of X-rays (though of course the number emitted per second is inversely proportional to the square of the distance between the plate and the source). On the other hand, however distant the illuminated body may be from the source of light or X-rays, in other words, however low the intensity of the radiation the well-known phenomenon of interference characteristic of waves can still be produced. The reconciliation of these two aspects of the phenomenon, namely the independence of the energy of the ejected photo-electrons of the intensity, on the one hand, and the wave character of the radiation on the other, constitutes one of the most formidable problems which physical science has ever encountered. The former of these features seems to require that the radiation is corpuscular in character, while the latter seems to require that it is undulatory and spreads out continuously in all directions.

Recent developments of the quantum theory, more especially the wave mechanics of de Broglie and Schroedinger, suggest the solution of this problem, but meanwhile we shall confine our attention to the historically important explanation of photo-electric phenomena which we owe to Einstein, who about the year 1905 suggested that light is propagated through space in the manner of a corpuscular radiation, each corpuscle (or light quantum) having the energy $h\nu$. While this hypothesis frankly ignores those phenomena, such as interference, which have an indubitably undulatory character; it has the merit of explaining the facts of photo-electricity and allied phenomena. When a light quantum falls on a metal plate, the whole of its energy $h\nu$ may be given up to an electron. Part of this energy, 4, is used up in dragging the electron away from the metal and the rest is retained by the electron as kinetic energy; so that

$$\tfrac{1}{2}mv^2 = h\nu - \phi. \tag{24}$$

The quantity ϕ is called the work function and is characteristic of the illuminated material. If the incident radiation has a frequency ν_0, such that the energy $h\nu_0$ is just sufficient to drag the electron out, so that its kinetic energy is zero, then

$$0 = h\nu_0 - \phi,$$

and therefore equation (24) becomes

$$\tfrac{1}{2}mv^2 = h\nu - h\nu_0; \tag{24a}$$

with lower frequencies than ν_0 it is clear that no electrons can be ejected at all. Equation (24) has been verified experimentally and the constant h contained in it found to be identical with the h in Planck's radiation formula within the limits of experimental error. When very high frequencies are involved, *e.g.*, those of X-radiation hv is so large that equation (24) becomes practically

$$\tfrac{1}{2}mv^2 = h\nu;$$

and if we consider the converse phenomenon, *i.e.,* the excitation of X-rays by bombarding a metal with electrons, we should expect the highest frequency of the excited X-rays to be given by this equation, or by

$$Ve = h\nu \tag{25}$$

if V represents the drop of potential between the cathode and anti-cathode and e the electronic charge. This has been verified by Duane. X-radiation of lower frequency than that given by (25) can in general be excited, because the colliding electron may lose part of its energy in causing changes in the electronic constitution of the atoms with the consequent emission of X-radiation characteristic of the material bombarded.

The Compton Effect.—When ordinary light or X-radiation falls on a body there are in general, in addition to a possible photo electric emission, if the wave-length is short enough, two further observable consequences: (1) part of the incident beam is scattered by the body, *i.e.*, a radiation, the character of which is identical with or very closely similar to the incident radiation proceeds from the irradiated material, and (2) the atoms of the material may be excited to emit a radiation characteristic of the material (Barkla's characteristic or *fluorescent* radiation). While the classical theory requires that the scattered radiation (1) should be exactly similar to, *i.e.*, should have the same frequency and in other respects should be a replica of the incident radiation, the light-quantum hypothesis of Einstein leads us to expect the scattered radiation to have a slightly lower frequency (longer wave-length) than the incident radiation. This was first deduced and observed by the American physicist, A. H. Compton, and is named after him the Compton effect. We regard the light-quantum or photon, as it is sometimes called, as a sort of corpuscle possessing the energy hv or h/τ, where v and τ are respectively the frequency of the vibration associated with the corpuscle and the corresponding period. We further suppose the corpuscle to have the momentum h/λ, where λ is the wave-length of the fight. Since $\lambda\nu = C$, the momentum will also be equal to $\frac{h\nu}{C}$. The application of the principles of conservation of energy and momentum leads to a simple solution of the problem of the collision between a photon or corpuscle and an electron as explained in the article COMPTON EFFECT. Indeed, in the simple case where the electron is supposed to be at rest before the collision, it is obvious. without entering into mathematical details, that the effect of the collision will be to reduce the energy of the photon, since the electron must acquire some energy. Therefore hv will be less than $h\nu$ and consequently ν' will be less than v.

Theory **of** Spectra.—Regularities in the spectrum of hydrogen were discovered as early as 1885 by Balmer and much further progress of this kind was made subsequently by Rydberg, Ritz and others. The first to calculate wave-lengths successfully from an assumed dynamical model of the emitting atom appears to have been J. W. Nicholson, whose work is published in a valuable series of papers on the spectra of nebulae and the solar corona in 1911 and 1912. He ascribed certain nebular and coronal spectral lines, which could not at that time be associated with known terrestrial elements, and which did not apparently exhibit the types of regularity of series spectra, to hypothetical elements nebulium and protofluorine, the atoms of which he supposed to have a structure like that suggested by Rutherford to explain the laws of the scattering of α particles by matter. (See ATOM.) He applied mathematical methods very similar to those employed by Clerk-Maxwell in his study of the motion of the rings of Saturn, and from the dynamical properties of these atoms of hypothetical elements he calculated the wave-lengths of a very large number of coronal and nebular lines by identifying the frequencies of the radiation emitted by them with those of the small vibrations of the electrons perpendicular to and also in the plane of the circle on which they were situated.

The differencebetween the calculated and observedwave-lengths was probably in no case as great as 4 Angstrom units and at least one of these lines, $\lambda = 4{,}353$ Å.U., supposed to be emitted by nebulium, was calculated by Nicholson before it was actually observed as one of the lines in the spectrum of the great nebula in Orion. In the earlier papers only ratios of frequencies were calculated—there being no means of fixing the angular velocity of the electrons in the atomic ring. One frequency was therefore assumed to be identical with that of a suitable observed line, the others being then calculated from the ratios. In 1912, however, Nicholson published the discovery that the angular momentum of the atom has to be an integral multiple of $h/2\pi$ in order to give the frequencies of the observed lines. Although we have been forced to give up the view that the coronal and nebular lines which Nicholson investigated are due to a type of atom not found on the earth, his work nevertheless represents the first successful application of the quantum theory to spectra, and the relations he discovered between Planck's constant and angular momentum of the atom furnished an important part of the foundation for the great work of Niels Bohr which followed, and which must be regarded as the most considerable of the contributions to the modern theory of spectra and atomic structure. The earliest of Bohr's papers involving the quantum theory appeared in 1913 and contains two basic principles. (See ATOM.)

(1) The first of these, which we shall term Bohr's postulate, connects (we might say identifies) the spectral terms (see SPECTROSCOPY) with the energy levels or the energies of the emitting atom in its different stationary states. The frequencies (or wave numbers) of all the lines of series spectra can be expressed as dif-

ferences of certain quantities called spectral terms (combination principle of Ritz). Bohr supposed each spectral term to be identical, numerically, with the energy of the emitting atom in a corresponding stationary state divided by Planck's constant

$$\text{Spectral term} = \frac{\text{Energy}}{h}.$$

It is to be observed that in this connection we are dealing with spectral terms for calculating frequencies properly so called, *i.e.*, the number of waves emitted per second. Since the waves emitted during a second are spread over a distance of C centimetres (C= velocity of light) the *wave* number, *i.e.*, the number of waves in a centimetre, will be obtained by dividing the frequency by C. For the calculation of wave numbers we have therefore

$$\text{Spectral term} = \frac{\text{Energy}}{Ch}.$$

(2) The second basic principle is the connection discovered by Nicholson between angular momentum and Planck's constant. Bohr employed this relation to fix the stationary states of the sort of atom he contemplated. In this early form of the quantum theory he considered the simplest atoms of the Rutherford type, consisting of a positively charged nucleus of relatively small dimensions and large mass M, with a charge equal to Ze, where Z is a positive integer and e is the elementary unit of charge, $4\cdot774\times10^{-10}$ e.s.u.. and 3 single planetary electron with a mass m and the same numerical charge e. The simplest kind of motion of such a system is that in which the nucleus and electron (A and B in fig. 4) travel in circular orbits, the radii of which we shall represent by R and r respectively, with the atomic centre of gravity as their common centre. In V and v are the respective velocities of nucleus and electron, and if T represents the total kinetic energy of the system, we get the following equations from the principles of conservation of energy and momentum and the inverse square law of force:

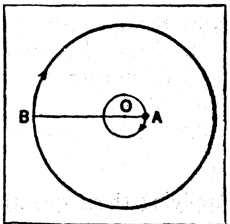


FIG. 4.—TWO CIRCLES REPRESENTING THE ORBITS OF THE NUCLEUS, A, AND THE ELECTRON, B, WITH O THE CENTRE OF GRAVITY OF THE SYSTEM AND THE COMMON CENTRE OF BOTH CIRCLES

$$\frac{m}{M} = \frac{V}{v} = \frac{R}{r} = s, \text{ a small constant,} \tag{26}$$

$$2T = mv^2(1+s) = \frac{mv^2}{\epsilon} = \epsilon\frac{Ze^2}{r}, \tag{27}$$

where ϵ has been written for $\frac{1}{1+S}$. We now fix the stationary states by Nicholson's angular momentum relation, which is expressed by

$$2\pi mvr + 2\pi MVR = nh,$$

or if we eliminate M, V and R by equations (26),

$$2\pi mvr(1+s) = nh$$

or

$$2\pi mvr = \epsilon nh. \tag{28}$$

If we now eliminate r and v by means of equations (27) we get

$$T = \frac{2\pi^2 m\epsilon Z^2 e^4}{n^2h^2} \tag{29}$$

To fix the arbitrary constant in the energy of the atom we shall adopt the convention which assigns the value zero to the potential energy of the system when the electron and nucleus are separated by an infinite distance. The potential energy W will then be expressed by

$$W = -\frac{Ze^2}{r+R} = -\epsilon\frac{Ze^2}{r} \tag{30}$$

It will be seen from (27) that $2T = \epsilon\frac{Ze^2}{r}$,

and therefore $2T + W = 0$,

or, since the energy $E = T + W$,

$$T + E = 0. \tag{31}$$

Now combining this last result with that given in equation (29) we get

$$E = -\frac{2\pi^2 m\epsilon Z^2 e^4}{n^2h^2}. \tag{29a}$$

Bohr's postulate then gives us for a spectral term

$$\frac{E}{h} = -\frac{2\pi^2 m\epsilon Z^2 e^4}{h^3}\cdot\frac{1}{n^2}, \tag{32}$$

or

$$\frac{E}{h} = -Z^2R\cdot\frac{1}{n^2}, \tag{33}$$

and for the frequencies of the spectral lines

$$\nu = Z^2R\left(\frac{1}{n^2} - \frac{1}{n'^2}\right), \tag{34}$$

where R (Rydberg's constant) is defined by

$$R = \frac{2\pi^2 m\epsilon e^4}{h^3}. \tag{35}$$

In equation (34) v represents frequencies properly so called, but if we define R by

$$R = \frac{2\pi^2 m\epsilon e^4}{Ch^3}, \tag{35a}$$

the equation (34) will give wave numbers.

A hydrogen atom was supposed by Bohr to be of the type described, with the integer Z (the atomic number) equal to unity. A helium atom he supposed to have a doubly charged nucleus, $Z=2$, and in its neutral state two electrons, so that the atomic model just described, with $Z=2$ represents an ionized helium atom, $Z=3$ represents an ionized lithium atom and so on. Putting $Z=1$ and $n=2$ in equation (34), we have Balmer's formula. The value of R calculated by (35a) is in entire accord with the observational value. By substituting the known values of m, h, e and C in (35a) and taking the approximate value unity for ϵ we find R to lie between 109,000 cm.$^{-1}$ and 110,000 cm.$^{-1}$. Spectroscopic data furnished the value 109,677·6 cm.$^{-1}$ in the case of hydrogen.

The deduction of equation (34) was one of Bohr's greatest triumphs. It rendered a complete account of Balmer's formula and predicted other spectral series of hydrogen. Four of these are now known observationally, namely, the

Lyman series, $n=1$, $n'=2$, 3, 4, . . .
Balmer series, $n=2$, $n'=3$, 4, 5, . . .
Paschen series, $n=3$, $n'=4$, 5, 6, . . .
Brackett series, $n=4$, $n'=5$, 6, 7, . . .

In the case of the (singly) ionized helium atom (34) becomes

$$\nu = 4R\left(\frac{1}{n^2} - \frac{1}{n'^2}\right)$$

For example if we put $n=4$ we have the series of lines,

$$\nu = 4R\left(\frac{1}{4^2} - \frac{1}{n'^2}\right) = R\left\{\frac{1}{2^2} - \frac{1}{\left(\frac{n'}{2}\right)^2}\right\}.$$

This series may be regarded as a superposition of two series, one in which n' is even and another in which n' is odd. If n' is even it follows that $\frac{n'}{2}$ is equal to an integer n'' and we have the series

$$\nu = R\left(\frac{1}{2^2} - \frac{1}{n''^2}\right),\ n''=3, 4, \cdots$$

If n' is odd we have $\frac{n'}{2} = n'' + \frac{1}{2}$ where n'' is again an integer, and we have the series

$$\nu = R\left\{\frac{1}{2^2} + \frac{1}{(n''+\frac{1}{2})^2}\right\},\ n''=2, 3, \ldots$$

The former of these is Balmer's series, which Bohr thus showed could be emitted by helium as well as by hydrogen. The latter series was observed by Pickering in the spectrum of the star ζ Puppis in 1896 and was naturally, but erroneously thought to be due to hydrogen. We must notice, however, that R is slightly different for hydrogen and helium, because the number ν, though always near unity is a little greater in the case of helium. Equation (35) gives us

$$\frac{R_{\text{helium}}}{R_{\text{hydrogen}}}=\frac{\epsilon_{\text{helium}}}{\epsilon_{\text{hydrogen}}}$$

or

$$\frac{R_{\text{helium}}-R_{\text{hydrogen}}}{R}=\frac{\epsilon_{\text{helium}}-\epsilon_{\text{hydrogen}}}{1}$$

approximately. Now the mass of a helium nucleus is known to be about 3·97 times the mass of a hydrogen nucleus and the difference between Rydberg's constant for helium and for hydrogen is found from spectroscopic observations to be about 44.5 cm.$^{-1}$, therefore

$$\frac{44\cdot5}{109700}=\frac{1}{1+\dfrac{m}{3\cdot97M}}-\frac{1}{1+\dfrac{m}{M}}=\frac{m}{M}\left(1-\frac{1}{3\cdot97}\right)$$

approximately, where M is the mass of a hydrogen nucleus or practically the mass of a hydrogen atom. Therefore

$$\frac{M}{m}=1840 \text{ approximately.}$$

This result is in excellent agreement with that obtained by more direct methods.

GENERAL QUANTUM THEORY

So far we have been concerned with systems possessing only one degree of freedom, actually or virtually, and consequently only one quantum number to fix a stationary state. In 1915 W. Wilson and A. Sommerfeld succeeded, independently of one another, in finding appropriate rules or conditions for fixing the stationary states of systems of more than one degree of freedom. These quantum conditions may be illustrated by the aid of the type of atom we have already studied. For the sake of simplicity we shall ignore the motion of the massive nucleus and regard the centre of mass of the atom as situated in the nucleus itself—an assumption which in any case is very near the truth. The electron has, of course, three co-ordinates. Since, however, its orbit lies in a plane, we can choose our system of reference so that one of the three is a constant and we need pay no further attention to it. We have then a system which has virtually two degrees of freedom. The principle of energy gives us the equation

$$\tfrac{1}{2}mv^2-\frac{Ze}{r}=E, \tag{36}$$

where the same convention as before is used in fixing the arbitrary constant in the energy and where the symbols have again the same meaning, except that r, the distance of the electron from the attracting nucleus, is not in general the radius of a circular orbit. In polar co-ordinates, r and θ, the equation becomes

$$\tfrac{1}{2}m\left(\frac{dr}{dt}\right)^2+\tfrac{1}{2}mr^2\left(\frac{d\theta}{dt}\right)^2-\frac{Ze^2}{r}=E, \tag{36a}$$

and if we express the velocities in terms of the corresponding momenta, p_r and p_θ defined by

$$p_r=m\left(\frac{dr}{dt}\right)$$

$$p_\theta=mr^2\left(\frac{d\theta}{dt}\right),$$

we obtain

$$\frac{p_r^2}{2m}+\frac{p_\theta^2}{2mr^2}-\frac{Ze^2}{r}=E. \tag{36b}$$

When E is negative, the orbit of the electron is elliptical or circular and each of the integrals,

$$\left.\begin{aligned}J_1&=\oint p_r dr\\ J_2&=\oint p_\theta d\theta\end{aligned}\right\} \tag{37}$$

extended over the period of motion of the electron, is a definite constant depending on the energy and angular momentum of the system. It is convenient to represent the constant angular momentum by Ω, so that $p_\theta=\Omega$ and

$$J_2=2\pi\Omega. \tag{38}$$

From (36b) we have $p_r=\sqrt{\left(2mE+\dfrac{2mZe^2}{r}-\dfrac{\Omega^2}{r^2}\right)}$;

whence we obtain $J_1=2\pi\left(\dfrac{mZe^2}{\sqrt{-2mE}}-\Omega\right)$. (39)

Equations (38) and (39) enable us to express the constants E and Ω in terms of the Js. We have

$$\left.\begin{aligned}E&=-\frac{2\pi^2mZ^2e^4}{(J_1+J_2)^2}\\ \Omega&=\frac{J_2}{2\pi}\end{aligned}\right\}. \tag{40}$$

Now the quantum conditions of Wilson and Sommerfeld make each of the phase integrals, J_1, J_2 etc., equal to the product of a positive integer (which may sometimes be zero) and Planck's constant, h:

$$\left.\begin{aligned}J_1&=n_1h\\ J_2&=n_2h.\end{aligned}\right\}. \tag{41}$$

Applying these quantum conditions in equations (40) we get

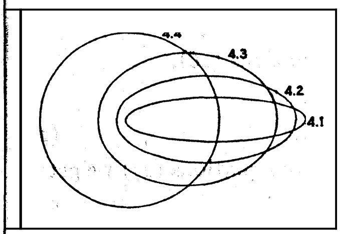
$$\left.\begin{aligned}E&=-\frac{2\pi^2mZ^2e^4}{n^2h^2}\\ \Omega&=\frac{n_2h}{2\pi}\end{aligned}\right\}, \tag{40a}$$

where n means n_1+n_2. The expression for the energy (40a) is in agreement with that originally given by Bohr (29a). The absence of the factor ϵ is due to our ignoration of the motion of the massive nucleus which is equivalent to making ϵ equal to unity. The validity of equations (40a) is not now confined to circular orbits, but extends to orbits which are elliptical in shape. The quantum conditions (41) restrict the eccentricities of the ellipses to those expressed by the formula

$$(1-\epsilon^2)^{\frac{1}{2}}=\frac{n_2}{n_1+n_2},$$

where ϵ is the eccentricity. The integers n_1 and n_2 are called the radial and azimuthal quantum numbers respectively. It is easy to show that for a given energy, or a given value of the total quantum number $n=n_1+n_2$, all the possible ellipses in which the electron may travel have a major axis of the same length.

In fig. 5 are illustrated the ellipses for which the total quantum number is 4. For instance, the ellipse 4.3 has a radial quantum number $n_1=1$, and an azimuthal quantum number $n_2=3$. Bohr prefers to characterize an orbit by specifying its total and azimuthal quantum numbers. He employs the letter k for the latter number and his general symbol for an orbit is n_k. The orbit 4·3 for example would be described by Bohr as a 4_3 orbit. The orbit for which n_2 or k is zero is obviously not one of those in which the electron is permitted to travel, since it is a straight line through the nucleus. It may be remarked that the quantum conditions (41) are in agreement with Planck's hypothesis for a simple harmonic oscillator, since the area of the closed curve in fig. 2 is given by $\oint pdq$.



FROM E. N. DA C. ANDRADE, "STRUCTURE OF THE ATOM" (G. BELL & SONS)

FIG. 5.—POSSIBLE ELLIPTIC ORBITS OF THE ELECTRON WHEN THE TOTAL QUANTUM NUMBER IS 4

We are now in a position to give a more general description of the quantum theory, or at any rate that part of it which is based on the quantum conditions (41). We shall denote the coordinates of a dynamical system by q_1, q_2, q_3, . . . and so, as is usual, the corresponding generalized momenta by $p_1, p_2, p_3, \ldots$. If it happens, as it does in many important cases, that the system is conservative from the point of view of classical dynamics, or sufficiently nearly so to be treated as such, and if the coordinates can be so chosen that p_1 is a function of q_1 only, p_2 a function of q_2 only and so on, the variables then being said to be separable, it can be shown that each q librates between definite limits and associated with each libration is a dehnite fundamental frequency of libration ν_1 of the coordinate q_1, ν_2 of q_2 and so on. Such systems are said to be conditionally periodic. Each of the phase integrals

$$J_1=\oint p_1dq_1,$$
$$J_2=\oint p_2dq_2,$$
$$\cdot \quad \cdot \quad \cdot \quad \cdot$$

where, in each case, the integration is extended over the complete range of values of the corresponding q and back to its original value again, is a constant and we can express the energy of the system E, and also the other constants of integration, as functions of the J's, just as we did in the simple example described above;

$$E=\text{function }(J_1, J_2, \ldots)$$

where, in general, there are as many J's as the system has degrees of freedom. The stationary states are now fixed by equations (41). We thus obtain an expression for the energy of a stationary state in terms of quantum integers of the constant h and of constants which are inherent in the system, such as electronic charge and mass, etc., and we are in a position to calculate frequencies of radiation by applying Bohr's postulate.

According to the principles of classical dynamics the fundamental frequencies of libration are given by

$$\left.\begin{aligned}\nu_1&=\frac{\partial E}{\partial J_1}\\ \nu_2&=\frac{\partial E}{\partial J_2}\end{aligned}\right\};\qquad (42)$$
$$\cdot \quad \cdot \quad \cdot$$

and the general expression for the frequencies of the radiation which such a system would emit if the classical *theory* were true, would be

$$\nu=\frac{\partial E}{\partial J_1}s_1+\frac{\partial E}{\partial J_2}s_2+\cdots,\qquad (43)$$

where s_1, s_2, etc., are integers. It sometimes happens that the number of independent fundamental frequencies is less than the number of degrees of freedom, *i.e.*, one or more of the frequencies calculated by (42) can be expressed in terms of the remaining frequencies. In such a case the motion is said to be degenerate. The Bohr atom described above is an instance of this. If we differentiate E in (40) with respect to J_1, we get for the frequency of the radial motion of the electron,

$$\nu=\frac{4\pi^2mZ^2e^4}{(J_1+J_2)^3},$$

and we obtain precisely the same value for ν_2 the frequency of revolution of the electron in its orbit when we differentiate with respect to J_2, so that in this case $\nu_1=\nu_2$.

Let us write the change in energy AE due to a transition from one stationary state to another in the following form,

$$\Delta E=\Delta E_1+\Delta E_2+\cdots,$$

where ΔE_1 is the change in energy associated with ΔJ_1, the change of J_1, due to the transition, and ΔE_2 is the change in energy associated with ΔJ_2 and so on. Obviously

$$\Delta E=\frac{\Delta E_1}{\Delta J_1}\cdot\Delta J_1+\frac{\Delta E_2}{\Delta J_2}\cdot\Delta J_2+\cdots;$$

Now we must necessarily have

$$\Delta J_1=s_1h,$$
$$\Delta J_2=s_2h,$$

where $s_1, s_2, \ldots$ are integers positive or negative including zero, therefore

$$\Delta E=\frac{\Delta E_1}{\Delta J_1}s_1h+\frac{\Delta E_2}{\Delta J_2}s_2h+\cdots.$$

If we divide both sides by h, the left hand member will be the frequency of the emitted (or absorbed) radiation according to Bohr's postulate, and therefore

$$\nu=\frac{\Delta E_1}{\Delta J_1}s_1+\frac{\Delta E_2}{\Delta J_2}s_2+\cdots.\qquad (43a)$$

Correspondence **Principle.**—It will be noticed that there is a close similarity between (43) and (43a), and, in fact, when J_1, J_2, etc., are individually very big compared with ΔJ_1, A J_2, etc., the two formulae (43) and (43a), the former giving frequencies of radiation calculated from the classical theory and the latter those given by the quantum theory, become identical. If the quantum theory is to represent the facts this asymptotic approach to the classical theory, when large energies are involved, is essential, as has already been pointed out. Now one of the striking facts about spectra is that while the frequency (or wave number) of any spectral line is equal to the difference of two spectral terms (combination principle), the converse is not always true. That is to say the difference between a pair of spectral terms does not in every case represent an observed frequency (or wave number). Using the language of the quantum theory we may say that the atom is not at liberty to make any transition it likes from one stationary state to another.

Certain restrictions have to be placed on the values of the integers, s_1, s_2, etc., in (43a). These restrictions have found their expression in the past in the form of selection rules (Rubinowicz, Sommerfeld and others), mostly deduced from the principle of conservation of angular momentum. They were superseded by the comprehensive correspondence principle of Bohr. According to this principle the integers s_1, s_2, etc., in (43a) must have the same values as those of the classical formula (43). In simple harmonic motion (the type of motion of the pendulum described above when the amplitude is small), the energy associated with a stationary state is equal to nhw, if ω is the frequency of oscillation, and according to Bohr's postulate

$$\nu=(n-n')\omega,$$

where ν is the frequency of the radiation emitted when a transition from a stationary state corresponding to a higher to one of a lower energy level takes place, *i.e.*,

v=SW,

where s is an integer. Now according to the classical theory s is restricted to the value 1 and the correspondence principle requires that we must adopt this value in applying the quantum theory. When applied to our simple Bohr atom the correspondence principle requires that s_2 (the change of the azimuthal quantum number n_2, or Bohr's k) during a transition must be $+1$ or -1 (unless the atom is under the influence of an external field). If we were concerned only with this special type of atom and neglect, as we have done, relativistic refinements, this would not be of the slightest consequence, since the frequency of the emitted radiation is determined by the change of $n=n_1+n_2$ and is not, therefore, affected (for a given change of n) by the changes in the individual integers.

If, however, we turn to a more complicated sort of atom, *e.g.*, a neutral sodium atom, it becomes of great importance. According to Bohr this atom consists of a nucleus having a charge of 11 units of positive electricity, with 10 electrons travelling in orbits arranged relatively closely round it and a more isolated electron travelling in an orbit which we may regard as roughly elliptic. A sodium atom therefore resembles the simple hydrogen atom. Indeed, if we were to imagine the 10 inner electrons to be very close indeed to the nucleus, the outer electron would behave in almost exactly the same way as the electron in the hydrogen atom, since we have an atom consisting of a small but massive inner structure, with a net charge of one positive unit. In consequence, however, of the fact that the inner orbits do extend out from the nucleus, the outer electron may, if n_2 or k is small, have its perihelion (or perinucleon) actually within the boundary of the inner system of orbits. If k is large the orbit of the outer electron may be quite outside this boundary. In these circumstances the energy of the outer electron is not determined by the sum $n=n_1+n_2=n_1+k$, but by the individual values of n_1 and k. For a given n the energy is least (numerically greatest, if we remember the sign of E) when $k=1$ and increases progressively with k. We shall have a set of spectral terms for which $k=1$, another set for which $k=2$ and so on. Bohr supposes $k=1, 2, 3, 4 \ldots$ for S, P, D, F terms respectively. The circumstance that k changes by $+1$ or -1, and not by zero or any other number, corresponds to the spectroscopic fact that we have combinations of S and P, P and D, or D and F terms, but not for instance combinations of S and D, or S and F terms.

Fine Structure of Spectral Lines.—In generalizing the quantum theory Sommerfeld made a very important application of it in an investigation of the fine structure of the lines of the spectra of hydrogen and helium. He took into account the fact that the mass of an electron (or of any particle) according to the theory of relativity, depends on its velocity. The effect of this dependence is to make the kinetic energy equal to

$$m_0C^2\left\{\frac{1}{\left(1-\frac{v^2}{C^2}\right)^{\frac{1}{2}}}-1\right\},$$

instead of $\frac{1}{2}mv^2$, where m_0 is the mass of the electron when at rest or in slow motion and C is the velocity of radiation in empty space. The expressions for the momenta differ from those in the ordinary theory by having m replaced by $m_0/\sqrt{(1-v^2/c^2)}$. The expression for the energy of a stationary state becomes for a hydrogen atom approximately

$$E=-\frac{Rh}{n^2}\left\{1+\frac{Rh}{2m_0C^2n^2}\left(1+4\frac{n_1}{n_2}\right)\right\}. \tag{44}$$

The $H\alpha$ line for example is due to transitions from states where $n=3$ to states where $n=2$. There are apparently six different sorts of transitions by which $H\alpha$ radiation may be emitted, since there are 3 states for $n=3$ and two states for $n=2$. These are shown in the following table.

THE STATIONARY STATES OF A HYDROGEN ATOM CORRESPONDLUG TO $n=3$ AND $n=2$, AND THE PERMITTED TRANSITIONS.

$n=3$		$n=2$	
n_1	n_2	n_1	n_2
0	3	0	2
1	2	1	1
2	1		

The integer n_2 cannot be zero, because this would correspond to a rectilinear motion through the nucleus. We have seen, however, that n_2 must change by $+1$ or -1 and in no other way according to the correspondence principle, and therefore the number of possible transitions is reduced to three. H_α then consists of three lines all close together. Two of the three are so very close to one another that the system is practically a doublet. The separation is approximately that of the two terms corresponding to $n=2$ namely $0{\cdot}365\text{cm.}^{-1}$. How small this is can be judged by comparison with the separation of the D lines of sodium, which is $17{\cdot}18\text{cm.}^{-1}$. It is easy to see that the correspondence principle requires that each line of Lyman's series is associated with only one kind of transition, and is therefore single.

This theory of the fine structure of spectral lines is in excellent accord with the observations made before and soon after its development; but the improved photometric methods developed in quite recent times have given the problem quite a different character—without impugning the accuracy of the relativistic formulae in Sommerfeld's theory. There is no doubt that the spectrum of hydrogen must be classed with the spectra of the alkali metals, lithium, sodium, etc., and in the present state of the theory H_α, for example, has seven components, two pairs of which, however, coincide, so that there are five distinct components instead of the *three* of the older theory.

Stark Effect.—In the year 1913 Johannes Stark discovered that each of the Balmer lines of hydrogen, which, for the purposes of this paragraph, may be considered to be single lines, since the effect we are about to study is of a much bigger scale of magnitude than that of the fine structure of the individual lines, splits up into a group of lines symmetrically situated with regard to the original line when the emitting atoms are subjected to a strong external electric field. The complete explanation of this phenomenon is one of the greatest successes of the quantum theory and was given independently by Epstein and Schwarzschild. The mathematical problem involved was actually solved by the German mathematician, Jacobi, in the earlier half of the last century. It is only possible to give the barest outline of it here. We may neglect the motion of the massive nucleus and suppose it provisionally to be at the origin of rectangular coordinates. The applied electric field we shall take to be in the direction of the X-axis. If ρ represents the perpendicular distance of the electron from the X-axis, the proper coordinates to use in order that the variables may be separated in the sense explained above are ξ, η and ϕ, where

$$x=\frac{\xi^2-\eta^2}{2},\quad \rho=\xi\eta,$$

and where ϕ is the azimuthal angle about the X-axis. Epstein and Schwarzschild showed that the energy of the system is given by

$$E=-\frac{2\pi^2mZ^2e^4}{J^2}-\frac{3}{8}\,\frac{J(J_\xi-J_\eta)}{\pi^2mZe}F, \tag{45}$$

where F is the intensity of the applied field, $J=J_\xi+J_\eta+J_\phi$, and the terms involving squares and higher powers of F have been ignored. The quantitizing formulae (41) give us

$$E=-\frac{2\pi^2mZ^2e^4}{n^2h^2}-\frac{3}{8}\,\frac{n(n_\xi-n_\eta)}{\pi^2mZe}F, \tag{45a}$$

as the general expression for the energy of a stationary state, where $n=n_\xi+n_\eta+n_\phi$. The correspondence principle indicates that n_ϕ changes by $+1$, -1, or 0 during a transition from one stationary state to another, and that when $\Delta n_\phi=0$ the emitted radiation is polarized with its vibrations parallel to the direction of the field and in the other cases perpendicular to the field. Kramers has successfully applied the correspondence principle to explain the observed relative intensities of the components. Finally it may be added that Bohr has worked out the problem of the Stark phenomenon by the method of secular perturbations, much used by astronomers. Essentially this consists in making use of the fact that the motion of a planet round the sun or of an electron round the nucleus is to a first approximation elliptical, but we can get a more accurate result by studying the small perturbations of this elliptic motion by the external disturbing bodies or by the applied external field.

Zeeman Effect.—When a source of light such as a sodium flame or a discharge tube is placed in a sufficiently intense magnetic field, we find on observing the spectrum with apparatus of suitable resolving power that each original spectral line is replaced by a number of lines. (See ZEEMAN EFFECT.) The energy equation (40) of a simple Bohr atom has to be modified in the following way when the atom is subjected to a uniform magnetic field of intensity H:—

$$E=-\frac{2\pi^2mZ^2e^4}{(J_1+J_2+J_3)^2}\pm\frac{eH}{4\pi mC}J_3, \tag{46}$$

where terms involving H^2 and higher powers are ignored. In this equation the definitions of the phase integrals J (37) have been extended by replacing the mechanical momentum p by a more general momentum which is the vector sum of p and the product $-eA$ of the charge on the electron and the electromagnetic vector potential. This extension, which was suggested by W. Wilson in 1921, plays an important part in recent developments of the quantum theory. J_3 above is the phase integral associated with the azimuthal angle about the axis of the magnetic field. The application of the classical method (42) indicates that the motion of the electron in the presence of the magnetic field is that which would result if we were to superpose on its motion in the absence of a field a rotation or precession about the axis of the field equal to $\frac{eH}{4\pi mC}$ revolutions per second (Larmor's theorem).

The quantum theory was first applied to the phenomenon by Debye and by Sommerfeld in 1916. Their methods were equivalent to fixing the stationary states in the way already described (equations [41]); using the extended integrals, and then applying Bohr's postulate. This leads, with the help of the correspondence principle, to the result given by the classical theory and only succeeds in explaining what is known as the normal Zeeman effect. In fact the last term in equation (46) becomes

$$+(n_3-n'_3)\,\frac{eH}{4\pi mC};$$

and the correspondence principle indicates, just as in the Stark effect, that n_3-n'_3 must be $+1$, -1, or 0. The anomalous phenomenon (observed when the magnetic field is not too intense) may be concisely described in the following way: the "magnetic" term in (46) has to be put in the form

$$g\cdot n_3\cdot\frac{eH}{4\pi mC},$$

instead of simply $n_3\frac{eH}{4\pi mC}$.

The factor g, called the splitting factor (Aufspaltungsfaktor), is characteristic of the spectral term, and n_3 is not always an integer, but may differ from an integer by &. The splitting factor is always expressed by

$$g=1+\frac{j(j+1)+s(s+1)-l(l+1)}{2j(j+1)},$$

where j is a quantum number characteristic of the term, s is a number which is supposed to represent the angular momentum of spin of the electron in terms of the unit $h/2\pi$, or the resultant momentum if more than one electron is involved. Where a single electron is involved $s=\$$. The quantum number l is equal to k – I where a single electron is involved. For example the sodium D_2 line is due to a transition from a P term for which $j=\frac{3}{2}$ to an S term for which $j=\frac{1}{2}$. For the former term $l=1$, since $k=2$, and for the latter $l=0$. Therefore g is equal to $\frac{4}{3}$ for the P term and 2 for the S term. The number n_3 has the values,

$$j,\ j^{-1},\ \ldots,\ -(j-I),\ -j;$$

i.e., in the case of the P term mentioned,

$$n_3=3/2,\ \tfrac{1}{2},\ -\tfrac{1}{2},\ -\tfrac{3}{2},$$

and in the case of the S term

$$n'_3=\tfrac{1}{2},-\tfrac{1}{2}.$$

Only such transitions are permitted for which $n_3-n'_3=+1$, 0, or -1, and the same rules determine the polarization as in the case of the normal effect.

Miscellaneous. — The principles of the quantum theory have been applied with great success to the study of X-ray emission and absorption spectra and the disentangling of the very complicated features of band spectra (see BAND SPECTRUM) has been greatly facilitated by, and indeed would hardly have been possible without, the indications which the theory has provided. The main features of these spectra can be ascribed to changes in the rotational and vibrational energy of molecules. The kinetic energy of a rotating body is expressed by

$$E=p^2/2K, \qquad (47)$$

where p is its angular momentum, and K the corresponding moment of inertia, and since p is restricted to the values $n\ h/2\pi$, where n is an integer, we must have

$$E=\frac{n^2h^2}{8\pi^2K}. \qquad (47a)$$

As a matter of fact the newer developments of the quantum theory (see "Wave Mechanics" below), as well as the actual facts of band spectra, show that in some cases the energy of rotation is given by

$$E=\frac{n(n+1)h^2}{8\pi^2K} \qquad (47b)$$

A similiar remark applies to the energy of a simple harmonic vibration which is expressed by $(n+\frac{1}{2})h\nu$ instead of n hv.

The energy of gas molecules is very largely kinetic energy of rotation, and therefore equation (47b) has played an important part in the theory of the specific heats of gases and their dependence on the temperature.

An electron orbit, constituting, as it does, an electric current, possesses a magnetic moment, and the existence of stationary states involves the consequence that the magnetic moment of an electron orbit must be an integral multiple of a certain smallest value or unit. It is easy to establish that this unit of magnetic moment is $\frac{eh}{4\pi mC}$. It is called the Bohr rnagneton. (See MAGNETISM.)

Elementary considerations show that the mutual energy of a magnet and an external field is equal to $M_H{\cdot}H$, apart from a constant which we may take to be zero, where M_H means the component of the magnetic moment of the magnet in the direction of the field and. H is the intensity of the field. If now we turn to equation (46) and remember that $J_3=n_3H$, where n_3 is an integer, we see that the mutual energy of an electron orbit and a magnetic field is

$$n_3\cdot\frac{eh}{4\pi mC}\cdot H, \qquad (48)$$

and therefore the component of the magnetic moment in the direction of the field is

$$n_3\frac{eh}{4\pi mC}, \qquad (48a)$$

an integral multiple of a Bohr magneton. We must infer from this that the angle between the axis of the electron orbit and the applied field cannot vary continuously, but is restricted to certain quite definite values. If,for example, the total magnetic moment of the orbit were one Bohr magneton, then its axis must be directed along the external field, or along the opposite direction, or at right angles to the field according to the simple theory we have given. This kind of restriction is sometimes called spatial quantization and has received remarkable confirmation in the experiments of Gerlach and Stern. (See MAGNETISM.) More direct confirmation of the hypothesis of stationary states is furnished by the extensive investigations of critical potentials of gases and vapours.

NEW QUANTUM THEORY

So far we have been describing a theory which, broadly speaking, consists of two not very coherent parts, namely, Einstein's light-quantum theory and the theory based on stationary states and Bohr's postulate. Although as we have seen, it has been very successful, it does suffer from certain serious defects— quite apart from its logical weaknesses and obscurities. The chief of these are: —

1. It fails to meet the dilemma of the corpuscular and undulatory behaviour of light.

2. It fails to render any adequate account of those magnetic phenomena which are usually termed "anomalous," such as the Zeeman effect and the gyromagnetic effect.

3. The presence in the formulae of the Zeeman effect and band spectra of half quanta, *i.e.,* of multiples of h which are half integers, finds no explanation in the "classical" quantum theory. This difficulty would obviously still remain, even if a new quantum equal to $h/2$ were introduced.

There is a certain parallelism between the advance from the older or classical quantum theory to the newer theory and that from the old elastic solid theory of light to the later and much more adequate electromagnetic theory of Clerk Maxwell, and, no doubt, we shall long continue to use the language of the older quantum theory, and the fairly simple pictures it provides of atomic phenomena, just as we still use that of the elastic solid theory of light. The new theory has developed along two different lines, which, however, lead invariably to the same mathematical consequences, so that they are almost certainly just different aspects of one and the same theory. One of these aspects, known as wave mechanics, and historically the earlier and more interesting, was initiated by Louis de Broglie and further developed by E. Schroedinger. L. de Broglie's immediate objective was the solution of the dilemma (1); the other line of development is due to W. Heisenberg. He was inspired by a scientific outlook very prevalent among German physicists since the time of the Austrian philosopher, Ernst Mach, who insisted on the rigorous observance of the Newtonian principle of the avoidance of all hypotheses—"hypotheses seu *metaphysicae,* seu *physicae,* seu *qualitatum* occultarum, *seu mechanicae,* in *philosophia experimentali locum* non *habent*" (Newton, *Principia* Liber *tertius* p. 530, editio tertia).

Wave Mechanics.—The similarity of the laws of classical mechanics and geometrical optics was known long ago and forgotten or overlooked in modern times. The laws of reflection and refraction, it will be remembered, were subsumed by Fermat in the statement that the path selected by a ray of light in travelling from a point A to a second point B is that which takes a minimum time. (See LIGHT.) To be quite accurate we ought to say that the path of a ray of light is always one which occupies a minimum or a *maximum* time, with, of course, the intermediate possibility exemplified by the behaviour of curved mirrors and lenses, that all paths within wide limits may occupy the same time. The time taken by any point on a wave front to travel a short distance dq in a direction normal to the wave front is obviously dq/u, where u is the velocity of the wave (the phase velocity). The whole time occupied between two points A and B is made up of the sum of such elements dq/u and is written

$$\int_A^B dq/u.$$

Fermat's principle of minimum (or maximum) time may therefore be expressed by

$$\delta\int_A^B dq/u=0. \tag{49}$$

The symbol 6 is used to indicate that the expression in (49) represents the difference between the value of the integral (the time) measured along the actual path of the ray and that measured along a neighbouring path. It is important to note that the frequency v (or the period τ) is taken to be the same for both paths. Remembering this and that the velocity $u=\lambda/\tau$, where λ is the length of a wave, we see at once that an alternative statement of Fermat's principle is

$$\delta\int_A^B dq/\lambda=0 \tag{49a}$$

or the path of the ray of light is the one which contains the minimum (or maximum) number of waves.

In 1744 de Maupertuis, president of the Prussian Academy in the reign of Frederick the Great, enunciated the principle of least action which subsumes the laws of classical mechanics in a single statement, just as Fermat's principle does for geometrical optics. The naïve belief of de Maupertuis that his principle was based on the attributes of the Supreme Intelligence was not inappropriate, for it has turned out to be deeper and wider in its scope than any other in the whole range of physical science. For a system with one degree of freedom it may be stated in the form

$$\delta\int_A^B p\,dq=0, \tag{50}$$

where q is the positional coordinate and p the corresponding momentum. The symbol 6 represents a small variation *for* a given energy, E, just as in (49) it represents a small variation for a given period τ. If we adopt the *corpuscular* theory of light, still held in the time of de Maupertuis. it is not difficult to show that (50) actually coincides with Fermat's principle. In order to appreciate the wave mechanics of de Broglie and Schroedinger it is very important to realize that classical mechanics rests on the principle expressed by equation (50) or a simple generalization of it, namely

$$\delta\int_A^B \Sigma p\,dq=0 \tag{50a}$$

when we are concerned with systems with several degrees of freedom, in just the same way as geometrical optics rests on equation (49) or better (49a). It will be noticed that p and $1/\lambda$ are analogous things in the two formulae. The principle of action can be expressed in other ways besides that of de Maupertuis, The most important of these alternative forms is that due to Sir W. Hamilton and known as Hamilton's principle. We shall only remark about Hamilton's principle that it brings out a parallelism between E, the energy of a particle and $1/\tau$ in the corresponding optical problem, of precisely the same kind as we have found between p the momentum of the particle and $1/\lambda$.

De Broglie supposed every ultimate particle to be the manifestation of some kind of "phénomène périodique" and to be associated with a wave or a group of waves of a narrow range of frequencies. There is a well known distinction between the velocity with which a group of waves travels and the phase velocity or the velocity of the crests and troughs of the individual waves. According to de Broglie the velocity v of the particle should be identified with that of the group. This view is supported by the circumstance that the velocity of a group is given by

$$v=\frac{d(1/\tau)}{d(1/\lambda)}. \tag{51}$$

The parallelism we have recognized between E and $1/\tau$ and between p and $1/\lambda$ suggests that we should investigate the quotient $\frac{dE}{dp}$, and we find, in fact, on substituting $\frac{1}{2}mv^2$ for E and mv for p,

$$\frac{d(\frac{1}{2}mv^2)}{d(mv)}=v.$$

This is also the result we arrive at if we use the more elaborate relativistic expressions for E and p.

We now reach the crux of the wave mechanics. The way in which classical mechanics, and classical physical theory generally breaks down when we have to deal with sufficiently small scale phenomena, is just like the way in which geometrical optics fails when applied to paths which are not long compared with the wavelength of the light.

By way of illustration we shall study the case of a rigid body spinning about a fixed axis and not in a field of force. It will help us if we think of it as a thin uniform ring of mass m turning about an axis through the centre of the ring and perpendicular to its plane. Apart from a constant, the energy of the ring is identical with its kinetic energy t. We shall use the letter q to represent the distance a mark on the ring has travelled from some chosen zero position, and R to represent the radius of the ring which is, of course, constant. In this example the energy E and the momentum p of the ring remain constant during its motion, and the simplest kind of de Broglie wave we can associate with it may be expressed in the form

$$\psi=A\cos 2\pi\left(\frac{t}{\tau}-\frac{q}{\lambda}\right), \tag{52}$$

where A, λ and τ are constants. We shall postpone the enquiry about the significance of ψ. This equation represents a wave of ψ, travelling in the direction of increasing q with a velocity λ/τ and it may be written in the form

$$\psi=A\cos\frac{2\pi}{h}\left(\frac{h}{\tau}t-\frac{h}{\lambda}q\right), \tag{52a}$$

where, so far, h may be any quantity, but if we agree that it shall be identical with Planck's constant, and remember the parallelism between E and $1/\tau$ and between p and $1/\lambda$ we are almost forced to adopt the hypothesis $E=h/\tau$ and $p=\frac{h}{\lambda}$ and so we have

$$\psi=A\cos\frac{2\pi}{h}(Et-pq) \tag{52b}$$

Now it is clear that if q is increased by $2\pi R$, *i.e.*, if the ring is turned once round, the original condition of things is reproduced and we must, therefore, demand that the value of ψ, or more precisely the part of it depending on q, is unaltered. Therefore the increase of the argument of the cosine, namely, $\frac{2\pi}{h}p\cdot 2\pi R$ numerically, must be equal to $2\pi n$ where n is an integer, or $p\cdot 2\pi R=nh$. We recognize in this equation a case of the familiar quantizing conditions (41) which enter wave mechanics quite naturally and have not to be imposed in the arbitrary and ad *hoc* manner of the older theory. Since the kinetic energy $\tau=p^2/2m$ we have, just as in the earlier theory,

$$\tau=\frac{n^2h^2}{8\pi^2mR^2}=\frac{n^2h^2}{8\pi^2K},$$

where $K=mR^2$ is the moment of inertia of the ring about the axis of spin.

In the case of a rigid body which is not in a field of force and can turn freely about a fixed point, we have two coordinates, q_1 and q_2, and their corresponding momenta, and the problem is much more complicated. It will suffice to say here that the demand that ψ must be one-valued now leads to the formula

$$\tau=\frac{n(n+1)h^2}{8\pi^2K},$$

which, as we have pointed out before, is actually required by spectroscopists to explain the phenomena of bands and which the older quantum theory is wholly unable to produce.

In order to utilize the wave theory of mechanics to the fullest extent, we must resort, as we do in optics, to the differential equation of the state of undulation. Turning again to the example of the rigid body spinning about a fixed axis, the appropriate differential equation is

$$\frac{\partial^2\psi}{\partial q^2}=\frac{1}{u^2}\frac{\partial^2\psi}{\partial t^2}. \tag{53}$$

This is the type of equation which represents plane waves travelling in the direction q with the constant velocity u, or the type of equation which represents the vibrations of a cord. The appropriate solution, in the case of a cord fixed at both ends, for example, consists of a sum of particular solutions so chosen as to satisfy the given initial or boundary conditions. The solution represents the motion of the cord as a superposition of vibrations consisting of a fundamental one and harmonic overtones, the frequencies of which are integral multiples of the fundamental one. The difference between this old-fashioned problem and the one we have in hand lies, not in the differential equation or its solution, but in the character of the "boundary" conditions which have to be satisfied and which, in this case, lie in the requirement that #must be a one-valued function of q. Since $u=E/p$ and $p^2=2m(E-V)$, where V is the potential energy—the part of the energy not dependent on the velocity and which in this example is constant, we have

$$\frac{\partial^2\psi}{\partial q^2}=\frac{2m(E-V)}{E^2}\frac{\partial^2\psi}{\partial t^2}. \tag{54}$$

This is called the Schroedinger equation of the problem and the "boundary" conditions require that E–V in the particular solution shall have one of the values:

$$\frac{1^2h^2}{8\pi^2K},\ \frac{2^2h^2}{8\pi^2K},\ \frac{3^2h^2}{8\pi^2K},\text{ etc.}$$

It follows from $E=h/\tau=h\nu$, if we denote the constant $\frac{V}{h}$ by ν_0, that the state of undulation is a superposition of vibrations with the frequencies:

$$\nu_0,\ \nu_0+\frac{1^2h}{8\pi^2K},\ \nu_0+\frac{2^2h}{8\pi^2K},\text{ etc.}$$

Let us now examine the simple Bohr atom in the light of wave mechanics. It is convenient to start out by representing the position of the electron by rectangular coordinates for which we shall use the letters x, y and z instead of q_1, q_2 and q_3. For simplicity we shall ignore the motion of the nucleus, as we have done already, and suppose it to be situated at the origin. The wave equation is now

$$\frac{\partial^2\psi}{\partial x^2}+\frac{\partial^2\psi}{\partial y^2}+\frac{\partial^2\psi}{\partial z^2}=\frac{1}{u^2}\frac{\partial^2\psi}{\partial t^2} \tag{55}$$

The same process which led to equation (54) may be applied here, and so we get for the wave equation

$$\frac{\partial^2\psi}{\partial x^2}+\frac{\partial^2\psi}{\partial y^2}+\frac{\partial^2\psi}{\partial z^2}=\frac{2m\left(E+\frac{Ze^2}{r}\right)}{E^2}\frac{\partial^2\psi}{\partial t^2} \tag{55a}$$

where we have replaced V, the potential energy, by $\frac{-Ze^2}{r}$, r being the distance of the electron from the nucleus or origin. If E is negative, that is if the electron is travelling in an elliptic orbit, the requirements that ψ must be a one-valued function of position and finite restricts E to the values

$$E=-\frac{2\pi^2mZ^2e^4}{n^2h^2},$$

where n is an integer, and the state of undulation round about the nucleus consists of a superposition of vibrations the frequencies of which are expressed by

$$\nu_n=\frac{2\pi^2mZ^2e^4}{h^3}\cdot\frac{1}{n^2}.$$

We recognize here the spectroscopist's spectral terms. The function ψ is usually written in a form equivalent to

$$\psi=a_1\epsilon^{i(2\pi\nu_1t-\delta_1)}+a_2\epsilon^{i(2\pi\nu_2t-\delta_2)}+\text{etc.}, \tag{56}$$

where $i=\sqrt{-1}$ and all the other quantities are real. If we employ $\bar\psi$ to represent a corresponding expression in which $\sqrt{-1}$ is replaced by $-\sqrt{-1}$ it will be seen that the product $\psi\cdot\bar\psi$ may be expressed in the following form

$$\psi\cdot\bar\psi=A+A_{12}\cos\{2\pi(\nu_1-\nu_2)t-D_{12}\}+\text{etc.} \tag{57}$$

Therefore $\psi\cdot\bar\psi$ represents a state of undulation, in the region surrounding the atom, which is a superposition of vibrations the frequencies of which are *differences* of spectral terms. This state of undulation must be identified with light waves or vibrations, and Schroedinger has made the suggestion that the value of $\psi\cdot\bar\psi$ at any place is identical with the electric density at that place. This, of course, involves giving up the old picture of an electron revolving in an elliptic or other orbit about the nucleus in favour of one which depicts a complicated distribution of negative electricity, the density of which falls off asymptotically to zero at great distances from the nucleus. This new picture of an atom has the great advantage of close conformity to Clerk Maxwell's electromagnetic theory of light. It also provides us with a means of fixing what has hitherto been indeterminate about the function ψ. We must lay down that the quantity e which we have hitherto described as the charge on the electron, shall be identical with

$$\int\psi\bar\psi\,dv, \tag{58}$$

where dv is a small element of volume and the summation indicated by the symbol $\int$ is extended over all space. It must be pointed out, however, that there is another interpretation of ψ which has much to be said for it, and which does not require us to give up the picture of an electron in orbital motion, namely, one which regards the value of $\psi\cdot\bar\psi dv$ at any given time as a measure of the probability that the electron is within the volume dv at that time.

We cannot, in this article, deal with the manner in which problems connected with polarization, intensity, etc., are dealt with by the wave mechanics. It will suffice to say that the new theory accomplishes all that the older quantum theory does, and in a manner which is much more coherent and complete, and that it goes far beyond it. In quite recent times it has received remarkable confirmation from observations of Davison and Germer, G. P. Thomson and others, on the scattering and diffraction of electrons. These observations are, in the main, just what the theory predicts. A stream of electrons, each having a definite momentum p, constitutes, according to the theory, a beam of waves with the wave length $\lambda = h/p$, and the investigations mentioned entirely bear out this prediction.

Matrix Mechanics.—This originated independently of wave mechanics, but its character can be described most conveniently with the help of the relationships between the two. We shall confine our attention to systems with one degree of freedom for which the classical equations of motion are:

$$\frac{dp}{dt} = -\frac{\partial H}{\partial q}, \qquad \frac{dq}{dt} = \frac{\partial H}{\partial p}, \tag{59}$$

provided the energy H is expressed as a function of p, q and t. We are concerned with the case where the system is conservative, so that H is a function of p and q only. For example, in the case of a particle in simple harmonic motion

$$H = \frac{p^2}{2m} + \frac{\mu}{2}q^2,$$

where m is the mass of the particle and μ is the restoring force per unit displacement. These equations of Hamilton (59) are retained in matrix mechanics; but the quantities involved in them, q, p, H are replaced by matrices. A matrix is a set of numbers arranged like the constituents of a determinant (*q.v.*). The product of two matrices is the matrix in which the constituent in the mth row and nth column is obtained by multiplying each constituent of the mth row of the first matrix by the corresponding constituent in the nth column of the second matrix, and adding the resulting products. This rule gives two products which are not, in general, identical, *i.e.*, the constituent in the mth row and nth column of one product is not generally the same as that in the corresponding place in the other product. The very essence of matrix mechanics is bound up with this ambiguity. (See DYNAMICS.)

We have next to explain what sense is to be attached to the operations $\frac{\partial}{\partial q}, \frac{\partial}{\partial p}, \frac{d}{dt}$ as applied to matrices. The mn constituent of a typical matrix in the new mechanics is represented:

$$x_{mn} = a_{mn}\epsilon^{2\pi i\nu_{mn}t}, \tag{60}$$

where $i = \sqrt{-1}$ and ν_{mn} is that frequency which, in the language of the older theory, is associated with a transition from the state m to the state n. The operation $\frac{d}{dt}$ is carried out on a constituent in the ordinary way; therefore

$$\frac{dx_{mn}}{dt} = 2\pi i\nu_{mn}x_{mn}. \tag{61}$$

Turning to wave mechanics, we find Schroedinger's function ψ in the particular solutions of the wave equation has the property

$$\frac{\partial\psi}{\partial q} = \pm\frac{2\pi ip}{h}\times\psi \tag{62}$$

If we adopt the + sign this equation means that the operation $\frac{\partial}{\partial q}$ when *performed* on ψ, is equivalent to multiplying it by $\frac{2\pi ip}{h}$, *i.e.*,

$$\frac{\partial}{\partial q} \equiv \frac{2\pi ip}{h}, \tag{63}$$

where $\equiv$ expresses equivalence. We shall not discuss the significance of the ambiguity of sign beyond saying that it cancels out in virtue of the corresponding ambiguity in the product of two matrices. We have further

$$\frac{\partial}{\partial q}x\psi = \frac{\partial x}{\partial q}\times\psi + x\frac{\partial\psi}{\partial q},$$

or

$$\frac{\partial}{\partial q}x\psi - x\frac{\partial}{\partial q}\psi = \frac{\partial x}{\partial q}\times\psi,$$

which means

$$\frac{\partial}{\partial q}x - x\frac{\partial}{\partial q} \equiv \frac{\partial x}{\partial q}; \tag{64}$$

or, remembering (63) we get

$$\frac{2\pi i}{h}(px - xp) \equiv \frac{\partial x}{\partial q}, \tag{65}$$

which is an expression of the equivalence of two operations when carried out on the function ψ. This last equation, or equivalence, is used to define the "differential quotient" of a matrix x with respect to the matrix q, the expressions px and xp being identified in an appropriate way with the two products of the matrices p and x. With the help of the Hamiltonian equations (59) we easily find that

$$\frac{2\pi i}{h}(Hx - xH) \equiv \frac{dx}{dt} \tag{66}$$

and

$$\frac{2\pi i}{h}(xq - qx) \equiv \frac{\partial x}{\partial p}. \tag{67}$$

Briefly, we may say that matrix mechanics simulates Hamiltonian dynamics, but instead of numbers we have matrices or "q" numbers, as they are sometimes called, and instead of ordinary differentiation we have the processes defined by (65) (66) and (67).

If a matrix y in the new mechanics is "constant," *i.e.*, if $\frac{dy}{dt} = 0$, it can be shown that it is a diagonal matrix. The constituents y_{mn} for which m is different from n are all zero. The matrix H itself must therefore be such a diagonal matrix. Now the rule for multiplying matrices (or determinants) makes the mn constituent of the product AB of two matrices A and B equal to the sum

$$\sum_k A_{mk}B_{kn}$$

therefore the mn constituent of the product Hx is equal to

$$H_{mm}x_{mn}$$

on account of the property of H, which has just been explained. Similarly the mn constituent of the other product xH is equal to

$$x_{mn}H_{nn},$$

therefore equation (66) is equivalent to

$$\frac{2\pi i}{h}(H_{mm} - H_{nn})x_{mn} = \frac{dx_{mn}}{dt}$$

or since $\frac{dx_{mn}}{dt} = 2\pi i\nu_{mn}x_{mn}$, (see equation 61) we have

$$\frac{H_{mm} - H_{nn}}{h} = \nu_{mn}. \tag{68}$$

This is, of course, Bohr's postulate, and we learn that the constituents of the diagonal matrix H are identical with the energy levels of the older theory.

It will be observed that if we replace x in equation (65) by q we have

$$\frac{2\pi i}{h}(pq - qp) \equiv 1 \tag{69}$$

where the right hand side means a matrix (the unit matrix) the diagonal constituents of which are all equal to unity and the others zero. Equation (69) occupies a position in matrix mechanics corresponding to that occupied in the older theory by the Wilson-Sommerfeld conditions (41).

Much has been written in recent times about the irrational character of the quantum theory. This irrationality is simply an expression of the difficulty—perhaps of the impossibility—of a coordination of quantum phenomena in the old-fashioned causal space-time manner. It seems possible to retain the notion of elementary particles, electrons, photons, etc., located in space and time—or more probably in a 5-dimensional continuum. If we do this it would appear that the de Broglie-Schroedinger undulations become merely a mathematical implement for computing probabilities, and cannot be regarded as physical entities in the ordinary sense of that term. There appears to be no determination in small scale events, except such of a statistical kind, and the very sharply-defined extrinsic causality of the macroscopic world has its being in the fact that probabilities may be so great as to be practical certainties.

QUARANTINE, a term originally applied to the old sanitary preventive system of detention of ships and men, unlading of cargo in lazarets, fumigation of susceptible articles, etc., which was practised at seaports on account of the plague, in connection with the Levantine trade. It is now a thing of the past in Great Britain and in the majority of other states. But, in common usage, the same word is applied to the sanitary regulations which are the modern substitutes for quarantine. *See* PLAGUE.

QUARE IMPEDIT, in English law, a form of action by which the right of presentation to a benefice is tried. It is so called from the words of the writ formerly in use, which directed the sheriff to command the person disturbing the possession to permit the plaintiff to present a fit person, or to show cause "why he hinders" the plaintiff in his right. The action was one of the few real actions preserved by the Real Property Limitation Act, 1833, and survived up to 1860. The effect of the Common Law Procedure Act, 1860, s. 26, was to assimilate proceedings in *quare impedit* as far as possible to those in an ordinary action. It is now brought against a bishop to try the legality of his refusal to institute a particular clerk. Except when a person presented is refused on the ground of doctrine or ritual, *quare impedit* became obsolete on the passage of the Benefices Act, 1898. (*See* BENEFICES.) In the United States, owing to the difference of ecclesiastical organization, the action is unknown.

QUARITCH, BERNARD (1819–1899), English bookseller and collector, was born at Worbis, Germany, on April 23, 1819. He went to London in 1842, and was employed by Bohn the publisher. In 1847 he started a bookseller's business off Leicester square, becoming naturalized as a British subject. In 1848 he started to issue a monthly *Catalogue of Foreign and English Books.* About 1858 he began to purchase rare books, one of the earliest of such purchases being a copy of the Mazarin Bible, and within a period of forty years he possessed six separate copies of this rare and valuable edition. In 1860 he removed to Piccadilly. In 1873 he published the *Bibliotheca Xylographica, Typographica et Palaeographica,* a remarkable catalogue of early productions of the printing press of all countries. He became a regular buyer at all the principal book-sales of Europe and America, and from time to time published a variety of other catalogues of old books. Amongst these may be mentioned the *Supplemental Catalogue* (1877), and *General Catalogue* of *Old Books and Manuscripts* (12 vols., with supplements, 1887–8). By this time Quaritch had developed the largest trade in old books in the world. He died at Hampstead on Dec. 17, 1899, leaving his business to his son.

QUARLES, FRANCIS (1592–1644), English poet, was born at Romford, Essex, and baptized there on May 8, 1592. He was entered at Christ's college, Cambridge, in 1608, and subsequently at Lincoln's Inn. He was made cupbearer to the Princess Elizabeth, Electress Palatine, in 1613, remaining abroad for some years; and before 1629 he was appointed secretary to Ussher, the primate of Ireland. About 1633 he returned to England, and spent the next two years in the preparation of his *Emblems.* In 1639 he was made city chronologer, a post in which Ben Jonson and Thomas Middleton had preceded him. At the outbreak of the Civil War he took the Royalist side, drawing up three pamphlets in 1644 in support of the king's cause. He died on Sept. 8, in that year. Quarles married in 1618 Ursula Woodgate, by whom he had eighteen children.

Of the numerous works of Quarles the only one which has importance is the *Emblems,* originally published in 1635, with grotesque illustrations engraved by William Marshall and others. The forty-five prints in the last three books are borrowed from the *Pia Desideria* (Antwerp, 1624) of Herman Hugo. Each "emblem" consists of a paraphrase from a passage of Scripture, expressed in ornate and metaphorical language, followed by passages from the Christian Fathers, and concluding with an epigram of four lines. The *Emblems* was immensely popular but little esteemed by critics.

An edition of the *Emblems* (Edinburgh, 1857) was embellished with new illustrations by C. H. Bennett and W. A. Rogers. These are reproduced in the complete edition (1874) of Quarles included in the "Chertsey Worthies Library" by Dr. A. B. Grosart.

QUARRYING, the art of winning or obtaining from the earth's crust the various kinds of stone used in construction, road building and the various manufacturing processes for which rock minerals are employed, the operation being, in most cases, conducted in open workings. There are two distinct types of quarrying, one being that employed in the quarrying of what is constantly referred to as "building stone," for which purpose the stone must be obtained in large unshattered blocks or masses, and the other, the quarrying of stone in rough irregular shapes for road building, concrete aggregate, fluxing and various manufacturing processes, for which purposes it must be broken up, crushed or pulverized in preparing it for utilization. The quarrying of stone in blocks for use in construction may be further divided, as will be described later, into the several types of quarrying processes that are employed by reason of the character and physical properties of the different types of rock used for "building stone."

Building Stone.—According to their general character and composition, building stones are broadly classed as granites, sandstones, limestones, marbles and slates. Under the first of these heads is included a number of crystalline rock species, of igneous origin such as granite, syenite, gneiss, schist, etc., which to the geologist are quite distinct, but which in commerce are all spoken of as granite. They are chiefly composed of one or more minerals of the felspar group mingled with one or more of the micas or with hornblende and usually contain quartz. Sandstones are sedimentary rocks chiefly composed of fragments of quartz consolidated by pressure or cemented into solid rock by silica and oxide of iron. Of these there are many varieties, including bluestone and flagstone used for foot-pavements. Thoroughly cemented sandstones are termed quartzites. Limestones are rocks also of sedimentary origin and consist principally of carbonate of lime or of a combination of the carbonates of lime and magnesia. Their chief variations are the crystalline form known as marble and the deposit from mineral springs known as Mexican onyx.

The type of limestone used principally for building stone is the oolitic variety, a calcareous-sand rock made up of shells and shell fragments on the sea floor consolidated into a solid mass or in layers and later uplifted to become a part of the land. Slates are mudstones or shales hardened by heat and pressure and rendered fissile by the latter agent. Chemically they consist chiefly of hydrous silicate of alumina. Theoretically, the sedimentary rock, sandstone, limestone and slate are of a layered formation, although certain limestones and sandstones are massive in character, while all granites are massive, and have no bedding or stratification like sandstones and limestones; but all rock masses are usually found to be more or less affected by movements of the earth's crust which occur as a result of its constant readjustment to the cooling and shrinking interior, so that the rocks are divided by cracks or fissures, which are commonly known as joints. In the massive granites these joints, which usually occur in two or more planes at right angles to one another, are of the greatest importance to the quarryman, as they enable him to separate masses of stone with approximately parallel faces In gneisses the parallel arrangement of the minerals usually coincides with a direction of easy cleavage known to quarrymen as the "rift"; at right angles to this direction is usually one less easy parting, known as the "grain." Sandstones and limestones being stratified rocks which have been formed as sediments in bodies of water, whether their beds are found in the normal position of horizontality, or whether they have been tilted and folded by earth movements, the direction of easiest separation is coincident with the original planes of sedimentation and parallel to them. Strictly speaking, the term rift applies only to massive crystalline rocks, the term bedding-plane being a better one to apply to sedimentary rocks.

In gneisses, sandstones and limestones, joints also occur; and while frequently convenient for the division of the beds into masses of useful size, they may be a detriment, as when they occur so close together as to fall within the limits of a block suitable or economically usable for commercial purposes. In commerce the various kinds of building stone are usually designated by the name of the locality or region in which the quarry is situated. In the case of the more important varieties this geographic name usually conveys to the architect or builder sufficient information concerning colour, texture and other properties of the material.

Methods of Quarrying. — The methods of quarrying vary with the composition and hardness of the rocks, their structure, cleavage and other physical properties; also with the position and character of the deposits or rock-masses. In the quarrying of building stone, the general purpose of the work is to separate the material from its bed in masses of form and the size best adapted to the intended use. Cutting the stone to accurate dimensions, dressing, moulding and finishing by tooling, rubbing or polishing are subsequent operations not involved in quarrying. Crushing all kinds of hard, durable stone to angular fragments for macadam type roads and for concrete aggregate is also an operation subsequent to quarrying.

The practice of quarrying consists in uncovering a sufficient surface of the rock by removing superficial soil, sand, clay, or overborder of overlaying waste rock by some suitable process or by sinking a shaft or slope, and then with proper tools or explosive, detaching blocks of form and size adapted to the purpose in view. Frequently the exposed outer portion of the rock has been either cut up and eroded away in fissures or has been affected by the action of various atmospheric agencies, until it has become discoloured or softened by decay. This weathered material must be removed before stone can be obtained for economic use in the production of dimension stone. .

The separation of blocks of building or dimension stone is ordinarily carried on by some specific variation of one of the two general present-day methods of quarrying known respectively as the "blasting" and "channeling" process. Blasting is used for the harder rocks that do not tend to shatter and channeling for most other kinds of rock. The blasting process consists of drilling holes along the outlines of the block to be removed, and then, by exploding blasting-powder in the holes, exerting sufficient force to overcome the cohesion of the rock and rend it asunder. In many quarries it is found most convenient to separate a large mass and afterwards divide it into blocks of the required size, by drilling holes for further charges of blasting powder, or by driving wedges into these to split the rock. When the rock is stratified, or has an easily determined rift, the holes are drilled at right angles to the plane of separation.

When there is no stratification or rift, or these natural planes of separation are too far apart, or when the position of the joints is not advantageous, a row of horizontal holes must be drilled into the face or breast of the quarry, along which separation is effected either by blasting or the use of wedges. At certain American quarries, in a granite which has no rift or direction of ready cleavage, compressed air has been brought into service to effect the separation of extensive layers. A hole is drilled as deep as the desired thickness of the layer to be separated, and a small charge of dynamite is exploded at the bottom of it. This develops a cavity in which a small charge of powder is next exploded, producing a crack or crevice parallel to the surface of the rock, A pipe for conveying compressed air is now sealed into the opening, and gradually increasing pressure is introduced. This results in the gradual extension of the crevice developed by the explosion of the powder. In the absence of compressed air, water under pressure may be used and also small powder charges exploded at intervals of a few days.

Crushed-stone Quarrying. — A very large and important branch of the quarry industry has recently come into existence, since the era of improved highways and the extensive use of Portland and other hydraulic cements; this is distinguished from "building or dimension stone" quarrying and is generally referred to as crushed-stone quarrying. The object of crushed-stone quarrying is to drill, blast with high explosives and remove or excavate the stone in the cheapest possible manner from either hillside or pit quarries, so that it may be loaded with power shovels and then be fragmented by crushing and grinding machinery of various types to commercial sizes for aggregate, or pulverized to be manufactured into cements. The quarrying of stone for flux in manufacture of steel and glass, for burning into lime and for various other mineral industries also falls in this category. Commercial sizes for crushed stone will vary from 5 to 6 in. in greatest dimension (limestone fragments for lime kilns or blast furnaces) to dust, which has many commercial uses. The commonest and largest uses of crushed stone are for surfacing highways and for use as aggregate with bituminous binders or Portland cement to make concrete. Most commercial crushed-stone quarry operations differ in no essentials from open-pit mining. There are also numerous underground quarry-mining operations for the purpose of winning crushed stone for similar purposes.

In thinly bedded sandstone, where vertical joints are frequent, it is often possible to separate the desired slabs and flagstones with crowbars and wedges, without drilling or the use of explosives. When blasting is necessary, some form of gunpowder is generally used, rather than a violent explosive like dynamite, in order to avoid shattering the rock. This, however, applies only to dimension stone. When the production of broken stone for road-making, concrete or similar purposes is the sole end in view, violent explosives are preferred.

Channeling Machines. — In limestones and marbles and in the softer sandstones, the channeling process is almost invariably employed. Channeling machines, driven by steam, compressed air, electricity, or a combination of these are used, by which vertical or oblique grooves or channels can be cut with great rapidity to a depth of from 8 to 12 feet. A level bed of rock is cleared, and on this are laid rails, along which the machine moves opposite to the bottom of the channel cut. After the channels are cut and a row of holes drilled perpendicular to the channel — opposite the bottom of the channel cut — wedges are driven and the required blocks or cuts of stone are separated from the ledge. These cuts, frequently of great size, running 60 to 80 ft. in length, by 10 to 12 ft. in depth and 4 to 5 ft. in width in some limestone quarries, are then with the aid of the derrick power turned over on the side, after which they are drilled and split up into blocks of convenient sizes for transportation and handling. These are called mill blocks, and are usually from 3 to 4 ft. by 3 to 5 ft. in cross-section and 6 to 12 ft. in length.

When the beds of stone to be quarried are comparatively thin, with heavy overburden, or when to remove the whole of the overlying mass of earth or rock would be too expensive, it has been found convenient to treat the quarry as if it were a mine, and to rely upon methods similar to those practised in mining,

OPEN–CUT QUARRYING

1. **Open-cut** method of excavating Vermont granite by hand. 2. Turning over a large cut of limestone in an Indiana quarry. 3. Georgia marble quarry. Depth at time photograph was made, 80 feet. Weight of block being hoisted, 14 tons. 4. **Hoisting** blocks of granite from a Vermont **quarry.** 5. Gang-saw used for sawing marble. The cutting tool, a steel saw-blade aided by the abrasive action of a mixture of sand and water, cuts the blocks into the required thickness. 6. Marble quarry in Alabama, showing large cranes used for hoisting. 7. General scene at a **Bedford,** Ind., quarry. The large cut is shown "turned over" at the left, and being split up into smaller blocks before hoisting to railroad cars

Since great advances have been made in both the quarrying and working of building stone during recent years, few articles will be found that are really up to date. As a supplement to the following references the reader is referred to the more recent articles on the subject of quarrying that have appeared in trade press and technical publications of this industry as the most reliable source of additional information.

See Institution of Quarry Managers, *Quarrying* (Conway, 1924); G. C. Mance, *Power Economy and the Utilization of Waste in the Quarry Industry of Southern Indiana* (Indiana Univ. Studies, 1917), also the *Quarry Managers' Journal* (Conway). (F. J. H. M.)

QUARTER DAYS, the days that begin each quarter of the year; in England, March 25 (Lady day), June 24 (Midsummer day), Sept. 29 (Michaelmas day) and Dec. 25 (Christmas day). They are the days on which it is usually contracted that rents should be paid and houses or lands entered upon or quitted. In Scotland there are two legal terms, May 15 (Whitsunday) and Nov. 11 (Martinmas); these, together with the two conventional terms, Feb. 2 (Candlemas) and Aug. 1 (Lammas), make up the Scottish quarter days. In the Scottish burghs, however, the removal terms are May 28 and Ncv. 28. In the United States the quarter days are, in law, the 1st of January, April, July and October.

QUARTERMASTER, a commissioned officer of a unit whose chief duty is the care of the stores, rations, equipment, etc. Quartermasters were mentioned as early as 1447, and were found on the regimental lists of the Army in Ireland in 1660. The former title was "harbinger's clerk," the quartermaster-general being styled the Harbinger. Early quartermasters were usually warrant officers (unless holding a separate combatant commission), except in the Household Cavalry, where they were always commissioned officers. Cavalry regiments usually had a quartermaster to each troop but infantry never had more than one to a battalion. In the British service the rank is reserved for warrant officers and N.C.O.'s of exceptional ability and continuous exemplary conduct. *(See* OFFICERS.) In the U.S.A. there is a Quartermaster Corps which performs the duties comparable to the quartermaster-general's branch of the British service. In the French service similar duties are carried out by the *intendance,* the executive branch of which is officered by *officiers d'administration* recruited from *sous-officiers* (warrant officers and sergeants). (T. J. E.)

Naval quartermasters are petty officers in rank or, in smaller vessels, are selected leading seamen or able seamen, who in harbour perform, under the officer of the watch or officer of the day, duties comparable to those of a night-watchman during the dark hours, while during working hours they assist the duty officers by attending to the details of the routine, the good order of the quarter deck, the employment of the duty boats and the general curriculum of the ship's company. At sea the quartermaster is stationed at the wheel and either steers himself, under the orders of the officer of the watch or navigating officer, or closely supervises the seaman who is steering, to ensure that he keeps a good course and promptly and quickly obeys any orders given for the movements of the helm.

In a big ship the quartermasters are usually assigned for service in four watches. In smaller ships they may also combine the duties of boatswain's mate. The term is also used in the mercantile marine, where a quartermaster's duties are similar to those on a man of war. In old navy days the quartermaster's duties are described as being to supervise "stowing the ballast and provisions in the hold, coiling the cables in the platforms, overlooking the steerage of the ship, keeping the time by the watch glasses, and in turn overlooking the purser's steward in his delivery of provisions, etc." (E. A.)

QUARTER SESSIONS, COURT OF, in English law, the name for the justices of the peace of any county, riding, parts, division or liberty of a county, or of any county of a city or county of a town, in general or quarter sessions assembled; it includes the court of the recorder of a municipal borough having a separate court of quarter sessions. The word "general" in this context is contrasted with "special" or "petty." The court is a local court of record having a limited criminal jurisdiction, and also to some extent civil jurisdiction. As a court of record it has, in addition to its other jurisdiction, power to punish summarily without the assistance of a jury contempts committed in its presence, such as insults to the justices or disturbance of its proceedings. At the present time the whole of England and Wales is within the local jurisdiction of some court of quarter sessions.

The court derived its name from the direction in a statute of 1388 that the "justices shall keep their sessions in every quarter of the year at the least." By s. 22 of the Criminal Justice Act 1925, general quarter sessions for any county must be held at such times within the period of 21 days immediately preceding or immediately following March 25, June 24, Sept, 29 and Dec. 25 in every year as may be fixed. The justices are free to sit oftener by adjournment of the quarterly sessions to another time, and even to another place, in their county, or to hold additional sessions. All the sessions thus held are "general," though not all may be "quarter" sessions. The Assizes and Quarter Sessions Act 1908 gave the useful power of dispensing with the holding of quarter sessions if there is no business to transact, and under the Criminal Justice Act 1925 there is power to dispense with the grand jury where all persons committed have pleaded guilty.

In all the counties, except that of London, the justices in the commission elect a chairman and vice-chairman, neither of them necessarily a lawyer, to preside at the sittings of the court, In the county of London there are a paid chairman and deputy chairman, who must be barristers of at least ten years' standing, and are appointed by the Crown. Under the Quarter Sessions Act 1858 the court may sit in two divisions of at least two justices at the same time and place, but not simultaneously in separate parts of the same county.

The jurisdiction of the court of quarter sessions of a borough does not depend upon the commission of the peace, but upon the Municipal Corporations Act 1882. Before the Municipal Corporations Act 1835, many boroughs had criminal jurisdiction under their charters. Under that Act and the Act of 1882 a grant of quarter sessions to a city or borough is made by the Crown in council on petition of the town council. The recorder (*q.v.*), a barrister of not less than five years' standing appointed by the Crown, is sole judge of the court.

The city of London is not subject to the Municipal Corporations Act 1882, and its court of quarter sessions is created by the city charters, and is held before the mayor and aldermen with the recorder. It does not now sit to try indictments, which all go to the Central Criminal Court.

Criminal Jurisdiction.—Courts of quarter sessions in counties and boroughs have both original and appellate jurisdiction depending on the commission of the peace and on legislation beginning in 1344. This jurisdiction is derived in counties from the commission of the peace. The jurisdiction of quarter sessions is governed chiefly by the Quarter Sessions Act 1842, and they are forbidden to try the following offences: treason or misprision of treason; murder, capital felony or any felony (except burglary) which is punishable on a first conviction by penal servitude for life; offences against the king's title, prerogative, person or government, or against either House of parliament; offences against the Official Secrets Acts 1911 and 1920; offences subject to the penalties of praemunire; blasphemy and offences against religion, and composing or publishing blasphemous, seditious or defamatory libels; and various other offences prohibited by statutes. But their jurisdiction has been extended by the Criminal Justice Act 1925 and certain offences under the Perjury and Forgery Acts and other statutes and the so-called "long firm" frauds are cognisable by quarter sessions. Trials before the court with a jury are governed by the same procedure as trials on indictment in a court of assize. Under the Vagrancy Act 1823 and amending Acts, they have special powers of sentencing incorrigible rogues sent to them by courts of summary jurisdiction.

An appeal lies to quarter sessions from convictions by a court of summary jurisdiction only where such an appeal is expressly given by statute. *(See* SUMMARY JURISDICTION)

Civil Jurisdiction.—By legislation in and since 1888 most of the administrative powers and duties of justices in general and quarter sessions have been transferred to the incorporated and elective councils of counties, boroughs and urban and rural districts. But the justices still possess certain original, civil or quasi-civil jurisdiction with respect to licensing and as to closing highways. Most of the civil jurisdiction of quarter sessions is now appellate, *i.e.,* with reference to orders made by justices.

Rating appeals, although they are still made to quarter sessions, are heard by a committee of the justices of the county appointed by such sessions (Rating and Valuation Act 1925). The procedure as to each form of appeal depends partly on the statute by which it is given and partly on the general provisions of the Summary Jurisdiction Acts. Decisions on law may be reviewed by the High Court (king's bench division) by means of certiorari, mandamus or prohibition. Convictions on indictment before courts of quarter sessions are within the provisions of the Criminal Appeal Act of 1907, except convictions on indictments for obstruction or non-repair of a public bridge, highway or river, from which an appeal lies to the court of appeal in the same way as in the case of civil actions tried at assizes. Persons dealt with as incorrigible rogues are also within the Act of 1907. Quarter sessions can state a case on a point of law on an appeal to them against a conviction by a court of summary jurisdiction, and if they decline to do so may be ordered to state a case by the High Court (Criminal Justice Act 1925). (W. F. C.; W. DE B. H.)

United States.—There is no court of quarter sessions in the United States. Courts of other names, differing in the various jurisdictions, perform its functions.

QUARTER SQUARES. Among the labour-saving devices for multiplying is one which seems to be of Hindu origin and which may be stated as follows: to find the product of two numbers, take the difference between a quarter of the square of their sum and a quarter of the square of their difference. For example, $9\times8=\frac{1}{4}(9+8)^2-\frac{1}{4}(9-8)^2=\frac{1}{4}(289-1)=72$. It depends upon the algebraic identity, $ab=\frac{1}{4}(a+b)^2-\frac{1}{4}(a-b)^2$. If the computer has a table of squares sufficiently large, the method has considerable value, and this is more evident if he has a table of quarter squares. The plan is given in various Arabic works, as in al-Karkhî's *al-Kâfî fî'l-Hisâb* (c. 1020).

See J. Blater, Table des Quarts de *carrés* de *tous les* nombres *entiers* de 1 *à* 200000 (1888). For a discussion of the subject, with a bibliography and a description of related methods see H. Mehmke, *Numerisches Rechnen*, in W. F. Meyer, *Encyklopädie* der mathematischen Wissenschaften, Band I., pp. 944–952.

QUARTER-STAFF. A staff of wood from six to nine feet in length, used as a means of attack and defence; originally no doubt it was the cudgel or sapling with which many heroes are described by early writers as being armed. The quarter-staff attained great popularity in England in the middle ages. It was usually made of oak, the ends often shod with iron, and it was held with both hands, the right hand grasping it one quarter of the distance from the lower end (whence the name) and the left at about the middle.

Egerton Castle (Schools and Masters of Fence) says that the staff was the "foil," or practice-substitute for the long sword or two-hander. In earlier times it may also have been used as a practice weapon for the spear and bill. In the prints illustrative of the life of Richard Beauchamp, earl of Warwick (1382–1439), reproduced in Joseph Strutt's Manners, Customs, Arms, Habits, etc. of *the Inhabitants* of England, may be seen a combat between two knights after they have splintered their lances and dismounted, in which both are fighting with pointed staves about as long as a quarter-staff and held in the same manner. In the 17th century the staff was still popular in England.

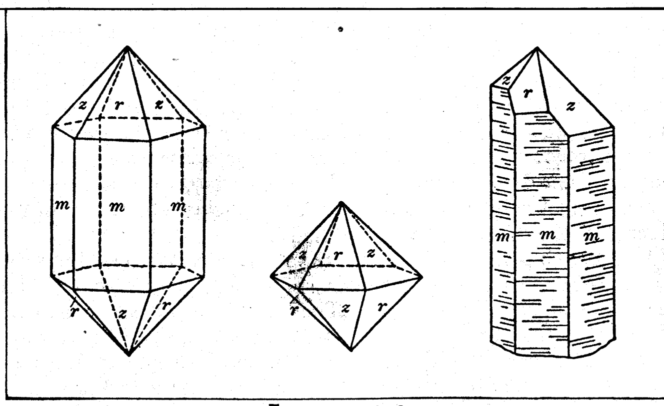
At the present time the quarter-staff is used to a limited extent in military circles as a school for bayonet play. (See FENCING.) (A. R. H.)

QUARTER TONES, in music. Although the semitone, or half tone, was formerly defined as "the smallest interval recognized in music" much smaller intervals have always been employed in oriental music (see INDIA), and in recent years attempts have been made by various musicians to introduce similar intervals, such as quarter tones, in Western music. Foremost among these has been the Czech composer and theorist, Alois Haba, who has written a number of works based on the quarter-tone system, though so far, it must be said, without securing for them much appreciation even at the hands of the best disposed listeners. To the contrary, the opinion expressed has usually been that the effect was too closely akin to that of instruments playing out of tune to be agreeable, although it may be that with further experience of the music it might produce a more favourable impression. Another who theorized on the subject, and considered incidentally the possibility of employing even smaller intervals than quarter tones, was the eminent pianist and composer Busoni, while John Herbert Foulds, an English composer, has done the like. (See HARMONY.)

QUARTZ, a widely distributed mineral species, consisting of silicon dioxide, or silica, SiO_2. It is the commonest of minerals, and is met with in a great variety of forms and with very diverse modes of occurrence. The various forms of silica have attracted attention from the earliest times, and the water-clear crystallized variety was known to the Greeks as *κρύσταλλος* (clear ice), being supposed by them to have been formed from water by the intense cold of the Alps; hence the name "crystal," or more commonly rock-crystal, applied to this variety. The name quartz is an old German word of uncertain origin used by G. Agricola in 1529.

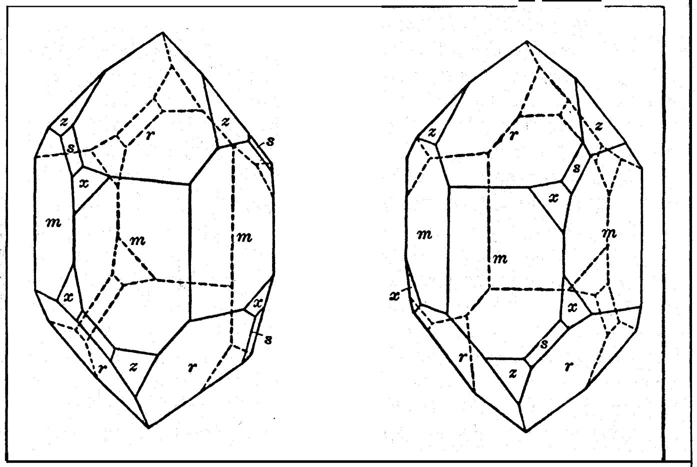
Quartz is a mineral which is put to many uses. Several of the varieties are cut into gems and ornaments, balance weights, pivot supports for delicate instruments, agate mortars, etc.; or used for engraving, for instance, cameos and the elaborately carved crystal vases of ancient and mediaeval times. Clear transparent rock-crystal is used for optical purposes; fused quartz is also used for the construction of lenses and laboratory vessels, and is drawn out into the finest elastic fibres and used for suspending mirrors, etc., in physical apparatus; for striking fire, flint is used even to the present day; and buhrstone, a cellular variety of chalcedonic quartz from the Tertiary strata of the Paris basin, is largely used for millstones. Quartz is a valuable grinding and polishing material, and is used for making sandpaper and scouring-soap, also in the manufacture of glass and porcelain, "silver sand" being a pure quartz sand.

Crystallography.—Quartz crystallizes in the trapezohedral class of the rhombohedral division of the hexagonal system. Crystals of this class possess neither planes nor centre of symmetry, but only axes of symmetry; perpendicular to the principal triad axis there are three uniterminal dyad axes of symmetry. Usually, however, this lower degree of symmetry is not indicated by the faces developed on the crystals. The majority of crystals of



FIGS. 1, 2 & 3

quartz are bounded only by the faces of a hexagonal prism $m\{2\bar{1}\bar{1}\}$ and a hexagonal bipyramid (fig. 1), though sometimes the prism is absent (fig. 2). Frequently the faces are of different sizes (fig. 3): mis-shapen crystals are common and sometimes very puzzling, but they can always be orientated by the aid of the very characteristic striations on the prism faces, which serve also to distinguish quartz from other minerals of similar appearance. These striations (fig. 3) are horizontal in direction, being parallel to the edges of intersection between the prism and pyramid faces, and are due to the frequent oscillatory combination of these faces. The apparent hexagonal bipyramid is really a combination of two rhombohedra, the direct rhombohedron *r*{100} and the inverse rhombohedron *z*{$22\bar{1}$}. The faces of these two rhombohedra exhibit differences in surface characters, those of *r* being usually brighter in lustre than those of *z;* further, the former often predominate in size (figs. 4 and 5), and the latter may sometimes be completely absent. When both the prism and the rhombohedron *z* are absent, the crystals



FIGS. 4 AND 5

resemble cubes in appearance, since the angles between the faces of the rhombohedron are 85° 46'. The additional faces *s* and *x* (figs. 4 and 5), which indicate the true degree of symmetry of quartz, are of comparatively rare occurrence except on crystals from certain localities. The six small faces *s*{$41\bar{2}$} situated on alternate corners at each end of the crystal, are called the "rhomb" faces, because of their shape; if extended they would give a trigonal bipyramid. The "trapezohedral," or "plagihedral," faces *x*{$4\bar{1}\bar{2}$} belong to a trigonal trapezohedron. The two crystals shown in figs. 4 and 5 are enantiomorphous, *i.e.,* they are non-superposable, one being the mirror reflection of the other: they are left-handed and right-handed crystals respectively. The faces *s* are striated parallel to their edge of intersection with r; this serves to distinguish *r* and *z,* and thus, in the absence of *x* faces, to distinguish left- or right-handed crystals. Numerous other faces have been observed on crystals of quartz, but they are of rare occurrence. The basal plane, so common on calcite and many other rhombohedra1 minerals, is of the greatest rarity in quartz, and when present only appears as a small rough face formed by the corrosion of the crystal. Faces of prisms other than *m* are also small and of exceptional occurrence. Etched figures, both natural and artificial (in the latter case produced by the action of hydrofluoric acid), on the faces of the crystals are in accordance with the symmetry, and may serve to distinguish left- and right-handed crystals.

Twinned crystals of quartz are extremely common, but are complex in character and can only be deciphered when the faces *s* and *x* are present which is not often the case. Usually they are interpenetration twins with the principal axis as twin-axis; the prism planes of the two individuals coincide, and the faces r and *z* also fall into the same plane. Such twins may therefore be mistaken for simple crystals unless they are attentively studied; but the twinning is often made evident by the presence of irregularly bounded areas of the duller *z* faces coinciding with the brighter *r* faces. In a rarer type of twinning, in which the twin-plane is {$52\bar{1}$} (a plane truncating the edge between *r* and z), the two individuals are united in juxtaposition with their principal axis nearly at right angles (84° 33'). A few magnificent specimens of rock-crystal twinned according to this law have been found at La Gardette in Isère, and in Japan they are somewhat abundant.

Electrical and Optical Characters.—The pyro-electric characters of quartz are closely connected with its peculiar type of symmetry and especially with the three uniterminal dyad axes. A crystal becomes positively and negatively electrified on alternate prism edges when its temperature changes. A similar distribution of electric charges is produced when a crystal is subjected to pressure; quartz being thus also piezo-electric. Use is made of this property in detecting extremely minute changes of pressure in the depth-sounding apparatus of submarines and in the resonators of radio-detectors.

In its optical characters, quartz is also of interest, since it is one of the two minerals (cinnabar being the other) which are circularly polarizing. This phenomenon is connected with the symmetry of the crystals, and is also shown by the crystals of certain other substances in which there are neither planes nor centre of symmetry. A ray of plane-polarized light traversing a right-handed crystal of quartz in the direction of the triad axis has its plane of polarization rotated to the right, while a left-handed crystal rotates it to the Ieft. A section 1 mm. thick, cut perpendicular to the principal axis of a quartz crystal, rotates the plane of yellow (D) light through 22°, and of blue (G) light through 43'. Such a section when examined in the polariscope shows an interference figure with a coloured centre, there being no black cross inside the innermost ring (this is not shown in very thin sections). Superimposed sections of right- and left-handed quartz, as may sometimes be present in sections of twinned crystals, exhibit Airy's spirals in the polariscope. The indices of refraction of quartz for yellow (D) light are $\omega=1{\cdot}5442$ and $\epsilon=1{\cdot}5533$; the optic sign is therefore positive.

Other Characters.—Quartz has a hardness of 7 (being chosen as No. 7 on Mohs' scale), and it cannot be scratched with a knife; its specific gravity is 2.65. There is no distinct cleavage; though an imperfect cleavage may sometime* be developed parallel to the faces of the rhombohedron *r* by plunging a heated crystal into cold water. The glassy conchoidal fracture is a characteristic feature of the crystallized mineral. A peculiar rippled or "thumb-marked" fracture is sometimes to be seen, especially in amethyst (*q.v.*), and is due to repeated intergrowths of right- and left-handed material. The mineral is a non-conductor of electricity; it is unattacked by acids with the exception of hydrofluoric acid, and is only slightly dissolved by solutions of caustic alkalis. It is infusible before the gas blowpipe, but in the oxyhydrogen flame fuses to a clear colourless glass, which has a hardness of 5 and specific gravity 2.2.

When heated, quartz undergoes a series of remarkable changes. At 575° C it passes over into β-quartz, with a change in the degree of crystal-symmetry from rhombohedral-trapezohedral to hexagonal-trapezohedral and an alteration of the various physical properties. At 870° this 8-quartz changes over into β-tridymite, and this again at 1,470° to β-cristobalite, the inaterial finally melting at about 1,710°.

Many peculiarities of the growth of crystals are well illustrated by the mineral quartz. Thus in "ghost quartz," in which one crystal is seen inside another, the stages of growth are marked out by thin layers of enclosed material. In "capped quartz" these layers are thicker, and the successive shells of the crystal may be easily separated. "Sceptre quartz," in which a short thick crystal is mounted on the end of a long slender prism, indicates a change in the conditions of growth. Crystals with a helical twist are not uncommon. Enclosures of other minerals (rutile, chlorite, haematite, goethite, actinolite, asbestos and many others) are extremely frequent in crystals of quartz. Cavities, either rounded or with the same shape ("negative crystals") as the surrounding crystal, are also common; they are often of minute size and present in vast numbers. Usually these cavities contain a liquid (water, a saline solution, carbon dioxide, or petroleum) and a movable bubble of gas. The presence of these enclosed impurities impairs the transparency of crystals. Crystals of quartz are usually attached at one end to their rocky matrix, but sometimes, especially when embedded in a soft matrix of clay, gypsum, or salt, they may be bounded on all sides by crystal faces (figs. 1 and 2). In size they vary between wide limits, from minute sparkling points encrusting rock surfaces and often so thickly clustered together as to produce a drusy effect, to large single crystals measuring a yard in length and diameter and weighing half a ton.

The characters as given above apply more particularly to crystals of quartz, but in the various massive and compact varieties the material may be quite different in general appearance. Thus in the microcrystalline chalcedony the lustre is waxy, the fracture fibrous to even, and the external form botrysidal or stalactitic: flint and chert are compact and have a splintery fracture: jasper is a compact variety intermixed with much iron oxide and clay and has a dull and even fracture. Further, these varieties may be of almost any colour, whereas transparent crystals have only a limited range of colour, being either colourless (rock-crystal), violet (amethyst), brown (smoky quartz) or yellow (citrine).

Occurrence.—Quartz occurs as a primary and essential constituent of igneous rocks of acidic composition such as granite, quartz-porphyry and rhyolite, being embedded in these either as irregularly shaped masses or as porphyritic crystals. In pegmatite (graphic granite) and granophyre it often forms a regular intergrowth with felspar. It is also a common constituent, as irregular grains, in many gneisses and crystalline schists, a quartz-schist being composed largely of quartz. By the weathering of silicates, silica passes into solution and quartz is deposited as a secondary product in the cavities of basic igneous rocks, and in fact in the crevices and along the joints of rocks of almost all kinds. Extensive veins of quartz are especially frequent in schistose rocks. Vein-quartz, often of economic importance as a matrix of gold, may, however, in some cases have been of igneous origin. In mineral veins and lodes crystallized quartz is usually the most abundant gangue mineral; the crystals are often arranged perpendicular to the walls of the lode, giving rise to a "comby" structure. In limestones of various kinds it occurs as nodules and bands of chert and flint, being in this case of organic origin. Quartz being a mineral very resistant to weathering agencies, it forms the bulk of sands and sandstones; and when the sand grains are cemented together by a later deposit of secondary quartz a rock known as quartzite results. Pseudomorphous quartz, *i.e.*, quartz replacing other minerals, is of frequent occurrence, and as a petrifying material replacing organic remains it is often met with. As a deposit from hot springs, quartz is much less common than opal. Crystals of quartz may be readily prepared artificially by a number of methods; for example, by heating glass or gelatinous silica with water under pressure.

For particulars respecting the special characters, modes of occurrence and localities of the more important varieties of quartz, reference may be made to the following articles: AGATE, AMETHYST, AVENTURINE, BLOODSTONE, CAIRNGORM, CARNELIAN, CAT'S-EYE, CHALCEDONY, CHRYSOPRASE, FLINT, JASPER, MOCHA-STONE, ONYX, SARD AND SARDONYX. For other forms of silica see OPAL and TRIDYMITE[1]. (L. J. S.)

Recent research on the physical chemistry of silica has shown that at 870° C under atmospheric pressure quartz inverts to tridymite, which again at 1,470° C changes to cristobalite. These changes are, however, exceedingly slow in coming about, and in actual practice, as in the manufacture of silica bricks for furnace linings, the temperature actually employed has to be considerably above 870° C if the change is to be reasonably complete, a point of much practical importance, owing to the large volume-change during the inversion (about 15%). Cristobalite, on the other hand, has nearly the same volume as tridymite, so that it does not matter much which is present in the finished brick.

For details see C. N. Fenner, *Amer. Journ. Sci.*, vol. xxvi., 1913, pp. 331–348, or for a short summary, R. H. Rastall, *Physico-Chemical Geology*, 1927, pp. 216–220. (R. H. RA.)

QUARTZITE, in petrology, a sandstone which by the deposit of crystalline quartz between its grains has been compacted into a solid quartz rock. As distinguished from sandstones, quartzites are free from pores and have a smooth fracture, since when struck with the hammer they break through the sand grains, while in sandstones the fracture passes through the cementing material and the rounded faces of the grains are exposed, giving the broken surface a rough or granular appearance. The conversion of sandstone into quartzite is sometimes the work of percolating water under ordinary conditions. In the Reading beds of England, which are for the most part loose sands, there are often many large blocks of quartzite which weather out and are exposed at the surface, being known as grey-wethers. The silicification of these rocks must have taken place at no great depth and under ordinary pressures. Most quartzites, however, are found among ancient rocks, such as the Cambrian or Pre-Cambrian and are products of metamorphism.

A normal quartzite has in microscopic section its clastic structure well preserved; the rounded sand grains are seen with patches of new quartz in the interspaces, and the latter is often deposited in crystalline continuity, so that the optical properties of the grains are similar to those of the material which surrounds them: a line of iron oxides or other impurities often indicates the boundary of the original sand grain. As might be expected, however, many of the oldest quartzites have been crushed by folding movements and the quartz consists in large part of a mosaic of small crystalline fragments of irregular shape with interlocking margins; these are called "sheared quartzites," and when they contain white mica in parallel crystalline flakes they become more fissile and pass into quartz-schists. Where sandstones are altered by intrusive rocks they are often converted into pure quartzite, the heat evidently occasioning the deposit of interstitial quartz.

The commonest minerals in quartzite, in addition to quartz, are felspar (microcline, orthoclase, oligoclase), white mica, chlorite, iron oxides, rutile, zircon and tourmaline. Except felspar they are usually present only in small quantity; the less frequent accessories include hornblende, sillimanite, garnet, biotite, graphite, magnetite and epidote. In colour quartzites are often snowy white; they frequently have a fine angular jointing and break up into rubble under the action of frost. Quartzites are too hard and splintery to be used as building stones to any large extent: they furnish a thin and very barren soil, and because they weather slowly tend to project as hills or mountain masses. (J. S. F.)

QUARTZ-PORPHYRY, in petrology, the name given to a group of hemi-crystalline acid rocks containing porphyritic crystals of quartz in a more fine-grained matrix which is usually of micro-crystalline or felsitic structure. In the hand specimens the quartz appears as small rounded, clear, greyish, vitreous blebs, which are crystals (double hexagonal pyramids) with their edges and corners rounded by resorption or corrosion. Under the microscope rounded enclosures of the ground-mass or fluid cavities are often seen; these are frequently negative crystals with regular outlines resembling those of perfect quartz crystals, and many of the latter contain liquid carbonic acid and a bubble of gas which may exhibit vibratile motion under high magnifying powers. In addition to quartz there are usually phenocrysts of felspar, mostly orthoclase, though a varying amount of plagioclase is often present. The felspars are usually cloudy from the formation of secondary kaolin and muscovite throughout their substance; their crystals are larger than those of quartz and sometimes attain a length of two inches. Not uncommonly scales of mica are visible as hexagonal plates. Other porphyritic minerals are few, but hornblende, augite and bronzite are sometimes found; the augite and hornblende are in most cases green, and are frequently decomposed into chlorite, but even then can usually be identified by their shape. A colourless rhombic pyroxene (enstatite or bronzite) occurs in a limited number of the rocks of this group and readily weathers to bastite. Apatite, magnetite, and zircon, all in small but frequently perfect crystals, are almost universal minerals of the quartz-porphyries.

Structure. — The ground-mass is finely crystalline and to the unaided eye Bas usually a dull aspect resembling common earthenware; it is grey, green, reddish or white. Often it is streaked or banded by fluxion during cooling, but as a rule these rocks are not vesicular. Two main types may be recognized by means of the microscope — the felsitic and the microcrystalline. In the former the ingredients are so fine-grained that in the thinnest slices they cannot be determined in this way. Some of the rocks show perlitic or spherulitic structure; such were probably originally glassy (obsidians or pitchstones), but by lapse of time have slowly passed into a very finely crystalline state. This change is called devitrification; it is common in glasses, as these are

[1]Still another form of silica is known as cristobalite (named after San Cristobal, its locality in Mexico), which, like tridymite, is of rare occurrence in nature as minute crystals in the cavities of certain lavas.

essentially unstable.

A large number of the finer quartz-porphyries are also in some degree silicified or impregnated by quartz, chalcedony and opal, derived from the silica set free by decomposition (kaolinization) of the original felspar. This re-deposited silica forms veins and patches of indefinite shape or may bodily replace a considerable area of the rock by metasomatic substitution. The opal is amorphous, the chalcedony finely crystalline and often arranged in spherulitic growths which yield an excellent black cross in polarized light. The microcrystalline ground-masses are those which can be resolved into their component minerals in thin slices by use of the microscope. They prove to consist essentially of quartz and felspars, which are often in grains of quite irregular shape (micrographic). In other cases these two minerals are in graphic intergrowth, often forming radiate growths of spherulites consisting of fibres of extreme tenuity; this type is known as granophyric. There is another group in which the matrix contains small rounded or shapeless patches of quartz in which many rectangular felspars are embedded; this structure is called micro-poikilitic, and though often primary is sometimes developed by secondary changes which involve the deposit of new quartz in the ground-mass. As a whole those quartz-porphyries which have microcrystalline ground-masses are rocks of intrusive origin. Elvan is a name given locally to the quartz-porphyries which occur as dikes in Cornwall; in many of them the matrix contains scales of colourless muscovite or minute needles of blue tourmaline. Fluorite and kaolin appear also, and these minerals as a whole are due to pneumatolytic action by vapours permeating the porphyry after it had consolidated but probably before it had entirely cooled.

Older Forms.—Many of the older quartz-porphyries which occur in Palaeozoic and Pre-Cambrian rocks have been affected by earth movements and have experienced crushing and shearing. In this way they become schistose, and from their felspar minute plates of sericitic white mica are developed, giving the rock in some cases very much of the appearance of mica-schists. If there have been no phenocrysts in the original rock, very perfect mica-schists may be produced, which can hardly be distinguished from sedimentary schists, though chemically somewhat different on account of the larger amounts of alkalis which igneous rocks contain. When phenocrysts were present they often remain, though rounded and dragged apart while the matrix flows around them. The glassy or felsitic enclosures in the quartz are then very suggestive of an igneous origin for the rock. Such porphyry-schists have been called porphyroids or porphyroid-schists, and in America the name aporhyolite has been used for them. They are well known in some parts of the Alps, Westphalia, Charnwood (England), and Pennsylvania. The *hälleflintas* of Sweden are also in part acid igneous rocks with a well-banded schistose or granulitic texture.

The quartz-porphyries are distinguished from the rhyolites by being intrusive rocks. All Tertiary acid lavas are included under rhyolites. (J. S. F.)

QUASSIA, the generic name given by Linnaeus to a small tree of Surinam (Quassia amara), superseded for medical purposes in 1809 by the bitter wood or bitter ash of Jamaica, Picrasma excelsa, which has similar properties and can be obtained in larger pieces. Since that date this wood has continued in use in Britain under the name of quassia to the exclusion of the Surinam quassia, which, however, is still employed in France and Germany. Picrasma excelsa is a tree 50 to 60 ft. in height, and resembles the common ash in appearance. It is found also in other West Indian islands, as Antigua and St. Vincent. Quassia amara is a shrub or small tree belonging to the same natural order as Picrasma, viz. Simarubaceae, but is readily distinguished by its large handsome red flowers arranged in terminal clusters. It is a native of Panama, Venezuela, Guiana and northern Brazil. Jamaica quassia is imported into England in logs several feet long and often nearly one foot thick. The wood is nearly white, has a pure bitter taste, and is without odour or aroma. It is usually met with as turnings or raspings, the former being obtained in the manufacture of the "bitter cups" which are made of this wood. The chief constituent is a bitter neutral principle known as quassin. It exists in the wood to the extent of about $\frac{1}{10}\%$. It forms crystalline needles soluble in alkalis, chloroform and 200 parts of water. There is also present a volatile oil. The wood contains no tannin, and for this reason quassia, like chiretta and calumba, may be prescribed with iron. The infusion is useful as a bitter tonic—a group of substances of which calumba is the type—and is also a very efficient anthelmintic for the thread-worm (*Oxyuris vermicularis*). It is a substitute for hops.

QUATERNARY, in geology, the time-division which comprises all the time which has elapsed from the end of the Pliocene to the present day. The term was proposed by J. Desnoyers in 1829. The Quaternary is thus the fourth of the great time-divisions in the geological scale—the Primary or Palaeozoic, the Secondary or Mesozoic and the Tertiary or Cainozoic being the first three—but it represents relatively such a small space of time that some geologists hesitate to give it equal rank, and regard it merely as a subdivision of the Tertiary. Broadly, as the Tertiary may be called the Age of Mammals, the Quaternary may be called the Age of Man. Although man or his ancestors were evolved during the Tertiary, it is in the Quaternary that man becomes the dominant animal. Two divisions of the Quaternary period are usually recognized:—

1 Pleistocene
2 Recent or Holocene

In England many extinct species of animals and mollusca occur in the lower but not in the upper division.

General History of the Quaternary Period.—The faunas of the later Pliocene indicate a definite lowering of temperature and with the opening of the Pleistocene both fauna and flora begin to assume a definitely arctic character. A period of intense cold then ensued—usually known as the Glacial period (*q.v.*) or the Great Ice age. The greater part of the British Isles north of a line from South Wales to the mouth of the Thames came under the influence of ice action. As a belt circling the North Pole, there were several ice-caps, similar to the one that covers most of Greenland at the present day, and the various ice-caps or ice-centres waxed and waned in relative importance in such a way that the same district was sometimes affected by ice from one centre, sometimes by ice from another centre. Finally climatic conditions were ameliorated and the ice retreated. It left in its wake not only great stretches of purely glacial deposits such as boulder clay, but the waters derived from the melting of the ice gave rise to torrents spreading over the still frozen ground and depositing great fans of gravel and sand. After the retreat of the ice a broad tract of cold desert or tundra encircled the Northern Hemisphere. This seems to have given place to a broad belt of wind-swept steppeland where great clouds of fine dust filled the air and were deposited as a mantle of loess. With the increase of humidity, forests sprang up and clothed the greater part of Europe north of the Mediterranean region, and it is in this Forest period that we are still living. This general sequence of events was interrupted by minor cycles which are adequately discussed by C. E. P. Brooks in his book The Evolution of Climate. It will be obvious that the ice-sheets were the controlling factors in Pleistocene times. Very few animals or plants, if any, could live in the regions actually covered by ice; in consequence the glacial deposits are devoid of fossils. Round the margins of the ice extensive floras and faunas existed; they migrated under the influence of fluctuations in the intensity of the cold. One finds thus at least three sets of Pleistocene deposits: (a) glacial deposits without fossils; (b) contemporaneous extra-glacial deposits such as river gravels and cave deposits with mammalian and other land or fresh-water fossils, and indications of the presence of man (artefacts or implements, etc.); (c) contemporaneous marine deposits with fossils. The great problems of Quaternary geology centre around the correlation of the different sets of deposits and of the sequence of events they indicate.

At least five chronological scales have been instituted for Quaternary deposits: (a) that based on a study of marine faunas where, unfortunately, each province has its own history, and those best known are the Baltic, North sea and Mediterranean;

(b) that based on a study of mammalian faunas; (c) that based on a study of human cultures, specially as exemplified by artefacts; (d) that based on a study of the sequence of plant formation in peat mosses; (e) that based on the history of continental deposits—glacial, fluvio-glacial, lacustrine and fluviatile, with their fossils, if any. In addition, a most important method of study of the Quaternary sequence is that of land forms—the rising or falling of the level of the sea relative to the land; the cutting of valleys by rivers and the formation of successive terraces; the formation of successive shore lines by seas and lakes.

Marine Faunas of the Period.—In the Mediterranean three stages are distinguished. The Sicilian has occasional rare forms, such as *Cyprina islandica* and *Buccinum undatum,* no longer living in the Mediterranean, but found in colder seas. Deposits of this age are found in the basin of Palermo, Sicily, hence the name. The Tyrrhenian has no longer any extinct species, but several living now in warmer seas. At this period the level of the Mediterranean seems to have been about 50 to 100 ft. above its present level. The third stage is that of the present-day fauna of the Mediterranean. In the Baltic sea a detailed succession has been worked out in connection with the complex history of the area—at times a fresh-water lake, at times a sea salter than at the present day. It was in the Swedish lakes left after the retreat of the ice that De Geer worked out his famous chronology, by which the duration of the stages of the Pleistocene in years can be calculated.

Mammalian Faunas of the Period.—The Quaternary mammals fall into four groups: (a) tundra species such as the lemming, arctic hare, arctic fox, reindeer and musk-ox; (b) steppe species, such as jerboa, steppe marmot, horse, etc.; (c) a group of southern species—a warm fauna—including some extinct and embracing rhinoceros (several species), cave lion and cave hyena; (d) a group of extinct species including Elephas antiquus, (early Pleistocene), and *Elephas primigenius* (the mammoth, late Pleistocene). It is not easy to trace the movement of Quaternary faunas, but there were living in the British Isles and Europe before the oncoming of the Ice age a number of southern and extinct species (*Elephas* antiquus) which appear to have retreated to the continent with the oncoming of the cold. In this connection it may be noted that the Strait of Dover was probably not cut through till the close of the Glacial period. Other animals, including man, retreated to caves within the British Isles (cave lion, cave bear, cave hyena). Associated with the cold conditions are the arctic animals such as the mammoth and reindeer, followed as the ice retreated by the gradual re-establishment of the modern fauna.

Human Culture of the Period.—This subject is discussed elsewhere. Older Palaeolithic man (Strepian, Chellean and Acheuléen cultures) lived in the open river valleys (River Drift man) before the oncoming of the cold; newer Palaeolithic man (Mousterian, Aurignacian, Solutrian and Magdalenian culture) lived in caves. Neolithic man, with his polished stone implements, was post-Glacial and belongs to the Holocene rather than the Pleistocene.

History of the Continental Deposits.—These deposits are discussed in the article GLACIAL PERIOD. Special interest attaches to the succession of river terraces, such as the famous series of the Thames or Somme. The First terrace of the Thames lies about 130 ft. above the present level of the river and has remains of mammoth. The Second or High (Swanscombe) terrace lies about 100 ft. above the Thames. It has implements of Chellean and Acheuléen and possibly Mousterian types, remains of mammoth and *Elephas* antiquus and a number of extinct mollusca (*Unio* littoralis and *Neritina grateloupiana*). The Third or Middle terrace lies about 50 ft. above the Thames and has Palaeolithic "floors" with Mousterian implements. Nearly all the Mollusca are still living but mammals include the mammoth. The South or Low terrace embraces the low-lying gravels of Kew, Richmond, etc., lying 10 to 25 ft. above sea-level. The Buried Channel represents a period when the level of the river must have been lower than at present. The latest deposits are the extensive stretches of alluvium (Holocene).

Turning to the coastal deposits, in pre-Glacial or early Pleistocene times the sea seems to have been higher than at present and hence there is frequently a pre-Glacial raised beach round the coasts of Britain. With the oncoming of the Glacial period the sea rose still higher and during the retreat of the glaciers the 100 ft. raised beach, 50 ft. raised beach and 25 ft. raised beach respectively were formed, especially in Scotland. At a later date the sea sank below its present level and this is the age of the Neolithic submerged forests and buried channels. For convenience one refers to the movement of the sea relative to the land; actually the change may have been of the land in relation to the sea-level. See also GLACIAL PERIOD.

Boule, *Les Hommes Fossiles* (Paris, 2nd ed. 1922); G. Dubois, "Recherches sur les terrains quaternaires du Nord de la France" (*Mem. Soc. geol. Nord.* viii. 1924). In these works will be found references to classical authorities. Reference should also be made to the writings of E. Anteos in America.
(L. D. S.)

QUATERNIONS is the algebra of vectors—quantities, like force, velocity and acceleration, that have both magnitude and direction. Ordinary numbers (scalars) have merely magnitude. All positive numbers (integral, fractional or irrational) may be represented by the points of a straight line lying on one side of some point O which we conceive as corresponding to zero, as if the straight line were the indicator of a thermometer (fig. 1). If the line be horizontal, then the positive numbers are usually represented by the points to the right of O, the zero-point, and the negative numbers correspond to the points to the left of O (temperatures below zero). The totality of numbers corresponding to the points on this line are called real numbers. Thus far, the numbers introduced represent magnitude only and there is no direction implied by a number except the distinction between backward and forward.

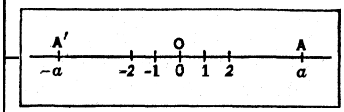


FIG. 1

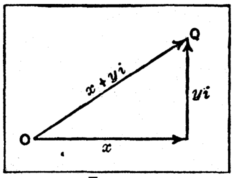

FIG. 2

Vectors in a Plane.—If we wish to have numbers which indicate direction in a plane as well as distance we can use ordinary complex numbers (see COMPLEX NUMBERS). To do this, we note that, since $(-1)\,a=-a$, then multiplication of any number by negative one rotates the line segment OA representing a through two right angles. But, since $\sqrt{-1}\,\sqrt{-1}=-1$, this shows that multiplication by $\sqrt{-1}$ must rotate OA through one right angle. Thus we can represent any point in the plane of this page by a number $x+yi$ where x and y are real numbers and where i is written for $\sqrt{-1}$. Better still, (fig. 2) we can think of the number $x+yi$ as representing the directed line segment OQ, or vector as we say (see VECTOR ANALYSIS).

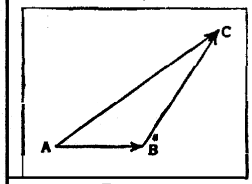

FIG. 3

One of the most familiar examples of a vector is position of a point with respect to some other point, *e.g.,* the position of a building is four blocks south and two blocks east of the city hall. Other examples are displacement through a certain distance in a certain direction, velocity, acceleration, momentum, force, rotation. Vectors are contrasted with ordinary numbers or scalars, examples of which are distance, time, temperature, volume, mass, work, energy (figs. 3 and 4).

Since the displacement AB followed by the displacement BC has the same effect as the single displacement AC, then the sum of the two vectors AB and BC is the vector AC. The multiplication of any number $a+bi$ by the number $x+yi$ means performing on the vector $OP=a+bi$ the same operation which changes the vector OU= 1 into the vector $OQ=x+yi$, and hence is a rotation of the vector OP through the angle 8, followed by a stretching in the ratio of ρ to 1 where ρ is the length of OQ (shrinking, if ρ be less than 1) and thus obtain the vector OR. Multiplication of ordinary complex numbers obeys the commutative law—that is, if u and v be any two complex numbers, then $uv=$ vu; and it also obeys the associative law—that is, if u, v and w be any three complex numbers, then $(uv)w=u(vw)$. (See the articles COMMUTATIVE and ASSOCIATIVE LAWS, respectively.) These two laws are so familiar that we have taken them for granted, but we shall have to discard one of them when we come to quaternions. Thus the field of ordinary complex numbers is the algebra of distances and directions in a plane. (See LINEAR ALGEBRAS.)

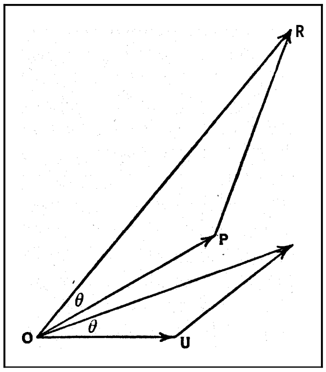

FIG 4

Vectors in Space.—When Sir W. R. Hamilton (1805–1865) tried to invent an algebra for vectors in space, he discovered some peculiarities which at first seemed disconcerting. By analogy with the algebra of vectors in a plane, he tried to represent every vector in space in the form $x+yi+zj$ where 1, i and j denote unit vectors in three mutually perpendicular directions (fig. 5a). This seems natural, inasmuch as any vector (displacement, force, etc.) in space is compounded of a vector in a north-and-south direction, a vector in east–west direction and a vector in an up-and-down direction. Now in the field of complex numbers multiplication obeys, (1) the commutative law, and (2) the associative law, while (3) division—the inverse of multiplication—is uniquely possible when the divisor is not zero. Hamilton, however, discovered that for space it is impossible to define an algebra which possesses all three of these properties. He tried to invent an algebra of vectors for space which should possess the second and third properties and discovered that there is no such algebra in which ij is expressible in the form $x+vi+zj$. Accordingly, he was forced to assume that the algebra was of order four instead of order three; and thus every quaternion is of the form $yi+zj+wk$ where i, j, k denote unit vectors in three perpendicular directions and where the product of two vectors is of the form $a+bi+cj+dk$. That is, although the algebra of vectors in a plane has only two units, the algebra of vectors in space has four units. This discovery of Hamilton makes one realize that man cannot invent law; he can only discover the primordial laws of the universe.

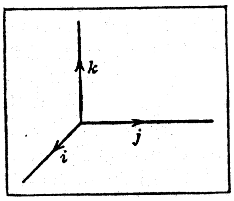

FIG. 5A

Quaternions.—When x, y, z, w are real numbers and i, j, k are the above unit vectors, any number of the form $q=x+yi+zj+wk$ is called a (real) quaternion. A vector is simply a quaternion with $x=0$ and a scalar is a quaternion with $y=z=w=0$. To make it concrete, we shall think of i as the unit vector toward the south, j as the unit vector to the east and k as the unit vector up. In the diagram, the plane of the page represents a vertical east–west plane viewed from the south; the vectors j and k are in this plane and i points to the south. As for vectors in a plane, multiplication by a vector of length p is equivalent to a stretching in the ratio of p to 1 compounded with a rotation in the counter-clockwise direction. Multiplication of any vector in the east–west vertical plane by i (on the left) is equivalent to a rotation in that plane through a right angle in a counter-clockwise direction as seen from the south. Similarly, multiplication by j or k is a rotation through a right angle in the direction indicated in the diagram. Since rotation through two right angles in the same plane reverses the direction, then $i^2=-1$ and also $j^2=-1=k^2$. From this (see fig. 6) we see that i rotates j into k and thus $ij=k$, whereas j rotates i into k reversed and thus $ji=-k$. Similarly, $jk=-kj=i$ and $ki=-ik=j$. Substituting these values for the products, we see that the product of any two quaternions $q=x+yi+zj+wk$ and $Q=X+Yi+Zj+Wk$ is $qQ=a+bi+cj+dk$ where $a=xX-yY-zZ-wW$, $b=yX+xY-wZ+zW$, $c=zX+wY+xZ-yW$, $d=wX-zY+yZ+xW$. Any quaternion q and its conjugate $q'=x-yi-zj-$ wk satisfy the quadratic equation $\omega^2-2x\omega+N(q)=0$ where $N(q)=qq'=x^2+y^2+z^2+w^2$ is the norm of q. Note that this gives a factorization of $x^2+y^2+z^2+w^2$, which cannot be factored in the field of complex numbers.

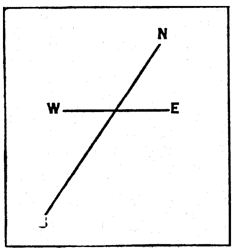

FIG. 5B

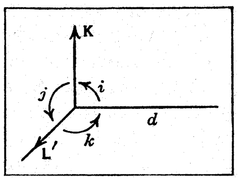

FIG. 6

From the above, it follows that the product $\alpha\beta$ of any two vectors has the form $-\alpha\,.\,\beta+\alpha\times\beta$ where $a\cdot\beta=ab\cos\theta$, where a and b are the magnitudes of α and (3, respectively, and θ is the angle through which a has to be rotated in order to make it extend in the same direction as (3; and α it $\beta=ab(\sin\theta)\gamma$ where γ is the unit vector perpendicular to a and β as indicated in the diagram (fig. 6). When we use $\alpha\cdot\beta$ and $\alpha\times\beta$ separately, we are using *vector* analysis (*q.v.*, due to J. W. Gibbs). The amount of work done by a force F acting through the displacement β is $F\,.\,\beta$. The area swept out by the vector a through displacement β is $\alpha\times\beta$ which means that we have to regard area as a vector. Theorems in geometry can be easily proved with quaternions (vector analysis), sometimes with great brevity; but its most important use is in mathematical physics.

"Ausdehnungslehre," due to H. Grassmann (1809–1877), is like quaternions in that it is an algebra in which some of the elements or numbers are vectors; but it is unlike quaternions in that the fundamental element is the point and the product of two elements of the same kind is an element of a different kind. Moreover, Ausdehnungslehre is not associative and applies to space of any number of dimensions.

BIBLIOGRAPHY.—Sir W. R. Hamilton, Lectures on *Quaternions* (1853). This is the classic on the subject; the long introduction is most interesting and suggestive to a layman. P. Kelland and P. G. Tait, Introduction to Quaternions (1873, 3rd ed. 1904). An excellent text-book; does not use calculus until the last quarter of the book; contains many applications and exercises. E. B. Wilson, Vector Analysis (1901), an expansion of a short pamphlet on the Elements of Vector *Analysis* (1881–84), by J. W. Gibbs. This book pre-supposes a knowledge of trigonometry and the elements of the calculus; it contains many applications to geometry and physics; the first two chapters, however, do not use calculus. J. B. Shaw, Vector Calculus (1922). A text-book on quaternions, with applications to physics; intended for those familiar with the elements of calculus; mature; many exercises. H. Grassmann, *Die Ausdehnungslehre* (Leipzig 1878–96). This is the classical work on this subject, but is highly technical. E. W. Hyde, *Grassmann's Space Analysis* (4th ed. 1906). A primer on Grassmann's work; does not use calculus but requires more intellectual maturity than Gibbs-Wilson. (O. C. H.)

QUATORZAIN, the term 'used in English literature, as opposed to "sonnet," for a poem in 14 rhymed iambic lines closing (as a sonnet strictly never does) with a couplet. The distinction was long neglected, because the English poets of the 16th century had failed to apprehend the true form of the sonnet, and called Petrarch's and other Italian poets' sonnets quatorzains, and their own incorrect quatorzains sonnets. Almost all the so-called sonnets of the Elizabethan cycles, including those of Shakespeare, Sidney, Spenser and Daniel, are really quatorzains. They consist of three quatrains of alternate rhyme, not repeated in the successive quatrains, and the whole closes with a couplet.

QUATRAIN, sometimes spelt *Quartain,* a piece of verse complete in four rhymed lines. The length or measure of the line is immaterial. This form has always been popular for use in the composition of epigrams, and may be considered as a modification of the Greek or Latin epigram.

QUATREFOIL or **QUARTERFOIL,** in architecture, a decorative form of four lobes or cusps, usually of approximately the shape of a four-leafed clover, and frequently with the whole surrounded by an enclosing circle.

QUAVER, in music, a note representing an eighth part of a semibreve, wherefore it is known as an eighth note in America and an *Achtelnote* in Germany.

QUEBEC. The northeastern province of Canada bounded on the southwest and west by part of Ontario, James bay and Hudson bay, on the north by Hudson strait and Ungava bay, on the east by the coast of Labrador and the Gulf of St. Lawrence, on the south by the Bay of Chaleur, New Brunswick, Maine, New Hampshire, Vermont, New York and part of Ontario. Its greatest extent is from the U.S. border, 45° N., to Cape Wostenholme, about 62° 30' N., and from Hudson bay, at a point 80° W. to Anse Sablon about 57° W. The total area is 594,534 sq.mi., or about one-sixth the total area of Canada. The area includes 71,000 sq.mi. of fresh water.

Climate. — There are wide variations in temperature, from arctic to semi-tropical, isotherms curving northeastward. The maximum and minimum temperatures at Quebec city in 1940 were: January max. 29° F., min. −15° F.; July max. 85° F., min. 49° F. Higher and lower temperatures are not uncommon. Movement of large cold air masses is generally from west to east. Cold fronts usually move rapidly from west to east; warm fronts from southwest to northeast. The climate of the eastern section is much affected by the Atlantic. Precipitation decreases from south to north *e.g.,* in 1940 30 in. rain, 151 in. snow in the south (Quebec) decreasing to 17 in. rain, 79 in. snow in the north (Mistassini).

Population. — The 1941 census was 3,331,882, of which about 85% were French-Canadians. English-speaking people are mainly centred in the larger cities, in Pontiac and Abitibi counties, where there are many new Canadians, the Saguenay and St. Maurice industrial areas, Gaspé and the eastern townships north of the New Hampshire and Vermont border.

Physiography and Geology. — The most recent physiographical studies divide the province into three main regions: Canadian Shield, St. Lawrence, Appalachian. The Canadian Shield region includes all territory north and northeast of an irregular line between the Lake of Two Mountains on the Ottawa river and Cap Tourmente on the St. Lawrence a few miles northeast of Quebec. Most of the area is bedded on Laurentian and Pre-Cambrian rock (chiefly granite and granite gneisses); the southern section, north of Montreal and Quebec, is mainly Pre-Cambrian schist and granite; the western central section, around the Canadian National railway near the Ontario border, is Pre-Cambrian.

The main physiographic feature is the Laurentian mountains which form the south section of the Canadian Shield; irregular rocky hills, oldest on the continent, few of the summits now being over 2,000 ft. above sea level; the total area is about equal to that of the American Rockies. These hills are studded by thousands of lakes, cut by river valleys so deep that voyages without too many portages can be made by canoe or small boat through and across the ranges. The most remarkable of these valleys is that of the Saguenay which, after a swift descent from the Lake St. John reservoir, falls into a vast chasm running from west to east, in places almost 2,000 ft. above and 300 fathoms below sea level. Hundreds of rivers, large and small, flow southward and northwestward ensuring to Quebec a huge potential water power which, with the forests covering the hills and valleys, preserving and preserved by this water supply, constitute an enormous reservoir of resources.

One sub-region, Abitibi, on both sides of the Canadian National main line and reaching the Ontario border, is heavily mineralized; both Abitibi and the level region surrounding Lake St. John have soils suitable for cultivation, the former largely clay covered by other soils of varying nature, the latter also clay with a lighter topsoil. The rest of the area has a light moraine soil supporting both softwood and hardwood forests, but not otherwise fertile.

The St. Lawrence region includes (1) an area divided by the river, narrowing from about 60 mi. breadth at Montreal to about 20 mi. breadth at Quebec; (2) an area on the south side of the river only, stretching about 300 mi. northeast from Quebec and 6 to 10 mi. in depth. This region has been divided into three sub-regions, the Montreal Plain, the St. Lawrence Valley between Montreal and Quebec and the South Shore (Cote Sud) below Quebec. The Montreal plain is low, 250 ft. or less above sea level. The surface slopes evenly and very slowly down to the river on both sides and also downward from northeast to southwest, *i.e.,* against the direction of the river. The basement is of Ordovician rock broken near Montreal by the Monteregian hills, remnants of considerable volcanic mountains now almost completely eroded. The soil consists of clay and sand from the Champlain sea with more recent deposits and is in most places good, although large parts have become sour. Considerable areas are covered by newly formed peat. The St. Lawrence Valley basement is likewise Ordovician rock; a mixed soil lies on a clay bed, much deeper on the south than on the north shore. The South Shore is comparatively level, lying on Ordovician rock with many outcrops. At its centre a subsidiary range, about 40 mi. in length, separates the river from the arable land. The soil is mainly sandy, although there are considerable areas of black vegetable deposit, in one section already turned to peat, and is strewn with glacial boulders.

The rest of the province constitutes the Appalachian region, mainly Ordovician with lesser amounts of Cambrian and Devonian dotted with granite, and serpentine hills, well weathered and largely tree-clad, rising in the centre of the region to about 3,000 ft. The Gasp6 peninsula in the east has a central axis of Devonian rocks with considerable traces of oil ending in a high, narrow and precipitous promontory (Cape Gaspé). On the north side are the Shickshock mountains, much folded and faulted. On the south side is another range, with red sandstone and conglomerate along the western end of the Bay of Chaleur. At the east end of the south shore of the peninsula is a much eroded shoreline of rocks filled with fossil shells from which a one-time peninsula, Perce rock, has comparatively recently been cut.

History. — Prior to its cession to Britain most of the present province of Quebec and also a vast ill-defined area stretching from the far west to the Alleghenies and from the Great Lakes to the Gulf of Mexico, as well as the French territories on the North Atlantic, were subject to the crown of France under the name of New France; the district in the St. Lawrence and watershed area was called Canada. Government was held closely in the hands of the crown at Paris; the governor, advised by a "Sovereign Council," had some powers of initiative but he was called to task if he overstepped and was rivalled by the bishop. His chief financial adviser, the intendant, was responsible to Paris for economic control. Except for elections of churchwardens, very few official traces of democratic government existed. "Canada" was by 1750 the home of about 65,000 French Canadians, descendants of settlers who had been arriving during a century and a half. They had a quasi-manorial system of land tenure: *Seigneurs* received grants of about six miles frontage and generally greater depth on the St. Lawrence and like areas in the interior. These were parcelled out to *habitants* who paid annual dues, mostly in kind, to the seigneur as well as making special payments on transfers of property. Traces of the system are only now (1943) disappearing. There were about 15,000 bourgeois in Quebec, Montreal and Trois Rivières where the seigneurial system also existed. There was a complete system of land registration and a notarial system for land transfers, marriage contracts, gifts, etc., which were unchanged at the cession and which, modernized, still remain. Births, marriages and deaths were recorded in the church of one or both of the persons concerned. These French Canadians who had become completely differentiated from the French (now mainly officials and soldiers), calling themselves Canadiens and not French, attributed vast importance to all these customs, to the civil law and to their religion.

After the victory of Wolfe at Quebec, a British military government carried on very satisfactorily, making no important changes. By the treaty of Paris, Feb. 10, 1763, New France passed formally to Britain. This treaty followed in one respect the terms of the capitulation of Quebec in 1759, which had provided *inter alia* that the French Canadians were to retain their houses, goods, effects *and privileges* and that the Catholic Church was to be preserved. The treaty also provided for the maintenance of the Catholic Church but subject to the laws of Britain (under which Catholics were debarred from almost all offices). The "privileges" of the capitulation, taken as meaning French civil law and customs, were maintained, but English law was to be followed so far as compatible with them. This to most judges meant that the common law of Britain prevailed and as no French Canadians knew what that law was there was great confusion.

The province of Quebec as a governmental and geographical entity first appeared under the name of The Government of Quebec in a proclamation made by the crown of Great Britain (in virtue of the somewhat dubious royal prerogative right to legislate for newly conquered territory) on Oct. 7, 1763. This proclamation reached Quebec Aug. 10, 1764. The "Government" included the St. Lawrence valley, except for what is now the Ontario section, and the Ottawa valley, bounded on the north by a line from Lake Nipissing to Lake St. John. The governor and captain general was authorized to, and did, set up a council to make laws and ordinances replacing the "Sovereign Council." The governor in council was also authorized to, but did not, set up a popular assembly. The confusion as to law and religion resulting from the proclamation, as well as the wish of the British government to curb the American settlers to the south, brought about the Quebec Act of 1774 which set up the "Province of Quebec" including most of the area now in the United States west of the Alleghenies. This act guaranteed the maintenance of French civil law and customs and freedom of worship. An executive and a legislative council, both nominated by the crown, were set up and both still exist, although the executive council, under fbe same name, has become a provincial cabinet.

The French Canadians were used to bureaucracy and were well enough pleased with the Quebec act to fight the invading Americans in 1775, and not at all concerned when the treaty of Paris in 1783 set the southern boundary west of the Quebec-Maine mountains back to the 45th parallel. In 1791, by the Constitutional act (enacted June 10, 1790), a government was set up for "Upper Canada" west of the Ottawa (except for a small triangle at the junction of the Ottawa and St. Lawrence) and "Lower Canada" extended by the act over the Magdalen islands, Anticosti and Quebec Labrador. The act provided for Lower Canada an appointive legislative council (15) and an elective assembly (50). The appointive council was at first all-powerful and there were many abuses of power, but there was little complaint until after the War of 1812, in which the French Canadians again fought, and, in Lower Canada, defeated the Americans. The revolutionary ideas inspired "liberals" (French- and English-speaking) in the assembly; the struggle for responsible government and judges independent of the government which ensued culminated in the "rebellion" of the "patriotes" in 1837.

The Union act (July 23, 1840) became law on July 23, 1841, uniting Lower and Upper Canada as Canada East and Canada West, with one council and one assembly in which the two sections had equal numbers, the French language being for the first time recognized although only for debate. After a conflict with the governor responsible government, in the modern sense, came into effect in 1841. The union was never much more than nominal, since the practice was to require a majority of the representatives from each section to pass any act while many acts referred to one section alone. The powers of self-government vested in the colonial parliament gradually increased, judicial reform was obtained, the French language was accepted for all purposes in 1849. In 1867, at confederation, the province of Quebec reappeared with its own lieutenant governor, legislative council and assembly. French-Canadian control of Quebec was assured but the rights of the powerful and rich English-speaking minority were carefully safeguarded, particularly their control over their own education. They (1943) constitute only about 15% of the population, but the growing French-Canadian majority has scrupulously regarded its obligations.

The boundary of Quebec on the north at confederation was the height of land north of the St. Lawrence valley. This was extended to the Eastmain and Hamilton rivers in 1898 and to Hudson strait in 1912. The boundary between Quebec and Labrador (as an adjunct of Newfoundland) was decided by the Labrador Act (1825). The boundary was placed as a line due north from Anse Sablon, and for over a century Newfoundland was presumed to have jurisdiction only over the coastal strip of Labrador, not over the interior (practically unknown). Exploration and the prospect of development raised dispute as to the boundary and in 1927 a decision of the privy council awarded to Newfoundland all of interior Labrador draining to the Atlantic (110,000 sq.mi.). The period after confederation left the government of Quebec practically unchanged; parliamentary procedure and democratic practice follow British precedent even more than that of most other provinces but the French-Canadian majority is quite firmly in the saddle. Quebec is a French-speaking island in North America owing allegiance to a king who for it (and perhaps correctly) is king of Canada, interpreting the Atlantic Charter as confirming its right to its own religion, laws and language.

Government.—The king is represented by the lieutenant governor, appointed for a renewable term of years by the governor general in council. The legislative council has 24 members, each sitting for a geographical district, appointed for life by the lieutenant governor in council (Quebec is the only province with such a body). The legislative assembly has 87 members, each elected for a constituency. Rural constituencies are larger but far less populous than urban. The distribution of powers between the three sections is identical with that between king, lords and commons in Britain, the assembly having complete control of taxation and finance. Treasury bills issued under orders-in-council must be covered by appropriate votes. All private and some public bills are discussed in and reported by appropriate committee sessions at which persons affected may appear personally or by legal representative before passage. Otherwise the formalities duplicate those of the parliament at Westminster. The premier leads in the assembly, and a leader named by the government, generally also a minister without portfolio, in the council. The executive council is the provincial cabinet; its members must, as a rule, hold seats in the assembly, thus ensuring maintenance of the representative principle. Members are premier, provincial treasurer, provincial secretary, attorney general, ministers of roads, public works, colonization, game and maritime fisheries, lands and forests, trade and commerce and municipal affairs, health and welfare, labour and mines, each of whom has one or more deputies while the premier has a "chef du cabinet" ranking as a deputy minister. There are generally a number of ministers without portfolio, of whom the leader of the council is generally one. Elections are governed by the Provincial Elections act, substantially in accord with British practice. There are two parties, Liberal and National Union; a local organization of each usually selects a candidate prior to an election. Independents may run if nominated. Municipal government is carried on by 76 county municipalities and rural and urban municipalities generally under the Cities and Towns act and municipal code, although there are many special charters and acts which demand much parliamentary time for their enactment and revision.

Agriculture.—In 1941 there were 154,184 occupied farms, an increase of 13.5% in 10 years. Main products and values (1940 figures): Spring wheat 522,000 bu., $473,000; oats 44,290,000 bu., $19,254,000; barley 3,888,000 bu., $2,219,000; spring rye 103,000 bu., $84,000; peas 318,000 bu., $794,000; beans 153,000 bu., $375,000; buckwheat 2,144,000 bu., $1,278,000; husking corn 183,000 bu., $168,000; mixed grains 4,502,000 bu., $2,373,000; flax 140,000 bu., $347,000; potatoes 13,125,000 bu., $10,416,000; turnips, beets, etc. 5,957,000 bu., $2,455,000; hay and clover 5,223,000 bu., $46,373,000; fodder corn 552,000 bu., $2,472,000; alfalfa 57,000 bu., $618,000. Quebec's place among the provinces (1940) was as follows: Acreage fifth, with 6,104,000; value of crops fourth, with $89,531,000; value per acre third, $44; total value of farms second, $901,213—about 20% of the Canadian total.

The main features of Quebec agriculture are (1) Family farming: on most farms most of the work is done by the farmer and his family, eliminating most of farm labour costs. (2) Farm arts and crafts—mainly in eastern section where most of the wool produced is woven locally. (3) Co-operation increasing very rapidly: In 1940 there were 364 co-operatives (against 167 in 1936) with 26,790 members; of these 214 were butter and cheese producers, 196 were purchasing agencies, 92 livestock sales agencies. Total sales were $14,389,622.72 (against total revenue of $213,116,000). Total purchases $12,582,847.02. (4) Farm credits (under Revised Statutes of Quebec 194 Chap. 113): A farmer whose debts exceed 65% of the value of his farm may borrow 75% thereof, provided his creditors accept this in full payment. A farmer establishing a new farm may borrow 75%. Interest is 3% per annum, plus 2.714% amortizing loan in 25 years. Total outstanding loans Dec. 31, 1941, were $43,602,262.

The department of agriculture includes director of services, chairman of council of services, head of administrative service (secretary of council), heads of agricultural economics. animal husbandry, horticultural service, each with subdivisions. The province is divided into 20 districts, in each of which there is a district agronomist with a staff of one agronomist for each county and a number of assistant and special agronomists with demonstration farms, etc. The province assists agricultural colleges.

Education.— Education in Quebec has three main branches (1) formal school system; (2) college and university system; (3) technical and special schools. There is a growing system of adult education.

(1) Formal system—under control partly of government, partly of committees. Superintendent of education (appointed by the government) is chairman of a council of education which does not sit as such but is divided into a Catholic and a Protestant committee, each with its secretary (a deputy minister). The Catholic committee includes all Roman Catholic bishops, an equal number of laymen, and some additional members. The Protestant committee has half the number of members and a number of associate members. In virtue of sec. 93 of the B.N.A. act the Protestant committee has sole control of the curriculum in, and recommends all government grants to, Protestant schools. The Catholic committee deals likewise with Catholic schools. Under jurisdiction of the committees are (a) Catholic elementary, complementary, intermediate and high schools, colonization area schools, and Catholic high schools; (b) Protestant elementary, intermediate and high schools. With the universities each committee controls normal schools. There are a few private schools (English-speaking). In school municipalities (erected and divided by the government), commissioners are elected by majority (Protestant or Catholic) and trustees by minority. In large cities there are two sets of commissioners. These finance schools and pay teachers.

(2) The college and university system is independent of government control except where agreements exist: (a) 32 classical colleges (Roman Catholic) with about 10,000 pupils give an 8-year arts and science course leading to a university *baccalaureat.* Convent schools train a large number of girls. Sir George Williams college (Y.M.C.A.) gives a degree course; (b) McGill university (non-sectarian), Montreal and Ste. Anne de Bellevue, have arts and science, professional and graduate faculties. Three Protestant theological colleges are affiliated. Bishops' university (Anglican) at Lennoxville, mainly residential, gives several degree courses. Laval university, Quebec, and Montreal university, with several affiliated schools, provide many branches of professional training.

(3) Technical and Special Schools. Under the department of the provincial secretary, affiliated to universities for standards and degrees, are the School of Higher Commercial Studies, Montreal, with a theoretical and practical curriculum; schools of fine arts at Montreal and Quebec; Polytechnic school, Montreal (university level); School of Tourism. Also, not affiliated, 9 technical schools, 70 schools of arts and manufactures, 1 school of furniture, 5 deaf, dumb and blind schools, 1 school for mental cases. Under the department of agriculture are 3 superior, 5 intermediate, 5 juvenile (orphan) schools, 1 dairy school, 201 domestic science schools. Departmental schools exist for mines, fisheries, forestry, domestic arts (statistics for 1940–41).

(4) Adult Education is carried on in 5 housekeeping schools, 90 night schools, 66 dressmaking schools, by McGill university in Montreal and rural areas, by department of education and Canadian Legion educational services.

Forests.—Quebec forests are the most important asset of the pravince. By a 1939 calculation the net value of Quebec forest products was $101,755,803 out of a Canadian total of $271,723,416.

The total forest area covers about 262.300 sq.mi. of which 153,231 sq.mi. are still in the hands of the crown. Of the balance, 75,369 sq.mi. are leased and 26,580 sq.mi. are privately owned. Varieties are spruce, balsam fir, white pine, red pine, jack pine, hemlock, cedar (white and red), tamarack, birch, maple, basswood, elm, ash, white birch, aspen, poplar, oak (white, red, burr), butternut, cherry, beech, walnut, hickory. Control is by the department of lands and forests.

Mineral Production.— Mineral production is characterized by very rapid recent growth owing to the rediscovery of copper (known to the Indians and described by them to Jacques Cartier in 1535) in Abitibi and the finding of gold in the same district. The region as known stretches about 120 mi. east from the Ontario border about the northern line of the Canadian National railway and varies from 10 to 40 mi. in width. A considerable group of modern cities and towns (Rouyn, Noranda, Amos, Val d'Or, Duparquet, LaSarre, etc.) has developed in consequence. As a world producer Quebec takes first place in one article only, asbestos of the serpentine type which exists throughout the Appalachian region. The main production is concentrated southeast of Montreal (Thetford, Black Lake, Asbestos). In 1940 the production was 346,805 tons valued at $15,619,815, about 60% of the world total, mainly shipped to the United States as raw material. In value gold was in 1940 of first importance accounting for $39,122,257 out of a total mineral production of $86,418,934.

Power and Manufactures.— The development of manufactures has marched with that of hydro-electric power, now probably the most extensive per capita of population, having increased from 2,165,445 h.p. on Jan. 1, 1928, to 4,837,343 h.p. on Jan. 1, 1943. The Shipshaw plant near Arvida on the Saguenay is designed to add 1,000,000 h.p. in 1943. Partly because of this power supply, and partly because of favourable labour conditions, manufacturing returns grew from $158,287,994 in 1901 to $1,045,757,585 in 1939 when the main products and receipts were pulp and paper $103,564,981, nonferrous metals $86,005,322, cottons $49,176,421 (70% of Canadian total), tobacco, etc. $39,986,847 (85% of Canadian total), factory clothing $79,366,964, meat packing $36,007,706, petroleum products $33,329,907.

Transportation and Communication.— The St. Lawrence waterway forms a section of the shortest route between Europe and the central United States, furnishing deep water communication to Quebec's main ports, Montreal, Sorel, Three Rivers, Quebec and (via the Saguenay) Port Alfred. Montreal is one of the most important rail-water-air connecting points in North America and Quebec manufactures are largely based on transportation facilities. The development of aviation should not change the situation since Quebec is at the centre of a web of potential great-circle flying trade routes to areas of economic importance (*e.g.,* North and Central Africa). Air: Canadian Pacific Air lines provide local facilities along the north shore of the St. Lawrence (Montreal to Bagotville and Lake St. John points and to Blanc Sablon, north from Lake St. John and north from Seneterre) total about 1,500 mi. Other lines. Trans Canada Air lines, Montreal to Maritime provinces, Newfoundland, Ontario and west; Canadian Colonial airlines to New York; North Eastern Air lines to Boston. Montreal airport, headquarters of R.A.F. ferry command became of vital war importance in 1941. Rail: Canadian Pacific 1,629.6 mi. (total rail, Canada and U.S., 21,005 mi., total air and water under normal conditions about 180,000 mi.); Canadian National 2,901.3 mi. (total Canada and U.S. 23,556 mi.); Alma and Jonquieres 10.6 mi.; Canada and Gulf Terminal (east from Mont Joli) 38.1 mi.; Napierville Junction (connection to U.S.) 27.1 mi.; Nipissing Central (west from Rouyn-Noranda) 26.7 mi.; Quebec Railway Light and Power (east from Quebec) 25.4 mi.; Roberval & Saguenay 29.0 mi.; St. Lawrence and Adirondack (New York Central) 46.5 mi.; Temiscouata (south from Rivière du Loup) 69.4 mi. Water: Seagoing lines: (1939) Canadian Import, Canadian National, Canadian Pacific, County lines (German lines), Elder Dempster, Furness Withy, Hudson's Bay, Imperial Oil, American Pioneer, Constantine, Norwegian-American, Ellerman, Head, Scandinavian-American. Inland lines: Canada steamships, Clarke steamships, Paterson lines, and many small vessels. Roads: 1st class, 6,645 mi. built and maintained by the provincial government (department of roads), 2nd class, 11,098 mi.; 3rd class, 20,843 mi. built and maintained by the provincial and local authorities. After many years of experiment, difficulties caused by weather extremes have been largely overcome. The Quebec countryside has retained a picturesque and old-world aspect and this with its remarkable scenery makes the province a tourist centre.

Communications. Canadian Pacific, Canadian Northern and Canadian government telegraphs (latter designed for navigation messages in lower St. Lawrence), Bell telephone west of Quebec and a number of small connecting telephone companies. Through service is very good but local connections east of Matane are somewhat irregular. Marconi transatlantic beam terminals are at Yamachiche and Drummondville. Private short wave sets are under normal conditions used for messages to mines and other outlying points. Air mail is carried by Canadian Pacific Air lines to the north shore of the St. Lawrence below Quebec.

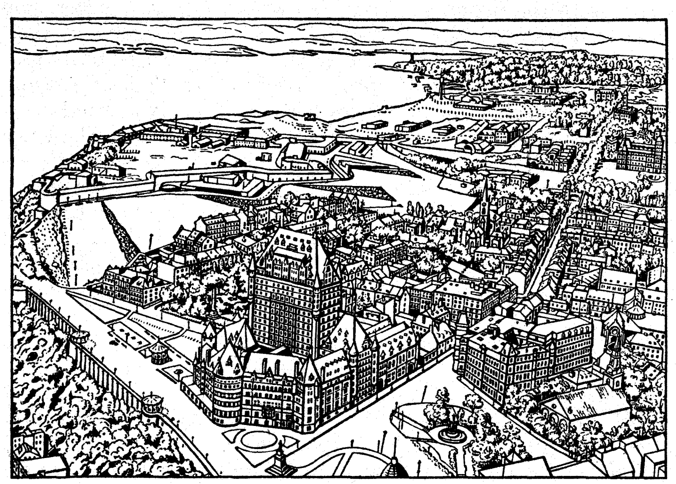
QUEBEC, the capital of the Canadian province of the same name, situated on the north bank of the river St. Lawrence, at its junction with the St. Charles, about 300 mi. from the gulf of St. Lawrence and 180 mi. by river northeast of Montreal, in 71° 12′ 19.5″ W. and 46° 48′ 17.3″ N. The origin of the name Quebec has been much disputed, but it is apparently the Algonkin word for a strait, or sudden narrowing, the river at its junction with the St. Charles being about 2,500 yards wide, but narrowing opposite Cape Diamond to 1,314 yards. Pop. (1941) 150,757.

Quebec is built on the northern extremity of an elevated tableland which forms the left bank of the St. Lawrence for a distance of 8 mi. The highest part of the headland is Cape Diamond, 333 ft. above the level of the water, and crowned by the citadel; towards the St. Lawrence it presents a bold and precipitous front, while on the landward side and towards the St. Charles the declivity is more gradual.

The harbour of Quebec is spacious and deep enough for the largest ships, the new wharves near Wolfe's cove add much to the present accommodation afforded by the Louise basin; the harbour is closed by ice only three or four months in the year. Quebec has the largest dry dock in the world.

Quebec consists of an upper and a lower town, the two connected by steep, winding streets and by an elevator. Much of the lower town still recalls the older portions of such French provincial towns as Rouen or St. Malo; the streets, with one or two exceptions, are narrow and irregular, but it remains the principal business quarter of the city. In the upper town, where the streets are wider and well paved, are the better-class dwelling houses and public buildings, most of the churches, public parks and many retail shops. Beyond the citadel are the historic Plains of Abraham, now become the National Battlefields Park, where the British army in Canada in 1849 marked the spot where Wolfe fell by a simple, high column. In the Governor's Garden is the famous monument dedicated to the two generals who fell in the battle, Wolfe and Montcalm. A point of much interest in the upper town is Dufferin Terrace, a magnificent promenade overlooking the St. Lawrence, 1,400 ft. long and 200 ft. above the level of the river.



BY COURTESY OF THE CANADIAN PACIFIC RAILWAY

QUEBEC. SHOWING A VIEW OF THE UPPER TOWN

The old town, which resembles a French provincial town, lies below. The citadel, 333 ft. above the river, is seen to the left on the river front. In the foreground is the modern Dufferin Terrace with the Hotel Frontenac built in the style of a French Chateau

Part of this terrace occupies the site of the old Château St. Louis, which was destroyed by fire in 1834. Near by, and in full view of the river, is the Château Frontenac, erected by the Canadian Pacific railway on the model of an old French chateau. Nothing remains of the fortifications erected under the French régime. The present walls and the citadel, which covers an area of about 40 acres, were built in 1823–32. Since then several of the gates have been destroyed, and others rebuilt, but in other respects the walls are practically intact, and, though obsolete as fortifications, add greatly to the picturesqueness of the city. Between 186j and 1871 three forts were built on the Lévis side of the river, but were neither manned nor armed. Quebec's natural position still makes it one of great military strength, though depending on naval control of the sea and of the gulf of St. Lawrence.

Churches and Institutions. — Although almost nine-tenths of the population are Roman Catholics, there are several Protestant churches, among them the Anglican Cathedral, built in 1804. Of the numerous Roman Catholic churches the most noteworthy is the Cathedral, the Basilica, founded in 1647 and enlarged at various times, containing some valuable paintings and relics. Fire destroyed this in 1922, but it has since been rebuilt on the original model. Perhaps the most interesting, historically, is a church in the lower town, the Notre Dame des Victoires, erected in 1688, and named in honour of the defeat of Phips in 1690 and the shipwreck of Sir Hovenden Walker in 1711. Laval university, which receives its name from the first bishop of Quebec, who founded in 1663 a seminary for the training of priests, is under Roman Catholic control. It was instituted in 1852 by royal charter from Queen Victoria, and in 1876 received a charter from Pope Pius IX. It includes faculties of theology, law, medicine and arts, a library of over 130,000 volumes, a museum and a picture gallery. The Ursuline Convent, founded in 1641, possesses some good paintings and a number of relics, among them the skull of Montcalm. High schools and numerous academies are supported by Protestants under the dual system of education in the province. The Literary and Historical Society, founded by Lord Dalhousie in 1824, is the oldest chartered institution of the kind in Canada. The principal benevolent institutions are the Marine Hospital, the Hôtel Dieu, founded in 1639 by the Duchess of Aiguillon, and the asylum at Beauport controlled by the Grey Nuns. The provincial parliament buildings erected in 1878–1892, are set in extensive grounds and finely ornamented with statues. The seat of the lieutenant-governor is at Spencerwood, outside the city.

Commerce, Industries, etc.—Quebec owes its electric light, electric tramcars, and industrial plants to a plentiful supply of power from Montmorency Falls (268 ft. in height) and Shawinigan Falls. The climate is severe, but bracing, the mean temperature in winter being 10° and in summer 68°. The city returns three members to the Provincial House of Assembly and four to the House of Commons. Economically, Quebec was long the chief port of Canada; then followed years of reverses when Montreal became the shipping port. Recently increased railway facilities at Quebec, greater difficulty for larger ships reaching Montreal, the development of vast water powers near Quebec, all contribute to an improved commercial and industrial position for that city. The Quebec bridge, connecting the north and south shores of the St. Lawrence river at Cap Rouge, 9 m. from the city, was completed in 1917, aften ten years of work and two serious accidents to the structure. The completion of the bridge made possible the running of six railways simultaneously into Quebec from the south shore. The Canadian National Railway now has a line running into Quebec from Prince Rupert, thus affording a much shorter route from west to east; the Canadian Pacific also gives ample connection with other parts of the country. The industries of the city are largely determined by the two great natural resources of the province, forests and water power. The Anglo-Canadian Pulp and Paper Company recently opened what is claimed to be the most modern pulp and paper mills in the world; the power is from the Shawinigan Falls and the capacity will be 3,000 tons a week. Manufactures include machinery, cutlery, gunpowder, musical instruments, ropes, steel, boots and shoes.

In May, 1927, the first annual Canadian Folk Song and Handicraft festival was held at the Château Frontenac under the auspices of the National Museum of Canada, for the purpose of developing and preserving an appreciation of the old folk-music and arts and crafts of Canada.

History. — The first known white man to visit Quebec was Jacques Cartier, the French navigator, in 1535, who found on the site a large Indian village, called Stadacona. In July, 1608, the present city was founded, and named by Champlain. Its growth was slow, and in 1629 it had but two permanently settled families, with a shifting population of monks, officials and fur traders. In that year it was captured by the English under Sir David Kirke (1597–1656; *see* H. Kirke, *The First English Conquest* of Canada, 1871, reprinted 1908), but in 1632 it was restored to the French by the Treaty of St. Germain-en-Laye. In 1663 the colony of New France was created a royal province, and Quebec became the capital. In 1690 Sir William Phips, governor of Massachusetts, attempted to reconquer it with a fleet and army fitted out by New England, but was defeated by the French governor, Frontenac. In 1711 a great British expedition sent against it under Sir Hovenden Walker was shipwrecked in the gulf of St. Lawrence. and the French held possession till 1759 (*see* below), when it was captured by the British troops on the 18th of September, five days after the battle of the Plains of Abraham; it was finally ceded to Great Britain by the treaty of Paris in 1763. In 1775 the American generals Montgomery and Benedict Arnold attacked the city, but Montgomery was killed (Dec. 31, 1775) and Arnold was compelled to retreat in the following spring. From 1763 till 1791 Quebec was the capital of the province of Quebec, as then existing; from 1791 till 1841 the capital of Lower Canada; from 1851–55 and from 1859–65 the capital of the United Province of Canada, and since 1867 the capital of the province of Quebec as part of the Dominion. (A. P. Co.; W. S. Wa.)

Wolfe's Quebec Expedition, 1759.—Both in itself and also as the central incident of the British conquest of Canada, the taking of Quebec is one of the epics of modern military history. The American campaigns of the Seven Years' War, hitherto somewhat spasmodic, were, after Amherst's capture of Louisburg in 1758, co-ordinated and directed to a common end by that general, under whom James Wolfe, a young major-general of thirty-three years of age, was to command an expedition against Quebec from the lower St. Lawrence, while Amherst himself led a force from

New England by Lake Champlain on Montreal. Wolfe's column consisted of about 8,000 troops, and was convoyed by a powerful fleet under Admiral Saunders.

The voyage to Quebec was not the least hazardous phase of the expedition, for the currents and shoals of the St. Lawrence were notorious, and its achievement—due largely to the skill of Captain Cook, later famous as the discoverer—astonished the French. Vaudreuil, the governor, wrote: "The enemy have passed sixty ships of war where we dare not risk a vessel of a hundred tons by night and day." Wolfe disembarked on the Isle of Orleans, four miles below Quebec, on June 27. The defenders were commanded by Montcalm, a soldier whose character and abilities, like Wolfe's, need no comment here. The French were superior in numbers, but a considerable part of their force was irregular, and *morale* and discipline were indifferent. On the other hand their position was of great natural strength. Wolfe began the attack by seizing Point Lévis, and thence bombarding Quebec across the St. Lawrence. This, however, affected the main defences of the upper city but little, and they were protected from closer attack by the St. Lawrence and the St. Charles. The third side of the triangle was the "plains of Abraham," to which it was thought there was no approach from the river.

Trusting in this obstacle and in the guns of the city to control the narrow passage which led to the upper reaches of the river, Montcalm entrenched his army on the north shore just below Quebec, between the St. Charles and the Montmorency. Wolfe tried various baits to entice his opponent out of his fastness, but after wasting some weeks, he decided to cross the St. Lawrence 7 m. below Quebec and to fight his way to the city by the St. Charles side. But Montcalm's fortified posts spread out from Quebec through Beauport as far as the Montmorency, and this formidable obstacle checked the English advance at the outset. A mile to the west of Montmorency, there was a narrow strip of land between the river and the heights where the French had built redoubts. Wolfe now planned to land here with all the available grenadiers and part of a brigade hoping, by the capture of a detached redoubt, to tempt the French army down to regain it, and so bring on a battle in the open. Meanwhile two other brigades were to be ready to ford the lower reaches of the Montmorency and join him.

On July 31, the attempt was made, covered by the guns of several ships and by the batteries across the Montmorency gorge. But when the troops got ashore, the grenadiers rushed impetuously on the enemy's entrenchments without waiting for the main body to form up. As a storm of fire broke in their faces, a storm of rain broke on their heads, and the steep slopes, slippery with blood and rain, became unclimbable, as the muskets became unfireable. Realising that his plans had gone awry, Wolfe broke off the fight and re-embarked the troops. It was a severe set-back, and the French were proportionately elated. The Governor wrote, "I have no more anxiety about Quebec." Wolfe's fragile health gave way under the disappointment, and despondency set in in the English camp. But as soon as the young leader had recovered a little, he summoned his brigadiers and worked out a plan for attacking by the upper waters and the heights of Abraham. Access to the heights could be obtained, it was found, by a tiny cove (the Anse du Foulon, now called Wolfe's cove), from which a steep footpath led to the summit. It was no place for artillery, and even for infantry the climb was long and exhausting, but the attempt was made. If it seemed desperate, the annals of military history show that even the most hazardous indirect approaches have often succeeded where the easy direct approach has failed—because the former does not follow the line of natural expectation. Here, one favourable factor was that for some weeks British frigates and smaller vessels had been slipping past the guns of Quebec, as part of a scheme to cut off the French supplies from upstream. On September 3 Wolfe evacuated the Montmorency camp, and on the 5th, after concentrating his forces on the south shore, marched the bulk, some 3,600, overland up the river bank, and embarked them in the ships.

Each day the ships drifted up and down with the tide, perplexing the French command and wearing out their troops with ceaseless marching and counter-marching. At last, just before sunset on Sept. 12, Admiral Saunders with the main fleet drew out along the shore opposite Montcalm's camp below Quebec, and, lowering their boats to suggest a landing, opened a violent fire. This ruse admirably fulfilled its purpose of fixing the enemy, for Montcalm concentrated his troops and kept them under arms during the night—miles away from the real danger point. And while they were straining their eyes to detect the threatened landing, a lantern rose to the maintop of the *Sutherland,* miles up river, and 1,600 troops of the first division noiselessly embarked in their flat-boats. At 2 A.M. as the tide began to ebb, two lanterns rose and flickered, and the whole flotilla dropped silently down-stream, the troops in boats leading. Discovery was narrowly averted when a French-speaking officer twice replied to a sentry's challenge from the shore, his deception helped by the fact, of which deserters had told Wolfe, that the enemy were expecting a convoy.

The landing was safely made at the Foulon cove: a band of picked volunteers swarmed up the steep face of the cliff, and overpowering the French picket on the summit, covered the landing of the main body. Before dawn the army, reinforced by another 1,200 troops under Colonel Burton direct from the south bank, was moving towards Quebec. Wolfe had found, on the heights of Abraham, the open battlefield for which he had thirsted. Should he be beaten he was certainly in a desperate position, but he had sure ground for confidence in the quality of his own men to offset the French quantity in open battle.

Wolfe disposed his force in a single line—to gain the utmost fire effect, wherein lay his strength,—with his left thrown back to guard the inland flank, and one regiment—Webb's (the 48th)—in reserve. Montcalm, warned too late, hurried his troops westwards across the St. Charles and through the city. Wolfe's bait this time had succeeded, even beyond expectation, and Montcalm attacked before his whole force was ready, probably because part was pinned by fear of the threatened landing below Quebec.

The clash was preceded by an attempt of the Canadian irregulars and Indians to work round Wolfe's left, but if their fire was galling, their effort was too uncontrolled to be effective. About 10 A.M. the French main body advanced, but their ragged fire drew no reply from the British line, obedient to Wolfe's instructions that "a cool well-levelled fire is much more destructive and formidable than the quickest fire in confusion." He himself was shot through the wrist, but, wrapping a handkerchief round it, continued his calls to the men to hold their fire. At last, when the French were barely forty yards distant, the word was given, and the British line delivered a shattering volley, repeated it, and then, on Wolfe's signal, charged a foe already disintegrating. At the head of his picked grenadiers Wolfe was an inevitable target. A bullet penetrated his groin, a second his lungs, and he fell, unobserved by the charging ranks. A few minutes later he was dead. His dying words, when told that the enemy were on the run—"Now God be praised, I die happy,"—are historic. But the words preceding these are a finer tribute to him as a general—even on the point of death: "Go, one of you, with all speed to Colonel Burton and tell him to march Webb's regiment down to the St. Charles River, and cut off the retreat of the fugitives to the bridge."

In the city all was confusion, for Montcalm had been gravely wounded in the rout, and that night the wreckage of the French army streamed away up the river in flight. With the death of Montcalm and Townshend's energetic pressing of the siege, Quebec surrendered four days later. (B. H. L. H.; X.)

Sutherland, *The Province of Quebec* (Montreal, 1922); M. J. Pelton, *Natural Resources of Quebec* (Ottawa, 1923); Willa Cather, *Shadows on the Rock* (1931).

QUEBEC ACT, the title usually given to a bill which received the royal assent on June 22, 1774. This act extended the boundaries of Quebec to include much of the country between the Ohio and the Mississippi. The French inhabitants of the province were granted the liberty to profess "the religion of the Church of Rome"; the French civil law was established, though in criminal law the English code was introduced. Government was vested in a governor and council, a representative assembly not being granted till the Constitutional Act of 1791.

The granting of part of the western territory to Quebec, and the recognition of the Roman Catholic religion, greatly angered the American colonies. On the other hand, it did much to keep the French Canadians from joining the Americans in the coming struggle. The act is still regarded by the French in Canada as their great charter of liberty.

QUEDLINBURG, a town in the Prussian province of Saxony, Germany, on the Bode, near the northwest base of the Harz mountains, 12 mi. S.E. by rail from Halberstadt. Pop. (1939) 30,235. Quedlinburg was a fortress of Henry the Fowler about 922, its early name being Quitlingen. It joined the Hanseatic League. The abbey of Quedlinburg was founded by Otto the Great and it owned, at one time, a territory about 40 sq.m. in area. The abbesses ranked among the princes of the empire, and had no ecclesiastical superior except the pope. The town at first strove to maintain its independence of them, and to this end invoked the aid of the bishop of Halberstadt. In 1477, however, the abbess Hedwig compelled the bishop to withdraw, and for the next 200 years both town and abbey were under the protection of the elector of Saxony. In 1539 the townsmen accepted the reformed doctrines and the abbey was converted into a Protestant sisterhood. In 1697 the elector of Saxony sold his rights over Quedlinburg to the elector of Brandenburg. The abbesses, however, retained certain rights of jurisdiction, and disputes between them and the Prussian Government were frequent until the secularization of the abbey in 1803.

QUEEN, the title of the consort or wife of a king ("queen consort"), or of a woman who is herself the sovereign ruler of a State ("queen regnant"); the widow of a former reigning sovereign is a "queen dowager," and, when the mother of the reigning sovereign, a "queen mother." For the position of the queen in English constitutional law see CONSORT, and for her household see HOUSEHOLD, ROYAL.

QUEEN ANNE'S BOUNTY, the name applied to a perpetual fund of first-fruits and tenths granted by a charter of Queen Anne, and confirmed by statute in 1703, for the augmentation of the livings of the poorer Anglican clergy. First-fruits (annates) and tenths (decimae) formed originally part of the revenue paid by the clergy to the papal exchequer. The former consist of the first whole year's profit of all spiritual preferments, the latter of one-tenth of their annual profits after the first year, but the First Fruits and Tenths Measure 1926 has made provision for the extinction of *annates* and decimae in most cases and for their redemption in the remaining cases. In accordance with the provisions of two Acts (5 and 6 Anne, c. 24, and 6 Anne, c. 27) about 3,900 poor livings under the annual value of £50 were discharged from first-fruits and tenths. Since that date there has been a large mass of legislation dealing with Queen Anne's Bounty, the effect of which will be found set forth in a Report of a Joint Select Committee on the Queen Anne's Bounty Board (1900). (See TITHES.)

QUEEN ANNE'S LACE: see WILD CARROT.

QUEENBOROUGH, a municipal borough in the Faversham parliamentary division of Kent, England, in the Isle of Sheppey, close to the junction of the Swale and Medway, 2 mi. S. of Sheerness on the S.R. Pop. (1938) 2,919. Area, 2.2 sq.mi. A fortress, called Sheppey castle, existed from an early period guarding the passage of the Swale river. Queenborough castle was built about 1361 by Edward III, who named the town after Queen Philippa and made it a free borough, with a governing body of a mayor and two bailiffs. The town has regained its prosperity by the establishment by the railway company of a branch line from Sittingbourne in connection with a service of mail and passenger steamers to Flushing (Holland).

QUEEN CHARLOTTE ISLANDS, a compact group lying off the northern part of the coast of British Columbia, and forming part of that province of Canada. Pop. (1941 census) 2,335; area 3,780 sq.mi. It was named by Captain Dixon, who visited the islands in the "Queen Charlotte" in 1787. Although the islands promise to became important because of their excellent harbours, the discovery of good seams of bituminous coal (beside the anthracite already known), their abundant timber of certain kinds and their prolific fisheries, comparatively little settlement has taken place. The fisheries (largely halibut and herring) of Hecate strait, which separates these islands from the mainland and its adjacent islands, are wonderfully productive. There are also two whaling stations on the islands. Steamers run fortnightly from Prince Rupert to Queen Charlotte city. The natives, the Haida people, constitute one of the finest and most artistic races of the west coast of North America.

QUEENSBERRY, EARLS, MARQUESSES AND DUKES OF. The Queensberry title, one of the many with which the Scottish house of Douglas (*q.v.*) is associated, originated in the creation of SIR WILLIAM DOUGLAS (d. 1640) as earl of Queensberry in 1633. He was the eldest son of Sir James Douglas of Drumlanrig (d. 1616). His grandson WILLIAM the 3rd earl (1637–1695), was created marquess of Queensberry in 1682 and duke of Queensberry in 1684; he held many high offices in Scotland under James II. His son JAMES DOUGLAS, the 2nd duke (1662–1711), was the royal commissioner to the famous Scottish parliament which met in 1700, and just after the accession of Anne in 1702 he was made one of the secretaries of state for Scotland. In the latter part of 1703 he came under a temporary cloud through his connection with the Jacobite intriguer, Simon Fraser, Lord Lovat. Queensberry was deprived of his offices, but in 1706 he was again commissioner to the Scottish parliament; in this capacity he showed great ability in carrying through the treaty for the union of the two crowns. In 1708 he was created duke of Dover and marquess of Beverley. In 1709 he was appointed third secretary of state.

CHARLES DOUGLAS, the 3rd duke (1698–1778), who had been created earl of Solway in 1706, was lord justice general from 1763 until his death in October 1778. In 1720 he married Catherine, daughter of Henry Hyde, 4th earl of Clarendon; this lady, a famous beauty, although very eccentric, was the friend of many of the wits and writers of her day, notably of Gay, Swift and Walpole. Their two sons predeceased the duke, and when he died his British titles, including the dukedom of Dover, became extinct, but the Scottish titles passed to his cousin, WILLIAM, 3rd earl of March (1724–1810).

This William Douglas, who now became the 4th duke of Queensberry, is best known by his sobriquet of "Old Q." On the turf he was one of the most prominent figures of his time, and his escapades and extravagances were notorious. From 1766 to 1776 he was vice-admiral of Scotland, and in 1760 he was made a lord of the bedchamber by George III.; but later he was an associate of the prince of Wales, being removed from his office in the royal household in 1789. He died unmarried, and the dukedom of Queensberry and some of his other titles, together with his fine seat Drumlanrig Castle, now passed to HENRY SCOTT, 3rd duke of Buccleuch, in whose family they still remain; but the marquessate of Queensberry descended to SIR CHARLES DOUGLAS (1777–1837), the representative of another branch of the Douglas family, who became the 5th marquess. In his family the marquessate remained.

QUEENSLAND, a state of the Commonwealth of Australia, occupying 670,500 sq. miles (22·54%) in the north-east of the continent. A coast-line of 3,000 miles—after that of Western Australia the longest of any individual State—bounds it on the north from the Gulf of Carpentaria and on the north-east and east from the Coral Sea and the Pacific Ocean, Cape York Peninsula being the only outstanding feature of the horizontal profile. In the west the boundary runs successively with that of North Australia and Central Australia along long. 138° E., with that of South Australia along lat. 26° S. and long. 141° E. to the north-west comer of New South Wales. On the south the boundary marches with that of New South Wales along lat. 29° S., by the Upper Darling (Barwon-Macintyre-Dumaresq) rivers and the Macpherson Range to Point Danger. The waters and islands to the north of Cape York nearly to the coast of New Guinea, as well as the Great Barrier Reef, are included within the political boundaries. The maximum length (north–south) is c. 1,300 miles; the maximum breadth (east–west) c. 900 miles.

Physiography.—Physiographically the area falls into two main divisions, the eastern highlands and plateaux and the western plains and lowlands, each of these again containing two main elements. Lowlands occupy the north-west and south-west corner of the State, viz., a broad fringe round the Gulf of Carpentaria (*q.v.*) and irregular semicircles in the south-west and south, portions of the Lake Eyre and Upper Darling basins respectively. Mostly under 500 ft. above sea-level they are relieved here and there by low swellings (Grey, Beal, McGregor "ranges") and rise gradually eastwards as gently undulating country to levels of about 1,000 ft. They consist superficially mainly of younger (Cretaceous–Tertiary) rocks covered in the lower parts by spreads of (flood) alluvium and the Great Artesian Basin (max. bore-depth 7,000 ft.) underlies practically the whole, and also extends beyond them (*v. inf.*). Between the Gulf and the interior plains a broad swell or saddle (500–1,000 ft.) of older (Palaeozoic) rocks — the Selwyn and Kynuna highlands — connects the eastern highlands with the Barkly Tableland (North Australia) and the great tableland of Western Australia and brings valuable mineral deposits near to the surface. Eastwards the lowlands merge gradually into highlands which occupy the eastern two-thirds of the State. They consist of: (a) A broad belt of uplands and plateaux (upwards of 1,000 ft.) due partly to up-warping of the crust or, where they are higher, usually to great basalt flows. Cape York Peninsula is flanked along the east by a low sandstone-capped ridge which mounts southwards. From its south-eastern corner the main belt begins and runs southwards to about Charleville, Roma, and the south-eastern corner of the State. (Cf. the basalt Darling Downs.) OP the few parts which rise above 2,000 ft. (*e.g.,* Clarke Range; Buckland Tableland) the most noteworthy is the Atherton Plateau in the north-east, where an area of c. 15,000 sq. miles all over 2,000 ft. rises eastwards to over 4,000 ft. (Mount Bartle Frere, 5,438 ft.) and falls abruptly upon the coast. This belt now forms the main watershed. (b) Along the coast runs a line of granite masses — and in the south-east a series of volcanic (Tertiary) cones (Peak Range and Glasshouse Mountains) — which are the relics of a former range and earlier watershed now largely broken down and submerged. For the remarkable eastern and north-eastern coast of Queensland, with its islands, rock promontories, north-south inlets, sunken plains, and the beauty, amounting sometimes to grandeur, of its mountain-buttressed sounds, is due to a series of vertical movements, in which subsidence has on the whole predominated, and which have cut transversely across the former relief. Thus the Great Barrier Reef (*q.v.*) has probably been built upon the submerged edges of the former land-mass, while the flat shorelines and low shelving plains of the Gulf of Carpentaria (*q.v.*) are apparently due to elevation. In this surface, not itself naturally rugged except along the east, the coastward-draining streams are excavating considerable basins, eroding out gorges, sharpening residual highland strips into "ranges" and introducing a scenery of wild and broken upper scarplands, roomier and richer lower valleys and, often, silt-choked deltaic plains. The natural drainage of Queensland, which includes many fine streams, is of four main types: the Gulf, the eastern coast, the Darling (Barwon), and the Lake Eyre (Eyre, Cooper's, etc., Creeks, Diamantina, and others). The subject has been referred to under AUSTRALIA: Drainage, and, broadly speaking, only the streams of the two first types-are perennial and of much economic value. On the other hand, practically the whole of the interior south-west of a line from Normanton (Gulf of Carpentaria) to Warwick (except a semicircle westwards from Cloncurry) — in all 376,000 sq. miles or 56% of the State — is underlain by the water-bearing beds of the Great Artesian basin, of which some 50,000 sq. miles of "intake" beds are exposed along the eastern highlands and are thought to receive seepage and soakage from that source. Water is struck at depths varying from 10 ft.–7,000 ft. and the 1,362 flowing wells (1926) yielded nearly 292 mill. gal. a day, besides which some 1,800 other wells yielded "sub-artesian" or pumped supplies. In the nine years 1914–23 the yield of the Queensland wells diminished by 4.6% per ann. or, averaging the yield with the number of bores, 6% per ann.

QUEENSLAND ABORIGINES. THROWING BOOMERANGS

Climate. — With 359,000 sq. miles (·535) of her territory north of the tropic of Capricorn, Queensland has a warm to hot climate — a mean ann. temp. of over 70° F everywhere in the south-east. Temperatures naturally increase northwards and north-westwards, while the range of temperature increases inland. Thus, in the south, the coastal parts have av. ann. temps. of 85°–45° F, the interior 93°–41° F, northern coastal 88°–58°, northern interior 96°–51° F. Frosts, though not universally common, are liable to occur during 5–7 months or more in the south-east and during decreasing periods further west and north-west. The rainfall, which tends to show a summer max. increasingly towards the north and the interior, varies between wide limits both in average and in annual amounts. Most of it comes from the ocean lying to the east and north-east and the seaward parts of the Atherton Plateau are the wettest in Australia, having an average fall of 144–165 in. with not uncommon falls of 200 in. and over, and at various other parts along the east and north-east (Cape York Peninsula; Mackay, and in the extreme south-east) averages of 60–70 in. are found. The whole of Cape York Peninsula and most of the eastern highland fringes and river-basins average 30 in., but inland the amounts rapidly fall off to less than 10 in. in the south-west (Birdsville: 6.4 in.). The fall is also mostly unreliable, very heavy falls alternating with relative scarcity. Thus over the inland and Gulf portions of the State (534,680 sq. miles), while the mean ann. fall is 19·9 in., the actual yearly average: varied (1888–1913: 26 yr.) from 9 in. to 33.3 in., and even the coastal areas (135,820 sq. miles), with a mean ann. fall of 52·3 in. ranged during the same period from 26.85 to 73.4 in. (Cf. Harvey Creek: 254.8 in.–So. j in.) The effect of these conditions upon river flow, vegetation, and economic conditions in general is such that special precautions and provisions are necessary to secure stability. Along the lowlands of the coast the heat is humid and, to those unaccustomed to it, uncomfortable. The interior, though often hot and trying — Boulia has had as many as 76 consecutive days with shade temperatures over 100° F — is not unhealthy. From Dec.–April (mainly) the coastal parts are liable to hurricanes — an average of one or two a year. They come mainly from the east, but sometimes from inland, and may work considerable destruction. (For further climatic details *see* BRISBANE, ROCKHAMPTON, TOWNSVILLE, CARPENTARIA, GULF OF. For vegetation and fauna *see* AUSTRALIA.)

Population, Settlement **and** Development. — The population of Queensland — 947,789 in 1933 plus some 17,700 aboriginals and half-castes — represents a density of 1·41 per sq. mile, after Western Australia and the Northern Territory the lowest in the Commonwealth, and males show an excess over females of 5·57%. In the 1926 census her birth-rate (22·58 per 1,000) came third after that of Tasmania and New South Wales, her death-rate (9.39 per 1,000) is relatively low, and her rate of increase has been consistently high in recent years (1921–26: 2·81%, the highest in the Commonwealth). Settlement varies in different areas, and about two-fifths of the population is concentrated in the south-east. A large part of the remainder is contained in individual areas spaced out along the east coast up to and including the Atherton Plateau, with centres Maryborough, Rockhampton, Townsville, Cairns, etc.; settlement in the south and centre is spreading westwards along the main railway lines; nearly 23% of the State is unoccupied, and a much greater proportion has a negligible population density. Geographically the following areas may be distinguished: (i.) the great plains and downs of the central west and north-west interior with their almost exclusively pastoral occupation; (ii.) the eastern highlands, with some outliers — notably that of the Cloncurry area in the north-west — with hitherto mainly mining but also pastoral industries; (iii.) the south-east districts with an expanding and intensifying mixed agricultural and dairying régime, as well as mining and some manufactures; (iv.) the eastern coastal lowlands with prevailing sub-tropical to tropical agriculture, some dairying and timber-cutting; (v.) the coasts with their harbours, ports, trade and commerce, besides some manufacturing and fishing interests.

The pastoral industry is by no means confined to the interior plains. Some of the largest cattle-stations are in the coastal belt, and many sheep are kept as an element in the mixed-farming areas of the south-east. Queensland is pre-eminently the pastoral State, itself, in certain respects, a sign of youthful development. Droughts, though often fairly local, cause severe fluctuations: thus in 1926, 31·64% of the total number of sheep was lost, 4,500,000 head (84.4% of the total loss) through drought, the remaining losses being due to disease, dingoes and natural causes. The state of the cattle industry also gives cause for concern. (See AUSTRALIA.) Yet Queensland had (1926) 460,000 sq. miles (296,000,000 acres—68·6%) of her total area occupied for pastoral purposes (cf. 1921: 313,000,000 ac.—73·7%) and the value of her pastoral products (1926: £21,118,000) is greater than that of any other State. Artesian water (*v.* p. 842) has worked a revolution, 4,325 bores (440 Government; 3,885 private) serve an area of 8,300 sq. miles (2,300 miles of "drains") and supply c. 290,000,000 gal. a day.

Sheep, nearly all merinos, have varied in recent years between 20,000,000–16,000,000 (1926: 16,861,000), c. 20% of the Commonwealth's total, second only to New South Wales. Holdings ("runs" or "stations") are still often large: the largest was (1923) c. 5,000 sq. miles, and holdings of under 60,000 ac. are called "grazing farms" or "selections," but the tendency is towards smaller and more-intensively managed units. In 1926 there were 4,860 owners of holdings having an average flock of 3,470 head apiece.

Cattle, which average 5,500,000–7,000,000 head (1926: 5,465,000, including 611,000 dairy cattle), represent 48% of the Commonwealth's total, Queensland leading easily in this respect. Cattle (for slaughter) have a much wider range than sheep, thrive in the hot and humid north and east coastal districts, but are more dependent on ample food and water supplies—the drought of 1925–26 caused the loss of c. 1,000,000 head—and do not pay so well as sheep. There were (1926) 45,000 cattle owners with average herds of 122 each, but much larger holdings and herds exist in the eastern coastlands and in the north-west (10,000–50,000 head). (See CARPENTARIA, GULF OF.)

Of the total pastoral production (1925–26: £21,118,000) wool represented nearly £11,000,000 (c. 159,000,000 lb.; 1927: c. 115,000,000 lb.); live stock slaughtered (cattle, sheep, goats, rabbits), £10,124,500 (339,350,000 lb., of which about 210,000,000 lb.—247·25 lb. per caput—were for home consumption). (For chief towns and settlements: v. p. 844, TRANSPORT.)

(ii.) The ancient rocks of the Eastern Highlands, with the outlying area in the north-west (Cloncurry, etc.) contain the bulk of the State's mineral wealth. The gold, copper, and silver output has declined (1926). On the other hand the output of tin (1926: £174,000) was maintained, while that of coal is steadily rising (1921: £831,000; 1926: £1,100,000 nearly), and these, with lead (c. £116,000) make the bulk of the total production of minerals and quarry products (1926: £1,608,000). Tin is worked in the district behind Cooktown (north), at Stanthorpe (south-east), and at Kangaroo Hills near Townsville (1926: £31,500), but the mineral fields of the Atherton Plateau behind Cairns (*q.v.*), notably those of Herberton (120 miles), are the most productive. Coal is scattered over the eastern highland belt. The seams at present (1926) mainly worked are those of the Ipswich (650,000 tons); Bowen (175,000 tons); Wide Bay (Burrum, Maryborough, *q.v.*) (110,000 tons); Darling Downs (105,000 tons); with smaller amounts from the Blair Athol (Clermont), Rockhampton, Mount Morgan, Bundaberg and other districts. Queensland coals have a great range of variety and utility—anthracite (Dawson-Baralaba field) to bituminous (Ipswich), and the reserves are 412,000,000 tons actual, 2,201,000,000 probable. The State owns and works coal mines on the Bowen, Baralaba, Styx River and Mount Mulligan fields, besides mineral-testing batteries and drilling plants in various mining areas. An opal field of value exists at Anakie (Rockhampton–Longreach railway) east of Emerald (1926: £6,800) and other gems (sapphires, etc.) occur.

(iii.) The South-eastern portion of Queensland—*i.e.*, the area contained approximately south and east respectively of the air-lines Gympie to Roma and Roma to Warwick—being relatively cool, in parts elevated, and easily accessible from the coast, is on the whole the most progressive and rapidly developing portion of the State. Here is the Brisbane basin, a fertile lowland, drained by a network of streams (rivers: Brisbane, navigable for light craft to Ipswich, Logan, etc.), open to the sea but enclosed elsewhere by highlands (2,000–3,000 ft.), with ample rainfall (30–70 in. and upwards), coal reserves (v. sup., Ipswich field) capital city and leading port, and excellent commercial position. Along the coast are further fertile and well-watered lowlands, possessing in addition attractive scenery (Glasshouse Mountains) and seaside resorts (Southport; Coolangatta); while further inland (Dalby to Roma), are good wheat and fruit-growing soils and climate which merge into the more purely pastoral western interior. Here, therefore, is the most highly and rapidly growing population, with the bulk of the State's dairying, arable agriculture (including all the wheat-growing), and manufacturing industries, in addition to a fair proportion of the production of minerals (v. sup.) and temperate and sub-tropical climate fruits. Purely pastoral industries, along with large holdings, are yielding to closer settlement and to mixed (including wheat and sheep) farming. There were, 1926, 28,250 agricultural farms in the State, with an average of 45.6 ac. each. The total area which is cultivated in Queensland is relatively small: (1926) 1,278,000 ac. —of which 550,000 ac. was cultivated grassland—or only 0·55% of the total occupied area and 0·25% of the area of the State. Partly this is due to the fact that development is recent but partly to uncertain rainfall (v. p. 842: Climate) so that the figures of annual production show remarkable variations. In dairying Queensland ranks third after New South Wales and Victoria, with 612,000 head of dairy cattle yielding 132,000,000 gal. of milk per ann. The Brisbane Basin (Beaudesert, Ipswich, etc. areas) the Wide Bay (Gympie) district, and the Darling Downs (Toowoomba, Warwick, and other districts) lead in production and associated are butter and cheese and preserved milk manufacturing (50–60,000,000 lb.; 9–12,000,000 lb.; 6,500,000 lb. per ann. respectively), bacon-curing (16–18,000,000 lb.), besides poultry and bee-keeping. Of cultivated crops, maize is most generally suited to the climate and is widely grown (135,000–150,000 ac., 2–3,000,000 bu. per ann. competing with New South Wales for first place; av. yield 22 bu.). Dairying and maize cultivation are extending all up the east coast, but wheat is confined to the 10–15 in. winter (April–Oct.) rainfall areas of the Darling Downs and westwards as far as Roma. The amount and yield varies widely according to season (55,000–185,000 ac.; 380,000–2,000,000 bu.; 1927: 3,700,000 bu.; yield 5–18 bu. per ac.). Some wheat may in future be grown in the summer-rain areas further north (*e.g.*, Emerald district), but other cultures will probably always limit production. Fodder crops (hay, lucerne) and potatoes are of some importance, while fruits-bananas, pineapples (v. p. 844), but mainly citrus, grapes, etc. (*e.g.*, Roma)—and "northern" varieties in cooler areas (*e.g.*, Stanthorpe) are widely grown. Queensland's total agricultural production is valued at £12–13,000,000 (1926: £12,553,000), or without sugar and tropical fruits, £4,670,000. Dairy production (raw products only) is valued at £6,380,000, giving a total of £11,400,000 for the raw agricultural products and fruit of the south-east area.

The eastern coastal highlands and scarps carry considerable areas of well-grown forests; in the north more of the tropical rain-forest (brush), further south more of the temperate rain-forest. Soft and hard woods—the latter mainly eucalyptus—occur, and in the south are large areas of pure eucalypt forests (*e.g.*, Gympie-Darling Downs; Macpherson Range). Timber-felling and sawmilling are carried on right up the coast but of the 250 sawmills in the State nearly 200 are in the southern districts and they produced (1926–27) 104,000,000 cu.ft. of sawn timber and sleepers (£2,070,000), over half being pine, one-third hardwoods, the remainder including "cedar," "oak," silkwood, silky oak, etc. The total Queensland output of dressed timber (1925–26) was valued at £1,580,000, besides £860,000 firewood, etc. The State Forest Service holds in working trust 5,200,000 ac. timber reserves and dedicated forests, besides 156,200 ac. reserved as National Parks. In addition *c.* 34,000 ac. of plantations or cultivated forest areas had (1927) been created.

(iv.) The Coastal Lowlands, though they consist of a series of individual and more or less independently developed units—the main coast railway-line now complete from Brisbane to Cairns will assist in drawing them together—have many common features in virtue of their physical composition (rough highland interior., river basins, rich alluvial lowlands, coast-lines, estuarine or rock-sheltered deep-water harbours, hot humid climate). Thus their present by no means fully developed economy is capable of summary survey, and for further details reference may be made to the towns mentioned below. In many respects the Brisbane area also can not be distinguished from its northern analogues. Cattle (v. p. 843), and to an increasing extent dairying even as far north as Cooktown, are common to nearly all—the former naturally more and more restricted to wilder and rougher ground, the latter to richer workable ground within reach of factories and markets. Mining has already been dealt with, the most important area at present being that of the Atherton Plateau, based upon Cairns (*q.v.*). Timber, in some cases a by-product of settlement, is sawn in 50 mills—19,200,000 cu.ft. (£515,000), noteworthy being the 12,500,000 cu.ft. of softwoods from the northern districts, in particular the Atherton Plateau. Along the east coast very poor areas alternate with others having extremely rich soils. The agricultural products at present commonly associated with the latter areas are sugar, tropical fruits, and, more recently, cotton, though the cultivation of ground-nuts or peanuts (1926: 775 tons) and tobacco is developing and others again (*e.g.,* coffee) are physically, if not at present economically, possible. Large possibilities, for dairying no less than for agriculture, lie by way of irrigation for which climate, soils, river régimes, and commercial situations are peculiarly favourable. In 1926, *c.* 38,000 ac. were under irrigation in Queensland, the Dawson River being by far the most important area under development (see ROCKHAMPTON) ; further the Burdekin River (Inkermann area 5,000 ac., being extended to 10,000 ac.), besides numerous smaller undertakings.

Sugar is grown in rich bottom-lands with a high rainfall (40–60 in.). In 1926 *c.* 266,500 ac. were under cultivation for sugar (*i.e.,* other than fodder cane), of which 190,000 ac. were cut and yielded 2,926,000 tons of cane, valued at £6,355,000 (1927: 3,575,000 tons cane yielded 487,000 tons raw sugar). In sugar-production Queensland outdistances New South Wales (*q.v.*) the only other Australian producer, but her yields (15–20 tons cane per acre) are lower than those of New South Wales (34·2 tons). Of tropical fruits the chief are bananas (1925–26 15,000 ac.; crop valued at £750,000) and pineapples (4,000 ac.; £301,000), but mangoes and others have also some importance. "Mediterranean" fruits—oranges (1926: £116,000), peaches, apricots, etc., are extensively grown but perhaps mainly in the south-east of the State (v. p. 843). The banana industry is not free from serious insect pests the nature of which is being investigated. The sugar industry is conducted under fiscal and labour conditions which lend it a somewhat artificial appearance. (*See* AUSTRALIA.) Cotton-production, on the other hand, though physically possible over considerable areas, is less amenable to economic "hot-house" methods and the future of the industry, for which great hopes were entertained, is dubious. (1926: 18,740 ac. bearing, 9,060,000 lb. [unginned] cotton valued at £190,000; 1927: rather over 7,000,000 lb. unginned.)

(v.) To distinguish the coast of Queensland as a separate geographical entity is not so artificial when it is remembered that much of the manufacturing industry, as well as of trade and commerce is concentrated in the ports; that the last-named is conducted by means of shipping or over railway systems based upon the ports, and that these play an at present altogether major part in the general development of the State. Fisheries (see AUSTRALIA and BARRIER REEF) are mainly for pearl, turtle, trochus shell, and the total ann. value of all products (1925–26) was £420,000. There are two State fish-supply establishments (turnover 1926–27: £45,000). Manufactures are mainly those concerned immediately with the working up of raw materials—the making of butter, cheese, preserved milk, jams, etc.; bacon-curing, meat-freezing and preserving; tanning; sugar-crushing; saw-milling; smelting, etc. They are naturally located where circumstances demand, *e.g*, smelters at Cairns; sugar-crushing mills: various cane-centres, *e.g.,* Mackay; meat-works mainly near ports. Ipswich and Toowoomba, and other towns possessing coal, have developed important railway engineering or repair works, while most towns, according to their development, have a variety of minor industries. Brisbane (*q.v.*), however, is by far the greatest centre: of the total number of factories in the State (1926: 1,897) with an output (crude value added by process) of £18,135,000, Brisbane has 677 factories with output £17,225,000.

The total value of Queensland's production—primary and manufacturing—is estimated (1925–26) at £63,243,000 or £73·44 per head of population; the (corrected) index number during the decade 1916–26 having varied between 1·046 (1924–25) and 0·939 (1925–26) of the production in 1911. (*Cf.* Commonwealth as whole: 1925–26: 0·950.)

Trade was valued (1926–27) at £28,219,000 (*cf.* 1925–26: £40,158,000—variations being due mainly to bad seasons), of which exports represented £14,721,000 (£16 13s. 9d. per caput) and imports £13,498,000 (£15 6s. od.), these figures representing "overseas" trade only, though interstate trade amounts perhaps to about as much again. The chief items of export were wool (£8,500,000); sugar (£1,638,000); dairy products (£1,625,000); meat, excluding bacon (£1,460,000) ; hides, leather, tallow, rabbit-skins (£1,013,000)—total pastoral: £10,872,000; total agricultural and dairy: £3,348,000; mineral: £34,200. The chief ports, in order of importance are (1927): Brisbane (total overseas trade: £23,496,000); Townsville: £1,547,000; Cairns: £1,227,000; Rockhampton: £761,000; Gladstone: £411,000; Mackay: £330,000 (*qq.v.*).

Of interest are the State (Queensland Government) trading and other enterprises which besides mines, batteries, drilling plants (*see* p. 843, section ii.) included (1927) 5 saw-mills (net capital value: £82,000); 14 cattle stations (total stock: 212,000); 112 retail trading establishments and agencies with a turnover of £1,100,000, in addition to the State services (including railways) usual in Australian States. The State public revenue was (1927) £18 6s. 1d. per caput and expenditure from revenue £18 13s. 10d.

Transport in Queensland ranges from the camel train and bullock-waggon of the pioneer to railway and motor traction and air transport. Motor-cars are, as elsewhere on the great plains of Australia, working a revolution, but a still greater is being worked by the aeroplane. Queensland "squatters" have shown great enterprise in the use of aeroplanes, not only for personal use, but also for the conveyance of fodder to drought-stricken herds. Official air-services covered (1926–27) 164,000 miles with the loss of 4 persons killed and 1 injured. The most important line is that linking the terminals of the 3 main railway systems—Charleville, Longreach, Cloncurry, with Mount Isa, Cammooweal and, by recent arrangement, continued to North Australia (825 miles in all). In the "bush," roads are mainly dirt tracks, liable to floods and "washaways" in wet seasons. There were (1927) 5,150 miles of gazetted roads in the State and 60,877 motor vehicles. Of railways, besides 302 miles (1925–26) of private (light) lines serving cane-fields, mines, etc., there were (1926–27), 6,300 miles (3′ 6″ gauge) Government lines. The main systems are based upon the ports, viz., Brisbane: with a fairly well-developed "branch-work" of lines serving the Brisbane Basin, the Darling Downs, and longer trunk lines serving the pastoral interior, south-west to centres such as Goondiwindi and Dirranbandi (416 miles), west to Roma, Charleville (483 miles), Quilpie (608 miles) and Cunnamulla (*c.* 600 miles); Rockhampton (*q.v.*), in addition to a local "branchwork," has a main trunk system serving the pastoral centres Emerald (branch lines to Blair Athol 240 miles, Spring-sure 206 miles), Barcaldine (361 miles), Blackall and Yaraka (476 miles) and Longreach (428 miles), with extension under construction to Winton and Elderslie; Townsville, a similar trunk-line to Charters Towers (83), Hughenden (236), Winton (368), Cloncurry (481), itself a centre for a branching system serving the mining area (Dajarra, 582 miles); Cairns likewise serves as a base for the Atherton Plateau and Forsayth lines into the interior. The main coast line links Brisbane with all the coast towns as far as Cairns, and Brisbane itself is linked with Sydney via Warwick—Stanthorpe—and Tenterfield (New South Wales). The new "direct" route (standard gauge: 4′ 8½″) is under construction from Warwick to Kyogle (New South Wales). In addition various ports (Bundaberg, Cooktown, Maryborough, Normanton, etc.) have smaller sections of local lines. It is proposed to join the western termini of the great inland lines by a transverse south-east-north-west line which will probably be continued via Camooweal and the Barkly Tableland to Daly Waters (North Australia, *q.v.*) thus linking this territory as well as the northern and north-western portions of Queensland with Brisbane and Sydney (the latter via Bourke, New South Wales). The capital cost of Queensland's railway lines (including lines not yet open) was (1926–27) £60,162,380 and the deficiency upon working for the year £1,964,-365. (See AUSTRALIA: Railways.)

Queensland has a well-developed post and telegraph system and in addition sub-marine cables from Southport to Vancouver Island via Norfolk Island, Suva, Fanning Island, thence overland to Montreal, etc.; also Southport to Sydney; and, in addition to services of regular overseas steamship lines, coastal shipping services plying up the east coast to Thursday Island, the Gulf of Carpentaria and Darwin (North Australia). (O. H. T. R.)

HISTORY

Explorers.—The Portuguese may have known the northern shore nearly a century before Torres, in 1605, sailed through the strait since called after him, or before the Dutch landed in the Gulf of Carpentaria. Captain Cook passed along the eastern coast in 1770, taking possession of the country as New South Wales. Flinders visited Moreton bay in 1802. Oxley was on the Brisbane in 1823, and Allan Cunningham on Darling downs in 1827. Sir T. L. Mitchell in 1846–47 explored the Maranoa, Warrego, and Barcoo districts. Leichhardt in 1845–47 traversed the coast country, going round the gulf to Port Essington, but was lost in his third great journey. Kennedy followed down the Barcoo, but was killed by the blacks while exploring York peninsula. Gregory, between 1855 and 1858, examined the Gilbert river and made his way right to Brisbane. Burke and Wills crossed western Queensland in 1860. Landsborough, Walker, M'Kinlay, Hann, Jack, Hodgkinson and Favenc continued the researches, and squatters and miners opened new regions.

Early History.—Before its separation in 1859 the country was known as the Moreton bay district of New South Wales. A desire to form fresh penal depots led to the discovery of Brisbane tiver in Dec. 1823, and to the proclamation of a penal settlement there in Aug. 1826. The convict population was gradually withdrawn again to Sydney, and in 1842 the place was declared open to free persons only. The first land sale in Brisbane was held on Aug. 9, 1843. An attempt was made in 1846, under the colonial ministry of Gladstone, to establish at Gladstone on Port Curtis the colony of North Australia for ticket-of-leave men from Britain and Van Diemen's Land. Earl Grey, when secretary for the colonies, after strong colonial representations, arrested this policy, and broke up the convict settlement. In 1841 there were 176 males and 24 females; in 1844, 540 in all; in 1846, 1,867. In 1834 the governor and the English rulers thought it necessary to abandon Moreton bay altogether, but the order was withheld. The first stock belonged wholly to the colonial Government, but flocks and herds owned by settlers came on the Darling downs in 1841. In 1844 there were 17 squatting stations round Moreton bay and 26 in Darling downs, having 13,295 cattle and 184,651 sheep. In 1849 there were 2,812 horses, 72,096 cattle, and 1,077,983 sheep.

Some settlers who sought a separation from New South Wales offered to accept British convicts if the ministry granted independence. In answer to their memorial a shipload of ticket-of-leave men was sent in 1850. In spite of the objection of Sydney, the Moreton bay district was separated from New South Wales by an Order in Council of May 13, 1859, and proclaimed the colony of Queensland. The population was then about 20,000, and the revenue £6,475.

The Constitution, which was based upon the New South Wales Act of 1853, provided for 16 electoral districts, with a representation of 26 members. A legislative council was also formed, to which the governor of New South Wales, Sir William Denison, appointed five members, holding office for four years, and Sir George Ferguson Bowen, the first governor of the new colony, eight life members. Robert (afterwards Sir Robert) George Wyndham Herbert was the first premier, and held office until 1866. The white population at the end of 1859 was 25,788, and exports were valued at £500,000. In the next six years the population was quadrupled and trade trebled. The first Parliament opened on May 29, 1860. In the same year a board of general education was established and State aid to religion abolished.

Gold mining is the foundation upon which much of the progress of the colony has been built. The Gympie field was discovered in 1867, Charters Towers and the Palmer diggings in 1872, and the celebrated Mount Morgan mine in 1881. In 1900, dredging the northern rivers for gold became an established industry. In 1924, Queensland produced 98,841oz. of gold, more than one-seventh of the Australian total.

Political History.—A resolution in favour of payment of members was carried in 1871. In the following year, electoral representation was increased to 42 members, and the first agent-general in London, Richard Daintree, was appointed. Railway building began in 1864, and in 1872 the Railways Act Amendment Act authorized the construction of railways by private enterprise, land being offered as compensation for outlay. This act was passed during the administration of A. H. Palmer, the only premier of importance during the period 1866–79.

On Jan. 21, 1879, Mr. (afterwards Sir Thomas) McIlwraith first became premier. The opposition was led by Mr. (afterwards Sir Samuel) Griffith, and the political history of Queensland from that date to 1893 is, in effect, the political biography of these two remarkable men. In 1881 Mr. R. L. Jack, the government geologist, introduced artesian well-boring, which contributed largely to the subsequent prosperity of Queensland. In 1883 in view of Germany's activities in the Papuan gulf the police magistrate at Thursday island was instructed by Queensland to proceed to Port Moresby and take possession of the unappropriated portion of the island in the name of the Crown. The step needed no justification when it is remembered that Papua lies nearer to Queensland than Tasmania to Victoria. This act was afterwards—to the indignation of Australia—repudiated by Lord Derby; and, eventually, under the Berlin Treaty of 1886, England and Germany entered into joint possession of that part of New Guinea lying east of 141°E. In 1887 the number of seats in the assembly was increased to 72 and the department of agriculture was established.

The first sugar crop was grown by the Hon. Louis Hope at Cleveland about 1862. From that date, Kanaka labour on the sugar plantations was a burning question in Queensland politics. After the defeat of Sir Thomas McIlwraith in 1883, on the issues of coloured labour and land-grant railways, Mr. Griffith formed his first administration. The period which followed was marked by labour troubles and financial difficulties. In Dec. 1884, a royal commission reported that many islanders had been deported by "force and fraud." In view of this report, the Griffith Government passed an act prohibiting the importation of Kanakas after 1890. The impending stoppage of Kanaka labour and the low price of sugar almost ruined the planters. In 1890 a financial crisis occurred. A coalition ministry with Griffith as premier and McIlwraith as treasurer was formed, and in 1892 Sir Samuel Griffith announced his conversion to the policy of continuing Kanaka labour on the sugar plantations and also of building land-grant railways. From this year there was no further State legislation on the subject of Kanaka labour; but, in 1904, the Federal Government prohibited the importatian of Kanakas, and by 1906 had deported most of those in Australia. Since then the industry has made progress under a system of bounties and excise tariffs. Sir Samuel Griffith, who had been chief justice in Queensland since 1893, afterwards became chief justice of the Federal high court, and played an important part in bringing Queensland within the Federation.

(See AUSTRALIA.)

The history of Queensland continued to be a story of industrial disputes and financial distresses. Ultimately Queensland became a stronghold of the Labour party, which was in power from 1915–27. The legislative council and capital punishment were both abolished in 1922. Two important acts were passed in the same year, the Primary Producers Organization act, which aimed at a united national organization of agriculture, and the Primary Products Pools act, which created boards to control all markets.

In 1927 the strike of the sugar-cane workers raised an issue of importance when it spread to the railway unions, but was defeated by the firmness of the premier, Mr. McCormack.

Queensland governments have passed various land acts, now in favour of the pastoralist, now in favour of the farmer, but on the whole in favour of the latter. Experiments in such legislation were made easy by the fact that the state held unalienated no less than 643,428 sq.mi. out of the total area of 668,497 square miles.

According to the census of 1927, 69% of Queenslanders were living in the country. Only Tasmania had a larger proportion of her population on the land.

The Queensland policy, unique in Australia, of developing a railway system from several maritime centres instead of from one capital city, may have helped to bring about this satisfactory result.

But it must not be forgotten that Queensland enjoys a uniform rainfall near the coast from Cooktown southward, and that she possesses 234,000 sq.mi. of territory having a rainfall of over 20 inches. (H. D. N.)

QUEENSTOWN, Australia: see TASMANIA.

QUEENSTOWN, Eire: see COBH.

QUEENSTOWN, a town in the province of Cape of Good Hope, Union of South Africa, in the upper valley of the Great Kei river, 154 mi. N.W. of East London by rail, 31° 53' S., 26° 52' E.; altitude 3,544 feet. Population 12,868. The town is the centre of a good wheat and wool-producing area. European pop. (1936), 6,723.

QUELIMANE, QUILIMANE or KILMANE, a town of Portuguese East Africa, in 18° 1' S., 36° 59' E., 14 mi. inland from the mouth of the river Quelimane or QuaQua (Rio dos Bons Signaes).

The river during the rainy season becomes a deltaic branch of the Zambezi, with which it is connected by a channel called Mutu.

There is ample and deep anchorage, but the entrance is obstructed by a bar, over which there is 9 ft. of water at low tide, and about 26 ft. at high water springs. The town (officially São Martinho de Quelimane) is unhealthy. There are 355 Europeans and 3,403 natives and Indians.

The trade of Quelimane, formerly the only port for the produce of the Zambezi valley, declined after the establishment of Chinde (*q.v.*), but of recent years the progress of agricultural and industrial development has been remarkable (see PORTUGUESE EAST AFRICA).

The town has telegraphic communication with the province, and telephonic communication with the interior. There is a wireless station.

It is the starting point of the railway to Mocuba, and a line runs to Maquival, a large *prazo* belonging to the Zambezia company.

The imports for the town are cotton goods, foodstuffs and hardware; exports are copra, groundnuts, sugar, sisal, cotton, sesamum and beans,

The Quilimane river was entered by Vasco da Gama in 1498, who there discovered an Arab settlement. The present town was founded by the Portuguese in the 16th century, and became in the 18th and the early part of the 19th centuries one of the great slave marts.

It was the starting point of Francisco Barreto's expedition to the country of the Monomotapa in 1569, and of David Livingstone's up the Zambezi to Lake Nyasa in 1861. Until 1853 the trade of the port was forbidden to any save Portuguese.

The European population, until the last quarter of the 19th century, consisted mainly of convicts from Portugal.

See Delagoa Bay Directory (annually), and South and East Africa Yearbook Guide (annually).

QUELPART (CHAI-JU), an island to the south of Korea, used as a Korean penal settlement. It measures 40 mi. from east to west and 17 mi. from north to south. It rises gradually from the seaboard, is heavily wooded and is cleared for cultivation to a height of 2,000 ft. There are several crateriform hills, and Hali San (Mount Auckland) has an altitude of 6,558 ft. The island is entirely volcanic, and the soil is finely disintegrated lava.

The estimated population is 115,000, Korean by race, language and costume. There are about ninety villages. The valleys and slopes are carefully cultivated in fields divided by stone walls. Apart from agriculture, the industries consist in the manufacture of fine bamboo hats and mats, and wooden combs for export and local use. For fishing the islanders use double-decked raft boats. similar to those of southern Formosa. Their lucrative pearl fisheries have been practically monopolized by the Japanese, who use proper diving apparatus. A valuable product is a species of clam, the shell of which furnishes a specially iridescent mother-of-pearl, which the natives barter with the Japanese for inlaying lacquer. European goods are not imported, but Japanese articles find ready barter. There are no markets, and few shops.

Chu-sung, the capital and seat of government, a few miles from Port Pelto, has a black lava wall 25 ft. high, with three gates and towers; an imposing audience hall in Chinese style; and a great bell tower, with a fine bronze bell, sounded to drive off "evil dragons." Its population is estimated at 17,000. The governor has a hereditary antiquated army for coercive purposes.

There are no good harbours, and the only anchorage for large vessels is Tai-chung, or Yung-su, at the east end, with g to 13 fathoms of water. Pelto has ancient breakwaters for the protection of small boats, erected probably by the Mongol conqueror, Kublai Khan, who in 1273 built on Quelpart one hundred ships for the invasion of Japan.

QUENTAL, ANTHERO DE (1842–1891), Portuguese poet, was born in the Azores, and studied at the University of Coimbra. After the publication of one volume of verse, he joined the revolt of the young men which dethroned Castilho, the chief living poet of the elder generation, from his place as dictator over modern Portuguese literature. He adopted socialist opinions, worked as a compositor in Paris, though he had independent means, visited the United States, and then returned to Lisbon, where he worked actively for socialism. He found his way through a series of disappointments to the mild pessimism, a kind of Western Buddhism, which animates his later productions. His melancholy was increased by a spinal disease which. after several years of retirement, eventually drove him to suicide in his native island. Quental seldom attempted any other form of composition than the sonnet, but few poets who have chiefly devoted themselves to this form have produced so large a proportion of really exquisite work. The comparatively few pieces in which he either forgets his doubts and inward conflicts, or succeeds in giving them an objective form, are among the most beautiful in any literature.

His friend, Oliveira Martins, edited the sonnets (Oporto, 1886), supplying an introductory essay; and an interesting collection of studies on the poet by the leading Portuguese writers appeared in a volume entitled ***Anthero de Quental. In Memoriam*** (Oporto, 1896). The sonnets have been turned into most European languages; into English by Edgar Prestage (***Anthero de Quental, Sixty-four Sonnets,*** 1894), together with a striking autobiographical letter addressed by Quental to his German translator, Dr. Storck.

QUERCITRON BARK is the inner bark of Quercus *velutina,* a native of the middle and southern states of America. The exterior bark is removed from the tree by shaving, and the inner portion, which contains the colouring matter, is detached and ground. The colouring matter of quercitron bark is quercitrin, $C_{21}H_{22}O_{12},H_2O$, a glucoside which by hydrolysis with acid yields quercetin, $C_{15}H_{10}O_7$, and the sugar rhamnose, $C_6H_{12}O_5$. When quercitron bark is exhausted with hot water under pressure, the extract deposits a crude quercitrin, which is known commercially as "yellow flavine." A second variety known as "red flavine," prepared by digesting an extract of the bark at the boil with dilute acid, is in reality a crude quercetin. These products dye wool mordanted with aluminium and tin bright yellow and orange shades and were, at one time, used in admixture with cochineal for obtaining scarlets of a specially vivid character. For dyeing purposes in Great Britain quercitron bark has been supplanted by the less costly old fustic; in America, however, it replaces the latter. (A. G. P.)

QUERCY, a county in France before the Revolution. The district, which derives its name from the Gallic tribe of the Cadurci, was bordered by Limousin, Rouergue, Armagnac, Périgord and Agenais. In the middle ages it was divided into upper, or black, Quercy, and lower, or white, Quercy, the capital of the former being Cahors and of the latter Montauban. Its two other chief towns were Figeac and Moissac.

Early in the 6th century Quercy passed under the authority of the Franks, and in the 9th century, it was part of the Frankish kingdom of Aquitaine. At the end of the 10th century its rulers were the powerful counts of Toulouse. Later, the possession of the district was in dispute between the kings of England and France. In 1259 lower Quercy was ceded to England; in 1360 the treaty of Brétigny assigned the whole county to Edward III., but in 1440 the English were finally expelled. In the 16th century Quercy was a stronghold of the Protestants, and the scene of a savage religious warfare. The civil wars of the reign of Louis XIII. centred around Montauban.

QUERÉTARO, a city of Mexico, capital of the State of Querétaro, 167 miles by railway N.W. of the national capital. Pop. (1930) 32,585, including a large Indian element. Querétaro is served by the Mexican Central railway. The city stands on a plain at the foot of the Cerro de las Campanas, 6,168 ft. above sea-level. Among the important buildings are the cathedral (said to have been built originally about 1535, and subsequently restored at various times), the Iturbide theatre (in which occurred the trial of Maximilian). the Government offices, the Federal palace and the churches of Santa Rosa, Santa Clara and San Augustín. The Federal palace and the church of Santa Rosa are examples of the work of the celebrated Mexican architect, Francisco Eduardo de Tresguerras (1765–1833), who restored the church of Santa Clara also. The water-supply is brought over a fine aqueduct 5 m. long, dating from the 18th century. Among manufactures are cottons, woollens, pottery and ironwares. The city has one of the oldest and largest cotton factories in Mexico.

Querétaro occupies the site of an Otomie Indian town dating from about 1400. It was captured by the Spaniards in 1531 and was raised to the rank of a city in 1655. It was the scene of a revolutionary outbreak against Spain in 1810. In 1848 a Mexican congress met here to ratify the treaty of peace with the United States, and in 1867 Querétaro was the scene of Maximilian's last stand against the Republicans (under Escobedo) which resulted in his capture and execution on the Cerro de las Campanas north of the city. Querétaro was the seat of the convention which adopted the Constitution of 1917.

QUERÉTARO-ARTEAGA, a central State of Mexico, area, 4,433 square miles. The population for 1910 and 1930 was 244,663 and 234,058, respectively. The State belongs to the elevated plateau region, with its semi-arid conditions. The northern part is traversed from east to west by the wooded Sierra Gorda, whose spurs reach southward to the central districts. The central and southern parts are covered by plains, broken by low hills. The rivers are small and flow chiefly to the San Juan, a part of the Pánuco drainage basin. There are some small lakes and swamps, and a number of mineral springs. Indian corn, beans and considerable quantities of wheat are grown. Silver, gold, copper, mercury, lead, tin, antimony, precious stones and semi-precious stones like opals are found, in some cases in very rich deposits. The Mexican Central and Mexican National railways cross the south end of the State and afford transportation facilities for the agricultural districts, but the mining districts of the north are still dependent upon old methods. The capital of the State is the historic city of Querétaro (*q.v.*) with a population of 32,585 in 1930.

QUESNAP, FRANÇOIS (1694–1774), French economist, was born at Méré, near Paris, on June 4, 1694, the son of an advocate and small landed proprietor. He studied surgery at Paris, where he qualified as a surgeon, and in 1737 he was appointed perpetual secretary of the academy of surgery founded by François la Peyronie. In 1744 he graduated as a doctor of medicine, became physician in ordinary to the king, and afterwards his first consulting physician.

Quesnay is mainly remembered, however, for his work as an economist. About the year 1750 he became acquainted with Jean C. M. V. de Gournay (1712–1759), and round these two men was formed the philosophic sect of the *Économistes* or the *Physiocrates.* The most remarkable men in this group were the elder Mirabeau (author of *L'Ami des hommes,* 1756–60, and *Philosophie rurale,* 1763), Nicolas Baudeau *(Introduction à la philosophie économique,* 1771), G. F. Le Trosne *(De l'ordre social,* 1777), André Morellet (best known by his controversy with Galiani on the freedom of the corn trade), Mercier Larivière and Dupont de Nemours. Adam Smith, during his stay on the continent in 1764–66, made the acquaintance of Quesnay and some of his followers, to whom he refers in his *Wealth of Nations.* Quesnay died on Dec. 16, 1774, having lived long enough to see his great pupil, Turgot, in office as minister of finance.

The *Tableau économique,* Quesnay's principal work, may be considered the principal manifesto of the school. It was highly esteemed by the followers of Quesnay, and is named by the elder Mirabeau, in a passage quoted by Adam Smith, is one of the three great inventions which have contributed most to the stability of political societies, the other two being those of writing and of money. Its object was to exhibit by means of certain formulae the way in which the products of agriculture, the only source of wealth, would, in a state of perfect liberty, be distributed among the several classes of the community (namely, the productive classes of the proprietors and cultivators of land, and the unproductive class of manufacturers and merchants), and to represent by other formulae the modes of distribution which take place under systems of Governmental restraint and regulation, with the evil results arising from such violations of the natural order. It follows from Quesnay's theoretic views that the one thing deserving the solicitude of the practical economist and the statesman is the increase of the net product; and he infers also what Smith afterwards affirmed, on not quite the same ground, that the interest of the landowner is "strictly and indissolubly connected with the general interest of the society." A small *édition de luxe* of this work, with other pieces, was printed in 1758 in the palace of Versailles under the king's immediate supervision.

Quesnay's system is expounded in two articles on "Fermiers," and "Grains" in the *Encyclopédie* of Diderot and D'Alembert (1756, 1757); a discourse in the *Physiocratie* of Dupont de Nemours (1768); *Maximes Generales de gouvernement Cconomique d'un royaume agricole* (1758); *Tableau économique* (1758); and *Dialogue sur le Commerce et des traveaux des artisans.* Collections of his works are published by Guillaumin (Paris), and Oncken (Frankfort, 1888). A facsimile reprint of the *Tableau Cconomique,* from the original ms., was published by the British Economic Association (London, 1895). *See* also F. J. Marmontel, *Mémoires; Mémoires de Mme. du Hausset;* H. Higgs, *The Physiocrats* (London, 1897).

QUESNEL, PASQUIER (1634–1719), French Jansenist theologian, was born in Paris on July 14, 1634, and joined the French Oratory in 1657. His Jansenist sympathies led to his banishment from Paris in.1681. He took refuge with the friendly Cardinal Coislin, bishop of Orléans; four years later, however, foreseeing that a fresh storm of persecution was about to burst, he fled to Brussels, and took up his abode with Antoine Arnauld (*q.v.*). There he remained till 1703, when he was arrested by order of the archbishop of Malines. After three months' imprisonment he made a highly dramatic escape, and settled at Amsterdam. where he spent the remainder of his life. After Arnauld's death in 1694 Quesnel was generally regarded as the leader of the Jansenist party; and his *Réflexions morales sur le Nouveau Testament* played almost as large a part in its literature as Jansens's *Augustinus* itself. The bull *Unigenitus* (1713) condemned 101 sentences from the *Réflexions morales.* Quesnel died at Amsterdam on Dec. 2, 1719.

See also Mme. Albert Le Roy, *Un Janseniste en exil* (Paris, 1900; and Maulvault, *Répertoire de Port Royal* (Paris, 1902).

QUETELET, LAMBERT ADOLPHE JACQUES (1796–1874), Belgian astronomer, meteorologist and statistician, was born at Ghent on Feb. 22, 1796, and educated at the lyceum of that town. He lectured in Brussels from 1819 onwards, and in 1828 he was appointed director of the new royal observatory which it had been decided to found, chiefly at his instigation. From 1834 he was perpetual secretary of the Brussels Academy, and published a vast number of articles in its *Bulletin,* as also in his journal, *Correspondance mathématique* et *physique* (11 vols., 1825–39). He died at Brussels on Feb. 17, 1874.

Quetelet published in 1835 his principal work, *Sur l'homme et le développement de ses facultés, ou essai de physique sociale* (2nd ed., 1869), containing a résumé of his statistical researches on the development of the physical and intellectual qualities of man, and on the "average man" both physically and intellectually considered. His ideas are further developed in his *L'Anthropométrie, ou mesure des différentes faculte's de l'homme* (1871).

A detailed *Essai sur la vie et les travaux* **de** *L. A. J. Quetelet,* by his pupil and assistant E. Mailly, was published at Brussels in 1875.

QUETTA, the capital of British Baluchistan, India, which also gives its name to a district. It rose to prominence in 1876, when Sir Robert Sandeman founded a residency there. The name is a variation of the word *kwat-kot,* signifying a fortress, and the place is still locally known as Shal Kot. Quetta is the southernmost point in the line of frontier posts and system of strategic railways on the north-west frontier of India, 536 m by rail N. of Karachi. It forms the headquarters of a division and of the Western Command. The railway was built in 1879, with a view to its continuance to Kandahar; but its present terminus is New Chaman on the Afghan border. A branch line to Nushki was completed in 1905 and carried on to Duaz-ab during the World War. The cantonment and civil station of Quetta stand in the open plain about 5,500 ft. above sea-level, within a ring of mountains (such as Takatu, Murdar and Chiltan), which overlook it from a height of over 11,000 ft. North of Quetta is the open plain leading to Pishin and the Harnai, also traversed by the Sibi-Pishin railway, which passes through the fortifications. These defensive works, stretching from the base of Takatu to the foot of the Mashelak hills on the west, bar the way to advance from the Khojak pass. During the last quarter of the 19th century Quetta grew from a dilapidated group of mud buildings, with an inferior bazaar and a few scattered remnants of neglected orchard cultivation, into a strong fortress, and one of the most popular stations of the Indian army. The Indian Staff College opened here in 1907. Trade mart for western Afghanistan, eastern Persia, and much of central Asia, its population grew to 60,272 by 1931. However a disastrous earthquake practically destroyed the city in June 1935, claiming a toll of from 20,000 to 40,000 lives—the most fatal quake in twenty years.

The District of Quetta (including Pishin) has an area of 4,806 sq.m. The actual line of valley which contains Quetta and the Bolan pass was originally rented from the khan of Kalat. This perpetual leasehold was afterwards extended so as to include Nushki and give the British government the command of the trade route to Seistan. The Quetta district is administered, together with the assigned districts of Pishin, Tal Chotiali and Sibi by a regular staff of civil officials, the head being known as the Agent to the Governor-General.

See Thornton, *Life of Sir Robert Sandeman* (London, 1896); *Quetta-Pishin District Gazetteer* (Ajmer, 1907). (T. H. H.)

QUEVEDO Y VILLEGAS, FRANCISCO GOMEZ DE (1580–1645), Spanish satirist and poet, was born at Madrid, and was educated at the University of Alcalá. At 21 he was in correspondence with Justus Lipsius on questions of Greek and Latin literature.

He betook himself to the court where the cynical greed of ministers, the meanness of their flatterers, the corruption of the royal officers, the financial scandals, afforded ample scope to Quevedo's talent as a painter of manners. In 1611 he fought a duel in which his adversary was killed, fled to Italy, and later on became secretary to Pedro Téllez Girón, duke of Osuna, and viceroy of Naples. Thus he learned politics (the one science which he had perhaps till then neglected), initiated himself into the questions that divided Europe, and penetrated the ambitions of the neighbours of Spain, as well as the secret history of the intriguers protected by the favour of Philip III. The result was that he wrote several political works, particularly a lengthy treatise, La *Politica de Dios* (1626). The disgrace of Osuna (1620) compromised Quevedo, who was arrested and exiled to his estate at La Torre de Juan Abad in New Castile. On the death of Philip III. (March 31, 1621), Olivares recalled him from his exile and gave him an honorary post in the palace, and from this time Quevedo resided almost constantly at court, exercising a kind of political and literary jurisdiction due to his varied relations and knowledge, but especially to his biting wit, which had no respect for persons. In the midst of incessant controversy he found time to compose a picaresque romance, the *Historia de* la *Vida del Buscón . . .* (1626); to write his *Sueños* (1627), in which all classes are flagellated; to pen a dissertation on *The Constancy and Patience* of *Job* (1631), to translate St. Francis de Sales and Seneca, to compose thousands of verses, and to correspond with Spanish and foreign scholars. But Quevedo was not to maintain unscathed the high position won by his knowledge, talent, and biting wit. An anonymous petition in verse enumerating the grievances of his subjects was found, in Dec. 1639, under the very napkin of Philip IV. Suspicion fell on Quevedo, who had enemies glad to confirm them. He was arrested on Dec. 7, and kept in rigorous confinement in the monastery of St. Mark at Leon till the fall of Olivares (1643). Two years later he died at Villanueva de los Infantes. (J. F.-K.)

Fernandez-Guerra y Orbe (annotated by M. Menendez y Pelayo) 1897–1907 (Soc. de Bibliófilos Andaluces). *See* also E. Mérimée, *Essai sur la vie et les oeuvres de Francisco de Quevedo* (1886).

QUEZAL or **QUESAL,** one of the most beautiful of birds, an inhabitant of the mountains of central America. This bird, *Pharomacrus mocinno,* is one of the trogons (*q.v.*), and in body is about the size of a turtle-dove. The plumes of the tail, which may measure $3\frac{1}{2}$ft., are golden-green and, before the Spanish conquest, were only allowed to be worn by chiefs. The rest of the plumage is green above and scarlet below. In the female the tail is short. The eggs are a pale bluish-green.

QUEZALTENANGO, the capital of the department of Quezaltenango, Guatemala, 120 mi. by Pan-American highway W. of Guatemala City and 70 mi. inland from the Pacific port of Champerico. Pop. (1940) 33,538. It is on the river Siguila, and at the foot of the volcano Santa Maria. In size the second city in the republic, it has a large agricultural trade and manufactures of linen, woollen and cotton goods. Its inhabitants are mainly Indians or mestizos of Quiché descent. Quezaltenango was the capital of a Quiché kingdom, and was known as Xelajú. In 1524 it was conquered by the Spaniards under Pedro de Alvarado. In 1902 it was almost completely destroyed by an earthquake and an eruption of Santa Maria.

QUEZON, MANUEL LUIS (1878–), Philippine statesman, mas born at Baler, on the island of Luzon, and studied law at Santo Tomas university in Manila For a time he joined the insurrectionist movement of Emilio Aguinaldo against the U.S.A., but later he swore allegiance to the territorial administrators and became a provincial prosecutor. From 1907 to 1909 he was a member of the Philippine assembly, from 1909 to 1916 resident commissioner to the U.S. Congress, and from 1916 to 1935 president of the Philippine senate. He was elected first president of the Commonwealth of the Philippines Sept. 17, 1935.

QUIBERON, CAMPAIGN AND BATTLE OF. Several plans were made for the invasion of the British Isles by the French during the Seven Years' War, and in 1759 an army was assembled at Vannes in Brittany, with its transports lying in the Morbihan, the landlocked waters inside Quiberon bay. To protect this force while undertaking the invasion, the French planned to unite their fleets at Toulon and Brest; but these ports were blockaded by Admiral Edward Boscawen and Admiral Sir Edward Hawke respectively. During July 1759 Boscawen was compelled to take his squadron to Gibraltar for provisions and refitting, and Admiral de la Clue led the Toulon fleet through the straits of Gibraltar with the idea of reaching Brest. But he was pursued from Gibraltar by Boscawen, and in the running fight which finished in Lagos bay his force was completely disorganized and defeated.

Meanwhile Hawke continued the blockade of Brest with the utmost pertinacity, but on Nov. g, 1759, he was forced to run into Torbay by lack of stores and exceptionally bad weather. On Nov. 14 he was again at sea; but by this time the French had learnt of his withdrawal, thanks to some ships from the West Indies which reached Brest without being held up. Admiral Conflans took the Brest fleet to sea on the same day that Hawke left Torbay (Nov. 14), and headed south. Hawke, on learning from one of his scouting ships the course taken by the French, also headed south. Continual changes of wind and weather made consistent navigation extremely difficult, but on the morning of Nov. 20 both fleets were about 30m. off Belle-Ile. Conflans, seeing a few English ships under Commodore Duff watching Quiberon bay, stood in close to capture them, but on sighting Hawke's fleet to the north-west, he changed his mind and determined to run into the bay itself, keeping his fleet as closed up as possible.

On sighting the French, Hawke signalled "line abreast" in order to concentrate his force, and followed this up by "general chase" and "line of battle ahead." Hawke's leading ships crowding sail with a fresh north-west gale astern of them, soon began to overhaul the French, who were sailing in close order at the speed of the slowest. At 2:30 p.m., just as Conflans was rounding Belle-Ile, his rearmost ships began to be attacked, and soon afterwards both fleets swept into the bay, between the Cardinal islands and the Four sandbank. Inside the bay, owing to its peculiar shape, the sea was terrific; there were innumerable reefs and sandbanks; the short winter's day was rapidly closing in; and both fleets were driving towards a lee shore. There were 21 of the line in each fleet, but the French had a great advantage in carrying pilots who knew the coast, and with scarcely three hours' daylight left there seemed little chance of a decisive action, especially as it was almost impossible to open the lower deck gun-ports. Nevertheless, two French ships were sunk and another was captured before Hawke made the signal to anchor. Next morning, Nov. 21, the French fleet scattered; seven ships after throwing their guns overboard ran up the River Vilaine, and nine ran out to sea for Rochefort, one sinking on the way. A ship which had struck the night before but had not been captured ran on the Four in trying to escape and was burnt, together with two English ships which had also run aground. Conflans' flagship, the "Soleil Royal," which had anchored nearly in the middle of the English fleet, ran herself ashore on Nov. 21 and was burnt by her own crew. An attempt to burn the ships in the Vilaine by a boat attack was abandoned, owing to bad weather and the strong defences of the river mouth. Nevertheless, the French Brest fleet was now quite useless as a tactical combination, and "had we had but two hours more daylight," wrote Hawke, "the whole had been totally destroyed or taken; for we were almost up with their van when night overtook us." With both their fleets defeated, the French were now compelled to abandon their invasion project, and cease all major naval operations for the rest of the war.

QUICHE, the most important Indian nation in Guatemala at the time of the Spanish conquest. To-day the Quiché tongue, a Maya dialect, is spoken by about 275,000 pure-blooded natives throughout the Departments of Quiché, Quezaltenango, Totonicapán, Retalhuleu and Sacatepéquez.

Quiché history and tradition are preserved in a book known as the *Popol Vuh,* written by a native shortly after the Conquest. It relates four attempts to create a satisfactory world and people it. On the last attempt the gods made four men: Balam-Quitze, Balam-Agab, Mahucutah and Igi-Balam. Of these the first three became the ancestors of the Quiché. As first constructed these men had too many divine attributes to suit the gods, so their wits were dulled, but in compensation they were given wives. At this time the other Indian tribes were created and they all went to Tulan Zuiva to receive their household gods. The Quiché god, Tohil, then made the first fire by striking it from his sandal, while the other Indians learned the art from the Quiché. To gain this end, with one exception, they were tricked into giving human hearts in sacrifice. All then started to migrate to Guatemala, and when they arrived the first sunrise took place. Then the four leaders withdrew to the woods, and, after the Quiché had successfully fought a war, these holy men died. They were succeeded by their sons who immediately departed on a mystic journey to the East where they received the insignia of temporal power at the hands of the great king, Nacxit, who also taught them the secret of writing.

Upon the return of their leaders the Quiché settled in stone wrought cities, and from this point the *Popol* Vuh assumes a definitely historical character. It describes the reigns of many kings and pictures in detail their wars with neighbouring nations. The apogee of Quiché power was reached under Kicab, who made tributary all his neighbours, but these conquests were never consolidated into a kingdom. Fighting continued with varying fortunes until the arrival of the Spaniards.

In 1524 Pedro de Alvarado, the lieutenant of Cortés, entered Guatemala. The Quiché had received warning of his coming and of the strength of the Spanish arms from the Aztec emperor Montezuma. They had hastily made peace with warring neighbours but were unable to unite them in a common defence. Their preparations to repel Alvarado were impeded by the death of their king, Tanub. His successor, Tecum Umam, met the Spaniards with a huge army upon the plains of Zelahuh near the modern Quezaltenango. There followed a series of desperate actions in which the Indians failed to withstand the Spanish cavalry and artillery, backed by a force of native allies. Finally Tecum Umam personally attacked Alvarado and after unhorsing him was slain. Then the Quiché retreated to their capital, Gumacaah, leaving innumerable dead along the banks of a stream to this day known as Xiquiguel, the river of blood. However, the Quiché were not yet conquered, and the new king, Chignauivcelut, endeavoured to entice Alvarado into his capital, so that he might burn the houses over the Spaniards' heads while his men cut off their retreat over the narrow causeway by which the city was entered. Alvarado discovered this plan, captured the Quiché by stratagem and hanged the king. Thus the opposition was broken.

At the time of the conquest a king ruled the Quiché in regal style. He was surrounded by 24 councillors who gave the ruler their advice and acted as judges and revenue collectors. The principal towns were governed by appointed lieutenants who, however, had no jurisdiction over the nobility. Each governor had his council organized in the same fashion as the king's. All these officials and others down to the rank of door-keeper of the council were drawn from the nobility who took great care to preserve the purity of their blood.

To-day the Quiché live in small villages in the highlands of Guatemala, for the most part on various coffee plantations where the Indians are held in a state of peonage. Some of the towns, however, particularly Chiquinula, Nahualá and Chichicastenango, have maintained a semi-independence and run their affairs with little interference from the Central Government. Chichicastenango is of peculiar interest because its inhabitants claim descent from the Quiché nobility, and recognize one of their number, Manuel Ajanel, as king.

QUICHERAT, JULES ETIENNE JOSEPH (1814–1882), French historian and archaeologist, was of Burgundian origin. His father, a working cabinet-maker, came from Paray le Monial to Paris where Quicherat was born on Oct. 13, 1814. He was educated at the college of Ste. Barbe and at the École des Chartes. Inspired by the example of Michelet, who had just written an admirable work on Joan of Arc (*q.v.*), he published the text of the two trials of Joan, adding much contemporary evidence on her heroism in his *Procès de condamnation et de rehabilitation de Jeanne d'Arc* (5 vols. 1841–1849), as well as half a volume of *Aperçus nouveaux sur l'histoire de Jeanne d'Arc.* He wrote full biographies of two chroniclers of Louis XI., one very obscure, Jean Castel (in the *Bibliothbque d'École des Chartes,* 1840), the other, Thomas Basin, bishop of Lisieux, a remarkable politician, prelate and chronicler. Quicherat also published the works of the latter (4 vols., 1855–1859). In 1849 he was appointed professor of diplomacy at the École des Chartes. He died at Paris on April 8, 1882.

Bibliography.—After his death his unpublished papers were printed in *Mélanges d'archéologie et d'histoire,* vol. i., Celtic, Roman and Gallo-Roman antiquities, ed. A. Giry and Aug. Castan (1885), and vol. ii., *Archéologie du moyen âge,* ed. R. de Lasteyrie. His *Histoire de la laine,* on which he was occupied for many years, was missing from his papers, and only the introductory chapters (up to the 11th century) of his lectures on archaeology were found. Among his lectures published in contemporary reviews are La *formation française des anciens noms de lieu* (1867); *De l'ogive et de l'architecture dite ogivale* (1850); *L'Âge de la cathe'drale de Laon* (1874); and *Histoire du costume en France* (1875; 2nd ed., 1877), a popular work.

QUICHUA, a South American Indian tribe and stock, the ruling people of Peru when the Spaniards arrived. The Quichuan stock then included the Quichuas proper and the many vassal tribes of the ancient empire of Peru. To-day it numbers some three millions. They are skilful farmers and herdsmen. (*See* Peru; South America: *Ethnology.*)

BY COURTESY OF THE UNIVERSITY OF PENNSYLVANIA
QUICHUA INDIAN OF PERU

QUICKENING. A popular term for the first movements of the developing child perceived by the mother. This generally occurs about the fourth month of pregnancy. (*See* Embryo.)

QUICK-MATCH. A quickfiring wick or fuse, made by saturating cotton-wick with a paste of starch and gunpowder and carefully drying it. Used to connect the various parts of a firework, it carries the flame from one part to another. It was formerly also used for firing industrial and military explosives.

QUICKSILVER, a common name for mercury (*q.v.*).

QUIETISM, a complicated religious movement that swept through France, Italy and Spain during the 17th century. Its chief apostles were Miguel de Molinos, a Spaniard resident in Rome; Fénelon, the famous French divine, and his countrywoman, Madame Jeanne Marie Guyon. Quietism was essentially a reaction against the bureaucratic ecclesiasticism always latent within the church of Rome, though it had come more especially to the front during the struggles of the counter-Reformation carried through by the Jesuits. Like their contemporaries, the French Jansenists, and the Quakers and Anabaptists of northern Europe, the Quietists fell back on a doctrine of immediate inspiration of the individual conscience. To the many God spoke only in general terms through the Church; but to the few He made His will directly known. But how did He do so? How distinguish the voice of God from the vagaries of our own imagination? Quietism offered an easy test. The less "sense of proprietorship" a man had in his own good actions—the more they came from a source outside himself—the surer might he be that they were divine. If, on the other hand, they were the fruit of his deliberate thought and will, that was enough to show that they did not come from God; but from his sinful self, Hence the first duty of the Ouietist was to be "passive."

The Spanish monk, Juan Falconi, who is generally reckoned as the father of Quietism, died in the odour of sanctity in 1632; some thirty years later his fellow countryman, Molinos, transported his doctrines to Rome, where they gained unbounded popularity with bishops and cardinals, and even with pope Innocent XI. In 1675 Molinos published the *Guida Spirituale,* the great text-book of his school. But his success soon aroused the suspicion of the Jesuits, the great champions of militant ecclesiasticism. "Passivity" accorded ill with a zealous frequentation of the confessional, their chief centre of influence. Failing to turn public opinion against Molinos in Rome, they brought pressure to bear on Louis XIV. through his confessor, Père La Chaise. At the instance of the French ambassador Molinos was arrested (1685); his papers were seized, and his chief disciples examined by the Inquisition. Two years later he was convicted of heresy, and sentenced to imprisonment for life.

The later stages of the Quietist drama were played out in France. Here Quietist ideas had long been spreading under the leadership of enthusiasts like François Malaval (1627–1719), a blind layman of Marseilles. A more romantic figure was Jeanne Marie Guyon (1648–1717), a widow of good family and remarkable personal charm, who devoted her life to missionary journeys on behalf of "passivity." In 1688 fate brought her to the French court, where she made a great impression on Mme. de Maintenon and other persons of quality. But her most illustrious convert was Fénelon, then tutor to the duke of Burgundy, eldest son of the Dauphin. Mme. Guyon and Fénelon made Quietism famous. In 1697 Bossuet was at work on an *Instruction sur les états d'oraison,* which was intended to distinguish once for all what was true in Quietism from what was false. Fénelon, feeling sure that Bossuet would do the Quietists less than justice, determined to be beforehand with him. While Bossuet's book was still in the press, he suddenly brought out an *Explication des maximes des saints.* The little volume raised a violent storm. For two years Fénelon was at feud with Bossuet; he was banished from Versailles; finally, he was censured by the pope (1699), although in very measured terms. This condemnation, and Fénelon's bitter controversies with Bossuet, proved the death-blow to official Quietism.

Bibliography.—H. Heppe, *Geschichte der quietistischen Mystik* (Berlin, 1875), covers the whole subject. On the place of Quietism in the history of religious thought *see* W. R. Inge, *Christian Mysticism* (London, 1899); on its psychology *see* H. Delacroix, *Etudes sur le mysticisme* (Paris, 1908); J. Denis, *Mémoires de l'Académie de Caen* for 1894; W. James, *The Varieties of Religious Experience* (London, 1902). *See* also the articles on Bossuet; Fénelon; Mme. Guyon; and Molinos.

QUILL, a term applied to the bare, hard, hollow tube of the feather of a bird, also to the large flight feathers or *remiges,* and especially to the strong feathers of the goose, swan, or crow used in the making of quill pens (*see* Feather and Pen). Certain ancient stringed instruments were played with a *plectrum* or plucker made of the quill of a bird's feather, and the word has thus been used of a *plectrum* made of other material.

QUILLER-COUCH (kwil'lur ko͞och), **SIR ARTHUR THOMAS** (1863–), English writer (pseudonym "Q"), born in Cornwall on Nov. 21, 1863. He was educated at Clifton college and Trinity college, Oxford, where he was afterwards appointed lecturer in classics (1886–87). While he was at Oxford he published (1887) his *Dead Man's Rock* (a romance in the vein of Stevenson's *Treasure Island),* following it up with *Troy Town* (1888) and *The Splendid Spur* (1889). Gaining some journalistic experience in London, mainly as a contributor to the *Speaker,* in 1891 he settled at Fowey in Cornwall, and wrote several Cornish tales, including *The Blue Pavilions* (1891), *The Ship of Stars* (1899), *Hetty Wesley* (1903), *The Shining Ferry* (1905). He published several volumes of critical articles, *Adventures in Criticism* (1896); *On the Art of Writing* (1916); *Studies in Literature* (1918; 2nd series, 1927; 3d series, 1929), and *Shakespeure's Workmanship* (Bristol, 1918). In 1898 he completed R. L. Stevenson's *St. Ives.* From his Oxford days he was known as a writer of excellent verse; most of his poetical work is contained in *Poenzs and Ballads* (1896). In 1895 he published a delightful anthology from the 16th and 17th century lyrists, *The Golden Pomp,* followed in 1900 by the invaluable *Oxford Book of English Verse 1250–1900,* probably the best general anthology of English verse, the *Oxford Book of Ballads* (1910), the *Oxford Book of Victorian Verse* (1912) and the *Oxford Book of English Prose* (1925). In 1910 Quiller-Couch was knighted. In 1912 he was appointed King Edward VII professor of English literature at Cambridge, and was elected fellow of Jesus college, Cambridge. A complete edition of the *Tales and Romances of Sir Arthur Quiller-Couch* began in 1928; *Poems* (1929).

QUILLOTA, a town of Chile in the province of Valparaiso, on the left bank of the Aconcagua river, 20 mi. above its mouth and 26 mi. E N.E. of the city of Valparaiso. Pop. (1940) 17,220. The valley is noted for its beauty, fertility and healthfulness, and is the centre of thriving fruit and wine industries. Among its fruits is the "chirimoya" *(Anona Cherimolia).* Quillota is situated on a railway between Valparaiso and Santiago.

QUILON, a seaport of India, on the Malabar coast, in the state of Travancore. Pop. (1931) 33,739. The palace of the maharaja of Travancore stands on the bank of Quilon lake.

QUIMBY, PHINEAS PARKHURST (1802–1866), American mental healer, was born at Lebanon, N H , on Feb. 16, 1802. In 1838, while in business as a clock-maker in Belfast, Me., his interest in hypnotism was aroused by a series of lectures. He studied the subject and delivered lectures. His experiments extended through mental suggestion to mental healing, sometimes accompanied by physical manipulation, which he practised at Portland, Me., having among his patients Mrs. Patterson, later Mary Baker Eddy. He died at Belfast, Me., on Jan. 16, 1866.

See A. G. Dresser, ***The*** *Philosophy* of *P. P. Quimby.*

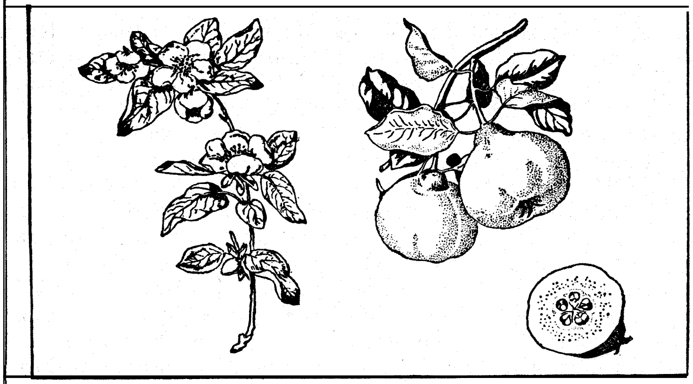
QUIMPER, formerly Quimper-Corentin, a town of France, capital of the department of Finistère, on the Odet 158 mi. N W. of Nantes and 68 mi. S.E. of Brest on the railway between those towns. Pop. (1936) 18,814. Quimper, or at least its suburb Locmaria, was occupied in Roman times, and traces of the ancient foundations exist. Later Quimper became the capital of Cornouailles and the residence of its kings. It is said to have been Grallon Meur who brought the name of Cornouailles from Great Britain and founded the bishopric, first held by St. Corentin about 495. Hoel, count of Cornouailles, united the countship with the duchy of Brittany. Quimper suffered in the local wars of succession. In 1344 it was sacked by Charles of Blois. Monfort failed to take the town in 1345, but it opened its gates to his son John IV in 1364 after the victory at Auray. Remains of the town walls (15th century) are preserved in the terrace of the episcopal palace and near the college. Quimper is the seat of a prefect and of a bishopric in the province of Rennes. The cathedral of St. Corentin (13th to 16th centuries), with a fine façade (c. 1425), is a splendid example of the Gothic style in granite. Famous Breton pottery is made here.

QUIMPERLÉ, a town of western France, in the department of Finistitre, at the confluence of the Isole and the Ellé which unite to form the Laita, 28 mi. E.S.E. of Quimper by rail. Pop. (1936) 6,475. Quimperlé grew up round the abbey of Ste. Croix, founded in the 11th century, the restored romanesque basilica of which still remains. The church of St. Michel (14th and 15th centuries), with a fine tower, crowns the hill above the town. The chapel of Lothéa, in the forest of Carnoet is the scene of the famous annual "Pardon des Oiseaux" (Pilgrimage of the Birds). There are granite deposits; food is preserved; metal boxes, furniture, agricultural implements, etc. are manufactured.

QUIN, JAMES (1693–1766), Irish actor, was born in London Feb. 24, 1693. He first appeared on the stage as Abel in Sir Robert Howard's *The Committee* at the Smock Alley Theatre, Dublin. Quin's first London engagement was in small parts at Drury Lane, and his first triumph was as Bajazet in Nicolas Rowe's *Tamerlane* (Nov. 8, 1715). The next year he appeared as Hotspur at Lincoln's Inn, where he remained for 14 years. On July 10, 1718, he was convicted of manslaughter for killing Bowen, another actor, in a duel. The affair was regarded as an accident. In 1721 a drunken nobleman reeled on to the stage of the theatre and assaulted the manager, Rich, whose life was saved by Quin's prompt armed interierence. This resulted in a riot, and thereafter a guard was stationed in all theatres. In 1732 Quin appeared at Covent Garden, returning to Drury Lane from 1734 to 1741, and in 1742 was again at Covent Garden, where he remained until the close of his career. On Nov. 14, 1746, Quin played Horatio and Garrick Lothario to the Calista of Mrs. Cibber in Rose's *Fair Penitent* to an enthusiastic audience. Quin was a serious rival of Garrick. His Richard III was pronounced inferior to Garrick's; but his Falstaff was preferred. Quin's last regular appearance was May 15, 1757, as Horatio in the *Fair Penitent,* though in 1758 he twice played Falstaff for the benefit of friends. He retired to Bath, where he lived a gay life. Quin died on Jan. 21, 1766. He was buried in the abbey church at Bath. Quin's character is summarized by Smollett in *Humphrey Clinker.* See *The Life of Mr. James Quin, Comedian,* 1766.

QUINAULT, PHILIPPE (1635–1688), French dramatist and librettist, was born in Paris on the 3rd of June 1635. By 1670 he had written some 16 or 17 comedies, tragedies, and tragi-comedies. In 1671 he contributed to the singular miscellany of *Psyché,* in which Corneille and Molière also had a hand, and which was set to the music of Lulli. Here he showed a remarkable faculty for lyrical drama, and from this time till just before his death he confined himself to composing libretti for Lulli's work. His libretti are among the few which are readable without the music, and which are yet carefully adapted to it. Coming at the time when opera became fashionable out of Italy, he had much to do with establishing it as a permanent European *genre.* His first piece after *Psyché* was a kind of classical masque, *Les Fêtes de l'Amour et de Bacchus* (1672). Then came *Cadmus* (1674), *Alceste* (1674), *Thésée* (1675), *Atys* (1676), one of his best and *Isis* (1677). All were classical in subject, as was *Proserpine* (1680), which was superior to any of them. *The Triumph of Love* (1681) is a mere ballet, but in *Persée* (1682) and *Phaeton* (1683) Quinault returned to the classical opera. Then he finally deserted it for romantic subjects, in which he was even more successful. *Amadis de Gaule* (1684), *Roland* (1685), and *Armide* (1686) are his masterpieces, the last being the best. Quinault died Nov. 26, 1688. The best edition of his works is that of 1739 (Paris, 5 vol.).

QUINCE, a fruit tree concerning which botanists differ as to whether or not it is entitled to take rank as a distinct genus, *Cydonia,* or as a section of the genus *Pyrus* (family Rosaceae, *q.v.*). The name *Cydonia oblonga* is to be preferred to *Pyrus cydonia.* Bailey gives five varieties of *C. oblonga,* namely, vars. *lusitanica, maliformis, pyriformis, marmorata* and *pyramidalis.* The quinces are much-branched shrubs or small trees with entire leaves, small stipules, large solitary white or pink flowers like those of the pear or apple, but with leafy calyx lobes and a many-celled ovary, in each cell of which are numerous horizontal ovules. The fruits may be round and flattened or somewhat pear-shaped, with large leafy calyx persisting on the mature fruit.



QUINCE (CYDONIA OBLONGA); SHOWING BLOSSOM IN FULL BLOOM (LEFT), PEAR-SHAPED QUINCE SHOWING SEED BOX (RIGHT)

The common quince is a native of Persia and Anatolia, and perhaps also of Greece and the Crimea. By Franchet and Savatier *C. oblonga* is given as a native of Japan, with the native name "maroumerou." It is certain that the Greeks knew a common variety upon which they grafted scions of a better variety from

Cydon in Crete, whence it was obtained and from which the later names have been derived. The fragrance and astringency of the fruit of the quince are well known, and the seeds formerly were used medicinally for the sake of the mucilage they yield when soaked in water. The quince is but little cultivated in Great Britain; in Scotland it seldom approaches maturity, unless favoured by a wall. The fruit has a strong aroma and in the raw state is astringent; but it makes an excellent preserve, and is often used to give flavour and sharpness to stewed or baked apples.

The Japanese quince, formerly considered in the genus *Cydonia* but now known as *Chaenomeles lagenaria,* has been widely used as an ornamental plant in gardens as a shrub, particularly because of the beauty of its flowers that appear on the stems before the leaves open fully in late winter and early spring months. Some of the small shrubs bear large green fragrant fruits that are quite inedible in the fresh state but have been used in making preserves.

The quince was formerly grown in home fruit gardens and commercial plantings in the northeastern United States but later became the least esteemed of all tree fruits for orchards in that area. The fruit is almost inedible in the uncooked state, and other fruits are preferred in the fresh state for the diet. It thrives under the same systems of cultivation as do apples and pears and does fairly well along fence rows, where it may be given little care. The quince is susceptible to a bacterial disease called fire blight, which is also a serious hazard to Pear growing in the United States. Trees that are not forced into strong vegetative growth by pruning and fertilization are less susceptible to the fire blight disease. The trees are subject to the same scale insects that attack apples and pears and should receive the same dormant spray treatment for the control of these pests. The fruits are golden yellow in colour and the flesh takes on a pink colour when cooked, giving an attractive colour to jellies and conserves made from this fruit. Orange is the most commonly grown variety. Champion is another of the more important varieties. Quince stocks are used on which to graft the pear to dwarf the tree and hasten early bearing. The Angers variety, imported from France, is the most important stock used for dwarfing pears. (F. P. C.)

See W. W. Robbins, *Botany of Crop Plants* (Philadelphia, 1924); L. H. Bailey, *Standard Cyclopedia of Horticulture* (1914–27) and *Manual of Cultivated Plants* (1924).

QUINCKE, GEORGE HERMANN (1834–1924), German physicist, was born at Frankfurt on the Oder on Nov. 19, 1834. He was appointed "privat-docent" at Berlin university in 1859. Between 1860 and 1872 he held various teaching posts. He was professor of physics at Würzburg (1872–75) and at Heidelberg from 1875 until he retired in 1907. He died on Jan. 13, 1924.

Quincke carried out a number of observations on surface tension. He also wrote papers on the reflection of light at metal surfaces, on the penetration of light into the second medium in the case of total reflection, and on elliptic polarization. Quincke also devised methods of measuring the magnetic permeability of liquids and the dielectric constants for non-conductors.

QUINCY, JOSIAH (1744–1775), American patriot, son of Josiah Quincy (1709–84), was born in Boston on Feb. 23, 1744. Between 1767 and 1770, he contributed several papers to the Boston *Gazette* that were flaming tirades against British oppression. After the "Boston massacre," he and John Adams defended Capt. Preston and the accused soldiers and secured their acquittal. From this time on he wrote repeated letters to the Boston Gazette and published several books in which he urged opposition to England. In Sept. 1774 he left for England where he consulted with leading Whigs as to the political situation in America; on March 16, 1775 he started back, but he died on April 26 in sight of land.

See the *Memoir of the Life of Josiah Quincy, Jr., of Massachusetts* (Boston 1825, 2nd ed., 1874), by his son.

JOSIAH QUINCY (1772–1864), son of the above named, American lawyer and author, was born in Boston on Feb. 4, 1772. He graduated from Harvard in 1790, studied law and was admitted to the Ear in 1793, but was never a prominent advocate. He served in the Massachusetts senate in 1804–05; and was a member in 1805–13 of the national House of Representatives. After leaving Congress, he held various political offices until in 1823 he became mayor of Boston. As mayor he brought about municipal reform, and in 1829 resigned to become president of Harvard college. He remained president until 1845 during which time he made many reforms in grading, finances, etc. His last years were spent on his farm in Quincy, where he died on July 1, 1864.

He wrote a *Memoir* of his iather (1825); a *History of Harvard University* (1840), the *Journals of Mayor Samuel Shaw* (1847); *The History of the Boston Athenaeum* (1851); *The Municipal History of the Town and City of Boston* (1852); a *Memoir of the Life of J. Q. Adams* (1858); and many practical contributions to agriculture. See Edmund Quincy, *Life of Josiah Quincy* (Boston, 1867).

JOSIAH QUINCY (1802–1882), son of the last named, was mayor of Boston in 1845–49; his brother Edmund (1808–77) was a prominent abolitionist and author. Josiah Quincy (1802–82) had two sons—Josiah Phillips (1829–1910), a lawyer and author; and Samuel Miller, who became a brigadier-general in the Union army. Josiah Quincy (1859–1919), a son of Josiah Phillips Quincy, was mayor of Boston in 1895–99. (B. B. K.)

QUINCY, a city of western Illinois, U.S.A., on the Mississippi river, 110 m. N.W. of Saint Louis; the county seat of Adams county. It is on Federal highway 24 and is served by the Burlington Route and the Wabash railways, and by river barges and steamers. Pop. (1930) 39,241; 40,469 in 1940 by the federal census The city is built on a picturesque bluff above the river and is surrounded by rich farm lands. It has beautiful parks covering 300 ac., one of which embraces prehistoric Indian mounds, and is the seat of the Illinois State Soldiers' and Sailors' home (1887) with 222 ac. of grounds. The assessed valuation of city property for 1940 was $34,449,095. Bank clearings in 1940 amounted to $32,143,000. In 1822 John Wood, the first white settler, built a log cabin there; and on March 4, 1825, the day of the inauguration of John Quincy Adams, the hamlet of ten inhabitants was made the county seat. In honour of the new president the county was named Adams, the town Quincy, and the public square (now Washington park) was called John's square. The town was incorporated in 1834 and was chartered as a city in [illegible]. In 1850, it[illegible] of 6,902, it ranked next to Chicago among the cities of the state.

QUINCY, a city of Norfolk county, Massachusetts, U.S.A., on Massachusetts bay, just south of Boston, occupying 16·77 sq mi. between the Neponset river on the north and Fore river on the south. It is served by the New York, New Haven and Hartford railroad. Pop. 47,876 in 1920, 29% foreign-born white; 1940 it was 75,810. It is a beautiful residential suburb of great historic interest and has distinctive manufacturing industries, with an output in 1939 valued at $41,475,411. The Quincy granite quarries have been celebrated since the middle of the 18th century. The first freight railway in the United States was established there in 1825.

On Fore river are shipyards (established 1900) which have built many of the modern vessels of the U.S. navy, including 36 destroyers during the war of 1914–18. The city has 2,600 ac. of parks and playgrounds. A settlement known as Merry Mount or Mt. Wollaston was established within the present bounds of Quincy in 1625 by Thomas Morton (*q.v.*), but was abandoned after his arrest; and in 1634 a second settlement was made, by Puritans. In 1792 Quincy was set off from Braintree and incorporated as a town (named in honour of John Quincy, 1689–1767) and in 1888 it was chartered as a city. It was the home of the Hancocks and the Adamses, the birthplace of the first governor of Massachusetts and of two presidents of the United States. The houses in which John Adams and John Quincy Adams were born (built in 1681 and 1716) and the Edmund Quincy homestead (1685) are colonial museums, open to the public. The granite for King's chapel, Boston, in 1752, and for the Bunker Hill monument, in 1826, was quarried in Quincy.

QUINET, EDGAR (1803–1875), French historian and man of letters, was born at Bourg-en-Bresse (Ain), on Feb. 17, 1803. His first publication, the *Tablettes du Juif Errant,* appeared in 1823. He obtained considerable credit irom his translation (1827) of Herder's *Philosophie der Geschichte.* At this time he met Michelet, and also Cousin, who procured him a post on a Government mission to the Morea in 1829. On his return he published *La Grèce Moderne* in 1830. His reputation for speculative Republicanism ruined his hopes of employment after the February revolution, but he joined the staff of the *Revue des deux Mondes*. The most remarkable of the numerous essays which he contributed to it was on *Les Epopées françaises du XIIème siècle.* In 1839 he was appointed professor of foreign literature at Lyons, and in 1841 was transferred to the chair of southern literature at the Collège de France. The *Génie des religions,* embodying his brilliant lectures at Lyons, appeared in 1842. In 1846 the Government put an end to his lectures, because he introduced into them polemic against Ultramontanism.

Quinet took part in the revolution of 1848, and was returned for Ain to the Constituent and then to the Legislative Assembly, where he figured among the extreme radical party. He wrote many pamphlets during the Second Republic, attacked the Roman expedition and was an uncompromising opponent of Prince Louis Napoleon. He was banished from France after the *coup d'état* and settled at Brussels, where he lived for seven years, and published *Les Esclaves* (1853) and *Marnix de Sainte-Aldégonde* (1853). Quinet was restcred to his chair after the fall of the Empire, and during the siege of Paris wrote vehemently against the Germans. As deputy for the department of the Seine (1871) he opposed the terms of peace between France and Germany. He died on March 27, 1875.

BIBLIOGRAPHY.—In addition to the works mentioned above, Quinet wrote *Les Révolutions d'Italie* (1848); *Histoire de mes idées* (1858); *Le Siège de Paris et la defense nationale* (1871); *La République* (1872); *Le Livre de l'exilé* (1875 and later). Three volumes of letters and some other works were published posthumously. A complete edition of his works was published in 28 volumes in 1877–79. His second wife, in 1870, published certain *Mémoires d'exil,* and *Lettres d'exil* followed in 1885. In that year Prof. George Saintsbury published a selection of the *Lettres à sa mère* with an introduction. *See* also E. Paris, *Libres penseurs religieux* (1905); R. Heath, *Early Life and Writings of Edgar Quinet* (1881).

QUININE, the most important alkaloid contained in cinchona bark (*see* CINCHONA, ALKALOIDS OF).

Physiological **Action.**—Our knowledge of this subject is mainly due to Professor Binz of Bonn. Quinine is a bactericide, many bacteria being killed by a ·2% solution, but is more definitely poisonous to minute animal organisms especially malarial parasites.

The first feature of the internal action of quinine is its intensely bitter taste. This induces a reflex secretion from the salivary and gastric glands, followed or accompanied by increased vascularity of the gastric mucous membrane, and some activity of the muscular wall of the stomach. This means that the appetite is strengthened, and digestion rendered more rapid and complete, In this sense alone quinine is a tonic.

The action of quinine on the blood itself—quite apart from its action on malarial blood—is of great complexity and importance. Whilst it is not a haematinic, in that it does not increase the number of the red blood corpuscles, it very markedly influences the stability of the compounds of the haemoglobin with oxygen. Like alcohol and prussic acid, quinine interferes with oxidation, so that oxyhaemoglobin is relatively unable to give up its oxygen to the tissues, the metabol'ism of which is therefore greatly modified. This property is doubtless partly—though not wholly—explanatory of the antipyretic action of quinine.

The action of quinine on the circulatory apparatus is not marked. It is only in very large doses that it weakens the intracardiac nervous ganglia, slows and weakens the pulse, and dangerously lowers the blood pressure, Similarly the depressant action on the respiratory centre in the medulla oblongata occurs only after the administration of enormous doses.

The action of quinine on the temperature is important, for it is the safest of all known antipyretics. Its action on the normal temperature is *nil.* The drug is not an *antithermal.* But when the temperature is raised, quinine will frequently lower it. The action is not due to any influence on the thermic centres, nor to any production of diaphoresis, but to the influence of quinine upon the stability of oxyhaemoglobin. Quinine was the first antipyretic used.

In some of the lower vertebrates quinine reduces the activity of the spinal cord, but in the human species it appears to stimulate the nervous mechanism of the uterus and it is therefore included under the class of *oxytocic* or *ecbolic* drugs.

Therapeutics.—The supreme value of quinine is as a specific antidote to malaria, against which it also possesses a powerful prophylactic action. Ten or fifteen grains of the sulphate are often given three times a day for this latter purpose, and smaller doses of the much more efficacious acid hydrochloride convey even more certain immunity. In treating malaria with this drug certain important facts are to be observed. Quinine administered by the mouth or by any other means will soon enter the blood, and will then kill the *haematozoon malariae,* whether it be contained within corpuscles or free in the blood-plasma. There is one exception, however. Quinine is apparently powerless to kill the organism when it is in its reproductive phase. This phase corresponds to the pyretic attack. It is therefore useless to administer quinine during a malarial paroxysm. Two successful methods may be adopted. The quinine may be given in a single large dose—go grains of the sulphate or 20 of the acid hydrochloride—an hour or two before the attack is due, *i.e.* just before the parent organism in the red blood corpuscles is about to discharge the new generation of young parasites into the blood-plasma. An equally effective method, which may be combined with the above, is to give the quinine in 10-grain doses of the acid hydrochloride every four hours between the attacks. Whichever method be adopted, the paroxysm that was expected will probably not appear.

Quinine is largely used as a bitter tonic in doses of about half a grain. The acid hydrochloride is the best salt to employ. It has some analgesic power, and is a safe and often efficient drug in the treatment of neuralgia, even when the patient has not had malaria.

Cinchonism is the name applied to the congeries of toxic symptoms which follow the prolonged administration of quinine, but may appear after one small dose in certain persons. The symptoms closely resemble those of salicylism, and also, though in less degree, those of carbolism. The patient is deaf, but complains of ringing in the ears, which may assume various forms, especially in musical people. In persons who display a pronounced idiosyncrasy towards cinchonism, the symptoms may often be successfully averted if small doses of hydrobromic acid—10 minims of the dilute solution—are given with the quinine.

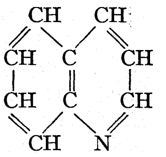
QUINNAT (*Oncorhynchus tschawytscha*), the most important salmon (*q.v.*) of the North American Pacific coast. It has been naturalized in New Zealand.

QUINOA (*Chenopodium quinoa*), a small annual herb of the goosefoot family (*Chenopodiaceae*), very similar to the common lamb's quarters (*q.v.*), native to Bolivia, Chile and Peru, where it has long been cultivated as a food plant by the native peoples of the Andean plateau. The plant produces a great profusion of very small seeds, which are ground into meal and made into cakes or gruel or boiled like rice; the green parts are used as a pot herb like spinach. (*See* CHENOPODIUM.)

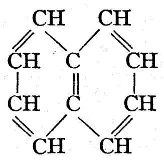
QUINOLINE is a colourless, highly refractive oil, of specific gravity 1·095, and b.p. 239° C. It has a peculiar characteristic smell and is only slightly soluble in water, but freely soluble in the usual organic solvents. It is alkaline to litmus. As a mono-acid base it forms crystalline salts such as the hydrochloride, which are very soluble in water. Quinoline, C_9H_7N, occurs with its homologues in the fraction of coal tar and bone-oil bases boiling between 230–250° C. It was first obtained from coal tar by Runge in 1834, and later Gerhardt showed that it was produced when cinchonine, quinine and other alkaloids were distilled with potash. Crude quinoline is obtained from coal tar and bone-oil by a process similar to the extraction of pyridine (*q.v.*), but since it is difficult to separate from its homologues, it is usually prepared synthetically by a method devised by Skraup, in which a mixture of aniline, glycerine, nitrobenzene and concentrated sulphuric acid is heated until reaction proceeds without further heating. Since this reaction is often very violent, arsenic acid is sometimes used as an oxidizing agent in place of nitrobenzene, in which case the reaction proceeds more smoothly and gives a cleaner product. During the reaction the glycerine is converted into acrolein which condenses with the aniline to form acrolein-aniline, and oxidation converts this to quinoline.

Being a tertiary amine, quinoline gives quinolinium or quaternary ammonium salts with alkyl iodides or methyl sulphate. It forms double salts with inorganic salts, *e.g.*, the platinichloride $(C_9H_7N)_2,H_2PtCl_6,2H_2O$. When potassium dichromate is added to a solution of quinoline hydrochloride, the sparingly soluble quinoline dichromate is formed. Nitric and chromic acids have no action on quinoline, but alkaline permanganate oxidizes it to quinolinic acid ($\alpha\beta$-dicarboxypyridine).

Constitutionally, quinoline bears the same relation to naphthalene that pyridine bears to benzene, for it may be considered as a compound formed by the fusion of a benzene ring with a pyridine ring:—

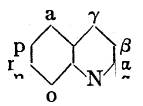


Quinoline



Naphthalene

And quinoline differs from pyridine just as naphthalene differs from benzene in chemical reactivity. The formation of quinolinic acid on oxidation shows the presence and stability of the pyridine ring in quinoline. The existence of the benzene ring follows from the Skraup synthesis. The pyridine nucleus takes up hydrogen more readily than the benzenoid part of the molecule: reduction with tin and hydrochloric acid yields a tetrahydroquinoline, whilst the decahydride is obtained with greater difficulty. Numerous substitution products of quinoline are known, and the position of any substituent in the molecule is designated in accordance with the scheme shown in the formula, the letters o, *m*, *p*, and a, standing for the terms ortho-, meta-, para-, and ana-.



Derivatives with the substituents in the benzene nucleus are prepared by the methods in use for the introduction of such groups into benzene and naphthalene; or the substituted benzene derivative can be subjected to the quinoline synthesis given above. It is more difficult to introduce halogen, nitro- or similar groups into the pyridine nucleus.

α-Hydroxyquinoline can be obtained in 80% yield by strongly heating quinoline with potash. The hydroxyquinolines are important because of their relationship to the alkaloids. Those with the hydroxyl in the benzene nucleus are conveniently prepared from aminophenols.

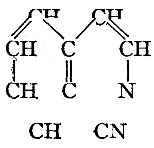
a-Hydroxydihydroquinolines are obtained by the action of alkalis on the alkyl quinolinium iodides. The hydroxide or ammonium base first formed isomerizes into the less ionized α-hydroxydihydroquinoline, which is a pseudo-base. These compounds are distinguished by a remarkable reactivity of the hydroxyl group, forming alcoholates and condensing readily with aniline, phenylhydrazine and hydroxylamine. This great reactivity, together with the capacity that the a- and y-methylquinolines possess for condensing with aldehydes and similar compounds, is utilized in the preparation of the magnificent blue and red dyes of the cyanines, isocyanines and apocyanines. These dyes are used as sensitizers in photography for rendering the plate orthochromatic.

α-Aminoquinoline can be obtained directly from quinoline by treatment with sodamide, as well as by the usual methods for preparation of amino derivatives. The aminoquinolines can be diazotized and coupled to form azo dyes in the same way as aniline, but they are not of great use.

Homologues.—Of the homologues of quinoline, the most important are quinaldine, lepidine and y-phenylquinoline. Quinaldine is α-methylquinoline and is present in coal tar, forming about 25% of the quinoline fraction. It may be readily prepared synthetically by condensing aniline with acetaldehyde by means of hydrochloric acid. It is a colourless liquid, b.p. 247° C. The methyl group is very reactive, condensing readily with aldehydes, and with phthalic anhydride to form the dye known as quinoline yellow. A red isocyanine dye is prepared by treating the mixed ethiodides of quinoline and quinaldine with alcoholic potash. Lepidine or y-methylquinoline also occurs in coal tar. It is produced when the alkaloid cinchonine is distilled with potash. Similarly y-phenylquinoline is related to the quinia alkaloids. Many of the higher homologues of quinoline have been found among the coal tar bases.

Chromic acid oxidizes the methylquinolines to the corresponding quinolinecarboxylic acids. Potassium permanganate produces pyridinetricarboxylic acids.

Uses.—Certain quinoline derivatives find use in medicine for antiseptic, antifebrile and analgesic purposes. The base itself has been used as an insecticide. Isoquinoline, C_9H_7N, the isomeride of quinoline was discovered in coal tar in 1885, but forms only about 1·5% of the quinoline fraction. It has the constitution shown in the formula, which is confirmed by its synthesis and oxidation products. It was separated from the quinoline in coal tar by the fractional crystallization of the mixed sulphates. Isoquinoline can be prepared synthetically by passing benzylidene-ethylamine through a hot tube and by the reduction of homophthalimide. It is a solid, m.p. 23° C, and boils at 240° C. As a tertiary amine and a mono-acid base, it has many reactions in common with quinoline. It is the parent body of many alkaloids. Its most important use is for the preparation of quinoline red, a dye employed as a photo-sensitizer. (J. Ro.)



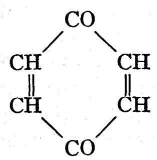
Isoquinoline

QUINONES in organic chemistry a group of compounds derived from the aromatic hydrocarbons and containing two ketonic groups, CO. (*See* KETONES.) The quinones are of twofold importance, first as being intermediates in the manufacture of synthetic dyes, and secondly as forming the basis of a theory of colour among organic compounds.

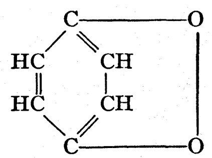
Among the quinones employed in dye production the most important is anthraquinone (*q.v.*), but a few others have found employment, such as acenaphthenequinone (see ACENAPHTHENE) and phenanthrenequinone. (*See* PHENANTHRENE.) Benzoquinone and its halogenated derivatives have also come into use as dye intermediates. There are two main divisions of quinones depending on the relative position of the ketonic groups. The *para*-quinones contain the two ketonic groups at opposite ends of the aromatic ring in the so-called "para-position," whereas in the *ortho*-quinones the two ketonic groups are adjacent to one another. So far there is no decisive indication of the existence of *meta*-quinones.

The para-benzoquinone, or ordinary quinone (formula I.), is prepared by the oxidation of aniline with sodium dichromate and dilute sulphuric acid. It sublimes in golden yellow needles, melting at 115·7° C and dissolves in ether, alcohol or hot water. It has a characteristic pungent smell.

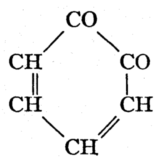
Benzoquinone is also formed during the aerial oxidation of benzene vapour over vanadium pentoxide; maleic anhydride is also produced in this process owing to further oxidation of the benzene nucleus.



(I.)



(II.)



(III.)

p-Benzoquinone is a tautomeric substance behaving as if it possessed either of the formulae (I.) or (II.). The oxidising power of benzoquinone on hydriodic acid, hydroxylamine or phenylhydrazine suggests the peroxide structure (formula II.). With hydroxylamine hydrochloride, however, it yields either the mono- or di-oxime and with as-benzoylphenylhydrazine or 2:4:6-trinitrophenylhydrazine it condenses to form hydrazones. These reactions indicate the diketonic structure (formula I.) which is now generally used for this quinone. With potassium chlorate and hydrochloric acid it furnishes tetrachlorobenzoquinone (chloranil), a colour intermediate. Other benzenoid *p*-quinones resemble p-benzoquinone in their general physical and chemical properties. An interesting confirmation of formula (I.) is afforded by the synthesis of para-xyloquinone (formula V.) from diacetyl (2 mols., formula IV.) under the influence of warm, aqueous caustic alkali (H. von Pechmann, 1888).

(IV.) $CH_3{\cdot}CO{\cdot}CO{\cdot}CH_2H$
$CHH_2{\cdot}CO{\cdot}CO{\cdot}CH_3$

 (V.)

o-Benzoquinone (formula III.) was obtained in chloroform solution by C. L. Jackson in 1901 by the action of iodine on the lead derivative of catechol; it was isolated in 1908 by R. Willstatter and Muller by silver oxide oxidation of catechol dissolved in an inert solvent. It was then obtained either in red or colourless crystals. The red variety, which is inodorous, non-volatile and decomposes below 70° C, is most probably the truly quinonoid compound as its colour corresponds with that of the more stable tetrabromo-o-benzoquinone, which crystallises in dark red prisms first obtained by Stenhouse in 1875.

From the hydrocarbon toluene, ail three possible quinones have been obtained, namely two *ortho*-toluquinones and one *para*-toluquinone; the first two are unstable red substances, odourless and non-volatile like *o*-benzoquinone, the last, resembles p-benzoquinone in its odour, volatility and yellow colour.

The three quinones of naphthalene are discussed under that hydrocarbon (*q.v.*).

Cedriret or *Coerulignone* is a quinone of interesting type (formula VI.) obtained by treating with alkali bichromate the acetic acid solution of pyrogallol dimethyl ether which is present in beechwood or birchwood tars (C. Liebermann, 1873).

(VI.) 
 (VII.)

The crude quinone which slowly separates is dissolved in phenol below 30° C and reprecipitated by alcohol in the form of dark blue needles. Other heteronuclear quinones of the diphenyl series have since been described by R. Willstatter and others.

Quinones on reduction yield colourless dihydro derivatives termed quinols. The combination of quinone and quinol gives rise to a quinhydrone which is more coloured than the quinone itself. Quinol and p-benzoquinone give a green quinhydrone. Quinone chloroimide and dichloroimide, $O{:}C_6H_4{:}NCl$ and $ClN{:}C_6H_4{:}NCl$ are yellow compounds volatile in steam and produced by the action of bleaching powder on *p*-aminophenol and *p*-phenylenediamine respectively.

Quinone-diamine, $HN{:}C_6H_4{:}NH$, produced by oxidising *p*-phenylenediamine in ethereal solution with silver oxide, is colourless, m.p. 124° C (R. Willstatter, 1904).

The foregoing quinones all contain unsaturated aromatic hydrocarbon rings, but camphorquinone (formula VII.), obtained by the hydrolysis of isonitrosocamphor, is a bright yellow substance melting at 198° C.

The quinonoid theory of colour is dealt with in the article COLOUR: Influence of Chemical Constitution.

BIBLIOGRAPHY.—T. E. Thorpe, *Dictionary of* Applied Chemistry, vol. v., 1924, contains a comprehensive article on Quinones and their derivatives. (G. T. M.)

QUINSY, a common term for acute suppurative tonsilitis (*q.v.*).

QUINTAIN, an instrument used in the age of chivalry in practising for the tournament (O. Fr. *quintaine,* from Lat. *quintana,* a street between the fifth and sixth maniples of a camp, where warlike exercises took place). An early form consisted of the wooden figure of a Saracen armed with shield and sword; the object being to strike the figure on the forehead between the eyes.

As late as the 18th century running at the quintain survived in English rural districts.

QUINTESSENCE, in ancient and scholastic philosophy, the name given to the fifth immaterial element, over and above the four material elements, air, water, earth and fire, which Aristotle assumed to be permeating the whole world, and called *οὐσία*; in mediaeval philosophy this was called *quinta essentia,* the fifth essence.

QUINTILIAN [MARCUS FABIUS QUINTILIANUS] (c. A.D. 35–95), Roman rhetorician, was born at Calagurris in Spain. The years from 61 to 68 he spent in Spain, probably in the retinue of the future emperor Galba, with whom he returned to the capital. For at least 20 years after the accession of Galba he was at the head of the foremost school of oratory in Rome. Vespasian created for him a chair of rhetoric. About the year 88 Quintilian retired from teaching and from pleading, to compose his great work on the training of the orator (*Institutio* Oratoria). After two years' retirement he was entrusted by Domitian with the education of two grand-nephews, whom he destined as successors to his throne. Quintilian gained the titular rank of consul, and probably died not long before the accession of Nerva (A.D. 96). A wife and two children died early. His great work, the *Institutio* Oratoria, is in form a manual on the training of a public speaker; in fact it is the outline of a liberal education. As an orator, a teacher and an author, Quintilian set himself to stem the current of popular taste which found its expression in what we are wont to call silver Latin; but apparently he did not attempt to modify the primary cause of it—the excessive concentration on poetry in the early stages of literary training. In his youth the influence of the younger Seneca was dominant. But the chief teacher of Quintilian was a man of another type, one whom he ventures to class with the old orators of Rome. This was Domitius Afer, a rhetorician of Nîmes, who rose to the consulship. His great model was Cicero, of whom he speaks at all times with unbounded eulogy, and whose faults he could scarce bring himself to mention; nor could he well tolerate to hear them mentioned by others. The reaction against the Ciceronian oratory which had begun in Cicero's own lifetime, had acquired overwhelming strength after his death. Quintilian failed to check it, as another teacher of rhetoric, equally an admirer of Cicero, had failed—the historian Livy. The great movement for the poetization of Latin prose which was begun by Sallust ran its course till it culminated in the monstrous style of Fronto. The teachers and audiences in the schools of declamation, and in the courts the judges, juries and audiences alike, demanded the startling, quaint or epigrammatic, and the speakers practised a thousand tricks to satisfy the demand.

Starting with the maxim of Cato the Censor that the orator is "the good man who is skilled in speaking," Quintilian takes his future orator at birth and shows how this goodness of character and skill in speaking may be best produced. The scheme followed is the standard division into three periods, supervised by the litterator, the *grammaticus,* and the *rhetor* respectively. Under the first the child receives elementary instruction, under the second he is grounded in literary criticism and scholarship generally as well as in what we call grammar, especial emphasis being laid on poetry; the third stage studied much the same authors, though more attention was given to prose, but with a direct view to the practice of oratory. The parts of the work which relate to general education are of great interest and importance. Quintilian postulates the widest culture; there is no form of knowledge from which something may not be extracted for his purpose; and he is fully alive to the importance of method in education. Yet he develops all the technicalities of rhetoric with a fulness to which we find no parallel in ancient literature. Even in this portion of the work the illustrations are so apposite and the style so dignified and yet sweet that the modern reader, whose initial interest in rhetoric is of necessity faint, is carried along with much less fatigue than is necessary to master most parts of the rhetorical writings of Aristotle and Cicero. The passages which review Greek and Latin literature are the most famous of all. There is a considerable traditional element in these, greater on the Greek than on the Latin side; but substantially posterity has concurred in his judgment. In the divine government of the universe he seems to have had a more than ornamental faith, though he doubted the immortality of the soul. As to politics Quintilian, like others of his time, felt free to eulogize the great anti-Caesarian leaders of the dying republic, but only because the assumption was universal that the system they had championed was gone for ever.

The Latin of Quintilian is not always free from the faults of style which he condemns in others. It also exhibits many of the usages and constructions which are characteristic of the silver Latin. But no writer of the decadence departs less widely from the best models of the late republican period. The language is on the whole clear and simple, and varied without resort to rhetorical devices and poetical conceits.

Besides the *Znstitutio Oratoria,* there have come down to us under Quintilian's name 19 longer (ed. Lehnert, 1905) and 145 shorter (ed. Ritter, 1884) *Declamationes,* or school exercitations on themes like those in the *Controversiae* of Seneca the elder. The longer pieces are certainly not Quintilian's. The shorter were probably published, if not by himself, at least from notes taken at his lessons. Editio princeps, Carnpames (Rome, 1470). Of the editions of the whole works the chief is that by Burmann (1720); of the *Znstitutio Oratoria* that by Spalding, completed by Zumpt and Bonnell (1798–1834, 5th ed., Meister, 1882).

QUINTUS SMYRNAEUS, Greek epic poet, probably flourished in the latter part of the 4th century A.D. He is sometimes called Quintus Calaber, because the only ms. of his poem was discovered at Otranto in Calabria by Cardinal Bessarion in 1450. According to his own account (xii. 310), he tried his hand at poetry in his early youth, while tending sheep at Smyrna. His epic in 14 books, known as Τὰ μεθ' Ὅμηρον or *Posthomerica,* takes up the tale of Troy at the point where Homer's Iliad breaks off (the death of Hector), and carries it down to the capture of the city by the Greeks, their departure and dispersal in the storm. The poet has no originality; in conception and style his work is ciosely modelled on Homer.

Editio princeps by Aldus Manutius (1504); Köchly (ed. major with elaborate prolegomena, 1850; ed. minor, 1853); Z. Zimmermann, author of other valuable articles on the poet (1891); *see* also Kehmptzov, *De Quinti Smyrnaei Fontibus ac Mythopoiia* (1889); C. A. Sainte-Beuve, *Etude sur . . . Quinte de Smyrne* (1857); F. A. Paley, *Quintus Smyrnaeus and the "Homer" of the tragic Poets* (1879); G. W. Paschal, *A Study of Quintus Smyrnaeus* (Chicago, 1904).

QUIPUS. The Peruvian *quipus* consists of a number of thongs or cords hanging from a top-band or cross-bar, generally forming groups, often with an equal number of cords in each group, with cords from these and again from the last. Knots occur rarely on the main cord. In its simplified form, knots are merely tied upon the individual cords. In its more elaborate forms the cords are of different colours, and are knotted together so as to form open loops of various shapes. In the Antiguedades Peruanas, we are told that the knots of the *quipus* in all probability indicated only numbers originally, but that as time went on the skill of the makers became so great that historical events, laws and edicts could thus be communicated. In every place of any importance there was an official whose business it was to interpret *quipus* received from a distance, and to make *quipus* himself. If, however, the *quipus* came from a distant province, it was not intelligible without an oral explanation. The art of interpretation of *quipus* is lost, so that it is impossible to ascertain how far the knots were merely a mnemonic for the messenger, and how far they were intelligible without explanation to a stranger. Recent examination of a series of complete *quipus* suggests knowledge of an astronomical nature, similar to that of the Mayas, and the use of these devices for magical purposes. Similar mnemonics were used amongst the Chinese, the Tibetans and other peoples of the Old World. See KNOTS.

BIBLIOGRAPHY.—See Leland Locke, *The Ancient Quipus* (1923); E, Nordenskiöld, *The Secret of the Peruvian Quipus* (1925).

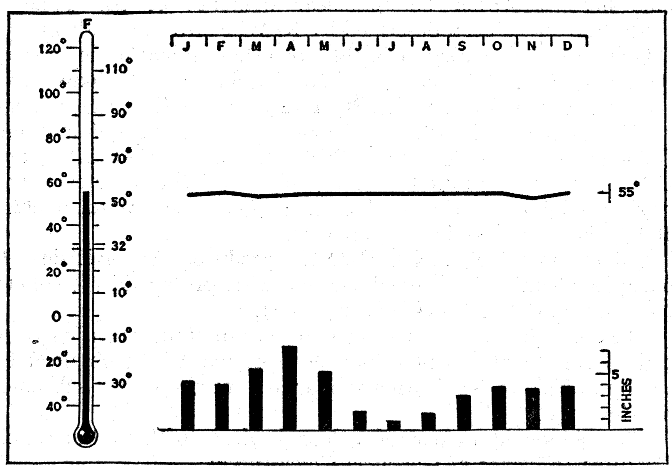
QUIRINUS (*kwĭ-rī'nus,* Lat. *kwĭ-rē'nōōs*) was the third (after Jupiter and Mars) of the purely Roman gods. The name Quirinus is adjectival in form, and it would seem to mean "he of *quirium,*" a word generally taken since Niebuhr to signify a very ancient Sabine settlement which united with the Palatine community to form the original Rome; but (see Kretschmer in Glotta, x. 147 et seq.) it may well mean "assembly" (*covirium*), and therefore the god may be "he of the assembly or assembled host." The identification, in the last century of the republic, of Quirinus with the deified Romulus has greatly obscured his real nature, but we know he resembled Mars (q.v.), had a flamen, the third in rank of the greater flamines, and a college of Salii. His temple lay on the *collis Quirinalis,* and his festival, the Quirinalia, was on Feb. 17. Associated with him in cult were a goddess, Hora, and certain minor deities, the Virites Quirini.

See Wissowa, *Relig. u. Kultus* (2nd ed.), p. 153, and Roscher's *Lexikon.*

QUIRITES (*kwĭ-rī'tēz*), earliest name of the burgesses of Rome (see QUIRINUS). In the phrase "populus Romanus Quirites (or Quiritium)," it denoted the individual citizen as contrasted with the community. Hence ius Quiritium in Roman law denotes full Roman citizenship. Whether the word ever had military associations is a point much debated, but if so it lost them at an early date and came to designate Roman citizens in their civil, as distinct from their military, capacity, and referred solely to Romans concerned in domestic affairs. Thus Caesar is said to have quelled a mutiny among his legionaries by the device of addressing them as "Quirites" (citizens). (See ROMAN LAW.)

QUITMAN, a city of southern Georgia, U.S.A., the county seat of Brooks county; on federal highway 84, and served by the Atlantic Coast Line and the South Georgia railways. Pop. 4,149 in 1930; 4,450 in 1940. It has several mills and factories, and is a shipping point for melons, garden truck, and other agricultural produce. The city was founded in 1858 and incorporated in 1859.

QUITO, the capital of the republic of Ecuador, and of the province of Pichincha, situated in lat. 0° 14′ S., long. 79° 45′ W., about 114m. from the Pacific coast and 165m. in a direct line north-east of Guayaquil, with which it is connected by a railway completed in 1908. In 1941 the population of Quito was estimated at 142,440. It occupies a small basin of the great central plateau formed by the volcano Pichincha on the west, the Puengasi ridge on the east, and ridges north and south formed by spurs from the eastern side of Pichincha. The ground upon which the city is built is uneven and is traversed from west to east by two deep ravines (quebradas), one of which is arched over in great part to preserve the alignment of the streets. The city is in great part laid out in rectangular squares, the streets running nearly



WEATHER GRAPH OF QUITO. THE MERCURY INDICATES THE NORMAL ANNUAL MEAN TEMPERATURE. THE CURVE SHOWS THE NORMAL MONTHLY MEAN TEMPERATURE. AND THE COLUMNS INDICATE THE NORMAL MONTHLY PRECIPITATION

with the cardinal points of the compass. The houses of Quito are chiefly of the old Spanish or Moorish style. The building material in general use is sun-dried bricks, which in the better houses is covered with plaster or stucco. The public buildings are of the heavy Spanish type. Facing the principal square (Plaza Mayor), and occupying the whole south side, is the cathedral; on the west side is the government palace; on the north the archbishop's palace; and on the east the municipal hall. The elevation of this plaza is 9,343ft. above sea-level. The finest building in the city is the Jesuits' church, the façade of which is covered with elaborate carving. Among public institutions are the university, which occupies part of the old Jesuit college, an astronomical observatory, and 11 large monastic institutions, six of which are for nuns. One of the convents, that of San Francisco, covers a whole block, and ranks among the largest institutions of its kind in the world. A part of it is in ruins, and another part has been for some time used as military barracks by the government. The university has faculties of theology, law and medicine, and has 200 to 250 students, but it is antiquated in character and poorly supported. The eminent botanist and chemist, Dr. William Jameson (1796–1872), was a member of its faculty for many years. There are a number of retail and wholesale firms. The city exports include hides and forest products from the wooded mountain slopes near by. Religious paintings of a mediaeval type are produced in large numbers and exported. The native manufactures include tanned leather, saddles, shoes, ponchos, woollen and cotton cloth, fibre sandals and sacking, blankets, coarse matting and woollen carpets. Quito artisans show much skill in wood and ivory carving and in gold and silver work. The women excel in fine needlework.

Quito derives its name from the Quitus, who inhabited the locality a long time before the Spanish conquest In 1533 Sebastian Benalcazar took peaceable possession of the native town and in 1541 it was elevated to the rank of a Spanish city. Its full title was San Francisco del Quito, and it was capital of the province or presidency of Quito down to the end of Spanish colonial rule. It has suffered repeatedly from earthquakes.

QUIT RENT, a yearly payment, a relic of the feudal system, made by the copyholders or freeholders of an English manor to its lord. It is a customary payment based on immemorial usage. It is called quit rent because it acquits the tenant of all dues and obligations to the lord. When paid by a freeholder, quit rent is called chief rent. This form of rent has its origin in the feudal services due to the manor, compounded for an annual payment (see RENT).

In the United States the term quit rent is used to describe a perpetual rent reserved upon the conveyance of a fee simple, more commonly known as a fee-farm rent, a ground rent, or rent charge.

QUIXOTE, DON (in Spanish Don Quijote), the hero of Cervantes' (q v.) romance (part 1, 1605: part 2, 1615), which was originally conceived as a satire of farcical incident directed against the romances of chivalry. *(See* SPANISH LITERATURE.) He has given his name in all European languages to a type of character which misses practical success by supposing that common humanity is governed by ideals as exalted or as imaginative as its own.

QUM, a province and town in Persia. The province lies between Tehran, north, and Kashan, south, producing abundant grain, and cotton of a very long staple. The revenue amounted to 342,088 krans in 1926–27 (about £7,602). Qum, the administrative headquarters, in 34° 39' N. and 50° 55′ E., has an elevation of 3,100 ft. Pop. (1935) 25,000. It is a stronghold of the Shiah faith and has many tombs of saints and pious persons including the shrine of Fatima, sister of the Imam Riza; and the town is visited by large numbers of pilgrims. The later Safavis are buried at Qum. The walls of the town are dilapidated, but though the bazaars are poor, a brisk trade is carried on during the pilgrim season. The industries are the making of glass, pottery and shoes.

BIBLIOGRAPHY.—A. Houtum-Schindler, *Eastern Persian Irak,* Special publication, *R.G* S., 1897; A. V. Williams Jackson, *Persia past and present,* 1906; H. R. d'Allemagne, *Du Khorassan au pays des Backhtiaris. Trois mois de voyage en Perse,* 1911.

QUOIN, in architecture, originally any vertical external corner of a building; more generally applied, at present, to large cut stones used either to form an accurate corner in a wall of rough rubble or brick or else to furnish a decorative termination to a wall surface of any material. Projecting stone quoins, frequently rusticated, or with the edges slightly recessed or bevelled, are common decorative features in the high Renaissance work in Italy, the early 17th century work in France and the Palladian style in England; in these styles they are used not only at the corners of a building, but also often at the edges of windows and doors. In much 18th century work in Scandinavia, England and America, projecting quoin shapes are formed with brick.

QUOITS, a pastime resembling the ancient discus-throwing which formed one of the five games of the Creek pentathlon (*see* DISCUS), the two main differences between the ancient and modern sports being that the quoit is ring-shaped (one surface being rounded, the other—the back--being flat) and is lighter than the discus, and its throwing is a test rather of accuracy than strength. Few traces of a game resembling quoits (O.Fr. *coiter, quoiter,* to incite) can be found on the continent of Europe, and its origin may be sought for on the borderland of Scotland and England. There are references to it in the Midlands dating from the beginning of the 15th century, and it was one of the games prohibited in the reigns of Edward III. and Richard II. in favour of archery. According to the modern rules (1869 code modified), two iron or steel pins 18yd. apart are driven into the ground, leaving 1in. exposed. Each is situated in the centre of an "end," a circle of stiff clay 3ft. in diameter. The quoits, made of iron, may be of any weight, but are usually about g lb. each. They must not exceed $8\frac{1}{2}$in. in diameter, or be less than $3\frac{1}{2}$in. in the bore, or more than $2\frac{1}{4}$in. in the web. When delivering his quoit a player must stand within 4ft. 6in. of the centre of the end and at its side. Matches are played between teams or individuals, the object of the game being to throw the quoit as near to the pin as possible, a "ringer"; *i.e.,* a quoit actually surrounding the pin, counting two, and a quoit nearer to the pin than any of the adversary's, counting one. A match may be for any number of points, the team or player scoring that number first being the winner. In championship matches all quoits farther than 18in. from the end, are foul and removed. All measurements are made from the middle of the pin to the nearest edge of the quoit. If one or more quoits are lapped, the one most accessible is first measured and withdrawn. All quoits on their backs are a foul.

The championship of America is rewarded by the "Bell Medal," presented by the Grand National Curling Club of America.

(T. A. C.)

QUORUM, in its general sense, a term denoting the number of members of any body of persons whose presence is requisite in order that business may be validly transacted by the body or its acts be legal. The term is derived from the wording of the commission appointing justices of the peace which appoints them all. jointly and severally to keep the peace in the county named. It also runs—"We have also assigned you, and every two or more of you (of whom [*quorum*], any one of you the aforesaid A, B, C, D, etc., we will shall be one) our justices to inquire the truth more fully," whence the justices so named were usually called justices of the *quorum.* The term was afterwards applied to all justices, and subsequently, by transference, to the number of members of a body necessary for the transaction of its business.

QUOTATION, a passage repeated from the writings or speech of another. The verb "to quote" comes from Med. Lat. *quotare* (from *quot,* how many), to refer to by numbers, *i.e.,* of page, chapter, etc., also to separate into chapters, verses, etc. The term is also applied to the statement of the current prices of goods, commodities, stocks and shares (*see* STOCK EXCHANGE).

Useful lists of familiar quotations may be found in the following:—H. T. Riley, *Dictionary of Latin and Greek Quotations,* ed. Bohn; J. K. Hoyt and A. L. Ward, *The Cyclopaedia of Practical Quotations, English and Latin* (1892) ; Cassell's *Classified Quotations* (1924) ; J. Bartlett, *Familiar Quotations* (1926) ; C. N. Douglas, *Forty Thousand Quotations* (1921) ; Putnam's *Dictionary of Thoughts* (1930).

QUO WARRANTO, in English law, the name given to an ancient prerogative writ calling upon any person usurping any office, franchise, liberty or privilege belonging to the Crown, to show "by what warrant" he maintained his claim. the onus being on the defendant. It lay also for non-user or misuser of an office, etc. If the Crown succeeded, judgment of forfeiture or ousterlemain was given against the defendant. *(See* OUSTER.) The procedure was regulated by statute as early as 1278 (the statute of *Quo Warranto,* 6 Edw. *I.* ch. 1), which was superseded by the modern form of an information in the nature of a quo warranto, exhibited on behalf of the Crown or a private person called the relator. The information will not be issued except by Ieave of the court on proper cause being shown. It lies where the office is of a public nature and created by statute, even though it is not an encroachment upon the prerogative of the Crown. Where the usurpation is of a municipal office the information is regulated by 9 Anne ch. 25 (1711). Such an information must, in the case of boroughs within the Municipal Corporations Act, 1882, be brought within 12 months after disqualification (s. 225); in the case of other boroughs, within six years after the defendant first took upon himself the office. Though nominally a criminal it has long been really a civil proceeding, and has recently been declared to be so.

In the United States, quo warranto is the proper remedy under the statutes of the various states to ascertain the right of a person to an office of a public nature, or one in a corporation. It also is used to test the validity of a franchise held by a municipality or a public service corporation. Some states have substituted by statute information in the nature of quo warranto and other remedies, and where such substitution has been made, quo warranto is improper.

FOUNDED A·D· 1768

R The letter corresponding to modern R in the ancient Semitic alphabet was 4 (resh). Greek rho is found in a form practically unchanged in the early inscriptions from the island of Thera. The same form also occurs in early inscriptions from Attica and Corinth and in the Chalcidic alphabet. The most usual Greek form was rounded P and this is the form in which the letter occurs in the Lydian alphabet. A form D in which the loop is extended to the bottom of the vertical stroke also occurs in both the eastern and western alphabets. This was the form of the letter in the Umbrian and Oscan alphabets of Italy, although it is not found in Etruscan, the form in which is P or q. In the latter, however, the loop reaches nearly to the ground. In the Chalcidic alphabet a form R with an additional oblique stroke occurred. and this was taken over into Latin and exaggerated, so that we find the forms R, R and R. The last of the three survived.

NAME OF FORM	APPROX-IMATE DATE	FORM OF LETTER

THE DEVELOPMENT OF THE LETTER "R" FROM THE EARLIEST TIMES TO THE PRESENT DAY

The minuscule form has been subject to many variations. In cursive Latin of the 6th century occurred a form ⋁ in which the loop has disappeared, the three right-hand oblique strokes, or the loop and oblique stroke, being reduced to a single stroke. The Irish form in the 7th century was ɲ in which a similar process had taken place, but the remnants of the loop and oblique stroke had become extended in a horizontal direction. On the basis of this was formed the Carolingian r, in which the vertical stroke was not extended below the line. The Carolingian form is the minuscule r of modern printing, but in handwriting it still contends with the form ʌ, resembling the Latin cursive tradition.

The sound represented by the letter has been the liquid, formed by contact between the tip of the tongue and the palate. The tip of the tongue is sometimes also rolled. In certain continental countries the sound is pronounced farther back in the mouth than in England. In southern England the sound is a very weak one, and when final is completely dropped (*e.g.*, in the words *mother*, steamer, etc.). The ancients recognised a difference in the sound as pronounced by the Greeks and Romans. The Greek R was probably unvoiced or whispered, a fact expressed by placing the rough breathing over the letter when initial and by spelling Greek words containing this letter, when they were borrowed into Latin and the modern languages, by the combination rh.

(B. F. C. A.)

RA, the Egyptian solar god, one of the most important figures in the Pantheon. See EGYPT: Religion.

RABA BEN JOSEPH BEN HAMA (c. 280–352), Babylonian rabbi or amora. He is closely associated in his studies with Abaye. The latter was head of the Academy at Pumbeditha. Raba founded a new school at Mahuza, which eventually became so long as Raba lived the only academy in Babylonia (Persia). The development of Talmudic Law (or Halakkah) was much indebted to this rabbi, whose influence in all branches of Jewish learning was supreme. His friendship with the King Shapur II. enabled Raba to secure a relaxation of the oppressive laws enacted against the Jews of Persia.

See Graetz, *History of* the *Jews* (Eng. trans., vol. ii., ch. xxi.) ; Bacher, *Agada der* Babyl. *Amoraer,* p. 108, etc., and 114–133.

RABAH ZOBEIR (d. 1900), the conqueror of Bornu (an ancient sultanate on the western shores of Lake Chad, included since 1890 in British Nigeria), was a half-Arab, half-negro chieftain. He was originally a slave or follower of Zobeir Pasha (*q.v.*), and is said to have formed one of the party which served as escort to Miss Tinne (*q.v.*) in her journeys in the Bahr-el-Ghazal in 1862–64. In 1879, Zobeir being in Egypt, his son Suleiman and Rabah were in command of Zobeir's forces in the Bahr-el-Ghazal. They persisted in slave-raiding, and denied the khedive's authority, and Gordon sent against them Romolo Gessi Pasha. Gessi captured Suleiman and routed Rabah, who in July 1879 fled westward with some seven hundred Bazingirs (black slave soldiers). He made himself master of Kreich and Dar Banda, countries to the south and south-west of Wadai. He eventually established himself in Bagirmi, a state south-east of Lake Chad. In 1893 Rabah overthrew the sultan of Bornu. In his administration of the country he showed considerable ability and a sense of public needs. To the British, represented by the Royal Niger Company, Rabah gave comparatively little trouble. Early in 1897 he began an advance in the direction of Kano, the most important city in the Fula empire. The news of the crushing defeat by Sir George Goldie of the Fula at Bida, induced Rabah to return to Bornu. He now turned his attention to the French. Bmile Gentil had in this same year (1897) reached Lake Chad, via the Congo and Bagirmi, and had installed a French resident with the sultan of Bagirmi. As soon as Gentil had withdrawn, Rabah again fell upon Bagirmi, and forced sultan and resident to flee. In 1899 the French sent an expedition to re-conquer the country, but it was only after a third encounter (April 22, 1900) that Rabah was slain and his host defeated. The chieftain's head was cut off and taken to the French camp. In this battle Major Lamy, the French commandant, also lost his life.

The French continued the campaigh against Rabah's sons, two of whom were killed. Rabah had left instructions that if his army was finally defeated by the French, his successor should return to Bornu and make friends with the British. Rabah's third son, Fader-Allah, accordingly threw himself entirely upon British protection. But, in the later part; of 1901 Fader-Allah, who had 2,500 riflemen, again made aggressive movements against the French. In retaliation, Captain Dangeville pursued him into British territory. A battle was fought at Gujba, Fader-Allah being defeated. He fled mortally wounded and died the same night.

Connected accounts of Rabah's career are contained in É. Gentil's *La Chute de l'empire de Rabah* (Paris, 1902) and in M. von Oppenheim's *Rabeh und das Tschadseegebiet* (Berlin, 1902).

RABAT (*Ribàt*), a city on the Atlantic coast of Morocco, in 34° 3' N., 6° 46' W., 130 m. S. of Cape Spartel, on the southern side and at the mouth of the Bu-Regreg, which separates it from Salk on the northern bank, administrative capital of the French protectorate, seat of the general residency of France in Morocco. The native town and the mellah form a trapeze, protected from the open winds by a rise of land occupied by vast cemeteries. It is defended on the north by the Kasba of the Oudaïa, built on the cliff which rises at the mouth of the Bu-Regreg; a fine gateway (12th century) gives access to it; there is a museum in the neighbouring medersa (university). Three kilometres to the south of Rabat is the Hassan tower, a magnificent minaret of the Almohade period, and still further to the south the necropolis of Chella, which contains the tombs of the Merinides dynasty. The Dar-el-Makchzen (palace of the sultan) rises to the south-west. Important European quarters, with houses surrounded by gardens, have been arranged outside, and at a certain distance from, the native town; they are traversed by wide avenues. The general residency and the administrative offices are situated in the Touargas quarter. The harbour, impeded by a bar, is difficult of access; works are proceeding with a view to improving the channel, but Rabat, situated between Kenitra and Casablanca, does not seem called to a great commercial future, and will remain above all an elegant residential town. Pop. (1930) 55,348; 27,986 are Muslim, 4,218 Jews, 23,144 Europeans including 16,388 French civilians and 2,342 French soldiers. In 1913 there were only 300 Europeans.

Several towns have followed one another at the mouth of the Bu-Regreg. The most ancient settlement was at Chella, which, under the Romans, was called Sala Colonia. There were on the same spot a Berber town, which was succeeded, in the 12th century, by Salk on the right bank of the river. About the same time the Almohade sultan, Abd-el-Mumen, founded Rabat-el-Fath, the camp of victory, from which the town of Rabat takes its name; it was there that assembled the contingents of the holy war destined against Spain; it was also called Sala-el-Djedid, Salé the New, in opposition to Sala-el-Khedim, Salé the Old. In the 17th century Rabat received numerous Andalusians expelled from Spain, and became an independent republic of famous corsairs, at first rival, then vassal of Salé. The Alauit dynasty endowed it with many monuments, But the real rise of Rabat dates from the French protectorate (1912).

(1905–08); Henri Basset et Levi-Provençal, *Chella: une nécropole Mérinide* (*Hesperis,* 1922); *H.* de la Casinière, *Les municipalités marocaines* (Casablanca, 1924).

RABAUT, PAUL (1718–1794), French pastor of "the Church of the Desert" (see HUGUENOTS), was born at Bédarieux, near Montpellier, on Jan. 29, 1718. In 1738 he was admitted as a preacher, and after a year's study (1740–41) at the Lausanne Seminary, received charge of the church of Nimes. In 1744 he was vice-president of the general synod. During the persecution of 1745–1752 Rabaut went into hiding, and in 1753 a price was put on his head. During the years that followed he sought, with Antoine Court and others, to place French Protestantism on a solid basis and to improve their legal position. In 1785, when he was visited by General La Fayette, it was arranged that Rabaut's son, Rabaut Saint-Btienne, should go to Paris on behalf of the Reformed Church. In November 1787 Louis XVI.'s edict of toleration was signed, though it was not registered until Jan. 29, 1788. Two years later liberty of conscience was proclaimed by the National Assembly, of which Rabaut Saint-Étienne was chosen vice-president, and it was declared that non-Catholics might be admitted to all positions. After the fall of the Girondists, however, in which Rabaut. Saint-Étienne was involved, Paul Rabaut, who had refused to renounce his title of pastor, was arrested, dragged to the citadel of Nimes, and kept in prison seven weeks (1794). He died Sept. 25, 1794, soon after his release.

See J. Pons de Nimes, *Notice biographique sur Paul Rabaut* (1808); Charles Dardier, *Paul Rabaut, ses lettres à Antoine Court* (1884) and *Paul Rabaut, ses lettres à divers* (1891).

RABAUT SAINT-ETIENNE, JEAN PAUL (1743–1793), French revolutionary, was born at Nîmes, the son of Paul Rabaut (*q.v.*), the name of Saint-Etienne being assumed from a property near Nimes. In the Constituent Assembly he worked on the framing of the constitution, spoke against the establishment of the republic, and voted for the suspensive veto, as likely to strengthen the position of the crown. In the Convention he sat among the Girondins and was proscribed with his party. He went into hiding, but was discovered and guiliotined Dec. 5, 1793.

See J. A. Dartique, *Rabaut St.-Étienne à l'Assemblée Constituante* (1903).

RABBAN BAR SAUMA (*fl.* 1280–1288), Nestorian traveller and diplomatist, was born at Peking about the middle of the 13th century. He started on a pilgrimage to Jerusalem, and travelling by way of Tangut, Khotan, Kashgar, Talas in the Syr Daria valley, Khorasan, Maragha and Mosul, arrived at Ani in Armenia. Warnings of the danger of the routes to southern Syria turned him from his purpose; and his friend Rabban Marcos suggested Bar Sauma's name to Arghun Khan, sovereign of the Ilkhanate or Mongol-Persian realm, for a European embassy, then contemplated, to conclude an anti-Muslin1 alliance with the chief States of Christendom. Bar Sauma set out in 1287, with Arghun's letters to the Byzantine emperor, the pope and the kings of France and England. He went first to Constantinople, then to Rome. The papacy being then vacant, a definite reply to his proposals was postponed, and Bar Sauma passed on to Paris, where he visited Philip IV. In Gascony he met King Edward I. of England, probably at Bordeaux. On returning to Rome, he was cordially received by Pope Nicolas IV., who gave him communion on Palm Sunday, 1288, allowed him to celebrate his own Eucharist in the capital of Latin Christendom, commissioned him to visit the Christians of the East, and entrusted to him the tiara which he presented to Mar Yaballaha. His narrative is of unique interest as giving a picture of mediaeval Europe at the close of the crusading period, painted by a keenly intelligent, broad-minded and statesmanlike observer.

See J. B. Chabot's translation and edition of the *Histoire du Patriarche Mar Jabalaha III. et du moine Rabban Cauma* (from the Syriac) in *Revue de l'Orient latin,* 1893, pp. 566–610; 1894, pp. 73–143, 235–300; O. Raynaldus, *Annales Ecclesiastici* (continuation of Baronius), A.D. 1288, ss. xxxv.–xxxvi.; 1289, s. lxi.; C. R. Beazley, *Dawn of Modern Geography* (1897, etc.) ii. 15, 352; iii. 12, 189–190, 539–541.

RABBI, a Jewish title (Hebr. רַבִּי, My teacher or master; διδάσκαλε, John I., 38) or *Rab* (master) or *Rabbēnu* (our master; Hebrew) or *Rabbān* (our master: Aramaic) are titles applied to Jewish scholars or doctors of the Law, but not used by them in speaking of themselves. They spoke of themselves as *Talmidhē Hakhāmim* (disciples of the wise); in later days a spiritual head of a congregation would style himself הצעיר or הקטן (cf. title page of S. Singer's Authorized *Daily* Prayer *Book).* Rab in biblical Hebrew means "great" and in later Hebrew "master" as opposed to *'ébhedh* or servant. These titles must be differentiated and the *locus classicus* is the famous letter of Sherira (see GĀON) from which it is clear that *Rab* is a Babylonian and Rabbi a Palestinian title. In Rabbi and *Rabbēnu* the pronominal suffixes "my" and "our" soon lost all force. Rabban was reserved for the Patriarchs, the first to bear the title being Gamaliel I. (*haz-Zāqen*), who presided alone over the Sanhedrin. Sherira emphasizes the fact that the earlier authorities (*e.g.,* Hillel) bore no titles. As regards the relative rank of the variants he says, "Rabbi is higher than Rab and Rabban is higher than Rabbi: higher than Rabban is the simple name." This means that the earliest untitled authorities are the most distinguished: these are followed by the Patriarchs and then by the Palestinian Tannaites (see GĀON) and Babylonian scholars successively. It is clear that in the days of Jesus titles were not used and some modern scholars therefore consider Matthew xxiii., 7, 8: Mark x., 51: John xx., 16 as anachronisms. The

Toṣefta to *'Eduyōth* (end) maintains that Rabbi denotes a teacher with at least two generations of disciples: in process of time antiquity makes him regarded as Rabban and by the time the second generation of disciples is forgotten he is styled by his own name alone. On the other hand Judah I., the redactor of the Mishnah is often known as Rabbi *κατ' ἐξοχήν*, while the Amora Abba *Arika* was generally styled Rab. The title of Rabbi was later conferred by ordination (Semikhah or laying on of hands): a still later term is *hattārath hōra'ah* or *facultas* docendi. The Qaraites in the tenth century who rejected Rabbinic tradition designated their opponents as Rabbanites. In mediaeval times Rabbēnu was used of distinguished scholars. In modern days Rabbi or Rab is often a courtesy title.

RABBIT, a well known rodent, formerly called cony. The rabbit, Oryctolagus *cuniculus,* is a member of the family Leporidae (see RODENTIA). From the hare (*q.v.*) the rabbit is distinguished by its smaller size, shorter ears and feet, absence of black on the ears and grey colour; by the facts that the young are born naked and blind and that it lives in burrows in the ground. It breeds from four to eight times a year, a litter comprising three to eight young. It begins to breed at the age of six months and lives seven or eight years.

Originally inhabiting the western half of the Mediterranean basin, the rabbit has spread, partly by the agency of man, throughout temperate Europe, and it is still extending its range. Introduced into New Zealand and Australia, where natural enemies were few, it has increased beyond bounds and is now an unmitigated nuisance. In North America some 57 forms are known, of which the commonest is the cottontail (Sylvilagus *floridanus*). (See HARE for other American Leporidae.)

The rabbit has long been domesticated, and the variations produced are greater than in any other mammal except the dog (*q.v.*). For not only has the weight been quadrupled and the structure of the skeleton modified, but the proportionate size of the brain has been reduced (cf. the domestic duck) and the colour and texture of the fur remarkably altered. The old English lop-eared breed may have ears 23 in. from tip to tip and 6 in. in width. The hardy and prolific Belgian hare resembles the true hare in colour and form, while a similar but larger variety is the (so-called) Patagonian rabbit. The Angora rabbit has very long fur, which is of commercial value; the most valued variety is the albino. The Dutch breed is small and particoloured, being dark posteriorly and white anteriorly. The silver grey is much esteemed for its skin, while the Flemish giant is the biggest of all breeds.

Modern dressing and dyeing methods have developed rabbit fur (known to the fur trade as "coney") into the most satisfactory of low priced furs for wearing qualities. Because it lends itself readily to dyeing it is used in great quantities in imitation of such furs as squirrel, seal, beaver, nutria, Chinchilla, muskrat, ermine, leopard and still others. Various tame varieties of rabbits, which are heavier, and have a fur stronger and less liable to shed, are being raised in increasing numbers, especially in Belgium and France, to supply the demand. Because of the excellent felting properties of rabbit fur it now forms the largest proportion of fur going into the manufacture of felt hats. Forty to fifty rabbit skins furnish material for a dozen hats. Rabbit fur is also in demand for upholstery purposes. The supply of rabbits for the hat industry comes chiefly from Australia (which for some years has averaged 70,000,000 skins annually), New Zealand, Belgium, France and England.

RABBŪLĀ, a distinguished bishop of the Syrian church early in the 5th century. He was a native of Kenneshrin, a town some few miles south of Aleppo and the seat of a bishopric. He resided for some time in a monastery, and then passed to a life of greater hardship as a solitary hermit. On the death of Diogenes, bishop of Edessa, in the year 411–412, Rabbūlā was chosen his successor. On one occasion he visited Constantinople and there preached before Theodosius II. (who was then favourable to Nestorius) and a great congregation a sermon in denunciation of Nestorian doctrine, of which a portion survives in the Syriac version. He became the friend of Cyril of Alexandria, with whom he corresponded, and whose treatise De recta *fide* he translated into Syriac. The version survives in a British Museum ms.; see Wright's *Catalogue* p. 719. He died in August 435.

RABELAIS, FRANÇOIS (c. 1495–1553), French author, was born at Chinon on the Vienne in the province of Touraine. The date of his birth is uncertain: it has been put by tradition, and by authorities long subsequent to his death, as 1483, 1490 and 1495. Most 17th-century authorities give the earliest date, and this also accords best with the age of the eldest of the Du Bellay brothers, with whom Rabelais was (perhaps) at school. In favour of the middle date, the testimony of Guy Patin (1601–72), a witness of some merit and not too far removed in point of time, is invoked. The only contribution which need be made here to the controversy is to point out that if Rabelais was born in 1483 he must have been an old man when he died, and that scarcely even tradition speaks of him as such. It is said that he had four brothers and no sisters, that his father had a country property called La Devinière, and was either an apothecary or a tavern-keeper. An indistinct allusion of his own has been taken to mean that he was tonsured in childhood at seven or nine years old; and tradition says that he was sent to the convent of Seuilly. From Seuilly at an unknown date tradition takes him to the convent school of La Baumette near Angers, where he is supposed to have been at school with the brothers Du Bellay, with Geoffroy d'Estissac and others. He certainly entered the Franciscan monastery of Fontenay le Comte some time before April 5, 1519, by which date he held a position sufficiently senior to sign deeds for the community. The letters of the well-known Greek scholar Budaeus, together with some notices by André Tiraqueau, a learned jurist, to whom Rabelais rather than his own learning has secured immortality, show what manner of life the future author of *Gargantua* led in his convent. The letters of Budaeus show that an attempt was made by the heads of the convent or the order to check the studious ardour of these Franciscans; but it failed, and there is no positive evidence of anything like actual persecution. Papers were seized as suspicious, then given back as innocent; but Rabelais was in all probability disgusted with the cloister—indeed his great work shows this beyond doubt. In 1524 his friend Geoffroy d'Estissac procured from Clement VII. an indult, licensing a change of order and of abode for Rabelais. From a Franciscan he became a Benedictine, and from Fontenay he moved to Maillezais, of which Geoffroy d'Estissac was bishop. But even this learned and hospitable retreat did not apparently satisfy Rabelais. In or before 1530 he left Maillezais, abandoned his Benedictine garb for that of a secular priest, and, as he himself puts it in his subsequent *Supplicatio* pro *Apostasia* to Pope Paul III., per *seculum* diu *vagatus fuit.* For a time the Du Bellays provided him with an abode near their own château of Langey, but on Sept. 17, 1530, he entered the faculty of medicine at the University of Montpellier, becoming bachelor on Nov. 1, a remarkably short interval, which shows what was thought of his acquirements. Early in 1531 he lectured publicly on Galen and Hippocrates, and his stay at Montpellier, which lasted rather more than a year at first, was renewed at intervals for several years.

In 1532, however, he had moved from Montpellier to Lyons. He was appointed before the beginning of November physician to the Hôtel Dieu, with a salary of 40 livres per annum, and lectured on anatomy with demonstrations from the human subject. He edited for Sebastian Gryphius, in the single year 1532, the medical *Epistles* of Giovanni Manardi, the *Aphorisms* of Hippocrates, with the *Ars* Parva of Galen, and an edition of two supposed Latin documents, which, however, happened unluckily to be forgeries.

At this time Lyons was the centre of an unusually enlightened society, and indirectly it is clear that Rabelais became intimate with this society. A manuscript distich, which was found in the Toulouse library, deals with the death of an infant named Théodule, whose country was Lyons and his father Rabelais, but we know nothing more about the matter. What makes the Lyons sojourn of the greatest real importance is that at this time probably appeared the beginnings of the work which was to make Rabelais immortal. There is no doubt that both Gargantua and Pantagruel were popular names of giants in the Middle Ages, though no mention of the former in French literature much before Rabelais's time has been traced. In 1526, however, Charles de Bordigné, in a satiric work of no great merit, entitled *la Légende de Pierre Faifeu,* has the name Gargantua with an allusion, and in 1532 (if not earlier) there appeared at Lyons *les Grandes et inestimable chroniques du grand et énorme géant Gargantua.* This is a short book on the plan of the later burlesques and romances of the Round Table. Arthur and Merlin appear with Grandgosier, as he is here spelt, Galemelle (Gargamelle), Gargantua himself, and the terrible mare. But there is no trace of the action or other characters of *Gargantua* that was to be, nor is the manner of the piece in the least worthy of Rabelais. No one supposes that he wrote it, though it has been supposed that he edited it and that in reality it is older than 1532, and may be the direct subject of Bordigné's allusion six years earlier. What does, however, seem probable is that the first book of *Pantagruel* (the second of the whole work) was composed with a definite view to this chapbook and not to the existing first book of *Gargantua,* which was written afterwards, when Rabelais discovered the popularity of his work and felt that it ought to have some worthier starting-point than the *Grandes chroniques.* The earliest known and dated edition of *Pantagruel* is of 1533, of *Gargantua* 1535, though this would not be of itself conclusive; but the definite description of Gargantua in the title as "Père de Pantagruel," the omission of the words "second livre" in the title of the first book of *Pantagruel* while the second and third are duly entitled "tiers" and "quart," the remarkable fact that one of the most important personages, Friar John, is absent from book ii., the first of *Pantagruel,* though he appears in book i. *(Gargantua),* and many other proofs show the order of publication clearly enough. Besides this, 1533 saw the publication of an almanac, the first of a long series which exists only in titles and fragments, and of the amusing *Progizosticatioiz Pantagrueline* (still, be it observed, Pantagrueline, not Gargantuine). Both this and *Pantagruel* itself were published under the anagrammatic pseudonym of "Alcofribas Nasier," shortened to the first word only in the case of the *Prognostication.*

On Oct. 23, 1533, *Pantagruel* was condemned by the Sorbonne, and in Jan. 1534 Jean du Bellay, passing through Lyons on an embassy to Rome, engaged Rabelais as physician. The visit did not last very long, but it left literary results in an edition of a description of Rome by Marliani, which Rabelais published in Sept. 1534.

In the spring of 1535 the authorities of the Lyons hospital, considering that Rabelais had twice absented himself without leave, elected Pierre de Castel in his place; but the documents do not imply any blame, and the appointment of his successor was once definitely postponed in case he should return. In the summer of 1535 Rabelais once more accompanied Jean du Bellay, now a cardinal, to Rome, and stayed there till April in the next year. To this period belong letters to Geoffroy d'Estissac, the already-mentioned *Supplicatio pro Apostasia,* and the bull of absolution which was the reply to it. This bull freed Rabelais from ecclesiastical censure, and gave him the right to return to the order of St. Benedict when he chose, and to practise medicine. He took advantage of this bull and became a canon of St. Maur. In 1537 he took his doctor's degree at Montpellier and lectured on the Greek text of Hippocrates, and in July 1538 he was present in the capacity of *maître des requêtes* at the canference between Francis I. and Charles V. at Aigues-Mortes. In 1540 we find him for the third time in Italy in the service of Guillaume du Bellay-Langey, elder brother of Jean, who was governor of Piedmont; and according to the letters of Pellicier, bishop of Montpellier and ambassador to Venice, Rabelais was then employed by him to collect mss. for the king's library. In Dec. 1540 he was compelled to return to France to clear himself of a charge of having revealed diplomatic secrets, but he rejoined Guillaume du Bellay at Turin in the following spring, and remained in his service until he died on Jan. 9, 1543. Rabelais wrote a panegyrical memoir of Guillaume, which is lost, and the year before saw the publication of an edition of *Gargantua* and *Pantagruel,* book i., together (both had been repeatedly reprinted separately), in which some dangerous expressions were cut away. Nothing at all is known of his life, whereabouts, or occupations till the publication of the third book, which appeared in 1546, "avec privilège du roi," which had been given in Sept. 1545.

Up to this time Rabelais, despite the condemnation of the Sorbonne referred to above, had experienced nothing like persecution or difficulty. Even the action of Dolet, who in 1542 reprinted the earlier form of the books which Rabelais had just slightly modified, seems to have done him no harm. But the storm of persecution which towards the end of the reign of Francis I. was fatal to Dolet himself and to Des Périers, while it exiled and virtually killed Marot, threatened him. It is certain that he passed nearly the whole of 1546 and part of 1547 at Metz in Lorraine as physician to the town at the salary of 120 livres, and Sturm speaks of him in a contemporary letter as having been "cast out of France by the times," and says that he himself in another letter gives a doleful account of his pecuniary affairs and asks for assistance. At Francis's death on March 31, 1547, Du Bellay went to Rome, and at some time not certain Rabelais joined him. He was certainly there before June 1548, and he was still there in Feb. 1549, when he dates from Du Bellay's palace a little account of the festivals given at Rome to celebrate the birth of the second son of Henry II. and Catherine de' Medici. This account, the *Sciomachie* as it is called, is extant. In the same year a monk of Fontevrault, Gabriel du Puits-Herbault, made in a book called *Theotimus* the first of the many attacks on Rabelais. It is, however, as vague as it is violent, and it does not seem to have had any effect. Rabelais had indeed again made for himself protectors whom no clerical or Sorbonnist jealousy could touch. The *Sciomachie* was written to the cardinal of Guise, whose family were all-powerful at court, and Rabelais dedicated his next book to Odet de Châtillon, afterwards cardinal. Thus Rabelais was able to return to France, and in 1550 was presented to the livings of Meudon and St. Christophe du Jambet. There is very little ground for believing that the "curé of Meudon" ever officiated or resided there. He certainly held the living for less than three years, resigning it in Jan. 1553 with his other benefice, and at the episcopal visitation of 1551 he was not present.

Some chapters of Rabelais's fourth book had been published in 1548, but the whole did not appear till 1552. The Sorbonne censured it and the parlement suspended the sale, taking advantage of the king's absence from Paris. But it was soon relieved of the suspension. He died, it is said, on April g, 1553, but actual history is quite silent save on the point that he was not alive in May of the next year, and the legends about his deathbed utterances—"La farce est jouée," "Je vais chercher un grand peut-être," etc.—are altogether apocryphal. The same may be said of the numerous silly stories told of his life, such as that of his procuring a free passage to Paris by inscribing packets "Poison for the king," and so forth.

Ten years after the publication of the fourth book and nine after the supposed date of the author's death there appeared at Lyons 16 chapters entitled *l'fle sonnante par maistre François Rabelais,* and two years later the entire fifth book was printed as such. In 1567 it took place with the others, and has ever since appeared with them. But from the beginning of the 17th century there have been disbelievers in its authenticity. The opponents of the book rely (1) on the testimony of a certain Louis Guyon, who in 1604 declared that the fifth book was made long after Rabelais's death by an author whom he knew, and who was not a doctor, and on the assertion of the bibliographer Du Verdier, about the same time, that it was written by an "écolier de Valence"; (2) on the fact that the anti-monastic and even anti-Catholic polemic is much more accentuaf ed in it; (3) on the arguments that parts are apparently replicas or rough drafts of passages already appearing in the four earlier books; and (4) that some allusions are manifestly posterior to even the farthest date which can be assigned for the reputed author's decease. On the other hand, it is urged that, though Guyon and Du Verdier were in a sense contemporaries they wrote long after the events, and that the testimony of the former is vitiated, not merely by its extreme vagueness, but by the fact that it occurs in a plaidoyer, tending to exculpate physicians from the charge of unorthodoxy; that Du Verdier in another place assigns the Prognostication *Pantagrueline* to this same unknown student of Valence, and had therefore probably confused and hearsay notions on the subject; that the rasher and fiercer tone, as well as the apparent repetitions, are sufficiently accounted for on the supposition that Rabelais never finally revised the book, which indeed dates show that he could not have done, as the fourth was not finally settled till just before his death; and that it is perfectly probable, and indeed almost certain, that it was prepared from his papers by another hand, which is responsible for the anachronous allusions above referred to. But the strongest argument, and one which has never been attacked by authorities really competent to judge, is that the "griffe de l'aigle" is on the book, and that no known author of the time except Rabelais was capable of writing the passage about the Chats *fourrés,* the better part of the history of Queen Whims (La Quinte) and her court, and the conclusion giving the Oracle of the Bottle.

Gargantua and *Pantagruel* are, unfortunately, so little read that some sketch of their contents is necessary. The first book, *Gar*gantzia, describes the birth of that hero (a giant and the son of gigantic parents), whose nativity is ushered in by the account of a tremendous feast. In this the burlesque exaggeration of the pleasures of eating and drinking, which is one of the chief exterior notes of the whole work, is pushed to an extreme. Very early, however, the author becomes serious in contrasting the early education of his hero—a satire on the degraded schools of the middle ages—with its subsequent and reformed stage, in the account of which all the best and noblest ideas of the humanist Renaissance in reference to pedagogy are put with exceptional force. Gargantua is recalled from Paris, whither he had been sent to finish his education, owing to a war between his father, Grandgosier, and the neighbouring king, Picrochole. This war is described at great length, the chief hero of it being the monk, Friar John, a very unclerical cleric, in whom Rabelais greatly delights. Picrochole defeated and peace made, Gargantua establishes the abbey of Thelema in another of Rabelais's most elaborate literary passages, where all the points most obnoxious to him in monastic life are indicated by the assignment of their exact opposites to this model convent. The second book introduces the principal hero of the whole, Pantagruel, Gargantua's son, who goes through something like a second edition of the educational experiences of his father. Like him, he goes to Paris, and there meets with Panurge, the principal triumph of Rabelaisian character-drawing, and the most original as well as puzzling figure of the book. Panurge has almost all intellectual accomplishments, but is totally devoid of morality. This book, like the other, has a war in its latter part; Gargantua scarcely appears in it and Friar John not at all. It is not till the opening of the third book that the most important action begins. This arises from Panurge's determination to marry—a determination, however, which is very half-hearted, and which leads him to consult a vast number of authorities, each giving occasion for satire of a more or less complicated kind. At last it is determined that Pantagruel and his followers (Friar John has reappeared in the suite of the prince) shall set sail to consult the Oracle of the Dive *Bouteille*. The book ends with the obscurest passage of the whole, an elaborate eulogy of the "herb pantagruelion," which appears to be, if it is anything, hemp. Only two probable explanations of this have been offered, the one seeing in it an anticipation of Joseph de Maistre's glorification of the executioner, the other a eulogy of work, hemp being on the whole the most serviceable of vegetable products for that purpose. The fourth and fifth books are entirely taken up with a description of the voyage. Many strange places with stranger names are visited, some of them offering obvious satire on human institutions, others, except by the most far-fetched explanations, resolvable into nothing but sheer extravaganza. At last the Land of Lanterns, borrowed from Lucian, is reached, and the Oracle of the Bottle is consulted. This yields the single word "Trinq," which the attendant priestess declares to be the most gracious and intelligible she has ever heard from it. Panurge takes this as a sanction of his marriage, and the book ends abruptly. This singular romance includes the most bewildering abundance of digression, burlesque amplification, covert satire on things political, social and religious, miscellaneous erudition of the literary and scientific kind. Everywhere the author lays stress on the excellence of "Pantagruelism," and the reader who is himself a Pantagruelist (it is perfectly idle for any other to attempt the book) soon discovers what this means. It is, in plain English, humour, which may be said to consist in the extension of a wide sympathy to all human affairs, together with a comprehension of their vanity. Moroseness and dogmatism are as far from the Pantagruelism of Rabelais as maudlin sentimentality or dilettantism. Perhaps the chief things lacking in his attitude are, in the first place, reverence, of which, however, from a few passages, it is clear he was by no means totally devoid, and secondly, an appreciation of passion and poetry.

For a general estimate of Rabelais's literary character and influence the reader may be referred to the article FRENCH LANGUAGE AND LITERATURE.

However, there are three questions without the discussion of which this notice of one of the foremost writers of the world would not be worthy of its present place. These are—What is the general drift and purpose of *Gargantua* and Pantagruel, supposing there to be any? What defence can be offered, if any defence is needed, for the extraordinary licence of language and imagery which the author has permitted himself? What was his attitude towards the great questions of religion, philosophy and politics? These questions succeed each other in the order of reason, and the answer to each assists the resolution of the next.

According to some expositors, Rabelais is a sober reformer, an apostle of sound education, of rational if not dogmatic religion, who wraps up his morals in a farcical envelope partly to make them go down with the vulgar and partly to shield himself from the consequences of his reforming zeal. According to others, Rabelais is all this but with a difference. He is not religious at all; he is more or less anti-religious; and his book is more or less of a general protest against any attempt to explain supernaturally the riddle of the earth. According to a third class, the Rabelaisian legend does not so much err in principle as it invents in fact. Rabelais is the incarnation of the "esprit Gaulois," a jovial, careless soul, not destitute of common sense or even acute intellectual power, but first of all a good fellow, rather preferring a broad jest to a fine-pointed one, and rollicking through life like a good-natured undergraduate. But it is impossible to think that any unbiased judge reading Rabelais can hold the grave-philosopher view or the reckless-goodfellow view without modifications and allowances which practically deprive either of any value. Those who identify Rabelais with Pantagruel, strive in vain to account for the vast ocean of pure or impure laughter and foolery which surrounds the few solid islets of sense and reason and devotion. Those who identify Rabelais with Panurge can never explain the education scheme, the solemn apparition of Gargantua among the farcical and fantastic variations on Panurge's wedding, and many other passages; while, on the other hand, those who insist on a definite propaganda of any kind must justify themselves by their own power of seeing things invisible to plain men.

No one reading Rabelais without *parti pris,* but with a good knowledge of the history and literature of his own times and the times which preceded him, can have much difficulty in appreciating his book. He had evidently during his long and studious sojourn in the cloister acquired a vast stock of learning. He was, it is clear, thoroughly penetrated with the instincts, the hopes, and the ideas of the Renaissance in the form which it took in France, in England and in Germany—a form, that is to say, not merely humanist but full of aspirations for social and political improvement, and above all for a joyous, varied, and non-ascetic life. He had thoroughly convinced himself of the abuses to which monachism lent itself. Lastly, he had the spirit of lively satire and of willingness *desipere* in *loco* which frequently goes with the love of books. It is in the highest degree improbable that in beginning his great work he had any definite purpose or intention. The habit of burlesquing the *romans d'aventures* was no new one, and the form lent itself easily to the two literary exercises to which he was most disposed — apt and quaint citation from and variation on the classics and satirical criticism of the life he saw around him. Here and there persons are glanced at, but for the most part the satire is typical rather than individual, and it is on the whole a rather negative satire. In only two points can Rabelais be said to be definitely polemic. He certainly hated the monkish system in the debased form in which it existed in his time; he as certainly hated the brutish ignorance into which the earlier systems of education had suffered too many of their teachers and scholars to drop. At these two things he was never tired of striking, but elsewhere, even in the grim satire of the *Chats fourrés,* he is the satirist proper rather than the reformer. It is in the very absence of any cramping or limiting purpose that the great merit and value of the book consist. It holds up an almost perfectly level and spotless mirror to the temper of the earlier Renaissance. The author has no universal medicine of his own (except Pantagruelism) to offer, nor has he anybody else's universal medicine to attack. It is not indeed possible to deny that in the Oracle of the Bottle, besides its merely jocular and fantastic sense, there is a certain "echo," as it has been called, "of the conclusion of the preacher," a certain acknowledgment of the vanity of things; but it is little more than a suggestion, and is certainly not strengthened by anything in the body of the work. Rabelais is, in short, if he be read without prejudice, a humorist pure and simple, feeling often in earnest, thinking almost always in jest. He is distinguished from the two men who alone can be compared with him in character of work and force of genius combined — Lucian and Swift — by very marked characteristics. He is much less of a mere mocker than Lucian, and he is entirely destitute, even when he deals with monks or pedants, of the ferocity of Swift. He neither sneers nor rages; the *rire immense* which distinguishes him is altogether good-natured; but he is nearer to Lucian than to Swift, and Lucian is perhaps the author whom it is most necessary to know in order to understand him.

If this general view is correct it will probably condition to some extent the answer to be given to the two minor questions stated above. The first is connected with the great blemish of *Gargantua* and *Pantagruel*—their extreme coarseness of language and imagery. Rabelais's errors in this way are of course, looked at from an absolute standard, unpardonable. But judged relatively there are several, we shall not say excuses, but explanations of them. In the first place, his comparative indecency has been much exaggerated by persons unfamiliar with early French literature. The form of his book was above all things popular, and the popular French literature of the middle ages as distinguished from the courtly and literary literature, which was singularly pure, can hardly be exceeded in point of coarseness. Moreover, Rabelais's coarseness, disgusting as it is, has nothing of the corruption of refined voluptuousness about it, and nothing of the sniggering indecency which disgraces men like Pope, like Voltaire, and like Sterne. The general taste having been considerably refined since, Rabelais has in parts become nearly unreadable — the worst and most appropriate punishment for his faults. As for those who have tried to make his indecency an argument for his laxity in religious principle, that argument hardly needs discussion. It is notoriously false as a matter of experience.

This brings us to the last point — what his religious opinions were. He has been claimed as a free-thinker of all shades, from undogmatic theism to atheism, and as a concealed Protestant. The last of these claims has now been very generally given up, but the accusation of free-thinking, if not of directly anti-Christian thinking, has always been more common. Those who hold this opinion, however, never give chapter and verse for it, and it may be said confidently that chapter and verse cannot be given. The sayings attributed to Rabelais which colour the idea are purely apocryphal. Even a jest at the Sorbonne couched in the Pauline phrase about "the evidence of things not seen," was removed by the author from the later editions. It must be remembered that the later middle age, which in many respects Rabelais represents almost more than he does the Renaissance, was, with all its unquestioning faith, singularly reckless and, to our fancy, irreverent in its use of the sacred words and images. On the other hand, there are in the book expressions which either signify a sincere and unfeigned piety of a simple kind or else are inventions of the most detestable hypocrisy. For these passages are not, like many to be found from the Renaissance to the end of the 18th century, obvious flags of truce to cover attacks — mere bowings in the house of Rimmon to prevent evil consequences. They are always written in the author's highest style, a style perfectly eloquent and unaffected; they can only be interpreted (on the free-thinking hypothesis) as allegorical with the greatest difficulty and obscurity, and it is pretty certain that no one reading the book without a thesis to prove would dream of taking them in a non-natural sense. There is absolutely nothing within the covers of Rabelais's works incompatible with an orthodoxy which would be recognized as sufficient by Christendom at large, leaving out of the question those points of doctrine and practice on which Christians differ. Beyond this no wise man will go, and short of it hardly any unprejudiced man will stop.

BIBLIOGRAPHY.—The first complete edn. of R. was publ. by J. Martin (Lyons, 1567). It is computed that 60 edns. were printed before the close of the 16th century (P. P. Plan, *Biblio. rabelaisienne,* 1532–1711, 1904). The first critical edn. of importance is that of Le Duchat (Amsterdam, 1711). Since the elaborate edn. of E. Johanneau (9 vols., 1823) there have been many edns., M. Marty-Laveaux in the Collection Lemerre (6 tom, 1868–1903), R. Lefranc, and others. There have been many commentaries independent of edns., from J. Bernier's *Jugement et Nouvelles Observations sur les oeuvres . . . de M. F. Rabelais* (1697), onwards.

See monographs by E. Noel (1850); A. Mayrargues (1868); J. Fleury (1876); P. Stapfer (the best) (1889); H. Hatzfield (Leipzig, 1923); J. Plattard, *La Vie de Fr. R.* (1929); also L. Saineanu, *La Langue de R.* (2 tom., 1922–23), and *Le cinqulme livre de R.* in Probltmes Littéraires du seizit-me sit-cle (1927); P. Villey, *Les grands écrivains du XVI siècle, R. et Marot,* in Bibl. Littéraire de la Renaissance, Tom. XI. (1923); J. Boulenger, *R. à travers les ages,* bibl. (1925); W. Nicati, *R. notre maître; son oeuvre, sa doctrine, le Pantagruelisme* (1926); *see* also *Revue des Études Rabelaisiennes* (1903–12), contd. as *Revue du seizième siècle* (1913, in prog).

Rabelais was very early popular in England, and Sir T. Urquhart trans. the earlier books in 1653; Motteux finished it with an extensive commentary in 1694. In 1893 there was a new trans. (2 vols) by W F. Smith. For English criticism *see* A. F. Chappell, *The Enigma of R., an essay in Interpretation* (1924); N. H. Clement, *The Infl. of the Arthurian Romances on the five books of R.* (Univ. of California, 1926). *See* also S. P. Putnam, *Rabelais: Man of the Renaissance* (1929).

RABIES: *see* HYDROPHOBIA.

RABIRIUS, a Latin epic poet of the age of Augustus. Among the papyrus fragments discovered at Herculaneum in the early part of the 19th century were sixty-seven (mutilated) hexameters, referring to the final struggle between Antony and Octavian and the death of Cleopatra, generally supposed to be part of a poem by Rabirius, since Seneca (*De Benef.* vi. 3, 1) informs us that he wrote on those subjects. If genuine, they justify the qualified commendation of Quintilian rather than the exaggerated praise of Velleius Paterculus (ii. 36, 3), who couples Rabirius and Virgil as the two most eminent poets of his time.

Fragments in E. Bährens, *Fragmenta Poetarum Romanorum* (1885); W. Scott, *Fragmenta Herculanensia* (Oxford, 1885); O. Ribbeck, *Geschichte der römischen Dichtung,* ii. (1889); M. Schanz, *Geschichte der rdmischen Litteratur,* ii. 1 (1899); Teuffel, *Hist. of Roman Literature* (Eng. trans., 1900), 252, 9.

RABIRIUS, GAIUS, a Roman senator, who was defended (63 B.C.) by Cicero in a speech still extant. Nearly forty years after the death of Saturninus, Titus Labienus was put up by Caesar to accuse Rabirius of the murder. The obsolete accusation of *perduellio* was revived, and the case was heard before Julius and Lucius Caesar as commissioners specially appointed (*duoviri perduellionis*). Rabirius was condemned, and the people were on the point of ratifying the decision on appeal when Metellus Celer dissolved the assembly.

A nephew known as C. RABIRIUS POSTUMUS, was also defended by Cicero (54 B.C.) in the extant speech *Pro Rabirio Postumo,* when charged with extortion in Egypt and complicity with Aulus Gabinius (*q.v.*).

See Cicero, *Pro Rabirio,* ed. W. E. Heitland (1882); Dio Cassius, xxxvii. 26–28; H. Putsche, *Uber das genus judicii der Rede Ciceros pro C. Rabirio* (Jena, 1881); O. Schulthess, *Der Prozess des C. Rabirius* (Frauenfeld, 1891).

RACAN, HONORÉ DE BUEIL, MARQUIS DE (1589–1670), French poet, became page at the court of Henry IV. and then entered the army, seeing some active service. In 1625 he published his most important work, *Bergeries,* a dramatic pastoral. Racan was a follower of Malherbe, and was one of the original members of the French Academy. He died in February 1670.

His *Oeuvres complètes* which include versions of the Psalms and sacred odes, were edited by Tenant de Latour in 1857, and the edition includes a biographical notice. *See* Sainte-Beuve, *Causeries du lundi.*

RACCONIGI, a town of Piedmont, Italy, in the province of Cuneo, 24 mi. S. of Turin, and 31 mi. N. of Cuneo by rail. 837 ft. above sea-level. Pop. (1936) 6.552 (town), 8,209 (commune). It has a royal château (1570), which in 1900 became the summer residence of the king of Italy.

RACCOON or **RACOON,** the typical representative of a family *(Procyonidae)* of American arboreal CARNIVORA (*q.v.*). The raccoon has a curious habit of washing its food in water before eating it. The typical raccoon *(Procyon lotor)* is a thickly built animal about the size of a badger, with a coat of long coarse greyish-brown hairs, short ears, and a bushy black-and-white-ringed tail. It extends over the whole of the United States and stretches on the west northwards to Alaska and southwards into Central America, where it attains its maximum size. The following notes are from Dr. C. Hart Merriam's *The Mammals of the Adirondacks:*—

THE RACCOON OR "COON" (PROCYON LOTOR), OF NORTH AMERICA

"Raccoons are oinnivorous beasts and feed upon mice, small birds, birds' eggs, turtles and their eggs, frogs, fish, crayfish, molluscs, insects, nuts, fruits, maize, and sometimes poultry. Excepting alone the bats and flying-squirrels, they are the most strictly nocturnal of all our mammals. . . . They haunt the banks of ponds and streams, and find much of their food in these places, such as crayfish, mussels, and fish, although they are unable to dive and pursue the latter under water. . . . They are good swimmers. . . . The raccoon hibernates during the severest part of the winter. . . . It makes its home high up in the hollow of some large tree, preferring a dead limb to the trunk itself. . . . From four to six young are . . . born at a time. . . . The young remain with the mother about a year."

The South-American species, *P. cancrivorus,* the crab-eating raccoon, differs by its shorter fur, larger size, more powerful teeth, and other minor characters. It extends over the whole of South America, as far south as the Rio Negro.

RACCOON-DOG (*Nyctereutes procyonoides*), a small wild dog, found in China, Japan and Amurland. The total length is about 32in. The prevailing hues are black and dusky yellow. In habit these dogs are nocturnal. In winter they feed on fish, and in summer on mice, forming small packs to hunt their prey.

RACEME, in botany, an inflorescence in which the main stem continues onwards, bearing the flowers on lateral branches, as in the wallflower (*q.v.*). A compound raceme is called a panicle. *(See* FLOWER.)

RACES OF MANKIND. The study of the varieties of the human race has occupied the attention of thinkers from early times. Two entirely different forms of classification have been employed, one based on the study of the skull, the second, and more generally used method, on superficial characters, such as skin and hair, which may be observed on the living man. To some extent these two methods have been combined in modern times.

Cranial Form.—Apart from Sergi, who elaborated a method of classification based on *cranial form,* the shape being estimated by viewing the skull from on top, most anthropologists have preferred to take measurements. especial importance being attached to the cephalic index—the percentage ratio of the length to the breadth—but numerous other measurements have been made, mostly of little value for classification. W. L. H. Duckworth suggested the combination of three characters on the skull, the cranial capacity, the cephalic index and the degree of prognathism (measured by taking the angle which the most projecting part of the jaw makes with the forehead). On the basis of the possible combinations of these criteria Duckworth divided mankind into seven groups.

Coefficient Method.—Karl Pearson devised a method, termed the coefficient of racial likeness, which aims by a method of averaging at including a very large number of measurements in a single figure The method is complex, and depends on the difference between a series of measurements taken on a set of skulls belonging to one race, and those taken on a second set. There is less difference in those closely allied than in those more distantly related and the coefficient is correspondingly smaller or bigger. The rather complex mathematical processes involved are the chief disadvantage of the coefficient method.

Colour Groups.—The oldest grouping of mankind, still in popular use, is that of skin colour. It has been suggested that the degrees in pigmentation of the human skin are due to the effects of environment, either to sunlight or humidity or a combination of both, the evolutionary changes which took place at an earlier date having become part of the heritage of the races we know to-day. Although the darkest skins are to be found in the tropics, whereas the fairest occur in the temperate climate of western Europe, attempts to correlate skin colour and environment break down when specific cases are considered. Some exceptions can be explained by recent immigration, others again, especially in the individual, by racial admixture, for where races are mixed we may find members of the same family who are very differently pigmented. On the whole the average value of the skin colour in various groups is correlated with other criteria, which appear to be good bases for classification.

One of the most important of these is the cephalic index. Taking the length as 100, the proportion of the breadth seldom falls below 70 or over 90, and it is usual to describe those peoples with an index below 75 as *dolichocephalic* (long-headed), those above 80 as *brachycephalic* (short-headed), the intermediate group being *mesocephalic.* Taken by itself, either in the individual or the race, the cephalic index is by no means a certain guide. We find brachycephalic, mesocephalic and dolichocephalic groups in all the greater divisions of mankind. In the individual, a series of 6,000 Japanese contained one man with an index of 69, and one of 96, and in a continuous series between these two extremes over 700 (about 12%) having indices between 80 and 81, the average being just under the latter figure.

Of the characters generally in use, however, the cephalic index shows most consistently the lowest *relative* variation within small groups. It is therefore of great value for classifying smaller units within the wider divisions, but deductions can only be drawn from the average of a reasonably large number of individuals, at least 50 of the same sex. The practice of artificial deformation may to a certain extent obscure the true head form, and where it occurs the cephalic index is often of little value.

Usually long heads are associated with long faces and vice versa, the face being then termed harmonic. A certain use of this fact has been made for classificatory purposes. There are other features of facial form which appear to be characteristic of different races, but are difficult to measure exactly.

Stature and Nose Form.—The *average* stature is a useful criterion. The form of the nose is estimated by an index formed by taking the length from the root to the junction with the upper lip as 100 and expressing the breadth across the nostrils as a percentage. Professor Thomson, to whom the idea was due, and Buxton have shown that the nasal index tends to be high in those countries where the air is moist and hot and low where it is cold and dry, the various combinations of these two factors being associated with corresponding nasal indices. The correlation is high with certain very marked exceptions, of which the most important is the Australian aborigines. It seems probable that they migrated from a hot, moist climate, and that they have retained the form of nose most appropriate to such a climate. The evolution of any character needs the time factor, especially when, as in this case, evolution by elimination has played an important part.

Hair Form.—On the basis of the form of the hair, mankind may be divided into straight-haired (*leiotrichous*), woolly-haired (*ulotrichous*) and an intermediate group of wavy or curly-haired (*cymotrichous*). Certain types are difficult to define, but usually the distinction is clear-cut. All types of hair may occur in the same population, where racial admixture has taken place, but normally the variation is slight in the same group.

In section the woolly hair is flat and ribbon-like, straight hair is round, wavy and curly hair showing an elliptical form. Here also there may be a certain correlation with environment. The woolly hair occurs for the most part in the Tropics and may form a protection against the sun, being associated with special sweat-glands. The period at which the evolution of the hair form took place is uncertain, but it remains the most convenient basis for the ultimate classification of the great groups of man, the other criteria being subordinated to it. In this classification physical criteria alone have been used; all cultural or linguistic terms have been avoided. Owing to historical reasons certain peoples have been named after the languages they speak, and subsequently these terms have been applied to physical types. Terms like Malay, Dravidian, Mongo! and Bantu are used as if they could be applied to races and not merely to peoples speaking certain groups of languages.

Other Classifications.—The classification given below is based on the anatomical characters already discussed; attention has, however, been recently directed towards certain physiological characters as a basis of racial differentiation. Several criteria have been put forward, amongst them the different reactions of the blood sera in divergent races and the effect of the ductless glands on the macroscopical anatomical characters. Although great stress has been laid on the latter, especially by Sir Arthur Keith, neither this nor other physiological criteria have to the present time been sufficiently investigated to form a basis for a novel classificatory method.

Straight-haired Groups.—The straight-haired peoples correspond to a large extent to the races called by some writers Mongol or Mongoloid, or "the Yellow-Brown Race." All these peoples possess cheek-bones of a greater or lesser degree of prominence. In most cases the face is flattened, often markedly so. The skin is usually yellow, shading into a coppery yellow or brown on one side, and on the other, especially in women, a pale almost white yellow tinge. In Asia the cephalic index tends to vary between mesocephaly and brachycephaly, with some marked cases of the latter form. In America the Eskimo are dolichocephalic and a wide range of mesocephaly and brachycephaly occurs among the other tribes.

While Haddon divides this race into three groups on the basis of a cephalic index, it is probably more convenient to adopt a primary geographical division and to separate the Leiotrichi into an Asiatic and American group, since the latter have been separated from their kinsmen in Asia for a long time and have to a certain extent specialised.

Asiatic Groups.—There are three groups in Asia, a northern or Arctic group, a central group, the Pareoeans (the Dwellers beside the Dawn) and a southern or Proto-Malay, it being possible that the two latter groups, formerly included under the term Southern Mongoloid, should be classed together.

The northern group is rather indeterminate, and includes a number of tribes living in the circumpolar regions of Asia and extending even as far west as northern Scandinavia, where they are represented by the Lapps. Most of these peoples have mixed with other races, to which fact their diversity is due, but they certainly include a mesocephalic and a round-headed subdivision. In eastern Asia at least there is a more northerly group, living in the most easterly extension of the continent and a more southerly group, but the difference is probably due to racial admixture, consequent on the intrusion of the peoples who brought in the Turko-Mongol culture from the west and thus divided the northern and central groups of the straight-haired peoples.

In Korea there is a narrow belt which forms a connecting link between the northern and the Pareoean peoples. The latter differ most strikingly from their northern neighbours in having less prominent cheek-bones and a broadish nose. In the north of China they are often tall; in the south, where the type is found in greater purity, they are short and more stockily built. The Japanese represent a special variety of this type; they have mixed considerably with the Ainu, and this, at least in some cases, has altered their physical type.

The southern extension of these peoples, the Proto-Malays, are widely spread in south-eastern Asia and in the islands. They have been mixed with the various other peoples of this region and it is often difficult to distinguish them except by their broader heads.

The straight-haired peoples also extend into Central Asia, where they are known as Turks and Mongols. These terms are cultural and linguistic, and cannot be used in a racial sense. Great racial admixture has undoubtedly taken place in this region and much of the population is closely connected with the peoples of the west, but types occur with straight hair and other characters which show affinities with the Arctic group.

Most remote from the straight-haired peoples and showing certain relationships to them are the Polynesians, who live on the islands of the Pacific from Samoa to Easter I. and Hawaii to New Zealand. They probably represent an old mixture between the Proto-Malays and a group of the curly-haired people called Nesiots (islanders, see below), but other admixture has taken place and their position is difficult exactly to determine.

The *Amerinds.*—As regards the American aborigines, for whom the term *Amerind* has become conventionalised, it has been disputed whether they should be considered to belong to one race or not. The Eskimo, who to-day inhabit the Arctic coast of America, with a western extension into Asia, and an eastern into Greenland, once lived as far south as the coast of Massachusetts, and survived near Quebec till comparatively recent times. They differ from the other inhabitants of America in many respects notably in having extremely long skulls (the western Eskimo differ somewhat in this respect), which are compressed laterally and are very high-pitched. They have broad faces, an unusual feature in people with a long skull, and very narrow noses. The jaws are exceptionally well-developed and the individual teeth are very large, possibly owing to the nature of their food.

The Amerinds themselves vary considerably in most of those characters usually considered to be of racial significance. Hrdlicka, ho ever, believes that they all belong to the same race. Verneau has recently affirmed the concurrence of types akin to the Melanesians, a view previously held by others also. Haddon suggests with every degree of probability that side by side with the straight-haired peoples there is a cymotrichous type, which he has called Palaeo-Amerinds.

The subdivisions of the true straight-haired Amerinds are somewhat complicated and need not be discussed in great detail. The best basis for division is the cephalic index, but stature and other features must be taken into consideration. The nasal index, it should be noted, increases towards Central America.

The peoples of the north-west coast are most closely allied to the inhabitants of Asia, and are distinguished from the other Amerinds by their lighter skin colour. East of the Rockies and extending over the great plains and into the woodland area there is a group of tall tribes with mesocephalic heads, of whom the Sioux are a typical example. On the east coast in ancient times there was a different type with longer, narrower heads. On the American plateau and extending into central and southern America there is a round-headed type, of short stature and with straight noses, to whom the Maya of ancient times were akin. The Aztecs were more long-headed and their relationship with the more northerly peoples can be traced through some of the inhabitants of northern Mexico to-day.

The ethnology of South America is as yet not fully established, but several types can be distinguished, one akin to the Maya peoples and a different type, with a round head and tall stature, in Patagonia, oi whom the Fuegians are a branch. Side by side with these straight-haired peoples there exist traces of a curly-haired race, both in ancient deposits and also among some modern tribes. With the exception of the Palaeo-Amerinds the distribution of the straight-haired peoples is continuous, the Bering Strait dividing the Asiatic and American branches.

Woolly-haired Groups.—The woolly-haired people have an extremely discontinuous distribution, namely, an eastern habitat which stretches from the continent of Asia to Fiji, and a western, the greater part of Africa. Attempts have been made to bridge this gap. Hüsing believes that in ancient times short dark curly-haired peoples occurred on the Persian Gulf in localities where negroes are still found. These negroes are, however, the descendants of imported slaves, and there is no information of a definite character to support Hüsing's contention. Some of the jungle tribes of south India are said to have negroid characters, but at present no evidence has been collected to bridge the gap between the two groups, and the characters which link them may be due not to community of ancestry but to the effects of a tropical environment. While the original centre of dispersion of these peoples is at present uncertain, there are almost certainly secondary centres of dispersion in north-east Africa and eastern Asia.

In addition to woolly hair all these peoples have the following characters in common: dark skins sometimes almost black, broad noses, usually a rather small brain in relation to their size, especially among the taller members of the group, with forearms and shins proportionately long. In the skeleton there is a smoothness of contour which even in adults often recalls the bony form of a child, and among some members of the group the forehead has that prominent and smooth form which is so characteristic of the infant of our own race. In both eastern and western groups there is a division which includes some very small or pygmy peoples and another of medium or tall-statured tribes.

Eastern Group.—The eastern group may be divided on this basis into the pygmy Negritos and the taller Papuans and Melanesians. The former are all dark-skinned and have heads which are slightly rounded, the cephalic index varying from just under 80 to about 83. There are slight local differences due to the extreme isolation to which these peoples have been subjected Four separate geographical groups occur, one in the Andaman Islands (the Andamanese), one in the central regions of the Malay Peninsula and eastern Sumatra (the Semang), a third in various parts of the Philippine Is., usually called after a well-known tribe, the Aeta and a fourth group called after a tribe in the western mountains of Dutch New Guinea, the Tapiro, who have left traces in other parts of New Guinea and probably also in parts of Melanesia. All these groups are isolated from one another and occupy as it were almost the circumference of a circle. The Andamanese occupy a very special position, both racially and geographically; they have been isolated for a long period and until recently were not in contact with any other race. Such measurements as have been taken indicate that these people are remarkably true to type and show little variation from the average. They are probably the one human group which can be considered a "pure" race.

The Papuans and Melanesians are distinguished from the Negritos by their greater stature and narrower heads; the former probably represent the original stock. At one time they had a wide distribution throughout all Melanesia, probably to Australia, and the extinct Tasmanian aborigines seem to have been a variety of this stock. To-day Papuans are found in New Guinea and in some of the most easterly of the Indian Archipelago islands. They may be distinguished from their kinsfolk by their retreating forehead, prominent brow-ridges and the form of their noses, which are often prominent and rounded, with a down-turned tip.

The Melanesians are extremely variable and include a variety of racial elements, though the basis of the stock is Papuan. The racial mixing which has taken place will account for the fact that, although they are usually woolly-haired. all varieties of hair are found. Stature is equally variable, although the average height is under 5 ft. 3 inches. The prominent brow-ridges so characteristic of the Papuans is not common and the nose is usually smaller than in these peoples. The Melanesians have a wide distribution from the coastal regions of New Guinea and the neighbouring islands to the Pacific from New Caledonia to the Admiralty Is., and as far eastwards as Fiji; formerly they seem to have extended over most of the Pacific.

The Bushmen.—The Bushmen, who belong to the second group of the woolly-haired peoples, are also short, though not of pygmy stature; they differ from the other Ulotrichi in having yellowish skins. Now restricted to the Kalahari desert, they formerly ranged over the whole of south Africa and possibly over a much wider area. Their hair is short and curls into little tufts like pepper-corns, giving the appearance of bald patches. The head is small and low and there is little or no forward projection of the jaw. The most distinctive character of the Bushmen is a great development of the buttocks (steatopygia); this feature is specially developed in the women. The Hottentots are closely allied to the Bushmen and possess most of the characters already described. They represent a cross between the latter and other negroid stocks.

True Negroes.—The true negroes inhabit the Guinea Coast, but their original range seems to have been over most of tropical Africa. They are tall with black or dark brown skins, long narrow heads and retreating foreheads and prominent jaws. The lips are thickened and everted and the nose is very broad. They have mixed with other elements and have produced hybrid stocks. In the upper Nile valley numerous tribes, called Kilotes, are to be found; they are characterised by a very tall stature, a 'slender build and extremely narrow heads. There is also a more round-headed strain, due probably to an early admixture with some curly-haired people. Most, if not all, of the Nilotes have been considerably altered by contact with other non-negro peoples. In central and southern Africa there are numerous negroid tribes characterised by a variety of physical form, due no doubt to racial admixture. The majority are long-headed with considerable variation in stature.

The Pygmies—In the equatorial forests certain pygmy tribes live. These Kegrillos differ from the tall negroes not only in their stature but also in the lighter colour of their skin, which is often yellowish and covered by a light down, and in the more rounded form of the head; the nose is broader even than that of the negro.

Curly-haired Groups.—The third great division of the human race, the curly-haired or Cymotrichous, occupies in many ways an intermediate position between the other two groups. Its distribution is world-wide, and it includes both undifferentiated and highly differentiated groups of mankind. The white races belong to this class. The centre of dispersion of the group was probably somewhere in Asia, but the precise limits of this cradle land have not yet been determined.

The hair varies from wavy to curly, and, whereas in other races it is, with but few exceptions, black or dark brown, in this group every shade occurs from a dead black to a fair straw colour; the brown, however, predominates. The skin colour is equally variable. Most members of this race have a fairly large brain in relation to their body size, but some of the more primitive members are extremely small-brained. The forehead in the males has usually a well-marked prominence over the eyes, the so-called "bar of Michael Angelo." The face is never flattened nor are the lips everted. The stature is very variable, but no pygmy types are found.

Every degree of cephalic index is found, and this still remains the most convenient method of simple classification. The race, however, contains certain sub-races which appear to be more primitive than others and the division into primitive and more advanced groups brings out certain points which may otherwise be overlooked. The primitive which survive are the Proto-Nordics, the Proto-Indics and the Australian aborigines. The Palaeo-Amerinds also probably belong to this class. The rnore advanced peoples include a dolichocephalic group, a mesocephalic and a brachycephalic group.

Proto-Nordics.—The Proto-Nordics appear at one time to have had a wide distribution over northern Asia. Some of the present inhabitants of the Turkoman steppes present this type in an undifferentiated form. The Ainu, who have within comparatively recent times been driven out of the main islands of Japan, and who still inhabit the northern island (Hokkaido) Saghalien, and to the south the Riukiu islands. This curious people are of medium stature, very stockily built, with large heads and a marked bar across the forehead. They have an abundance of hair on the head and body and long, wavy beards. Their eyes are straight as in Europeans and their general appearance contrasts very strongly with the Japanese who to-day live amongst them.

Proto-Indics.—The Proto-Indics may be classed geographically into three. possibly four, divisions: first, the jungle tribes of southern India (some of the more primitive tribes of northern India also have affinities with this stock); secondly, the Vedda, the most primitive of the inhabitants of Ceylon; and thirdly, some of the more primitive peoples of the southern part of the Malay Peninsula, of whom the best-known are the Sakai and Senoi. In Sumatra and Celebes and possibly elsewhere in the Malay Archipelago there survive tribes who may be considered as a fourth division of the Proto-Indics, but here they have for the most part been mixed with other stocks. In much of southeastern Asia there is a racial background of Proto-Indics who have been overlaid by other invaders, but the stock has survived in a relatively pure state in the places enumerated above. The Proto-Indics have curly hair, very dark and often nearly dead black skins, a short stature and extremely broad noses.

The Australian *Aboriginal.*—The Australian aborigines almost certainly belong to the same stock, but they possess some special characteristics which may be due to the length of time they have been isolated from the parent stem. The skin is usually of a dark chocolate brown, the hair, which is somewhat variable but usually curly, is frequently very abundant on the face and body. The stature is medium, the nose very broad, and their most distinctive feature is the great bony development of the skull, including a great massing of bone over the eyes and a big development of the jaws and teeth. Whereas the Proto-Indics, notably the Veddas, have extremely small skulls, those of the Australians, though often containing an extremely small braincase, are always massively built, and the beetling brows, low forehead and projecting lower part of the face give the males a very characteristic appearance.

Advanced Long-kepded Types.—The long-headed peoples of less primitive type can be divided into several groups, but it seems extremely probable that all belong to the same stock; most of them can be distinguished from the Proto-Indics by their greater stature, and all by the narrower form of the nose. Local groups of these peoples have become separated into sub-races which breed true.

Eastern Groups.—The most easterly representatives of these stocks in Asia are the *Nesiots,* who are found mixed with the straight-haired, round-headed Proto-Malays in the Malay Archipelago, in the Philippines, sporadically in southeastern Asia and in the interior of southern China; the exact extension of these peoples is not yet fully known. In southern India a large proportion of the population belongs to a second group, Chersiots (mainlanders, as opposed to Nesiots, islanders). They are here much mixed with Proto-Indics and round-heads. In the northern part of India the proportion of the round-heads is much greater, and in the northwest the round-headed element predominates. In Rajputana and in the Punjab there is another group of long-heads, to be distinguished from the Chersiots by their taller stature, fairer skins and narrower noses. These Haddon terms Indo-Afghans.

Western Groups.—Further west, in the horn of Africa and the desert between the Nile and the Red Sea, this stock is dominant in the population, though frequently mixed with negroes. These tribes represent the modern descendants of the Proto-Egyptian population. Among the groups of this stock with a white complexion several varieties may be distinguished: one, the *Eur-african,* seems only to occur in isolated spots in north Africa and western Europe, including part of the British Isles, another is met with among the Bedouin Arabs, while the third or Mediterranean race forms the fringing population of the Mediterranean sea and the western Atlantic seaboard of Europe. In the eastern Mediterranean it is inextricably mixed with the Armenoid peoples.

Among the Mesocephals Haddon includes three groups; two, however, the Pyrenean and the Atlanto-Mediterranean are probably hybrids. The third, the Nordic, is more clearly marked and is characterised by fair skin and hair, blue eyes and a tall stature. To-day they form one element in the population of the British Isles and northern France, Belgium and Holland, and northern Germany. They predominate in Scandinavia.

The Round-headed Group.—The great round-headed branch of the Cymotrichi is conveniently called Eurasiatic. It extends all along the great mountain chain from the central plateau of France on the west to the Himalayas on the east. The Alpine branch of the family is distributed along the central massif of Europe into central and even Eastern Asia, the Armenoid or Illyrio-Anatolian has a more limited range in southeastern Europe and western Asia. They may be distinguished by the extreme flatness and height of the head. In the Pamirs, in Persia, and extensively in central Asia and in India, a separate branch of this race, the Pamiri, is found, while locally in western Europe isolated examples of two early groups. the Prospectatores and the "Beaker Folk" still survive. They probably resulted from early crossing of round-heads with Mediterranean and Nordic man respectively. All these peoples are marked by the roundness of their heads, their brown, auburn or black hair and somewhat sallow or olive skins. The eyes vary from brown to hazel, but blue eyes are found.

Most of the migratory movements which resulted in the present distribution of mankind took place too far back in history for us to estimate their exact course, but in all probability human stocks were evolved near the places where we first find them recorded in historic times. Some migrations belong to the domain of ancient history, but it is very doubtful how far these movements have actually affected the physical type. In all probability ethnological history has consisted chiefly of the gradual extension of dominant types. (See A. C. Haddon, Races of Mankind, 1924.)

RACHEL (1821–1858), French actress, whose real name was Elizabeth Felix, the daughter of poor Jew pedlars, was born on Feb. 28, 1821, at Mumpf, in the canton of Aargau, Switzerland. At Reims she and her elder sister, Sophia, afterwards known as Sarah, joined a troupe of Italian children who made their living by singing in the cafés, Sarah singing and Elizabeth, then only four years of age, collecting the coppers. In 1830 they came to Paris, where they sang in the streets, Rachel giving such patriotic songs as the *Parisienne* and the *Marseillaise* with a rude but precocious energy which evoked an abundant shower of coppers. Étienne Choron undertook to give the two sisters gratuitous instruction, and after his death in 1833 they were received into the Conservatoire. Rachel made her first appearance at the Gymnase in Paul Duport's La *Vendéenne* on April 4, 1837, with only mediocre success. On June 12, 1838, she made her *début* at the Théâtre Français, as Camille in Corneille's Horace, when her remarkable genius at once received general recognition. In the same year she won a great triumph as Roxane in Racine's *Bajazet,* but it was in *Phèdre,* which she first played on Jan. 21, 1843, that her peculiar gifts were most strikingly manifested. Her range of characters was limited, but within it she was unsurpassable. She excelled in the impersonation of evil or malignant passion, in her presentation of which there was a majesty and dignity which fascinated while it repelled. By careful training her voice, originally hard and harsh, had become flexible and melodious, and its low and muffled notes under the influence of passion possessed a penetrating quality that was irresistible. Perhaps her most successful appearance in plays by contemporary authors was in 1849 in Scribe and Legouvé's *Adrienne Lecouvreur,* which was written for her. In 1841 and in 1842 she visited London, where her interpretations of Corneille and Racine were the sensation of the season. In 1855 she made a tour in the United States with comparatively small success, but her powers had begun to deteriorate. She died of consumption at Gannet, near Nice, on Jan. 4, 1858, and was buried in the Jewish part of the cemetery of Pkre Lachaise in Paris. Rachel's third sister was Lia Felix.

RACHILDE (MME. ALFRED **VALLETTE,** née ETMERY) (1862–1938). Rachilde made her name by a series of powerful. sensational novels, dealing in many cases with abnormal personalities. She was an admirable critic, and was for many years one of the principal critics of the *Mercure de France.*

Her works include *Monsieur Vénus* 1889, latest ed. 1926); *La Tour d'Amour* (1899); *La Maison Vierge* (1920); *Les Rageac* (1921); *Le Grand Seigneur* (1922). *See* André David, *Rachilde* (1924).

RACHMANINOFF, SERGEI VASSILIEVITCH (1873–1943), Russian composer and pianist, was born on his father's estate Oneg, near Ilmen Lake, Government of Novgorod, on April 2, 1873. At nine he became a pupil of Demjansky's at the St. Petersburg Conservatoire, going three years later to the Moscow Conservatoire, where he studied piano under his cousin; Siloti, and composition under Taneiev and Arensky. In 1892 he won a gold medal with his opera *Aleko,* which was favourably received when produced at Moscow, 1893. Concert tours in Russia and elsewhere followed. In 1899 he appeared in London as pianist, conductor and composer, and in 1902 he had great success in Vienna. In 1903 he went back to Moscow where he remained for three years as piano professor at the Maryinsky Institute, also conducting at Imperial opera. Subsequently he lived for several years in Dresden where he devoted himself mainly to composition, varied by occasional concert tours. In 1909 he paid his first visit to the United States; while in 1912–13 he conducted the Moscow Philharmonic Symphony orchestra. After the Russian revolution he escaped to Sweden, with his family, and in 1918 took up his permanent residence in the United States.

Among Rachmaninoff's many compositions, particularly notable are the *Second Symphony* in *E Minor,* his piano concertos, opp. 1, 18 and 30, *Rhapsody on a Theme by Paganini,* and *Etudes Tableaux.* His *Recollections,* dictated to his editor, Oskar von Riesmann, was published in 1934. He was internationally known for his creative ability as a composer, and for his technique and interpretation as a pianist. He died in Beverly Hills, Calif., March 28, 1943.

RACINE, JEAN (1639–1699), French tragic dramatist, was born at La Ferté-Milon (Aisne), and was christened on Dec. 22, 1639. His father was a solicitor, and held the office of *controleur au grenier à sel* at La Ferté. Racine's mother died when he was little more than a year old and his father married again but himself died soon afterwards, whereupon the poet went to his grandparents, who had strong Jansenist leanings. He was sent to the grammar school at Beauvais, and in Oct. 1655 was transferred to the school which the "Solitaires" had established at Port Royal. He was a diligent student, and wrote verse both in Latin and French, his Port Royal odes being far from despicable. In 1658 he was entered at the Collkge d'Harcourt, and it is clear from his correspondence, which, as we have it, begins in 1660, that he was not at all of an austere disposition at this time, and that he was already given up irrevocably to literature. The marriage of Louis XIV. was the occasion of an ambitious ode, *La nymphe de la Seine,* which earned 600 livres, and in 1660 Racine finished one piece, *Amasie,* and undertook another, *Les Amours d'Ovide,* for the theatre. The first, however, was rejected by the actors of the Marais, and it is not certain that the other was ever finished. Racine's letters show that he was intimate with more than one actress at this time; he also made acquaintance with La Fontaine, and the foundations of the legendary "society of four" (Boileau, La Fontaine, Molière and Racine) were thus laid. In Nov. 1661 he went to Uzès in Languedoc to live with his uncle the Père Sconin, vicar-general of that diocese, whose attempts to secure a benefice for him were, however, in vain. Racine was back in Paris before the end of 1663, and an ode on the recovery of Louis XIV. from a slight illness secured him another grant of 600 livres in the summer of 1664. The ode in which he thanked the king for his presents, *La Renommke,* is said to have introduced him to Boileau, to whose censorship he was deeply indebted. Unfortunately there is a break in his correspondence after Nov 1663, and from this time forward the gossip of the period, and the *Life* by his son Louis, who was only six years old when his father died, are our main sources.

The first but the least characteristic of the dramas by which Racine is known, *La Thébaide,* mas played by Molière's company at the Palais Royal theatre on June 20, 1664 In Feb. 1665 the greater part of his second acted play, *Alexandre le Grand,* was read before a distinguished audience at the Hôtel de Nevers, and Molière's company played it on Dec. 4. But a fortnight afterwards *Alexandre* was played, "de complot avec M. Racine," says La Grange, by the rival actors at the Hôtel de Bourgogne, and Racine's friendship with Molière ended in consequence. If, however, *Alexandre* was the occasion of showing the defects of Racine's character as a man, it raised him vastly in public estimation as a poet. He was now for the first time proposed as a serious rival to Corneille, and the contrast between the two was accurately apprehended and put by Saint Evremond in his masterly *Dissertation sur l'Alexandre,* still the best criticism of the faults of Racine, though not of the merits, which had not yet been fully seen. It may be added that in the preface of the printed play the poet showed the extreme sensitiveness to criticism which often accompanies a tendency to criticize others. These defects of character showed themselves still more fully in another matter. The Port Royalists detested the theatre, and in Jan. 1666 Nicole, their chief writer, spoke of dramatic poets as "empoisonneurs publics." Racine immediately published a letter to the author, which, though very smartly written, is full of savage personalities. He had written a second pamphlet and was about to publish it when fortunately Boileau, who had been absent from Paris, returned and protested against the publication. It remained accordingly unprinted till after the author's death, and in later years he expressed bitter regret for having published the first.

After this disagreeable episode Racine's life, for ten years and more, becomes simply the history of his plays, if we except his liaisons with the actresses Mademoiselle du Parc and Mademoiselle de Champmeslé, and his election to the Academy on July 17, 1673. The series of his unquestioned dramatic triumphs began with *Andromaque* (Nov. 1667), and this play may perhaps dispute with *Phèdre* and *Athalie* the title of his masterpiece. It is much more uniformly good than *Phèdre,* and the character of Hermione is the most personally interesting on the French tragic stage. Whatever may be thought of the *tragédie pathétique* (a less favourable criticism might call it the "sentimental tragedy"), it could hardly be better exemplified than in this admirable play, which owes its success to the application of the most delicate art to the conception of really tragic passion. *Andromaque* was succeeded, at the distance of not more than a year, by the charming comedietta of *Les Plaideurs* (printed on Dec. S, 1668). At first it was a complete failure, though Molière is reported to have said on leaving the house, "Que ceux qui se moquoient de cette pièce meritoient qu'on se moquoient d'eux"; but the piece was suddenly played at court a month later; the king laughed, and its fortunes were restored. It was followed by a very different work, *Britannicus,* which appeared on Dec. 13, 1669. This was much less successful than *Andromaque,* and seems to have held its own but a very few nights. Afterwards it became very popular, and even from the first the exquisite versification was not denied. But the complete nullity of Britannicus himself and of Junie, and the insufficient attempt to display the complex and dangerous character of Nero are not redeemed by Agrippina, who is really good, and Burrhus, who is solidly painted as a secondary character. Voltaire calls it "la pièce des connaisseurs," a double-edged compliment. The next play of Racine has, except *Phkdre*, the most curious history of all. Henrietta of Orleans proposed the subject of *Bérénice* to Corneille and Racine at the same time, and both plays, but especially Racine's, were successful. *Bajazet,* first played on Jan. 4, 1672, has great technical merit, but it is impossible to imagine anything less oriental than the atmosphere of the piece, which is scarcely saved by its ingenious scenario and admirable style. This charge is equally applicable with the same reservations to *Mithridate,* which appears to have been produced on Jan. 13, 1673, and was extremely popular. Racine's next attempt, *Iphigénie,* was a long step backwards and upwards in the direction of *Andromaque.* Greek tragedy gave examples which prevented him from flying in the face of the propriety of character as he had done in *Bérénice, Bajazet,* and *Mithridate.* The date of its appearance is very uncertain. It was acted at court on Aug. 18, 1674, but it does not seem to have been given to the public till the early spring of 1675.

The last and finest of the series of tragedies proper was the most unlucky. *Phbdre* was represented for the first time on New Year's Day 1677, at the Hôtel de Bourgogne. Within a week the opposition company launched an opposition *Phbdre* by Nicolas Pradon, who had been employed to write it by the duchess of Bouillon and other influential enemies of Racine. So well had their measures been taken that the finest tragedy of the French classical school was all but driven from the stage, while Pradon's was a positive success. The unjust cabal against his piece no doubt made a deep impression on Racine. But it is impossible to decide exactly how much influence this had on the subsequent change in his life. For 13 years he had been constantly employed on a series of brilliant dramas. He now broke off his dramatic work entirely and in the remaining 20 years of his life wrote but two more plays, and those under special circumstances and of quite a different kind. He had been during his early manhood a libertine in morals and religion; he now became irreproachably domestic and almost ostentatiously devout. No authentic account of this change exists; what is certain is that Racine reconciled himself with Port Royal, accepted their doctrine of the incompatibility of the stage and the Christian life, and on June 1 married Catherine de Romanet and definitely settled down to a quiet domestic life, alternated with the duties of a courtier. His wife had money, and he had possessed for some time the post of treasurer of France at Moulins. His annual "gratification" had been increased from 800 to 2,000 livres, and in the year of his marriage he and Boileau were made historiographers-royal with a salary of 2,000 crowns. Racine's labours brought him, in addition to his other gains, frequent special presents from the king, and in 1690 he further received the office of "gentilhomme ordinaire du roi," which afterwards passed to his son. He had two sons and five daughters.

The almost complete silence which Racine imposed on himself after the comparative failure of *Phèdre* was broken once or twice even before the appearance of his two last exquisite tragedies. The most honourable of these was the reception of Thomas Corneille on Jan. 2, 1685, at the Academy in the room of his brother. The discourse which Racine then pronounced turned almost entirely on his great rival, of whom he spoke even more than becomingly. But it was an odd conjunction of the two reigning passions of the latter part of his life—devoutness and obsequiousness to the court—which made him once more a dramatist. Madame de Maintenon had established an institution at Saint Cyr for the education of poor girls of noble family; the tradition of including acting in education was not obsolete, and the favourite asked Racine for a new play suited to the circumstances. The result was the masterpiece of *Esther,* with music by Moreau, the court composer and organist of Saint-Cyr. The beauty of the chorus, the perfection of the characters and the wonderful art of the whole piece need no praise. Almost immediately the poet was at work on another and a still finer piece of the same kind, and he had probably finished *Athalie* before the end of 1690. The fate of the play, however, was very different from that of *Esther* The public cared very little for it, but the just judgment of posterity has ranked *Athalie,* if not as Racine's best work (and there are good grounds for considering it to be this), at any rate as equal to his best. Thenceforward Racine was practically silent, except for a brilliant *Histoire abrégée de Port Royal* and four *cantiques spirituels,* in the style and with much of the merit of the choruses of *Esther* and *Athalze.* The general literary sentiment was against him, and his weakness for spiteful epigrams cost him many friends. At last even the king withdrew his favour. He died April 21, 1699, and was buried at Port Royal.

Racine may be considered from two very different points of view,—(I) as a playwright and poetical artificer, and (2) as a dramatist and a poet. From the first point of view there is hardly any praise too high for him Every advantage of which the Senecan tragedy adapted to modern times was capable he gave it. He perfected its versification; he subordinated its scheme entirely to the one motive which could have free play in it,—the display of a conventionally intense passion, hampered by this or that obstacle; he set himself to produce in verse a kind of Ciceronian correctness. The grammar-criticisms of Vaugelas and the taste-criticisms of Boileau produced in him no feeling of revolt, but only a determination to play the game according to these new rules with triumphant accuracy. The result is that such plays as *Phèdre* and *Andromaque* are supreme in their own way. But his greatest achievements in pure passion—the foiled desires of Hermione and the jealous frenzy of Phbdre—are cold, not merely beside the crossed love of Ophelia and the remorse of Lady Macbeth, but beside the sincerer if less perfectly expressed passion of Corneille's Cléopâtre and Camille. He had cut away from himself, by the adoption of the Senecan model, all the opportunities which would have been offered to his remarkably varied talent on a freer stage, though the admirable success of *Les Plaideurs* makes us regret that he did not experiment further in comedy.

BIBLIOGRAPHY.—The first collected edition of Racine's works appeared in 1675–76; the last which appeared in the poet's lifetime (1697) was perhaps revised by him. Among the innumerable posthumous editions the most important is that of P. Mesnard in the *Grands écrivains* series (8 vols, 1865–73). Louis Racine's **Life** was first published in 1747. Among English imitations are the *Distressed Mother* of Ambrose Philips (1712) and the *Phaedra and Hippolytus* of Edmund Smith (acted in 1707); and there is a complete verse translation by R. B. Boswell (1889–91). *See* Sainte-Beuve, *Portraits Littéraires,* vol i., and for recent criticism the studies by G. Larroumet (1898) and J. Lemaître (1908), and the *Life* by Mary Duclaux (1925). The case for and against Racine has been concisely stated by G Lytton Strachey in *Books and Characters* (1922) and J. C. Bailey in *The Claims of French Poetry* (1907).

RACINE, LOUIS (1692–1763), French poet, second son of Jean Racine, was born in Paris on Nov. 6, 1692. *La Grace* (1720) and *Religion* (1742), his most important work, are inspired by a sincere piety, and are written in verse of uniform clearness and excellence. His other works include epistles, odes, among which the *Ode sur l'harmonie* (1736) should be mentioned, *Mémoires* (1747) of Jean Racine, and a prose translation of *Paradise Lost* (1755). Louis Racine died on Jan. 29, 1763. He was characterized by Voltaire as "le bon versificateur Racine, fils du grand pobte Racine."

His *Oeuvres complètes* were collected (6 vols) in 1808.

RACINE, a city of southeastern Wisconsin, U.S.A., on Lake Michigan, at the mouth of the Root river, 60 mi. N. of Chicago; a port of entry and the county seat of Racine county. It is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific, the Chicago, North Shore and Milwaukee, and the Milwaukee electric railways and by motor coach lines. Pop. 58,593 in 1920 (28% foreign-born white); in 1930, 67,542; and in 1940, 67,195 by the federal census.

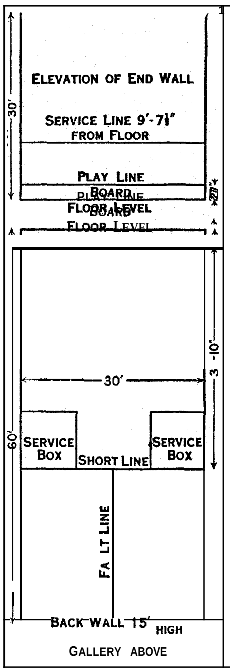
Racine is one of the most important manufacturing centres in the state. It has a good harbour, open throughout the year. There are 163 manufacturing establishments, having products valued at $103,177,883 annually Assessed valuation of property for 1940 was $94,303,946. There are fine bathing beaches and recreation parks along the lake. One of the cemeteries encloses some prehistoric Indian mounds. Early in the 19th century a French trader, Jambeau, established himself on the Root river. and in 1834 Gilbert Knapp, a lake captain, induced a group of men from Chicago to settle at the mouth of the river. The village was called Port Gilbert, but in 1837 the French name of the river was adopted. Racine was incorporated as a village in 1831 and chartered as a city in 1848.

RACKETS or **RACQUETS,** a game played in an enclosed court with a ball and an implement with which the ball is struck called a racket. This is about 2½ft. long and the head is tightly strung with cat-gut. No standard dimensions are laid down.

In the earliest days of the game, the head of the racket was inclined like a tennis racket. Later it was pear-shaped. In modern days it is nearly circular and some 7 or 8in. in diameter. The average weight of a racket is about g oz. and it is made of ash. Experiments have been made with metal frames but with no practical success. The balls are one inch in diameter and weigh one ounce. They are made of strips of cloth tightly wound over each other and then bound with twine, with a sewn covering of smooth white leather. In England the floor of courts is black or red in colour and the walls black.

In India and some other places in the East, where the floor and walls of the court are painted white, black balls are used. There has been no standard size laid down for a racket court but the great majority of courts are about 60ft. long by 30ft. broad. Both the single and the double or four-handed game are played in courts of this size nowadays. Formerly there were several courts as large as 80ft. by 40ft. built specially for the double game, but one or two of these alone now remain. Modern racket courts have four walls and a roof, but in India some courts are left unroofed for the sake of coolness.

The floor, which must be perfectly level and smooth, is made of cement. The floor cannot be too hard, since the faster the ball travels, the better the game; similarly the walls, which should be built of masonry faced with cement and most carefully smoothed, cannot be too hard and fast. The front and side walls are about 30ft. high, the back wall being about half that height, with a gallery for spectators (containing the marker's box) above it. The court is entered by a door in the centre of the back wall, which, when shut, must be perfectly flush with that wall, and without any projecting handle. The court is lighted from the roof. The diagram shows the divisions and the markings of the court. On the front wall is fixed a wooden board, the upper edge of which, 27in. from the floor, constitutes the "play-line," and which usually fills the whole space from that height to the floor; and at a height from the floor of gft. 7½in. is a second line, called the "cut-line" or "service-line," usually painted red or green. At a distance of 35ft. 10in. (in a court 60ft. by 30ft.) from the front wall and parallel to it, a line is painted on the floor, from wall to wall, called the "short-line"; and from the centre of the short-line to the centre of the back wall is the "fault-line," dividing into two equal rectangles the space between the back wall and the shortline. These lines again are usually red or green in colour.



PLAN AND ELEVATION OF RACKETS COURT

The rectangles are the service-courts and are called the right-hand and left-hand court respectively. Against the side walls outside these courts, but so that one side in each case is formed by the short-line, are squares called the service-boxes.

The Game. — Rackets is usually played either by two persons ("singles"), or four persons playing two against two ("doubles"); and the general idea of the game is the same as that in lawn tennis and fives, the object of the player in all these games being to score a point by striking the ball either before it reaches the ground or on its first bound, in accordance with the rules of the game, in such a way that his adversary may fail to make a "good," *i.e.,* a valid, stroke in return. In the four-handed game one of each set of partners takes the right-hand court and his partner the left. The game consists of 15 points called "aces." Aces can only be scored by the "hand-in" (the player, or side, having the service), and the "hand-out" must therefore win a stroke or strokes to obtain service before he or they can score an ace; in "doubles" each of the partners serves in turn, and both must therefore be ousted before "hand-out' obtains the service; but to this rule the first hand of each game affords an exception (see below). The right to serve first is determined by the spin of a racket and the service must be made in the following manner. The server, standing with one foot at least inside one of the service-boxes, must toss the ball from his hand, and while it is in the air he must hit it with his racket so that it strikes the front wall above the service-line and falls to the floor within the service-court on the opposite side; after striking the front wall the hall may, but need not, strike the side wall or back wall, or both, and it may do so either before or after touching the floor. The serve is a "fault" if the ball (1) strikes the front wall above the board but on or below the service-line, in which case it is called a "cut"; or (2) touches the floor on the first bound, outside the proper service-court, when it is called "short" or "fault" according to the position of its pitch (see below). If the "hand-out" player to whom the fault is served "takes" it (*i.e.,* if he plays at it), the fault is condoned and the play proceeds as if the serve had been good. If, however, the fault be not taken, the server must serve again from the same box; and if he serves a second fault he loses his "hand" or innings, and his partner or his opponent, as the case may be, takes his place. Two consecutive faults have thus the same result as the loss of a stroke in the rally by the "hand-in." A serve which makes the ball strike the board, or the floor before reaching the front wall, or which sends it "out-of-court" (*i.e.,* into the gallery or roof of the court), counts the same as two consecutive faults; it costs the server his innings. Skill in service is a most important part of proficiency in rackets; a player can seldom become first-rate unless he possesses a "strong service." A great deal of "cut" may be imparted to the ball by the stroke of the racket, which makes the ball in its rebound from the wall behave like a billiard ball carrying "side" when striking a cushion; and when this "cut" is combined with great pace in the bound of the ball off the side wall, the back wall, and the floor, at varying angles which the server has to a great degree under his control, it becomes exceedingly difficult for hand-out to "get up" the service (*i.e.,* to hit it on the first bound, sending it above the play-line on the back wall), and still more so to make a good stroke which will render it difficult for his adversary in his turn to get up the ball and thus continue the rally. Racket courts vary very much in pace and conditions and in some service is very much easier of return than in others, but it not infrequently happens that a long sequence of aces, sometimes the whole 1 j aces of a game, are scored consecutively by service which hand-out is unable to return. A noteworthy instance of successful service occurred in the semi-final tie of the doubles Amateur Championship matches at the Queen's Club in 1897 when W. L. Foster opened service and scored all the aces in the first two games, and added six in the third, thus putting on a sequence of 36 aces before losing his "hand." To obtain first service is therefore an initial advantage, although in doubles it is limited by the rule that only one partner shall have a "hand" in the opening service.

The server may begin in either of the service boxes; but when he has started, the service must proceed from the two boxes alternately till the close of the innings of the side, whether singles or doubles. When the other side obtains the innings they may in like manner begin in either box, without regard to where the last service of their opponents was delivered. In singles, hand-out changes sides in the court after each serve, answering to the change over of the server: in doubles the serve is taken alternately by the two hand-out players, who permanently occupy the right- and left-hand courts respectively, being allowed to change the order in which they receive the service at the end of any game or rubber. Except in the rare case of left-handed players most of the play in the left half of the court, including the taking of service on that side, is back-handed; and the stronger of the two partners in back-hand play usually, therefore, takes the left-hand court. The best position in the court for the hand-out about to take the serve depends entirely on the nature of the service, and he has to use his judgment the instant the ball leaves the server's racket in order to determine where it will strike the floor and at what precise point in its course it will be best for him to attempt to take it. A strong fast service, heavily cut, that sends the ball darting round the corner of the court, leaving the back wall at an extremely acute angle, or dropping almost dead off it, can only be got up by standing near the back wall a long way across the court and taking the ball by a wrist stroke at the last instant before it falls to the ground a second time. On the other hand, when the server avoids the side mall altogether and strikes the back wall direct and hard, whether he achieves a "nick" serve (*i.e.,* the ball striking precisely in the angle between the back wall and the floor) or hits the wall high up, hand-out will have little time to spare in changing position to get within reach of the ball. Many good players make a practice wherever possible, especially in the case of heavily cut service, of taking the service on the volley (*i.e.,* before the ball reaches the ground), sometimes of taking the ball after it leaves the side wall and before it reaches the back wall; practice alone enables the player to decide with the necessary promptitude how each stroke is to be played. In returning the service, or in playing any stroke during the rally, the ball may strike any of the other walls before the front wall. This "boasted" stroke is quite legitimate, often most valuable and sometimes indispensable. The tendency, however, in modern rackets is towards using it too frequently. Good play consists for the most part in hard low hitting, especially as close as possible along the side walls into the corners of the back wall. One of the most effective and beautiful but difficult strokes in rackets is the drop which occurs when the ball is hit so that it only just reaches the front wall and drops close to it. The "half-volley," in which the ball is struck at the moment of its contact with the floor and before it has had time to rise, is employed with great effect especially in hard play; it makes the return much quicker than when the ball is allowed to rise to the full length of the bound, and requires corresponding quickness on the part of the adversary.

If hand-out succeeds in returning the serve, the rally proceeds until one side or the other fails to make a good return. A good return means (1) that the ball is struck by the racket before its second bound on the floor, and without its having touched any part of the clothes or person of the striker or his partner; (2) that it is hit against the front wall above the board without first touching the floor or going out of court; and (3) that it returns off the front wall into play (*i.e.,* to the floor of the court or to an adversary's racket) without going out of court. If hand-in be the one to fail in making a good return, he loses his "hand," and (in singles) hand-out goes in and proceeds to serve; in doubles one of the hand-in partners loses his "hand," and the second partner goes in and serves till he in turn similarly loses his "hand," except that in the case of the opening service in the game there is (as already mentioned) only one "hand" in any event. If hand-out fails to make a good return to the serve or to any stroke in the rally, hand-in scores an ace, and the side that first scores 15 aces wins the game. When, however, the score reaches "13-all" (*i.e.,* when each side has scored 13 aces), hand-out may, before the next serve is delivered, declare that he elects to "set" the game either to five or three, whichever he prefers; and similarly when the score stands at "14-all," hand-out may "set" the game to three. He makes this declaration by calling "set-5!" or "set-3!" and it means that five aces, or three aces, as the case may be, shall be required to win the game. It is the player's first duty to give the opponent full room for his stroke, but in the confined space of a racket court it is not always easy and sometimes, especially in doubles, absolutely impossible not to obstruct him. The rules, therefore, carefully provide for "lets" (an old English word for impediment or hindrance) when in matches a "let" is claimed by any one of the players and allowed by the referee, or the referee and two umpires, as the case may be, the service or rally counts for nothing and the server shall serve again from the same service box.

In ordinary games, the marker makes the decision as to a let. It is the duty of the marker, who occupies a box in the gallery, to "call the game." As soon as the server serves the ball the marker calls "Play!" if the ball strikes the front wall above the service-line; and "Cut!" if it strikes below the service-line; if the ball falls in front of the short-line the marker calls "Short!"; if the wrong side of the fault-line he calls "Fault!"; but whether to be "cut," "short," or "fault," the serve counts as a fault in its effect. To every good return, as to every good serve, the marker calls "Play!" If a return is made after the second bound of the ball (called a "double") the marker calls "Double!" or "Not up!"; if the ball is hit into the gallery, or against its posts or cushions, or above the girders or cross-beams of the roof, he calls "Out-of-court!" At the end of every rally he calls the state of the game, always naming first the score of hand-in: — "One-love" (love being the term for zero) meaning that hand-in has scored one ace and hand-out nothing, "Two-love," "Five-all," "Five-ten," "Fourteen-eleven," when one player reaches 14 it is customary for the marker to call "game-ball," *e.g.,* "14–11 game-ball." When one side has scored 15, the marker calls "Game!" He then in similar fashion calls the state of the match — "Two games to one," or whatever it may be — before the beginning of the next game. The server in possession at the end of the game continues to serve in the new game, subject as before to the rule limiting the first innings of the game to a single "hand." The usual number of games in matches is five for singles, and seven for doubles. In matches where there are umpires and a referee, there is an appeal to them from the marker's decision except as regards questions relating to the service, on which the marker's decision is final.

Records. — Attempts have been made to trace rackets, like tennis, to an ancient origin; but although it is doubtless true that the striking of a ball with the hand or some primitive form of bat is one of the oldest forms of pastimes, and that rackets has been evolved from such an origin, the game as now known can hardly be said to have existed before the 19th century. The first school which took to rackets was Harrow in the '20s of last century. It was about the middle of the century that closed courts of the modern pattern began to be built, and the founding of Prince's club in 1853 increased the popularity and standing of the game immensely. Here there were a number of courts and the match court was a great favourite—"Old Prince's" came to an end in 1886 and the next year the Queen's club courts were built and were ready for play in 1888—the present Prince's club, Knightsbridge, which has a rackets court, was opened in 1889. Nowadays, largely owing to the expense of the game, there is not so much play except at the English public schools as heretofore, and a number of courts have gone out of use in the last few years. Several have been converted into squash rackets courts including one of the two formerly existing at Queen's club, one of those at Prince's club, and the one at Lord's.

Championships. — The first professional or "open" or world's champion as it may be called was Robert Mackay who claimed the title in 1820. He was succeeded by Thomas and John Pittman, John Lamb and J. C. Mitchell who held it from 1846–60, when he was beaten by Francis Erwood of Woolwich. In 1862 Erwood was beaten by Sir William Hart-Dyke, the only amateur to hold the world's championship until 1937, when D. S. Milford, Great Britain, beat Norbert Setzler, U. S. A.

In 1863 Sir William resigned to H. J. Gray, the first of a large family of great professional players. William Gray, who was champion from 1866 to his death in 1875, was the greatest player of this era of rackets. He had most beautiful style and command of the ball and he was noted for his drop volley. His greatest match was played against an American professional named Foulkes, Gray being the winner. The next champion was H. B. Fairs, of Prince's club, known as "Punch" who, though he was diminutive in stature, was also a splendid player. He died in 1878 and was succeeded by another Gray, Joseph, who held the title from 1878–87. In that year Gray was beaten by Peter Latham, then a boy of 22, who holds the reputation of being the greatest player who has yet appeared. Gray won the first of the two rubbers in this match by four games to three but was beaten in the second at Manchester much more easily. From that date until 1902 Latham reigned supreme. He defended his title against yet another Gray, Walter of Charterhouse in 1888 and against George Standing in 1891 and 1897. The match in 1897 was played at Queen's club and in New York where Standing had gone from Prince's club, Knightsbridge, to become professional, and excited intense interest. Latham here, perhaps, had the hardest fight of his career but again he triumphed. In 1901 he played Gilbert Browne, then of Prince's club, and defeated him easily. In 1902 Latham resigned the title which he had held so long and worthily. In 1895 he had also won the championship of tennis and so held the two titles conjointly from 1895–1902, an unparalleled feat. Latham's first engagement was in Manchester. He was appointed as professional at Queen's club, West Kensington, in 1888, and with one interval, when he was privately employed by Sir Charles Rose at his tennis courts at Hardwick and Newmarket, he has been there ever since. In 1903 W. Jamsetji, a Parsee player, with a particularly fine fore-hand stroke beat Browne and he held the title until 1911, when he was beaten by Charles Williams of Harrow, who has since the World War gone as professional to the Chicago club. Williams in the interval had beaten Walter Hawes (Wellington) for the English professional championship and E. M. Baerlein, the amateur champion for the British championship. Just before the war Williams lost the open championship to Jock Soutar of Philadelphia who has defended it twice since, once against Williams and once against "Blondy" Standing. In 1929 Williams regained the title and has successfully defended it since then.

Very little is known of the form of the early amateur players. In the days of old Prince's club (1853–86) among the leading amateurs in addition to Sir William Hart-Dyke were R. D. Walker, C. J. P. Clay, J. D. Cobbold, R. O. Milne. J. Spens, an army officer in the '70s and '80s, held the reputation of being the best player in England. G. E. A. Ross in India was extremely good. Other soldier players of note of this time and a little later were T. Gallwey, A. Cooper-Key, G. A. Tower, C. D. King. In 1888, when the Queen's club was opened, an amateur championship was established and since then all the greatest amateur players have appeared in it. Spens competed the first year but he was then past his prime and was beaten by C. D. Buxton. The two greatest modern amateurs are generally reckoned to be H. K. Foster, who won the title eight times, and E. M. Baerlein who has won nine. Of the other winners E. M. Butler was a great player and stylist and so was P. Ashworth. F. Dames-Longworth, for many years a master at Charterhouse, where he did a great deal for rackets, was famed for his back-hand service. E. H. Miles was a clever player though not of commanding style. S. H. Sheppard, another clever player and quite tireless, is the only army officer who has won. E. B. Noel was the first left-hander to be successful. B. S. Foster had beautiful style footwork and hitting powers. H. W. Leatham relies to some considerable extent on clever placing but he can serve well and hit hard when he likes. The Hon. C. N. Bruce is a splendid server and fine hitter. C. C. Pell, the winner in 1925, is the leading American player. He is very good all round with a strong service and much judgment.

The winners of the championship have been:

Singles

1888. C. D. Buxton.
1889. E. M. Butler.
1890. P. Ashworth.
1891. H. Philipson.
1892–1893. F. Dames-Longworth.
1894–1900. H. K. Foster.
1901. F. Dames-Longworth.
1902. E. H. Miles.
1903. E. M. Baerlein.
1904. H. K. Foster.
1905. E. M. Baerlein.
1906. Maj. S. H. Sheppard.
1907. E. B. Noel.
1908–11. E. M. Baerlein.
1912–13. B. S. Foster.
1914. H. W. Leatham.
1920–21. E. M. Baerlein.
1922. Hon. C. N. Bruce.

Singles—Continued

1923. E. M. Baerlein.
1924. H. W. Leatham.
1925. C. C. Pell.
1926–28. J. C. F. Simpson.
1929. C. S. Crawley.
1930. Capt. G. N. Scott-Chad.
1931. Capt. V. A. Cazalet.
1932–1934. I. Akers-Douglas.
1935–36. D. S. Milford.,

The doubles championship was started two years after the singles. Some of the most famous pairs have been H. K. Foster and P. Ashworth, E. M. Baerlein and E. H. Miles, F. Dames-Longworth and F. H. Browning, H. W. Leatham and Hon. C. N. Bruce, J. C. F. Simpson and R. C. O. Williams. The winners have been:

Doubles

1890. P. Ashworth and W. C. Hedley.
1891. P. Ashworth and E. L. Metcalfe.
1892. E. M. Butler and M. C. Kemp.
1893. F. H. Browning and H. K. Foster.
1894. H. K. Foster and F. C. Ridgeway.
1895. F. Dames-Longworth and F. H. Browning.
1896. H. K. Foster and P. Ashworth.
1897. H. K. Foster and P. Ashworth.
1898. H. K. Foster and W. L. Foster,
1899. H. K. Foster and P. Ashworth.
1900. H. K. Foster and P. Ashworth.
1901. F. Dames-Longworth and V. H. Pennell.
1902. E. M. Baerlein and E. H. Miles.
1903. H. K. Foster and B. S. Foster.
1904. E. H. Miles and E. M. Baerlein.
1905. E. H. Miles and E. M. Baerlein.
1906. E. H. Miles and F. Dames-Longworth.
1907. W. L. Foster and B. S. Foster.
1908. F. Dames-Longworth and V. H. Pennell.
1909. E. M. Baerlein and P. Ashworth.
1910. B. S. Foster and Hon. C. N. Bruce.
1911. B. S. Foster and Hon. C. N. Bruce.
1912. H. W. Leatham and H. A. Denison.
1913. B. S. Foster and H. W. Brougham.
1914. E. M. Baerlein and G. G. Kershaw.
1920. E. M. Baerlein and G. G. Kershaw.
1921. Hon. C. N. Bruce and H. W. Leatham.
1922 and 1923. J. C. F. Simpson and R. C. O. Williams.
1924–1927. Hon. C. N. Bruce and H. W. Leatham.
1928. Hon. C. N. Bruce and A. C. Raphael.
1929. J. C. F. Simpson and R. C. O. Williams.
1930. Lord Aberdare and H. W. Leatham.
1931. J. C. F. Simpson and C. S. Crawley.
1932. K. A. Wagg and I. Akers-Douglas.
1933. K. A. Wagg and I. Akers-Douglas
1934. Lord Aberdare and P. W. Kemp-Welch.
1935. K. A. Wagg and I. Akers-Douglas.
1936. J. C. F. Simpson and C. S. Crawley.

In America a national singles championship and doubles championship have been established for many years. Among leading American amateur players have been B. S. de Garmendia, G. R. Fearing, Quincy Shaw, Payne Whitney, L. Waterbury, Clarence Mackay, P. D. Haughton, C. C. Fell, S. F. Mortimer, W. Hewitt Morgan, H. D. Sheldon, E. M. Edwards, etc.

See E. B. Noel and the Hon. C. N. Bruce, First Steps to Rackets (1925). (E. B. N.)

RACKHAM, ARTHUR. (1867–1939), English illustrator, born Sept. 19, 1867. He studied at the Lambeth School of Art, London. His first publication was the illustrated Rip van *Winkle* (1905), followed by Peter *Pan* (1906), Alice in Wonderland and the Ingoldsby Legends (1907). In 1906 he gained a gold medal at Milan, and in 1911 at Barcelona. He was elected associate of the Société Nationale des Beaux-Arts in 1912, and in 1919 became master of the Art Workers' guild. Later illustrations include those to Undine, *Grimm's* Fairy Tales, Aesop's Fables, Dickens's *Christmas* Carol, *Comus*, *The* Tempest, *The Compleat* Angler, Poe's Tales of *Mystery and* Imagination, and Peer Gynt.

RADAUŢI, a town in Bukovina, Rumania, 35 m. S. by W. of Czernowitz by rail. Pop. (1930) 16,808, of which about 70% were Germans and 28% Rumanians. It was formerly the seat of a Greek bishopric, removed to Czernowitz in 1786, and possesses a cathedral (1402) with the tombs of Moldavian princes.

RADCLIFFE, ANN (1764–1823), English novelist. only daughter of William and Ann Ward, was born in London on

July 9, 1764. She was the author of four famous novels: *The Sicilian Romance* (1790), *The Romance of the Forest* (1791), *The Mysteries of Udolpho* (1794) and *The Italian* (1797). When she was twenty-three years old she married William Radcliffe, an Oxford graduate and student of law. He gave up his profession for literature, and afterwards became proprietor and editor of the *English Chronicle*. After *The Italian* she gave up writing for publication. She died on Feb. 7, 1823. *Gaston de Blondeville* (1826) was published after her death, as were her *Poems* (1834). In the history of the English novel, Mrs. Radcliffe deserves at least the credit of originating a school of which she was the most distinguished exponent. She had a genuine gift for scenic effect, and her vivid imagination provided every tragic situation in her stories with its appropriate setting. Sir Walter Scott wrote an appreciative essay for the edition of 1824, and Christina Rossetti was one of her admirers. She exercised a great influence on her contemporaries, and "Schedoni" in *The Italian* is one of the prototypes of the Byronic hero.

There are modern editions of *The Italian* (1884); *Udolpho* (1903); and *The Romance of the Forest* (1904). *See* D. Scarborough, *The Supernatural in Modern English Fiction* (1917); C. F. MacIntyre, *Ann Radcliffe in Relation to her Time* (1920); E. Birkhead, *The Tale of Terror* (1921).

RADCLIFFE, JOHN (1650–1714), English physician, born at Wakefield, a well-known physician in the reigns of William III and Anne. He left property to University college for founding two medical travelling fellowships and for building the Radcliffe observatory, hospital and library at Oxford, and enlarging St. Bartholomew's hospital in London. Radcliffe was elected M.P. for Bramber in 1690 and for Buckingham in 1713. He died at Carshalton on Nov. 1, 1714.

See J. B. Nias, *Life of John Radcliffe* (1918).

RADCLIFFE, a municipal borough in the Heywood and Radcliffe parliamentary division, Lancashire, England, on river Irwell, 8 mi. N.W. of Manchester on the L.M.S.R. Pop. (est. 1938), 27,030. Area, 7.7 sq.mi. In the church of St. Bartholomew the tower arch dates from the early 15th century. Radcliffe was incorporated in 1935. There are collieries, cotton and chemical manufactures, and the making of small wares.

RADEBERG, a German town in the *Land* of Saxony, on the Roder, 10 mi. N.E. of Dresden. Pop. (1939) 16 076. It has an old castle.

RADEGUNDA, ST. (d. @;), Frankish queen, was the daughter of Berthaire, king of the Thuringians. Berthaire was killed by his brother Hermannfried, who took Radegunda and educated her, but was himself slain by the Frankish kings Theuderich and Clotaire (529), and Radegunda fell to Clotaire, who later married her. She left him when he unjustly killed her brother, and fled to Medardus, bishop of Poitiers, who consecrated her as a nun. Radegunda stayed in Poitiers, founded a monastery there, and lived for a while in peace. The queen died on Aug. 13, 587.

RADEK, KARL (1885–), Russian politician, was born in Lwów (Lemberg) and he was educated at the universities of Cracow and Berne. In 1904 he became a member of the social democratic party of Poland and Lithuania. During the revolution of 1905 he spent a year in prison, and subsequently became a member of the editorial staff of social democratic newspapers in Poland, Leipzig and Bremen which supported the left wing of the German social democrats. During the World War, after some months of illegal anti-militarist activity in Germany, he established himself in Switzerland where he wrote for the Berne *Tageblatt*. He took part in the Zimmerwald and Kienthal internationalist conferences in Sept. 1915 and April 1916. After the Russian revolution of March 1917 he crossed Germany, together with Lenin, Zinoviev, Martov and others, and remained in Stockholm as the representative of the central committee of the Bolshevik party, issuing a weekly bulletin on the Russian revolution in French and German. After the second revolution, in Nov. 1917, he took part in the Brest-Litovsk peace negotiations. When the German revolution broke out in 1918 he made his way illegally to Germany, where as a representative of the central committee of the Russian Communist party he took a very active part in reorganizing the German Communist party, working in its central committee after the murders of Karl Liebkneckt and Rosa Luxemburg on Jan. 16, 1919. He was imprisoned in Germany from Feb. to Dec. 1919.

On his release from prison Radek returned to Russia, where he became one of the leading members of the praesidium of the Communist International. He returned illegally to Germany, however, and took part in the organization of the joint congress of German Communists and Left Independents. He mas made a scapegoat for the failure of the German Communists to seize power in the autumn of 1923, and, on account of his support of the "Right" groups of the German Communists, he lost his authority in the Communist International, losing his place in its executive committee and in the central committee of the Russian Communist party. He was a most prolific writer in the Russian press on various questions of international politics. Expelled from the Communist party in 1927, he was re-admitted in 1930. In Jan. 1937, he was tried with 16 others for plotting against the Soviet Union and was sentenced to 10 years' imprisonment. He was released after serving only four years of his term, however, in order that he might serve as a propagandist.

RADETZKY, JOSEF, COUNT OF RADETZ (1766–1858), Austrian soldier, was born at Trzebnitz in Bohemia in 1766, of an old noble family, originally Hungarian. He joined the army as a cadet in 1785. Next year he became an officer, and in 1787 a first lieutenant in a cuirassier regiment. He served as a galloper on Lacy's staff in the Turkish War, and in the Low Countries during the Revolutionary War. In 1795 he fought on the Rhine, and next year with Beaulieu against Napoleon in Italy. His personal courage was conspicuous; at Fleurus he had led a party of cavalry through the French lines to discover the fate of Charleroi, and at Valeggio, with a few hussars, rescued Beaulieu from the enemy. Promoted major, he took part in Wurmser's Mantua campaign. As lieutenant-colonel and colonel he displayed bravery and skill at Trebbia and Novi (1799), and at Marengo was hit by five bullets.

In 1801 Radetzky received the knighthood of the Maria Theresa order; in 1805 he was promoted to major-general and given a command in Italy under the archduke Charles, and thus took part in the successful campaign of Caldiero. Peace again afforded him a short leisure, which he used in studying and teaching the art of war. In 1809, now a lieutenant field marshal, he fought at Wagram, and in 1810 received the commandership of the Maria Theresa order and the colonelcy of the 5th Radetzky hussars. From 1809 to 1812, as chief of the general staff, he was active in the reorganization of the army and its tactical system, but, unable to carry out the reforms he desired owing to the opposition of the Treasury, he resigned the post. In 1813 he was Schwarzenberg's chief of staff, and as such had considerable influence on the councils of the Allied sovereigns and generals. He had a considerable share in planning the Leipzig campaign and as a tactician won great praise at Brienne and Arcis sur Aube. He entered Paris with the allied sovereigns in March 1814, and returned with them to the Congress of Vienna.

He then resumed his functions as chief of the staff, but his ardent ideas for reforming the army came to nothing in the face of the general apathy. His zeal added to the number of his enemies, and in 1829, after he had been for twenty years a lieutenant field marshal, it was proposed to place him on the retired list. The emperor, unwilling to go so far as this, promoted him general of cavalry and shelved him by making him governor of a fortress. In 1834, however, his services were again required in Italy, first under Frimont, and then in chief command.

In 1836 Radetzky became a field marshal. Apathy and parsimony caused the authorities again to neglect his many suggestions, and the outbreak of the wars of 1848 found the Austrian army in an unprepared condition through no fault of Radetzky's. Nevertheless, recalled to command, he conducted his famous operations in the Quadrilateral, leading up to the triumph of Novara on March 23, 1849. (*See* ITALIAN WARS.) To the soldiers of his army who idolized him, he was always simply "Vater Radetzky." He died, still in harness, though infirm, on Jan. 5, greatly mourned by all whom he had commanded.

RADFORD, a city of Virginia, U.S.A., in Montgomery county, but administratively independent; 44 mi. W. of Roanoke, on federal highway 11 and the Norfolk and Western railway. Pop. (1940) 6.990. The city lies in a beautiful region, between the Blue Ridge and the Allegheny mountains.

RADHANPUR, a native state of India, in the western India States Agency, Kathiawar, Bombay. It is situated in the north-western corner of Gujarat, close to the Ran of Cutch. The country is an open plain without hills and with few trees. It contains an area of 1,150 sq m. with a population in 1931 of 70,530.

RADIATION, RAYS. Modern physics has developed mainly as a result of an intensive study of radiations and rays. and their relation to matter. It is possible to make a distinction between the two terms, but they are generally used by men of science as more or less synonymous. We have on the one hand the vast field of electromagnetic radiations, all travelling through empty spaces with the same velocity, the velocity of ordinary light. According to the wave-length of these radiations we speak of wireless waves, infra-red radiation, visible light, ultra-violet light, X-rays or y-rays; the order given being that of decreasing wave-length. On the other hand we have radiations which consist of streams of particles all moving in the same direction, either corpuscles of electricity, not associated with ordinary matter, as in cathode rays, or material particles which may be either charged or uncharged, such as positive rays or molecular rays. These particles may travel with any velocity, from zero, up to, in extreme cases, a velocity approaching that of light. We might distinguish between the two classes by agreeing to confine the term radiation to electromagnetic waves, and to restrict the term rays to streams of particles, but while a tendency in this direction is traceable it is by no means correct to represent this convention as one invariably used by experts. For instance, it is quite usual in dealing with β-rays, which are swift electrons, and thus corpuscular in nature, to speak of the scattered radiation and the transmitted radiation, and even to refer to the atoms of radioactive matter thrown back by the discharge of particles as a recoil radiation. (*See, e.g.,* Rutherford's Radioactive *Substances.*) On the other hand it is a commonplace to speak of rays of light. To indicate further the way in which, in actual practice, the terms are used indifferently it may be recalled that in a previous edition of the *Encyclopædia* electromagnetic radiation was dealt with, in different aspects, both under the heading RADIATION and under the heading RAY.

ELECTROMAGNETIC RADIATION

Considerations of electromagnetic radiations are involved in nearly every branch of modern physics, and various aspects of the subject are 'treated in separate articles, notably ELECTRICITY; LIGHT; QUANTUM THEORY; X-RAYS, NATURE OF: Rontgen Rays; SPECTROSCOPY; ELECTRIC WAVES; WIRELESS TELEGRAPHY. The biological effects of radiation are dealt with under the heading RADIOTHERAPY. In this article a general survey is made of the whole range of radiations, with the object of showing how the different types merge into one another, and discussing certain characteristic differences which are associated with different ranges of wave-length.

It may be well to give here the units used for measurement of the shorter wave-lengths. These are:

The micron	= one-millionth of a meter	= 10^{-4} cm.,	denoted by μ
The millimicron	= one-thousandth of a micron	= 10^{-7} cm.,	" " $\mu\mu$
The Ångström unit	=	10^{-8} cm.,	" "AU
The Siegbahn unit	=	10^{-11} cm.,	" " X

The millimicron is often used for giving visible and ultra-violet wave-lengths, and the Siegbahn unit for giving X-ray and y-ray wave-lengths. These two units are not employed in this article, but are inserted for completeness.

Historical.—The fact that there are radiations outside the limits of the visible spectrum was demonstrated by Sir William Herschel in 1800. He found that a thermometer showed a higher temperature when placed in the red end of the spectrum than in the blue, and a still higher temperature beyond the red end, where nothing could be seen. Two years later Ritter and Wollaston independently proved the existence of rays beyond the violet end by establishing that the chemical action of light on silver chloride was even stronger there than in the visible violet. These ultra-violet rays were called at the time "dark chemical rays." The wave nature of the ultra violet was proved by Young, who with the help of paper impregnated with silver chloride produced a record of Newton's rings formed by these invisible rays, the rings being smaller than those formed by the visible violet, which proved the smaller wave-length. The interference properties of the infra-red were established by Fizeau and Foucault in 1847. By the use of a very small alcohol thermometer, read with a microscope, they were able to demonstrate small differences of temperature at different points, corresponding to the alternations of intensity in the interference pattern produced in the infra-red by a suitable arrangement of two mirrors, or by diffraction at a straight edge, as with visible light. (See LIGHT.) Fizeau made measurements of wave-length in the infra-red about this time. In 1842 Becquerel photographed part of the ultra-violet spectrum. By 1850 it had already been definitely established that beyond the red end of the spectrum were invisible radiations of longer wave-length, and beyond the violet invisible radiations of shorter wave-length, and that those rays could be reflected, refracted, polarised and made to interfere in just the same way as the visible rays. In 1884 Langley made accurate measurements in the infra-red as far as $5{\cdot}3\mu$ by means of the diffraction grating, and virtually inaugurated a new branch of spectroscopy. Mascart, in 1864 and 1866, took the first photographs of the ultra-violet which were good enough for wave-length determination.

The electromagnetic waves, first generated by H. Hertz in 1888, were soon proved to have all the properties of light waves, as was to be anticipated from Maxwell's theory. (See ELECTRIC WAVES; ELECTRICITY; LIGHT.) Hertz himself, using parabolic reflectors to obtain definite beams, established the reflection and refraction of the rays, using a large prism of pitch for the latter purpose. (See ELECTRIC WAVES) Polarisation was produced by means of screens of parallel wires, which take the place of the Nicol prisms used in experiments with ordinary light, and also by reflection. Interference, and later dispersion, were also demonstrated with Hertzian waves. The velocity of propagation along wires, measured by Blondlot and by Trowbridge and Duane, was found to be equal to that of light. There is, then, no doubt of the essential similarity in nature between Hertzian waves and light.

The wave-length of Hertzian waves was found by different methods; it varies with the dimensions of the apparatus used for generating the waves. The length of the waves used in wireless telegraphy is measured in hundreds of metres, as against the few hundred-thousandths of a centimetre that give the length of visible light waves. Every source of alternating current is an emitter of very long electromagnetic waves: a dynamo, for instance, running at 3,000 revolutions per minute generates waves of length six thousand kilometres.

At the other end of the scale, in the region of very short waves, lie the X-rays, discovered by Rontgen in 1895, and the y-rays, discovered by Villard in 1900. The nature of these rays was long in doubt, for until 1912 the view that they were neutral particles had its supporters, as well as the view that they were electromagnetic waves. In this year Laue, Friedrich and Knipping established the diffraction of X-rays by crystals, and shortly after W. H. and W. L. Bragg showed how the wave-length of X-rays could be measured by reflection at crystal faces. (See X-RAYS, NATURE OF: *Röntgen Rays;* SPECTROSCOPY.) More recently (1925, 1926) A. H. Compton and R. L. Doan, as well as J. Thibaud, have succeeded in demonstrating the diffraction of Röntgen rays by ruled gratings, of the type used for measuring the wave-length of ordinary light. the rays being made to graze the grating at a very small angle The refraction of Rontgen rays was established at about the same time, by making the rays strike the face of a glass prism, near the apex, at a very fine glancing angle.

The value found for the refractive index by these experiments, as also by the total internal reflection which can be established, is less than unity, as given by the theoretical dispersion formula. Although the velocity of the Rontgen rays has not been measured directly, all the other properties of an electromagnetic wave have been shown to be possessed by the Rontgen rays. In particular, the wave-lengths of all the characteristic X-rays have been carefully recorded, ranging from 22 A.U. to ·1 A.U. As for the y-rays, in 1914 Rutherford and Andrade measured the wave-length by the crystal method, and showed them to be of essentially the same nature as Rontgen rays.

The Electromagnetic Spectrum.—Extending from wave-lengths of some miles to wave-lengths of a few hundredths of an Ångström unit (or a few ten-thousandths of an Ångström unit if we admit radiations which have not yet been measured by any direct diffraction method), there is a range of electromagnetic waves which is often spoken of as comprising over sixty octaves, the term octave, by analogy from sound, being applied to a band of vibrations extending from a given frequency to double that frequency. Of this range only one octave is visible radiation, namely that comprising wave-lengths from 8×10^{-5} to 4×10^{-5} cm., but all the other radiations are propagated with the same velocity as visible light and exhibit the characteristic phenomena which are associated with transverse waves, in particular reflection, refraction, polarisation and interference in its many aspects. Recent researches have served to emphasize the common nature of radiations of widely different frequency: for instance E. V. Appleton has shown that interference phenomena can be obtained with the Hertzian waves used in wireless telegraphy by reflection from the Heaviside layer, and has repeated a variety of experiments on interference and polarisation, usually performed in the laboratory with waves of length of the order 5×10^{-5} cm., over distances of miles with waves whose length is a few hundred metres. (See WIRELESS TELEGRAPHY.)

The whole electromagnetic spectrum is diagrammatically represented in the accompanying chart, in which the wave-lengths are set out vertically on a logarithmic scale, to avoid the compression to vanishing point of the shorter wave-length which would be inevitable if a linear scale were adopted. The ends of the spectrum are not definite: waves of frequency as low, that is, of wave-length as great, as may be desired can be generated by rotating a coil in a magnetic field, while at the short wave-length end of the range we have the penetrating cosmic radiations, whose wave-length is shorter than that of the y-rays, but can only be roughly estimated from the absorption. Starting at the top with wave-lengths of ·01 Angstrom units (10^{-10} cm.), which are of the order of the shortest y-ray measured by Ellis ($\cdot5\times10^{-10}$ cm.), we proceed by way of longer γ-ray wave-lengths to X-rays, the rays used for radiotherapy lying in the region 6×10^{-10} cm. to 10×10^{-10} cm. while those used in diagnosis lie generally between 2 and 3×10^{-9} cm. The X-rays merge into the ultra-violet, which in its turn leads into the visible spectrum. On the other side of the visible spectrum we have the infra-red, which leads to a vast range of Hertzian radiations, 28 octaves in extent, succeeded by the ill-defined region of very long waves to which reference has already been made. The frequencies, obtained by dividing the velocity 3×10^{10} cm./sec. by the wave-length in cms., are given on the extreme left: self-explanatory notes as to the method of generation and detection of the waves are added. Detailed information as to the various classes of radiation is given in the articles RADIOACTIVITY; X-RAYS, NATURE OF: Rontgen Rays; SPECTROSCOPY; LIGHT; HEAT; ELECTRIC WAVES; WIRELESS TELEGRAPHY.

While the spectrum was first extended by investigation of the prolongation of the optical spectrum on either side, and thus showed a continuous range of wave-lengths, the Hertzian waves as first investigated had wave-lengths very much greater than those of any measured infra-red radiation, while the X-rays first measured, although forming a continuous range with the y-rays on the short wave-length side, proved, on the long wave-length side, to be very much shorter than the shortest ultra-violet. The gaps between the Hertzian waves and the infra-red, and between the X-rays and the ultra-violet were until recently unexplored regions, in spite of the many efforts that had been made to produce and detect waves there. Since 1922, however, the gaps have been closed, and it is now possible to carry out experiments with waves at any part of the sixty odd octaves of the electromagnetic spectrum.

The gap between the infra-red and the Hertzian waves has been bridged by advances from both sides. The production of shorter and shorter Hertzian waves has been effected by the use of smaller and smaller oscillators. Lebedew (1895) and Lampa (1896) respectively obtained waves which they estimated as of wave-length 6 mm. and 4 mm., but Mobius, who published his results in 1920, considers that these waves must have been of length 1 cm. and 7 mm. respectively. He himself obtained waves 7 mm. long, with which appeared overtones of much shorter wave-length, but such measurements could not be reproduced exactly. The quest for short Hertzian waves was carried much further by Nichols and Tear, who published their final results in 1923. Lebedew and Lampa had constructed oscillators which consisted of minute platinum cylinders, 1·3 mm. long and ·5 mm. thick, arranged axially end to end, with a gap between them. The current from an induction coil had to leap across small spark gaps to reach the oscillator. Nichols and Tear worked on similar lines, but with great experimental skill succeeded in reducing the dimensions of the oscillator still further. The two cylinders which formed the oscillator proper were of tungsten, each being ·2 mm. long and ·2 mm. thick, with an oil-immersed gap of ·01 or ·02 mm. between them. (It appears from a note published by K. K. Darrow in the Bell *System* Technical Journal, Vol. 3, Number 3, 1924, that the dimensions of the cylinders were subsequently reduced to ·1 mm. long and ·1 mm. diameter.) The waves proceeding from the gap were focussed into a parallel beam by a lens of paraffin wax, and then fell on the interferometer used for measuring the wave-length, which was of the simple form due to Boltzmann. This consists of two plane mirrors mounted one above the other, one stationary and the other movable in such a way that the two always remain parallel. Half the beam falls on each mirror. The reflected beam was brought to a focus by a second paraffin wax lens. The intensity distribution of the resulting radiation was measured, as heating effect caused by the rays falling on a conductor, by a modified form of radiometer (*q.v.*). With such apparatus Nichols and Tear obtained waves the length of whose fundamental was as low as 1·8 mm., and in certain cases very prominent harmonics of wave-length ·22 mm. These harmonics were apparently the fundamental wave-length of the part of the minute oscillator cylinders which projected through the glass into the oil, and predominated, so that it may be claimed that Nichols and Tear extended the Hertzian spectrum down to ·22 mm.

More recently still Glagolewa-Arkadiewa has pushed things further by the use of an entirely new type of generator. This consists of a suspension of fine metal filings in machine oil, kept in constant motion by a rotating disc. The spark from an induction coil passes through a mass of closely packed filings separated by oil. This disposition has the advantages that the vibrators, consisting each of a pair of filings, are exceedingly small, which makes the wave-length small: that there is a very large number of them, which gives the requisite intensity: and that they are constantly renewed, which prevents the spark burning them away at the end. The wave-lengths are investigated with a Boltzmann interferometer, while as a detector special thermocouples are used. With this apparatus Glagolewa-Arkadiewa has measured wave-lengths of from 50 mm. down to ·1 mm. This represents the limit reached at the present time (1928) in the way of short wave-lengths produced by what, in spite of all modifications, is essentially the method of Hertz.

The approach from the infra-red side was mainly carried out by Rubens and his collaborators. Important advances were made by the method of *Reststrahlen* ("rest-rays" or "residual rays"). The method depends upon the fact that certain crystals have a strong absorption, accompanied by metallic reflection, for a small range of wave-lengths in the infra-red, at a frequency correspond-

USED IN RADIOLOGY 3 Octaves
Generation
Emitted when atomic nuclei disintegrate.
Detection
As for X-Rays but more penetrating, less readily absorbed & generally more 'vigorous'.
GAMMA RAYS
Generation
Emitted by sudden stoppage of fast-moving electrons.
Detection
(a) Photography. (b) Phosphorescent effects with suitable materials. (c) Chemical action. (d) Ionisation of gases. (e) Emission of electrons from hot bodies of the same nature as photo-electric effects. (f) Diffracted if suitably reflected by a crystal: show no ordinary reflection or refraction. (g) Penetrate all matter to a greater or less extent.
X-RAYS 14 Octaves
Generation
Radiated from very hot bodies & emitted by ionised gases.
Detection
(a) Photography. (b) Phosphorescent effects with suitable materials. (c) Chemical action. (d) Ionisation of gases. (e) Photo-electric effects. (f) Can be reflected & refracted & diffracted by finely ruled gratings.
ULTRA-VIOLET RAYS 5 Octaves
Generation
Radiated from hot bodies & emitted by ionised gases.
Detection
(a) Produce sensation of light. (b) Photography (c) Chemical action. (d) Photo-electric effects. (e) Can be reflected & refracted & diffracted by ruled gratings.
VISIBLE RAYS 1 Octave
SOLAR RADIATION Limiting Wave Lengths Reaching the Earth
Generation
Heat radiations from hot body.
Detection
(a) Heating effects on thermo-couples & on bolometers. (b) By rise of temperature of receiving body. (c) Photographic effects on special plates. (d) Can be reflected & refracted by comparatively coarsely ruled gratings.
INFRA-RED RAYS 9 Octaves
Generation
Stop gap discharge. Oscillating Triode-valve.
Detection
(a) Coherer. (b) Spark across minute gap in resonant receiving circuit. (c) Can be reflected, refracted & diffracted.
SHORT HERTZIAN WAVES 17 Octaves
HERTZIAN WAVES 28 Octaves
Generation
Spark-gap discharge.
Oscillating Triode-valve
Detection
(a) Coherer (b) By conversion into alternating current which can then be detected or measured (c) By rectification, with or without "heterodyning" & production of audible telephone signals
USED IN WIRELESS 11 Octaves
Generation
Coil rotating in magnetic field.
Detection
(a) Mechanical. (b) Electrical. (c) Magnetic. (d) Thermal effects of alternating currents.
SLOW OSCILLATIONS CORRESPONDING TO VERY LONG WAVES
Approximate Frequencies
Wave Lengths in Centimetres
Wave Lengths in Ångström Units

ing to the period of vibration of the crystal itself. (See LIGHT, *Refraction in Absorbing* Media; SOLID STATE.) The reflection is strongly selective, that is, very much stronger for the particular narrow range of wave-lengths than for wave-lengths on either side. In consequence repeated reflection from a few (say four) surfaces leaves only the selectively reflected rays present in any intensity. With rock salt and sylvite (potassium chloride) rest-rays of wave-length 52μ and 63μ respectively are obtained, while with thallium iodide rest-rays as long as 152μ result. An advantage of the method of rest-rays is that the experimenter has at his disposal a broad beam, with the consequent relatively high intensity.

A technique which led to the measurement of still longer wave-lengths is the method of focal isolation employed by Rubens and R. W. Wood. The radiation from a suitable source is allowed to pass through a quartz lens, quartz being very transparent and also particularly refracting (refractive index 2.2) for the very long rays. The distance of the source from the lens is so arranged that while the shorter heat and the light waves actually diverge after leaving the lens the long heat rays come to a focus, which is isolated by a hole in a screen. A stop at the centre of the lens prevents the direct passage of practically unrefracted rays through the hole. To purify the radiation still further a second quartz lens with a central stop is used to refract the radiation passing through the hole, The wave-length is measured by an interferometer with quartz plates, maxima and minima of intensity being obtained. With a Welsbach gas mantle wave-lengths of 107μ or so were measured. Replacing the gas mantle by a quartz-enclosed mercury vapour lamp Rubens and von Baeyer (1911) found two bands of very long wave-length, one at about 218μ and the other at 342μ. They used an interferometer of Boltzmann type for the analysis of the radiation. Later (1921) Rubens used a grating made of wires a millimetre thick, with millimetre inter-spaces, to disperse the radiation into a spectrum, and confirined the presence of strong radiations at these wave-lengths, with measurable radiation extending to wave-lengths as long as 400μ. It is probable that the radiation of the mercury lamp is not a temperature radiation (see HEAT), but due to the motion of charged ions; for instance Lindemann has suggested that positively and negatively ionised atoms, separated by about the same distance as the atoms in liquid mercury, may form doublets which rotate like double stars, and has shown that this would lead to wave-lengths of the order required.

As regards radiation from a black body of the hollow-space (*Hohlraum*) type used by Lummer and Kurlbaum (see BLACK BODY), Rubens and Michel made detailed measurements on a radiation as long as 52μ from such a source. It is therefore clear that the gap between Hertzian waves produced by discharge between microscopic particles on the one hand, and infra-red rays produced from hot solids and vapours on the other hand has been closed with an ample overlap, the Hertzian waves extending down to 100μ, and the infra-red rays reaching up to 400μ.

The first great step in the modern extension of the ultra-violet was taken by Schumann, who, by using fluorite lenses and prisms and special plates, in which the emulsion was deliberately made very poor in gelatine, since gelatine has a marked absorption for the far ultra-violet, pushed the recorded limit to 1,220 **A.** He showed (1893) that radiations between 1,800 and 1,200 A. are strongly absorbed by air, and hence that it was necessary to work with the spectrograph in vacuo. (See SPECTROSCOPY.) At about 1,200 A.U. fluorite becomes opaque to the radiation, so that for his work on the still shorter waves Lyman, whose researches extend from 1906 to the present day, used a concave grating without lenses or mirrors, the grating itself forming images of the slit on the photographic plate. The spectrograph was necessarily enclosed in a vessel which could be evacuated. Lyman has reached 500 A. During the years 1923–1928 Millikan and his collaborators made further very important advances into the extreme ultra-violet. The source used is the so-called "hot spark" between electrodes of the metal whose spectrum is being investigated: the spark gap is very short and situated in a highly evacuated space, of pressure ·00001 mm. of mercury or less, and the discharge from a powerful battery of condensers charged by an induction coil is passed intermittently. Specially ruled gratings are used, and the pressure in the whole apparatus maintained at the lowest possible level. The limits reached with the line spectra of certain elements are as follows: carbon 360.5 Å.U., zinc 317·3 Å.U., iron 271·6 A.U., silver 260 A.U., nickel 202 A.U. and aluminium 136·6 Å U. This 136.6 A.U. represents the extreme short wave limit measured by the ordinary methods of optical, as distinct from X-ray, spectroscopy.

Turning to the advance from the X-ray side, the longest waves measured by the methods of crystal diffraction originated by the Braggs are about 13 A.U., *e.g.,* L a for copper is of wave-length 13·3 Å.U., while one of the N series lines of thorium, which seems to represent the limit, is of wave-length 13·8 Å.U. The measurement of rays in the gap between 13.8 Å.U. and 136·6 Å.U. presents peculiar difficulties, because all the wave-lengths in question are particularly easily absorbed, even by gases at low pressure, and because the diffraction methods break down in this region. As an example of the absorption it may be mentioned that Holweck finds that a sheet of celluloid ·00027 mm. thick—and celluloid has a particularly low absorption coefficient in this region—transmits only 3 per cent of the radiation in the neighbourhood of 310 A.U., where the absorption is at a maximum. It is consequently necessary to maintain a very good vacuum in the apparatus, and, if any solid diaphragm is used, to make it exceedingly thin. The rays are usually detected either by their photoelectric effect (see PHOTO-ELECTRICITY) or by the ionisation which they produce in a gas at low pressure.

McLennan, Horton, Hughes and others have employed various forms of apparatus in which the surface of a solid is bombarded by electrons accelerated by a measured difference of potential, the radiation so excited being detected and measured by its photoelectric effect on a metal plate. The highest possible vacuum is maintained in the apparatus, so that the incident electrons have the full energy corresponding to the voltage drop. A curve connecting this voltage with the photoelectric current released by the radiation is obtained, and sharp changes in direction of this curve are taken to indicate the appearance of a new radiation, whose wave-length can be calculated from the corresponding voltage. Such a voltage is a resonance potential (*q.v.*). The plate from which the photoelectric current is measured has to be very carefully shielded from any diffusion of ions by arrangements of charged gauzes which vary in disposition in the apparatus of different workers. The method has also been applied to gases, which are bombarded by electrons of known energy. (See RESONANCE POTENTIAL.) Holweck, on the other hand, has employed a different method, separating the part of the vessel where the short waves are produced from the part where their effect is measured by a solid diaphragm, which stops all disturbing ions. The celluloid films which he uses for this purpose have a thickness of 10^{-5} cm. or less. The intensity of the radiation is measured by the ionisation produced in a gas, the pressure of which varies for different experiments, but is generally of the order of a few millimetres of mercury, as contrasted with pressures of the order of ·00005 mm. of mercury in the generating part of the apparatus. A sudden change in the ionisation corresponds to the attainment of a resonance potential, from which the wave-length is calculated as in the other type of experiment. The apparatus can also be used to measure the absorption of these extremely soft (*i.e.,* easily absorbed) radiations.

The result of these measurements of resonance potential is to reveal the existence of characteristic radiations from given elements, of the nature of an extension of the X-ray line spectra (see X-RAYS, NATURE OF: *Röntgen* Rays), in the region noted, and Holweck's experiments have shown in addition a continuous, or non-characteristic, radiation from 25 volts to 280 volts ($\lambda = 500$ Å.U. to $\lambda = 44$ Å.U.). Typical characteristic lines, for which concordant results have been obtained by several different workers, occur, for the L series of magnesium, aluminium, chlorine, argon, at 46, 68, 200 and 245 volts respectively, corresponding to wave-lengths 269, 182, 62 and 50 Å.U. For the K series of carbon, nitrogen, oxygen, fluorine, neon, Holweck has obtained, by his ionisation method, lines at 280, 397, 528, 684 and 864 volts, corresponding to wave.

lengths 44·1, 31·1, 23·4, 18·1, 14·3 Å.U. respectively. It should be noted that the first three of these lines are in good agreement with the measurements of Mohler and Foote, while Holweck by his method has further obtained an aluminium line at 1,555 volts ($\lambda = 7.95$ Å.U.) which agrees precisely with the K absorption edge determined by Fricke by the method of crystal diffraction. This agreement is important, as it gives additional assurance that the results of the ionisation potential methods have been correctly interpreted.

By these measurements of critical potential wave-lengths have, then, been measure'd from 269 down to 14·3 Å.U. which comfortably bridges the gap between wave-lengths measured by the help of ruled gratings, and those measured by crystal diffraction. The methods of crystal diffraction have been used with X-rays to measure wave-lengths down to ·107 Å.U., the K absorption edge of uranium, while the shortest y-ray measured by Rutherford and Andrade, with the crystal method, was ·072 Å.U. C. D. Ellis and L. Meitner have independently measured much shorter y-ray wave-lengths by the help of the natural and secondary β-ray spectra, a method which is essentially photoelectric. (See PHOTO-ELECTRICITY.) The measurements of Ellis stretch from wave-length ·26 Å.U. to ·005 Å.U., and thus have an ample overlap with the lengths measured by crystal diffraction. This ·005 Å.U. represents the shortest wave-length of which the measurement has much claim to accuracy.

The estimates of the wave-lengths of the very penetrating cosmic radiations investigated by Kohlhorster and later by Millikan depend upon the extrapolation of the absorption law far beyond the limits of our experimental knowledge.

Millikan's latest measurements (*Physical* Review, xxxii., 533, 1928) show that the cosmic radiation is not homogeneous, but consists of two main bands, one having an absorption coefficient $\mu =$ ·35 per metre of water ($\mu\rho =$ ·0035 per cm.), and the other being resolvable into two radiations for which $\mu =$ ·08 and $\mu =$ ·04 per metre of water respectively. This rough resolution into a discontinuous spectrum invalidates the method of generation of the rays formerly suggested, namely that the energy of the radiation might be supplied by the impact of high speed electrons against the nuclei of atoms, for this would be expected to produce a general radiatiop. The fundamental assumptions underlying any explanation so far imagined are: (1) that a frequency ν can be derived from the absorption coefficient of the cosmic radiation by the use of some formula to extrapolate the frequency-absorption relation into regions of low-absorption for which no laboratory measurements are available; (2) that the quantum of energy $h\nu$ must be released by some single atomic process. The problem is to find an atomic process which will liberate so large an amount of energy as the very high frequencies derived by (1) require.

The Einstein relation between mass and energy (*see* RELATIVITY and also NUCLEUS, section Stability of *Nucleus: Atomic Energy*) associates any loss of mass with an emission of energy. There is evidence for a change of mass when protons and electrons are packed together to form a nucleus (see NUCLEUS) and Aston has, from his experiments, obtained a curve' showing the "packing effect" for all elements. (See ISOTOPES.) From this curve it is clear that for the lighter elements, of atomic weight less than 80 or so, energy can only be given out when the nuclei are built up from protons, and not when they break down. The heavier elements would, it is true, give out energy on disintegrating, for they lie beyond the minimum in Aston's curve, and the radioactive elements provide actual examples of atoms disintegrating with emission of energy in the form of a- and β-rays (with y-rays as a secondary phenomenon). However, the energy given out per atom by radioactive disintegration is not sufficient to account for the cosmic radiation. Using a formula of Dirac to obtain a frequency from the absorption coefficient Millikan has argued that the cosmic radiation for which $\mu =$ ·35 per metre of water must originate in the formation of helium from hydrogen in outer space. It is shown in NUCLEUS that there is a loss of energy $4{\cdot}6 \times 10^{-5}$ ergs ($4{\cdot}3 \times 10^{-5}$ ergs with the latest figures, used by Millikan) per atom of helium formed, which from the quantum relation $E = h\nu$ corresponds to a wave-length of ·00046 Å.U. Dirac's formula gives an absorption coefficient ·30 per metre of water for such a frequency, which agrees well enough with the necessarily very rough figure derived from experiment. Reasoning on similar lines, the formation of oxygen from hydrogen in a single act gives rise to a radiation of wave-length ·00010 Å.U., which has an absorption coefficient of ·08 per metre of water: this agrees exactly with that of one of the other cosmic radiations observed by Millikan. The formation of silicon from hydrogen leads to a radiation for which $\mu =$ ·041 per metre of water, agreeing with the second of the more penetrating cosmic radiations of Millikan. Helium, oxygen and silicon are elements which appear in great abundance everywhere in the heavens, which lends plausibility to this theory of the generation of cosmic rays, although the creation of an element like silicon in one act out of 28 atoms of hydrogen is a process which offers grave difficulties to the physical imagination.

As a result of recent experiments it can be said, then, that we have knowledge of an unbroken range of electromagnetic radiations from wave-lengths of hundreds of metres down to wave-lengths of a few hundred-thousand-millionths of a centimetre, and have evidence of cosmic radiations of still shorter wave-length.

Generation of the Radiations.—When we consider electromagnetic radiations in free space, any distinction into groups of different wave-length is purely arbitrary, for the velocity and mechanism of propagation is exactly the same throughout the spectrum. When, however, we turn to the relationship between radiation and matter, and in particular the emission and absorption of radiation, there are certain distinctions which, while giving no sharp boundaries of wave-length between different classes of radiation, do nevertheless divide the radiations into broad natural groups. These distinctions are based upon the nature of the vibrator, or of the quantum mechanism, which gives rise to the undulations.

Starting at the long wave-length end of the spectrum, the Hertzian waves are generated by oscillations of electricity in macroscopic systems of conductors. The atomic or molecular nature, or even crystal structure of the metals constituting these conductors does not enter directly into the calculations from which the frequency of a given system can be derived: the conductors can be treated as uniform and homogeneous, and the problem of the oscillations as strictly analogous to those of mechanical oscillations of systems of springs and masses. The size and geometry of the system determines the wave-length; the engineering stations of the wireless telegraph companies, with their mighty aerials, produce wave-lengths measured in hundreds of metres, while minute oscillators whose size is measured in fractions of millimetres produce wave-lengths of the same order as their own linear dimensions.

The infra-red radiations are produced by a variety of oscillators, if we merely consider an arbitrary group of wave-lengths from ·8μ to 400μ say. The atomic mechanism of quantum jumps executed by an outer electron, which is responsible for line spectra (see ATOM, QUANTUM THEORY, SPECTROSCOPY), leads to certain lines situated well in the infra-red: for instance Brackett (1922) has measured two hydrogen lines, of wave-length 4·05μ and 2·63μ, which can be represented by putting $n' = 4$, $n = 5$, 6 in the general Balmer formula $\nu = R\left(\frac{1}{n'^2} - \frac{1}{n^2}\right)$. Such lines, however, are not representative of infra-red radiations, but should be classed with the optical spectra. More typical are the band spectra consisting of nearly equidistant lines in the far infra-red (in the neighbourhood of 100μ), and the band-spectra consisting of two branches of equidistant lines, with a gap between them, observed in the near infra-red (in the neighbourhood of 5μ). (See BAND SPECTRUM.) These spectra are usually observed as absorption spectra, but emission and absorption are effected by the same mechanism. It has been established beyond doubt that the bands in the far infra-red are due to molecules rotating, the possible rotations being fixed by quantum conditions, and interchanges between stationary states leading to emission or absorption, while the bands in the near infra-red are due to vibrations within the molecule, the distance between the nuclei of the constituent atoms varying periodically. These vibrations are superposed on the rotations, and likewise governed by quantum conditions. The details of their mechanism are described in the article BAND SPECTRUM; what it is desired to emphasise here is that the periodic changes in question, whose frequency is typical of the infra-red, are molecular in nature, the motion being of the molecule as a whole, often supplemented by motions of the atoms, treated as rigid wholes, within the molecule. As soon as changes within the atom itself are added to these motions the corresponding bands are no longer in the infra-red, but in the visible and ultra-violet.

Another case of vibrations of the infra-red class is offered by the rest rays, to which reference was made in the preceding section. The oscillations here in question are those of ionised atoms making up the structure of the crystal in question, and can be calculated, as shown by Born and his collaborators, by considering the possible vibrations of the crystal lattice. Here again we are dealing with vibrations of atoms considered as rigid wholes, governed by interatomic forces. It may be said, then, that frequencies of the orders usually associated with the infra-red are connected with the vibrations of atoms or molecules as a whole, under the influence of their mutual attractions and repulsions, and not with changes within the atom.

The radiations of a heated "black body" (*q.v.*) include theoretically the whole spectrum, but the only portions of measurable intensity with laboratory sources are the visible and infra-red. Planck's law giving the distribution of energy throughout the spectrum of black-body radiation at any temperature (see HEAT, QUANTUM THEORY) has been experimentally confirmed, within the limit of experimental error, from $\cdot 5\mu$ to 50μ, the validity in the long wave region 4μ to 52μ having been the object of a special research by Rubens (1921). The theoretical deduction of the formula, although Planck himself assumed the existence of resonators or vibrators within the solid, need not involve any assumption as to the nature of the vibrators involved in the proof, the reasoning being of a thermodynamical nature, which demands no precise mechanism. It is possible, as Einstein has shown, to deduce the formula on the assumption that the radiation is given out by atoms executing quantum jumps, as demanded by Bohr's theory, but as the distribution of radiation is quite independent of the atomic nature of the black body the precise character of the quantum jumps is immaterial. The radiation from a heated solid cannot be atomic, in the sense that the radiation from a gas is, for the behaviour of the atomic electrons must be influenced by the electric field and radiations of the surrounding atoms. It is, then, probably something which partakes of the nature of both an atomic and a molecular radiation, in that the atoms cannot be considered as rigid wholes, as they can for the infra-red bands, nor yet as independent entities within which quantum changes take place, as they can for the line spectra. Vibrating systems of every possible frequency are demanded by the theory, and they can be provided by some such scheme as that sketched, which is necessarily vague, as there is at present no precise knowledge of the mechanism of radiation from solids.

The generation of line spectra in the visible and ultra-violet region has been explained in terms of Bohr's quantum theory of spectra which is fully discussed under ATOM; QUANTUM THEORY, SPECTROSCOPY. Different stationary states of the atom are determined by the behaviour of the outermost electrons of the groups of electrons which surround the nucleus, and passage from one stationary state to another is accompanied by the emission of a radiation of given frequency. By this mechanism of quantum changes among the outer electrons a vast range of frequencies is emitted, for Brackett's hydrogen lines in the far infra-red, to which reference has already been made, are generated in this way, while Millikan's lines in the extreme ultra-violet are due to such changes in atoms which are already multiply ionised, that is, have lost outer electrons. The band spectra in the visible and ultra-violet are likewise due to quantum changes among the outer electrons in atoms constituting a molecule, the molecule executing changes of its own at the same time. The characteristic mechanism of the visible and ultra-violet is therefore an affair of the outer electrons.

The X-ray line spectra originate in similar quantum changes among electrons, but here it is the inner electrons of the atom that are involved, among which are associated with jumps much greater changes of energy than those among the outer electrons. (See X-RAYS, NATURE OF: *Röntgen Rays.*) The γ-rays are not generated in the electron distribution round the nucleus, but proceed from the nucleus itself. The mechanism of their production is still uncertain. (See NUCLEUS.) The origin of the very penetrating cosmic radiation is still less understood; reference has already been made to Millikan's theory that it is due to atomic nuclei in the process of manufacture.

To sum up, then, corresponding to wide range of wave-lengths of the electromagnetic spectrum there is a range of generators of widely different sizes. The longest waves are generated by large installations of coils of wire, condensers and so on, and generators constructed on these principles can be reduced in size until the oscillator system consists of two minute metal filings. Then there are systems of vibrating molecules such as we have in crystals and in solid bodies in general, which generate radiations in virtue of their heat motion. Another type of generator is the single molecule, effective in the gaseous state, which gives rise to infra-red radiations as long as the atoms can be treated as minute rigid bodies. When changes within the atom itself are taken into account we have another type of generator, and this type can be further subdivided according as the inner or the outer electrons are considered. When the outer electrons only are involved in the generation of radiation we can treat the nucleus and innermost electrons as forming a rigid system: when the inner electrons are in question we can still treat the nucleus as a minute rigid body. Finally, we have to consider the nucleus itself as a generator of vibrations, so that, descending the scale of wave-lengths, we start without the need of considering any atomic or molecular mechanism, and there in succession can treat molecule, atom and nucleus as rigid, finally being forced to take into consideration changes within the nucleus itself.

The ranges of wave-length generated by the types of system just outlined overlap one another widely, as has been already indicated. Changes in the atom can generate lines in the far infra-red: some nuclear y-rays are of longer wave-length than the hardest X-rays, generated by the extra-nuclear electrons. From the purely empirical point of view it may be best to group the radiations according to wave-length, or according to methods of measurement, especially as a sound theoretical basis is still to seek in some regions: from the theoretical point of view it seems preferable to group the radiations according to their method of origin. A rough analogy from acoustics, which must not be pressed too far, may be offered. Air vibrations might be grouped according to wave-length, or according to origin. In the latter case the division might be into inaudibly low notes originating in the vibration of planks: drum notes, piano notes, and whistle notes. Such a classification is quite without the theoretical meaning that attaches to the subdivision of electromagnetic radiations, according to classes of natural vibration, but may serve to distinguish the two points of view.

Absorption of Radiation.—In the article LIGHT, the absorption of light is explained in terms of damped oscillators of given free period, present in the absorbing substance, and the connection between absorption and dispersion is expounded. In the articles ELECTRICITY and ELECTRIC WAVES the properties of the Hertzian waves, as predicted by Maxwell's theory, are described. In the present section the actual course of absorption of the radiations, as the wave-length is varied from one end of the range to the other, is discussed, stress being laid rather upon the facts of observation, the fundamental theories being considered in the articles quoted. The differences of absorption exhibited by the radiations of different regions constitute one of the most striking features of the interaction of radiation and matter.

On Maxwell's theory, metals, in which the electrical conductivity is very high (meaning that an actual convection of electric charge, as distinct from a displacement current, is easily set up in the medium), reflect radiation very well, and also absorb very strongly that part of the radiation which is not reflected. The higher the conductivity, the larger the coefficient of absorption, It is an experimental fact that in the region of Hertzian waves the absorption by metals is very high: for instance Branly found that tinfoil ·008 mm. thick did not let the waves through in measurable intensity. From the same theory it follows that perfectly insulating dielectrics should be perfectly transparent. This has also been to some extent confirmed experimentally, Righi having shown by a direct method that sulphur, ebonite, paraffin and selenite are quite transparent to waves 5 to 20 cms. in length, but glass, marble and wood absorb to some extent, The comparatively good transmission of long electromagnetic waves by substances which are, broadly speaking, non-conducting, is a familiar fact to people living in brick houses who use an inside aerial for the reception of broadcast waves.

According to Maxwell's theory absorption is entirely governed by the conductivity of the medium, and a relation can be worked out which gives the absorption coefficient in terms of the conductivity and the dielectric constant. A great number of measurements have been made by Drude and his followers on the absorption of feebly conducting substances, such as electrolytes and low pressure gases. Qualitatively the relation holds in all cases. Quantitatively it has been confirmed for water solutions of salts, of which the conductivity is measured directly, while the dielectric constant is taken as being that of water. With many organic substances, however, especially those containing hydroayl groups, the measured absorption is greater than that given by the theoretical formula. Drude tried to explain this by the presence of resonators of the type that account for optical absorption, with a large damping coefficient, but there seems no possibility of resonators of sufficiently large free period. A more promising theory is that of Debye, who looks for the explanation in the presence of dipoles in the molecules, which tend to set themselves in the direction of the electric force. When the oscillations are comparatively slow, as in the Hertzian region, the dipoles can follow more or less the alternations of electric force, provided the medium is not too viscous, and dissipate the energy, but when the alternations are very rapid, as in the optical region, they have no time to orient themselves, on account of their great inertia. Some substances show narrow regions of anomalous dispersion in the Hertzian region which do not accord with this explanation. Speaking broadly the Hertzian waves do experience the strong absorption in good conductors and the feeble absorption in dielectrics which can be explained on Maxwell's theory without any consideration of the structure of the medium, or its chemical nature.

The longer infra-red waves are also well removed from the region where the oscillators of the type considered in optical dispersion make themselves felt, and many of the consequences of Maxwell's theory, based on the assumption of a structureless medium, have been confirmed with such waves by Rubens and others, such as the proportionality of the refractive index to the square root of the dielectric constant for non-conductors. For such experiments the long infra-red waves possess the advantage that they do not necessitate the large-scale apparatus required for Hertzian waves many ccntimetres in length. Considering the absorption of infra-red and optical radiations a distinction must be made between the absorption associated with metallic reflection and that conditioned by the atomic oscillators. In the case of strong reflection, exhibited by such crystals as those used for isolating the rest-rays, as well as by metals, the absorption is in general so high that the radiations do not penetrate any appreciable distance into the substance. (The effect takes place with crystals only for a radiation whose frequency agrees with that of the free period of the natural vibration of the crystal.) The surface colour, using the term in a general sense, to apply to invisible as well as to visible radiations, is approximately complementary to the colour transmitted by an exceedingly thin layer, as exemplified by the green light transmitted by a gold leaf, which appears yellow by reflected light. In the case of the ordinary absorption associated with anomalous dispersion, the radiations penetrate further into the body, and the colour by reflected light is the same as the colour by transmitted light. Right down into the optical and ultra-violet region the opacity of metals holds, but it ceases in the X-ray region, where the oscillations are far too rapid to affect the electrons which are responsible for the conduction. It may be noted that there is a certain selectivity in the metallic reflection in the optical region which is not accounted for by the simple Maxwellian theory: for instance gold reflects red selectively as can be seen by reflecting light many times between two plane gold surfaces. The issuing light is deep red.

A large number of measurements of the absorption of radiation by metals has been made by Hagen and Rubens. The absorption coefficient, defined by them as the reciprocal of the thickness which reduces the incident radiation to one-tenth of its initial intensity, varies somewhat with the wave-length, but has a value of the order of 10^5 cm.$^{-1}$ for gold and silver, for instance, in the visible and near infra-red.

While metals show the same opacity to the visual region as to the long waves, the behaviour of non-conducting or badly conducting substances in this region is widely different. All such substances show regions of marked selective absorption either in the visual region or in the neighbouring ultra-violet or infra-red, the theory of dispersion resting upon the presence of absorption bands in this range. A few of the most important examples will be given. Glass, which transmits the visible radiations so well, is opaque for the infra-red and the ultra-violet except in regions immediately adjoining the visible. The ordinary glass fire screen offers a familiar proof of the opacity for infra-red, and this opacity is also the cause of the high temperature prevailing in glass-houses. The visible radiations enter the glass-house and heat the soil, but the very long heat rays emitted by the soil cannot escape. Quartz is transparent in thicknesses of some centimetres to the infra-red beyond 70μ, but has a strong absorption from 4·5μ to somewhere about this value. It is also transparent in the ultra-violet down to 1,800 A.U. Substances which transmit the infra-red well are sylvin, rock-salt, and fluorite down to about 23, 15 and 9μ respectively. The substances transparent to the visible are familiar to everybody, as are coloured glasses with selective absorption. The ultra-violet is often divided into groups by the absorption of various substances: 3,800–3,400 Å.U., glass ultra-violet, transmitted by ordinary glass: 3,400–3,000 Å.U., Jena glass ultra-violet, transmitted by Jena and other glasses specially prepared for the purpose: 3,000–2,200 Å.U., quartz-glass ultra-violet: 2,200–1,800 Å.U., quartz crystal ultra-violet: 1,800–1,200 Å.U., fluorspar ultra-violet, The absorption of glass both for the ultra-violet and the infra-red is a matter that is, to a certain extent, under the control of the glass maker, Crookes prepared glasses very opaque to the far red and near infra-red for the use of furnace-men, while there are many special glasses designed both to stop the ultra-violet as near the visible as possible and to transmit it as far into the short-wave region as possible. The position of the absorption bands of solids in the visible and the adjacent parts of the spectrum is not determined atomic properties, but molecular properties.

Of particular interest is the absorption of the atmosphere for radiation, as it determines the limits of the sun's radiations which reach us. At the long wave-length end of the spectrum the intensity of the radiations has been carefully measured by Abbot up to 5·3μ where the energy is practically zero, probably owing to a strong absorption band of water vapour, which extends to 6.5μ. There are signs of a feeble transmission of infra-red between 10 and 13μ, but it is established that there are no measurable radiations between wave-length 15μ and 300μ. This is in any case not entirely due to atmospheric absorption, for if the sun be treated as a black body of temperature 6,000° absolute it can be calculated that the intensity of radiations of wave-length greater than 15μ would only be about 3/10,000ths of the total energy. In the infra-red of wave-length less than 6·5μ there are marked absorption bands due to carbon dioxide and water vapour.

At the other end of the spectrum the atmosphere transmits the ultra-violet down to about 3,000 Å.U. The limit varies, of course, with the thickness of the atmosphere traversed, and hence is different in summer and in winter. Measurements made in Switzerland by Dorno show that according to the season and the time of day the shortest wave-length of the sun's spectrum present in measurable intensity varies between 2,976 and 3,197 Å.U. It may be noted that it is quite a narrow kange of wave-lengths from about 2,800 to 3,100 Å.U., with a sharp maximum at about 3,000μ that can produce sunburn (light erythema), which accounts for the great variation in the burn produced by strong sunlight at different times of year, for the greatest action lies just in the region about which the limit of wave-length transmitted by the atmosphere oscillates with the seasons.

The great absorption of all matter for the radiation of the extreme ultra-violet, on both sides of 300 Å.U., has already been emphasized. From this region onwards the penetrating power of the radiation increases as the wave-length becomes shorter. With X-rays any distinction between conductors and non-conductors ceases, for the absorption here is entirely an atomic affair, and depends upon the binding of the inner electrons by the nucleus. Sharp absorption edges correspond to the frequencies at which the quantum energy of the radiation first suffices to eject an electron from a given inner group. (See X-RAYS, NATURE OF: *Röntgen* Rays.) For very hard X-rays, shorter than the K absorption edges of the elements considered, the absorption of a given element is proportional to the third power of the wave-length, while for a given wave-length and different elements it is proportional to the fourth power of the atomic number of the element, and thus independent of the periodic physical and chemical properties of the absorbing substance.

Broadly speaking, then, in the Hertzian region the behaviour of the radiation incident on matter can be explained in terms of the macroscopic electric conductivity, without consideration of the mechanism by which the conduction takes place. In the extreme infra-red the free-period of the crystal lattice makes itself felt, and the phenomenon of metallic reflection by crystals is observed in restricted regions, but outside these regions the laws of the Hertzian waves are obeyed. In the visible and adjacent regions the phenomena of absorption and dispersion are governed by damped oscillators of determined free-period, the nature of which is discussed under LIGHT. The chemical constitution and physical state of the body is of prime importance in these regions, and each substance has its regions of high absorption. For the absorption of the very short waves of the X-ray and y-ray region only the inner regions of the atom play a part, and conductivity in particular, and chemical and physical state in general, cease to have any important influence.

The question of the absorption spectra of gases and vapours is considered in full under BAND SPECTRUM and SPECTROSCOPY.

The Nature of Radiation.— The theoretical significance of the study of radiation for modern physics cannot be over-estimated, and most of the articles on physical subjects will be found to have some bearing on the subject. The hypothesis of an ether was created to account for the passage of radiation in interstellar space, and peculiarities of the behaviour of radiation—in this particular case visible light—led to the theory of relativity, as described in the articles RELATIVITY and ETHER. The consideration of the distribution of energy in the spectrum of black body radiation, which comprises, as far as experiment is concerned, the visible and infra-red, led to the Quantum Theory (*q.v.*), which has found significant application in such apparently remote subjects as specific heat. The particular study of radiation termed Spectroscopy (*q.v.*) is at the basis of the modern theory of the atom. The theory of Maxwell and the consequent discovery of long wave radiations by Hertz have left their mark in every branch of theoretical physics. To attempt a full list would be to run over every branch of physical science.

The extension of the electromagnetic spectrum constitutes one of the great unifying principles of modem science, and is a part of the attempt to explain everything in terms of electric and magnetic forces which is characteristic of the age. Until very recently there was, however, a sharp distinction made between radiation and matter. The interaction of the two, both in the way of the emission of radiation by matter and the action of matter on radiation falling on it, has proved to be a subject full of difficulties and paradoxes, in spite of the continued assault of the best brains of science on the problems presented. One group of phenomena is sufficiently explained by a wave theory of radiation; another group seems to demand for radiation a corpuscular character. (See PHOTOELECTRICITY, COMPTON EFFECT.) During the last few years a promising path to a general solution seems to have been found in the theory of wave mechanics initiated by L. de Broglie and Schrodinger. On this theory the distinction between matter and radiation becomes very shadowy. An electron is a certain singularity in a group of waves, and while waves possess certain of the properties of particles, at the same time particles possess many wave-properties. The electromagnetic theory of light was the great achievement of the last quarter of the past century: the explanation of matter in terms of electric charges was the great achievement of the first quarter of the present century. The next period bids fair to be one in which electric charges and radiation will be explained on a common basis, as different manifestations of something more fundamental, but at present less definite, foreshadowed by the wave function in the new wave mechanics.

The subject of wave-mechanics is discussed at more length in the article QUANTUM THEORY.

CORPUSCULAR RADIATIONS

The more detailed properties of the different classes of corpuscular rays are dealt with in other articles, cited as occasion arises. What is here given is a general review of the various types of rays and their relationship to one another.

The corpuscular radiations may be divided into the following groups: (a) Radiations consisting of streams of electrons, often referred to generically as cathode rays, since they were first observed coming from the cathode in an exhausted tube. In this group are included the β-rays from radioactive bodies. (b) Radiations consisting of streams of charged atoms or charged molecules, often called canal rays, since they were first observed passing through holes, or canals, in the cathode. These atoms are generally positively charged, and are sometimes referred to as positive rays, but since negative and neutral atoms are found in conjunction with the positive the name is not altogether suitable, although retained from long usage. The a-rays from radioactive bodies fall within this group. (c) Radiations consisting of streams of uncharged atoms of low velocity, obtained by evaporating an element in a vacuum so high that the free path of the escaping atoms is very large. Such rays are known as atomic rays.

Class (c) can clearly be included in class (b) if desired: the distinction is here made because the mode of generation of the rays and the state of charge are different. The characteristic feature of classes (b) and (c) is that the corpuscles which constitute the radiation have the mass of atoms, which is many thousand times the mass of the electron. Andrade has suggested calling this class of rays mass rays, a term which makes no reference to the state of charge, and this term has been adopted by Aston.

Electronic Radiations.— The cathode rays were discovered by Hittorf in 1869 in the course of his work on the discharge in an exhausted tube. He recognized that the rays streamed in a straight line from the cathode, and discovered that they were deflected by a magnet, behaving in this respect "like a simple current." In 1892 Lenard showed that the rays could pass through very thin metal foils, and so succeeded in obtaining them outside the tube in which they were generated. Later it was proved by J. J. Thomson and others that the rays consisted of streams of electrons, not associated with matter in the ordinary sense, moving with a velocity governed by the potential difference applied to the tube. This work, and the properties of cathode rays in general, is treated in the article ELECTRICITY, CONDUCTION OF: GAS.

The velocity of cathode rays is often expressed in volts, it being understood by this that the velocity in question would be acquired by an electron moving freely through a potential difference of the number of volts specified. Very small velocities' can be obtained by releasing electrons from a metal plate by illuminating it with violet or ultra-violet light (see PHOTOELECTRICITY), or from a metal wire or strip by heating it (*see* THERMI-

ONICS), and applying small accelerating or retarding Gelds. Ramsauer has obtained, with the help of a magnetic field and a system of screens, homogeneous beams of electrons of velocity as low as 1 volt (6×10^7cm./sec.). At the other end of the scale we have the β-rays from radium C which have velocities up to ·998 that of light. This is a velocity of $2{\cdot}994\times10^{10}$ cm./sec., and would need a field of 7.5 million volts to produce it artificially. Cathode rays of every velocity between these two limits are known in the laboratory, the region of velocities occupied by the spontaneous @-radiationsfrom radioactive bodies overlapping with an ample margin the upper limit of velocity producible in tubes by an artificially applied potential difference.

The difference in absorption is one of the most striking distinctions between cathode rays of different speed. For very slow electrons the absorbing cross-section of the atom is of the same order as the size of the atom determined by the accepted methods. Ramsauer and his school have shown very important abnormalities of absorption for electrons whose velocity is in the neighbourhood of a few volts, a comparatively high absorption here diminishing to an abnormally low one as the velocity drops to a volt or so, but these results do not affect the general order of the absorbing cross-section. As the velocity of the electrons increases the absorption becomes less and less: for velocities of 25, 2,560, 24,680, 261,500 and 662,000 volts the relative coefficients of absorption are as 18,000,000, 800,000, 2,900, 19 and 6. This means that the very swift electrons can pass freely through practically the whole cross-section of an atom, meeting less and less obstruction in so doing the higher their velocity. For the rays of highest velocity, which are not, of course, obtained artificially from a tube, but are @-rays, the cross-sectional area of an atom which acts so as to stop the electron is of the order of a millionth of the whole cross-section.

In Lenard's original experiments on the passage of cathode rays through windows of thin aluminium foil, the potential fall was of the order of 30,000 volts. The issuing rays, easily detected by the luminosity which they produce in a screen covered with a suitable phosphorescent substance (*e.g.,* barium platinocyanide), traverse a distance of the order of a centimetre of air at atmospheric pressure before becoming too weak to be observed. Of recent years cathode rays of very much higher velocity, and consequently much longer range, have been produced. There are many experimental difficulties in the way of constructing a tube that will stand up to 100,000 volts and more, but these have been overcome by W. D. Coolidge. In his tube the electrons proceed from a hot-wire cathode, of the type used in the Coolidge X-ray tube (see X-RAYS, NATURE OF: *Röntgen* Rays), in a hemispherical focussing cup, and issue into the air through a window of thin nickel foil, supported by a grid of molybdenum against the pressure of the atmosphere. The window is also the anode, and special precautions have to be taken to preserve the glass near it from puncture. Potentials as high as 200,000 volts have been used by Coolidge. With such a voltage the cathode rays can be detected at a distance of more than 40 cms. from the window in atmospheric air. Such rays are far inferior in speed to the β-rays of radium, but are produced by the tube in quantities far exceeding anything remotely possible with the quantities of radioactive substances available. The effects of this intense high speed cathode radiation are very remarkable. The rays produce a purple glow in the air round the window; they produce in calcite a phosphorescent glow which remains visible for hours after the exposure. The action on organic tissue of all kinds is very striking. Plant leaves after exposure dry up. The effects on animal tissue, as exemplified by a rabbit's ear, vary with the length of exposure. A very short exposure produces a tanning of the skin; an exposure of 1 second leads to the formation of a scab, which afterwards falls off with the hair, and is followed by a profuse growth of new hair which is, however, snow-white; an exposure of 50 seconds leads to scabs in the rayed area which leave a hole right through the ear when they fall. Bacteria are killed by the radiation, which also kills flies and beetles. Milk and butter quickly become rancid. Chemical effects have been produced in many other bodies, such as glue, gelatine and cane sugar, all of which break down under the bombardment of the swift cathode rays.

Mass Rays.—Charged atoms or molecules moving in beams can be produced in a variety of ways. They appear streaming through holes in a pierced cathode in the opposite direction to the cathode rays in a discharge tube and are thus called canal rays. Similar radiations of charged atoms can be produced from cathodes made of two parallel plates metallically connected, from two thin parallel wires used as a cathode, or other dispositions. Rays of material particles have also been observed travelling in the same direction as the cathode stream, and have been called retrograde rays by J. J. Thomson and K_1 rays by Goldstein. In all these cases the rays are derived from the low pressure gases present in the tube. Another method of obtaining such rays, which can be applied when the atoms in question cannot be obtained as a gas or a volatile compound, is to pack the anode of a discharge tube with a paste made of powdered graphite and a metallic salt: the rays then contain charged atoms of the metal in question. Such rays are known as anode rays, from their method of production, but they are of the same nature as the canal rays.

In a beam of canal rays the charged atoms are mainly positive, but neutral and negatively charged atoms exist aiongside. If a beam of positive atoms only be separated out by the application of a magnetic field, negative and neutral particles recreate themselves in the beam, as may be shown by a second magnetic field. This is due to the fact that an atom which starts in the beam as positively charged may become neutral by collision with an electron, or even negative by collision with a second electron. An equilibrium state is set up between positive, neutral and negative atoms, and, if the equilibrium is disturbed by separating out the positive ones, it establishes itself by new collisions a little further on. A moderately satisfactory theory of the reversals of charge has been worked out on the lines of the kinetic theory of gases, by considering the mean free path of charged and uncharged atoms passing through an assemblage of stationary particles. The important application of the canal rays and anode rays to the accurate measurements of the atomic weights of isotopes is described in the articles POSITIVE RAYS and ISOTOPES, where the existence of negatively charged atoms and of atoms with multiple charges also receives reference.

The a-rays from radioactive bodies are of the same nature as the positive rays in discharge tubes (except in that a-rays are always helium atoms, whereas positive rays of any element can be obtained), but have very much greater energy, just as the β-rays are of the same nature as cathode rays, but possess greater energy than can be obtained artificially. The energy of the a-particles of range 8.6 cms. from Thorium C corresponds to a fall through about ten million volts, and the energies with which a-particles are discharged from other radioactive bodies are all measured in millions of volts, as compared to the tens of thousands of volts concerned in the generation of the swiftest positively charged atoms in discharge tubes. There is thus no prospect of the generation of artificial a-rays in the laboratory. Corresponding to these voltages the velocity of the swiftest canal rays is of the order 10^8 cm./sec. (for example the highest velocity obtained for hydrogen canal rays is 3 to 4×10^8 cm./sec.) while the velocity of a-particles is of the order 2×10^9 cm./sec. It is well known that a-particles can pass through thin metal foils *(see* RADIOACTIVITY, NUCLEUS); the smaller velocity of the canal ray atoms does not enable them to penetrate foils as thick as those accessible to the a-rays, but nevertheless it has been demonstrated that they can penetrate matter. For instance swift canal rays of hydrogen and helium penetrate aluminium foil $3{\cdot}8\times10^{-5}$ cm. thick and mica 2 to 6×10^{-4} cm. thick, and hydrogen rays have been observed to go through gold foil of thickness from 7 to 21×10^{-6} cm.

Another point of resemblance between a-rays and canal rays has recently been established, namely that the a-rays can suffer changes of charge during their course. Along with the helium atoms of double positive charge a smaller number of helium atoms with only one positive charge can be observed, and a very few neutral atoms, but no negatively charged atoms. The smaller the velocity of the a-rays the greater the proportion of singly charged atoms; the neutral atoms are found only at very low velocities.

Another class of mass rays is constituted by the very much slower atoms obtained by evaporating a molten metal in a vacuum so high that the mean free path of the atoms leaving the metal surface is much greater than the dimensions of the vessel. By means of a suitable system of diaphragms pierced with slits or holes it can be arranged that the flying atoms take the form of a beam. If the temperature of the glass wall opposite the metal surface is suitable the beam of atoms forms a thin deposit where it strikes, but it must be observed that the necessary temperature is far below the solidification point of the metal. In cases where the deposit is too thin to be seen it can be "developed" by depositing silver on it from a silver nitrate solution, by a special technique. The velocity of such atomic rays, as they are termed, can be measured by rotating the vessel at a known speed and observing the consequent displacement of the line deposit made by a flat beam. The velocity found by this method agrees within experimental error with that to be anticipated on the kinetic theory of gases from the temperature of the molten metal, and this constitutes the first direct measurement of the velocity of atoms due to heat agitation. The velocity of a beam of silver atoms derived from molten silver at about 1,500° absolute is 6×10^4 cm./sec., as compared with about 10^8 cm./sec. for the atoms in canal rays and 2×10^9 cm./sec. for α-particles.

The atomic rays have found an important application in the experiments of Stern and Gerlach on the magnetic moment of atoms, described in the article MAGNETISM.

Finally, a word may be said on corpuscular radiations reaching the earth across space. The aurora borealis is attributed to the action of rays from the sun on the rarefied gases of the upper atmosphere at heights of 100 kilometres and more. The magnetic action of the earth on the charged particles constituting these rays concentrates the action in the polar regions. The data available do not suffice to establish with certainty whether these radiations consist of electrons, and so resemble β- and cathode-rays, or whether they consist of positively charged atoms, and so resemble the mass rays obtained in discharge tubes and a-rays. Vegard states that positive rays of hydrogen and helium with velocities of the order of 10^8 cm./sec. may produce an essential part of the aurora, but at the same time asserts that swift electrons combine a sufficiently great magnetic deflectibility and penetrating power to explain the distribution of luminosity and the height at which the aurora is produced. The corpuscular cosmic rays, influenced by the earth's magnetic field, must be carefully distinguished from the penetrating electromagnetic cosmic rays, discussed in the first part of this article.

BIBLIOGRAPHY.—Bibliographies of the various sections of the subject are given under ATOM; BAND SPECTRUM; ELECTRICITY; ELECTRICITY, CONDUCTION OF; ETHER; ISOTOPES; LIGHT; PHOTOELECTRICITY; POSITIVE RAYS; QUANTUM THEORY; RADIOACTIVITY; RELATIVITY; RESONANCE POTENTIAL; X-RAYS, NATURE OF; SOLID STATE; SPECTROSCOPY; ELECTRIC WAVES; WIRELESS TELEGRAPHY. *See* also LIGHT AND RADIATION IN RELATION TO HEALTH.

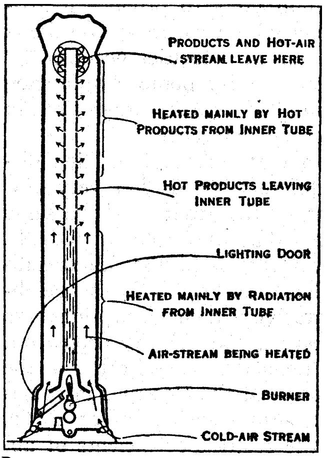
Vegard, "Recent Results of Northlight Investigations and the Nature of the Cosmic Electric Rays," *Philosophical Magazine, 42*, 1019, 1921; E. F. Nichols and J. D. Tear, "Joining the Infra-red and Electric Wave Spectra," *Proceedings National Academy of Sciences, 9*, 211, 1923. (E. N. DA C. A.)

RADIATOR, a device usually built of cast iron, steel, copper or brass, used in room or space heating for transferring heat from a heating medium such as steam, hot water, gas or electricity to the surrounding air in the room. Steam radiators act as condensers for steam received through pipes from a boiler outside of the room, the condensate returning through the same or separate set of pipes to the boiler. Water radiators cool the hot water received through pipes from a boiler outside of the room and permit this water to return to the boiler. Gas radiators are equipped with gas burners as a source of heat and are of the following types: gas warm air radiator; gas steam radiator; gas water radiator. A vented gas radiator is provided with a pipe connection from which the products of combustion can be conducted out of the room. In an "unvented gas radiator" the products of combustion are permitted to escape into the space being heated. In gas, steam and gas water radiators, the pressure of steam or temperature of water is used to regulate the amount of gas burned. Electric radiators are equipped with resistances or elements which generate heat when supplied with electric current. If the heat is transmitted directly from the resistance to the air of the room, they are sometimes called space heaters. If electric radiators use steam or water as a means of transferring heat from the electric element to the surface of the radiator they are known as electric steam or electric water radiators. (See HEATING AND VENTILATION; THERMOSTAT; COOLING SYSTEMS.) (C. FL.; X.)



DAVIS GAS-HEATED STEAMLESS RADIATOR. SHOWING INNER STEEL TUBE WHICH HEATS THE CAST-IRON BODY

RADIĆ, STJEPAN (1871–1928), Yugoslav statesman, was born at Trebarjevo, near Fiume, on July 11, 1871. He studied in Zagreb and Prague, being once expelled from the Lycée and twice imprisoned in the former city for Croatian and anti-Hungarian demonstrations. From 1897–99 he studied in Paris and later lived for a time in Semlin as Balkan correspondent to various newspapers, coming into contact with Serb political leaders, and settled in 1902 in Zagreb. In the same year he began to publish the *Hrovatsko Misao,* in which he outlined the programme of the Croatian Peasant Party, which first entered the Croatian Sabor, with 9 seats, after the elections of 1910, but soon became the most powerful political force in Croatia. In 1911–12 Radii was again imprisoned by the Magyar Ban of Croatia. During the World War he became an Austro-Hungarian Legitimist, but on the collapse of Austria-Hungary converted his party, which followed him implicitly, to republicanism. In Feb. 1919 he demanded for Croatia self-determination, and union with Serbia and Montenegro "with equal rights." Disagreement with the Serbs, however, led him back to prison March 1919–Feb. 1920 and March–Nov. 1920.

Radii now condemned his party to a long and singularly sterile period of opposition and Parliamentary abstention, until, tiring of this, he left Yugoslavia in July 1923 for a prolonged visit to London, Moscow and Vienna. He returned to Zagreb in Aug, 1924 with fresh ideas on Panslavism and the cooperation of workmen and peasants, and was imprisoned in Jan. 1925. In March, however, his nephew Pavle Radić (*q.v.*) effected a reconciliation. Radii was released, his party entered the Government. he himself became an enthusiastic supporter of King Alexander, and for a time himself entered the Yugoslav cabinet. His habit of embarrassing his colleagues as often and as highly as possible led to his resignation. He returned to opposition, which he conducted with such verve that a Government Deputy named Račić shot him in the stomach in the Skupština on June 20, 1928. On

Aug. 8, 1928, he died at Zagreb from the effects of his wound.

RADIĆ, PAVLE (1880–1928), Yugoslav statesman, nephew of the above, was born at Trebarjevo, near Fiume on Jan. 1, 1880. He settled in Zagreb as a banker. The coalition of Serb Radicals and Croat Peasants which existed fitfully in 1926–27 was mainly his work; but when it broke down, he rejoined the Opposition. On June 20, 1928, he was murdered in an unsuccessful attempt to save his uncle's life.

RADICAL, in English politics a supporter of the more extreme section of the Whig or the Liberal Party; in American politics, anyone who desires to make radical (Lat. radix, root) changes in the social order—hence usually a Socialist or Communist. The first use of the word in a political sense is generally ascribed to Charles James Fox, who in 1797 declared for a "radical reform." It was thenceforward used as a general term covering all those, from Sir Francis Burdett to Richard Carlile, who supported the movement for Parliamentary Reform. After the passing of the Reform Bill of 1832, the more adventurous of the reformers, of whom the chief organizers were Francis Place (London) and Joseph Parkes (Birmingham) remained in informal but continuous association. They exercised continual but vain pressure upon Lord John Russell and other Whigs, to agree to an extension of the franchise to the working-class. Their most effective work was done after 1835 in the reformed administration of the provincial towns, some of which they controlled from the first democratic election, and in which they had to remove the effects of years of corruption and indolence. Their spokesmen formed for some years a recognized group in the House of Commons, which included George Grote, Slingsby Duncornbe, Thomas Wakley and Joseph Hume. They were out of sympathy and touch with the organized section of the working-class owing to their support of the new Poor Law (1834) and their hostile attitude to the Chartists (see CHARTISM).

From about 1839, consequently, their influence suffered a decline, but it revived after about 1850 when Chartism was practically extinct. The National Reform League, whose president and leader was Edmond Beales, was most active in promoting the reform of the suffrage, achieved in 1867 for the towns and in 1884 for the country: Frederic Harrison, J. S. Mill, and Professor Beesly being the most distinguished of its theorists. The Radicals, through the group of officials known as the Junta, gained also complete control of the political mind of the trade unions and from 1874 to 1892 every trade unionist who gained a seat in Parliament sat as a Radical. Reynold's *Illustrated News*, the most popular Radical organ, somewhat exaggerated the respectable Radicals' view in its vehement Republicanism, its contempt for revealed religion and its advocacy of complete *laissez faire* in economics, but these principles were generally regarded as inherent in Radicalism. The London Radical clubs towards the end of the 19th century probably represented the most powerful single political grouping in the country. They were only induced by the personal intervention and prestige of Charles Bradlaugh to merge their identity in the new machine of the National Liberal Federation, controlled by Mr. Schnadhorst; and from that time we may date the disappearance of organized Radicalism. (R. W. P.)

RADICAL EMPIRICISM, in philosophy, is the theory that experience is the only test of reality and truth. This is the view of W. James (*q.v.*), and was so named by him.

See W. James, *Essays in Radical Empiricism* (1912).

RADIO is the combining form denoting relation to or connection with a ray, a radius, or radiation. In anatomy the term refers to the radius or outer of the two bones of the forearm as radio-carpal. In physics and chemistry it is used in connection with various forms of radiation as in radio-activity (*q.v.*). In electricity its general application is in association with electric waves (*q.v.*). In its specific application to radio communication the word is used to denote the transmission and reception of signals by means of radiated electromagnetic waves. The signals translated may be the ordinary sounds sensed by the ear or they may be the "signals" of images sensed by the eye which have been translated into "sound" signals, as in television. Communication by radio in its various forms, including such phases as wired wireless, wireless telegraphy, wireless telephone, general types of broadcasting, television, is too broad a subject to be treated adequately in a single article.

A basic discussion of atmospheric electricity is given in the article ELECTRICITY, ATMOSPHERIC. A study of the theory of Maxwell and others in the development of theory relative to electric waves is found in the article ELECTRIC WAVES. The theoretical concepts of wireless telegraphy are in the article WIRELESS TELEGRAPHY; the practical applications, including such data as international agreements, standard wave lengths, maps of communication lines throughout the world, are in the same article under a subheading, *Communication* by Wireless.

The principles of the action of heat on matter in generating atomic or subatomic electrically charged particles are found in the article THERMIONICS, while the article THERMIONIC VALVES treats of the several distinct types of vacuum tubes. The more important and most frequently encountered radio terms, numbering several score, are defined and described under their respective headings. The short radio subjects are in turn cross-referred to in the main practical articles listed below.

Television is found under the heading TELEVISION and the transmission of motion pictures by this and other means is discussed under the articles TELEVISION and MOTION PICTURE: *Technology*. Under TELEGRAPH and TELEPHONE is a study of transoceanic wireless telephone and wired wireless. All articles are supplemented by text illustration and photographs and, in many instances, by diagrams showing wiring arrangements and important technical data.

For the convenience of the reader the subject of broadcasting is divided into two main headings: (1) BROADCASTING and (2) BROADCAST MUSIC. The former article is subdivided into (a) a general survey of European practice, *(b)* a general survey of American practice, (c) tecnnical aspects or the engineering problems involved in broadcasting. The latter article is subdivided into two sections: (a) broadcast music in Great Britain and on the Continent and (b) broadcast music in America. In addition, the two major phases of broadcasting—reception and transmission—are dealt with in RADIO RECEIVER and MICROPHONE OR TELEPHONE TRANSMITTER.

So many new developinents are occurring in radio that it is impossible for a survey to predict tendencies even a few years hence; it is believed helpful, however, to include here the most important "peaks" that have been made in wireless progress. The following data are taken from an official bulletin of the U.S. Department of Commerce:

In 1827 Savary found that a steel needle could be magnetized by the discharge from a Leyden jar. In 1837 the first patent for an electric telegraph was taken out by Cooke and Wheatstone (London) and by Morse (United States). In 1840 Henry first produced high-frequency electric oscillations. In 1867 Maxwell read a paper from the Royal Society in which he laid down the theory of electromagnetism, which he developed more fully in 1873 in his electric waves that are now used in wireless telegraphy. In 1870 Von Bezold discovered that oscillations set up by a condenser discharge in a conductor give rise to interference phenomena.

In 1879 Hughes discovered the phenomena on which depends the action of coherer. In 1883 Fitzgerald suggested a method of producing electro-magnetic waves in space by the discharge of a conductor. In 1887 Hertz showed that electro-magnetic waves are in complete accordance with the waves of light and heat, and founded the theory upon which all modern radio signalling devices are based. In 1896 Marconi lodged his application for the first British patent for wireless telegraphy. He conducted experiments in communicating over a distance of $1\frac{3}{4}$ miles successfully. On Dec. 6, 1897, signals were transmitted from shore to a ship at sea, 18 miles distant. On Dec. 17, 1897, the first floating wireless station was completed. On June 3, 1898, the first paid radiogram was transmitted (from the Needles [Isle of Wight] station).

On March 30, 1903, the first transoceanic radiogram was published in *The Times,* London. In 1906 Dr. DeForest was granted a patent (Jan. 18) for a vacuum rectifier, commercially known as the audion. In the same year Gen. H. N. C. Dunwoody discovered the rectifying proportions of carborundum crystals, and Pickard discovered the similar properties of silicon crystals. These discoveries formed the basis of the widely used crystal detectors. In 1912 Frederick August Kolster, of the U.S. Bureau of Standards invented and developed the Kolster decremeter, which is used to make direct measurements of wave length and logarithmic decrement. In 1912 the first practical trials with wireless apparatus on trains were made on a train belonging to the Delaware, Lackawanna and Western Railroad.

In Oct. 1914, E. H. Armstrong was issued a patent covering the regenerative circuit, also known as the feed-back and the self-heterodyne circuit. On July 28, 1915, the American Telephone and Telegraph Co., working in conjunction with the Western Electric Co., succeeded in telephoning by wireless from Arlington, Va., to Hawaii, a distance of nearly 5,000 miles. On Oct. 26, 1915, the wireless telephone experiments were continued, communication being effected across the Atlantic from Arlington to the Eiffel Tower, Paris.

In 1919 the successful trans-Atlantic flights of the American "NC4" and of Alcock and Brown, and of the British dirigible "R34" focused attention upon the great value of radio for aviation purposes. On March 2, 1923, Louis Alton Hazeltine, of Stevens Institute of Technology, presented a paper before the Radio Club of America on tuned radio-frequency amplification with the neutralization of capacity coupling. Professor Hazeltine was granted a patent for the non-radiating neutrodyne receiver. In 1925 radio-compass (direction finder) came into greater use on board vessels. In 1926 directional or beam transmission developed to a point where it is considered practical for commercial usage. In 1927–28 Bell laboratories experiments effected successful transmission by wire and radio of television signals. In 1927–28 extension of radio-telegraphy to the principal countries of the world was accomplished.

RADIOACTIVITY. The subject of radioactivity deals with phenomena exhibited by a special class of bodies of high atomic weight of which uranium, thorium, radium and actinium are the best known examples. These substances possess the properties of spontaneously emitting radiations of a special character which are able to penetrate through matter opaque to ordinary light. The study of the radioactive bodies has proved of great importance in the development of modern Physics and has thrown a flood of light on the structure of the atom and the processes which may occur within it. It showed for the first time that the atoms of certain heavy elements are not permanently stable but break up with explosive violence and great emission of energy, leading to the production of a whole series of new elements which have a limited life. The disintegration of these atoms is accompanied by the expulsion of special types of radiation of great individual intensity which have been of great service in throwing light on the processes which take place in their absorption by matter. The alpha-particles have the greatest individual energy of any particle known to science and have proved invaluable in probing the inner structure of atoms and in effecting the artificial disintegration of certain light elements. A study of the scattering of alpha-particles by matter first disclosed the nuclear structure of atoms and provided us with methods of determining the charge carried by the nuclei of the elements. The examination of the chemical behaviour of the radioactive element first indicated the isotopic constitution of certain elements, *i.e.,* the existence of elements with almost identical physical and chemical properties but yet with different atomic weights and radioactive properties. This has led to the proof of the isotopic constitution of the ordinary elements. In many respects the wonderful series of transformations occurring in uranium and thorium provide data which cannot but prove of great value in attacking that most fundamental of problems—the constitution of atomic nuclei.

The beginning of Radioactivity dates from 1896, and was an indirect consequence of the discovery of the X-rays made a few months before by Rontgen. It was known that the production of X-rays in a vacuum tube was accompanied by a strong phosphorescence of the glass, and it occurred to several investigators that ordinary substances made phosphorescent by visible light might emit a penetrating radiation similar to X-rays. Following out this idea, H. Becquerel, a distinguished French physicist, exposed amongst other substances a phosphorescent compound of uranium, uranium-potassium sulphate, enveloped in paper beneath a photographic plate. A weak photographic effect was obtained. This was shown to be due to a penetrating radiation capable of passing through sheets of matter opaque to ordinary light. Further investigation showed that this photographic action was exhibited by all compounds of uranium and by the metal itself, and had nothing to do with phosphorescence. It was shown if the uranium were kept in darkness it did not vary appreciably with time. Becquerel showed that the rays from uranium like X-rays were capable of discharging a body whether positively or negatively electrified. A uranium compound brought close to the charged plate of a gold leaf electroscope causes a rapid collapse of the gold leaves. This property of uranium, and also of the radioactive bodies in general, has supplied a delicate and quantitative method of accurate comparison of the intensity of the radiations from substances under varying conditions. A modified form of gold leaf electroscope (see INSTRUMENTS, ELECTRICAL) has come into general use for comparison of the radioactivity of substances. Rutherford made a systematic examination of the discharging effect produced by the rays from uranium and showed that it was due to the production of charged carriers or ions in the volume of the gas through which the radiations pass. In an electric field, the positive ions travel to the negative electrode and vice versa, thus causing a discharge of the electrified body. If a sufficiently strong field is used, the ions are all swept to the electrodes before appreciable loss of their number can occur by recombination. The rate of discharge then reaches a steady maximum value which is not altered by a large increase in voltage. This maximum current through the gas is called the saturation current. The ions produced in gases by the rays from uranium and other radioactive substances are in general identical with those produced by X-rays, and the mechanism of conductivity of the gas is very similar in both cases (see ELECTRICITY CONDUCTION, *Through* Gases).

Some time after Becquerel's discovery, Mme. Curie made a systematic examination by the electric method of a large number of chemical elements and their compounds to test whether they possessed the "radioactive" property of uranium. Only one other element, thorium, was found to show this effect to a degree comparable with that of uranium—a result independently observed by Schmidt. Mme. Curie examined the activity of the various compounds of uranium and found that their radioactivity was an atomic property, *i.e.,* the activity was proportional to the amount of the element uranium present, and was independent of its combination with other substances. In testing the activity of the minerals containing uranium, Mme. Curie found that the activity was always four to five times as great as that to be expected from their content of uranium. If the radioactivity were an atomic phenomenon, this could only be explained by the presence in these minerals of another substance more active than uranium itself. Relying on this hypothesis, Mme. Curie made a chemical examination of uranium minerals in order to try to separate this new radioactive substance. In these experiments, the Austrian Government generously provided Mme. Curie with a ton of the residues from the State manufactory of uranium at Joachimstahl, Bohemia. At that place there are extensive deposits of pitchblende or uraninite which are mined for the uranium. After separation of the latter, the residues are three to five times as radioactive weight for weight as the uranium. From this residue Mme. Curie separated a substance far more radioactive than uranium, which she called polonium in honour of the country of her birth. This substance is usually removed with bismuth in the mineral, but by special methods can be partly separated from it. A further examination revealed the presence of a second radioactive substance which is normally separated with the barium, to which the name "radium" was given. This name was happily chosen, for in the pure state radium bromide has a very great activity—about two million times as great as an equal weight of uranium. By means of successive fractionations of the chloride, the radium was gradually concentrated, until finally the radium was obtained so that the barium lines showed very faintly. The atomic weight was found by Mme. Curie to be 226. Radium was found to give a characteristic spark spectrum of bright lines analogous in many respects to the spectra of the alkaline earths. Giesel in the early days took an active part in the preparation of pure radium compounds, and was the first to place preparations of pure radium bromide on the market. He found that the separation of radium from the barium mixed with it proceeded much more rapidly if the crystallizations were carried out using the bromide instead of the chloride. He states that six to eight crystallizations are sufficient for an almost complete separation. From the chemical point of view radium possesses all the characteristic properties of a new element. It has a definite atomic weight, a well-marked and characteristic spectrum, and distinct chemical properties. Its comparative ease of separation and great activity has attracted much attention to this substance, although we shall see that very similar radioactive properties are possessed by a large number of distinct substances.

In addition to polonium and radium, a number of other radioactive substances have been separated from uranium and thorium minerals which have an activity comparable with that of radium, although they have not been isolated in a pure state. Amongst these may be mentioned actinium, discovered by Debierne and Giesel, ionium, discovered by Boltwood and radiothorium and mesothorium discovered by Hahn.

Besides these substances in which the duration of the activity is measured by years a large number of radioactive bodies have been found which have a transient activity lasting for only a few minutes or hours. It will be seen that from the scientific point of view these short lived radioactive substances are just as important as those which have a much longer life.

Emanations or Radioactive Gases.—In addition to their power of emitting penetrating radiations, the substances thorium, actinium and radium possess another very striking and important property. Rutherford in 1900 showed that thorium compounds (especially the oxide) continuously emitted a radioactive emanation or gas. This emanation can be carried away by a current of air and its properties tested apart from the substance which produces it. These emanations all possess the property of ionizing a gas and, if sufficiently intense, of producing marked photographic and phosphorescent action. The activity of the radioactive gases is not permanent but disappears according to a definite law with the time, viz., the activity falls off in a geometric progression with the time. The emanations are distinguished by the different rates at which they lose their activity. The emanation of actinium is very short lived, the time for the activity to fall to half value, *i.e.,* the period of the emanation, being 3.7 seconds. The period of the thorium emanation is 54 seconds and of the radium emanation 3.8 days. This property of emitting an emanation is shown in a very striking manner by actinium. A compound of actinium is wrapped in a sheet of thin paper and laid on a screen of phosphorescent zinc sulphide. In a dark room the phosphorescence, marked by the characteristic scintillations, is seen to extend on all sides from the active body. A puff of air is seen to remove the emanation and with it the greater part of the phosphorescence. Fresh emanation immediately diffuses out and the experiment may be repeated indefinitely. The emanations have all the properties of radioactive gases. They can be transferred from point to point by currents of air. The emanations can be separated from the air or other gas with which they are mixed by the action of extreme cold. Rutherford and Soddy showed that under ordinary conditions the temperature of condensation of the radium emanation mixed with air was $-150°$ C.

The emanations are produced from the parent matter and escape into the air under some conditions. Rutherford and Soddy made a systematic examination of the emanating power of thorium compounds under different conditions. The hydroxide emanates most freely, while in thorium nitrate, practically none of the emanation escapes into the air. Most of the compounds of actinium emanate very freely. Radium compounds, except in very thin films, retain most of the emanation in the compound. The occluded emanation can in all cases be released by solution or by heating. On account of its very slow period of decay, the emanation of radium can be collected like a gas and stored, when it retains its characteristic properties for a month or more. A more detailed account of the properties of the radium emanation, which has proved of great practical importance, will be given later.

Active Deposits.—The radioactive emanations possess another very interesting and important property. The surface of any body exposed in the presence of an emanation acquires a temporary activity. Like the emanations this induced activity, as it was first termed, decays with the time though at quite a different rate from the emanation which causes it. The bodies made active behave as if they were covered by a very thin film of intensely active matter. The active substance can be removed partly by rubbing on the surface and can be dissolved by strong acids. On evaporating the acid, the active matter remains behind unchanged in amount. The active deposit obtained on a platinum wire or plate can be volatilized at a white heat and is again deposited on the cooler bodies in its neighbourhood. The activity can be concentrated to some extent on the negative electrode in a strong electric field, indicating that the radioactive matter carries a positive charge. We shall see later that this activity produced on bodies is due to a deposit of non-gaseous matter derived from the transformation of the emanations. Each emanation gives a distinctive active deposit which decays at different rates. The active deposits of radium, thorium and actinium are very complex, and consist of several types of matter. Several hours after removal from the emanation the active deposit from radium decays to half-value in 26 minutes, from actinium half-value in 34 minutes, from thorium half-value in 10·6 hours.

Radiations from Radioactive Substances.—All the radioactive substances possess in common the property of emitting radiations which darken a photographic plate and cause a discharge of electrified bodies. Very active preparations also possess the property of causing marked phosphorescence in some substances. Bodies which phosphoresce under X-rays usually do so under the rays from radioactive matter. Barium platinocyanide, the mineral willemite (zinc silicate) and zinc sulphide are the best known examples.

There are in general three types of radiation emitted by the radioactive bodies, called the α-, β- and γ-rays. Rutherford in 1899 showed that the radiation from uranium was complex and consisted of (a) an easily absorbed radiation stopped by a sheet of paper or a few centimetres of air which he called the α-rays and (*b*) a far more penetrating radiation capable of passing through several millimetres of aluminium, called the β-rays. Later Villard found that radium emitted a very penetrating kind of radiation, called the γ-rays, capable of passing before absorption through twenty centimetres of iron and several centimetres of lead. A large amount of work, of which a more detailed account will be given later, has been carried out to determine the nature of these radiations.

The Alpha-rays.—The α-rays consist of a stream of material particles which are projected at high speed from the radioactive matter. The α-particles from all types of radioactive matter are identical in mass and consist of charged atoms of helium projected with velocities of about 10,000 miles a second. The α-particles are expelled with a characteristic speed from each radioactive substance and have a definite distance of travel or "range" in matter before they are stopped. The range of the α-particles for different radioactive substances varies between about 3 cm. and 11 cm. in air at atmospheric pressure and temperature. Most of the energy emitted from radioactive bodies is in the form of α-rays.

The Beta-rays consist of a stream of electrons which are projected with high velocities, approaching in some cases that of light. Unlike the emission of α-particles, a radioactive body emits β-particles over a considerable range of velocity.

The Gamma-rays, which are of a very penetrating character, have been shown to be a type of X-rays of very high frequency. Usually the γ-rays accompany the emission of β-rays. Unlike the α- and β-particles, the γ-rays are undeflected by a magnetic or electric field. It will be shown that in general the γ-rays from a radioactive body consist of groups of electromagnetic radiations of widely different frequencies. The three types of radiation from active bodies are thus analogous in many respects to the radiations produced by the passing of an electric discharge through a vacuum tube at low pressure, but the individual intensity is on a much higher scale. In order to produce electrons of speed corresponding to those emitted by radium C, a voltage of three million would have to be applied to the tube, and to excite X-rays of the frequency of the y-rays at least two million volts would be necessary. Similarly the energy of the a-particle from radium C corresponds to nearly eight million electron volts. The a-rays from a deposit of radium C equivalent in activity to ten milligrams of radium, are of very great intensity; they blacken a photographic plate in a fraction of a second and produce intense luminosity in phosphorescent substances like zinc sulphide and willemite. Similarly the β and y-rays from such a source cause an evident luminosity in willemite and barium platinocyanide.

Theory of Radioactive Transformations.— We have seen that the radioactive bodies spontaneously and continuously emit a great number of α- and @-particles. In addition, new types of radioactive matter like the emanations and active deposits appear, and these are quite distinct in chemical and physical properties from the parent matter. The radiating power is an atomic property, for it is unaffected by combination of the active element with inactive bodies, and is uninfluenced by the most powerful chemical and physical agencies at our command. In order to explain these results, Rutherford and Soddy in 1903 put forward a simple but comprehensive theory. Unlike the atoms of the ordinary elements the atoms of radioactive matter are unstable, and each second a definite fraction of the number of atoms present breaks up with explosive violence, in most cases expelling an α- or @-particle with great velocity. Taking as a simple illustration that an α-particle is expelled during the explosion, the resulting atom has decreased in mass and possesses chemical and physical properties entirely distinct from the parent atom. A new type of matter has thus appeared as a result of the transformation. The atoms of this new matter are again unstable and break up in turn, the process of successive disintegration of the atom continuing through a number of distinct stages. On this view, a substance like the radium emanation is derived from the transformation of radium. The atoms of the emanation are far more unstable than the atoms of radium, and break up at a much quicker rate. We shall now consider the law of radioactive transformation according to this theory. It is experimentally observed that in all simple radioactive substances, the intensity of the radiation decreases in a geometrical progression with the time, *i.e.,* $I/I_0=e^{-\lambda t}$ where I is the intensity of the radiation at any time, t, I_0 the initial intensity, and λ a constant. Now according to this theory, the intensity of the radiation is proportional to the number of atoms breaking up per second. From this it follows that the atoms of active matter present decrease in a geometrical progression with the time, *i.e.,* $N/N_0=e^{-\lambda t}$ where N is the number of atoms present at a time t, N_0 the initial number, and λ the same constant as before. Differentiating, we have $dN/dt=-\lambda N$, *i.e.,* λ represents the fraction of the total number of atoms present which break up per second. The radioactive constant λ has a definite and characteristic value for each type of matter. Since λ is usually a very small fraction, it is convenient to distinguish the products by stating the time required for half the matter to be transformed. This will be called the period of the product, and is numerically equal to $\log_e 2/\lambda$. The average life of the atoms of a product before transformation is given by $1/\lambda$. As far as our observation has gone, the law of radioactive change is applicable to all radioactive matter without exception. It appears to be an expression of the law of probability, for the average number breaking up per second is proportional to the number present. Viewed from this point of view, the number of atoms hreaking up per second should have a certain average value, but the number from second to second should vary within certain limits according to the theory of probability. The theory of this effect was first put forward by Schweidler, and has since been verified by a number of experimenters, including Kohlrausch, Meyer, and Regener and H. Geiger. This variation in the number of atoms breaking up from moment to moment becomes marked with weak radioactive matter, where only a few atoms break up per second. The variations observed are in good agreement with those to be expected from the theory of probability. This effect does not in any way invalidate the law of radioactive change. On an average the number of atoms of any simple kind of matter breaking up per second is proportional to the number present. We shall now consider how the amount of radioactive matter which is supplied at a constant rate from a source varies with the time. For clearness, we shall take the case of the production of emanation by radium. The rate of transformation of radium is so slow compared with that of the emanation that we may assume without sensible error that the number of atoms of radium breaking up per second, *i.e.,* the supply of fresh emanation, is on the average constant over the interval required. Suppose that initially radium is completely freed from emanation. In consequence of the steady supply, the amount of emanation present increases, but not at a constant rate, for the emanation is in turn breaking up. Let q be the number of atoms of emanation produced by the radium per second and N the number present after an interval t, then $dN/dt=q-\lambda N$ where λ is the radioactive constant of the emanation. It is obvious that a steady state will ultimately be reached when the number of atoms of emanation supplied per second are on the average equal to the atoms which break up per second. If N_0 be the maximum number, $q=\lambda N_0$. Integrating the above equation, it follows that $N/N_0=1-e^{-\lambda t}$. If a curve be plotted (fig. 1) with N as ordinates and time as abscissae, it is seen that the recovery curve is complementary to the decay curve. The abscissae represent multiples of the time T for half the product to be transformed. The activity, which is proportional to the number of atoms present, falls to $\frac{1}{2}$ in the time T, $\frac{1}{4}$ in time 2T, and so on.

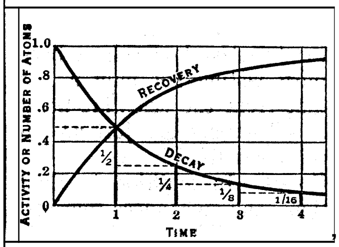


FIG. 1—CURVES ILLUSTRATING THE EXPONENTIAL LAW OF DECAY AND RECOVERY OF RADIOACTIVITY

This process of production and disappearance of active matter holds for all the radioactive bodies. We shall now consider some special cases of the variation of the amount of active matter with time which have proved of great importance in the analysis of radioactive changes.

(a) Suppose that initially the matter A is present, and this changes into B and B into C, it is required to find the number of atoms P, Q and R of A, B and C present at any subsequent time t.

Let λ_1, λ_2, λ_3 be the constants of transformation of A, B and C respectively. Suppose n be the number of atoms of A initially present. From the law of radioactive change it follows:

$$P=ne^{-\lambda_1 t}$$

$$dQ/dt=\lambda_1 P-\lambda_2 Q \qquad (1)$$

$$dR/dt=\lambda_2 Q-\lambda_3 R \qquad (2)$$

Substituting the value of P in terms of n in (1),

$$dQ/dt=\lambda_1 ne^{-\lambda_1 t}-\lambda_2 Q;$$

the solution of which is of the form

$$Q=n(ae^{-\lambda_1 t}+be^{-\lambda_2 t}),$$

where a and b are constants. By substitution it is seen that $a=\lambda_1/(\lambda_2-\lambda_1)$. Since $Q=0$ when $t=0$, $b=-\lambda_1/(\lambda_2-\lambda_1)$

Thus $$Q=\frac{n\lambda_1}{\lambda_1-\lambda_2}(e^{-\lambda_2 t}-e^{-\lambda_1 t}) \qquad (3)$$

Similarly It can be shown that

$$R=n(ae^{-\lambda_1 t}+be^{-\lambda_2 t}+ce^{-\lambda_3 t}) \qquad (4)$$

where

$$a=\frac{\lambda_1\lambda_2}{(\lambda_1-\lambda_2)(\lambda_1-\lambda_3)},\quad b=\frac{\lambda_1\lambda_2}{(\lambda_2-\lambda_1)(\lambda_2-\lambda_3)},\quad c=\frac{\lambda_1\lambda_2}{(\lambda_3-\lambda_1)(\lambda_3-\lambda_2)}.$$

It will be seen from (3) that the value of Q, initially zero, increases to a maximum and then decays; finally, according to an exponential law, with the period of the more slowly transformed product, whether A or B.

(*b*) A primary source supplies the matter A at a constant rate, and the process has continued so long that the amounts of the products A, B, C have reached a steady limiting value. The primary source is then suddenly removed. It is required to find the amounts of A, B and C remaining at any subsequent time t.

In this case of equilibrium, the number n_0 of particles of A supplied per second from the source is equal to the number of particles which change into B per second, and also of B into C. This requires the relation

$$n_0=\lambda_1 P_0=\lambda_2 Q_0=\lambda_3 R_0$$

where P_0, Q_0, R_0 are the initial number of particles of *A*, *B*, *C* present, and λ_1, λ_2, λ_3 are their constants of transformation.

Using the same notation as in case (1), but remembering the new initial conditions, it can easily be shown that the number of particles *P*, *Q* and *R* of the matter *A*, *B* and *C* existing at the time *t* after removal are given by

$$P=\frac{n_0}{\lambda_1}e^{-\lambda_1 t}$$

$$Q=\frac{n_0}{\lambda_1-\lambda_2}\left(\frac{\lambda_1}{\lambda_2}e^{-\lambda_2 t}-e^{-\lambda_1 t}\right),$$

$$R=n_0(ae^{-\lambda_1 t}+be^{-\lambda_2 t}+ce^{-\lambda_3 t}),$$

where

$$a=\frac{\lambda_2}{(\lambda_1-\lambda_2)(\lambda_1-\lambda_3)},\quad b=\frac{-\lambda_1}{(\lambda_1-\lambda_2)(\lambda_2-\lambda_3)},\quad c=\frac{\lambda_1\lambda_2}{\lambda_3(\lambda_1-\lambda_3)(\lambda_2-\lambda_3)}.$$

The curves expressing the rate of variation of P, Q, R with time are in these cases very different from case (1).

(c) The matter A is supplied at a constant rate from a primary source. Required to find the number of particles of A, B and *C* present at any time *t* later, when initially A, B, and *C* were absent.

This is a converse case from case (2) and the solutions can be obtained from general considerations. Initially suppose A, B and *C* are in equilibrium with the primary source which supplied *A* at a constant rate. The source is then removed and the amounts of A, B and *C* vary according to the equation given in case (2). The source after removal continues to supply *A* at the same rate as before. Since initially the product A was in equilibrium with the source, and the radioactive processes are in no way changed by the removal of the source, it is clear that the amount of A present in the two parts in which the matter is distributed is unchanged. If P_1 be the amount of A produced by the source in the time *t*, and P the amount remaining in the part removed, then $P_1+P=P_0$ where P_0 is the equilibrium value. Thus

$$P_1/P_0=1-P/P_0.$$

The ratio P/P_0 can be written down from the solution given in case (2). Similarly the corresponding values of Q_1/Q_0, R_1/R_0 may be at once derived. It is obvious in these cases that the curve plotted with P/P_0 as ordinates and time as abscissae is complementary to the corresponding curve with P_1/P_0 as ordinates. This simple relation holds for all recovery and decay curves of radioactive products in general.

We have so far considered the variation in the number of atoms of successive products with time when the periods of the products are known. In practice, the variation of the number of atoms is deduced from measurements of activity, usually made by the electric method. Using the same notation as before, the activity of any product is proportional to its rate of breaking up, *i.e.*, to $\lambda_1 P$ where P is the number of atoms present. If two products are present, the activity is the sum of two corresponding terms $\lambda_1 P$ and $\lambda_2 Q$. In practice, however, no two products emit a- or β-particles with the same velocity. The difference in ionizing power of a single a-particle from the two products has thus to be taken into account. If, under the experimental conditions, the ionization produced by an a-particle from the second product is *K* times that from the first product, the activity observed is proportional to $\lambda_1 P+K\lambda_2 Q$. In this way, it is possible to compare the theoretical activity curves of a mixture of products with those deduced experimentally.

Analysis of Radioactive Changes.—The analysis of the successive changes occurring in uranium, thorium, radium and actinium has proved a very difficult matter. In order to establish the existence of a new product and to fix its position in the scheme of changes, it is necessary to show (a) that the new product has a distinctive period of decay and shows some distinctive physical or chemical properties; (*b*) that the product under consideration arises directly from the product preceding it in the scheme of changes, and is transformed into the product succeeding it.

In general, it has been found that each product shows some distinctive chemical or physical behaviour which allows of its partial or complete separation from a mixture of other products It must be remembered that in most cases the amount of radioactive matter under examination is too small to detect by weight, but its presence is inferred from its characteristic radiations and rate of change. In some cases, a separation may be effected by ordinary chemical methods; for example thorium X is separated from thorium by precipitation of thorium with ammonia. The Th X remains in the filtrate and is practically free from thorium. In other cases, a separation is effected by a separation of a metal in the solution of active matter. For example, polonium (radium F) always comes down with bismuth and may be separated by placing a bismuth plate in a solution. Radium C is separated from radium B by adding nickel filings to a solution of the two. Radium C is deposited on the nickel. In other cases, a partial separation may be effected by electrolysis or by differences in volatility when heated. For example, when radium A, B and C are deposited on a platinum plate, on heating the plate, radium B is volatilized and is deposited on any cold surface in the neighbourhood. A very striking method of separating certain products has been observed depending upon the recoil of an atom which breaks up with the expulsion of an a-particle. Some of the residual atoms acquire sufficient velocity in consequence of the ejection of an a-particle to escape and be deposited on bodies in the neighbourhood. This is especially marked in a low vacuum. This property was independently investigated by Russ and Makower and by Hahn. The latter has shown that by means of the recoil, actinium C″ may be obtained pure from the active deposit containing actinium A, B and C, for C emits a-rays, and actinium C'' is driven from the plate by the recoil. In a similar way a new product, thorium C'', has been isolated and radium B may be separated from radium A and C. The recoil method has proved of great value in settling whether an a-ray product is simple or complex.

While in the majority of cases the products break up either with the emission of a- or β-particles, some products were at first thought not to emit any characteristic radiation and were called "rayless products." A closer investigation has shown that in most cases a 6-radiation of an easily absorbed type is emitted. Actinium is the only product in which no certain radiation has been detected but from other evidence there can be no doubt that β-rays of slow speed are emitted. The presence and properties of a product emitting a very feeble radiation can be easily inferred if it is transformed into a product emitting a marked radiation, for the variation of activity of the latter affords a method of determining the amount of the parent product. In the table below a list is given of the remarkable series of transformations occurring in uranium, thorium and actinium. The system of nomenclature is not ideal. In general, products of average life greater than one year have been given a distinctive name and are printed in italics. The successive products following the emanations are in all cases denoted by the letters A, B, C, etc. In some cases intermediate products have been discovered after a system of nomenclature has been accepted and have had to be named to indicate as far as possible their positions in the series. As the radioactive emanations are now known to be isotopic elements, the names radon, thoron and actinon have been suggested as distinctive and indicative of the similarity of these products.

Table of Radioactive Elements

Element	Atomic Wt.	Atomic No.	T	Rays	Range cm. α-Rays in air (15° and 760 mm.)
Uranium-Radium series.					
Uranium I . .	238·18	92	$4{\cdot}5\times10^9$ yr.	α	2·70
Uranium X_1 . .	234	90	23.8 days	β, γ	..
Uranium X_2 . .	234	91	1·15 min.	β, γ	..
Uranium *Z* . .	234	91	6·7 hr.	β	..
Uranium II . .	234	92	about 2×10^6 yr.	α	3·28
Uranium Y . . (3%)	230	90	24.6 hr.	β	..
Ionium . . .	230	90	about 9×10^4 yr.	α	3·19
Radium . . .	226	88	1580 yr.	α	3·39
Radon (Ra Emanation)	222	86	3.82 days	α	4·12
Radium A . .	218	84	3·05 min.	α	4·72
Radium B . .	214	82	26.8 min.	β, γ	..
Radium C . .	214	83	19·7 min.	α, β, γ	6·97
Radium D . .	210	82	16 yr.	β, γ	..
Radium E . .	210	83	5·0 days	β, γ	..
Radium F . . (Polonium)	210	84	136·5 days	α	3·92
Radium G· (end-product uranium-lead) . . .	206	82	..	..	..
Thorium series.					
Thorium . . .	232·1	90	$2{\cdot}2\times10^{10}$ yr.	α	2·90
Mesothorium I. .	228	88	6.7 yr.	β, γ	..
Mesothorium 2 .	228	89	6.2 hr.	β, γ	..

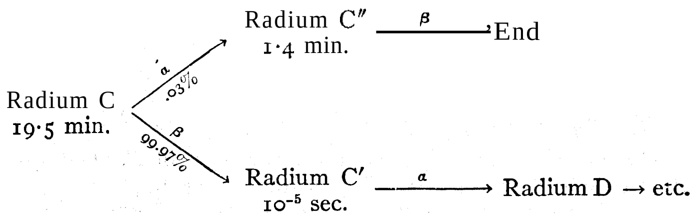
In the table T is the time-period of a product or the time required for the product to be half-transformed. It will be seen that the value of T, which is a measure of the relative stability of atoms, varies between $2{\cdot}2\times10^{10}$ years (Thorium) and ·002 second (Actinium **A**). The atomic weights and atomic numbers of uranium, radium, uranium-lead, thorium, thorium-lead have been directly determined by X-ray methods. The atomic weights and atomic numbers of the others are deduced on the assumption that the expulsion of an a-particle (helium atom) of charge 2 and mass 4 lowers the atomic number of the succeeding element by two units and the atomic weight by four. The expulsion of a β-particle raises the atomic number by one unit, but it is not supposed to influence the atomic weight to a detectable degree.

Branch **Products.**—In the great majority of cases each of the radioactive elements breaks up in a definite way, giving rise to one a- or @-particleand to one atom of the new product. Undoubted evidence, however, has been obtained that in a few cases the atoms break up in two or more distinct ways, giving rise to two or more products characterised by different radioactive properties. **A** branching of the uranium series was early demanded in order to account for the origin of actinium. While the latter is always found in uranium minerals in constant proportion with the uranium, Boltwood showed that the activity of the actinium with its whole series of a-ray products in a uranium mineral was much less than that given by a single a-ray product of the main radium series. The head of the actinium series is generally believed to be uranium Y, the branch product of the uranium series first observed by Antonoff. The branching is supposed to occur in the product uranium II, 3% going into the actinium branch and the other 97% into the main uranium series. The atomic weights of actinium given in the table are calculated on this basis. The more recently discovered product *protoactinium* is on this view the missing link between uranium Y and actinium.

The most striking cases of branching occur in the "C" products of radium, thorium and actinium, each of which breaks up in two or more distinct ways. In the case of radium C, a new substance called radium C" was obtained by recoil from a nickel plate coated with radium C. This product emitted only β-rays and had a period of 1·4 minutes. Fajans estimated that the amount of the product was only $\frac{1}{3{,}000}$ of that of radium C. To account for these results the following scheme of transformation has been proposed:—



where in the main branch a β-particle is first expelled, giving rise to radium C, which emits an a-particle. The reverse process is assumed to take place in the other branch. Radium C, which emits a swift a-particle, has an exceedingly short period of transformation, which has been measured approximately by Jacobsen, and found to be about 10^{-5} seconds. It is uncertain whether the radium C″ branch ends after the expulsion of a @-particle. The resulting product is an isotope of lead like radium D in the main branch.

In the case of thorium C, two sets of a-particles are observed, one-third of the total number having a range of 4.8 cm. and the remainder 8·6 cm. Here, as in radium C, Marsden supposed that the main series goes by a β-ray change to the C′ product. In actinium C, which also shows a dual transformation, Marsden found that 99·84% of the C atoms change with the emission of an a-particle of 5·15 cm. range to the C" product, the remaining 0·16% going to C, which gives a-particles of 6.4 cm. range. Subsequent research has shown that the modes of transformation of the C′ bodies are even more complicated than was at first supposed. Rutherford and Chadwick found two additional sets of a-particles which are emitted in very small numbers compared with the main group of particles. One group has a range in air of 9.3 cm. and the other 11·3 cm. Rutherford and Wood found in the thorium **C** a group of particles of a range 11·3 cm. while Meitner and Freitag found a small number of range 9.5 cm. No evidence has been obtained of the exact origin of these swift a-particles but they are probably due to different modes of disintegration of the C′ bodies. It is quite possible that a close examination of radioactive substances may reveal other examples of such complex methods of transformation, for, after the violent explosion that occurs during the breaking-up of an atom, more than one state of temporary equilibrium may be possible for the residual atom.

Relation Between Range of a-Rays and Period of Transformation.—We have seen that each α-ray product emits α-particles of characteristic velocity which have a definite range in air. It was early observed that there appeared to be a connection between the period of transformation of a product and the velocity of the a-particles emitted. The shorter the period of transformation, the swifter is the velocity of expulsion of the ff-particle. This relation was brought out clearly by the measurements of Geiger and Nuttall, where it was shown that if the logarithm of the range was plotted against the logarithm of λ, the constant of transformation, all the points lay nearly on a straight line.

A similar result has been observed for the thorium and actinium products. This relation, when carefully tested by Geiger, appears to be only a rough approximation. It is still of great interest as indicating a possible relation between the stability of the radioactive nucleus and the velocity of the expelled helium atom. This relation has proved very useful in forming estimates of the period of transformation of ionium and other substances before the results of more direct determinations were available. From this relation also the change which gives rise to the swift α-particle of radium C was believed to be exceedingly rapid. This has been confirmed by the detection of radium C' and measurement of its period. A similar conclusion is drawn for the product emitting the very swift a-particles from thorium C.

Chemistry of the Radio-elements (*see* RADIUM, URANIUM, etc.).—Apart from uranium and thorium, and a few special cases like radium and polonium, the radioactive products of short life exist in too small quantity to examine by the ordinary chemical methods; but by the use of the radioactive method of analysis, it was possible to form some idea of their chemical behaviour. Certain very interesting points soon came to light. Soddy found that the two elements, radium and mesothorium, although quite dissimilar in radioactive properties, were chemically so identical that it was impossible by chemical methods to separate one from the other. Other cases of this kind had long been suspected, viz., thorium and radiothorium, thorium and ionium and radium D and lead. He named such inseparable elements isotopes, since they appeared to occupy the same place in the periodic classification of the elements. (See ISOTOPES.)

Following the chemical study of the radio-elements by Soddy, Fleck and von Hevesy, an important generalisation connecting the chemical properties of the radio-elements was announced independently in 1913 by Russell, Fajans and Soddy. After the expulsion of an a-particle from a radioactive substance, the resulting product shifts two places in the direction of diminishing mass when the elements are arranged in families according to the Mendeleeff classification.

The expulsion of a p-particle causes a shift of one place in the opposite direction. For example, by the loss of an a-particle from ionium of group IV., the resulting product, radium, belongs to group II., while the loss of another particle gives rise to the emanation which occupies the group O, and so on. By this method the chemical properties of all the known radio-elements can be predicted from a knowledge of the radiations emitted from the products. This generalisation can be viewed from another important standpoint. From the work of Moseley, the properties of an element are defined by the atomic number which is believed to represent the resultant positive charge on the nucleus. The loss of an a-particle of mass 4, carrying two positive charges, lowers the atomic number by two units, while the emission of a β-particle raises it by one unit. On looking through the table of the radio elements on preceding page it will be seen that many of them can be grouped under the same atomic number. These represent the radioactive isotopes of which some of the more important are given below, preceded by the atomic numbers:—

81. Thallium (204), thorium C″ (208), actinium C″ (206).
82. Lead (207), uranium-lead (206), thorium-lead (208), radium D (210), thorium B (212), radium B (214), actinium B (210).
83. Bismuth (208), radium E (210), radium C (214), thorium C (212), actinium C (210).
84. Polonium (210), thorium A (216), radium A (218), actinium A (214).
86. Radon (222), thoron (220), actinon (218).
88. Radium (226), thorium X (224), mesothorium I (228), actinium X (222).
90. Thorium (232), radiothorium (228), ionium (230), uranium X_1 (234), uranium Y (230), radioactinium (226).

It will be seen that many of the radioactive elements are isotopic with known chemical elements. These radioactive isotopes differ not only in atomic weight but also in radioactive properties. The isotopes of lead are of special interest as they include the end-products of the uranium, thorium and actinium series—a question that will be discussed more fully later. It is of interest to note that polonium, actinium and protoactinium are new types of chemical elements which have no counterpart among the ordinary inactive elements.

Transformation of Uranium.—In 1900 the late Sir W. Crookes found that the β-ray activity of ordinary uranium could be removed by a single chemical operation and concentrated in an active residue. This is due to the separation of the product uranium X_1, of period 24 days, which emits β-rays and γ-rays. A complete analysis of the transformations of uranium has been a matter of much difficulty. Boltwood showed that the α-ray activity of uranium was about twice as great as that of a corresponding α-ray product in the uranium-radium series, indicating that uranium contained two successive α-ray products. This was confirmed by Geiger, who showed that the α-rays from uranium consisted of two groups with ranges 2·5 and 2.9 cm. respectively. These two α-ray substances, called uranium I. and uranium II. are isotopic, atomic weights 238 and 234 respectively. The latter, whose period is estimated at about 2,000,000 years, exists in relatively very small quantity compared with uranium I. Following the generalisation connecting the radiations and chemical properties of the series of radio-elements. Fajans predicted the presence of a new product with properties analogous to tantalum, and promptly succeeded in isolating it experimentally. The new product uranium X_2, sometimes called brevium, has a period of 1·15 minutes and emits swift β-rays. The series of changes is thus:—

$$\text{Ur I.}\rightarrow\text{Ur } X_1\rightarrow\text{Ur } X_2\rightarrow\text{Ur II}\rightarrow\text{Ionium.}$$

Antonoff discovered another β-ray substance called uranium Y, separated with uranium X_1, which has a period of 24.6 hours. This exists in too small quantity to be in the main line of succession, but is to be regarded as a branch product isotopic with uranium X_1, and is believed to be the first element of the subsidiary actinium series.

Rutherford and Geiger found the number of a-particles emitted per gram of uranium per second to be $2{\cdot}37\times10^4$. From this the period of uranium is calculated to be about 6,000,000,000 years.

Transformation of Radium— Radium is transformed directly into radon which in turn goes through a rapid series of transformations called radium A, B and C. The complete analysis of these changes has involved a large amount of work. Radon changes first into radium A, a substance of period 3 minutes emitting only a-rays. Radium A changes into radium B, a product of period 26 minutes emitting β-rays of penetrating power small compared with those emitted from the next product radium C. The products included under the title radium C have proved of considerable importance, for they not only emit very penetrating α-rays and β-rays, but are the origin of the y-rays arising from radium in equilibrium. We have already seen that radium C breaks up in a complex way. When a wire charged negatively has been exposed for some time in the presence of radon, it becomes coated with an invisible film of radium A, B and C. After removal from radon for 20 minutes, radium A has practically disappeared and the α-rays arise entirely from radium C. Radium C has proved very valuable in radioactive measurements as providing an intense source of homogeneous a-rays. Twenty-four hours after removal, the activity due to radium B and C has become exceedingly small. There still remains, however, a very small residual activity, first noted by Mme. Curie. This residual activity measured by the α-rays rapidly increases with the time and reaches a maximum in about three years. The active deposit of slow change was examined in detail by Rutherford and by Meyer and

Schweidler. It was shown to consist of three successive products called radium D, E and F. Radium D emits slow β-rays and is half transformed in about 16 years. Radium D changes into E, a β-ray product of period about 5 days, and E into F, an a-ray product of period 140 days. The product radium F is of special interest, for it is identical with polonium—the first active body separated by Mme. Curie. In a similar way it has been shown that radium D is the primary source of the activity observed in lead or "radiolead" separated by Hofmann. Radium D is a radioactive isotope of lead of atomic weight 210. It is always separated with the inactive lead present in a uranium mineral. It is interesting to note what valuable results have been obtained from an examination of the minute residual activity observed on bodies exposed in the presence of radon. On account of their special importance as sources of intense radiation a more detailed account will be given of radium and its origin, radon and polonium.

Radium.— The atomic weight of radium was found by Mme. Curie to be 226·45, using for the purpose about 0·4 gr. of pure radium chloride. A careful redetermination by Honigschmid with about one gram of radium gave a value 225.9, and is probably correct to 1 in 1,000. Mme. Curie and Debierne produced metallic radium by electrolysis of a radium salt with a mercury cathode. Radium resembles metallic barium, melts at about 700° C, and is rapidly attacked when exposed to the air.

The number of a-particles expelled per second from one gram of radium is an important constant which requires to be known with accuracy. At the present time, there is considerable difference of opinion as to its exact magnitude. Rutherford and Geiger (1908) found a number $3{\cdot}57\times10^{10}$, Hess and Lawson (1918) $3{\cdot}72\times10^{10}$, Geiger and Werner (1924) $3{\cdot}4\times10^{10}$, Jedrzejouski (1927) $3{\cdot}50\times10^{10}$. If the heating effect of radium and its products is entirely due to the kinetic energy of the expelled a-particles, the value should be about $3{\cdot}7\times10^{10}$. The rate of production of helium by radium leads to a value about $3{\cdot}6\times10^{10}$. The property of radium of producing an emanation has been utilized as a very delicate and certain method, not only of detection but of estimation of small quantities of radium. This "emanation method" depends upon the introduction of the emanation, liberated from a substance by boiling or heating, into a suitable electroscope. The rate of discharge of the electroscope due to the emanation affords a quantitative measure of the amount of radium present. In this way, it is not difficult to determine with certainty the presence of radium in a body which contains only 10^{-11} gram of radium. With care, 10^{-12} gram can just be detected, This emanation method has been employed with great success in measuring the quantity of radium in minerals and in rocks. A very simple method has been devised of determining the quantity of radium present when it is not less than $\frac{1}{100}$ milligram. The tube containing the radium is placed some distance from an electroscope which is surrounded by a lead screen about 3 mms. thick. This cuts off the α- and β-rays and the effect in the electroscope is then due to the penetrating y-rays. By comparison of the rate of discharge with that of a standard preparation of radium at the same distance, the quantity of radium can at once be deduced, provided the radium is in equilibrium. This is usually the case if the radium preparation is one month old. This method is simple and direct, and has the great advantage that the radium tube under test need not be opened, nor its contents weighed.

An international radium standard consisting of about 22 milligrammes of pure radium chloride has been prepared by Mme. Curie and is preserved in the Bureau International des Poids et Mesures at Skvres, near Paris. Secondary radium standards have been issued to all governments who wished to purchase them. These have been calibrated by y-ray methods both in Vienna and Paris, and are supposed to be correct within 1 in 200. The purchase and sale of radium have generally been conducted on certificates given in terms of this international standard.

The wide use of radium for therapeutic purposes, and its high cost—from £12 to £30 per milligram element—have led to close search for uranium deposits. The amount of radium in an old mineral is always proportional to its content of uranium in the ratio of 3.3 parts of radium by weight to 10,000 000 parts of uranium. Consequently, an old mineral containing 1,000 kgm. of uranium should contain 330 milligrams of pure radium. Initially several grams of radium were separated from the uraninite deposits in Joachimsthal, Bohemia, and some of the material, which was the property of the Austrian Government, was generously loaned to representative workers in radioactivity in England. A part of this radium is in the charge of the Radium Institute of Vienna, which is specially devoted to radioactive investigations.

The increasing demand for radium led to the working of low-grade ores, containing on an average only about 2% of uranium oxide, of which there are extensive deposits in Colorado and other parts of the United States. Until 1922 the greater part of the world supply of radium was produced in America, but in that year very rich deposits of uranium ore, containing about 20 times as much radium as the American ore, were found in the Belgian Congo, and the American production practically ceased. Large quantities of radium were employed by the Allies during the World War for night compasses, gun-sights, etc. The radium is mixed with phosphorescent zinc sulphide to form a paint which becomes continuously luminous but, owing to the destruction of the zinc sulphide by the rays, this luminosity gradually decays. Active preparations of mesothorium and radiothorium have also been used for a similar purpose.

Origin of Radium.— According to the transformation theory, radium, like all other radioactive products, must be regarded as a changing element. Preliminary calculations showed that radium must have a period of transformation of several thousand years. Consequently in order that any radium could exist in old minerals, the supply must be kept up by the transformation of some other substance. Since radium is always found associated with uranium minerals, it seemed probable from the beginning that uranium must be the primary element from which radium is derived. If this were the case, in old minerals which have not been altered by the action of percolating waters, the ratio of the amount of radium to uranium in a mineral must be a constant. This must evidently be the case, for in a state of equilibrium the rate of breaking up of radium must equal the rate of supply of radium from uranium. If P, Q be the number of atoms of uranium and radium respectively in equilibrium, and λ_1, λ_2 their constants of change, then

$$\lambda_2 Q=\lambda_1 P \quad \text{or} \quad Q/P=\lambda_1/\lambda_2=T_2/T_1.$$

where T_2 and T_1 are the half-periods of transformation of uranium and radium respectively. The work of Boltwood, Strutt and McCoy has conclusively shown that the ratio of radium to uranium in old minerals is a constant. Boltwood and Strutt determined the quantity of radium present in a mineral by the emanation method, and the amount of uranium by analysis. In order, however, to obtain a direct proof of the genetic relation between uranium and radium, it is necessary to show that radium appears after some time in a uranium compound from which all trace of radium has been initially removed. It can readily be calculated that the growth of radium should be easily observed by the emanation method in the course of one week, using a kilogram of uranium nitrate. Experiments of this kind were first made by Soddy, but initially no definite evidence was obtained that radium grew in the solution at all. The rate of production of radium, if it took place at all, was certainly less than $\frac{1}{10,000}$ part of the amount to be expected if uranium were transformed directly into radium. It thus appeared probable that another product of slow period of transformation existed between uranium and radium. Since uranium must be transformed through this intermediate stage before radium appears, it is evident that the initial rate of production of radium under these conditions might be extremely small. This conclusion has been confirmed by Soddy, who has shown that radium does ultimately appear in the solution which has been placed aside for several years and as theory predicts the amount increases as the square of the time.

Since the direct parent of radium must be present in radioactive minerals, one of the constituents separated from the mineral must grow radium. This was shown to be the case by Boltwood who found that actinium preparations produced radium at a fairly rapid rate. By the work of Rutherford and Boltwood, it was found that the growth of radium was not due to actinium itself, but to a new substance separated in some cases with the actinium. This new substance, which emits a-rays, was separated by Boltwood and called by him "Ionium." It has chemical properties very similar to thorium and as we now know is an isotope of thorium of atomic weight 230. Ionium is always separated mixed with the thorium which is present in the mineral. The period of ionium is probably about 76,000 years, indicating that the amount of ionium in uranium minerals is about fifty times the quantity of radium. It has not yet been directly shown that uranium produces ionium but there can be no doubt that it does do so. Since ionium produces radium, Boltwood and later Miss Gleditsch have determined by direct experiment the period of transformation of radium and have found a number in good agreement with other data on that subject. The constant relation between uranium and radium will only hold for old minerals where there has been no opportunity for chemical alteration or removal of its constituents by the action of percolating water or other agencies. It is quite possible that altered minerals of no great age will not show this constant relation. It secnis probable that this is the explanation of some results of Miss Gleditsch, where the relation between uranium and radium has been found not to be constant for some mineral specimens.

Polonium **and** Radium **D.**—Polonium (radium F) has proved of much importance in experimental work as a source of a-rays entirely free from β- and y-rays. The weight of polonium in equilibrium with one gram of radium is only about one-fifth of a milligram, so that it is difficult to obtain a sufficient quantity of this material for an atomic weight determination.

Mme. Curie separated the polonium from several tons of pitchblende and obtained an exceedingly active preparation of a few milligranirnes, but was unable to obtain it in a pure state, although several of its spectrum lines were detected. It was hoped by this experiment to decide whether polonium was transformed directly into lead, but this was found difficult to establish owing to the presence of impurities with the very small quantity of polonium. The most convenient source for obtaining strong sources of polonium is the radium D+E+F which accumulates in old radium preparations. These substances can be separated from the radium solution by chemical or electrolytic methods. A solution of the radium D thus obtained grows polonium and is thus a very convenient source for obtaining active plates coated with polonium. In this way, also, strong sources of radium D and radium E are obtainable.

Radon ***(Radium** Emanation).*—Radon is to be regarded as a typical radioactive product or transition element which exists in a gaseous form. It is produced from radium at a constant rate, and is transformed into radium A and helium. Its half-period of transformation is 3.83 days. Radon has been purified by condensing it in liquid air, and pumping out the residual gases. The volume of radon at normal pressure and temperature to be derived from one gram of radium in equilibrium is about 0·6 cubic millimetres. This small quantity of gas contains initially more than three-quarters of the total activity of the radium before its separation. In a pure state, radon is 100,000 times as active weight for weight as pure radium. Pure radon in a spectrum tube gives a characteristic spectrum of bright lines. The discharge in the gas is bluish in colour. Notwithstanding the minute volume of radon available, its boiling-point has been determined at various pressures. At atmospheric pressure Rutherford found the boiling-point to be $-67°$ C, and Gray and Ramsay $-71°$ C. Liquid radon appears colourless when first condensed; when the temperature is lowered, the liquid freezes, and at the temperature of liquid air glows with a bright rose colour. The density of liquid radon has been estimated at 5 or *6.*

Since the radium atom in breaking up gives rise to one atom of radon and one atom of helium, its atomic weight should be $226-4=222$. Radon appears to have no definite chemical properties, and in this respect belongs to the group of inert monatomic gases of which helium and argon are the best known examples. It is partially soluble in water, and readily absorbed by charcoal.

Radon has proved of great service not only in radioactive researches but also in therapeutic work, The radium salt is dissolved in an aeid solution and the emanation is pumped off with the large quantity of hydrogen and oxygen liberated by the action of the radiations on water. After sparking the mixture, the radon can be purified by condensation with liquid air. **A** very intense source of β- and y-radiation can be obtained by introducing the purified radon into fine capillary tubes. Such radon needles have been widely used for therapeutic purposes, while the use of very thin-walled tubes provides a powerful line source of α-rays. The β- and γ-activity of such tubes rises to a maximum about four hours after introduction of the radon, and then decays with the period of radon, viz., 3.83 days. The quantity of radon liberated from one gram of radium is called a ***curie*** and from one milligram a *millicurie.* The quantity of radon in a tube can be accurately determined by comparison of its y-ray activity with that of a radium standard, since the penetrating y-rays, both from the radium and the radon in equilibrium, arise mainly from the same product radium C.

Transformations of Thorium — The first product observed in thorium was the emanation of period 54 sec., and this gives rise to the active deposit, which has been shown to consist of at least four successive products called thorium **A,** B, C, C''. The emanation, after the emission of an a-particle, changes into a product of very short life emitting a-rays. Its period was found by Geiger and Moseley to be about $\frac{1}{10}$ second. The succeeding product, thorium B, emits only weak β- and y-rays with a period of 10·6 hours, changing into thorium C of period one hour. We have seen that thorium C breaks up in a complex way, emitting three distinct groups of particles. Thorium C'' is readily separated from C by the method of recoil. It emits penetrating β- and y-rays with a half period of three minutes. The active deposit as a whole decays ultimately with the period of thorium B, viz., 10·6 hours.

A special interest attaches to the product thorium X, first separated by Rutberford and Soddy, since experiments with it laid the foundation of the general theory of radioactive transformations.

A close analysis of thorium has led to the discovery by Hahn of a number of other important products. When the thorium X is separated from a thorium mineral or old thorium preparation, there appears with it another product called mesothorium I, of period 6.7 years, which is transformed with the emission of weak @-raysinto mesothorium 2, of period six hours, which emits swift β-particles and penetrating y-rays. This changes into an α-ray product, radiothorium, of period two years, which is transformed into thorium X.

Radiothorium is an isotope of thorium, while mesothorium I is an isotope of radium. The radiathorium can readily be separated from a solution of mesothorium and obtained in a concentrated form. Mesothorium when first separated would show a very weak activity, but in consequence of the growth of its subsequent product radiothorium, its activity would increase for several years. After reaching a maximum it would ultimately decay with the period of mesotborium, viz., 6.7 years.

Large quantities of mesothorium have been obtained as a by-product in the separation of thorium from monazite sands. This substance emits only β-rays but soon grows radiothorium and subsequent products which emit a-rays and penetrating β- and y-rays. As a source of powerful@-and y-radiation, this substance is very analogous to radium and can be obtained in about the same concentration. Since radium and mesothorium are isotopic elements, they are always separated together. Most commercial sources of thorium contain also uranium and radium, and consequently radium is always separated with the mesothorium and in relative amount depending upon the proportion of uranium to thorium in the mineral. Since mesothorium has a radioactive life short compared with radium, it commands a smaller price. The amount of mesothorium is standardised by comparison of its y-ray effect with a radium standard. Radiothorium, separated from preparations of mesothorium, is widely used instead of radium as sources of β- and y-rays for therapeutic purposes.

Transformations of Actinium. — Actinium of period about 20 years is believed to emit weak @-rays changing into radio-actinium, an a-ray product of period 19 days, first separated by Hahn. This changes into actinium X, an a-ray product of period 11 days, discovered by Godlewski. Then follows the actinium emanation of period 3.9 sec., which gives rise to four further products named actinium A, B, C, C″. Actinium A has the shortest life of any product whose rate of transformation has been directly determined. Its period, as determined by Geiger and Moseley and Fajans, is ·002 second. After emitting an a-particle, **A** changes into B, a product of period 36 minutes emitting weak β- and y-rays, analogous to thorium B. Actinium C of period 2·16 minutes undergoes a complex transformation, giving rise to two distinct groups of a-particles. The main branch gives rise to actinium C″ of period 4·8 minutes, which is readily isolated by the recoil method. Actinium C'', which emits β- and y-rays, is analogous in all respects to thorium C''.

In the above discussion on branch products it has been shown that the parent of actinium, called protoactinium, has been recently isolated by Hahn and Soddy. This substance emits a-rays and has an estimated period of 20,000 years. We have seen that the actinium series is believed to have its origin in a dual transformation of uranium X_1. The first branch product, representing about 3% of the total, is believed to be uranium Y, a /?-ray product of period one day. This is directly transformed into protoactinium.

Assuming a branching ratio of 3%, 1,000 kilograms of uranium contains 130 milligrams of protoactinium. Hahn and Walling have developed methods of purification with a view of determining its atomic weight. This constant should prove of great importance in fixing the atomic weights of the actinium series of products and in throwing light on the origin of the actinium series.

End-products of the Transformations. — After the radioactive transformations have come to an end, each of the elements uranium, thorium and actinium should give rise to an end or final product, which may be a known element or an unknown element of very slow period of transformation. Since the expulsion of an α-particle lowers the mass of the atom by four units, and there are eight a-ray products, the atomic weight of the end atom should be $238-8\times4=206$. The atomic weight of radium by this rule should be $238-3\times4=226$, a result in good accord with experiment. The atomic weight of the end-product of uranium is close to that of lead, viz., 207, and Boltwood early suggested that lead was the end-product of radium. Since in old minerals the transformations have been in progress for intervals measured by millions of years, the end-product should collect and be an invariable companion of the radio-element. Boltwood showed that lead is always present in old radioactive minerals, and in amount to be expected from their uranium content and geologic age.

This problem has been definitely attacked in the light of the chemical generalisation already given. It was clear from this that the end-products of uranium, thorium and actinium should all be isotopes of lead but with atomic weights 206, 208 and 206 respectively. In other words, uranium-lead if uncontaminated with ordinary lead should show a smaller atomic weight than ordinary lead (207), while thorium-lead should give a higher value. By the work of Richards, Soddy and Honigschmid, these conclusions have been definitely confirmed. The lowest value for uranium-lead is 206, and the highest for thorium-lead 207·7.

Since any admixture with ordinary lead tends to give a value nearer 207, these results may be considered as a definite proof of the nature and atomic weight of the end-products. In minerals containing both uranium and thorium the atomic weight of the mixture of the isotopes will depend on the relative amounts of these two elements and their relative rates of transformation. In unaltered minerals the determination of the amount of lead coupled with its average atomic weight allows us to determine the amount of uranium-lead even if some ordinary lead be present. In this way it should be possible to make a reliable estimate of the age of selected minerals and thus indirectly the age of the geologic strata (see GEOLOGY). The amount of helium in the mineral gives a minimum estimate of its age, for, except in the most compact minerals, some of the helium must undoubtedly escape.

Production of Helium. — In 1902 Rutherford and Soddy suggested that the helium which is invariably found in radioactive minerals was derived from the disintegration of radioactive matter. In 1903 Ramsay and Soddy definitely showed that helium was produced by radium and also by its emanation. From the observed mass of the a-particle, it seemed probable from the first that the a-particle was an atom of helium. This conclusion was confirmed by the work of Rutherford and Geiger, who showed that the a-particle was an atom of helium carrying two unit charges of electricity. In order to prove definitely this relation, it was necessary to show that the a-particles, quite independently of the active matter from which they were expelled, gave rise to helium. This was done by Rutherford and Royds, who allowed the a-particles from a large quantity of emanation to be fired through the very thin glass walls of the containing tube. The collected particle gave the spectrum of helium, showing, without doubt, that the a-particle must be a helium atom.

Since the particle is an atom of helium, all radioactive matter which emitsa-particles must produce helium. This has been found to be the case for every a-ray product that has been examined. The rate of production of helium by radium in equilibrium was measured with accuracy by Dewar, Boltwood, and Rutherford. In terms of the international radium standard, the rate of production of helium by one gram of radium in equilibrium with its three a-ray products has been found to be 164 cumm. per year. This value is in excellent accord with that calculated from the rate of emission of a-particles. The rate of production of helium by the radon, ionium and polonium has been found by Boltwood to be in fair agreement with calculation. Soddy has observed the production of helium by purified uranium, while Strutt showed that the rate of production of helium in uranium and thorium minerals was in good accord with calculation.

Strutt has made a systematic examination of the amount of helium present in many minerals and rocks which contain minute quantities of radium, and has utilised the results to estimate the age of the geological deposits. On account of the tendency of the helium to escape from minerals in the course of geologic ages, this method gives only a minimum estimate of the age of the mineral, except in the case of very dense and compact specimens. The measurement of the lead content should ultimately prove a more reliable method of estimating the age.

Heat Emission of Radioactive Matter. — In 1903 it was shown by Curie and Laborde that a radium compound was always hotter than the surrounding medium, and radiated heat at a constant rate of about 100 gram-calories per hour per gram of radium. The rate of evolution of heat by radium has been measured subsequently by a number of observers. There is no doubt that the evolution of heat by radium and other radioactive matter is mainly a secondary phenomenon, resulting largely from the energy of the absorbed radiation. Since the particles have a large kinetic energy and are easily absorbed by matter, all of these particles are stopped by the radium itself or by the envelope surrounding it, and their energy of motion is transformed into heat. The evolution of heat from any type of radioactive matter is thus proportional to the energy of the expelled a-particles, together with the energy of the β- and y-rays absorbed in the envelope. The energy supplied by the recoil of the radioactive atom after the expulsion of an α-particle is about 2% of the energy of the a-particle.

These conclusions have been confirmed by the measurements of Rutherford and Robinson, who found that each of the a-ray products gave a heating effect proportional to the energy of the a-particle and absorbed /?- and y-rays. Radon and its products when removed from radium were responsible for three-quarters of the heating effect of radium in equilibrium. The heating effect of radon, radium A and radium C decayed at the same rate as their activity. From their measurements they found that the total heating effect of radium in equilibrium surrounded by sufficient material to absorb all the radiations was 134·7 gram-calories per hour per gram. Of this, 123·6 gram-calories were due to the α-particles, 4.7 to the β-rays and 6·4 to the y-rays. The energy of the β- and γ-rays comes from radium B and radium C, but on account of their great penetrating power it is difficult to measure the γ-energy with accuracy. The results, however, show that the energy of the γ-rays is even greater than that of the β-rays, and the two together are equal to about 28% of the energy of the α-particles from radium C.

Measurements have been made of the heating effect of radium, uranium and thorium, and of uranium and thorium minerals. In each case the evolution of heat is of about the magnitude to be expected from the energy of the radiations.

Experiments on the evolution of heat from radium and its emanation have brought to light the enormous amount of energy accompanying the transformation of radioactive matter where α-particles are emitted. For example, the radon from one gram of radium in equilibrium with its products emits heat initially at the rate of about 109 gram-calories per hour. The total heat emitted during its transformation is about 14,500 gram-calories. Now the initial volume of radon from one gram of radium is ·6 cubic millimetres. Consequently one cubic centimetre of radon during its life emits $2{\cdot}4\times10^7$ gram-calories. Taking the atomic weight of the emanation as 222, one gram of the emanation emits during its life $2{\cdot}4\times10^9$ gram-calories of heat. This evolution of heat is enormous compared with that emitted in any known chemical reaction. There is every reason to believe that the total emission of energy from any type of radioactive matter during its transformation is of the same order of magnitude as for radon. The atoms of matter must consequently be regarded as containing enormous stores of energy which are only released by the disintegration of the atom.

Nature and Properties of the α-Rays.—Although the α-rays from active substances are of small penetrating power compared with the β- or γ-rays, they are responsible for most of the energy evolved by radioactive substances and contribute most of the ionization. Rutherford showed in 1903 that the α-rays were deflected in a powerful magnetic and electric field and consisted of positively charged atoms of matter projected with high velocity. From the first it seemed probable that the α-particle was an atom of helium carrying two positive charges, and this was subsequently confirmed in a number of ways. The value of e/m—the ratio of the charge on the particle to its mass—and the velocity can be determined from observations on the deflection of the pencil of rays by a magnetic field and electric fields. In this way Rutherford and Robinson in 1914 showed that the α-particle, whether from radon, radium A or C, gave a value of $e/m=4{,}820$ e.m. units, agreeing within the limit of error with the electrochemical value of $e/m=4{,}826$, assuming that the mass of the helium atom is 4·00 and that it carries two unit positive charges. The magnitude of the charge carried by each particle was measured by Regener and Rutherford and Geiger, and found to be twice that carried by the electron. The velocity of the α-particles expelled from radium C (of range 7·06 cm.) was found to be $1{\cdot}92\times10^9$ cm. per sec., or about $\frac{1}{15}$ the velocity of light. From this result the velocity of expulsion of all α-particles can be calculated from the relation found by Geiger, that $V^3=KR$ where V is the velocity of the particle and R its range in air. The evidence indicates that the α-particles from active products are in all cases atoms of helium. The α-particles from a given product are all emitted with constant velocity, which is characteristic for that product. We have already mentioned that the velocity of expulsion appears to be connected with the period of transformation of the element. The laws of absorption of the α-particle were first worked out by Bragg and Kleeman. On account of its great energy of motion, the α-particle travels in nearly a straight line through the gas, producing intense ionization along its track. The effects produced by the α-particle, whether measured by ionization, phosphorescence or photographic action, vanish suddenly after the α-particle has traversed a definite amount of matter. The definiteness of the end of the range of the α-particle of given velocity is remarkable. It is found that the ionization per centimetre of path due to a narrow pencil of α-rays increases with the distance from the active matter, at first slowly, then more rapidly, near the end of the range. After passing through a maximum value the ionization falls off rapidly to zero corresponding to the end of the range. If a uniform screen of matter is placed in the path of the pencil of rays the range is reduced by a definite amount proportional to the thickness of the screen. All the α-particles have their velocity reduced by the same amount in their passage through the screen. The ranges in air of the α-rays from the various products of the radio-elements have been measured and are usually impressed in terms of cm. of air traversed at 15° C and 760 mm. pressure. The ranges for the different products vary between 2.8 cm. and 11·3 cm.

Bragg has shown that the range of an α-particle in different elements is nearly proportional to the square roots of their atomic weights. This approximate empirical relation has proved very useful in estimating the reduction in range of the α-particles in traversing uniform sheets of different kinds of matter.

Rutherford and Geiger in 1908 devised an electrical method of counting the α-particles expelled from radioactive matter. The α-particle enters through a small opening into a metal tube containing a gas at a reduced pressure. The ionization produced by the α-particle in its passage through the gas is magnified several thousand times by the movement of the ions in a strong electric field. In this way, the entrance of an α-particle into the detecting vessel is shown by a sudden and large deflection of an electrometer.

A still more sensitive detector has been devised by Geiger consisting of a fine needle point opposite an opening in a metal tube, charged to a suitable voltage. This counter is equally efficient for β- as well as for α-particles. By the use of a string electrometer, photographic registration of the α-particles can be obtained for several thousand a minute. By magnifying the current by means of suitable amplifiers, the entrance of an α-particle into the detecting vessel can be made to operate a signal.

On account of its great energy of motion the effect due to a single α-particle can be detected in a variety of ways. Sir William Crookes first noted that the α-rays produce scintillations when they fall on a screen of phosphorescent zinc sulphide. It is now known that each of these scintillations is due to the impact of a single α-particle. The number of scintillations can be counted with the aid of a suitable microscope, and this method has proved of great utility in many investigations. Scintillations due to α-rays are observed in certain diamonds, but they are usually not so bright as in zinc sulphide. Kinoshita has shown that a single α-particle produces a detectable effect on a photographic plate. When the α-rays fall on a plate nearly horizontally the track of the α-particle is clearly visible under a high-power microscope. By the expansion method developed by C. T. R. Wilson, the track of the α-particle through the gas is made visible by the condensation of the water on each of the ions produced. In a similar way the track of a β-particle can be easily shown. The photographs of these trails bring out in a striking and concrete way not only the individual existence of α- and β-particles, but the main effects produced in their passage through matter.

When the α-rays fall on a sheet of matter, a cloud of slow speed electrons is emitted. These were first studied by Sir J. J. Thomson and were called by him the delta (δ) rays. Most of the δ-rays have an energy corresponding to only a few volts but a few particles are present which have much higher speeds, some reaching to twice the velocity of the α-particle. These δ-rays are a secondary phenomenon and are liberated from the atoms of matter by the action of the α-particle. The δ-rays can be best studied by photographing the tracks of α-particles in a Wilson chamber containing a gas at low pressure. The swifter δ-particles are able themselves to ionize the gas and their tracks are easily visible. Chadwick and Emeleus and also Auger have shown that the number and velocity of the swifter δ-rays agree excellently with the view that they are produced by the collision of the α-particles with the electrons in the atom. The primary process of ionization by the α-particle is the removal of the electron and the secondary ionization is produced by the swifter δ-particles. In general the primary ionization is about one-half of the total ionization observed.

The α-particle at the moment of its expulsion from a radioactive atom carries two charges and it was at first supposed that it retained this charge until very near the end of its range where the charge was neutralized by capture of two electrons. Later work, however, by Henderson and Rutherford showed that the α-particle changes its charge several thousand times in its passage through matter. When the a-rays pass through a sheet of matter in a good vacuum, the issuing rays consist of doubly charged, singly charged and neutral helium atoms. For high speeds, the doubly charged particles predominate; at low speeds most of the particles are singly charged or neutral. It seems clear that the α-particle in its passage through matter occasionally captures an electron and that this may be removed in a subsequent collision. This process of capture and loss of electrons is repeated many thousand times before the a-particle is brought to rest.

Although most of the a-particles travel in nearly a rectilinear path through absorbing material there is in general a small scattering or deflection of the a-particles in passing through matter, amounting on the average to a few degrees. This scattering increases with the atomic weight of the absorber and with reduction of velocity of the a-particle. In addition to this small angle scattering, a small fraction of the a-particles is deflected by collisions with heavy atoms through angles greater than a right angle. This large angle scattering is in general due to a close collision of an α-particle with a single atom of matter. A close study of the laws of single scattering of a-particles has been made by Geiger and Marsden. The observations on this large angle scattering first disclosed the nuclear structure of the atom and has given us most definite information on the laws of force inside the atom close to the nucleus and on the dimensions of atomic nuclei. (See NUCLEUS.) Blackett has obtained a number of expansion photographs showing close collisions of a-particles with the nuclei of light atoms like hydrogen, helium, nitrogen and oxygen. In general a forked track is obtained, one branch due to the scattered a-particle and the other to the recoiling nucleus.

Properties **of β- and** y-Rays.--We have seen that the @-particles, which are emitted by a number of radioactive products, consist of swift negative electrons spontaneously liberated during the transformation of active matter. The velocity of expulsion and the penetrating power of β-rays vary widely for different products. For example, the rays from radium B are much more easily absorbed by matter than the swift @-rays from radium C. At first sight, the laws of absorption of the β-particle by matter appear very different from those observed with α-particles. This is mainly due to the fact that the average @-particle has much less energy than the α-particle and is consequently much more scattered in passing through matter. This scattering is so marked that in general more than half the @-particles falling on a thin sheet of matter are reflected or rather scattered in the backward direction. The @-particles on the average have a very tortuous path before they are finally stopped. In the early days, it was found that the absorption of β-rays appeared to follow an exponential law and the different groups of 8-rays were characterized by a definite absorption coefficient. We now know that a group of homogeneous β-rays are not absorbed according to an exponential law at all and that the β-particles arising from disintegration of a single product are expelled over a wide range of velocity. In this respect a β-ray transformation is entirely different from an a-ray transformation where the a-particles are all expelled with the same speed. It has however been found that in general one disintegration electron comes from each transformed atom but the speed of the β-particles from different atoms may differ widely. It is difficult to account for the striking difference in the α- and β-modes of transformation. Meitner has suggested that the β-particles are initially liberated from the nucleus with identical speeds but that some lose part of their energy by collisions with electrons in escaping from the atom. If this were the case, we should expect on the average more than one 8-particle to escape from each disintegrating atom. Ellis, however, has shown that the heating effect of the @-rays from radium E is a measure of the actual energy of the escaping β-rays, supposing, as Emeleus observed, that one β-particle is expelled in each transformation. On the Meitner hypothesis, the heating effect should have been greater corresponding to that due to β-particles all liberated with the maximum speed.

Gray has shown that β-rays in passing through matter give rise to y-rays, and that these in some cases correspond to the characteristic X radiations observed by Barkla. The absorption of the y-rays has been determined by the electrical method. Radium B has been found to emit several groups of y-rays which differ in penetrating power. The greater part of the rays from radium C consist of penetrating y-rays which are nearly exponentially absorbed by matter. The ionization in an electroscope falls off according to the equation $I/I_0 = e^{-\mu d}$, where d is the thickness of matter traversed and μ the coefficient of absorption. When lead is used as an absorbing material the value of $\mu = 0{\cdot}5$ for the most penetrating y-rays from radium C. The absorption coefficient for different kinds of matter is proportional to the density, indicating that absorption depends on the mass of matter traversed.

There is undoubtedly a close connection between β- and γ-rays, and swift β-rays are usually accompanied by penetrating y-rays. For example, radium C, which emits very swift β-rays, some of which reach a velocity more than 0·98 of the velocity of light, gives rise to the most penetrating y-rays observed in the uranium-radium series. There is one very notable exception, viz., radium E which emits swift β-particles but very little y-radiations.

Jacobsen has recently found some evidence that in the disintegration of radium C, the y-radiation is not emitted until about 10^{-5} second after the expulsion of the β-particle. It may be that, in general, the y-ray does not accompany the expulsion of the @-particle but is liberated later due to a rearrangement of the constituents of the nucleus. If this be the case, the liberation of a y-ray represents a new type of transformation without change of the charge on the nucleus. On this view, it is to be supposed that in the case of radium E there is no subsequent y-ray transformation.

The detailed study of the β-ray spectra discussed below has led to the conclusion that the y-rays are characteristic radiations emitted from the radioactive nucleus in its rearrangement after the ejection of the β-particle. These radiations from the nucleus in their passage through the atom excite the characteristic radiations of the external electronic system. Thus the total γ-radiation of a radioactive atom consists not only of the y-rays from the nucleus, but also of the characteristic X-rays of the atom.

The first examination of the spectrum of the y-rays was made by Rutherford and Andrade in 1914 by reflection of the rays from a thin crystal of rock-salt, using a fine glass tube filled with radon as a source of y-rays. A complicated spectrum of bright lines was observed corresponding to the y-rays emitted by the 8-ray products, radium B and radium C. Lines were observed corresponding to the ordinary X-ray spectrum of the elements radium B and radium C, and also a number of other lines of much shorter wave-length. These results have been extended by the recent work of Frilley, who by the use of intense sources of radiation has been able to observe still shorter waves, corresponding in energy to about 700,000 volts. The angle of reflection of such short waves from rock-salt is only about 10 minutes of arc, and it does not seem feasible by this method to measure the wave-length of the still shorter waves which are undoubtedly present. This difficulty has been surmounted by the use of an entirely different method which is specially applicable to rays of high frequency and energy. A brief discussion of this method and its application follows:

When the β-rays from a product like radium B or radium C are bent by a magnetic field and fall on a photographic plate, a kind of magnetic spectrum is obtained. Superimposed on the continuous spectrum due to particles of all velocities (between certain limits) certain sharp lines are observed, each of which represents a definite group of β-rays which are emitted at the same speed. The velocity corresponding to each line in the spectrum has been determined for a number of β-ray products by Hahn and Lise Meitner. The magnetic spectrum of radium B and radium C was examined in detail by Rutherford and Robinson, and more than 50 lines were observed, representing β-particles projected over a wide range of velocity. The appearance of these lines in the spectrum appears to be connected with the emission of y-rays and is believed to be due to the conversion of the energy of the y-ray of definite frequency into the energy of an electron according to the quantum relation. When a thin layer of absorbing material is placed over the source, the primary β-rays diminish in velocity and the lines become broad and diffuse. At the same time, however, new groups of @-raysare formed by the conversion of y-rays into @-raysin passing through the absorbing material, and these give well-marked bands on the photographic plate, occupying very nearly the same position as those due to the primary @-rays before absorption. A study of the slight shift in the position of the band when the y-rays traverse elements of different atomic weights was made by Ellis. The results can be interpreted in the following way: A y-ray in traversing the absorbing screen interacts with one of the electrons in an atom and occasionally the energy E of the y-ray is transferred to the electron. The energy of the electron after escape from the atom is given by E–w where w is the work required to move the electron out of the atom. Since on the quantum relation the energy E of a y-ray is given by hv, where v is the frequency of the y-radiation and h the well known constant of Planck; it follows that $h\nu = E - w$. Since the energy, E–w, of the escaping electron can be deduced by its deflection in a magnetic field, and w is known from X-ray data, the frequency ν of the radiation is directly determined. On this view the origin of many of the lines in the primary, magnetic spectrum of the β-rays is at once revealed. A y-ray in escaping from the radioactive atom occasionally interacts with one of the outer electrons in the atom from which it originates, and communicates its energy to it. This electron may belong to any of the well known K, L, M, etc., levels in the atom, but the value of the energy w abstracted from the escaping electron depends on the level. It is greatest for the K level and rapidly diminishes for the L, M, etc., levels. In considering a large number of disintegrating atoms, there is a certain probability that a particular y-ray will be converted in one of these levels and consequently a number of lines will appear in the magnetic spectrum corresponding to the conversion of a single y-ray in the various electronic levels in the atom. Usually, the line due to conversion in the K level is much the strongest, but, for an intense y-ray, the lines due to conversion K, L, M and N levels can be observed. By observations of this kind, it is thus possible to determine the frequency of the y-rays by analysis of the magnetic spectrum of the @-rays.

Determinations of the frequencies of the main y-rays given by a number of radioactive elements have been made by this method by Ellis, Meitner, Thibaud, Black and others. In the case of radium B and radium C, the frequencies so determined agree well with the direct measurements made by the crystal method, so that it is clear that this powerful method can be safely applied for waves of the highest frequency. So far, the highest frequency observed corresponds to over two million volts.

The penetrating y-rays in general accompany a β-ray disintegration, and it has proved of great importance to settle whether the y-rays are emitted before or after the expulsion of the disintegration electron from the nucleus. This question has been attacked by a number of observers by different methods, ultimately leading to a definite proof that the y-ray always follows the emission of the disintegration @-particle, presumably after a short but unknown interval. For example, the y-rays which are ascribed to the disintegration of radium B of nuclear charge 82 actually arise from the nucleus of charge 83 resulting from the expulsion of a @-particlefrom radium B and are converted in the electronic levels of an atom of charge 83.

Ellis has obtained some evidence that the main y-rays from radium B and radium C can be interpreted by assuming a system of energy levels in the nucleus, analogous to the well known system of energy levels in the electronic system of an atom which have been postulated for the explanation of optical and X-ray spectra, but the wave-lengths of the y-rays are not yet known with sufficient precision to fix the levels with much certainty. The general evidence suggests that the y-rays are not due to the passage of an electron from one level to another in the nucleus, but to the movement of a more massive particle, possibly a proton, or helium nucleus.

In this connection, it may prove significant that y-rays are emitted from some products which break up with the emission of α-particles but no @-particles. Whatever may be the exact mode of origin of the y-rays, it seems clear that the high frequency v-rays originate in the nucleus of the transformed atom and represent the characteristic modes of vibration of parts of the nuclear structure.

Radioactivity of Ordinary Matter. — Apart from the well-known radioactive elements of high atomic weight, only two other elements have been shown to exhibit radioactivity to a detectable degree, viz., potassium and rubidium. Campbell showed that these elements emit only β-rays and in amount small compared with uranium. This property appears to be atomic, but no evidence has been obtained of any subsequent changes. If the β-particle comes from the nucleus of the atom, potassium should be transformed into an isotope of calcium, and rubidium into an isotope of strontium. Hervéy has partially separated the isotopes of potassium of atomic masses 39 and 41 by diffusion methods and concludes that the radioactive property is mainly concentrated in the heavier isotope.

Radium and thorium have been found to be distributed, but in very minute amount, in the surface rocks and soil of the earth. The emanation from the soil diffuses into the atmosphere and causes a small ionization which can be readily measured A penetrating y-radiation, no doubt due to the presence of radium and thorium in the earth's crust, has been observed near the earth's surface, but becomes very small over a lake or the sea.

Structure of Radioactive Nuclei.--On modern views, the atom consists of a central positively charged nucleus of very minute dimensions surrounded at a distance by a compensating distribution of electrons. (*See* ATOMS.) The ultimate constituents of the nucleus are supposed to be protons and electrons, the former in excess, but probably combinations of protons with electrons exist as secondary units within the nucleus. It seems clear that radioactivity is a property of the nucleus and that the primary a- and @-particles and the y-rays have their origin in the nucleus. Some of the secondary β-rays are due to the conversion of the energy of y-rays in passing through the outer electronic system of the atom while characteristic X-rays are also excited in the rearrangement of the outer atom. From consideration of the scatterings of α-rays by heavy elements and the energy of emission of a-particles from radioactive atoms, it has been suggested that the nucleus is a complex structure, consisting of a central, highly compact, inner nucleus surrounded at a distance by a number of satellites. Rutherford supposed these satellites to be electrically neutral and to be held in equilibrium by the enormous distorting forces arising from the intense electric field of the central nucleus. For some reason, one of the satellites circulating in a quantum orbit becomes unstable and escapes from the system, shedding two electrons as soon as the electric field falls to a certain critical value, and gaining further energy in its escape through the repulsive field. The final speed of ejection of the a-particle on this view depends on the quantum orbit from which it is liberated. It is suggested that some of the electrons circulate at high speeds close to the central nucleus and that the y-rays arise not from the @-electrons but from the fall of the neutral satellite from one quantum orbit to another. Enskog has suggested that the a-particles are held in equilibrium by magnetic attraction between the a-particles and central nucleus.

RADIO COMPASS, a radio receiving set which permits determination of the line of travel of waves as received from transmitting stations. *See* WIRELESS TELEGRAPHY; AERIAL NAVIGATION; NAVIGATION.

RADIO CORPORATION OF AMERICA, an American corporation incorporated in Delaware on Oct. 17, 1919.

The Radio Corporation of America, and its subsidiaries are engaged in the manufacture and sale of apparatus for radio purposes and for recording and reproducing sound, the operation of international, marine and domestic radio communication services, the operation of radio broadcasting stations and the supplying of programs for radio broadcasting. Prior to 1930 RCA, having no manufacturing facilities of its own, purchased from General Electric Company and Westinghouse Electric and Manufacturing Company all of the apparatus sold by them. In 1929 it acquired the Victor Talking Machine Company and as of Jan. 1, 1930, it acquired manufacturing rights and facilities from the General Electric and Westinghouse Companies. These were operated by RCA Victor Company, Inc. and RCA Radiotron Company, Inc., until Jan. 1, 1935, on which date all manufacturing activities were consolidated in RCA Manufacturing Company, Inc., a new company. The international radio communication services were operated by RCA until 1929 at which time they were transferred to R.C.A. Communications, Inc., a subsidiary. In 1935 these services consisted of direct radio circuits, linking the United States with 47 countries, and domestic radiotelegraph circuits connecting 11 United States cities. R.C.A. Communications, Inc. also operates services for the transmission by radio facsimile of pictures, maps etc., between New York–London, New York–Berlin and New York–Buenos Aires. In 1923 RCA commenced the operation of two radio broadcasting stations, WRC in Washington and WJZ in New York. The National Broadcasting Company, Inc., a wholly owned subsidiary, was organized in 1926, and acquired WEAF in New York. NBC programs 189 radio broadcasting stations and engages in network broadcasting on two coast-to-coast networks, the Red and the Blue. The authorized capital stock consists of 920,300 shares of $3.50 Cumulative Convertible First Preferred stock, of which 900,844·8 shares have been issued; 13,693 shares of "B" Preferred stock, authorized and issued; and 18,500,000 shares of common stock of which 13,881,016 shares have been issued. (J. G. H)

RADIOLARIA, a class of marine protozoans, usually planktonic, distinguished by a mineral skeleton. See PROTOZOA.

RADIOLOGY, that branch of science which deals with radiant energy and its physical laws. The term radiology is however often used to denote the application of radiant energy in medicine and that will be its reference here.

Classes of Radiations.— The association of various kinds of radiation with the science and practice of medicine has been a very gradual one, quickened in the last 30 odd years by the discovery of kinds of radiation of which mankind was ignorant, although they are all emitted by the sun. Five groups of aether disturbance are of interest in medicine: a region of radiant heat used in thermo-therapy, the region of light for helio-therapy, that of ultra-violet rays in actino-therapy, the group of radiations known as X-rays used in radio-therapy, but often called Rontgen-therapy in honour of the discoverer of the rays, and finally a group known as gamma rays which are the principal, though not the only, agent in radium-therapy (*q.v.*); this is often spoken of in France as Curie-therapy in honour of the discoverer of radium.

Though differing in many characteristics, these groups of radiation have the common feature of travelling with the speed of light. They are periodic electro-magnetic disturbances in the aether, not mechanical vibrations in any sense of the term.

More use is made in actual practice of measured values of the wave-lengths of these radiations than of their frequencies. Measurements of the wave-lengths of light were first made just over a century ago by Fraunhofer; he estimated the wave-length of the yellow light given out by a sodium flame to be ·0005888 mm. which was afterwards proved to be remarkably accurate. It is usual now to express measurements of wave-lengths in Angstrom units (Å.U.) one of these being equal to one hundred millionth of a centimetre. The bigger the value in Angstrom units, the longer the wave-length. The limits of vision for people of normal colour perception are generally held to extend over wave-lengths ranging from about 7,600–3,800 Å.U.; waves longer than this extend more or less indefinitely but the region adjoining the red rays is called Radiant Heat; on the shorter wave-length side is ultra-violet radiation, the part of medical interest being limited to the wave-lengths between 3,800 and 2,500 Å.U. Waves of shorter wave-length than this are very easily absorbed by practically all forms of matter except when the wave-length becomes very much shorter, then they become more and more able to penetrate matter; the waves from X-rays come in this division. Medical use is made of the rays which extend between the approximate limits 1–0·15 Å.U. Finally the group of gamma rays emitted by radium and other radio-active bodies extends between the limits of 0·04–0·07 Å.U., overlapping the short wave-length X-rays.

Importance in Medicine.—One of the first photographs sent out by Professor Rontgen in 1895 to scientific laboratories announcing his discovery of the X-rays was a picture of a hand showing that, by the help of the rays, one could literally see through the tissues; the soft tissues are less opaque to these rays than bone, so that if the hand is put between the X-rays and a photographic plate, a shadowgraph is formed on the plate.

Advances in Technique.— Some idea of the advances in the technique of radio-diagnosis may be got from the fact that in the early days of X-ray work, for a radiograph of the kidney for a suspected stone, an exposure of about 30 minutes was necessary; for such radiography now, exposures of less than one second are given. This extraordinary shortening of the time has mainly been brought about by three improvements in technique. The most important of these is an increased output of radiation from the X-ray tube; this has been achieved by the construction of more massive X-ray tubes which deal effectively with the large amount of heat generated when X-rays are produced, and by the design of much more effective transformers for the production and maintenance of the high voltages needed. The second and third improvements are on the purely photographic side. The thickness of the coating on the plate or film has been increased, and double-coated celluloid films are now very often used; and intensifying screens are used in close contact with the film of the photographic plate. When X-rays go through the object exposed, they excite these fluorescent intensifying screens, so that they give out light which acts directly on the photographic plate, which of course also receives the transmitted X-ray beam. By means of these technical developments successful cinematographic X-ray records of the movements of the limbs have been produced, but X-ray cinematography does not yet form part of the normal radiographic equipment of a hospital.

In the five years (1895–1900) following the discovery of X-rays, they were much used for therapeutic purposes, mainly for superficial conditions. In 1897 Henri Becquerel discovered that certain substances, of which radium is the prototype, are radio-active, in the sense that they give out rays spontaneously; these rays are of three kinds α, β and γ, the last being akin to X-rays. Similar attempts were soon made to test the therapeutic value of these rays (*see* RADIUM-THERAPY), and at the present time, there is a widely growing use of gamma rays and X-rays in the treatment of disease.

Tissue Reactions.— The tissues of the body respond to the five different groups of rays mentioned at the beginning, in very different ways. In what follows, references will mainly be made to the rays other than those constituting heat and light. Perhaps the most striking physical characteristic shared by ultra-violet, X-rays and gamma rays is that of liberating electrons from matter. No doubt this occurs when the tissues of the body are exposed to these rays.

Suppose that the skin of the abdomen is exposed to a beam of X-rays comprised within certain wave-lengths. With an adequate dose of radiation, a series of reactions occurs which lasts for several weeks; the skin becomes red, any hair there is will come out, a blister may develop and finally if the dose has been a very heavy one, a persistent sort of ulcer may form. Most of the X-rays falling upon the skin will penetrate to the deeper tissues and produce effects upon them which depend essentially upon the kind of organ or tissue irradiated. By suitable choice of the wave-lengths in a beam of X-rays, it is possible to give a sterilizing dose to the cells of the ovary, while causing no more damage to the skin than a transient erythema. Since the rays must be considerably weaker by the time they reach the ovary than they are on the skin, it is usual to say that X-rays have a selective action, meaning that they have apparently more effect upon some cells of the body than others and there is no doubt that this is so; and that it is equally true of gamma rays. Upon this main principle, the foundations of X-ray and Radium therapy have been laid. The difference in the sensitiveness of the normal tissues of the body to these rays covers a wide range; certain cells of the ovary and testicle, glandular structures generally and lymphocytes are profoundly affected by doses of X-rays which do not have very much effect upon muscle, cartilage or nerve cells. How far this is due to the structures of the cell being altered or to the function of the cell being interfered with cannot at present be said.

Treatment of Malignant Turnours.—One of the most important therapeutic uses of X-rays and gamma rays is for the treatment of malignant tumours (*see* TUMOUR). One of the essential principles underlying the treatment of malignant growths was established by Dominici in 1909, who showed that it was possible to irradiate certain malignant tumours causing more damage to them than to the adjoining normal cells. Dominici traced the changes which occur in the tumour under these conditions and found that degenerative changes were set up in the tumour cells which eventually led to their destruction. Such a process takes time for its full development and is influenced by the reaction of the normal tissues; should these normal tissues receive an overdose of radiation, it may prejudice the whole sequence of events. Observations of this kind have established the view that the action of X-rays and radium, when properly used, is unlike that of a cautery but depends essentially on giving pathological tissues a dose, which though harmful enough to ensure their degeneration, will not severely damage any of the normal tissues of the host.

It has been found that the reactions of living cells depend not only upon the actual dose of radiation which they absorb, but also upon the way in which the dose is given. The two chief ways in which a definite physical dose can be varied are either by using a source of strong intensity and applying it for a short time or by using a relatively weak source and applying it for a correspondingly long time, keeping the product of these two quantities the same. Some researches of Lazarus-Barlow, in 1914, showed that the columnar and epithelial tissues of the rat react in quite different ways when the dose was varied in this way; the columnar type of cell being less damaged by keeping the intensity high and the time factor small, while the opposite was the case with cells of the squamous type. Observations of this kind have an obvious bearing upon treatment when deciding the kind of dose required to ensure the degeneration of malignant growths in man.

At the present time, there is a considerable tendency to use rather weak sources of radiation applied for a long time; in some cases, the exposures last as long as 12 or 14 days. Care has however to be taken that the source is not too weak, for there is ample evidence to show that cells can adapt themselves to very weak irradiation. Some idea of the doses commonly used in gamma ray therapy may be obtained from the statement, that a concentration of about 1 milligram of radium element for each cubic centimetre of a malignant growth is often aimed at, and an adequate time of exposure with this concentration is in many cases found to be from 5–10 days. It is perhaps unnecessary to add that this dose is often departed from when conditions make it advisable. In most cases, it is easier to manipulate the gamma rays from radium than X-rays, and for this reason partly there is a growing tendency to use them for the irradiation of deep-seated organs.

It is often very difficult, and in some cases impossible, to get the best physical conditions for arranging the necessary uniform irradiation of a malignant mass; but there is no doubt that those who practise radiotherapy in any form nowadays, and have a sound knowledge of the physical characteristics of the radiation they use, can get much nearer the ideal conditions than was possible in the early days of radiotherapy. The encouraging signs of collaboration between clinical and laboratory investigations are likely in time to establish the subject on a sound quantitative basis. Although much remains to be done to explain the processes set up when the tissues are irradiated by ultra-violet, X-rays, or gamma rays, some of the main changes occurring in cells both normal and malignant, are now well recognized and have been made the subject of detailed study. It has been found too, that cells react differently according to their state of activity at the time of irradiation, and it is generally believed that cells in active division are more vulnerable to radiation than when in a resting stage.

Effects on Cell Life.—It is reasonable to expect that the effects upon cell life will depend on the amount of radiation to which they are exposed. The general principle enunciated by Grothus in 1818 that, "in photo-chemical actions only those rays which are absorbed can produce chemical change," is found to have a much more general application. The reactions of living cells appear to depend largely, though not wholly upon the amount of energy they absorb from the beam of radiation going through them. It has already been stated that, if the intensity of the radiation is too small, the cells can cope with it to a large extent, even though it be prolonged for a very long time. It has been found that the changes shown by cells depend to some extent upon the wave-length of the radiation producing the action, although the amount of energy actually absorbed may be the same, the result may be entirely different; these processes begun in living structures depend not only upon the energy let loose in the structures, but also upon the way in which it is set free.

Generalizations must always be difficult on a subject which is comparatively young; experimental advances too are apt to modify views which can only be held somewhat tentatively, but it is thought that the following may be stated as expressing views which are fairly generally held at present. They are taken from Radium, X-mys and *the Living Cell* by Colwell and Russ.

1. The cells of some tissues are more affected by a given dose of radiation than are the cells of other tissues when exposed to the same dose. This is generally known as selective action.
2. In some cases, at least, the cells of a tissue are more affected by a given amount of energy of one range of wave-lengths than they are by the same amount of energy of another range of wave-lengths. This is known as differential action.
3. Some cells, when in an active state of division are more affected by a measured dose of radiation than are similar cells in the resting stage.
4. Some cells respond to a dose of radiation in different ways, according to whether such radiation is administered so that a large intensity is coupled with a short period of exposure or a small intensity is coupled with a long period of exposure.

Instruction for Practitioners.—The widespread application of radiology in medicine has inevitably affected the courses of instruction laid down for qualifying medical degrees.

Not many years after the first therapeutic trials with X-rays and radium, injurious action on the skin was noticed, and later it was discovered that those who were giving frequent doses of the rays to patients were themselves being damaged; in some cases there was obvious damage to the skin which led eventually to a cancerous condition; in others, a state of anaemia existed, and others were sterilized. Deaths from repeated but unintentional doses of radiation had undoubtedly occurred. With such facts known, protective committees were formed in various countries to lay down measures for the protection of all workers.

In Great Britain, there has been very wide acceptance of the general guiding principles laid down by the X-ray and Radium Protection Committee whose publications are issued from the British institute of radiology. This Institute came into being in 1924 and marks a distinct era in the development of a branch of medicine, whose services in the diagnosis and treatment of diseases have certainly not yet reached the zenith of their attainment. *See* the article RADIOTHERAPY; X-RAYS; X-RAY TREATMENT. (S. RU.)

RADIOMETER, an instrument for measuring the intensity of the radiant energy of rarefied gases. It was noticed by Fresnel that a body delicately suspended in *vacuo* is apparently repelled by radiation. Sir W. Crookes was the first to make systematic experiments; he found that a light vane blackened on one side and bright on the other was repelled if radiation was allowed to fall on the blackened face. He constructed an instrument, which he called a radiometer or light-mill, by pivoting a vertical axle carrying vertical vanes inside an exhausted bulb; one side of each vane was blackened and the other side bright, the black sides all facing the same way round the axle. When rays from the sun or other light source, or dark radiation from a warm body, fall on the vane, the black sides are repelled more than the bright sides, and the vanes are set into rotation. The rate of rotation rises to a value which depends on the intensity of the radiation; the more intense the radiation the more rapidly do the vanes rotate.

That this is so is important, for it indicates that the force opposing the motion is one which increases as the rate of rotation increases. Now the friction of the pivot is independent of the rate of rotation, so that the main opposing force must be that due to the residual gas in the bulb, for the viscous drag on a body in motion through a gas increases as the speed increases.

The name "radiometer" arose from Crookes's idea that the instrument might be used to measure the intensity of radiation; with the instrument he constructed he was able to detect the radiation from a candle 19 meters away.

That it was necessary to blacken one side of each vane suggested that the effect was due to a difference of temperature between sides of the vane caused by the greater absorbing power of the black coating, and the question arose whether the rotation was caused by the direct impact of the radiation (somewhat as the rotation of a cup anemometer is caused by the wind), or whether it was caused by difference of pressure of the gas set up by the inequalities in temperature. This was settled by a very beautiful experiment performed by Sir A. Schuster. He suspended the case of the radiometer by a fine thread so that it was free to rotate about a vertical axis; a small mirror fixed to the case, which reflected a beam of light on to a scale, enabled him to observe any rotation. If the vanes were driven round by the direct action of radiation, then the viscous drag of the gas acting also on the inside of the bulb would drag the latter round in the same sense as the vane. If, on the other hand, the rotation were caused by stress in the gas, the couple which set the vanes in rotation would involve an equal and opposite couple on the case, and the case would thus begin to rotate in the opposite sense. As the rate of rotation of the vanes increased, the viscous opposition of the gas would increase until, when the forces due to viscosity became equal to the driving forces, the resultant on both the vane system and on the case would vanish; the vanes would continue in uniform rotation and the case return to its position of equilibrium. When the rotation ceased to fall on the vanes, there would no longer be any driving couple and the viscosity of the gas would bring the vanes to rest and impel the case in the direction of their rotation.

The experiment completely confirmed this second hypothesis, namely that the rotation of the vanes is due to mutual forces between them and the case. This was further confirmed by suspending the case in an inverted position so that the vane system was no longer free to rotate unless it took the case round with it. There was then no motion of the case. From Schuster's measurements of the angular deflection of the light-mill supported by a bi-filar suspension, O. Reynolds calculated the magnitude of the pressure difference on the two sides of the vane to be of the order of one thousandth of the gas pressure in the bulb.

Instead of allowing free rotation of the vane system on a pivot, it may be suspended by a quartz fibre. Radiation falling on the black face of the vane will then cause the system to turn round until the restoring couple, due to the torsion of the suspension, balances the deflecting couple due to the radiometer action. A small mirror, attached to the vane system and reflecting a beam of light on to a scale, enables very small deflections to be observed. Pringsheim in 1883 constructed such an instrument and used it for spectrographic investigations in the infra-red. In 1893 Nichols constructed a radiometer in which the mica vanes, one at each end of a horizontal arm, and each blackened on its front surface, were suspended by a quartz fibre. Radiation falling on both vanes would tend to turn them in opposite directions, and if they were correctly adjusted the system would not move under the influence of general stray radiation. The radiation to be measured was allowed to fall on one only of the vanes, and the resulting deflection of a spot of light reflected by a small mirror was observed. In 1901 Nichols improved his radiometer, by making it smaller, to such an extent that he was able to measure with it the radiation from individual stars.

The radiometer has been applied to measurements of ultra-violet radiation and to that of short Hertzian waves (wave length 1 to 2 mm.).

THEORY

O. Reynolds in 1874 had shown, on the kinetic theory of gases, that communication of heat from a solid to a gas would involve a reactionary force on the surface of the solid. On the same theory Sir W. Crookes in 1876 gave an explanation of the action of his light-mill; this was as follows: The temperature of a gas is, on the kinetic theory, proportional to the mean kinetic energy of translation of the molecules, and the pressure exerted by a gas on the surface of a solid is due to the bombardment of the surface by the molecules. If the solid and the gas are at the same temperature, the molecules, after striking the surface, will rebound with the component of their velocity normal, the surface merely reversed. If the surface of the solid is warmed, as in the case of the light-mill by radiation, heat will be imparted to the molecules which strike the surface, and they will rebound with greater velocity than they approach.

Vanes, black on one side and bright on the other, on which radiation falls, will be warmer on the black surface, and molecules striking them will rebound with a greater reactionary kick from the warm sides than from the cool sides, and thus produce a greater pressure on the warm sides; it is this extra pressure which sets the mill in rotation.

In this explanation it is assumed that the molecules do not very often collide with each other, that is to say that their mean free path is comparable with the dimensions of the vane. When this is the case the force is proportional to the pressure of the residual gas. If the pressure is higher, and the mean free path is small compared with the size of the vanes, the molecules after rebounding from the warm surface of the vane collide with other molecules imparting their increased energy to them, and the general temperature of the gas in the neighbourhood of the surface is raised; but this involves a reduction of the density of the gas, so that fewer molecules now strike the vane in unit time, and this reduction in the number of rebounding molecules compensates for the greater contribution of each to the pressure on the vane, so that over the central portion of the vane the pressures on both sides become equal. However, near the edge of the vane, molecules from the hot side can collide with molecules from the cold side and the temperature will be the mean of the temperatures on the two sides; the density near the edge will thus tend to be the same on the black as on the bright side. The greater reactionary kick of the molecules hitting the warm side is thus uncompensated by a reduction in the number of collisions. Thus when the mean free path is small, the excess pressure is confined to a narrow region round the edge of the vane, and the resultant force depends on the length of the edge and not on the area of the vane.

The calculation of the pressure on a warm surface formed the subject of another paper by O. Reynolds in 1876; in this he takes into account the Maxwell-Boltzman law for the partition of the energy among the degrees of freedom of the molecule. *(See* KINETIC THEORY.) He assumes that it has the three degrees of freedom corresponding to three mutually orthogonal directions in space, that is to say, he neglects the possibility of spin of a molecule or of any internal vibratory motion. He shows the close connection between thermal transpiration and the radiometer effect, and proves that slip of the gas over the surface of the vane must play an important part in the action of the radiometer. Such slipping had been observed by A. A. Kundt and E. G. Warburg in 1875 In their work on the viscosity of gases. He concluded that the pressure was proportional to the rate of divergence of the lines of heat flow: if these are parallel there is no excess pressure; where they diverge there is an excess pressure.

More recent investigators in Germany have attacked the problem mathematically. Among these may be mentioned Edith Einstein in 1922. She found an expression for the pressure between two plates, one of which was hotter than the other. Using the Maxwell-Boltzman law for the partition of the energy among the three translational degrees of freedom of the molecules, she arrived at the result that the normal component of the pressure is proportional to the gas pressure and to the *square* of the rate of flow through the gas.

In 1926 Sterntal, starting with the same assumptions but introducing the possibility of internal vibratory motion which may absorb energy and applying the Maxwell-Boltzman laws to all these degrees of freedom, showed that the normal pressure is proportional to the first power of the rate of flow of heat instead of its square.

His result is in fair agreement with experiment, while the terms which E. Einstein obtained were second order ones about 10,000 times smaller.

The Knudsen Gauge.—Knudsen in 1909 described an absolute manometer based on the fact that the radiometer effect depends on the gas pressure.

Consider two parallel plates in an inclosure in which the gas pressure p is sufficiently low for the distance between the plates to be small compared with the mean free path of the molecule. Let T_1 and T_2 be the absolute temperatures of the plates and T that of the containing vessel, then the pressure p' between the plates is related to p by the formula

$$p' = p\,\frac{\sqrt{T_1}+\sqrt{T_2}}{2\sqrt{T}}.$$

If one of the plates is at the same temperature as the containing vessel, *i.e.*, if T_2 equals T, we have

$$p' = \frac{p}{2}\left(\frac{\sqrt{T_1}}{\sqrt{T}}+1\right)$$

The excess pressure F which tends to move the plates is

$$F = p' - p = \frac{p}{2}\left(\frac{\sqrt{T_1}}{\sqrt{T}}-1\right).$$

It is assumed that the molecules take on impact the temperature of the plate; this, probably, is not quite true so that the formula is only an approximation.

Knudsen designed a number of gauges, most of which depended on a sudden change of temperature brought about by an admission of steam to one portion of the instrument. During the interval before radiation and conduction have established equality of temperature throughout, repulsion of a small moving part occurs; this motion is taken as a measure of the pressure. Other gauges have been devised by Angerer (1913), by Woodrow (1914) and by Schrader and Scherwood (1918), in which electrically heated strips repel small suspended vanes.

RADIO RECEIVER. Since the early days of the thermionic valve the design of radio receivers for telegraphy and telephony has undergone profound alteration. In particular, broadcasting has given an impetus to receiver design which has resulted in the creation of a new industry. Many and fanciful are the receivers which have been built to achieve certain purposes in this realm. The necessity for simplicity in the design and operation of broadcast receivers has compelled the designer to think hard and is responsible for numerous innovations by virtue of which receivers for modern radio telegraphy have also benefited. Progress in radio has been very rapid, due largely to the enormous public interest in the subject, to keen competition, and to the ever-widening circle of radio enthusiasts both amateur and professional. Such being the state of affairs, it is necessary here to restrict attention to the main principles governing radio reception. These principles

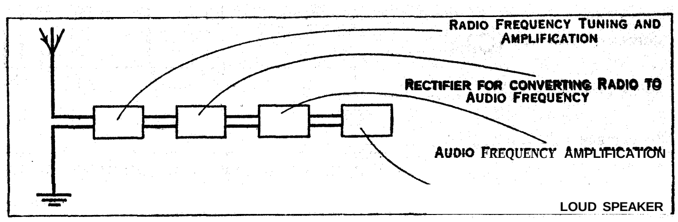

FIG. 1.—DIAGRAMMATIC REPRESENTATION OF A "STRAIGHT" RADIO RECEIVER WITH OPEN AERIAL

are illustrated by examples from modern practice, but it must be remembered that this practice is changing from year to year, almost from month to month. Put broadly, radio reception means the reception of signals from a certain distant transmitter with a reasonable degree of loudness and a *minimum* of interference from other sources of radio transmission. To accomplish this, certain conditions must be recognized and complied with.

The sensitivity of a radio telephone receiver depends upon the aerial system and upon the amplification due to the valves. An open aerial is much more sensitive than a frame or loop aerial, unless the open aerial is unusually small and situated indoors. However, in modern receiver design there is no difficulty in securing adequate signal strength when a frame aerial of but small dimensions is used. The frame is more selective and it also permits—in certain cases—a greater immunity from jamming, owing to its directional properties. There is a limit to the sensitivity of a receiver, and this is fixed by the promiscuous interference due to atmospherics, various radio transmitters, local noises due to tramways, electric motors, and the like. Interference of this nature can be collectively classed as "noise." When, therefore, the "noise" is sufficiently loud to interfere with the reception of a distant station, the limit of sensitivity for that station has been reached and no useful purpose is gained in increasing the amplification.

Selectivity and Quality.—To exclude unwanted signals it is essential that the receiver should be designed to *select,* when desired, a particular transmitting station to the exclusion of all others. To achieve this object a series of tuned circuits is incorporated in the receiver. These are usually associated with valves, so that selecting and amplifying are accomplished simultaneously. In either telegraphy or telephony the receiver must on any particular setting cover a band of frequencies. Suppose, for example, that in broadcasting the frequency of the transmitting station happens to be 800,000 cycles per sec.; the receiver should be capable, when set to this frequency, of receiving a band of frequencies of 10,000 cycles on each side of this with equal facility. The receiver should, therefore, in this case respond to a range from 790,000 to 810,000 cycles.

The *quality* of reproduction from a radio receiver depends upon a number of factors. One of these is the response characteristic of the receiver, apart from the loud-speaker or telephones. The receiver should respond equally to any frequency from 20 to 10,000 cycles—this being the compass required to accommodate all musical instruments—but there are few, if any, receivers which attain to this standard. Assuming that a receiver complies with this condition, when a series of notes of equal loudness are played in a broadcasting studio, they should all have the same loudness at the receiver provided a satisfactory loud-speaker is used. In listening to distant stations it will, in many cases, be found imperative—due to interference—to make the receiver so selective that the band of frequencies covered is much smaller than 20 to 10,000 cycles. When the upper frequencies (above 3,500 cycles) are reduced too much the reproduction becomes muffled and lifeless. Thus when interference is rife, high quality cannot be obtained

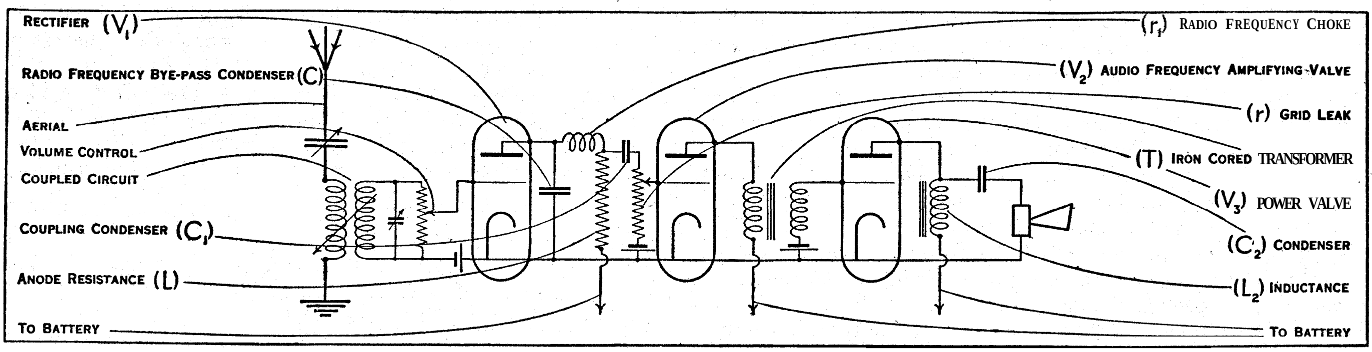

FIG. 2.—DIAGRAM OF CONNECTION OF RECEIVER FOR LOCAL BROADCASTING STATIONS

from distant stations. For with a sensitive receiver set to cover the whole musical scale, the signals are swamped by "noise," whereas with a selective receiver the essential musical characteristics are stifled by super-tuning. In general, distant reception and quality are mutually exclusive.

Where telegraphy is concerned, the selectivity can be much greater than in broadcast telephony. To get clear cut signals in the Morse code, it is necessary to receive a band of frequencies whose width increases with the speed of transmission. For example, to receive good signals at a speed of 100 words per minute, the receiver should respond equally to a band of frequencies 200 cycles on each side of the tune point. When the received band is narrowed down, the signals are ill defined, and instead of being square they become rounded. This is detrimental to relaying the signals and subsequently printing them at a central office. Moreover, when it is imperative to narrow the receiver frequency band to avoid interference, the more economical procedure is to reduce the speed of sending, thereby obtaining square signals which can be printed direct on a paper tape, instead of being laboriously transcribed and typed by an operator.

Receiving Instruments.—For broadcast reception, receiving instruments can be divided broadly into two classes: (1) those in which the incoming radio waves are amplified and selected at their original frequency, thereafter being rectified and amplified again at audible frequencies; (2) those in which the incoming waves are first amplified and selected at their original frequency, after which they are rectified and the frequency is reduced to an intermediate value, being still inaudible or supersonic before being rectified a second time and amplified at audio frequency. A receiver of the latter type is known as a supersonic heterodyne. Using ordinary three-electrode valves or triodes, it is possible to get a large overall magnification and a high degree of selectivity more readily by the supersonic method than by a method where all the radio amplification is effected without frequency change. Nevertheless, the quality of reception with a "straight" high frequency amplifier is usually superior to that obtained with a supersonic heterodyne. By suitable design there is reason to believe that the difference in quality could be made negligible. However, the recent introduction of the screened tetrode, this being a valve in which the electrostatic capacity—which is mainly responsible for self-oscillation in high or in low frequency amplifiers—between anode and grid is reduced to a small value, will make the design of the supersonic heterodyne more facile. A diagrammatic representation of a "straight" circuit is shown in fig. 1.

Although in 1928 the majority of receivers on the market which were suitable for broadcast work used ordinary triodes, we shall consider the more modern receivers in which screened grid valves (*see* THERMIONIC VALVE) are incorporated in the high frequency stages. A receiver suitable for use a few miles from a main broadcasting station is illustrated diagrammatically in fig. 2. Here an open aerial is used, this being flatly tuned, since selectivity is unimportant with very strong signals and flat tuning prevents the higher audible frequencies being appreciably attenuated. The aerial can be either directly connected to the grid and filament of the rectifier V_1, or via a coupled circuit. The latter method is shown. After rectification by what is known as the "anode bend" method, which utilizes the curved portion of the valve characteristic, the signals consist of two components (a) high or radio frequency, (b) low or audio frequency. The former are undesired in the output and must be removed or filtered out. With this end in view, an inductance, L, of small self-capacity, is inserted in the anode circuit of V_1, whilst a small condenser, C, is connected from the anode of V_1 to the negative pole of the battery. The radio voltage change occurs on the anode of V_1 and the inductance, L, chokes it back so that it is bye-passed by C and little or no radio enters the audio frequency amplifying circuits. The audio frequency causes a voltage change across a tapped resistance, r, which is passed on to the grid of V_2 by means of the condenser C_1 and resistance r_1—commonly known as the grid leak. The resistance r is tapped to control the output intensity. Valve V_2 is coupled to the power or output valve V_3 by means of an iron-cored transformer T, or by another resistance capacity unit. The loud-speaker is associated with valve V_3 either directly or in conjunction with a filter circuit or a transformer. The filter circuit, as shown by the inductance L_2 and condenser C_2, prevents the anode feed current from the battery to the valve—which is usually fairly large—from passing through the loud-speaker windings, and it also prevents the loud-speaker current from passing through the battery.

To secure a uniform response from the amplifying system over a wide frequency band—apart from the loud-speaker—the various valves and their associated components must be specially selected and properly designed. For example, if C_1 and r_1 are made too small, those frequencies below the middle of the pianoforte will be so weak as to be inaudible. The same result will occur if the inductance of the primary winding of transformer T is too small, or if the internal resistance of valve V_2 is too large. Also, the bye-pass condenser C must not be too large, or some of the higher audible frequencies will be bye-passed in addition to the radio. This bye-pass condenser and the equivalent grid-to-filament capacity of V_2 are responsible for reducing the upper audible frequencies above 3,000 cycles. Moreover, if the transformer T amplifies the upper frequencies more than the lower, there will be a degree of compensation. Over-compensation can be readily averted by augmenting the value of C. Thus transformer T should have a rising characteristic as shown in fig. 3.

FIG. 3.—DIAGRAM OF TRANSFORMER (PRIMARY 50 HENRIES) WITH D.E.5. VALVE

When an open aerial, either indoors or outside, is impracticable, a loop or frame aerial can be used for receiving the local broadcasting station. Where the receiver is quite near the transmitter, an open aerial can be replaced by a frame aerial. For reception at an increased distance from the transmitter, it will be necessary to augment the valve amplification when a frame aerial is used. This can conveniently be effected by adding a stage of high frequency amplification in the form of a screened grid valve. Thus we must modify fig. 2 by adding a screened valve prior to the rectifier and replacing the open aerial by a tuned frame aerial whose sides can be from 18 inches to 30 inches long. The result is shown in fig. 4. Here it will be seen that the frame is tapped at the centre

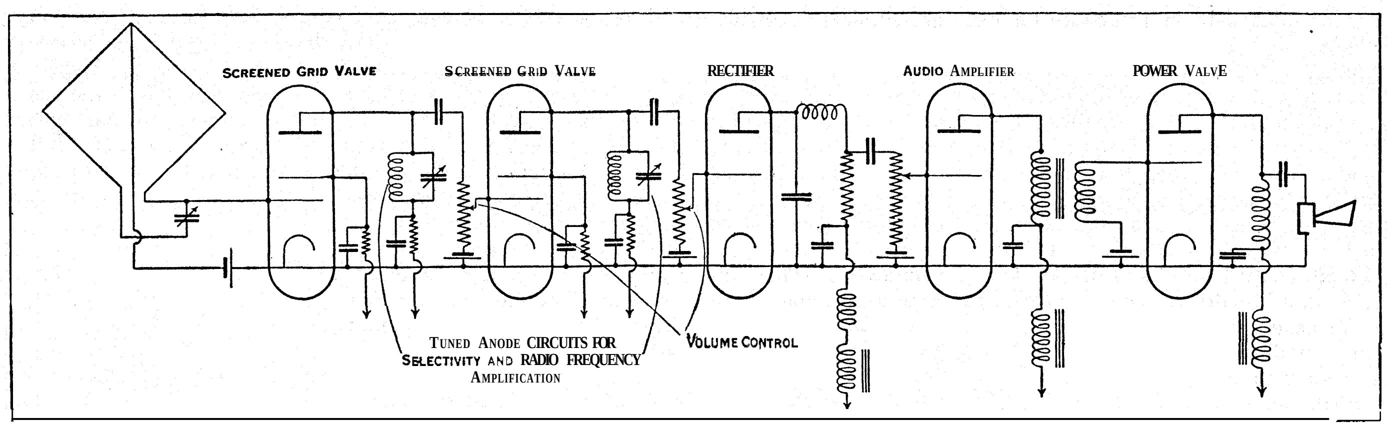

FIG. 4.— DIAGRAM OF RECEIVER FOR DISTANT BROADCAST RECEPTION, INCORPORATING H. T. FILTER SYSTEM. CENTRE TAPPED FRAME AERIAL AND TWO SCREENED H.F. VALVES

and only half of it connected across the grid and filament of the valve. This artifice is not always required for local reception, but is a useful artifice for distant reception. When a powerfui station, which it is desired to exclude, causes trouble, this mid point connection is often helpful in reducing the interference.

Distant Reception.— For the reception of stations 20 m. or more from a main broadcasting station the amplification must be still further increased. This can be accomplished in either the high frequency or in the low frequency portion of the receiver. It is better to achieve the desired result by increasing the high frequency amplification, for the two following reasons: (1) the response of the rectifier falls off rapidly when the strength of the incoming signals sinks below a certain level; (2) increased amplification must be accompanied by augmented selectivity, and the requisite electrical circuits can be incorporated in the high frequency portion of the receiver only.

As the amplification is increased, so also is the tendency of the receiver to generate spurious oscillations, particularly in the high frequency portion. In designing an instrument for distant reception, particular attention must be paid to the elimination of such effects. Moreover, it is imperative to screen each radio frequency circuit to prevent electromagnetic and electrostatic coupling, and to accomplish the same object, the radio frequency must be kept out of the audio frequency circuits. A very fruitful source of self-oscillation at radio and at audio frequency is to be found in the means used to supply filament and anode current to the valves. A battery, whether it be an accumulator or a dry cell, has an internal resistance which is by no means negligible when the voltage amplification runs into thousands. By virtue of this resistance, the relatively large alternating current in the valve preceding the rectifier causes a voltage drop which is applied to other radio frequency amplifying valves at the beginning of the amplifier. This causes enhanced amplification which usually culminates in self-oscillation, thereby putting the receiver out of action. A similar argument applies to the audio frequency portion of the receiver. To avoid this "coupling" due to the battery, it is absolutely essential to use a special system whereby the battery feed is electrically filtered or purged of the alternating current. The golden rule is that no alternating current, either of radio or of audio frequency, must pass through the battery. All alternating current is, therefore. bye-passed from the neighbourhood of the positive terminal of the high tension battery, to the negative terminal. In series with the first battery tapping point is connected an inductive resistance of low self-capacity, while across its outer terminal and the negative pole of the battery a condenser of large capacity is shunted. The resistance offers great impedance to the currents of radio frequency, whilst the condenser bye-passes them with ease. Hence the alternating current through the battery is negligible. A similar procedure is adopted for the audio frequency feed where an audio frequency choke is used in place of a radio frequency choke. Both choke and condenser must have much greater values than those for the radio frequency filter.

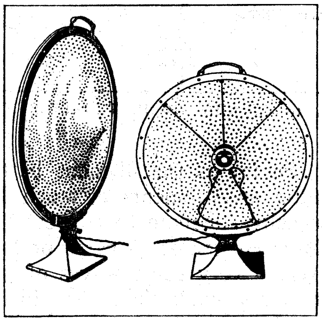
So far as the filament battery is concerned, the question of filter arrangements is much less acute. In this instance, it is usually adequate to connect the positive battery terminal via a large condenser to earth or to the metal screen of the receiver. Where very short waves of 50 metres are used, it is expedient to put a choke in one or in both filament legs. In a complete receiver designed on the above principles the centre tapped frame aerial is followed by two stages of high frequency amplification using screened grid valves with tuned anode coupling, the coils being of toroidal construction and having substantially no external magnetic field. The remainder of the circuit is identical with that in fig. 2. As a limiting case, three high frequency stages can be used, but great care must be exercised to obtain adequate screening of the various components. The side of the frame aerial in this case should not exceed about 12 in. in length, since the amplification is so enormous that signals are drowned by noise.

Degree of Amplification.— A few remarks on the amplification obtained in modern receiving sets may be of interest. There are two methods of expressing amplification:—(I) by the ratio of the input voltage to the power valve to that induced in the aerial by the electro-magnetic waves; (2) by the ratio of the electrical power in the loud-speaker to the power received by the aerial. The power amplification is enormously greater than the voltage amplification and is sometimes cited for purposes of advertisement. It is more usual in scientific circles, however, to consider the voltage amplification. Neglecting interaction of various components in a receiver, the total amplification is the product of the amplification per stage. With any type of valve the gain per stage is limited because of the ever present possibility of self-oscillation. Modern screened valves can be used to secure a stable gain of from 30 to 40 per stage over the wave range 300 to 600 metres. Taking, therefore, the magnification per stage of the last mentioned receiver we obtain the following approximate figures: 1st radio frequency ÷30, 2nd radio frequency ÷30, rectifier ÷20, 1st audio frequency ÷70. The product of these is 126,000. This, however, must be divided by 4 to allow for the audio frequency voltage modulation of the transmitter being only $\frac{1}{4}$ of the radio voltage on the aerial. The an~plification due to the frame has been neglected. It may be estimated at about 60, although higher values can be obtained at the expense of stability. Taking the modulation factor and the frame into account, we get a resulting factor of 20, so that the total magnification is just short of 2 million-fold.

Mains **Supply** Units.—To avoid the difficulties concomitant with high and low tension batteries, particularly the former, a number of schemes have been devised for supplying receivers with the necessary current from either alternating or direct current supply mains. This permits an adequate anode voltage being supplied to the power valve, so that a reasonable intensity of sound can be secured before "blasting" is encountered. A more extensive use of these supply units is advocated.

Radio Telegraphy.— Receivers for this purpose have been described in the appropriate place and it is only necessary to say here that although rhe principles involved are similar, the design technique is quite different. The low frequency portion of the amplifier is preceded as usual by radio frequency circuits and a detector, and a separate radio frequency oscillator is used to generate an audible beat note with the incoming radio frequency. Furthermore, the audio frequency consists of a series of circuits *tuned* to the beat note. Before being passed on to the recording instruments the audio note is rectified and smoothed, so that the result is a series of dots and dashes, in the Morse code, which can be considered as an interrupted direct current.

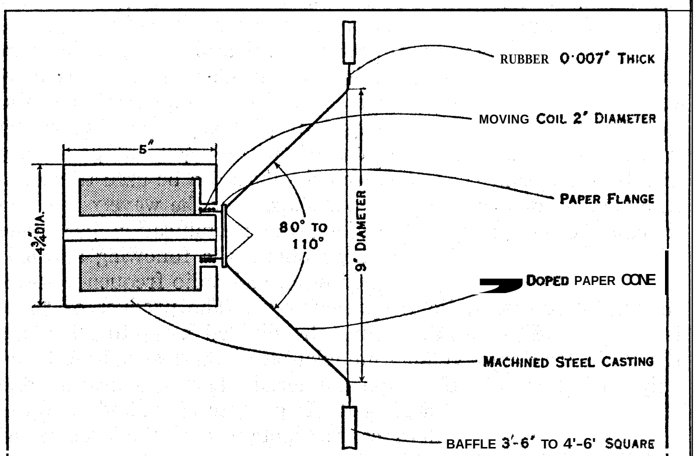
Loud Sounding Telephones (Loud-speakers) The output from a broadcast receiver is taken either to a telephone worn on the head or to some form of loud sounding telephone. The reception on a headphone cannot be realistic, since the original studio conditions and the degree of loudness are completely lost. To obtain more realistic, reproduction it is essential to employ some form of loud sounding telephone—which is not applied to the ear. The reproduction approaches most closely to the original conditions when the room where the loud-speaker is situated is heavily draped to damp the sound, and the intensity of sound from the loud-speaker is equal to that which would be heard by the listener were he or she situated at the same point in the studio as the microphone.



FROM N. W. MCLACHLAN, "WIRELESS LOUD SPEAKERS" (THE WIRELESS WORLD)

FIG. 5.—THE AUTHOR'S CLOTH CONE LOUD-SPEAKER. (LEFT) REAR VIEW; (RIGHT) FRONT VIEW WITH COVER REMOVED

The subject of loud-speakers is wide and varied and can only be touched upon lightly; and though there are numerous forms on the market few reproduce with any degree of accuracy. The essential components of a loud-speaker are some form of diaphragm to agitate the air and a mechanism for driving the diaphragm to and fro under the stimulus of the electric currents from the power valve of the receiver. The motion of the diaphragm reproduces—in a degree—the sounds which are picked up by the'microphone in the broadcasting studio or auditorium.



FROM N. W. MCLACHLAN, 'WIRELESS LOUD SPEAKERS" (THE WIRELESS WORLD)

FIG. 6.—COIL DRIVEN CONE WITH FLAT BAFFLE

When a large diaphragm is used the most general form is the cone. When small conical or flat diaphragms are used, *e.g.,* 2 in. diameter, the loud-speaker is fitted with a horn to increase the intensity of sound and provide the proper coupling between the diaphragm and the surrounding air. No horn is required with a large diaphragm, *e.g.,* 9 in. diameter, but to secure the requisite degree of intensity the two sides must be isolated as explained below. The material of the cone of a large diaphragm is usually some kind of paper, but impregnated fabric is also used, as in the author's cloth cone, fig. 5. When a large diaphragm is in action, at any particular instant the air at one side is compressed and on the other side rarefied (reduced in pressure). Now since one side is at a higher pressure than the other it is necessary to prevent a sound wave travelling from the side at higher to that at the lower pressure, and to avoid this effect the usual practice is to isolate the two sides of the diaphragm by mounting it either at the centre of a large flat board or in one face of a cabinet. Having mounted the diaphragm, it is essential to apply some form of driving force, the mechanism for which is actuated by the electric currents from the receiver. There are two main forms of loud-speaker drive for large diaphragms: (a) reed drive, (b) coil drive. Type (a) is characterized by a reed of steel or other suitable magnetic material poised over two pole pieces on which are wound many turns of wire. The magnetic circuit of the pole pieces is completed through a strong permanent magnet. Since the reed has a natural frequency and its response with frequency becomes gradually less at low and at high frequencies, care is required in designing the diaphragm and its peripheral support to secure a good acoustic register. Where only one reed is used, it is difficult to get full strength in both the lower and the upper register. In general, it is better to get a good upper and middle register. At the same time, it is very desirable to reduce resonances and harmonic tones not present in the original sounds to a minimum. This is accomplished in a new form of reed drive loud-speaker, the Amplion Lion.

FIG. 7.—EXPERIMENTAL COIL DRIVEN CONE

B. Multiplying wooden baffle, C. cradle holding pot, D. doped paper diaphragm, F. felt for damping, (FR) frame on which diaphragm is mounted, M. field magnet pot, (MC) magnet control rheostat and anti-spark resistance, S. diaphragm suspension, T. input transformer for moderate intensity, W. leading in wires to moving coil

The drive indicated as type (b) is capable of giving greater output in the bass register than the reed drive. A coil of wire, situated in the magnetic field produced by either a strong permanent or an electromagnet, is attached to the back of a paper cone, fig. 6. The speech and music currents are passed through the coil and cause the diaphragm to move accordingly. This class of instrument is capable of reproducing orchestras at their original strength. A replica of the coil drive instrument designed by the author and now operating on weekdays and on Sundays in the South Kensington Science Museum, is shown in fig. 7.

See N. W. McLachlan, *Loud Speakers.* (N. W. McL.)

RADIOTHERAPY is the treatment of disease by the application of rays of radioactive substances (*i.e.,* Rontgen rays). The discovery of X-rays by Rontgen in the autumn of 1895 marked an advance in the history of science, which, even yet, is not appreciated by the average individual. Rontgen himself realised immediately the value of his discovery to the science of medicine, and communicated it to the Physico-Medical Society of Wurzburg. Since then, if one excepts the years 1914–1918, hardly a month has passed without some innovation.

In 1910 the X-ray tube had varied but little from the original tube used by Rontgen and Crookes, the improvements in focusing and increasing the intensity of the rays being due to the labours of Campbell Swinton and chiefly to Prof. Jackson in 1896; indeed the modern focus tube (gas tube) has not materially changed since then. In this tube, the current is carried across the tube by a certain amount of gas, which is left behind in the process of evacuation. The current, impinging on a tungsten target, under a pressure of anything over 80,000 volts, results in the production of X-rays, which rays are now known to be electro-magnetic impulses of very short wave-length. The only disadvantage of this tube is that individual control of the current and voltage is not absolute owing to fluctuations in the amount of residual gas. Despite this, however, it is largely used and for many purposes possesses advantages over the Coolidge tube.

The Coolidge Tube.—At a later period Dr. Coolidge of New York discovered that a glowing body emitted electrons, and at once designed a new type of bulb in which the current was carried across the vacuum by a stream of electrons from a hot tungsten wire. The hotter the wire the greater the current which passed across the bulb. This, of course, solved the problem of separate control of the voltage and the current and thereby the problem of being able to reproduce exact working conditions at any interval. Unfortunately the hope, raised at first by the production of this tube, of obtaining an absolutely homogeneous beam of X-rays, was not realised.

The intensity of the X-rays depends upon the voltage employed to produce it and as the manufacture of high-potential generators (induction coils and step-up transformers) has improved out of all recognition since 1910, we can now produce rays of great intensity, far greater than are needed for radiographic purposes.

On the photographic side, improvements in technique have been very noticeable. the most noteworthy improvements being the use of intensifying screens to shorten exposures, double-coated films to increase the contrast of the negative and the Potter-Bucky diaphragm, the latter an ingenious contrivance for the purpose of cutting out secondary radiations and thereby sharpening the resulting picture.

During the years 1914–8 science was more or less subservient to the claims and the necessities of warfare, but even in this limited field X-rays were of enormous help. The localisation of bullets and shrapnel, which by any other means would have been impracticable, if not impossible, was carried out by numbers of experts, and to the energies of these men a host of soldiers practically owe their lives.

Employment in Diagnosis.—The past few years have seen great activity in the X-ray world. Improvements in technique previously mentioned have brought the use of X-rays into much greater prominence in the study and the diagnosis of internal diseases (*see* DIAGNOSIS). Skiagrams of the lungs, which were difficult to make and still more difficult to interpret, are now of the very greatest possible value in the study of diseases of the heart (*q.v.*) and lungs. It is no exaggeration to say that no diagnosis of disease of either of these organs is complete without an X-ray examination.

This advance is seen in the large hospitals for diseases of the chest; where formerly only a few hundred examinations were made, now the number amounts to thousands in the year. Whereas the air-filled lungs showed up clearly against the more dense, blood-filled heart and solid thoracic walls, the abdominal organs, that is to say the hollow viscera, being all of the same density, were all penetrated equally by X-rays and consequently were not readily differentiated on a plate. For a long time this difficulty appeared to be unsurmountable. Many substances were known to be opaque to X-rays but none of them could be taken with safety. Haudek, of Vienna, made careful experiments with bismuth sulphate mixed with jam and watched its progress through the oesophagus, but completely forgot to look for it in the stomach.

Use of Bismuth.—In 1901 Becker gave small doses of the same material and was the first to publish anything definite about the radiology of the alimentary tract. His results were confirmed in the same year by other workers, but the danger of poisoning (chiefly from metallic impurities in the bismuth) was so great that not sufficient could be given for diagnostic purposes, and nothing of any special value resulted. Somewhat later, the publication of a paper on the treatment of gastric catarrh by large doses of bismuth inspired Rieder, of Munich, to give large doses of bismuth in order to examine the stomach and intestines by means of X-rays.

Some few cases of poisoning were later reported, but with the help of the chemist an absolutely non-toxic preparation of bismuth carbonate came into use. The production of this non-toxic preparation of bismuth was difficult and it never attained to universal popularity. In 1910 experiments were made with barium sulphate—which was found to be almost as opaque as bismuth and not only much more readily freed from inorganic impurities but infinitely cheaper to use. With very few exceptions radiologists use some form of this salt in diagnoses.

The Gastro-intestinal Tract.—The production of a safe and suitable method of making the gastro-intestinal tract opaque very greatly stimulated the investigations which were being carried on as to the condition of the alimentary tract in health and in disease. The study of both is still far from complete but, even with the results so far attained, diagnosis of intra-abdominal conditions has been greatly improved and numerous complaints previously described as "indigestion" and "gastritis," for example, are now readily classified.

Cancer and Gastric Ulcers.—Cancer of the stomach gave fairly typical X-ray evidence, but gastric ulcer proved almost as elusive to the radiologist as to the clinician. Certain investigators had observed a "niche" or recess on the wall of the stomach but its significance was not appreciated. In the same year (1910), Haudek and others, but chiefly the former, produced definite evidence that the "niche" was in reality an ulcer on the gastric wall filled with barium. Since then many other signs indicative of gastric ulcer have been noted and now the diagnosis of this condition is not a difficult matter. Thanks to the labours of Carman, Miller, Gregory Cole and Barclay, the duodenum is becoming an open book to the radiologist particularly in respect of ulceration.

Therapeutic Values.—From the earliest days of the discovery of X-rays, they were known to have certain curative properties, and scientists all over the world have been experimenting to place this form of treatment on a sound and scientific basis. Intractable skin diseases (*q.v.*) which resisted every other remedy often responded to X-rays, and it was noticed that some forms of malignant disease disappeared after treatment by irradiation. Means of accurately measuring the dosage of the rays were not known, but cancer had become so terrible a scourge that they were utilised indiscriminately for its relief, and at times with disastrous results. From 1905 onwards methods of measurement improved and in 1914 a dose could be administered with a certain amount of accuracy, the risk of burning became almost negligible, and we are now in possession of instruments capable of giving precise knowledge as to the amount of X-rays falling upon a given area. A spectroscope is used which takes a photograph of the X-ray spectrum. Prom it the wave-length can be ascertained and the shorter the wave-length the more penetrating the X-ray.

Most of this work was carried on in Germany, where the idea prevailed that it was only necessary to get an intense enough ray and to measure it carefully in order to kill cancer. Apparatus for the production of these very intense rays was soon devised and before very long a great number of patients were undergoing treatment, so rapidly did this idea stimulate the popular imagination. In the early stages of this new form of X-ray therapy the results appeared to be most encouraging and the conquest of cancer was thought to be within reach. Subsequent statistics showed relief to be merely temporary. Great credit is, however, due to the early German workers and other pioneer specialists for the ingenuity and skill shown in standardizing and rendering accurate the dosage of X-rays; but as a method of treatment of cancer we are getting no better results than were obtained in 1910. Russ and Colwell (*Radium, X-Rays and the Living Cell*) put the matter thus: "In radiology applied to biological problems there is a double difficulty, for the intensity of the radiation used, whether it be X-rays or Radium is a quantity which under many experimental conditions presents very considerable difficulties in its accuracy of measurement, *and the animal itself provides a complex which refuses to be reduced to simple terms.*"

See X-RAYS; RADIOLOGY; X-RAY TREATMENT.

BIBLIOGRAPHY.—H. A. Colwell and S. Russ, *Radium, X-Rays and the Living Cell* (1924); R. Knox, *Radiography and Radio-therapeutics* (1919). (S. ME.)

RADISH, Raphanus sativus (family Cruciferae), an annual or biennial grown for its large, succulent root. The edible part of the root, together with some hypocotyl, forms a structure varying in shape, among varieties, from spherical, through oblong, to long cylindrical or tapered. Outside colour of the root varies from white, through pink to red, purplish and black. Size of edible part varies among varieties from a few grams in the most popular early American and European varieties to a kilogram or more in the late Japanese field type of radish, or daikon. As generally grown, flower stalks form the first season, bearing white or lilac veined flowers. The seeds are borne in a spongy, non-dehiscent, beaked pod called a silicle. The small, quick-growing spring varieties have a mild crisp, moderately firm flesh, and are quite perishable. The large, slow-growing summer and winter types have pungent, firm flesh. Winter varieties can be stored through the winter. The common radish is probably of oriental origin. R. *raphanistrum* is a wild radish found along the Mediterranean. The rat-tailed radish (R. *caudatus*) has no enlarged root, but bears enormous seed pods 8–12 in. long which are eaten fresh or pickled. R. *sativus* (var. *longipinnatus*) produces deeply pinnate leaves up to 2 ft. long; the roots are large, firm and are grown as a winter radish. This type is much grown in the orient and is generally known as Chinese radish. (V. R. B.)

RADIUM (Symbol Ra, atomic number 88, atomic weight 225.95) is the best known and the most important member of the radio-elements, discovered by Professor and Mme. Pierre Curie and G. Bémont of Paris in 1898. The position of radium in the periodic system of classification is unmistakably that of the heaviest member of the alkaline-earth metals, calcium, strontium and barium, and its chemical properties and all its physical properties, except the most important one, its radioactivity, are those to be expected from the element which occupies this position. It is as a radioactive substance, however, and not merely as a chemical element, that radium claims attention, and as such it is dealt with in the article RADIOACTIVITY.

The Disintegration of Radium. — A radio-element is one which possesses, in addition to the properties of a normal element, the power of emitting a- or @-particles. In so doing the element breaks up to form a new element, or, as it is expressed technically, it disintegrates. The first of these particles is a doubly-charged atom of helium, equal in weight to four units, which is expelled from the centre of the atom with a velocity of about 10,000 miles per second. This almost incredible velocity is surpassed by that of the other particle which is an electron, that is to say, a rapidly-moving single charge of electricity without mass. The velocity of the β-particle varies from about 50,000 miles per second to that of light, 186,000 miles per second. The β-particle is sometimes accompanied by a very penetrating radiation, the γ-ray, which is, in nature, akin to waves of light.

The rate at which disintegration occurs proceeds always according to one fixed plan. In a given interval of time, a second or a day or a year, a definite fraction of all the atoms which make up the radio-element, breaks up, and this fraction, fixed by Kature, cannot be varied by man; it is the same whether millions of millions of atoms are being considered or a few thousands only. No chemical combination of the radio-element with other atoms, no physical agency such as enormous temperatures or pressures seems able to affect the value of this fraction at all. For radium this fraction is $\frac{1}{2,280}$ per year: this means that if we were to weigh out 2.280 units of this element to-day, in a year's time 2,279 would be quite unchanged and 1 would have been broken up. The radium that has broken up, however, is not simply radium in some other form, it is something entirely different; the expulsion of either an α- or a β-particle has so altered the radium atom that it has become a new one. A radio-element, such as radium, consequently contains at least two kinds of atoms, those that have already broken up and those that have not. The unchanged atoms comprise what is called the parent substance; the residual atoms compose the product. This product is perfectly distinct from its parent in physical and chemical properties, and can be easily separated from it by the ordinary methods of analytical chemistry. Radium's product is the gaseous element radon (*q.v.*), which is the heaviest of the inert gases. Radium being a solid and radon a gas at the ordinary temperature, their separation is an obvious one. If now the product happens, like its parent, to be radioactive, a certain fraction of it will disintegrate in a unit of time to form a third substance, and this substance, if radioactive, will produce a fourth, the fourth a fifth, and so on, till a substance is reached which is not radioactive; whereon this series of radio-elements ends abruptly. Such a series is called a *disintegration series;* in it each element is the parent of the one that follows and the product of the one that precedes. Radium and radon are respectively the sixth and seventh of the disintegration series that begins with the rare element uranium and ends with the common element lead. (See RADIOACTIVITY.)

In the accompanying table are set out the elements of the uranium-radium-lead disintegration series, with the symbols by which they are described in the literature on radioactivity, the nature of the particle or ray expelled by the element, the atomic weights of the elements, and finally their atomic numbers. It will be seen from the table that when an a-particle is expelled, the atomic weight of the product is 4 units less and the atomic number two less than that of the parent; and that when a @-particle is expelled the atomic weight of the product is identical with that of the parent, but the atomic number is one greater. The reasons for this generalization are given under RADIOACTIVITY.

Name of element	Symbol	Radiation emitted	Approximate atomic weight	Atomic number
Uranium . . .	UI	α	238	92
	U-X_1	β	234	90
	U-X_2	β	234	91

	Ra-*B*	β	214	82
	Ra-*C*	β, γ	214	83
	Ra-*C′*	α	214	84
	Ra-*D*	β	210	82
	Ra-*E*	β	210	83
Polonium . . .	Po	α	210	84
Lead	Ra-Ω	. .	206	82

The implications of the bare statement that radium is a member of the uranium-radium-lead disintegration series are remarkable. The statement implies, firstly, that the only sources of radium in Nature are minerals containing uranium, for without the ultimate parent of the series there can be no series, and therefore no radium. Secondly, since radium is produced by the disintegration of its parent ionium and disappears on disintegrating into its product radon, the weight of radium in a mineral containing a given amount of uranium is fixed at the weight of radium which has the same number of atoms breaking up to form radon in a given interval of time as is produced in the same time by the disintegration of ionium. There is, thus, a definite ratio between the weight of uranium in a mineral and the weight of radium; experimentally this is found to be 1 to 0·00000033. To extract a gram of radium from a mineral which is half uranium, therefore, no less than 5·9 tons of the mineral must be worked up, or, to extract a pound, no less than 2,680 tons. In actual practice the minerals are rarely as rich as this, and one containing 1 gm. of radium in 10 tons of ore is considered rich; even minerals which contain only 1 gm. in 200 tons are worked. It is not surprising, therefore, that the price of radium is about £15,000 per gram.

Industrial Production. — The principal minerals containing uranium, and therefore radium, are pitchblende, carnotite and autunite. The first of these consists of the oxide of uranium, more or less pure, and is found principally in Czechoslovakia and in Belgian Congo; the second is a vanadate of uranium and potassium mined in Colorado, Utah, and Australia; the third is a phosphate of uranium and calcium mined in Portugal and in the U.S.A. The method of extracting radium varies with the nature and quality of the ore, but in broad outline, all processes consist of five main steps first worked out by Mme. Curie. These consist in getting the uranium mineral into solution, separating from the solution all metallic sulphates which are insoluble in water (these include the whole of the barium and the radium constituents of the mineral), the conversion of the sulphates into double salts, the purification of the compounds of radium and barium, and finally the separation of the radium from the accompanying barium by a process of fractional crystallization.

At St. Joachimstal in Czechoslovakia the broken-up pitchblende is treated with a mixture of nitric and sulphuric acids of such concentrations that, whereas the whole of the uranium goes into solution, the radium remains behind as insoluble sulphate along with impurities of calcium, barium and lead. These sulphates are then boiled several times with a solution of sodium carbonate and so converted into carbonates, and thence into chlorides. A repetition of this process separates the radium and barium from the impurities calcium and lead. Finally, owing to the fact that the chloride of radium is much more insoluble than that of barium in a solution of hydrochloric acid, it is possible to enrich a mixture of radium and barium chlorides in the former until finally radium is quite free from barium.

At Denver, Colorado, the carnotite is heated with a solution of concentrated nitric acid containing hydrochloric acid which dissolves the radium as well as the uranium and the vanadium. To this a solution of barium chloride is added. When the acidity of the solution is reduced by the addition of alkali the barium, and with it the radium and lead, are precipitated as sulphates and removed from the solution by filtration. These sulphates are then heated in a crucible of graphite with wood charcoal and so converted into the sulphides, which unlike the sulphates are easily soluble in hydrochloric acid. From this solution the lead is precipitated by one chemical reagent and the radium and barium by another. The enrichment of the radium in the radium-barium mixture is based on the comparative insolubility of the bromide of radium, and not, as at St. Joachimstal, on the comparative insolubility of the chloride.

Chemical Properties.—The principal compounds of radium are the sulphate $RaSO_4$, the chloride $RaCl_2$, the hydrated chloride $RaCl_2.2H_2O$, the bromide $RaBr_2$, the hydrated bromide $RaBr_2.2H_2O$, the sulphide RaS, the nitrate $Ra(NO_3)_2$, the carbonate $RaCO_3$, and the hydroxide $Ra(OH)_2$. Like the corresponding compounds of barium, strontium and calcium, these are all colourless compounds and their chemical properties may be summarized in the remark that they are exactly what would be expected from a study of the compounds of these three elements. It is not surprising therefore that a purely chemical study of radium compounds has not occasioned much interest. At 25° C the solubility of strontium sulphate is $\frac{1}{14}$ that of calcium sulphate, while that of barium sulphate is $\frac{1}{65}$ that of strontium; it is consistent that the solubility of radium sulphate is $\frac{1}{100}$ that of barium sulphate. As with sulphates, so with chlorides and bromides. On the other hand the lightest of the alkaline-earth metals, calcium, has the most insoluble hydroxide in water; it is to be expected therefore (and confirmed experimentally) that the heaviest, radium, has the most soluble hydroxide.

As with such a property as the solubility of typical chemical compounds, so with most other properties. The optical spectrum of radium, for example, is composed of a comparatively small number of lines of great intensity. The strongest line in the visible part of the spectrum is in the violet, and this line is a very sensitive test for the presence of radium. In this, radium resembles barium, strontium and calcium. They too have a comparatively small number of spectral lines of great intensity, the most prominent of which are used in chemical analysis as tests for their presence. Again, the method in use for the preparation of metallic radium is identical with that used for preparing barium, namely, first the metal is deposited by an electric current on to mercury, and then the volatile mercury is removed by distillation in a current of hydrogen. The metal which remains behind is white, melts at about 700° C, and greatly resembles barium in its chemical reactions. It must be preserved out of contact with the air; it dissolves in water and in all acids with the evolution of hydrogen, forming the hydroxide in the first case and the corresponding salt in the other cases. Radium is generally sold in the form of the chloride or the bromide. mixed, when impure, with the corresponding compound of barium. For the physiological effects of radium see RADIUMTHERAPY.

For scientific purposes standards of radium have been made with which any sample of unknown strength may be easily compared. The comparison is made not by their respective weights but by the intensities of their radiations. The international radium standard was prepared by Mme. Curie and is kept in France at Sèvres; secondary standards, carefully checked with the primary one, are kept in other places, particularly at the Radium Institute, Paris, the National Physical Laboratory, Teddington, England, the Physikalisch-technische Reichsanstalt, Berlin, the Radium Institut, Vienna and at the U.S. Bureau of Standards, Washington. The sample to be measured, which should exceed in intensity that of one-tenth of a milligram of pure radium, is sealed up in glass for at least one month, so that what is called the equilibrium quantity of radon and the successive products radium A, B, C and C′ have formed. The intensity of the γ-radiation from radium C is then determined by an electrical method under specified conditions which need not be detailed. Since there is a constant ratio between the intensity of the γ-radiation from radium C and the actual amount of this product, and also between the amount of this product and that of radium, the measure of the γ-radiation is a measure of the quantity of radium in the preparation under examination.

Radioactive Properties.—The chief particle emitted by radium on disintegration is an α-particle with a range in air of 3.39 cm. at 15° C and the ordinary pressure. (The range is a distance characteristic of a radio-element traversed by its α-particle, beyond which the latter cannot be identified by any known instrument.) The velocities with which the particles issue from the source of radium are identical and equal to 1,510 millions of centimetres (9,380 miles) per second. The number of α-particles emitted per sec. by 1 gm. of pure radium is about 37,000 millions, a number obtained experimentally by counting the flashes per second made by the impact of the particles on a luminescent screen of zinc sulphide, placed at a known distance from a minute fraction of radium of known mass. An idea of the colossal number of atoms which compose 1 gm. of radium (and similarly, of course, for any other substance) may be gained from the statement that despite the destruction of 37,000 millions of atoms of radium per sec. through disintegration, the actual loss of radium is only about 0·04% in a year.

No less remarkable is the amount of energy liberated by radium. This amounts to 25·5 calories per hour or 223,000 cal. per year for every gram of pure radium. This energy shows itself partly as heat (all radium preparations warm the objects in their near vicinity), and partly as light (glowing in the dark). Such an evolution of energy without apparent diminution (the diminution is only 1 in 2.280 parts in a year) is on much larger scale than that obtained from chemical reactions. It is much higher indeed than has been indicated because the figures given refer to radium free from its products. With its products radon, radium A, radium C′, and polonium, which themselves expel particles (see table), the energy evolution per year is as high as 1,236,000 calories. This, owing to the slow rate of decay of radium, will not be reduced to half, it may be calculated, until after 1,580 years, or to a quarter until after 3,160 years, or to an eighth until 4,740 years have gone by. The evolution will, in fact, go on for ever, although at a steadily diminishing rate. Such a rate of energy emission is about a million times greater than that from an equal weight of chemical reactants.

Radium, in addition to its α-particle, expels also a comparatively unimportant β-particle and a feebly penetrating γ-ray. These must not be confused, however, with the β-particles and the γ-radiation which are emitted by preparations of radium. If a preparation containing radium be sealed up so that its gaseous product radon may not escape, then quickly there form in it radon, radium A, B, C and C′ (which in a month have formed in maximum amount), and more slowly there form radium D, radium E and polonium (which in about 150 years reach their maximum amount). Since these products expel α- and β-particles, and in one case a penetrating γ-radiation, the radiations from radium appear much more complex than those from radium without these products. Radon, radium A, radium C' and polonium expel a-particles with ranges in air of 4·12, 4·72, 6.97 and 3·925 cm., respectively (cf. radium, 3.39 cm.); radium B and radium C expel very penetrating, and radium D and radium E feebly penetrating, β-particles; accompanying the β-particle from radium-C is a very penetrating γ-radiation.

Physiological Effects.—A strong source of radium, if left on the skin for some time, causes sores which have the appearance of burns; prolonged exposure to the radiations leads to atrophy of the part affected and perhaps to cancer. Under suitable conditions, however, the rays from radium have been successfully used in the treatment of cancer and are undoubtedly beneficial in this and similar conditions, though it cannot yet be said that radium is a "cure" for all forms of this scourge. Even when it cannot be averred that the rays heal, it is established that they relieve pain in cancerous conditions. Healthy tissue is from four to seven times more resistant to the action of the rays than diseased tissues, and in conditions in which the diseased tissue may be destroyed without any of the healthy tissue radium is very beneficial. Young plants benefit in growth when exposed to a certain small amount of radiation (it is administered principally as radon) but are harmed by a larger amount. In this respect the rays resemble other specifics which are beneficial in small, but harmful and even poisonous in large, amounts when applied to living things. A strong source of radium can destroy the vitality of seeds and kill the bacteria which cause typhus, cholera, anthrax and similar diseases; even caterpillars have been killed by the rays. In 1906 it was claimed that the rays from radium could cause spontaneous generation, a claim that was never confirmed and is now regarded as fantastic.

Soddy, *The Chemistry of the Radio-Elements* (1915), and *The Interpretation of Radium* (1920); A. S. Russell, *Chemistry of Radioactive Substances* (1922); G. Hevesy and F. Paneth (trans. R. W. Lawson), *Radioactivity* (1926, bibl.); S. Meyer and E. Schweidler, *Radioaktivität* (1927, bibl.). (A. S. R.)

RADIUMTHERAPY. Since 1913 the name Curietherapy has been applied, particularly in France, as a generic term to therapeutic methods in which radioactive bodies are employed. The term *radiumtherapy* is used primarily for curietherapy carried out by means of radium, and (by extension) by radioactive bodies derived from radium.

Radiumtherapy dates from the times immediately following the discovery of radium by the Curies (1898); it succeeded observation of the effects produced on the skin by radium tubes kept in its vicinity (Becquerel, P. Curie). The first case-notes on radiumtherapy were published by Danlos (1904).

There are two methods of employing radioactive bodies therapeutically. One consists in introducing them into the blood, so that they may be diffused throughout the organism: this is called general curietherapy. The other consists in producing a local action in the form of limited fields of radiation, and this is called local or focal *curietherapy*.

I. General **Curietherapy.**—In this imponderable quantities of radioactive bodies are used. These bodies act on the living tissue with the whole of their alpha-, beta-, and gamma-ray systems. Inasmuch as the alpha-ray system represents more than 90% of the energy released by the disintegration of radium and its disintegration-products, it is correct to say that general curietherapy is primarily an alpha-ray treatment.

Radium is no longer employed in general curietherapy, because, owing to its insolubility and slowness in disintegration, it remains for a long time, and not without danger, in the organism. It is, however, possible to inject radon (radium emanation), a solution or suspension of the active deposit of radon (radium A, B, C), or radium F or polonium (see RADIUM). In practice the gaseous radon is used.

Radon can be employed without danger because it does not accumulate (being eliminated by pulmonary ventilation) and lasts a very short time (period of semi-disintegration = 3·85 days). It is administered either by inhalation, or as a drink, or by subcutaneous or intravenous injection. By inhalation in closed cabinets an equilibrium lasting several hours can be established between the radon content of the confined atmosphere and that of the interior of the organism. The inhalation of the gases given off by the waters of radioactive mineral springs is a variety of general curietherapy. It is believed that radioactivity is a highly important factor in the efficacy of certain mineral springs.

It is in the treatment of some general diseases, of which chronic rheumatism is the most favourable type, that general curietherapy has been employed with the highest degree of success. The injection of considerable quantities of radon has also been advocated in the treatment of cancer, but the efficacy of this treatment requires confirmation.

The physiological and therapeutic actions of radioactive bodies introduced into the interior of the organism are sure and powerful, but insufficiently known; their use is not devoid of risk (particularly on account of their destructive effect on the haematopoietic cells). For this purpose, substances of the radium family have alternatives in the homologous substances of the thorium family. Thorium X in particular has a period of semi-disintegration of the same order as that of radon; it is not volatile, and is less rapidly eliminated than radon.

II. Focal **Curietherapy.**—This has gained a very important place in medical practice. In this method, radium and radon are superior to other radioactive bodies. The superiority of radium is due to the relatively large quantities available (now measurable in grammes) and to the constancy of its radiation, which is itself a result of the slowness with which spontaneous destruction proceeds. The chief advantage of radon is that the radium solutions from which it is periodically extracted can be preserved from loss. Notwithstanding the somewhat rapid decrease of radiation in the case of radon, the biological effects of a radium focus and a radon focus are approximately the same, if the rays are purified by filtration through similar screens.

Alpha-rays are not employed in focal curietherapy, as their penetrative power is very small.

General Technical **Principles.**—Dominici (1907) showed that equal efficacy is obtained through a greater thickness of tissue if the beta-rays and the less penetrative part of the gamma-rays are stopped by suitable filtration. This most important discovery led to the use of radium or radon foci enclosed in heavy metal cases, which filter all but the gamma-rays.

Radium is employed in the form of powdered sulphate (insoluble); with this salt the manufacturer completely fills cylindrical tubes. The length and diameter of these tubes are proportionate to the content desired. The powdered sulphate of radium is diluted with a suitable quantity of sulphate of barium, when a tube has to be completely filled with a small dose. Usually the tubes are made of platinum. The cavity is generally 0·5 or 1 mm. in diameter and from 10 to 30 mm. in length, and the wall of the tube 0·5 or 1 mm. thick. The strength of the filter can be increased as desired by the addition of a detachable case made of gold, lead, etc. The content of the tube is calculated in terms of radium element; for ordinary purposes it varies from 2 to 15 milligrammes. The tube is closed with a platinum stopper hermetically sealed with gold. One end of the tube is rounded; the other has a needle-eye through which a thread can be passed if necessary. The radioactivity of the tubes is not constant unless they are air-tight and it should therefore be measured from time to time.

Series of tubes are made containing the same weight of radium —*i.e.*, having the same power—and interchangeable. These series of sources of radiation can be used to make up radiant surfaces of any size, shape and power desired.

For radium puncture (see p. gog), hollow needles with iridio-platinum points are used. It is not advisable to charge these needles with more than 1 or 2 milligrammes of radium element. Their wall-thickness varies from 0·3 to 0·5 mm.

Radon is generally contained in glass capillary tubes, and these tubes serve the same purposes as radium in tubes and needles.

When the radiation has to act through normal tissues (such as the skin or a mucous membrane) which it is important to protect, each platinum tube is enclosed in a secondary filter, in the form of a casing of some substance of low density containing no heavy atoms (aluminium, rubber, cork, wax, etc.), so that the secondary burning rays emitted by the denser metal of which the tubes are made may be absorbed without any harmful additional radiation.

The aim of all processes of radiumtherapy should be to administer a uniform proportion of radiation throughout the volume of tissue to be treated (homogeneous radiation). Equality of radiation is hindered, however, by two phenomena—the dispersion of the rays, and their absorption.

Dispersion weakens the radiation from a punctiform focus in inverse proportion to the square of the distance. Its effects may be diminished by increasing: (a) the distance from the focus; (b) the radiant surface; (c) the number of positions of the focus (round or within the space to be radiated: "cross fire").

Absorption weakens radiation proportionately to the lowness of its penetrative power and to the thickness of the tissues. The injurious effects of unduly unequal absorption may be palliated by filtration.

The strength of the radiation is a matter of great importance. Excessive strength sets up radium necrosis, an accident of radiumtherapy which is often serious.

The strength of the radiation emitted can be measured with great accuracy by its constancy (radium) or its diminution according to a mathematical formula (radon), and is expressed either by the weight of radium or quantity of radon used and the length of the period of application (*i.e.,* milligramme-hours, millicurie-hours), or by the quantity of radon destroyed during application (i e., millicuries destroyed). The notation of the other circumstances of the application (filtration, distance, etc.) should be associated with that of the strength of radiation emitted.

General Biological Principles.—In its main applications radiumtherapy is based on the unequal radiosensibility of anatomic elements. As a general rule the idea is to effect a cure by electively destroying the diseased or neoplastic cells (as in malignant tumours), advantage being taken of the fact that these are more radiosensitive than normal cells.

Great importance attaches to the questions of relative radiosensibility, quantities absorbed, period of radiation, repeated or single treatment, auto-immunisation of the tissues to radiation, and perhaps to that of the different effects of rays of different wave-lengths. These questions, however, cannot be considered here. They are, moreover, common to radiumtherapy and rontgentherapy. The biological superiority of gamma rays over X-rays is mainly due to the greater penetrative power of the gamma rays.

Methods of **Radiumtherapy.**—The methods employed are: (1) intracavitary radiumtherapy; (2) interstitial radiumtherapy; (3) juxtacutaneous radiumtherapy; and (4) distant radiumtherapy. In many cases radiumtherapy is associated with röntgentherapy or surgery in various ways.

(1) Intracavitary *Radiumtherapy.*—This consists in introducing radioactive tubes, without rupturing the mucous membrane, into the natural cavities which form the site of a tumour or are close to a tumour. In such cases uncovered radium tubes are never used; the tubes are surrounded by light envelopes which not merely arrest the secondary radiation, but also, as far as possible, increase the focal distance. Many such applications of radiumtherapy have been abandoned. Those that survive affect cancers of the rectum, the prostate and bladder, and the uterus and vagina; fibromyomata of the uterus and haemorrhagic metropathies; and cancers of the buccal mucous membrance and the oesophagus.

Good palliative results can be obtained—sometimes readily, sometimes with difficulty—in most of the above-mentioned localisations of cancer. The only type of cancer, however, that is regularly cured—as often as by surgical treatment, and indeed probably more often—is the "pavement," cancer of the cervix uteri.

(2) Interstitial *Radiumtherapy.*—This consists in introducing the foci into the interior of the tissues through openings made for the purpose. In some cases a surgical operation is used as a mode of access (radium surgery). When possible, small foci are introduced by injection through the skin or mucous membrane covering the area to be treated. This method embraces several processes, of which the two following are the chief. One (the American method) is to inject into the tissues, with a trocar and a fine style, minute glass or gold tubes ("seeds") containing radon, and to leave them there. The other (radium puncture) consists in temporarily planting needles in the tissues, fixing them by suturing, and withdrawing them when the treatment comes to an end. The advantage of radium puncture with platinum needles is that effective filtration is possible.

Interstitial curietherapy has been applied to most of the localisations of cancer. The most striking results have been obtained from it in cancers of the mouth, especially of the tongue, in which the prognosis has been considerably improved.

(3) *Juxtacutaneous Radiumtherapy.*—In the early days of radiumtherapy, one or more tubes of radium were applied direct to the skin and kept in place with an adhesive. Later. radium was incorporated in a varnish or enamel, which was spread on metal supports in geometrical shapes. These radiant surfaces were then applied to the skin, being kept from touching it by a very thin sheet of filtrative metal and a certain thickness of gauze. Such methods were not fit to survive, and have been displaced by that of making, as required, supports of plastic materials (*e.g.,* a mixture of wax, paraffin and sawdust, known as Columbia paste). A layer of such a material, of an even thickness suitable to the distance desired (5 mm., 1, 2, etc., cm.), is moulded under heat (40–45° C) over the area to be treated and is then allowed to cool. Radium tubes containing equal quantities, whatever may be appropriate, are affixed to its outer surface at certain intervals. By this method radiant surfaces are obtained which are exactly right for each individual case.

The juxtacutaneous plastic radiant surface method can be applied to the treatment of lesions (notably cancers) of the skin, certain mucous membranes, the pharynx, the larynx, the nipple, etc., and of cancerous adenopathies. It has greatly improved the results of radiumtherapy in squamocellular cancers of the skin and the orifices of the skin.

(4) Distant *Radiumtherapy.*—The increase in the available quantities of radium has made it possible to establish foci containing several grammes of radium, and to increase the distances at which they operate, so that deep-seated cancers can be treated in the same manner as by X-rays. These appliances are so powerful that the focus has to be enclosed in a leaden case with a thick wall. This makes them very heavy, so that mechanical apparatus has to be used, which renders the appliance independent of the patient. Great results may be anticipated from this method, which is quite a new one.

Indications and Results.—The same diseases as are successfully treated with X-rays may be treated with radium. In the days when only small quantities of radium were available, and when no means of producing X-rays of great penetrative power was known, radium was reserved for the treatment of cancers by introducing foci into the natural cavities, and for strictly limited applications, chiefly in cases of small superficial lesions. Both agents can now be used, and it makes little difference whether the lesion is superficial or deep-seated.

In the treatment of dermatoses, inflammatory processes, tumours and benign hyperplasias, the same results can be secured more easily and inexpensively by the use of X-rays. This is also true of the treatment of the more radiosensitive neoplasms (seminomata, lymphosarcomata, myelosarcomata) and the less malignant epithelial cancers ("basal-celled" epitheliomata).

On the other hand, the treatment of the less radiosensitive cancers by radium has the advantage, that the normal tissues are much less affected by the gamma rays than by the X-rays, at the high concentrations that are essential if a cure is to be brought about.

It is far from true, however, that all kinds and all cases of cancer yield the same favourable results to radiurntherapy, The pathological condition in the treatment of which radiumtherapy has produced the most striking advance is the stratified "pavement" epithelioma developing epidermoidally (spinocellular, squamous-cell carcinoma). Whatever may be the site of this cancer, in the skin, in the lip, in the mouth, in the cervix of the uterus, etc., it can now be treated with prospects of cure as good as, if not better than, those afforded by surgical treatment in operable cases. On the other hand, cancers of the glandular organs (breast, prostate, liver, etc.), the prismatic-celled epithelia (stomach, rectum, etc.), the moulded connective tissues (fibrosarcomata), the nervous tissues, etc., are much less radiosensitive, and in such cases palliative results are obtained, but cures are infrequent.

Further, it is clear that, since radiumtherapy is a form of local treatment, its chances of success are greater where the lesion is a small one. Hence the practical importance of early diagnosis.

With its present methods radiumtherapy, as a means of attacking cancer, is difficult. It calls for very extensive and special knowledge, and requires the assistance of experts in various branches. For this reason there is a very proper tendency for it to be monopolized by special establishments which possess the equipment and staff required. (CL. R.)

BIBLIOGRAPHY.—There exists at the time of writing no complete treatise on radiumtherapy, but some of the latest and most important contributions to the literature of the subject may be found in the following publications: *Acta radiologica,* Stockholm; *The American Journal of Rontgenology and Radium Therapy,* New York; *Archives d'électricité médicale,* Bordeaux; *The British Journal of Radiology,* London; *Journal de Radiologie et d'Electrologie,* Paris; *Radiologica medica,* Milan; *Radiology,* Chicago; *Radiophysiologie et Radiothérapie,* Paris; *Strahlentherapie,* Berlin.

RADNORSHIRE, an inland county of Wales, bounded north by Montgomery, north-east by Shropshire, east by Hereford, south and south-west by Breconshire and north-west by Cardigan. Its area is 470.6 sq. mi., and it is consequently the smallest of the six south Wales counties. Pop. (1938) 19,540. The county is a highland region grading eastwards to the plain of the Severn. The western section is formed of Ordovician rocks which are succeeded eastwards by the Llandovery, Wenlock and Ludlow beds of the Silurian. This region forms part of the central Wales plateau with a general level of about 1,000 feet. To the east of the L.M.S. mid-Wales line that cuts the county diagonally from south-west to north-east the grits and shales of the lower Palaeozoic rocks are over-lain by the Old Red Sandstone which culminates in the rugged mass of Radnor forest (2,166 feet). The railway follows the lower Ithon valley (a tributary of the Wye) from near Builth Road to Llanbadarn Fawr. The Wye forms the south-west boundary of the county between Newbridge and Three Cocks, and divides Radnor forest from the Epynt mountains of Breconshire. Between Llandrindod and Builth is a disturbed area of Ordovician strata with masses of andesitic and diabasic igneous rocks. The region has also saline, sulphurous and chalybeate springs. East of New Radnor in the eastern section of the county an inlier of Wenlock rocks is surrounded by Ludlow beds; while at Old Radnor a ridge of very ancient rocks appears. The eastern half of the county is characterized by the number of river valleys that open out to the English plain and consequently offer important ways into the county from the East. In the north the Teme opens out to Knighton and Ludlow and forms the northern boundary of the county for a part of its course. The Lugg flows eastward past Presteign, and the Arrow past Kington, while the vale of Wye leads down to Hereford.

History and Early Settlement. — The heavily forested nature of the county in early times made it unsuited for settlement. Indeed, the region does not seem to have been densely peopled at any time. There are remains on the open higher ground especially in the north of the county of tumuli of uncertain date. Evidences of Bronze age and Megalithic cultures are almost entirely absent. There are, however, a few good examples of hill-top camps, especially at Burfa, and Castle Ring in the parish of Evenjobb. The Roman interests in the region seem to have centred on Castell Collen a focus of ways among the hills and on the road running due north from Brecon to Caersws. The post-Roman centuries were naturally times of difficulty in this region and the outstanding memorial of the time is the remains of Offa's Dyke that traversed the county. The best preserved sections are in the hilly districts west of Knighton and Presteign. Church dedications show the influence of the Celtic Saint movements of these centuries. Towards the close of the 9th century Maesyfed was absorbed into the middle kingdom of Powys, and in the 10th century it was included in the realm of Elystan Glodrudd, prince of Fferlys, or Feryllwg, who ruled over all land lying between the Wye and Severn. In the reign of William I., the Normans began to penetrate into Maesyfed, where, according to Domesday, the king already laid claim to Radenoure, or Radnor, in the lordship of Melenith (Moelynaidd), which was subsequently bestowed on the Mortimer family. The Domesday records are of interest in that they show evidences of cultural penetrations along the valley ways from the east. (English place-names west of Offa's Dyke, etc.) Influences from the plain have long been a feature of the social, religious and political life of the county. Later, the Norman invaders forced their way up the Wye valley, the de Braose family, lords of Elvel (Elfael), building fortresses at Painscastle and at Colwyn or Maud's Castle. The Wye valley long formed one of the debatable districts between Welsh and Normans. After the annexation of Wales by Edward I., the district of Maesyfed remained under the jurisdiction of the Lords-Marchers, represented by the families of Mortimer and Todeney.

The weakness of the Norman hold on many parts of the county is illustrated by the absence of large numbers of stone castles and the great number of those of the motte and bailey type. The valley ways show evidences of compact settlements in marked contrast to the single farms of the upland west. The difficult nature of much of the county throughout mediaeval times, together with the weak Norman hold, meant that the manorial system was very late in establishing itself. The ravages of the Black Death which were particularly severe in this region brought manorial conditions to an early end and the county became almost entirely dependent on sheep rearing. The increase in the number of sheep and the development of the wool trade and the great wool-markets of the Welsh Border — Shrewsbury, Ludlow, Hereford and Gloucester — were features of 14th and 15th century England. There was only one monastic house of consequence in this pastoral county, the Cistercian abbey of St. Mary, founded by Cadwallon ap Madoc in 1143 in "the long valley" of the Clywedog, 6 m. E. of Rhayader, and from its site commonly called Abbey Cwm Hir. Its existing ruins are insignificant, but the proportions of the church, which was 238 ft. long, are still traceable. The churches of Radnorshire are mostly poor and small

The political instability of the county continued throughout the 15th century and in 1402 Owen Glendower entered the Marches and raided the lands of the young Edward Mortimer, earl of March.

Radnorshire (Maesyfed) was created a county on the English model by the Act of Union (1536). It was parcelled out of the suppressed marches lordships. The new county was represented in parliament by two members, one for the county and one for the group of united boroughs. Together with the rest of moorland Wales the county was conservative and royalist during the 17th century, the local clergy during the commonwealth coming in for severe criticism under the administration of the Puritan Vavasor Powell (1617–70). The developments in the wool trade and local weaving attracted in the 16th and 17th centuries numbers of continental weavers, mostly religious refugees and the county is well known for the strong points of view it took later in religious matters. It was an old stronghold of the Quakers and later of the Baptists.

During the 20th century the rise of Llandrindod as a watering-place and the construction of the Birmingham reservoirs in the Elan valley have tended to increase interest in the county.

Occupations. — Good hay and cereals are raised in the valleys, oats being by far the chief crop. The extensive upland tracts, which cover over one-third of the total area of the county, afford pasturage for large flocks of sheep. The quality of the wool of Radnorshire has long been celebrated, and also the delicacy of the

Welsh mutton of the small sheep that are bred in this county. Important sheep fairs are held at Rhayader. There are practically no mining industries, nor are the quarries of great value.

The Central Wales branch of the L.M.S. enters the county at Knighton, traverses it by way of Llandrindod and passes into Brecknock at Builth Road Junction on the Wye. The G.W. Railway follows the course of the Wye, by way of Builth and Hay. Two small branch lines connect New Radnor and Presteign with the G.W.R.

There is no existing municipal borough, although New Radnor, now a mere village, was incorporated in 1561, and its municipal privileges were not formally abolished till 1883. The chief centres are Presteign, Llandrindod Wells, Knighton and Rhayader, all, except Rhayader, being urban districts. Radnorshire is included in the South Wales circuit, and Presteign ranks as the county town. The whole county together with that of Brecknock returns one member to parliament. Ecclesiastically, Radnorshire is divided into 46 parishes, the majority of which, lay after 1923 in the diocese of Swansea and Brecon, but, before that, had been for centuries included in the diocese of St. David's. Wartime population movements caused an increase of 10% in the Radnorshire population between Sept. 1939 and Feb. 1941.

RADOM, a town of Poland in the province of Kielce, 100 mi. by rail S. from Warsaw. Pop. (1931) 77,400, half of whom were Jews. The church of St. Waclaw, contemporary with the foundation of the town, was transformed by the Austrians into a storehouse, and subsequently by the Russian government into a military prison. The old castle is in ruins. Radom has several iron and agricultural machinery works and tanneries. In 1216 it occupied the site of what is now Old Radom. New Radom was founded in 1340 by Casimir the Great, king of Poland. Here Jadwiga was elected queen of Poland in 1382, and here too in 1401 the first act relating to the union of Poland with Lithuania was signed; the *sejm* or diet of 1505, where the organic law of Poland was sworn by the king, was also held at Radom. Several great fires, and the Swedish war of 1701–7, ruined the old city. After the third partition of Poland in 1795 it fell under Austrian rule; it was in 1815 annexed to Russia, and it was returned to Poland in 1918. Germany conquered Radom after bitter fighting in Sept. 1939.

RADON, known formerly as radium emanation or as niton, is the gaseous element (Symbol Rn) of atomic number 86 and atomic weight 222 produced by the disintegration of radium. It was discovered by Dorn in 1900. Its relation to the elements uranium and radium and to its successive products radium -*A*, -B, -C, -*C'*, -*D*, and -*E* and polonium are discussed under RADIUM. Radon is the heaviest member of the group of inert gases helium, neon, argon, krypton and xenon, and, like these elements, it is totally unable to form chemical compounds with other elements, and therefore may be said to have no chemical properties whatever. Its physical properties are described under RADIOACTIVITY.

In a mineral or solid preparation of radium, radon remains with the solid material, little of it escaping into the air. The higher the temperature to which the solid is heated the more easily does it escape, and at a temperature of 800° C practically the whole of the radon is expelled. When a solution of radium in water or acid is kept in a closed flask, radon is evolved together with oxygen and hydrogen produced by the decomposition of the water. After purification (*see* RADIOACTIVITY) radon is sealed up in a tube and used for scientific, medical, or other work.

Radon expels an α-o particle of range 4·12 cm. and disintegrates at such a rate that it diminishes by one-half every 3.83 days. A quantity of radon, therefore, freed from its parent, falls to half its original amount in 3.83 days, to a quarter in 7.66 days, to an eighth in 11·49 days, and so on. But it is a consequence of the disintegration theory of radioactivity that, in the solution of radium which has been freed from its radon, the latter grows as fast as it decays after separation from radium; that is to say, in 3.83 days one-half, in 7.66 days three-quarters, and in 11·49 days seven-eighths of the equilibrium amount of radon has reformed in the radium solution. If therefore the radon be pumped off from the radium solution once a week, nearly three-quarters of the maximum amount may be removed, purified, sealed up and used for experimental work. The valuable radium solution need not then be directly handled in experimental work. It generates under conditions of safety the radon which, with its successive disintegration products, is as valuable for most experimental work as radium itself. Should an accident befall the tube of radon, time (in waiting for more to accumulate in the solution of radium) but not the value of the radium, is lost; the interest on one's money, so to speak, has been spent, but the capital itself is still safe in the bank. Radon in tubes, of course, is not permanent in the sense that radium is permanent, for it diminishes in the manner already explained; but for most practical purposes that does not matter.

For Bibliography, *see* RADIUM. (A. S. R.)

RADOWITZ, JOSEPH MARIA VON (1797–1853), Prussian general and statesman, was born at Blankenburg in the Harz Mountains, his family being of Hungarian origin. As a lieutenant in the Westphalian artillery he was wounded and taken prisoner at Leipzig (1813), subsequently entered the Hanoverian service, and in 1823 that of Prussia, becoming chief of the general staff of the artillery in 1830. In 1836 he went as Prussian military plenipotentiary to the federal diet at Frankfort, and in 1842 was appointed envoy to the courts of Carlsruhe, Darmstadt and Nassau. He was an intimate friend of the crown prince (afterwards King Frederick William IV.), and the Prussian constitution of Feb. 1847 owed much to his *Gespräche aus der Gegenwart über Staat und Kirche,* published under the pseudonym "Waldheim" in 1846. In the Frankfort parliament he was leader of the extreme Right; and after its break-up he worked for the Unionist policy of Prussia in the Prussian diet and the Erfurt parliament. On Sept. 27, 1850, he was appointed minister of foreign affairs, but resigned on Nov, 2. In Aug. 1852 he was appointed director of military education. He died on Dec. 25, 1853.

Radowitz published, in addition to several political treatises, *Zkonographie der Heiligen, ein Beitrag zur Kunstgeschichte (1834)* and *Devisen und Mottos des spätern Mittelalters* (*ib.,* 1850). His *Gesammelte Schriften* were published in 5 vols. at Berlin, 1852–53.

See Hassel, *Joseph Maria von Radowitz* (1905, etc.).

RAE, JOHN (1813–1893), Scottish Arctic explorer, was born on Sept. 30, 1813, in the Orkney Islands. He studied medicine at Edinburgh university. He made a voyage as surgeon in one of the ships of the Hudson's Bay company, and was resident surgeon for ten years at the company's station at Moose Factory, at the head of James bay. In 1846 he made a boat-voyage to Repulse bay, and next spring surveyed 700 m. of new coast-line connecting the earlier surveys of Ross and Parry. He then joined the expedition under Sir John Richardson in search of Franklin; and in 1851, at the request of the Government he travelled some 5,300 m., much of it on foot, and explored and mapped 700 m. of new coast on the south side of Wollaston and Victoria Lands. For this achievement he received the Founder's gold medal of the Royal Geographical Society. In 1853 he commanded another boat-expedition fitted out by the Hudson's Bay company, which connected the surveys of Ross with that of Deane and Simpson, and proved King William's Land to be an island. He subsequently travelled across Iceland, and in Greenland and the northern parts of America, surveying routes for telegraph lines. He died at his house in London in 1893 and was buried in the Orkney Islands. He wrote *A Narrative of an Expedition to the Shores of the Arctic Sea in 1846 and 1847* (1850).

RAE BARELI, a town and district of British India, in the Lucknow division of the United Provinces. The town is on the river Sai, 48 m. S.E. of Lucknow. Pop. (1931) 18,180. It possesses many architectural features, chief of which is a strong and spacious fort of solid brick. Among other ancient buildings are the magnificent palace and tomb of nawab Jahan Khan, governor in the time of Shah Jahan, and four fine mosques. It is an important centre of trade, and muslins and cotton cloth are woven.

The DISTRICT OF RAE BARELI has an area of 1,749 sq.m. The general aspect of the district is slightly undulating, and the country is beautifully wooded. The soil is remarkably fertile, and the cultivation of a high class. The principal rivers of the district are the Ganges and the Sai. In 1931 the population was 974,127. The principal crops are rice, pulse, wheat, barley, millet and poppy.

RAEBURN, SIR HENRY (1756–1823), Scottish portrait-painter, was born at Stockbridge, Edinburgh, on March 4, 1756, the son of a manufacturer of the city. He was educated at Heriot's hospital, and at 15 was apprenticed to a goldsmith in Edinburgh. He began to paint miniatures; and, meeting with success and patronage, he extended his practice to oil-painting, being all the while quite self-taught. The goldsmith his master watched his pupil with interest, and introduced him to David Martin, the leading portrait-painter in Edinburgh. From him Raeburn received considerable assistance, and was given portraits to copy. When he was in his 22nd year he was asked to paint the daughter of Peter Edgar of Bridgelands and widow of Count Leslie. A month later she became his wife, bringing him an ample fortune; but the acquisition of wealth affected neither his enthusiasm nor his industry, He decided to visit Italy with his wife, and, in London, called upon and was kindly received by Sir Joshua Reynolds, who gave him excellent advice as to his study in Rome, commending to him in particular the works of Michelangelo. He also offered him more substantial pecuniary aid, which was declined as unneeded; but Raeburn carried with him to Italy many valuable introductions from the president of the Academy. In Rome he made the acquaintance of Gavin Hamilton, of Batoni, and of Byers, who advised him "never to copy an object from memory, but, from the principal figure to the minutest accessory, have it placed before him." After two years of study in Italy he returned to Edinburgh in 1787, where he began a most successful career as a portrait-painter. In that year he executed an admirable seated portrait of the second Lord President Dundas.

Interesting examples of his earlier portraits are those of Mrs. Johnstone of Baldovie and the three-quarter-length of Dr. James Hutton. The portraits of John Clerk, Lord Eldin, and of Principal Hill of St. Andrews belong to a somewhat later period. Raeburn was fortunate in the time in which he practised portraiture. Sir Walter Scott, Blair, Mackenzie, Woodhouselee, Robertson, Home, Ferguson and Dugald Stewart were resident in Edinburgh, and they all, along with a host of others less celebrated, honoured the painter's canvases. Of his fully matured manner the finest examples are his own portrait and that of the Rev. Sir Henry Moncrieff Wellwood, the bust of Dr. Wardrop of Torbane Hill, the two full-lengths of Adam Rolland of Gask, the remarkable paintings of Lord Newton and Dr. Alexander Adam in the National gallery of Scotland, and that of William Macdonald of St. Martin's Raeburn was considered less successful in his female than in his male portraits, but the exquisite full-length of his wife, the smaller likeness of Mrs. R Scott Moncrieff in the Scottish National Gallery, and that of Mrs. Robert Bell, prove that he could portray all the grace and beauty of the gentler sex.

Raeburn spent his life in Edinburgh, rarely visiting the metropolis, and then only for brief periods, thus preserving his own sturdy individuality. But though he, personally, may have lost some of the advantages which might have resulted from closer association with the leaders of English art, and from contact with a wider public, Scottish art certainly gained much from his disinclination to leave his native land. He became the acknowledged chief of the school which was growing up in Scotland during the earlier years of the 19th century, and to his example and influence at a critical period is undoubtedly due much of the virility of his followers and immediate successors Professional honours fell thick upon him. In 1812 he was elected president of the Society of Artists in Edinburgh, in 1814 associate, and in the following year full member of the Royal Academy. In 1822 he was knighted by George IV and appointed His Majesty's limner for Scotland He died at Edinburgh on the 8th of July 1823.

In his own day the portraits of Raeburn were excellently engraved by the last members of the great school of English mezzotint In 1876 a collection of over 300 of his works was brought together in the Royal Scottish Academy galleries; in the following year a series of twelve of his finest portraits was included in the winter exhibition of the Royal Academy, London; and a volume of photographs from his paintings was edited by Dr. John Brown.

See *Life of Sir Henry Raeburn, R A*, by his great-grandson William Raeburn Andrew (2nd ed., 1894), with complete catalogue of the exhibition of 1876; *Works* of *Sir Henry Raeburn, R A.*, with tributes by Dr John Brown and others (Andrew Elliot, Edinburgh); *Tribute to the Memory* of *Raeburn* by Dr. Andrew Duncan; the *Catalogues* of the loan exhibitions in Edinburgh of 1884 and 1901; and the Essay by W. E. Henley—*Sir Henry Raeburn* (1890) with a finely produced series of plates, printed by T. & A. (Constable); *Sir Henry Raeburn* by Sir Walter Armstrong, with an introduction by R. A. M. Stevenson and a biographical and descriptive catalogue by J L. Caw (1901).

RAEDWALD (d *c* 620), king of the East Angles, was the son of King Tytili. He became a Christian during a stay in Kent, but on his return to East Anglia he sanctioned the worship both of the Christian and the heathen religions. Very little is known about his reign, which probably began soon after 600. For a time he recognized the overlordship of Aethelberht, king of Kent, but he seems to have shaken off the Kentish yoke. He gained some superiority over the land south of the Humber with the exception of Kent and is counted among the Bretwaldas. Raedwald protected the fugitive Edwin, afterwards king of Northumbria, and in his interests he fought a sanguinary battle with the reigning Northumbrian king, Aethelfrith, near Retford in Nottinghamshire, where Aethelfrith was defeated and killed in April 617. He was followed as king of the East Angles by his son Eorpwald.

See Bede, *Historiae ecclesiasticae*, edited by C. Plummer (Oxford, 1896); and J. R. Green, *The Making* of *England* (1897–99).

RAEMAEKERS, LOUIS (1869–), Dutch cartoonist, was born at Roermond, Holland, on April 6, 1869. He was educated in Amsterdam and Brussels, and began his career by painting landscapes, portraits and posters. In 1908 he produced his first political cartoons, and subsequently gained international fame by his violent anti-German cartoons in the Amsterdam Telegraaf and other papers during and after the World War.

His cartoons have been published in *The Great War in 1916; The Great War in 1917; Devant l'Histoire* (1918); and *Cartoon History of the War* (1919).

RAETIA (so always in inscriptions, in classical mss. usually RHAETIA), in ancient geography, a province of the Roman empire, bounded on the west by the country of the Helvetii, on the east by Noricum, on the north by Vindelicia and on the south by Cisalpine Gaul. It thus comprised the districts occupied in modern times by the Grisons, the greater part of Tirol, and part of Lombardy. The land was very mountainous, and the inhabitants chiefly supported themselves by cattle-breeding and cutting timber, little attention being paid to agriculture. Some of the valleys, however, were rich and fertile, and produced corn and wine. Trade was also carried on in pitch, honey, wax and cheese Little is known of the origin or history of the Raetians, who are described as one of the most powerful and warlike of the Alpine tribes. It is stated by Livy (v. 33) that they were of Etruscan origin At the time when the land became known to the Romans, Celtic tribes were already in possession of it and had amalgamated so completely with the original inhabitants that, generally speaking, the Raetians may be regarded as a Celtic people, although non-Celtic tribes (Lepontii, Euganei) were settled among them They retained their independence until their subjugation in 15 B.C. by Tiberius and Drusus. At first Raetia formed a distinct province, but towards the end of the 1st century A.D. Vindelicia was added to it; hence Tacitus (Germania, 41) could speak of Augusta Vindelicorum (Augsburg) as "a colony of the province of Raetia." The whole province (including Vindelicia) was at first under a military prefect, then under a procurator; it had no standing army quartered in it, but relied on its own native troops and militia for protection In the reign of Marcus Aurelius it was governed by the commander of the Legio *iii. Italica*. Under Diocletian (*q.v.*) it formed part of the diocese of the *vicarius Italiae*. During the last years of the Western empire, the land was in a desolate condition, but its occupation by the Ostrogoths in the time of Theodoric, to some extent revived its prosperity. The chief towns of Raetia were Tridentum (Trent) and Curia (Coire or Chur). It was traversed by two great lines of Roman roads—one leading from Verona and Tridentum across the Brenner to Oenipons (Innsbruck) and thence to Augusta Vindelicorum; the other from Brigantium (Bregenz) on Lake Constance, by Coire and Chiavenna to Como and Milan.

Mommsen, *The Roman Provinces* (Eng. trans., 1886), i. pp. 16, 161, 196; Mary B. Peaks, *The General Civil and Military Administration of Noricum and Raetia* (Chicago, 1907).

RAFF, JOSEPH JOACHIM (1822–1882), German composer and orchestral conductor, was born near Zurich, Switzerland, on May 27, 1822, and educated chiefly at Schwyz. He was encouraged and assisted by Liszt and von Bulow, his opera, *König Alfred,* being produced at Weimar under Liszt's direction.

Raff lived at Weimar until 1856. In 1859 he married Doris Genast, an actress of high repute, and thenceforward devoted himself with renewed energy to the work of composition, displaying an inexhaustible fertility of invention and great technical skill. He resided chiefly at Wiesbaden till 1877, when he was appointed director of the Hoch-Conservatorium at Frankfort, an office which he retained until his death on June 25, 1882.

Raff's compositions included symphonies, quartets, concertos, sonatas and songs.

RAFFIA. A fibrous product consisting of the epidermal strips of the leaves of *Raphia ruffia* (from Madagascar) and R. taedigera (from Japan) largely employed as a binder twine in horticulture and in various kinds of handwork.

RAFFLE, a special kind of lottery, in which a particular article is put up as the prize, the winner being drawn for by lot out of the number of those who have paid a fixed sum for admission to the drawing; the total amount realized by the sale of tickets is supposed to approximate to the value of the object raffled for. The word appears in English as early as Chaucer (The *Parson's* Tale), where it is used in its original sense of a game of dice, the winner being that one who threw three dice all alike, or, next, the highest pair. The Fr. *rafle,* Med. Lat. *raffla,* was also used in the sense of a "sweeping-off" of the stakes in a game; it has been connected with Ger. raffen, to carry off.

RAFFLES, SIR THOMAS STAMFORD (1781–1826), English administrator, founder of Singapore, was born on July 5, 1781, on board a merchantman commanded by his father, Benjamin Raffles, when off Port Morant, Jamaica. He became a clerk in the office of the East India Company, and in 1805 was sent out to Penang as assistant secretary to the first governor. In addition to his duties as secretary he acted as Malay interpreter, and in 1807 he became secretary.

In 1808 his health gave way, and he was ordered for a change to Malacca. The East India Company had decided to abandon Malacca, and orders had been issued to dismantle it. Raffles drew up a report explaining the great importance of Malacca, and urging in the strongest manner its retention. Lord Minto was so impressed by the report that he at once gave orders ior suspending the evacuation of Malacca, and in 1809 the company decided to reverse'its own decision. In June 1810 Raffles, of his own accord, proceeded to Calcutta, where Lord Minto gave him the kindest reception. Raffles remained four months in Calcutta, and gained the complete confidence of the governor-general. He brought Lord Minto round to his opinion that the conquest of the island of Java, then in the hands of the French, was an imperative necessity. To prepare the way for the expedition, Raffles was sent to Malacca as "agent to the Governor-General with the Malay States." He did his work well and thoroughly—even to the extent of discovering that the short and direct route to Batavia by the Caramata passage would be a safe one for the fleet to take.

In August 1811 the expedition, accompanied by Lord Minto, and with Sir Samuel Auchmuty in command of the troops (11,000 in number, half English and half Indian), occupied Batavia without fighting. On the 25th a battle was fought at Cornelis, a few miles south of Batavia, and resulted in a complete English victory. On Sept. 18 the French commander, General Janssens, formally capitulated at Samarang, and the conquest of the island was completed. Lord Minto's first act was to appoint Raffles lieutenant-governor of Java. From September 1811 until his departure for England in March 1816, Raffles ruled this large island with conspicuous success. He increased the revenue eightfold at the same time that he abolished transit dues, reduced port dues to one-third and removed the fetters imposed on trade and intercourse with the Javanese by Dutch officialdom. In his own words, his administration aimed at being "not only without fear, but without reproach." He had a still greater ambition, which was, in his own words, "to make Java the centre of an Eastern insular Empire," and to establish the closest relations of friendship and alliance with the Javanese, whom he described as "a highly polished people, considerably advanced in science, highly inquisitive and full of penetration." It is interesting to note that when another great Englishman, Rajah Brooke, began his career in Sarawak in 1838, he announced: "I go to carry Sir Stamford Raffles's views in Java over the whole Archipelago."

In November 1817 Raffles quitted England on his return to the East, where the lieutenant-governorship of Fort Marlborough (Sumatra) had been kept in reserve for him. His administration of Sumatra (1818–23) was characterized by the same breadth of view, consistency of purpose and energy in action that had made his government of Java remarkable, He had not, however, done with the Dutch, who, on their recovery of Java, endeavoured to establish a complete control over the Eastern archipelago, and to oust British trade. This design Sir Stamford set himself to baffle, and by a stroke of genius and unrivalled statecraft he stopped for all time the Dutch project of a mare *clausum* by the acquisition and founding of Singapore on Jan. 29, 1819.

In 1824 Raffles returned to England to vindicate his acts to the East India Company. The court exonerated him from the charges made against him, but censured him for "his precipitate and unauthorized emancipation of the Companyls slaves," and after his death charged his widow to pay £10,000 for various items, which included the expense of his mission to found Singapore. Harassed by these personal affairs, he still found time to help in the foundation of the zoological society in London. His fine Sumatra collection formed its endowment. He died July 5, 1826.

See Lady Raffles, *Memoir of Sir Thomas Stamford Raffles* (1830); D. C. Boulger, *Life of Sir Stamford Raffles* (1897); Hugh Egerton, *Sir Stamford Raffles* (1899); J. Buckley, *Records of Singapore* (1903).

RAFFLESIA, a genus of plants of the family Rafflesiaceae with six species confined to Malaya. They are all parasitic on the roots of vines (Vitis). R. *Arnoldi* has the largest flower known, measuring 18in. across and weighing 15lb. with a smell like decaying flesh. It is pollinated by carrion-flies, and is the only part of the plant visible above ground, the remainder being reduced to a fungus-like mycelium.

RAFTER. A beam in a sloping roof to which is attached the framework for the slating, tiling or other external covering (*see* ROOFS).

O.E. raefter, a beam, in the special sense of a floating collection of timbers, gives the English "raft."

The ultimate base of this word is the root raf-, to cover, seen in Gr. ὄροφος, roof.

RAGAZ or RAGATZ, a famous watering-place in the Swiss canton of St. Gall, situated on the left bank of the Rhine. and by rail 61½ m. S.E. of Ziirich. It stands at a height of 1,696 ft., at the entrance to the magnificent gorge of the Tamina, about 3 m. up which by road are the extraordinarily placed Baths of Pfäfers. Since 1840 the hot mineral waters of Pfafers have been conducted to Ragaz, which has much increased in importance as a result. In 1930 its native population was 2,162, mainly German-speaking, while there were 1,500 Roman Catholics and 500 Protestants. About 2 m. by road above Ragaz are the 17th-century buildings (now the cantonal lunatic asylum) of the great Benedictine abbey of Pfäfers (720–1838), to which all this region belonged till 1798; while between them and Ragaz are the ruins of the 14th-century castle of Wartenstein.

RAGGED ROBIN (*Lychnis Flos-cuculi*), a perennial plant with pink, divided petals, belonging to the pink family, Caryophyllaceae (*q.v.*), native to Europe and Asia, common in Great Britain and naturalized in the eastern United States. It is a slender herb, about 1½ ft. high, and is much parasitized by a fungus, *Ustilago antherarum,* which forms its spores in the stamens, whence they are transported from plant to plant by insects.

RAGLAN, FITZROY JAMES HENRY SOMERSET, 1ST BARON (1788–1855), British field marshal, was the eighth and youngest son of Henry, 5th duke of Beaufort, by Elizabeth Boscawen, and was born on Sept. 30, 1788. Lord Fitzroy Somerset was educated at Westminster school, and entered the army in 1804. He served on the staff of Sir Arthur Wellesley in the expedition to Copenhagen (1807), and went with him to Portugal in 1808. During the whole of the Peninsular War he was at his right hand, first as aide-de-camp and then as military secretary. He was the first to mount the breach at Badajoz, and afterwards showed great resolution and promptitude in securing one of the gates before the French could organize a fresh defense. During the short period of the Bourbon rule in 1814 and 1815 he was secretary to the English embassy at Paris. On the renewal of the war he again became aide-de-camp and military secretary to the duke of Wellington. About this time he married Emily Harriet, daughter of the 3rd earl of Mornington, and Wellington's niece. At Waterloo he was wounded in the right arm and had to undergo amputation, but on the conclusion of the war resumed his duties as secretary to the embassy at Paris. From 1818 to 1820, and again in 1826–29, he sat in the house of commons as member for Truro. In 1819 he was appointed secretary to the duke of Wellington as master-general of the ordnance, and from 1827 till the death of the duke in 1852 was military secretary to him as commander-in-chief. He was then appointed master-general of the ordnance, and was created Baron Raglan.

In 1854 he was promoted general and appointed to the command of the British troops sent to the Crimea (see CRIMEAN WAR) in co-operation with a strong French army under Marshal St. Arnaud and afterwards, up to May 1855, under Marshal Canrobert. Here the advantage of his training under the duke of Wellington was seen in the soundness of his generalship, and his diplomatic experience stood him in good stead in dealing with the generals and admirals, British, French and Turkish, who were associated with him.

For the hardships and sufferings of the British soldiers in the terrible Crimean winter before Sevastopol, owing to failure in the commissariat, both as regards food and clothing, Lord Raglan and his staff were at the time severely censured by the press and the government; but it afterwards appeared that the chief neglect rested with the home authorities. He was made a field marshal after Inkermann. During the trying winter of 1854–55 his health was undermined. Disappointment at the failure of the assault of June 18, 1855, finally broke his spirit, and on June 28, 1855, he died.

See Kinglake, *Invasion of the Crimea* (1863–87); Hamley, *War in the Crimea* (1891).

RAGMAN ROLLS, the name given to the collection of instruments by which the nobility and gentry of Scotland were compelled to subscribe allegiance to Edward I of England between the conference of Norham in May 1291 and the final award in favour of Baliol in Nov. 1292, and again in 1296. Of the former of these records two copies were preserved in the chapterhouse at Westminster (now in the Record office, London), and it has been printed by Rymer (Foedera, ii. 542). Another copy, preserved originally in the Tower of London, is now also in the Record office.

The derivation of the word "ragman" has never been satisfactorily explained, but various guesses have been made. One is that the Scots spoke of such an instrument as "ragman" because of the numerous seals attached to it. The name "ragman roll" survives in the colloquial word "rigmarole," a rambling, incoherent statement.

RAGNAR LODBROK, Scandinavian ruler of the 8th or 9th century, supposed to have invaded England and France. It is nearly certain that such a person existed, but he has become a Scandinavian hero and the myths surrounding him are so extensive that it is difficult to separate the true from the fictional and to determine precisely what took place during his reign. One theory is that there were two men around whom the stories are woven: a prince named Ragnar Lodbrok, who died in 794; and another prince named Raginfrid or Regnier, who actually led the invasions of France and England, which did not take place until the 9th century, but who is known in Scandinavian history and legend as Ragnar Lodbrok also. In any case, the myths about the two men of the same name have become inextricably intertwined.

The story is that Ragnar Lodbrok sailed up the Seine river to Paris, which he captured and which was only redeemed by a ransom of 7,000 lbs. of silver. Later, the story runs, jealous of the reported achievements of his two sons, he planned to outdo them by invading England. He constructed two ships, the largest that had ever been built in Scandinavia, and sailed for Northumberland. He was captured by Aella, the Saxon king of Northumberland, after a valiant fight, and thrown alive into a pit of snakes, which stung him to death. His death song, the Lodbrokar-quida, has become a Scandinavian epic. His sons revenged him by killing Aella, and Northumberland ceased to be a Saxon kingdom and was looted and plundered by the Norsemen.

RAGNAROK, a Scandinavian myth telling of the death of the gods and the destruction of the world. The name is probably derived from the Old Norse words *regin* or rogn, god, and rok, reason, origin or history, although it is sometimes thought that the word comes from the Icelandic *ragna,* gods, and *rokr,* twilight. The story is contained in the Icelandic saga *Völuspá.* It tells of the war between the gods, led by Odin, and their evil opponents, led by Loki. The Ragnarok combines three common stories of the destruction of the world: the sinking of the earth into the sea and the devouring of the sun by a monster; a devastating winter; and the destruction of the earth by fire. In addition to the annihilation of the earth, the chief protagonists on each side are killed and there is a period of darkness and chaos. Afterwards, however, some of the gods who were not destroyed return to the earth, which has risen from the sea, and with them return a human couple, Lif and Lifthraser (Life and Vitality), who are the progenitors of a new race. This is the story used by Richard Wagner, the German composer, in his opera Gotterdammerung, the German word for "twilight of the gods."

RAGS. With the growth of the textile industries throughout the world, the consumption of rags of various sorts became enormous. The aggregate cannot be computed, but some conception of the dimensions of the trade may be gathered from the fact that the United Kingdom, in addition to consuming the greater part of her own production of rags, has a substantial import trade in linen, cotton and woollen rags. The linen and cotton rags are used in paper manufacture, and the woollen rags are employed in the textile industries. (*See* PAPER; SHODDY.)

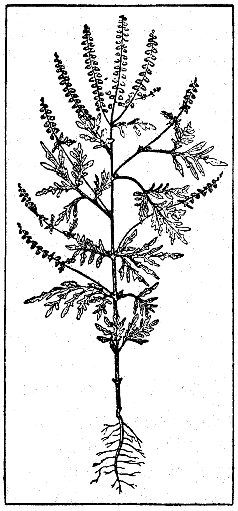
RAG-STONE, a name given sometimes to work done with stones which are quarried in thin pieces, such as the Horsham sandstone, Yorkshire stone, the slate stones, etc.; but this is more properly flag or slab work. Technically, rag-stone is an excellent material from the neighbourhood of Maidstone, near London; a very hard limestone of bluish-grey colour, peculiarly suited for mediaeval work. It is often laid as uncoursed work, or random work, sometimes as random coursed work and sometimes as regular ashlar. (*See* MASONRY.)

RAG-TIME: see JAZZ.

RAGUSA, a town and provincial capital of Sicily in the province of Ragusa, 70 mi. S.W. of Syracuse by rail and 32 mi. direct. It consists of an upper and a lower town united into one commune in 1926. Pop. (1936) 40,480 (town); 49,530 (commune). The city has an entirely new quarter, called Littorio. It has some churches with fine Gothic architecture, and is commercially important, a stone impregnated with bitumen being quarried and prepared for use for paving slabs by being exposed to the action of fire. Oil suited to Diesel motors is extracted. On the hill occupied by the castle of the lower town (Ragusa Ibla) stood the ancient Hybla Heraea, a Sicel town, under the walls of which Hippocrates of Gela fell in 491 B.C. During World War II Ragusa was severely bombed by the U.S. and British air forces prior to its occupation.

RAGUSA, Yugoslavia: see DUBROVNIK.

RAGWEED, the name given in North America to native plants of the genus Ambrosia (family Compositae). They are chiefly coarse annuals, with rough-hairy stems, mostly lobed or divided leaves, and greenish flowers borne in small heads, the male in terminal spikes and the female in the upper axils of the leaves. The common ragweed *(A. artemisiifolia)*, called also Roman wormwood, hogweed and bitterweed, found across the continent, grows from 1 to 7 ft. high, with thin, alternate or opposite, much-divided leaves. The great ragweed *(A. trifida)*, called also bitterweed and horse cane, native from Quebec to Saskatchewan and southward to Florida, Arkansas and Colorado, grows from 3 to 17 ft. tall, with opposite, entire or palmately three- to five-lobed leaves. Both the foregoing are annuals and often become pernicious weeds; their pollen, which is shed in great abundance in late summer, is a prolific source of hay fever. The western ragweed *(A. psilostachya)*, found from Illinois to Alberta and southward to California, Texas and Mexico, is similar to the common ragweed, but is a perennial and has thicker leaves.



FROM NEW YORK STATE COLLEGE OF AGRICULTURE AT CORNELL UNIVERSITY

COMMON RAGWEED (AMBROSIA ARTEMISIIFOLIA), WITH SPIKES OF POLLEN-BEARING FLOWERS, READY TO SHED THE POLLEN WHICH CAUSES HAY FEVER

RAGWORT (Senecio jacobaea), a common plant in European pastures and wasteland, growing to a height of over 2 ft., with heads of bright yellow flowers. It is allied to the groundsel (*q.v.*) and is one of the five noxious weeds whose removal in Great Britain is enforced by law. This weed, known also as staggerwort, is sparingly naturalized in North America from Newfoundland to Ontario and southward to Pennsylvania. In the United States and Canada various other species of Senecio are called ragwort, *e.g.*, the golden ragwort or swamp squaw-weed (S. *aureus*), a conspicuous wild flower of early summer, inhabiting swamps and wet meadows.

RAHAB, a Biblical character, who sheltered the spies sent by Joshua to investigate Jericho before the Jews crossed into Canaan. Rahab, whom Joshua ii speaks of as a harlot, admitted the spies to her house and concealed them from the messengers of the king of Jericho by hiding them under sheaves of flax on the roof. She sent the king's messengers away and then let Joshua's spies out of her window by a cord; and, since her house was built on the town wall, they escaped. In return, she asked that she and her family be spared from injury if the Israelites should take Jericho. This request the spies granted, telling Rahab that when the Israelites came, she should hang a red cord from the window through which the spies had escaped. This she did, and she and her family were saved. Later, when the Israelites had taken Jericho, Rahab was admitted to the community. Jewish tradition is that Rahab married Joshua and that eight prophets were descended from them. Another story is that she married Salmon, one of the spies, and that they were the parents of Boaz and thus she is an ancestor of David and of Jesus Christ. The Roman Catholic Church has made her a saint, whose day is celebrated Sept. 1. The Targum and the majority of older Jewish commentators translate the Biblical word *zōnāh,* used to describe Rahab as "innkeeper," deriving it from the root, *zūn,* "to feed," instead of from the root, *zānāh,* "to be a harlot"; but most versions translate "harlot."

RAHWAY, a city of Union county, New Jersey, U.S.A., on the Rahway river, 20 mi. S.W. of New York city. It is served by the Pennsylvania railroad, interurban trolleys and motorbus lines. Population in 1920 was 11,042 (18% foreign-born white); 16,011 in 1930; and 17,498 in 1940, by federal census. The city has attractive parks and many houses dating from colonial times. At the Old Peace tavern (still standing) Lafayette was entertained in 1824. The manufactures include vacuum cleaners, office equipment, furniture. automobile bodies and accessories, books, oil, bleaches, chemicals, cotton and wool waste and cereals. In the outskirts of the city is the New Jersey reformatory (1903) for men from 16 to 30 years of age. Rahway was settled in 1720; named after the Indian chief Rahwack of the tribe which owned the site; and was chartered as a city in 1858. A skirmish of the Revolution (called the battle of Spanktown, from the name by which the town was popularly known at the time) took place there in Jan. 1777.

RAICHUR, a town and district of India, in the state of Hyderabad, at the junction of the Madras and Southern Mahratta and Great Indian Peninsula railways, 351 mi. N.E. from Madras. Pop. (1931) 27,910. It gives its name to the doab, or tract between the rivers Kistna and Tungabhadra, which was the scene of much fighting betwekn Mohammedans and Hindus as debatable land during the 16th century. The district has an area of 6,791 sq.mi. and a population of 922,322. The town contains a well-preserved fort and palace. It is a thriving centre of trade, with a number of cotton ginning and pressing factories.

RAIFFEISEN, FRIEDRICH WILHELM (1818–1888), founder of the German system of agricultural co-operative banks. was born at Hamm on the Sieg on March 30, 1818. He entered the public service at Coblenz. The distress of 1846–47, which he attributed largely to absence of credit facilities for small peasant proprietors, led him to found the first agricultural co-operative credit societies (*Darlehnskassenvereine*), which ever since have been called after his name. He died Mar. 11, 1888.

Among Raiffeisen's writings are, Die *Darlehnskassenvereine als Mittel* eur *Abhilfe* (Neuwied, 1866; new ed., 1887); and *Kurze Anleitung zur Gründung* von *Darlehnskassenvereinen* (new ed., 1893).

See A. Wattig, Friedrich Wilhelm Raiffeisen (1890); H. W. Wolff, People's Banks. *A Record* of Social and Economic Success (1895); and Fassbender, Friedrich *Wilhelm* Raiffeisen (1902).

RAIGARH, a feudatory state of India in the Chhattisgarh division of the Central provinces. Area 1,486 sq.mi.; population (1931) 277,569. It is traversed by the Bengal-Nagpur railway with a station at Raigarh Town, 363 mi. from Calcutta. Fine tussore silk is produced at Raigarh town (pop. 8,667).

RAIKES, ROBERT (1735–1811), English educationalist, founder of Sunday schools, was the son of Robert Raikes, a printer in Gloucester and proprietor of the Gloucester Journal, and was born on Sept. 14, 1735. On the death of his father in 1757 he succeeded him in the printing business, which he continued to conduct until 1802. In 1780 he started a Sunday school at Gloucester, and although it was not the first of its kind, it was the first to attract general attention and thus was actually the beginning of the movement to provide schools for the instruction of children on Sunday. Raikes lived to witness its wide extension throughout England. He died on April 5,1811.

RAIL, the general English name for birds of the family *Rallidae,* to the two British species of which it originally applied. The first of the latter is the corncrake or land rail, Crex crex, recognizable by its monotonously repeated grating cry which has been aptly likened to the sound made by a rusty gate-hinge. It is a summer visitor to north Europe, retiring south in winter. The plumage is of various shades of brown above and yellowish-white below, rendering it very inconspicuous. It haunts the open country and agricultural land, the nest being on the ground, usually in long grass. Nine to 11 eggs are laid, of a cream-colour blotched with light red and grey. The young are hatched clad in black down.

The water rail, Rallus aquaticus, is less abundant than the preceding, but has a wide distribution, extending all over the old world north of the tropics. The call is harsh, loud and uttered only at intervals. It has a long partly-red bill and the plumage is darker than that of the land rail. It inhabits marshes. Closely related is the sora, or Carolina rail, *Porzana carolina;* also the coot (*q.v.*), moorhen (*q.v.*) and ocydrome. The "fin-foots" (Heliornis and Podica) show the extreme in adaptation to aquatic life in the development of a fringe round the toes (see COOT).

RAILWAY BENEFIT SOCIETIES: see FRIENDLY SOCIETIES.

RAILWAY EXPRESS AGENCY, INC., THE, was formed in 1929 by the Class I railroads of the United States to take over and carry on the express business formerly handled by the predecessor company, American Railway Express. It is a common carrier under jurisdiction of the Interstate Commerce Commission. Express is carried on approximately 10,000 passenger trains daily, and in 1938 the company handled 138,896,324 shipments. The air express service, established Sept. 1, 1927, transported more than 500,000 shipments wholly or in part during 1938.

The total mileage operated by the Railway Express Agency as of Dec. 31, 1938 was 281,384, including steam railroads, 205,015; electric lines, 2,685; transoceanic steamship lines, 5,366; coastwise steamship lines, 11,025; inland steamship lines, 4,178; airlines, 39,289; gas motor lines, 1,538. It has a vehicle fleet of 11,300 units, maintains approximately 23,000 offices (18,000 jointly with railroads) and employs approximately 57,000, including those employed jointly with railroads. See also EXPRESS.

RAILWAYS: In this article, railways are treated under the following heads:

A. History and development.
B. Engineering and general construction.
C. Economics.
D. Legislation.
E. The British railway groups.
F. The United States railroads.

For the development of railway engines, reference should be made to the article LOCOMOTIVE.

A. HISTORY AND DEVELOPMENT

The steam railway was a development of the wagon- or tramway frequently employed during the 16th, 17th and 18th centuries to haul minerals to rivers or ports, notably in the areas of the Clyde, the Tyne and South Wales. One of the most famous of these was the Sirhowy Tram-way incorporated in 1802. The invention of the steam engine induced Richard Trevithick (1771–1833) to design a steam engine mounted on wheels which generated sufficient power to move itself, in fact it became a locomotive. (See LOCOMOTIVE.) In 1802 it was tested on a circular track in London and two years later at Pen-y-darran near Merthyr, Wales, where it did not appear as a commercial success, and horse traction continued to reign supreme on the wagon-ways and tram-ways (see Section B). In 1811 John Blenkinsop (1783–1831) patented a design of rack railway, a toothed wheel on his locomotive working into a toothed rail beside the line as pinions work into a rack; this system proved successful on his Middleton colliery railway at Leeds, and is still employed in very different form on some of the world's mountain railways where very steep gradients are experienced. The following year William Hedley built two steam locomotives for the Wylam colliery near the Tyne, which trusted to their own weight for adhesion, and in 1814 George Stephenson (1781–1848) built his first locomotive.

The success Stephenson achieved enabled him to propose steam locomotives as the means of traction on the Stockton and Darlington Railway, projected in 1818, the first public passenger carrying railway in the world, which was opened Sept. 27, 1825. This railway, of single track with passing places every ¼m., was 38m. long and George Stephenson drove the first train, weighing about 90 tons, from Brusselton to Stockton; for some years the passenger traffic was carried by horse drawn coaches but these were finally withdrawn in 1833. Other early lines were the Kilmarnock and Troon, incorporated in 1808; the Gloucester and Cheltenham of 1809; the Plymouth and Dartmoor of 1819; the Stratford and Moreton of 1821; the Rumney; the Nantile, a plate-way in Carnarvonshire; the Cromford and High Peak; the Bolton and Leigh; and the Canterbury and Whitstable; all of 1825. The following year saw the incorporation of the Ballochney; the Edinburgh and Dalkeith; the Dundee and Newtyle; and the Garnkirk and Glasgow, all in Scotland, and the more famous Liverpool and Manchester in England. The Liverpool and Manchester is noteworthy because from the first it adopted locomotive power wholly as a form of traction, and was definitely built to carry passenger traffic as well as goods and minerals. Opened Sept. 15, 1830, it was 31m. long, with double line throughout, the average time for a passenger train to complete the journey was about 90 minutes and the average fare about 5s. In 1829 a contest had been arranged between various locomotive designers and the engines were tested at Rainhill, near Liverpool, George Stephenson's "Rocket" carrying off the prize of £500; other locomotives in the contest were the "Novelty" of John Braithwaite, and the "Sanspareil" of Timothy Hackworth. Both the "Rocket" and "Sanspareil" are preserved in the Science Museum, South Kensington, London. Great difficulties had to be overcome in the construction of the line through the opposition of the local landowners and of the canal interests, while the original cost was greatly increased owing to the difficulty of crossing Chat Moss, a large peat bog. Although the opening of the Liverpool and Manchester was marred by the fact that Huskisson (1770–1830), at that time one of the members of Parliament for Liverpool, was killed by one of the engines, the railway proved a great commercial success, with the result that railway projects were set on foot, not only throughout Great Britain, but on the continent pf Europe and in North America. The Carbondale and Honesdale line in Pennsylvania had used a British built steam locomotive, the "Stourbridge Lion," in 1829, while Stephenson sent to the Lyon-St. Etienne line in France, then about to be opened, two locomotives in the same year.

The British Main Lines.—Amongst the early British lines which were to form the great trunk railways of the later 19th century were the Grand Junction, which absorbed the Liverpool and Manchester; the London and Birmingham, incorporated in 1833; the Chester and Crewe; the Manchester and Birmingham, of 1837; and the Chester and Holyhead and the Lancaster and Carlisle of 1844.

The London, Midland and Scottish Railway.—These lines formed the nucleus of the London and North Western Railway (L.N.W.R.), which stretched from London (Euston Station) through Rugby, Stafford, and Crewe to Carlisle, with branches to Birmingham, Manchester, Liverpool, Holyhead, and through Central Wales. In Scotland, the L.N.W.R. worked closely with the Caledonian Railway (C.R.), a combination of the earlier Dundee and Perth, Scottish Midland, and Scottish Northeastern Railways. The Leicester and Swannington of 1830, together with the Birmingham and Gloucester, the Birmingham and Derby, the Midland Counties, the North Midland of 1836 and the Bristol and Gloucester of 1839, formed with other lines the Midland Railway (M.R.), as it was known prior to 1923. It stretched from London (St. Pancras) through Bedford, Leicester, and Derby to Leeds and Carlisle, with branches to Manchester, Bristol and York, in the shape of an X with its centre at Derby. The Scottish partner of the Midland was the Glasgow and South Western Railway, whose earlier title had been the Glasgow, Paisley, Kilmarnock and Ayr line. The great textile centres of Lancashire and Yorkshire were served for many years by an important railway of that name which resulted from a combination of the Manchester and Bolton of 1831 and the Manchester and Leeds of 1836. The present London, Midland and Scottish Railway (L.M.S.R.) is a combination of the London and North Western, the Midland, the Lancashire and Yorkshire, the Caledonian and the Glasgow and South Western railways, together with the smaller Furness, Highland, and North Staffordshire railways, in addition to many lines of purely local importance.

The Great Western Railway.—In the west of England I. K. Brunel's (1806–1859) broad gauge 7ft. railway, known from the time of its construction in 1835 as the Great Western Railway (G.W.R.), extended its sphere of activities through Somerset to Exeter by means of the Bristol and Exeter, and then by means of the South Devon, at one time worked atmospherically, to Plymouth and finally to Penzance. In South Wales it reached to Pembroke and later to Fishguard, a port for Ireland, while in the north it stretched to Birkenhead through Banbury, Warwick, Birmingham, Wolverhampton, Shrewsbury and Chester. The policy of amalgamation brought about by the Railways Act of 1921 (see Section D) did not alter the title of this line nor change its character as greatly as it did in the case of the other three railways, for the G.W.R. merely took over certain mineral lines serving the ports of South Wales, and one or two other railways, such as the Cambrian which served Cardigan Bay and the Midland and

South Western Junction line which ran southwards from Cheltenham to Andover.

London and North Eastern Railway.—The successful Stockton and Darlington Railway of 1825 naturally led to considerable railway construction in the north-eastern counties of England, and amongst the more important of these lines were the Newcastle and Carlisle, incorporated in 1829; the Leeds and Selby of the following year; the Whitby and Pickering of 1833; and the Hull and Selby, the York and North Midland, and the Great North of England of 1836. From these arose the erstwhile North Eastern (M.E.R.), which in turn took over the Stockton and Darlington, and gained almost complete railway monopoly of the country lying between the Humber and the Tweed, and stretched as far westwards as Leeds and Harrogate. Forming part of the "east coast route" to Scotland, the N.E.R. worked in close partnership with the North British (N.B.R.) in Scotland, whose ancestry dated back to the early Monkland and Kirkintilloch, the Edinburgh and Dalkeith, and the Ballochney lines. Centred on Edinburgh, the North British of 1844 gradually absorbed many small lines and finally ran from Berwick and Carlisle to Edinburgh, thence westwards to Glasgow, and northwards to Perth, Dundee and Montrose. North of Aberdeen was the Great North of Scotland (G.N. of S.R.), serving Elgin and many Scottish fishing ports.

On its southern boundary the N.E.R. worked in close harmony with the Great Northern (G.N.R.), opened in 1852 with its London terminus at King's Cross. This line with a main stem from London through Peterborough and Newark to just north of Doncaster formed the southernmost partner in the east coast route, but possessed also many branches serving Cambridge, Lincoln, Nottingham, Bradford, Leeds and Grimsby. In 1837 a small railway was incorporated known as the Sheffield, Ashton-under-Lyne and Manchester, which was destined to have a big future, under the title of the Manchester Sheffield and Lincolnshire. It gradually extended, eastwards to the Lincolnshire coast, and westwards to North Wales, while finally, like its neighbour the Midland, it effected an entry into London after much opposition from its rivals already established there, through Nottingham, Leicester and Rugby in 1899, changing its name to the Great Central (G.C.R.) in 1897. The London terminus is at Marylebone, which is reached by running alongside a London suburban railway, the Metropolitan.

The eastern neighbour of the G N.R. was the Great Eastern (G.E.R.), which resulted from a combination of Braithwaite's Eastern Counties, incorporated in 1836, with the Northern and Eastern and the London and Blackwall lines of the same year. By combination with the Eastern Union and the Norwich and Brandon, both of 1844, and many smaller lines, the G.E.R. obtained an almost complete monopoly of railway transport in East Anglia, and by means of a joint line with the G.N.R. spread northwards to Doncaster through Spalding, Lincoln and Gainsborough. Since 1922 the North Eastern, North British, Great North of Scotland, Great Northern, Great Central, and Great Eastern railways together with certain small lines, notably the Hull and Barnsley, have been combined and now form the London and North Eastern railway (L.N.E.R.), the second largest British system.

***The** Southern* Railway.—South of London there were combined to form the Southern Railway (S.R), by the Railways Act of 1921, three important railways, namely, the London and South Western (L S.W.R.); the London, Brighton and South Coast (L.B. & S.C.R.); and the South Eastern and Chatham railways (S.E. & C.R.). The L.S.W.R. began as a line from London to Southampton, incorporated in 1834, though what were destined later to be parts of this line were the Bodmin and Wadebridge in Cornwall which dated back to 1832, and the Taw Vale of 1838; it gradually covered the area between London, Southampton and Exeter, reaching Plymouth through North Devon and terminating at Bude and Padstow in Cornwall. By means of a joint line with the Midland it reached Bath, and came into contact with the Great Western at Weymouth, Reading, Exeter and Plymouth. At Portsmouth on the east it met the L.B. & S.C.R. which had originated in the London and Croydon line incorporated in 1835, and the London and Brighton of 1837. The former is of interest as it was at one time worked on the atmospheric system. By this method of propulsion power was derived from atmospheric pressure contained in a large diameter tube placed between the rails. A vacuum being formed ahead of the train, the carriages were propelled by the pressure behind; owing to leakages the system was not a success. The territory of the L.B. & S.C.R. covered roughly a triangle between London, Hastings and Portsmouth, with Brighton near the centre of the base line. At Tunbridge Wells and Hastings it maintained contact with the S.E. & C.R. In this latter case there was a managing committee (1899) to operate what were in reality two separate railways, the London, Chatham and Dover, and the South Eastern. The violent competition between these two railways led to a position such that practically every important town in Kent was served by both companies, and such a degree of competition was disastrous to the financial position of both. An early portion of the South Eastern was the London and Greenwich opened in 1836, with its London terminus at London Bridge, reaching the latter over 900 brick arches.

British Mileage.—Thus there are to-day, four great British railway systems, the L.M.S.R., the L.N.E.R., the G.W.R., and the S.R., each built up of many small lines, as the above brief outline illustrates. The commercial success of the Stockton and Darlington and the Liverpool and Manchester railways resulted finally in the railway mania of 1844–46, after which ensued the financial crisis of 1847 and a keen desire to obtain the economies of railway amalgamation. Though the Houses of Parliament throughout the 19th century based their railway policy mainly on the necessity of keeping competition alive, the World War of 1914–18 finally broke down that policy and created a complete reversal of it in the Railways Act of 1921, which forcibly amalgamated practically all the railways into the present four great systems, in certain cases amalgamating lines which had been refused permission to do so some years before (see Sections D and E). Other than the four big railways there exist certain lines jointly owned, such as the Cheshire Lines Committee, to the extent of two-thirds L.N.E.R., and one-third L.M S R.; the Midland and Great Northern, half L.N.E.R. and half L.M.S.R.; and the Somerset and Dorset, half S.R. and half L.M.S.R. In the London area there is a group of electrified passenger traffic lines (see Sec. B), mainly constructed in tunnels and known collectively as the Underground, while there is also the Metropolitan, a line electrified within London itself but still worked by steam traction north of Rickmansworth; in 1933 these, with other public passenger-carrying undertakings in the London area, were amalgamated under the London Passenger Transport Board. Lastly there are certain small light railways in various parts of Great Britain, some of a gauge narrower than the standard of 4ft. 8½in., notably the Eskdale line in the Lake District, the Romney, Hythe and Dymchurch line in Kent and certain lines in North Wales, as the Snowdon Mountain railway are examples of the rack rail system. The steady growth of the British railways is seen in the following mileage statistics:

	Miles		*Miles*
1825	26	1890	20,073
1844	2,236	1900	21,855
1850	6,635	1910	23,387
1860	10,410	1920	23,734
1870	15,310	1926	20,395*
1880	17,935	1933	20,251*

*Not including Irish Free State.

Since 1890 there have only been comparatively small additions to the railway mileage, route mileage taking no account of the presence of second, third or fourth tracks, but widenings have taken place and the figures for track mileage, which measures all tracks and converts them to a basis of one track only, are: in 1913, 36,448 miles; in 1933 (including sidings), 52,900.

Railways of Continental Europe: France.—The first railway in France, opened in 1827 from Saint-Etienne to Andrézieux, was like early British lines mainly for the haulage of coal. Of single track, it used horse traction, and did not carry passengers until 1832; the Saint-Etienne-Lyon line of 1830 used steam locomotives from its opening. In 1833 the French Government began to encourage railway construction and amongst the earlier lines authorized were those from Paris to Saint Germain and Versailles. By 1842 the French railways totalled 360 miles, but an Act of the same year provided for the construction of lines which were later to form the great trunk railway routes from Paris to Nancy and Strasbourg, Lyon and Marseilles, Bourges and Toulouse, Tours, Bordeaux, Bayonne and Nantes, Rouen and Havre, and, finally, Lille and Belgium. In addition were cross country routes from Bordeaux to Marseilles, and Dijon to Mulhouse; thus, by Jan. 1, 1852, 3,125 route miles had been authorized and 2,185 were being operated. Rapid development occurred during the Empire, while the leases granted to the private companies to operate the railways were to last 99 years, and the companies operating in any one territory were amalgamated to reduce competition. By 1870, 16,685m. were authorized of which 11,250 were being operated, figures which by 1875 had become 21,375 and 13,562 respectively; soon afterwards a State operated system was created which was later destined to take over the Ouest Railway. The total mileage of the big French railways in 1902 was 26,375. The French railway net consists of 7 large systems: the Paris-Lyon-Méditerranée, the Paris-Orléans, Midi, the Est, and the Nord, which are companies operating under the terms of a long lease. In addition there are the État (*i.e.,* the State) and the Alsace-Lorraine railways, the latter becoming French national property as a result of the World War (1914–18). Each system is practically a rail monopoly in its own territory. As well as the 7 large railways there is an important mileage of narrow gauge lines of local importance only, which in Great Britain would be termed light railways.

Germany.—In Dec. 1835 the first German railway was opened between Nuremburg and Fiirth. Thanks to Friedrich List a systematic plan of German railway construction was designed, but the independence of the different States somewhat interfered with this programme. It is curious that uniformity of gauge resulted from the importation of British locomotives and rolling stock. The first inter-State line was that from Magdeburg in Prussia to Leipzig in Saxony, opened in 1840, and as early as 1847 an association was formed of German railway administrations. Strict State control was exercised throughout the period of rapid construction commencing in 1846 and by 1855 5,410m. had been completed. An important characteristic of German railways has been, from the first, the large part played by international traffic; a second characteristic has been the great degree of State construction and ownership. The first State line was opened in Brunswick in 1838; by 1855 throughout Germany nearly 50% of the railway mileage was State owned. The Prusso-Austrian War of 1866 strengthened the Prussian railway system, as also did the Franco-German War of 1870, and by the latter year the main trunk network was largely complete, though few branch lines had been constructed. The lines of the French Est railway in Alsace and Lorraine became the property of the German Empire in 1871, while 1873 saw the establishment of an Imperial Railway Department. From 1876 onwards the privately owned railways were gradually absorbed by the State, Prussia acquiring the Berlin-Stettin and Cologne-Minden lines amongst many others by an Act of 1879. Thus by 1885 private railways in Prussia were practically non-existent. Bavaria had always favoured State railways and finally bought up the Pfalz railway in 1908. Saxony had adopted the same policy and took over the Leipzig-Dresden line in 1876. In Hesse-Darmstadt, the Hesse-Ludvig railway became State owned in 1896, the Mecklenburg railways being purchased by the State in 1889. Oldenburg, Wiirtemburg and Baden owned and operated their railways from the first; 1885–1900 saw great developments in local lines, many of which may be regarded as light railways. Thus by 1900 the total route mileage of standard gauge lines in Germany was 31,205, and 1,125m. of narrow gauge. The total route mileage in 1909 was 35,625. In 1920 the various German State railways became the property of the Reich, but in 1924 consequent on the recommendation of the Dawes Peace Plan, their status was altered to a company basis, so far as operation was concerned, on a lease of 40 years (see SECTION D).

Other European Railways.—State owned railway systems exist in Russia, Italy, Switzerland and Denmark, dating back to the 'forties, in Sweden, Norway and Portugal, dating back to the 'fifties and in Turkey and Greece to the 'sixties of last century, although State ownership and operation usually came many years after the opening of the first lines. Belgium possesses a State owned system, leased for 75 years from 1926 to an operating National company; in Spain, where railways date back to 1848, the lines are mainly company operated but closely connected with the State, as is the case with the Nederland Railway in Holland, which goes back to the '30s. Rumania, Czechoslovakia, Bulgaria, Yugoslavia and Austria all own and operate their systems, but in the case of Austria the railway balance sheet is kept separately from that of the State budget. In the majority of cases small private lines also exist but they are usually only local in importance.

The European railway mileage at the end of 1934 may be seen in the following table based on a compilation made by the Archiv für Eisenbahnwesen (translated by the Bureau of Railway Economics at Washington). Other railway mileage tables in this article are based on the same source.

European Railway Mileage

Country	Miles of line at end of year 1934	Miles of line in 1934 per 10,000 population
Austria	4,174	6·1
Belgium	6,372	7·9
Bulgaria	1,917	3·1
Czechoslovakia	8,649	5·9
Denmark	3,326	9·4
Estonia	899	8·0
Finland	3,463	9·4
France	33,282	8·0
Germany	36,426	5·5
Great Britain	20,409	4·5
Greece	1,980	3·2

Railways **of North** America.—Apart from the railways of the United States, which are dealt with in a separate section (see Section F), the two great systems of North America are the Canadian National and the Canadian Pacific. The Canadian National resulted from an amalgamation of the Grand Trunk, the Grand Trunk Pacific, the Canadian Northern, the National Transcontinental and other smaller railways. St. Johns, Quebec, saw the opening of the first railway in 1836, horse traction giving way to steam engines the following year, but the Grand Trunk resulting from an Act passed in 1851 may be said to commence the railway era in Canada, the Montreal to Toronto line having been completed in 1856. Stretching from Halifax, N.S., to Vancouver and Prince Rupert, and serving Moncton, N.B., Montreal, Toronto, Ottawa, Windsor, Winnipeg, Saskatoon, Regina and Calgary, its enormous route mileage of 23,750, the second largest in the world, is administered from Montreal with regional headquarters at Toronto, Moncton and Winnipeg, whilst its extensive lines in the United States, worked from Detroit, known as the Grand Trunk Western, stretch across Michigan from Detroit to Chicago; it also reaches New London, Conn., and Portland, Me.

The Canadian Pacific Railway was formed in 1881 and took over about 700m. of railway built by the Government, in addition to a capital grant of over £5,000,000 together with a temporary loan and 25 million acres of land. In return it was to construct a transcontinental railway from Montreal to Vancouver, which was completed in May, 1887. Many famous figures are connected with its early development, notably Lords Strathcona, Mountstephen and Shaughnessy, and Sir William Van Home. Controlling the Dominion and Atlantic line in Nova Scotia, and the Minneapolis, St. Paul and Sault Ste. Marie which terminates at Chicago, its lines stretch from St. John, N.B., to Vancouver; steamer services connect St. John with Nova Scotia and Vancouver with its Vancouver Is. lines at Victoria. Its main trunk line serves Fredericton, Quebec, Montreal, Ottawa, Toronto, Windsor, Winnipeg, Regina, Saskatoon, Edmonton and Calgary; it also operates steamer routes on the Atlantic and Pacific Oceans. A very prosperous railway, it owns 21,234m. of line inclusive of controlled lines; its growth and commercial success have been interlocked for many years with the growth and prosperity of Canada and the Canadian nation. The remaining lines in Canada and Newfoundland are comparatively short and of only local importance, but railway construction continues northwards, chiefly in the provinces of Quebec, Manitoba, Alberta and Ontario.

The Mexican railways are mainly of standard 4ft. 8½in. gauge, and include sections of such American railroads as the Southern Pacific, and Kansas City, Mexico and Orient. The biggest system is, however, that of the National Railways, which includes a considerable mileage of 3ft. lines. It operates the mileage of this gauge for the Interoceanic, Mexican Southern and Mexican Eastern Railways, while the standard gauge Mexican Railway is a line controlled from London.

North American Railway Mileage

Country	Miles of line at end of year 1934	Miles of line in 1934 per 10,000 population

Salvador	385	2·6
United States (incl. Alaska)	258,465	21·0
Total	332,233	Average 10·9

Railways of Asia.—India possesses a very extensive railway system mainly constructed to the 5ft. 6in. and the metre gauges. The railways are divided into three classes based upon the gross earnings in any one, a similar method to the Class I. and Class II. systems of the United States. There are 16 Class I. lines, earning Rs. 50 lakhs or over per annum, of which the largest are the Great Indian Peninsula, the East Indian, the Bombay, Baroda and Central India, the North Western, the Bengal and North Western, the Bengal-Nagpur, the Eastern Bengal and the Madras and Southern Mahratta. Many of these lines are purely operating companies, the railways being owned by the Indian Government, and as the leases run out are taken over wholly by the State. Thus the East Indian, serving Calcutta, Allahabad, Agra and Delhi, the first section of which was opened in 1854, was taken over Dec. 31, 1924, being later amalgamated with the Oudh and Rohilkhund, serving Benares and Lucknow, also taken over. The Great Indian Peninsula serving Bombay, Agra, Delhi and Cawnpore. has been worked by the Government from June 30, 1925, while the North Western, with headquarters at Lahore and serving the port of Karachi, in view of its strategic nature has for many years been a State railway. The Bengal and North Western, serving Lucknow, Benares and Allahabad, includes the Tirhut State Railway, and is owned and operated by a company; while the Bengal-Nagpur, stretching from Nagpur to Calcutta, possesses a contract which will not lapse for some years. The Bombay, Baroda and Central India is also operated by a company and possesses an important metre gauge system, as do the Madras and Southern Mahratta and the South Indian. The Eastern Bengal, however, possesses lines of several gauges and is a State system, as is Burma Railways, which were company operated till the end of 1928.

Ceylon has possessed a railway system since 1865. The railway network of the Federated Malay States is based on Kuala Lumpur. Railways also exist in Iraq, Palestine, Turkey in Asia, North Borneo, Dutch East Indies, Indo-China and the Philippine Is. The State railways of Siam are of metre gauge and over 1,900m. in length. In Siberia are long mileages of Russian railways, built to the 5ft. gauge, while a narrow gauge line exists in Cyprus. China possesses State and company owned railways; the former Chinese Eastern. now North Manchurian. was transferred to Japan and Manchuria, March, 1935; the South Manchuria has been Japanese since 1906. Hongkong possesses a standard gauge railway. Next in importance to India among Asian railways stands Japan, with a State owned and operated system of the 3ft. 6in. gauge, with mileage of nearly 9,500. The first section was opened in 1872; during the succeeding 20 years privately owned lines grew side by side with the State railways, but by 1887 only 240m. of railway had been constructed. Between 1897 and 1906 a considerable reduction took place in the number of privately owned lines, but they had been responsible for the construction of over 3,200 miles. In 1906 when the route mileage was almost 4,800 a railway nationalization bill was passed and nearly £50 million paid for over 2,800 miles. In 1927 the Japanese Government Railways had 200,000 employees; in addition there were 4,900m. of privately owned lines. A feature of the Japanese railway system is the use of ferry steamers for connecting up the islands over which the railway system spreads; some of these steamers are train ferries.

Asian Railway Mileage

Country	Miles of line at end of year 1934	Miles of line in 1934 per 10,000 population

Railways of Africa.—The most important railway system in Africa is that of the South African Railways and Harbours Administration, a Government owned and operated system of 3ft. 6in. gauge in the Union of South Africa. In 1860 a standard gauge 4ft. 8½in. line was opened at Natal, followed by a line of similar gauge between Cape Town and Wellington, but by 1870 less than 70m. had been completed. By 1881 the gauge had been changed to 3ft. 6in. and Cape Colony and Natal had commenced State ownership. Kimberley could be reached by rail in 1885 and Bloemfontein in 1890, the Orange Free State taking control of this section in 1897, the year when the railway first reached Bulawayo. In 1902 there were 4,900 route miles of railway in what is now the Union of South Africa, and when the railways were amalgamated under the Union Government the mileage amounted to over 7,000, which had increased to 9,600 in 1920, and to 12,200 in 1927, including the New Cape Central Railway absorbed in 1925 and the railways in South West Africa. In addition there exist over 400m. of private railways in South Africa. The 600m. line northwards from Vryburg to Bulawayo, Southern Rhodesia, through British Bechuanaland, is also administered by the S A.Rlys., while the main ports are operated by the same organization; thus competition between ports is eliminated and the closest coordination obtained with the railway working.

The Rhodesian Railways of 3ft. 6in. gauge, consistng of several companies, operate lines from Bulawayo north west through Victoria Falls, Broken Hill, to the Belgian Congo border, and north east through Salisbury to the port of Beira in Portuguese East Africa. From Beira there runs north the 3ft. 6in. gauge Trans-Zambesia Railway, terminating at Murraça on the Zambesi; from Chindio, on the opposite bank, commences the 60m. Central Africa Railway, which connects with the more important Shiré Highlands line at Port Herald. Both these lines are 3ft. 6in. gauge, and the latter runs through Blantyre in Nyasaland and terminates at Domira Bay on the west shore of Lake Nyasa; thus, excepting the crossing of the Zambesi, there is through rail connection from Cape Town to the lake itself. North of Nyasaland run the metre gauge Tanganyika Railways, westwards from Dar-es-Salaam to Kigoma and Mwansa; a further line runs westwards from Tanga to Arusha. Near Moshi connection is made with the Kenya and Uganda Railway; this latter line, of metre gauge and over 1,000 route miles long, is based on Mombasa and penetrates to Kisumu, Uganda, on Lake Victoria, with many important branches as well as lake, river and motor services. Northwards to the Sudan Government line at El Obeid there is no railway connection. The Sudan system, of 1,725 miles of 3ft. 6in. gauge, stretches north through Khartoum to Halfa, whence Nile steamers offer connection with the Egyptian Railways near Assouan. Sudan railway branches stretch to Kassala, Port Sudan and Kareima.

The metre gauge Franco-Ethiopian line runs from Djibouti to Addis Ababa in Abyssinia, while small lines exist on the islands of Madagascar, Mauritius and Reunion, and on the mainland at Lourenço Marques, Quelimane, Lindi, Mozambique and Massawa in Eritrea, the last named an Italian State Railway, as are two small lines at Tripoli and Benghazi. In Morocco, Algeria and Tunisia there exist several railways of the 4ft. 8½in. and metre gauges, of which the most important are the Algerian State system of nearly 2,000m. and the Paris-Lyon-Méditerraneé African lines of 750m. On the west coast of Africa railway systems serve the ports of Dakar, Konakry, Freetown, Bingerville, Sekondi and Lome. The 3ft. 6in. Nigerian Railway system, based on Lagos and Port Harcourt, extends about 1,675m. to Nguru near the French West African border, while various small lines serve Brazzaville, Leopoldville, Matadi, St. Paulo de Loanda, Benguella and Mossamedes. In the Belgian Congo a 3ft. 6in. line (having connection with the line from Benguella) runs northwards from Ndola on the Rhodesian frontier to Port Francqui, and isolated railways serve Stanleyville and Albertville.

Railways **of South** America.—The most important railways of South America have been constructed in Argentina, largely with British capital, and in certain cases possessing close connection with Great Britain. On Buenos Ayres are based the 5ft. 6in. gauge Central Argentine, 3,442m.; Buenos Ayres Great Southern, 5,075m.; Buenos Ayres and Pacific, 2,806m.; and Buenos Ayres Western, 1,926m.; while from Rosario southwards to Puerto Belgrano runs a railway (513m.) of that name. The first named stretches as far north as Tucuman, while the Chilean traffic is handed over to the Transandine line at Mendoza, near the Chilean Border. The 4ft. 8½in. gauge is represented by the Argentine North Eastern, and Entre Rios, together 1,563m., and the Buenos Ayres Central, 292m., the first of which reaches north as far as Corientes and Posadas on the Paraguay border. Important sections of metre gauge lines exist in Argentina, notably the 1,218m. Cordoba Central, reaching Tucuman through Cordoba; the Buenos Ayres Midland, 320m.; and the Argentine State system, 3,520m., which also possesses some mileage of the 5ft. 6in. gauge. The Transandine Railway (888m.) is metre gauge through its two sections, Argentine and Chilean, though connecting with the wider gauge lines at its termini. It reaches a height of 10,452ft. above sea-level; certain of the steepest sections of line were worked on the Abt rack rail system, but electrification permits (1929) the elimination of the rack.

In Chile the State Railways possess 3,100 route miles, with the 5ft. 6in. gauge running from Puerto Montt through Pueblo Hundido to Chanaral, north of which is the metre gauge Northern system, State owned, which runs almost to Iquique, situated on the Nitrate Railway, as is also Pisagua. The Transandine line joins the south to north stem almost due east of Valparaiso, while the Arica-La Paz line crosses Chile to enter Bolivia as does the narrow gauge Antofagasta-Bolivia Railway with nearly 600m. in Chile and 320 in Bolivia. This latter company leases and works the Bolivia Railway lines serving Atocha, Potosi, Viacha and Cochabamba. Amongst other Chilean lines may be mentioned the Taltal Railway of 164 miles. In Peru are the Central of Peru, (298m.) serving Lima from Oroya, and the Southern Railway of 550m., running between Cuzco and Mollendo, both lines of standard gauge 4ft. 8½in.; a few other lines exist, some of narrow

African Railway Mileage

Country	Miles of line at end of year 1934	Miles of line in 1934 per 10,000 population

gauge. Colombia possesses nearly 2,000m. of railway, Venezuela nearly 700 and Ecuador over 700m., whilst Dutch and British Guiana both possess small railway mileages. Paraguay possesses a standard gauge Paraguay Central (274m.) based on Asuncion, whilst Uruguay has company and State-owned lines, all of standard gauge, totalling about 1,660 route miles. Brazil can boast of four important metre gauge railways of over 1,000 route miles, of which the biggest is the Leopoldina based on Rio de Janeiro; a second, the Great Western of Brazil based on Recife, carries much cane sugar. The San Paulo and Central of Brazil are two important lines built on the jft. 3in. gauge, the former serving the port of Santos and the latter Rio de Janeiro, while the Paulista Railway possesses both metre and 5ft. gin. gauge mileages.

Railways of Australasia. — The railways of Australasia are almost without exception government-owned systems, a feature of many newly developed countries where private capital is not easily available to construct new railways, which must be built before the hinterland is settled and brought into agricultural production. The first line was, however, opened as a result of private enterprise in 1854 in the vicinity of Melbourne, Victoria; almost all the private lines in Victoria were taken over by the government in 1878 and form the nucleus of the Victorian Government system centring on Melbourne. By 1910 the State possessed nearly 3,400 route miles of 5ft. gin. gauge acquired or constructed at an average cost of £12,550 per mile. The Victorian Railways connect at Albury with the New South Wales 4ft. 8½in. gauge system, dating back to 1855, from which date practically all railway mileage in this State has been government owned; thus all goods by rail between Melbourne and Sydney or the North must be transhipped. In 1910 the New South Wales system consisted of 3,650 route miles, having cost £13,430 per mile on the average. The N.S.W. railway network is based on Sydney; besides serving Newcastle and Canberra, it also makes contact with the South Australia system at Broken Hill, and in the north runs through Queensland territory into Brisbane. The mileage of the 3ft. 6in. Queensland Govt. railways is very great per head of population and consists of a long coast line route between Brisbane and Cairns, with long westward branches to Cloncurry, Winton and Quilpie. The first line was opened in Queensland in 1865. Exchange traffic with the New South Wales system is transhipped either at Brisbane or at Wallangarra. The Queensland route mileage in 1920 was 3,660 and had cost £6,648 per mile, but the mileage has since been extended to over 6,600. The South Australian Government railways possess mileages of line built to the jft. 3in. and the 3ft. 6in. gauges, and in 1910 the former extended to over 600 and the latter to over 1,300 route miles; as illustrating the difference in cost created by the variation in gauge, the former cost £11,136 per mile and the latter only £5,892 per mile. The earliest line in South Australia was opened in 1856 at Adelaide, in the neighbourhood of which city the lines are of the broader gauge, while the northern lines are of the narrow gauge. The main tranship point between the two gauges is at Terowie and at Broken Hill with the New South Wales lines, — there being no break of gauge between Adelaide and Melbourne.

From Port Augusta in South Australia the 4ft. 8½in. standard gauge Transaustralian line, built and operated by the Commonwealth, runs westwards to Kalgoorlie in Western Australia, through traffic being operated in 1917 over this 1,050 mile line, which possesses a stretch of zoo miles without a curve. At both termini there is a break of gauge, for Kalgoorlie is on the 3ft. 6in. Western Australian system, the first line of which was opened in 1871 at Locksville. Perth did not obtain railway facilities until 1881. The early railways due to private enterprise were acquired by the Government in 1896, although there remain two private company railways, namely the Jarrah Belt and the Midland Railway Companies' lines, also of 3ft. 6in. gauge in Western Australia. By 1910 the Western Australian Govt. owned and operated 2,144 route miles which had cost £5,305 per mile, but since then the mileage has increased to over 5,000. In North Australia exists a 3ft. 6in. gauge railway running southwards from Darwin towards Daly Waters, constructed for development purposes and owned and operated by the Commonwealth. Presumably this line will gradually be extended in the form of a north to south transcontinental track to join the 3ft. 6in. Oodnadatta Railway already owned by the Commonwealth, which now runs from Port Augusta to Alice Springs. The problem of the Australian railways is primarily one of a difference of gauges, for transhipment of passengers and freight is expensive, not only in money but in time.

Tasmania possesses a Govt. owned gft. 6in. gauge system of 650 route miles centred on Hobart, though this city obtained its first railway in 1876, five years after Launceston, the other Tasmanian port. The Government acquired the Launceston and Western Railway in 1872 and by 1910 the system had grown to 445 miles and had cost £8,860 per mile. There also exists in Tasmania the small Emu Bay Railway. The New Zealand Government Railway system, which adopted the 3ft. 6in. gauge in 1869, extends to 3,500m. divided between the North and South Islands, in both of which the first railways were opened in the '60s. It was not until 1895 that the policy of State ownership became pronounced; since then the State system has absorbed all railways of importance in New Zealand. The New Zealand railways prove a difficult operating problem in that many of their lines are unconnected and heavy expenditure and difficult construction work will be required to weld the system together, although much progress has been made since the war period 1914–18. Having to traverse mountain ranges, the railways have had to construct long tunnels and to operate over very heavy gradients.

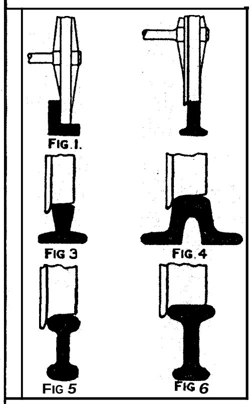
Railway Accidents. — In Great Britain and many other countries statistics are regularly published concerning the number of accidents occurring from the operation of railways. In general the casualties are divided into those suffered by passengers or employees and fatal or non-fatal accidents. Additionally, in Great Britain legislation (see Section D) has been passed ordering the railways to report accidents occurring to trains, but not necessarily resulting in injury to persons; and enquiries are held by Government Inspecting Officers, primarily in order to make recommendations to the railways so that similar occurrences may, so far as is possible, be avoided in the future. Great care must be exercised in any comparison between the railway accident statistics of various countries, the basis of compilation being different in almost every case, while frequently accidents which are reportable in one country would not be reportable in another. Difficulties also arise as to whether accidents between road vehicles and railway trains, as for instance at level crossings, should be included in the statistics of railway accidents or not. In certain countries figures are also available which show the casualties incurred not as a result of railway operation but which have taken place on railway property. In dealing with statistics of railway accidents the number of casualties should also be studied in relation to the amount of work done in the movement of passengers or freight, taking as an index the number of passengers or tons of goods carried in any one year, or the number of train miles operated by the railway.

The British railways have earned for themselves an enviable reputation for safety in view of the high average speed of the passenger trains, a position which has been obtained largely through very heavy capital expenditure ever since their original construction in the form of signalling equipment (see Railway *Signalling*, p. 950), very complete fencing of the track, raised platforms at stations and close and detailed examination of all rolling stock and locomotives. Strict Government regulation of railway construction coupled with the medical examination of employees have also assisted in attaining a very high safety record. In recent years also much stress has been laid upon the "Safety First" campaigns universally employed, not only in Great Britain but on many railways elsewhere, notably in Canada, South Africa, the United States and Germany. Campaigns of this nature have done meritorious work in reducing the number of accidents amongst employees as well as passengers, while the attention given by the British lines to ambulance work receives witness from the numerous competitions on each railway for challenge shields given to the most efficient ambulance team.

It will be seen that collisions and derailments are the main causes of train accidents. Both are preventable but the former, with the highly intricate signal devices which have been installed, are usually a result of a human failure or of the coincident failures of more than one piece of mechanism. Derailments may be due to an error of judgment resulting, for instance, in excessive speed on curves or mechanical defect in the train itself or a failure in the track. The most serious British railway accidents during the last sixty years were the collision of the L.N.W.R. Irish mail train with some wagons of petroleum at Abergele on Aug. 20, 1867, when 33 persons were killed; on Dec. 28, 1879, a North British Railway train was blown off the Tay Bridge and 73 persons were drowned; on July 1, 1906, a L.S.W.R. express was derailed owing to excessive speed at Salisbury, 28 persons being killed; and through a similar accident at Shrewsbury the following year, 18 lives were lost. The most terrible British railway accident occurred on May 22, 1915, on the Caledonian Railway at Gretna, when 2 passenger trains and a troop train special collided, with a loss of 227 lives, nearly all soldiers in the troop train. On Jan. 26, 1921, a head-on collision occurred in a single line section of the Cambrian Railway, 17 persons being killed, while later serious accidents are—a collision at Hull in Feb. 1927 on the L.N.E.R., and another at Darlington on the same line in June 1928. In the former 12 lives were lost, and in the latter 25. There has been a steadily decreasing trend of accidents over the last 70 years, although for a time after the war failures of material due to delayed repairs caused an increased number of breakages of couplings and similar parts. The Continental railways of Europe especially France and Germany suffered even more heavily in this respect owing to still greater arrears of maintenance, but this condition of affairs is being rapidly improved.

B. ENGINEERING AND GENERAL CONSTRUCTION

Track **or Permanent** Way.—The desire to move heavy minerals such as stone and coal more easily than by road led to the employment of "wagon-ways" in Great Britain during the 17th century. These "wagon-ways" merely consisted of wooden planks laid on the ruts caused by the cart wheels, but they enabled much greater loads to be hauled by horses, at that time the source of motive power. It soon became necessary to hold these planks in their proper position by means of sleepers or cross-ties, a name still used in America. Owing to the rapid wear of the planks it became the custom to cover them with metal plates, or strips, usually of iron, while the sleepers were covered with earth to prevent damage from the horses' hoofs. The use of metal on the planks in its turn created undue wear on the wooden wheels of the wagons, mainly of the chaldron type still visible on Tyneside; consequently iron wheels were adopted. Growth of traffic caused the strips to work loose, with the result that attempts were made to cast iron rails in 1767 at Coalbrookdale Iron Works. These rails were of the L type, namely a flat plate with a vertical section on the inner side to prevent the wheels from running off the rails (fig. 1). They were usually spiked to the wooden cross-ties, although in some cases they were mounted on stone blocks to reduce the wear on the cross-ties, which in that case were placed at much less frequent intervals. Plate rails of this type were used by Benjamin Outram on the Ticknall Tramway in 1799, and similar rails were used on the Surrey Iron Railway of 1801 and the Silkstone Railway of 1809. In order to hold the rail in position some of these plate rails were ⊢ shaped. In the north of England the edge type of rail (fig. 2) was preferred and became the prototype of the present railway rail. With the edge-rail the wheel rested on the top, with a flange to hold it to the rail designed as part of the wheel, and not as part of the rail, and running inside the latter. Blenkinsop's railway at Leeds in 1812 used rails of the edge type weighing 40lb. per yd., mounted upon pedestals. With the coming of steam traction the edge rail was almost universally adopted, except where the railway was of a tramway type designed to run along the highway. Cast iron rails of this date were usually about 3ft. long and were not connected at the ends. George Stephenson used the "half-lap" joint on his Killingworth Railway and, later, for the Stockton and Darlington line employed malleable iron rails weighing 28lb. per yd. The wrought iron edge-rail, often of the "fish bellied" type, was mainly used during the 'thirties of last century. In the case of the Liverpool and Manchester line it weighed 35lb. The pedestal of 1812 became the chair of the Liverpool and Manchester, which was spiked to the cross-ties and the rails wedged by compressed wooden keys into the chairs. On this line fish bellied rails gave place to parallel rails, namely, those of uniform cross section for all their length.



FIGS. 1–6.— RAIL TYPES **(1) Plate-rail, (2) edge-rail, (3) flat-bottomed rail, (4) bridge-rail, (5) double-headed rail. (6) bull-headed rail**

C. B. Vignoles (1793–1875) used the flat-bottomed rail (fig. 3) in England in 1836; it eliminated the chair since it could be spiked direct to the sleeper, while I. K. Brunel employed a bridge rail (fig. 4) on the Great Western Railway. Joseph Locke introduced the double-headed rail (fig. 5) in 1835, which theoretically enabled the rail to be reversed, but in practice damage caused to the base resting in the metal chair prevented this. The present design of "Lull," or single-headed rail (fig. 6) was evolved from the double-headed rail and has been standard in Great Britain for many years; the Great Western giving up its bridge-rail on the conversion of gauge in 1892. An important development was the adoption of the steel rail shortly after Bessemer invented his process of steel manufacture, though to-day many rails are manufactured by the open hearth process. During the 19th century the growth in length and weight of rails had been continuous and by 1894 the L.N.W.R. was using 60ft. rails, although in 1922 rails used by the other railways were mainly 40 or 45ft. long, and weighed between 90 and 100lb. per yd. In 1924 the British Standard Section Steel Rail weighed 95lb. per yd. with a lighter rail of 85lb. per yd. for branch lines. The L.M.S.R. uses 60ft. rails for its main line and this length is becoming more popular, although some railways still use 45ft. rails.

On Continental and other railways out of Great Britain the Vignoles, or flat-bottomed, rail holds almost universal sway since it requires less attention, but increased rail weights even up to 136lb. per yd. are used, and in many countries the rail is not spiked direct to the sleeper but rests on a metal plate. To join the rails a "fish plate" was designed, attributed to Stevens on the Camden and Amboy Railroad (U.S.), and adopted in England in 1847. These metal "fishes" were first wedged but later bolted on the inside to the two rails, making a suspended joint between two sleepers; for many years these two end sleepers were placed closer together than their neighbours. In British practice this policy still survives, although it is more widely prevalent in other countries. On British railways the rail joints are opposite but on other railways it is often the practice to stagger them, that is, place the rail joint of the left hand rail opposite to the centre of the right hand rail. The present British steel fish plate is held in position by four pear necked fish bolts. The design of the chair

RAILROAD PASSENGER ACCOMMODATIONS

1. Corridor of a German express train, showing private compartments
2. Interior of a first-class dining car, London and North Eastern Railway
3. A first-class compartment on a German express train
4. A salon on an International Wagon-Lits Company train, France
5. A private compartment on a German express
6. Cozy comfort in a streamlined American Pullman
7. Observation lounge in an American streamlined train
8. Stateroom on Pullman sleeping car, showing fixed bed, and individual toilet facilities
9. Standard Pullman sleeping car with semi-private compartments
10. Sectional berths on streamlined train
11. The dining car on a streamlined train
12. Novel buffet for meal service

with its attendant spikes for attaching it to the sleeper has suffered many modifications but the standard specification provides for a 46lb. chair with two galvanized coach screws driven through oak ferrules on the inner side of the rail and a similar one on the outside. Rails are slightly canted inwards in the chair and held by wooden keys, usually oak. In Great Britain wooden sleepers treated with creosote or some other preservative are universal although metal sleepers, largely used on railways of other countries, and concrete sleepers, have been used experimentally but do not last so well in Great Britain, or make for such smooth running. With the old bridge rail employed by Brunel, longitudinal sleepers underneath the rails were employed with fewer cross ties but the system died out with the conversion to the standard gauge of 4ft. 8½in. In America a reinforced concrete bed has been tried experimentally on the Père Marquette Railroad. The sleepers normally rest upon a bed of ballast with the top surface exposed so as to allow easy adjustments by the permanent way men. Granite or slag, broken into small pieces, is laid between the sleepers to ensure drainage and avoid dust. The depth of the road bed varies, but it should be wide enough to spread the weight and is often about 18in. deep, duly sloped to ensure draining the water outwards. A space of 6ft. has to be left between two pairs of rails, though in other countries than Great Britain this is wider, and consequently permits greater overhang of the rolling stock.

Construction. — The ideal location for a railway line is one which passes between two centres of trade in a straight line and over level country, thereby eliminating the need for extensive earthworks, whether to cut through a hill or to build up an embankment over a valley. In practice railways have to be constructed on the routes over which trade and commerce will flow and use has to be made of the best location available, bearing in mind the capital cost in relation to the traffic likely to be available after its completion. As a natural result of this position it is common to find in highly developed and industrialized countries railway locations which required considerable first cost and capital outlay to construct, with comparatively easy gradients and curves of a large radius, whilst in newly developed countries, where it is more problematical as to the amount of traffic which will be available for movement by rail, the line is constructed at first as cheaply as possible with heavy gradients and sharp curves, rendering it necessary at a later date to build expensive cut offs so that operating expenses may be reduced and the capacity of the railway increased. Where passenger traffic is expected to be an important source of revenue the railway must be designed to take passenger trains at high speeds. It will be realized that the location of a railway is necessarily a compromise between the desire to build the line as cheaply as possible and to construct it so that the costs of operation will be as low as possible. In hilly country the earth removed by the cuttings, or cuts, to permit the railway to pass through the higher ground, is used to form the embankments, or fills, upon which the track is enabled to cross the lower ground, while culverts, bridges and viaducts carry the railway over streams, rivers and depressions where an embankment would exceed 60ft. in height.

Gauges. — A railway may be constructed on one of several running gauges, this being the distance between the inner edges of the running rails. That which has come to be known as the standard gauge is 4ft. 8½in. This curious measurement was due to the transfer of the flange from the rail to the wheel when the plateways *(see* Track, page *922)* were abandoned, the old wagons of the 16th and 17th centuries being apparently 5ft. between wheels. This gauge is universal in Great Britain, except for a few light railways, and is practically universal for the United States and Canadian railways. On the Continent there are considerable mileages of metre and other smaller gauges, especially in mountainous districts, such as parts of Germany and Switzerland. The main trunk lines of Austria, Belgium, Bulgaria, Denmark, Czechoslovakia, France, Germany, Holland, Hungary, Italy, Jugo-Slavia, Norway and Sweden, are all approximately 4ft. 8½in., or so close to that gauge as to permit through running of locomotives and rolling stock. In Ireland the gauge is mainly 5ft. 3in. *(see* Section *A),* while in Spain and Portugal the lines are mainly jft. 6in. and in Russia 5ft.

In England the Eastern Counties line was originally built to a 5ft. gauge as was also the London and Blackwall, but these were later converted to the 4ft. 8½in. standard. When the Great Western was first constructed I. K. Brunel chose the 7ft., or broad gauge, but after a long drawn-out battle between the 4ft. 8½in. and the 7ft. gauges, the latter was in many places fitted with a third rail, or mixed gauge, to permit through running, and finally disappeared from the Great Western in May, 1892. It left as a legacy to the G.W.R., however, a wider loading gauge, namely, the maximum measurements to which rolling stock may be constructed or goods loaded. The importance of a standardized loading gauge, which unfortunately does not exist in Great Britain, is second only in importance to a standardized running gauge. By means of train ferry steamers, which carry locomotives and rolling stock on their decks, it is possible for British rolling stock to cross the Continent on the Harwich to Zeebrugge train ferry, traverse all central Europe, and by means of similar steamers between Sassnitz and Trelleborg to reach Scandinavia, or to cross the Straits of Messina to Sicily. Similarly continental railway rolling stock can arrive in England, if it is not too large for the smaller British loading gauge. Train ferry steamers are also used on the Great Lakes of North America, Japan and elsewhere. The running gauge in India is mainly 5ft. 6in., but there are large mileages of metre gauge lines as well as of other gauges, while in Japan the normal gauge is 3ft. 6in. The South African Railways are of the 3ft. 6in. gauge as is also the Sudan Government system, but the Egyptian State lines are built to the standard gauge, whilst the Kenya and Uganda railway is built to a metre gauge. The most important South American railways are based upon Buenos Aires and are mainly of the 5ft. 6in. gauge, though other gauges exist in Argentina, Brazil, Chile and Peru. The development of railways in Australia has suffered by the difference in the gauges adopted by the various State systems *(see* Section *A).*

ROLLING STOCK

Railway rolling stock comprises passenger carriages and goods or freight trucks, or wagons, both carriages and freight wagons being usually termed cars in Canada and the United States.

Passenger Carriages. — The earliest passenger carriages on the Stockton and Darlington and the Liverpool and Manchester railways were practically road coaches mounted on railway axles and wheels, and in the case of the former line were hauled by horses for some time after the line was opened. They were individually named, as were the road coaches of that date, as "Experiment," "Highflyer," and so forth, and the term passenger "coach" applied to railway passenger carriages still survives. The early carriages of about 1840 were 15ft. in length and weighed about 3 tons, with a width of about 7ft.; they were mounted on four wheels, and the majority of early railways catered for three classes of passengers. The first, who paid about 3d. per m., were carried in covered carriages corresponding to the interior of the road coach; the 2nd class passengers were usually provided with a roof, but the sides of the carriages were left open; whilst the 3rd class were carried in open wagons and provided with little or no seating accommodation. It was the normal practice to construct three "compartments" in each carriage, a first class in the centre and a second class at either end. Third class passengers were not conveyed by the more important trains.

Among the earliest improvements in construction was the introduction of spring buffers and screw couplings between the carriages, which tended to prevent jolts when the train was starting or stopping. About 1840 third class carriages began to have roofs, and by the Regulation of Railways Act 1844, the railways were ordered to provide sides to third class carriages, no mention being made of windows or lights. The same act compelled the railways to run one train per day at a minimum speed of 12 m.p.h., calling at every station and conveying passengers at a fare not greater than 1d. per mile. These trains became known as "Parliamentary" trains, and were the subject of much derision in the press of that period. Carriages which were nearly always constructed of wood gradually increased in length and were mounted on six in place of four wheels, while the width was gradually extended to 9ft. Further remnants of the old road coaching days lasted in the form of different coloured upper panels, while some lines painted the compartments different colours on the same carriage, a practice still employed by the Paris-Lyon-Méditerranée Railway of France, though for reasons of economy the majority of railways now paint their carriages a standard colour, throughout, a notable exception being the G.W.R. with its cream upper and chocolate lower panels.

By 1874 the carriages had increased so much in length that it became necessary to mount them on four axles, arranged in two pairs at either end of the carriage. Each pair was so designed as to swivel independently of the other pair, thus permitting a much easier passage of the curves owing to the carriage body remaining rigid while the bogie under-carriage turned in conformity with the rails on the curve. This system, in a very much improved form, is standard for nearly all railway passenger carriage construction throughout the world, by far the majority of new passenger rolling stock being built as 8-wheeled bogie carriages. Six-wheeled carriages continued to be built in Great Britain for suburban services until the end of the 19th century, but there have been very few 4 or 6-wheeled passenger carrying vehicles built for British railways since then, although on some Continental railways they remain the standard type for local trains. In France there exist some very long passenger coaches of about 60ft. mounted on two axles only, but such a design does not add to the comfort of the passenger on lines with sharp curves. In Canada and the United States all passenger cars have been mounted on two bogies with four or six wheels each from almost the commencement of the railway era. This policy was due to the less expensive permanent way provided in newly developed countries and the more usual presence of sharp curves. The addition of an extra axle to each bogie became necessary in North America on account of the great increase of weight consequent upon the adoption of steel carriage construction in the 20th century. On British and Continental railways the added weight caused by the two extra axles is not regarded as being balanced by the advantage of smoother running except in the case of dining or sleeping cars.

Sleeping Cars and Corridors.—British sleeping cars built by the Pullman Co. of America were used on the Midland Railway in 1874, the L.N.W.R. also using a sleeping car at that date. Pullman cars available for 1st and 3rd class passengers on payment of a supplementary charge are attached to many British railway trains, and sometimes form a whole train. They are also available for day use on the lines of the American "chair-cars." For many years all sleeping cars have been owned by the railway companies. In 1880 the G.N.R. provided dining cars on their London to Leeds trains; the Midland Railway was, however, the first company to offer these dining car facilities to third class passengers. The same railway in 1872 provided third class accommodation on all its trains, a policy which all the railways of the country were forced to adopt during the succeeding years. In 1875 the Midland Railway also abandoned the 2nd class, a policy which has become almost universal except on certain suburban and special services, such as boat trains. On French railways the three classes still exist but many fast trains are only provided with 1st and 2nd class carriages. The same is true of Belgium and Switzerland. In Germany there are four classes, but more than three are scarcely ever provided upon any one train, 1st and 2nd class on the fast main line trains, 2nd and 3rd on intermediate trains and 3rd and 4th on local slow trains.

The G.W.R. in 1890 put into service the first corridor trains, thereby permitting a passenger to reach the dining car by passing along a corridor usually placed on one side of the vehicle, and so also eliminating the special train stops made on nearly all the long distance runs to enable passengers to take their meals at the station restaurants. A movable covered gangway in the centre at the end of the coach is provided to ensure safety when passing from one carriage to another. Lavatory accommodation became standard in the case of corridor carriages during the early 'nineties. On certain railways, notably the Midland, the clerestory roof was introduced. It possessed a raised portion in the centre, and being fitted with glazed lights permitted increased light in the compartment and improved ventilation. It lasted on the M.R. until 1914 when it gave place to the British standard high rounded roof, technically known as the "semi-elliptical." The French and Belgian railways never adopted the clerestory, sometimes called the Pullman roof, but it was used in Germany for many years, and the vast majority of American and Canadian passenger cars are built with this design of roof.

All carriages built for long distance train services in Great Britain are designed to permit travellers to pass from one end of the train to the other, either by means of a side corridor or a centre vestibule. The former are known as compartment type corridor vehicles, while all dining cars are built to the latter design. Corridor trains permit the collection and examination of tickets by the railway officials while the journey is in progress, thereby also enabling time at stations to be cut down to a minimum, while permitting the passengers to distribute themselves more evenly throughout the train. On the other hand it lowers the seating capacity of the carriages by at least two seats per compartment, which constitutes a serious consideration in the case of suburban passenger traffic, especially during the hours of "peak" traffic, or "rush" hours, when seating capacity is strained to the uttermost. Consequently, suburban passenger trains in Europe are normally of the non-corridor type, though in certain countries, notably Switzerland, all the carriages are vestibuled.

Passenger Train Weights, Speeds.—The typical British corridor 8-wheel bogie carriage contains seven 1st class compartments or eight 3rd class compartments, seating respectively 42 and 64 persons on an empty, or "tare," weight of about 30 tons. It usually possesses a lavatory at either end and is about 60ft. long by 9ft. wide with a height from rail level to top of roof centre of about 13ft. Carriages usually possess steel frames and wooden bodies, sometimes metal sheeted, and in some cases a metal roof, but a wooden roof is more common. On Continental railways the modern all'steel express train carriage often weighs 40 to 45 tons; a greater degree of safety is claimed for that type of construction but the all-metal design is usually very much more noisy than the wooden type of carriage. The non-corridor bogie carriage for suburban service contains 8 or 9 compartments, seating 10 or 12 third class passengers and eight 1st class passengers on an empty or tare weight of 25 tons. A typical British express train often weighs between 400 and 500 tons empty, exclusive of the engine and tender; on the Continent a train of similar seating capacity would be heavier owing to the Continental carriage design. Pullman, dining and sleeping cars are the heaviest cars on European railways.

Oil was the earliest illuminant of railway carriages, giving way to gas lighting in the eighties, later improved by the addition of the incandescent gas mantle. Electric lighting was in use before the end of the century and is used for all new carriages, power being usually generated by a dynamo worked off the axle of the carriage when running. Carriages are heated by means of steam supplied by the engine, but in the case of electric traction other methods have to be employed. The steam heating system replaced the use of foot-warmers containing chemicals which gave off heat after being dipped in hot water. The screw coupling and side buffer are used on nearly all Western European carriages, the few exceptions in England being largely automatic centre couplings of the "buck-eye" type, the two jaws closing when the carriages are pushed together, but these are only fitted to Pullman or other carriages working in special trains. The L.N.E.R. has constructed many "articulated" sets of 2, 3 or 5 vehicles, the bogie being placed under two vehicles instead of at the ends of each. By this method weight is saved and, it is claimed, less oscillation and smoother running results.

In addition to passenger carrying vehicles there are many other railway vehicles which frequently form part of the composition of a passenger train; they consist of vans for luggage and parcels, horse boxes, vans for milk, fruit, theatrical scenery and motor cars. These vehicles are all fitted with the Westinghouse or vacuum automatic brakes for working on fast passenger trains. In Canada the passenger cars are very similar to those of the

United States, and the vestibuled centre corridor is universal; automatic couplings are standard on both passenger and freight trains in North America.

The fastest trains in Europe are found in Great Britain and France; high speeds in passenger traffic are also attained on the American railways, whilst the Australian, Canadian, Indian and Argentine railways offer high speed services with heavy trains. The fastest start-to-stop railway schedules in the world provide for a speed of about 60 or 61 m.p.h. but during the journey much greater speeds must necessarily be attained to offset the comparatively slow start and the low speeds caused by heavy gradients, curves, or the passage of junctions. In Great Britain fast passenger trains attain 90 m.p.h. and in March 1935 a L.N.E.R. train reached 108 m p.h. on the London-Newcastle run.

Wagons.—For the carriage of goods and mineral traffic a railway employs open or covered wagons, the latter sometimes known as box vans. The early British lines adopted for mineral traffic the chaldron wagon which had previously been in use on the "wagon-ways" drawn by horses. These wagons carried about 4 tons of coal and weighed between 2 and 3 tons empty. For general goods traffic the early wagons were less than 10ft. long. and if loaded with perishable traffic they were, and still are, often covered with creosoted tarpaulin sheets, a practice only used to any extensive degree in Great Britain where the use of covered vans is rendered difficult by the large percentage of traffic which has to be handled by crane at the numerous ports. The size of the British railway wagon has grown steadily but slowly as compared with foreign railway wagons; but the internal trade of the country is largely retail in its nature, while the average distance travelled by a consignment is comparatively small. The general practice of railway freight service is to offer a frequent service, as is done with passenger service, often with comparatively light trains. The average weight of consignments in a British freight train is about 140 tons, but the engine has also to haul the weight of the wagons themselves, hence the wagon designer is faced with the problem of constructing a wagon to hold the maximum weight and volume of capacity on the lightest tare, or empty, weight; with the increase of wagon capacity the less becomes the tare weight for each ton of capacity. Thus, a wagon to carry 6 tons may easily weigh 5 tons, but a wagon to carry 20 tons can be constructed to weigh only 10 tons; while in the United States there are many 100 ton coal cars weighing only 35 tons. The "high capacity wagon," as it is called, also occupies less space on the sidings, which is very important, but difficulties are experienced on the British railways in the use of such wagons by reason of the small clearances for such fixed structures as mine screens and the sharp curves on many sidings. It is an axiomatic rule of railway working that the most successful type of wagon is that which can circulate most freely and can, consequently, be carrying traffic for as many hours per week or month as possible. The average capacity of the railway-owned wagon in Great Britain is about 10½ tons, though the standard to which ali new wagons conform, other than "special wagons" for rails, boilers, plate glass and so forth, provides for a 12 ton capacity. Policies have been urged which aim at the adoption of a standard wagon of at least 20 tons, which would doubtless result in economies of railway operation, but it is very difficult for the railways to build a type of wagon which the trading community does not desire, and the latter in Great Britain has always insisted upon its preference for the small wagon unit in view of the retail nature of the country's trade.

Another characteristic of the British wagon position is the large number of privately owned wagons, that is to say, wagons owned by coal mining companies, coal merchants, quarry owners and others who provide their own wagons for the railway companies to haul. Each of these wagons is registered and there are middlemen in the form of wagon hiring firms who rent out their wagons to coal merchants and even railway companies, as required. Approximately 650,000 wagons are railway owned and about the same number it is believed are privately owned. On Continental and North American railways the percentage of privately owned wagons is very small, consisting mainly of wagons fitted as refrigerators, wagons carrying oil, petrol or acid tanks, or even wine tuns. While certain advantages are claimed for the system of extended ownership of privately owned wagons, nevertheless it adds considerably to the expense of railway operation consequent upon the added sorting and shunting of wagons in the various "marshalling yards."

Many important developments have taken place in wagon design beyond the steady growth in size. Spring buffers are now universal in Great Britain and on Continental railways, though the latter employ a screw coupling as with passenger trains, the British lines adhering to the "loose link" coupling which permits easier attaching or detaching of extra wagons. This difference is, once again, the result of the short average length of haul on British railways, and the frequency of junctions where the trains have to be reformed for the different sections of the line. British wagons are fitted with hand brakes, which according to a Government order of 1911, must be fitted on both sides of the wagons, but it will be many years before all wagons in circulation are fitted with a standard hand brake operated from both sides and applying to all four wheels. The modern wagon has almost invariably a metal frame though the body of the wagon is usually wooden, often on a metal frame-work; coal wagons in many countries are now made of metal. An important improvement which has very considerably assisted the running of the wagon itself has been the adoption of oil lubrication for the axle boxes instead of the solid grease previously universal. Comparatively few grease axle box wagons exist on the British railways, and none upon Continental or North American railways.

STATIONS AND TERMINALS

Passenger Stations.—A passenger station may be divided into three sections; the building which is to contain the booking and other offices necessary for the comfort of the passengers and the business of the railway staff, the platform by which the passengers enter or leave the trains, and the track lay-out at the platforms and in the yard outside the station. From the railway point of view the last is the most important, for upon it hinges the capacity of the station to deal with the maximum number of trains, especially at the hours of greatest traffic pressure. Few stations are exactly alike, and except for wayside stations, as for instance in Africa or on the Canadian prairie, no standard design can be adopted. In its simplest form the wayside station on a double track line in Great Britain, where all platforms are raised, consists of an "island" platform placed between the two lines, or two single sided platforms each serving one line. Intercommunication is provided by a footbridge or a subway, and on one platform is a booking office, where tickets are obtained, and other essential buildings. When trains can pass through a station the latter is known as the "through" type, and may consist of any number of platforms often with "bay," or "dead end," lines at one or each end of a wide platform. Amongst the largest "through" stations in Great Britain are the Waverley, Edinburgh (L.N.E.R.), with 1,390ft. platforms; Crewe (L.M.S.R.) with a platform of 1,509ft.; Snow Hill, Birmingham (G.W.R.) and Clapham Junction, London (S.R.) with 17 platforms.

The largest British stations are, however, the terminal, or "dead end," stations. In America these are often called terminals of the "stub end" design, and recent practice has tended towards a complete division of the station building with its circulating area (parcels, booking arid enquiry offices, and refreshment, cloak and waiting rooms, frequently including shops) from the platforms, termed technically the "train shed"; Windsor Station, Montreal (C.P.R.), is a typical instance of this design of station. In Great Britain, where coal of a less smoky nature is used by the locomotive, the need for this division has not been so important; thus the platforms are more closely connected with the station buildings, usually being joined in the case of modern designs by a wide concourse, with indicators showing the train departures and arrivals and newstands. Amongst the large London termini Waterloo, where reconstruction was completed in 1922, and Victoria (S.R.), with a 1,500ft. platform, are noteworthy in this respect, each possessing the arrangement by which a passenger arriving at the station on foot or by motor passes by way of the booking office through the circulating area, flanked by restaurant and cloak rooms, past the train indicator and timetables to the departure platforms. British railway stations are almost unique in that the majority of large termini are so arranged as to permit taxi cabs for hire to stand along a roadway provided by the side of the arrival platforms of the long distance trains. Gradually, in order to prevent the overcrowding of platforms, and the pilferage of luggage and parcels, the railways have extended the system of "closed" stations at all important centres, whereby access to the platforms is only permitted to those holding railway tickets or a platform ticket, for which a small charge, usually 1d., is made. Each platform usually accommodates only one train but where difficulty of obtaining land has elongated the station design very long platforms exist which can acccmmodate two trains; notable examples are Cambridge (L.N.E.R.), 1,375ft. long; Perth (L.N.E.R. and L.M.S.R.) of the "through" design, and Victoria Station above mentioned.

Another characteristic feature of large British and some Continental European railway stations are the great metal spans with glass roofs over several platforms and lines, of which notable examples exist in London at St. Pancras (L.M.S.R.), King's Cross (L.N.E.R.), and Paddington (G.W.R.). In Germany, Leipzig, claimed as the largest station in Europe, possesses this feature in a form of six arches, and with 26 platforms has a frontage of nearly 1,000ft. Hotel frontages form a further feature of British station planning in many of the more important stations. The Grand Central (1910) and Pennsylvania (1913) terminals in New York City demonstrated the advantages of electrification in permitting the development of building sights actually above the "train shed"; but the completion of the new Union Station at Chicago in 1925, serving four railways, has shown that such a development is possible even with the use of steam traction, in this latter case the station being designed to serve also as an office building. It is possible that the high land value in London may induce a similar policy there in connection with hotel developments. In South America one of the many fine stations is Retiro (1915), terminus of the Central Argentine at Buenos Aires, while Japan is justly proud of its Central Terminus at Tokyo, opened in 1913. It is, however, the track lay-out or design which determines the capacity of a busy station, and in the case of termini the yard where carriages may be stored, cleaned and examined, should be as close to the station as possible and preferably, though this is hardly ever possible, between the sets of inwards and outwards lines.

Layouts. — The lines leading into a terminus are often 6 or 8 in number, but 4 is more usual. In Great Britain, where trains keep to the left track and meet right side to right side, outwards traffic from a station will often be on the left hand side, but where the tracks enter a station sectionally, such as (1) down local line, (2) up local line, (3) down main line, (4) up main line, (5) down suburban line, (6) up suburban line, the platforms and station work can be divided sectionally, which is often advantageous. Where the entering or outside lines are in the order, down local, down main, up main, up local, it will be seen that every local train must cross both main lines either before entering or after leaving the terminal station; such a limiting design may, however, be offset by easier junction working outside the area of the terminus. It is the normal practice to place two lines between each platform, with the necessary cross over lines so that an engine may run round its train. The provision of three lines to allow for this movement is recognized as being wasteful of valued space. Short lines, where engines may wait to back on to their trains are necessary. Where electric traction is employed with multiple unit trains, engine movements are eliminated, thus increasing the platform capacity as measured by the number of trains dealt with each hour. Waterloo (London), excluding its tube station, possesses 21 platforms, and by means of electric and steam traction deals with about 1,200 trains every 24 hrs., carrying about 150,000 passengers in and out. Liverpool Street, London (L.N.E.R.), wholly operated by steam traction with only 18 platforms handles approximately the same number of trains per day, but nearly 250,000 passengers, of whom 85,000 arrive between 7 and 10 A.M. St. Lazare, Paris, with more platforms, and using steam and electric traction, deals with a roughly similar number of passengers. Notable stations in Canada are Windsor Street, Montreal, the new Toronto Union Station, and Winnipeg (C.N.R.), while in Australia, Flinders Street, Melbourne, is famous, as is the Central Station, Sydney, which possesses steam and electric traction and is one of the'most important railway stations in the world. The Ministry of Transport publishes the requirements for passenger lines in regard to railway construction and operation in Great Britain, which include important provisions as regards passenger stations, amongst which may be mentioned that trains should enter a station without reversing; that no fixed structure can be nearer than 6ft. from the platform edge, which must overhang not less than 12in.; the platform height must be not less than 2¾ft. nor more than 3ft.; while staircases of footbridges must have treads not less than 11in. and luggage lifts or subways must be provided at important stations. These regulations apply to new works and all reconstructed lines or stations; they set out also the requirements applying to bridges, level crossings, facing points and so forth.

Freight Stations. — These, for dealing with goods traffic, are of two main types; firstly, the town or city station, where goods are received for despatch by rail and inwards traffic by rail is dealt with, and secondly the tranship, or transfer, station, where wagons containing many small consignments for a large number of destinations are unloaded and reloaded so as to form a wagon load either for each station or a few adjoining stations, or for a second tranship station. By this method it is possible to reduce the delays incurred by waiting until a sufficient volume or tonnage of goods has been received at the originating station to warrant a through wagon, while it also minimizes the number of small wagon loads. One of the largest tranship stations is at Crewe (L.M.S.R.). Like many other tranship stations it adjoins a large "marshalling," or sorting yard. In certain cases the town freight station performs tranship work as well, there being certain advantages in, adopting this method where desirable, such as the more likely possibility of obtaining a full wagon load.

Reconstructed freight stations of modern design are those of the G.W.R. at Paddington and Lambeth (London) and Bristol. Present practice provides for two tracks between the platforms, which are E shaped so as to permit easy movement of the goods round the end of the platforms which consequently must not be too long; drop down bridges may be fitted to cross the tracks at intervals and motor or electrically driven trucks with trailers have largely replaced the manually pushed barrow where platforms are wide enough to accommodate them. Moveable cranes are frequently fitted on overhead runways, and where there is room the inwards traffic by rail is dealt with at different platforms from the outwards traffic. Where this is not possible the lines are said to be "set" with loaded inwards wagons in the morning, and after they have been dealt with the wagons are used for loading up traffic received by road for despatch during the late afternoon by rail. Adequate platforms for loading the road vehicles and turning space for the latter are important, as is also good lighting for night work and smooth platforms, now often of asphalt, on which the trucks may run easily. British town freight stations are often well provided with warehouse accommodation, especially at the ports, which enables them to be used as railhead distribution centres for large trading organizations. To save handling many small packages and to reduce pilferage a system of "containers" has been adopted which, in the form of large van bodies, can be wheeled or moved by crane to. and from railway wagons and road vehicles. These "containers," which can also be of an open type, useful for carrying bricks to avoid handling, are in use extensively in Great Britain and the United States, while their use is also spreading on Continental European railways. In Germany they sometimes take the form of milk or oil tanks.

The tranship station may consist merely of one or two island platforms, on to which the goods are unloaded, sorted and reloaded. The track connections serving the station should be very carefully studied in this case, to avoid the frequent use of locomotive power. Capstans worked electrically or hydraulically are often employed for this latter purpose. At every freight station, even of the smallest type, provision must be made for the loading and unloading of wagon load traffic, such as coal, stone and manure, direct to and from railways wagons and road vehicles.

Marshalling Yards.—While the tranship station acts as a kind of clearing house for the small consignments in the wagons,

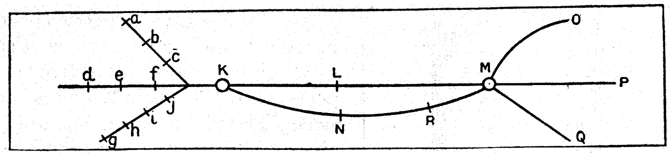

FIG. 7.—POSITION OF MARSHALLING YARDS

so the marshalling yard acts as a clearing house for the wagons of a train. It is customary for a large marshalling, or sorting, yard to be placed on the outskirts of a city such as Liverpool, or a coalfield such as that of South Yorkshire. The streams of traffic originating in the various docks, goods depots or mine sidings, are concentrated upon a large yard, as shown in the diagram at K (fig. 7), where the heavy trains are made up for the long main line haul to M, both through L and through N. At M may be situated another large yard where the trains are resorted for the stations on the lines MO, MP and MQ. Additionally, pick up trains will be formed at K, serving all stations on KLM, and possibly picking up traffic at L destined for R, which must be placed on a train for N or K when it reaches M.

There are many designs of marshalling yards such as might be required at M, but there are three main types: (1) the flat shunting yard, (2) the hump shunting yard, (3) the gravity shunting yard. The choice of design will rest upon the number of wagons to be dealt with in hours of greatest traffic, and also upon the physical characteristics of the ground which is available for use as a marshalling yard. In the case of a flat yard the train enters direct upon one of the sidings, and a shunting engine draws it out and proceeds to push the wagons, in "cuts" of one or more wagons at a time into the lines upon which trains for the varying destinations are being assembled. Flat shunting is in reality a pull and push system and bears hard on the couplings, on the engine brakes and on the rails. Where more wagons per hour must be sorted the train is usually left by the train engine on a reception siding outside the main "grid" of sorting sidings, and a powerful engine is attached to the rear of the train, which is then pushed over a "hump," or high shoulder of ground, and the cuts for each line are uncoupled as the wagons reach the crest of the hump, when the couplings are loose. The wagons thus released drop down by gravity on to the sorting sidings arranged in fan design from the bottom of the hump. One such hump line may serve 40 sorting sidings. An alternative system is to place the reception sidings upon a downward gradient leading to the sorting sidings, so that after the train engine has been uncoupled the wagons drop down by gravity themselves on to the various sorting sidings.

Wagons may be braked by hand or by means of rail brakes, or car retarders, operated by pneumatic or electrical power. These consist of rails placed inside the running rail so as to grip the flanges on the inside of the wheel. The Frolich system of rail brakes, as used in Germany, utilizes the weight of the wagon for braking purposes. In continuation of the sorting sidings, where possible it is desirable to have a few so-called departure sidings upon which the wagons on a train may be remarshalled into the order of the stations for which the wagons are destined. The marshalling yard is a nodal point in railway operating organization, and its working must be very carefully supervised.

SIGNALLING

Semaphore and Light Signals.—The signalling system is the means adopted to control the movements of a train by means of visible signals to the crew of the train. The signal may consist of an arm or other movement, replaced by lamp signals at night, and in the usually accepted sense of the term applies primarily to the signals fixed along the track. These fixed signals normally consist of discs, or semaphores, mounted on posts; the varying movements to indicate the two aspects of "danger" or "line clear" being replaced at night by a coloured light, red being standard for danger in Great Britain and green for "line clear." The improvement in electric lighting permits these red and green lights, known as "colour light" signals, to be seen clearly in daytime, and their use is increasing in preference to the semaphore and disc signs. Many early British signals were of the disc design, being placed at each station and road crossing gate. Space between trains was obtained by enforcing a time interval, often ten minutes, between the trains. The "semaphore arm" was used as early as 1845, while the use of more than one arm at junctions gave the engine driver a route indication. It has since become customary in Great Britain to place the semaphore signal for the less important lines on a bracket post, usually "stepped" so as to give the more important line the higher position.

With increasing speed it became necessary to give advance warning of a "stop" signal at danger; this signal in advance of the stop signal has come to be known as the "distant" signal, and being a warning only is fitted with a "fish tail" and shows a "yellow" light for the danger indication at night. Distant signals, usually about 600yd. ahead of the stop signal, the modern name of which is the "home" signal, are so "interlocked" that they cannot give a line clear aspect unless the stop signals are previously placed to give the "clear" indication. Before 1850, British railways began to adopt the system of working signals and points from a centralized frame in a cabin. In additiori to the distant and the stop signals, it has become customary to allow the trains to proceed beyond the home signal to the "starting" signal, also a stop signal (fig. 8), in that all trains must stop at it when it shows a danger indication. In time of fog, or in snowstorms, it is usual for trains to be stopped at the home signal, operation being assisted by the use of repeater signals, or miniature arms, which repeat the indication given by the semaphore arm, which may be invisible in thick fog. In England, where fog in winter often makes visibility of signals very difficult, fog signalling necessitates the employment of detonators which are placed on the track near semaphore signals to advise the engine crews of the signal indication. The engine explodes the detonators, or series of detonators, with a loud report. They are put in position by fogmen stationed at the foot of the signal, by means of detonator placing machines. On certain railways, notably in France, a detonator is frequently placed on the rail whenever the stop signal is placed at danger, being automatically withdrawn when the signal gives a "line clear" indication. This provides an engine driver, if he runs past his signal, with the knowledge that he has done so.

Ground signals showing the position of the points were often of the disc type, but the 20th century has seen a considerable adoption of the "banner" design, while the miniature semaphore arm is also employed. In Great Britain, because trains always run on the left hand track, the signals are placed, where visibility makes

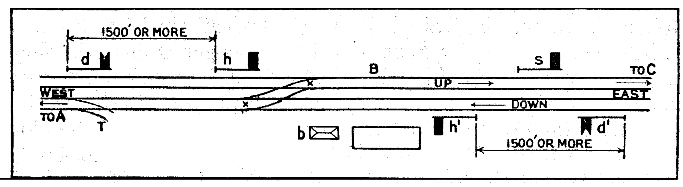

FIG. 8.—BLOCK SIGNALS: ENGLISH PRACTICE: TRAINS RUN ON LEFT-HAND TRACK, SIGNALS AT LEFT. ARMS ON LEFT OF POST

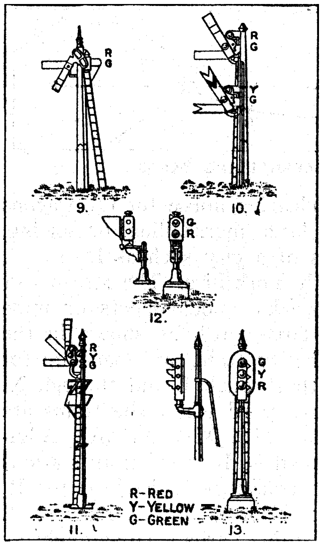
it possible, on the left hand side of the running line, although the railways differ in regard to whether the driver's position is on the left hand side of the engine or not. The signals are operated by means of levers in a signal cabin, which in turn pull a single wire, thus raising a balance weight on the signal, the latter falling through an angle of 60° in order to give a "line clear" indication. This type is known as the "lower quadrant" design (fig. 9). Manually operated signals in their normal position are kept "on," or at danger, namely at an angle of 90° with the signal post; if the wire should break, the balance weight carries the signal automatically to the "on" position. The use of double wires to operate the signals permits the elimination of balance weights, thus making the movement over a long distance easier for the signalman, but double wire signalling, which has been common on railways in Continental Europe and the Dominions, has not met with great favour in the past in Great Britain. The L.M.S.R. and the L.N.E.R. have expressed the intention of adopting "upper quadrant" signals (fig. 10 and 11), in the case of new construction, which to give the "off," or "clear" indication will be raised, instead of falling, through at least 60°. By the adoption of this "upper quadrant" design considerable economies are possible in connection with the rodding and balance weights on the signal post, which may be made of wood, reinforced concrete, metal poles or metal lattice work.

In addition to manual operation, points and signals may also be operated by electricity and compressed air, first used on the British railways by Sykes in 1875, or by a combination of both these systems. Meanwhile mechanical interlocking has given place in many installations to power interlocking of the all-electric or electro-pneumatic type, although in certain cases hydraulic power has been employed.

Block System.—This followed the inauguration of the electric telegraph line from Paddington to West Drayton in 1839, and was improved and extended to Slough by 1842, while two years later the single line Norfolk Railway was worked by telegraph from a central office. By 1854 the L.N.W.R. had adopted a three indication block signalling instrument which showed "line blocked," "line clear," and "train on line." The block system in essence consists of the refusal to permit a train to enter a successive section of line until the preceding train is clear of that section; with manual signal operation and control, movements in each section are controlled from one signal box. The block system, in replacing the time interval by a space interval, greatly increased the degree of safety. The simple block system was further improved and much greater safety obtained by the later adoption of the "lock and block" system, due largely to W. R. Sykes about 1875. The lock and block system prevented the signalman from placing the signals in the clear position for a second train until the preceding one was clear of the section; this was effected by means of locking the mechanical signals with electrical block instruments, which did not permit the movement of the starting signal at **A** until the lock was released by the signalman at the succeeding signal box B. In certain cases the wheels of the train, acting in connection with an electrical current passing through the rails and known as a "track circuit," releases by its own passage past a certain point the lock in the signal cabin. This "track circuit" is the essence of automatic signalling to be described later.

The lock and block system has contributed largely to the safety of British railways, the "absolute" block, namely rigid adherence to the block system, being standard on all passenger lines; the "permissive" block, which allows succeeding trains in the same section when under full control, is only admissible in stations and on lines used by freight trains. In countries other than Great Britain, including the United States, the "permissive" block system is, however, allowed on lines used by passenger trains. On single lines safety is obtained by the employment of a staff or "tablet" which is carried on the engine during its passage of the section. The Tyers tablet system of 1878 permitted, by means of the block system, the entry of a train at either end of the section, an impossibility where a single wooden staff was employed. By 1890 the "electric train staff" had been invented, which was an improvement on the tablet and permits successive trains to enter from either end of the section, but only one tablet can be withdrawn at a time, and that not until the preceding tablet for the section has been replaced at one end or the other.

Automatic Signalling was first installed by the Liverpool Overhead (of England) in 1893. At that time the track circuit (*see* Block System above) was hardly known. It consists in its simplest form of a section of the running rails, insulated from the rails on either side, being fitted with a battery at one end and a relay at the other, so connected that the current may circulate from the battery along one running rail through the relay and back to the battery along the other running rail. This current energizes the relay coils which pick up the armature, thus effecting contacts which remain closed until the two running rails are connected through the wheels and axle of a train. Signals controlled by circuits were first installed on the L.S.W.R. in 1902, and also adopted later on a section of the North Eastern Railway. Automatic signalling led to the use of day "colour light" signals (figs. 12 and 13) employed by the Liverpool Overhead in 1921; such a system is also used giving more than two aspects, thus the "light" signals between Marylebone and Wembley give a "danger," "caution" or "clear" indication; while the S.R. has gone one step further by providing a fourth aspect, namely two yellow lights on certain of its lines with the densest traffic. The semaphore signal can also give three aspects, namely 90°, 45°, and vertical, with the post, but in this case it must be of the "upper quadrant" type, such as has been in use at certain London stations and elsewhere since 1914.



FIGS. 9–13.— SEMAPHORES AND LIGHT SIGNALS
(9) "Lower Quadrant" semaphore, (10 & 11) "Upper Quadrant" semaphores, (12 & 13) types of light signals

Light signals are rapidly gaining in favour owing to their lower cost of installation, better visibility and identical aspect by day and night; also they require less space and can be placed on a level with the driver's eye. Modern signalling rests largely upon the use of the track circuit and electrical devices, which permit the use of long distance point and signal operation with adequate electrical "detectors" and "repeaters," while even level crossing gates are sometimes electrically operated and frequently electrically interlocked with the signals. One large electrically operated signal box may replace as many as five older mechanical manually operated boxes; thus, signalling is rapidly becoming one of the most important departments on a railway, partly owing to the great operating economies which it is able to make, and partly owing to the necessity of making the best use of tracks and rolling stock. Signals, at first installed to prevent collisions, have also become the means whereby a maximum traffic may be handled at a maximum speed with minimum costs, brought about by the aid they give in keeping the trains moving.

ELECTRIFICATION

The last decade of the 19th century saw the commencement of electric traction on railways and very considerable progress with railway electrification was made during the first twenty years of the 20th century, both in Europe and in the United States. Electrification for railway purposes possesses many advantages, amongst which the most important are the elimination of smoke and steam, the greater power which can be obtained from any given axle load, quicker acceleration and the rapid reversal of trains as a result of being able to drive electric trains of the "multiple unit" design from either end, thus eliminating engine movements in a terminus where space and time are strictly limited. The abolition of steam and smoke is most desirable where trains are running wholly or mainly in tunnels or within the limits of large cities, and especially in stations closely encompassed either by office or residential buildings. Greater power is most desired where gradients are heavy, as in Switzerland and other countries where important main lines cross mountain ranges, while quick acceleration and elimination of engine movements in a terminus are very advantageous in connection both with the suburban traffic of main line railways and the underground lines in large cities. **A** further important advantage accrues to electric traction in countries which possess practically no coalfields of their own, but frequently own important water power resources which can be harnessed to produce electricity, and consequently render them independent of other countries for the traction power used on their railways. Fortunately railway lines with heavy gradients naturally exist in many areas where there are swift flowing rivers.

Systems. — There exist several systems of utilizing the electricity generated at power stations for the movement of trains, and in Europe the choice of system has often resulted from a Government decision. Many considerations have to be taken into account, such as the first cost of construction, the operating and maintenance costs, the distance between the power stations and the electrified railway sections, speed and frequency of trains, as well as political considerations and the coordination of railway electrification with the supply of electrical power for industrial and domestic uses. The three main systems of railway electrification, each utilizing a different kind of current and possessing both advantages and disadvantages are (1) the continuous, or direct-current system; (2) the single phase alternating-current system; (3) the three phase alternating-current system. The direct-current system is that usually employed for suburban systems in connection with a comparatively low voltage, limited in early electrification schemes to 600 volts, in which case a third rail was used from which the current could be collected by shoes. This system required the construction of many substations, but permitted light weight and small dimensions, and is consequently well suited to adoption with multiple unit trains where the axles of many of the cars on the train can be used as driving axles, thus obtaining great adhesion and permitting the train to be driven from either end. In many modern installations voltages of 1,200, 1,500, 2,400 and 3,000 are now employed, in which case the current is collected from an overhead wire (while substations are designed to operate automatically, thus eliminating the need for attendants and can be shut down when not required); heavy currents can be collected from an overhead wire feed. Where traffic is dense a direct current of 1,500 volts is advantageous and is found in the United States, France, Japan, Holland, Czecho-Slovakia and Great Britain. In cases where traffic is less dense but the trains very heavy, such as on the Chicago, Milwaukee, St. Paul and Pacific in the United States and in South Africa, Chile, Mexico and Brazil, 3,000 volts is employed. The Chicago, Milwaukee, St. Paul and Pacific employs regenerative braking which utilizes the force of gravity on the downward gradients to generate current for return to the power stations.

The single phase alternating-current system possesses an important advantage in the use of comparatively little copper in the feeding circuits, through the use of a single contact wire overhead. Alternating current at high potentials, such as 16,500 volts, can be collected from this feeding wire, which receives the current from transformers frequently not protected from the weather. A small section of the S.R. in London was electrified on the 6,600 single phase A.C. system in 1909. The three-phase alternating-current system has been employed largely for main line use in Europe and is older than the high voltage direct current systems. The Italian State railways have adopted this system widely. Its advantage in part rests upon the three phase induction motor which can be wound for the full potential of 3,000 volts selected. Through the use of alternating current substations containing simple transformers only, requiring no attendance, economies were realized, but the necessity of utilizing double overhead contact wires with the low potentials of 3,000 or 4,000 volts has militated against the extensive adoption of the system, as has also the three phase motor with its characteristic of constant speed, though this latter is often useful in the case of lines with heavy gradients, since it permits the "regeneration" of electric power on falling gradients.

Main Line Electrification. — Amongst the great main line electrification schemes in Europe are those of the Swiss Federal railways; the Midi and the Paris-Orléans railways, and to a lesser extent the Paris-Lyon-MCditerranCe, in France; and important sections of the German Railway Company. In Spain, Norway, Czecho-Slovakia and Holland, there exist also important sections of main lines worked by electric traction. Steep gradients and the lack of coal resources were primarily responsible for the electrification schemes of Switzerland, Italy, Austria, Sweden, Norway, and the Midi Railway of France. The main coalfields of France are far distant from the territories served by the Midi and the Paris-Orléans lines, while the Paris-Lyon-Méditerranée scheme is connected with the operation of the Mont Cenis route to Italy with its long tunnel and steep gradients. Electrified sections of the German Railway in Bavaria, Baden, Silesia and Central Germany are largely those with heavy gradients at some considerable distance from the coalfields, while Spanish electrification was due to the same reason.

Apart from the Southern Railway, which, in recent years, has extended the electrification of its main lines as far afield as Hastings and Brighton, Great Britain does not possess any great main line electrification scheme, though the L.M.S.R. possesses important sections of electrified suburban traffic lines in the London, Liverpool and Manchester areas, while the L.N.E.R. at Newcastle has electrified certain of its suburban lines and a heavy traffic mineral line feeding Middlesborough. The G.W.R. in the London district runs electric trains in conjunction with the Metropolitan, a railway which possesses important electrified lines, parts of which are run in conjunction with the Metropolitan District Railway, a member of the Underground Group of electric lines to be mentioned later. Unlike the Metropolitan District, the Metropolitan caters for freight as well as passenger traffic and, consequently, may be classed with the four large British railways, whose electrified mileage in 1927 was as follows:—

Railway	Total route mileage	Electrified route mileage
G.W.R.	3,801	8·2
L.M.S.R.	6,942	104·2
L.N.E.R.	6,384	50·3
S.R.	2,194	361·5
Metropolitan .	52	31·9
Manchester, S. J. and A.	9·25	8·7

Electrified suburban sections of main line railways are found also on the German Railway at Berlin and on the State and the Paris-Orléans Railways at Paris, and in many other large cities.

In Asia electrified railways are found at Bombay in India, on the Great Indian Peninsula, and the Bombay, Baroda and Central India lines. Primarily of a suburban nature, the former is rapidly also becoming a main line electrification scheme. Japan possesses a large electrified mileage, being rapidly extended to embrace main line and suburban traffic on the 1,500 volt D.C. system; Java also has a small electrified section of the same type. In Australasia the New Zealand Railways have electrified a 5½m. tunnel section using 1,500 volt D.C.; whilst suburban electrification is being rapidly extended around the centres of Sydney and Melbourne. In Africa, the South African railways electrified a 175m. line section in Natal on the 3,000 volt D.C. system, and suburban electrified lines exist at Capetown. In South America, important electrified sections exist in Brazil (using 3,000 volt D.C.) and Chile, while Argentina employs 800 volt D.C.; the two first are of a main line character while the last deals with the suburban traffic of Buenos Aires. In North America, Mexico possesses a short electrified mileage on the 3,000 volt D.C. system; Canada employs electric traction mainly for tunnel sections, using 2,400 volt D.C. The United States possesses many noteworthy electrification schemes, notably the 660m. route mile section of the Chicago, Milwaukee, St. Paul and Pacific, and important mileages on the New York, New Haven and Hartford, the Virginian, the Norfolk and Western. the Illinois Central, the Pennsylvania, the Long Island, the Baltimore and Ohio, the Detroit, Toledo and Ironton, the Southern Pacific, the Erie, the Boston and Maine and the Great Northern railways.

Economies of Electric Traction.--On main line electrified sections it is normal to employ one or more electric locomotives which can be controlled by one driver, but for suburban traffic and almost universally on underground lines, except where steam trains are hauled over short electrified intermediate sections, it is usual to employ "multiple unit" trains, where the motors are

*Table showing the most important electrified sections of the World's Railways**

Country	Total route mileage	Route mileage electrified
Argentina	28,882	65·1
Australia	28,085	260·7
Austria	4,174	563·8
Brazil	22,280	251·0
Canada	47,010	31·2

*Underground, Light railway, and Inter-urban lines not included.

built into the passenger cars. Reversal of such trains may be cut down to about three minutes, where the trains are very short, or where a second driver is ready to enter the rear of the train as it arrives and drive it on the return journey. More rapid acceleration, together with the greater ease of fitting automatic stop signal devices, permits a closer headway than with steam trains, where frequent stops are concerned, whilst for tunnel sections and underground railways electric traction has come to be regarded as essential. The question as to whether to equip a steam railway for electrification is an ever present problem to many railway administrations and each individual case must be studied on its own merits. Against the advantages of electrification are high capital cost of equipping the line and adapting the rolling stock, while from the operating point of view it is a great advantage to possess each motive unit independent (as in the case of the steam locomotive) of any central power supply. The best method of comparing the two sorts of traction is by means of the net revenue, that is to say, the profit on operation. Electrification invariably attracts traffic, especially passengers, but it is usually more costly to operate, owing to the high interest charges on capital; hence its success will depend upon the amount of new revenue it can attract.

Underground and Elevated Electric City **Railways.**—City railways may be distinguished from tram or street railways in that they possess their own right of way, either above the streets in the form of elevated lines, or below ground in ordinary tunnels or, as in the case of many London railways, in tubes. Such railways normally only carry passengers. Their average journey is short, and the capital cost of construction per mile very high. The traffic is very unevenly spread throughout the day, and the speed and frequency of trains must be sufficiently great to enable them to compete with road services offered by omnibuses, tramways, or even walking. In Great Britain the only important elevated railway section is that of the Liverpool Overhead, claimed as the first electric overhead railway in the world and opened in 1893, 15 years after the elevated system appeared in New York. Sections of elevated lines also exist in other large cities, such as Paris, Berlin and Boston. Electric underground passenger railways exist in Great Britain almost wholly in the London area, an important exception being the Mersey Railway which, originally steam, adopted electric traction in 1903. The first London tunnel railway was the Metropolitan running between Bishop's Road and Farringdon Street and opened in 1863, from which the Metropolitan and the Metropolitan District lines of to-day, largely constructed on the "cut and cover" principle, developed. The "Inner Circle" section of these lines and the extension to Uxbridge was electrified in 1905, and since greatly extended. The City and South London, opened in 1890, was the first deep level line to be built in Great Britain on the "tube" principle, by means of shields invented by J. H. Greathead. Electric locomotives were used on the line, but like the later tubes, all trains are operated with multiple unit trains. In the case of the tube lines, amounting to about 50 route miles, each track runs in a single tube, with the stations built in tubes of large diameter. On the Central London gravity is used to assist the slowing and acceleration of the trains on arrival and departure at stations. New York, Paris, Berlin and Budapest all have underground electric railways, but London's system is primarily of the deep level type. Glasgow also has an underground line, while Chicago has a network of underground freight lines. London possesses a unique Post Office miniature underground electric railway, the system being worked from the stations with no crews on the trains. The cost of construction of such lines depends entirely upon geological strata and the extent to which sewers and underground streams are encountered, but in London it has varied between £250,000 and £1,000,000 a mile. The system of operation is quite distinctive from that of main line or even outer suburban railways, for speed and weight of trains are uniform at any one time, few trains pass stations without stopping, and the "headway" between trains is very close.

C. RAILWAY ECONOMICS

Capital. — Railway capital is the money expended upon the construction and equipment of the railway property, a railway company being permitted by its act of incorporation to raise capital for these purposes to the extent of a stated amount; in the case of the Great Northern Railway, as originally projected, the capital was to be £3,500,000 in shares of £100 with a deposit of £2 per share. The railways of Great Britain possess a high capitalization per route mile, resulting from the great opposition of landowners. Thus, in the case of the Liverpool and Manchester 86 landowners were opposed out of the 335 whose ground was required for constructing the lines. This has resulted in heavy legal costs and great difficulties in Parliament in obtaining the passing of the various railway acts. It has been estimated that in the case of the London and Brighton Railway the law charges alone averaged £3,400 per mile. The price of land in England at the time of railway construction 1825–70 was probably higher than in any other country, while the standard of construction was certainly second to none. Heavy traffic was visualized and many of the lines were built with double tracks, while no financial assistance was granted by the State either in the form of cash grants, loans at low rates of interest or in the form of free gifts of land, such as characterized so notably the construction of railways on the Continent of Europe and more especially in countries at that time practically undeveloped. Canada, perhaps, is one of the most extreme examples of this position, where the C.P.R. not only took over a State constructed railway, but received a cash grant as well as land, in return for constructing a line through to the Pacific Coast. In the United States, railways south and west of Chicago were granted Federal, State and municipal aids for construction in order to open up these territories.

The capital of the British railways was somewhat reduced as a result of amalgamation brought about by the Railways Act of 1921, owing to the exchange of shares and stock of the old companies for that of the new being based upon the market value of those stocks, which in reality meant the prospective earning power of the stocks in question. Thus, £100 of ordinary stock upon which, let us say, a dividend of 2% per annum had been made, and which was worth £40 at the time of amalgamation, was allotted £40 of the new stock which carried prospects of a 5% dividend. Thus large sums of nominal capital which had small earning power were converted into smaller sums of capital with more adequate earning power. By this process over £100 million of nominal railway capital was eliminated. The capital expenditure of all the large British railways at the end of 1933 was £1,149,892,098, a decrease of £56,324,625 on the total for 1926, and comparing with £1,141,543,561 in 1913. There are several measurements of British railway capital as shown in the annual returns of the Ministry of Transport. Thus:

	1913	1926
	£	£
Capital authorized	(not ascertained)	1,280,544,401
Capital created	(not ascertained)	1,198,193,149
Nominal capital	1,273,007,764	1,172,064,967

from which may be deducted the balance of nominal additions and deductions including those consequent upon the passing of the Railways Act 1921, namely,

	1913	1926
	£	£
	199,343,548	49,281,652
Issued capital	1,073,664,216	1,122,783,315
Add balance of premiums and discounts	29,485,626	30,046,880
Deduct calls in arrears and amount uncalled	106,548	27,517
Capital receipts from capital issued	1,103,043,294	1,152,802,678
Capital receipts from other sources	3,148,564	1,085,634
Total capital receipts	1,106,191,858	1,153,888,312
Total capital expenditure	1,141,543,561	1,206,216,723
Capital expenditure in excess of capital receipts	35,351,703	52,328,411

From these figures it will be seen that the British railways as a whole have been conservatively managed as regards finance, and there is no basis upon which to claim that watered capital has tended to increase the level of charges in the form of passenger fares and freight rates. It is noteworthy that the average rates of interest paid per cent of issued capital were 4.28% in 1913, 4·40% in 1925, and 3·73% in 1926, the last a year of acute industrial depression owing to the long drawn out deadlock in the coalfields and the general strike of that year. The capital of the four large railways at the end of 1927 was as follows:—

	Shares and stock	Loans or debenture stock	Total
	£	£	£
G.W.R.	112,561,194	39,881,299	152,442,493
L.M.S.R.	310,426,312	109,262,557	419,688,769
L.N.E.R.	259,413,404	114,163,817	373,577,221
S.R.	111,102,398	44,614,426	155,716,824

The percentage of shares and stock to total capital is much greater on British railways than in the case of the American railroads and is a source of financial strength.

While many attempts have been made to compare the capital per mile of the railways in different countries, such studies are made worthless through the divergence of political policies adopted with regard to early railway construction as earlier explained, through variations in the purchasing power of money at the different periods and wide differences in the number of tracks per route mile. The cost per route mile will naturally be greater in countries where there are long stretches of main lines with four or more tracks. Construction cost will also be greater in mountainous countries or on lines with an abundance of tunnels, on tube railways and on suburban lines where widenings are very costly. Frequently it may be profitable for a railway to widen a line, thus adding to capital expenditure, if by so doing maintenance and train operating charges are reduced; or if, by added facilities, it is possible through hauling more traffic to increase the net revenue. Denser traffic requires added signalling equipment which in turn forces expenditure in this direction. If comparisons are made between the capital per route or track mile between various countries care should be taken that the capital expenditure on ancillary services, such as hotels, steamboats and docks, are excluded from the British railway figure.

Expenditure and Receipts.—Apart from capital outlay which is expected to yield a return of interest in the form of added facilities or savings, operating expenses constitute the second type of railway expenditure. Of the total capital expenditure of the British railways, namely, £1,206,216,723 in 1926, £1,057,973,736 had been expended on the railway proper, such as lines open for traffic, rolling stock, land and buildings, and the balance of almost £50 million had been spent on road vehicles, docks, steamboats, hotels, canals, and so forth. Thus with 37,058 m. of line reduced to single track but excluding sidings, the capital per track mile in Great Britain has been about £28,550. "Expenditure in respect of railway working" on a British railway amounts to about 80% of the traffic receipts per annum. Variations exist between the companies but maintenance and renewal of way and works accounts for about 11%, of locomotives 6%, of carriages 4%, of wagons 4%, locomotive running expenses 20%, traffic expenses 28%, general charges including law and parliamentary expenses, compensation, national insurance and rates 7%. The ratio between expenditure on and the revenue derived from railway operation is known as the "operating ratio." In Great Britain as in many other countries the management has little power in the regulation of wage rates, which form a large proportion of total expenditure, and less as regards the level of freight rates which are determined by outside bodies. "Receipts in respect of railway working" are obtained from passenger and freight train traffic, the percentage from the former varying greatly between the four railways, being highest on the S.R. at 73½% and lowest on the L.N.E.R. at 354%.

Statistics.—Few branches of railway organization have extended more rapidly during the 20th century than that of statistics. With the growing size of railway administrations it has become necessary for those responsible for railway management to be able to visualize daily and weekly the degree of operating efficiency in each district of the railway, and to study the financial situation as it develops from day to day. Traffic when lost is hard to regain if the loss is only discovered some time afterwards. Similarly the unpunctuality of trains must be eliminated in the public interest as soon as possible. Railway statistics are also required by the Government departments responsible for the regulation of the railway industry, as well as by tribunals such as the Railway Rates Tribunal in Great Britain and the Interstate Commerce Commission in the United States, which are responsible for the regulation of railway charges scales. There are also large groups amongst the general public, such as financiers, bankers, economists and members of trade unions, to whom the figures of railway finance, traffic and general statistics are of the closest interest, while a nation has the right to know facts as to the physical condition of its most important form of land transport. Thus in each country there are published railway returns. In Great Britain they consist of annual returns and monthly statistics published by the Ministry of Transport; in the United States the Interstate Commerce Commission publishes an annual report and statistics concerning the American railroads, in addition to data on accidents, signalling, equipment, and so forth. In countries with State railways the annual reports usually give voluminous information, while in Germany the report of the Commissioner is a model for a report dealing with railway progress and finance. The statistics thus circulated to the public are usually termed *external* statistics, in addition to which. and wherever possible closely correlated to them, are figures dealing with railway operation which are primarily designed to help the railway management itself. These are known as *internal* statistics, and frequently deal with figures as to costs. In fact the development of cost statistics by railways has grown rapidly and with the fine margin existing between revenue and expenditure, as illustrated by the high operating ratio figure, continual stress is being laid upon accurate cost statistics. Unfortunately cost of movement of any one consignment by rail is difficult to arrive at in view of the large percentage of railway expenditure which is "fixed," that is to say. which continues irrespective of the amount of traffic hauled; one extra wagon on a freight train will add little to the cost of hauling the train. Each charge made for a passenger or a ton of freight should include an allowance to help to cover the fixed, or nearly fixed, items of expenditure.

Passenger Traffic.—Railway traffic may be divided into two main divisions: (1) that carried by passenger train, and (2) that carried by freight train. Passenger trains in Great Britain for many years carried three classes of passengers (see Section B: Rolling Stock), but the 2nd or intermediate class has gradually disappeared until it survives only on certain London suburban and Continental train services. The use of "Pullman" cars which cater for the 1st and 3rd class passenger upon payment of an extra charge has in practice added a "de luxe" class, but these cars are only used upon certain services of the L.M.S., L.N.E. and Southern railways. On the electric tube railways in London there is one class only, in order to assist rapid loading and unloading of passengers at the stations, where the stopping time is very short. An express train carries little besides the passengers, their luggage, post office mails and a certain amount of parcels traffic, but slower trains carry much milk traffic and sometimes horse boxes and wagons containing livestock, so that the revenue derived from a passenger train service may be varied. Special charges are made for luggage in excess of so many lb. weight per passenger, while workmen's tickets are issued for trains arriving at cities in the early morning, and special low rates charged for season tickets, which permit the holder an unlimited number of journeys within the period covered by the ticket.

Passengers are charged mileage rates of 1½d. for 3rd class, and half as much again for 1st class, but over 50% of passengers are carried at lower rates, either by means of season tickets, tourist, week-end, or other special tickets. Railways in nearly all countries where adequate road systems exist have lost traffic to road motor services to a serious extent, and in many cases are not carrying so many passengers as they did 10 years previously. In the South Western States of America, such as Texas, passenger traffic fell away by 60% in 8 years owing to the competition of the motor car, but that is a somewhat extreme case. Nevertheless railways throughout Europe and North America have been forced to exercise the maximum of effort to reduce their branch line costs, where much of the loss has taken place, and at the same time to make every effort to induce new passenger traffic. British railways have extended the use of road motor feeder services and have increased their train mileage, and while recent legislation has done much to stabilize the position, the tendency appears to be towards a decrease in short distance passengers and an increase in the number of passengers travelling longer distances. To provide an economical service on branch lines, certain railways employ rail motor cars, the engine forming part of the passenger car. These "rail motor cars" are light in weight, cheap to operate, and can carry a trailer when fitted with a high powered engine, which may be of steam, electric or petrol electric design. They can be operated from either end.

Freight Traffic.—Freight trains carry every kind of commodity, from perishable, such as fruit and meat, to manufactured products, such as machinery, etc., as well as bulk consignments of raw materials, as coal, iron ore, road stone, manure, grain and salt. Wherever possible train loads are made at the originating point, as in the case of coal from a mine, but the general tendency is for trade to become more retail as the transport service improves. Reliability of service enables reserve stocks to be cut down to a minimum, thus saving the interest charges on that stock, but entailing greater expense in handling as the average individual consignment grows smaller. The British railways carry over 350,000,000 tons of freight in a year of trade prosperity, the average revenue per ton for all classes of traffic amounting to about 7s., the revenue from freight traffic per route mile being about £5,000, and 15s. per train mile.

Freight traffic is divided into three main classes in the British official statistics, namely, general merchandise; coal, coke and patent fuel; and other minerals, all measured in tans, while livestock is measured by the number of animals. Great Britain is almost the only country which separates coal traffic from other freight traffic, due doubtless to the important percentage which that commodity forms of the total traffic carried. Since the average length of haul for all classes of freight traffic in Great Britain is only about 5jm., road motor services are able to compete successfully for the more valuable types of traffic. This may result in a dangerous condition of affairs, because to make good this loss of revenue, charges may have to be raised upon those heavy articles, such as heavy machinery, coal and raw materials, which are very unsuited for haulage by road. The freight rates or charges made for carrying consignments are closely regulated by the specially appointed Railway Rates Tribunal in Great Britain, where as in every other country the scale of charges is quoted on a mileage basis. For this purpose commodities are placed in classes according to intrinsic value, difficulty of handling, fragile nature or relation of volume to weight entailed. From the commencement of railway history it has been recognized that the greater the value of a commodity, the more it could afford to pay for haulage; thus silk is placed in a class where the goods have to pay more per mile than the scale in which cotton is found. Bulky and heavy articles, like bricks and coal, cannot afford to pay such high charges per mile as valuable metallic ores. In short, every article carried by a railway is to be found in the freight classification, the number of classes varying with each country, some only using 4 or 5 classes, others over a score. To obtain, therefore, the proper charge for haulage by rail, reference must first be made to the classification book, and then to the mileage charge made for that class of traffic. Freight rates are also said to "taper," that is the charge per mile grows less as the distance increases; this enables a commodity produced under the disadvantage of greater distance from the consuming centre to compete with commodities produced nearer at hand. Specially low rates, known as "exceptional rates" in Great Britain, are quoted by railways to allow producers served by their lines to compete with producers in other areas. Such special rates are found in almost every country, and frequently result in strong international competition, as in the case of coal produced in Great Britain, Germany, Poland and France.

Railway Organization— Many types of railway organization are in existence, owing to the problem that faces any two railways being different according to geographical or political conditions. A State owned and operated system will essentially have a different type of organization from a company owned and operated system. The former may be managed direct by a minister of railways or by a railway board, but in the majority of such cases the actual management is in the hands of one person, variously known as the director general, commissioner, president or general manager. The policy of a company owned railway is usually guided by a board of directors elected by the shareholders, the board appointing a president or general manager to organize and manage the system. The system will be divided into departments reporting to the general manager; the number and titles of such departments differ,but usually there are departments headed by:—(1) the chief engineer, who is responsible for the track and civil engineering work, (2) the mechanical engineer, responsible for rolling stock and locomotive design and maintenance, (3) the chief operating officer, responsible for operating the trains, mainly an expenditure department, and (4) the chief commercial officer, responsible for the charges made for passengers and freight carried, mainly a revenue department. In addition there are departments dealing with steamship services, hotels, docks, immigration, agricultural development, and so forth, depending upon the railway in question. Matters appertaining to labour relations, such as wage rates and the hours and conditions of work, are so important on British railways that the head of the staff department is usually a very high official and closely connected with the office of the general manager. Wage rates and hours and conditions of work are however primarily matters regulated by national agreements between the railways and the railway trades unions, of which the three important ones in Britain are the National Union of Railwaymen, the Associated Society of Locomotive Engineers and Firemen and the Railway Clerks Association. Disputes with the trades unions are the subject of negotiation by the Central Wages Board, and, failing agreement, by the National Wages Board, which includes in its composition reprzsentatives of the general public as well as of the railways and the trades unions. Increasing attention is being given to "relations with the public" and to advertising.

D. LEGISLATION

Great Britain.— Early railway legislation dealt primarily with the construction of railways and required the presentation of a bill to Parliament, which then authorized the company concerned to acquire the necessary lands, divert streams and possibly roads, and build tunnels, viaducts and embankments. Much of the earliest legislation was concerned with the question of adequate fencing of the right of way and protection of level crossings. Early railway bills were frequently opposed by rival railway bills and the opposition of landowners, which consequently increased the original cost of construction (see Section C). In return for the right to build a railway, which carried with it the understanding that no neighbouring parallel line would be constructed in such a manner as to divert all its revenue, it was realized at an early date that close regulation would have to be exercised on the charges which it made for carriage. Control of the standard of construction, so as to ensure safety both to passengers and to railway employees, stands out clearly throughout 19th century railway regulation in Great Britain, which consists of a series of acts resulting from the deliberations of select parliamentary committees, enquiries and royal commissions. An act of 1840 for regulating railways required returns concerning rates, fares, traffic carried and accidents, while a Regulation Act, 1842, made possible great improvements in rolling stock; that of 1844 is an important landmark as it visualized the possibility of State ownership 25 years later. In practice this never came about, but another of its provisions, relating to one train per day offering 3rd class accommodation, is the basis of cheap railway travel in Great Britain. The Railway Clauses Act, 1845, standardized railway bills, and the gauge commission of the same year did much to standardize the running gauge for the country. Amalgamation proved a difficult problem for Parliament for 70 years; until 1914, although hundreds of lines were gradually amalgamated, Parliamentary efforts were mainly directed towards the preservation of competition. The Railways Act, 1921, resulting from the upheaval of the World War largely reversed that position. The Act of 1850 recognized the Railway Clearing House formed 8 years previously, while the Railway and Canal Traffic Act, 1854, introduced the principle of prohibiting the bestowal of "undue preference" upon any trader by the railway, thereby creating a new era in railway regulation. During the ensuing 20 years various amending acts were passed, the amalgamation problem coming to the fore again during the '70s. Stricter government inspection of new lines was enforced in 1871, a law which still applies, in addition to the provisions it contained relative to the reporting of accidents involving loss of life, collision or derailment of a passenger train.

A Railway and Canal Traffic Act, 1873, of vital importance, forced the publication of the fares and rates schedules, which was followed by legislation of 1878 requiring the provision of continuous brakes on passenger trains; this latter resulted from a royal commissioll on railway accidents; the carriage of post office parcels by rail was the subject of an act of 1882. The Cheap Trains Act, 1883, made provision for the inauguration of cheap workmen's fares, a landmark in social, as well as railway, legislation; 6 years later came a law enforcing the use of the block system, interlocked signalling and automatic continuous brakes on passenger trains. Meanwhile a Railway and Canal Traffic Act, 1888, resulting from the long deliberations of a select committee, dealt with complaints of high railway charges. A uniform classification of freight was designed in connection with scales showing the maxima charges, upon which were based the Rates and Charges Confirmation Acts of 1891 and 1892. The form of maxima charges of 1893 lasted until 1928, although slight percentage advances were made in 1913 and further increased consequent on the higher prices ruling during and after the War. Labour conditions of railway employees received attention in 1891, introducing definite regulation of the hours of duty and rest periods, while the 20th century opened with the Railway Employment (Prevention of Accidents) Act, 1900, aimed at reducing accidents to employees. Working agreements between railways were discouraged by Parliament as late as 1911, as tending towards elimination of competition, but legislation was destined ten years later to amalgamate forcibly the companies in question. The Railway Companies (Returns and Accounts) Act, 1911, laid down rules of a more adequate presentation of the annual financial accounts and statistics, which still lasts in the form of a railway's annual report.

Railways Act, 1921.—An act of 1919 set up the Ministry of Transport, which took over the railway duties of the Board of Trade and the problem of the future policy with regard to the railways, which had been taken over by the Government at the commencement of the World War. During the war the railways were managed through an Executive Committee consisting of the existing general managers of the various railways; no praise could be too high for the splendid manner in which the railways carried enormous traffics during the war years, supplied large staffs, and much rolling stock and locomotives for work overseas, and while being unable to continue their normal repair and maintenance work built special ambulance trains and produced war stores from their own shops. The Railways Act, 1921. allotted £60,000,000 for division amongst the railways to make good arrears of maintenance and settle all claims against the Government, which had returned the railways to private ownership on Aug. 15, 1921. This important act, sometimes described as the Charter of the British Railways, (1) reorganized the railway system, (2) dealt with the regulation of the railways, (3) designed the principles upon which railway charges were to be based, (4) included important provisions concerning wages and conditions of the railway service, (5) touched on light railways, and (6) added certain general provisions. The first of these was brought about by the new grouping arrangements (*see* Section A), although, unlike the position in France and Germany, competition was retained, such as between London and Birmingham, The second aimed at economies brought about by standardization of rolling stock and physical equipment, such as electric traction. The third set up a Railway Rates Tribunal to be responsible for arranging the scales of rates and fares, and to be available for the reception of complaints by traders and the general public. The new scales came into force on Jan. 1, 1928, on the so-called "appointed day," and were based on a much enlarged freight classification. The Tribunal also was to design charges so as to yield a standard revenue to be earned by the railways, but in view of the competition of road vehicles this ideal is not an easy attainment. The fourth part of the act made provisions for the channels by which disputes regarding wages and conditions of work were to be discussed, namely, through a Central Wages Board and, failing agreement, a National Wages Board (*see* Section C: Railway Organization), though this arrangement did not succeed in preventing the withdrawal of the majority of railwaymen from work during the general strike in May, 1926. The fifth part, relating to light railways (*see* Section A), is comparatively unimportant, while the sixth made provision for the continuation of traffic facilities and flow of traffic, in addition to preserving the rights of those employed by the railways who might suffer from the results of railway amalgamation. The provisions of the Railways Act were far reaching and can only be judged over a long period of time. At one time nationalization was urged, and by some the act was regarded as a half-way measure, but reaction from Government control during the War was too strong to permit such a policy in 1921. Future legislation depends upon the degree of progress attained by the railways under the Act of 1921. Few railway laws in any country have been so far reaching in their provisions. (C. E. R. *S.*)

E. THE BRITISH RAILWAY GROUPS

The Four **Groups.—This** section describes briefly the part which is played by the railway systems of Great Britain in the economic life of its inhabitants. It will be shown that the services rendered by the several railway companies are concomitant with the present organization and distribution of industry. Attention will be mainly given to the four main-line railways of Great Britain, which were formed as a result of the Railways Act of 1921, namely, the London, Midland and Scottish Railway (L.M.S.R.), the London and North Eastern Railway (L.N.E.R.), the Great Western Railway (G.W.R.) and the Southern Railway (S. R.). Besides these, there are the London underground railways and Metropolitan Railway (all of which, since 1933, are amalgamated with the local omnibus, tramway, and motor-coach services in the London Passenger Transport Board), as well as a number of small railways in other parts of the country. Of the numerous classes of traffic carried by the four main line railways, the distinction between the carriage of passengers and of freight is fundamental. Contrary to popular expectation the latter is considerably more important, if measured in terms of revenue, than the former. In 1927, for example, the gross receipts earned by the railways for the carriage of passengers was approximately £70 million, whereas that earned for the carriage of freight, including mails, parcels and other articles carried in passenger trains, amounted to nearly £130 million. For this reason the carriage of freight will first be considered.

Since the beginning of the nineteenth century Great Britain has been under the sustained influence of those economic changes consequent upon the industrial revolution. These changes have been world-wide and can be described as a tendency towards the specialization of economic function, each person or group of persons producing or assisting in the production of some one particular article. Thus, whereas prior to these changes comparatively small areas were self-contained units, so far as their essential requirements were concerned, since that period there have developed large masses of population employed in industry and manufacture who are dependent for their existence upon commodities carried from distant lands, the sufficient growth or production of these commodities being, for all practical purposes, impossible near at hand. At the same time in other parts of the world are vast tracts of country whose inhabitants devote their entire energies to the pursuit of some particular form of agriculture. Between these two extremes are an indefinite number of producing areas all specializing in greater or lesser degrees. But in every case, not only must the surplus and specialized produce be carried away and distributed to those regions which are in need of them, but in exchange the requirements of those producers must be reclaimed from lands suited to the production of those requirements. Thus, an outstanding feature of the present industrial age is man's complete reliance upon long distance transport, whether it be by railway or by ocean going vessel; and the greater the degree of specialization of function, the greater the degree of his dependence.

In so far as the economic changes which have been taking place during the last hundred years have transformed Great Britain into a region, the inhabitants of which have become engaged very largely upon the manufacture and production of goods which are exported abroad in exchange for food and raw materials, her railways are engaged in the carriage of freight which is destined for export, or which has been imported. In this sense the railway systems of Great Britain should be looked upon as providing an essential link in the larger chain of communications by land and sea which enables not only the production of mines and factories to find their way into distant foreign markets, but in return, food and raw materials into the homes and factories of the land. In so far as Great Britain still produces to an important extent what is required by her own inhabitants, the railway systems are occupied in internal trade. Certain traffic that may appear to belong to the latter category, however, is in reality a part of the export trade; for example, the bringing together of raw materials and coal to be used in the manufacture of goods destined for export. Furthermore, shipment traffic is not in every case for export proper, a considerable quantity being carried to other ports of Great Britain. To illustrate the importance of this latter type of traffic, it may be cited that during the year 1925, 53% of the coal bought for use in Greater London came by rail; but of the 47% that came by sea, much the greater part also originated at British mines. The average length of rail haul for landsale coal during the month of January 1925 was 54·51m. whilst that for shipment was 24.26 miles. This brings out in sharp contrast the very different nature of the simple carriage of coal for export, from mine to port, and the wide distribution of landsale coal, not only to each and every gas works and factory, but to every coal consuming householder in the country.

The work of the British railway systems is not only then dependent upon the relative positions of areas of production and areas of consumption but also upon the position of ports. Areas of production differ widely according to the nature of the commodity produced. Certain specialized types of machinery may all be manufactured in a single factory, from which distribution is necessary either to the home market or to ports of export for the foreign market. Another type of product, notably that of agriculture, is grown over a widely diffused area. To illustrate the work undertaken by the railways in this connection, it is noteworthy that London draws her daily supply of milk from areas as far distant from herself and from one another as Norfolk, Lincolnshire, Shropshire, South Wales and Somerset. Similarly the market or consuming area may be widely diffused throughout the country, or may be one particular spot, as in the case of certain machinery required for further manufacture.

Thus, on the one hand there is the bringing together of commodities from a number of producing points scattered through the land to a single centre, and on the other hand the distribution of products from one or two manufacturing centres to a large number of places of consumption or ports. In this connection the position of the coal mining areas of Great Britain are of particular significance, for not only do coal fields directly give rise to the most important of all railway traffics, but their position has considerably influenced the whole distribution of industry, and therefore of population. The coal, coke and patent fuel exported from Great Britain and carried by the four main railway systems of Great Britain during the month of January 1925 (a month not unrepresentative of normal conditions) was shared as follows:—

British Railways Coal *Traffic:* Jan., *1925*

Railway	Tonnage	Average length of haul
		Miles
G.W.R.	2,640,112	21·31
L.N.E.R.	2,982,712	22.65
L.M.S.R.	871,187	39·09
S.R.	510	34·22

It will be seen from the average length of haul of the G.W.R. and L.N.E.R. that the coal fields served by these two railway systems, namely, the South Wales and the Northumberland and Durham areas respectively, enjoy special advantages for this traffic. The position of ports likewise is fundamentally controlled by the geographical factors which bring coast lines, estuaries, tides and rivers in suitable juxtaposition, while the distribution of population broadly coincides with the distribution of industry. No better summary of the general position is to be found than in a passage taken from Part II of the report published (1928) by a Government committee appointed in 1924, entitled Further Factors in Industrial and Commercial *Efficiency,* which reads as follows: "To sum up, the transport services have to provide for a population, nearly half of which is within fifteen miles of a large port, four-fifths of which is concentrated in or round towns, and more than half of which is grouped in five areas which between them comprise only one-tenth of the area of the country." Thus in so far as Great Britain's manufacturing centres are mainly localized around her great ports, the rail haul is often a matter of a few miles only. The Midland manufacturing area near Birmingham, as also Bradford, Leeds and Nottingham, are important exceptions to this generalization; furthermore, articles of value but of comparatively small bulk, such as the finished products of the cotton, woollen and artificial silk industries, are not necessarily exported from the port nearest at hand, but from the ports best situated as regards destination. Thus the manufactured products of the industrial North destined for Continental European markets find their way via Harwich, London, Dover and Southampton to the Continent. On the other hand, as regards imports, while wheat, sugar, tea and fruit arrive daily for distribution throughout the country, a classic example of the importation of raw material is that of raw cotton for the South Lancashire cotton industry, which, like so many other industries in Great Britain, is within easy reach of port facilities at Liverpool and Manchester.

With regard to the carriage of passengers, broadly speaking passenger travel is undertaken either for pleasure or for business purposes. So far as the latter is concerned there are certain outstanding characteristics of modern industry which give rise to passenger travel. The distribution of the numerous branches of many large firms throughout the country, the specialization of function as between different firms, the need of constant consultation, the personal negotiation of important contracts, or the exhibition of his samples by the commercial traveller, are all factors promoting travel. But undoubtedly the chief form of travel essential to modern industry is that between the worker's home and his place of work. Notably round London, but to a lesser degree round most business and manufacturing centres, many hundreds of thousands of people travel daily by railway to and from their homes situated in suburban or rural districts. While as regards passenger travel for pleasure, there is sufficient variety both of scenery and climate within Great Britain to engender considerable travel on this account. Furthermore, the very fact of the intense concentration of population leads men and women of all classes to leave the great cities for sea-side or country-side resorts. The eastern side of England, with its drier climate, the comparatively warm south and south-west coast, the beauties of the Lake District and Scotland, each gives rise to considerable holiday traffic. Last, but not least, the Continent itself is a large source of attraction, resulting in travel to those ports facing the Continent. (G. J. P.)

F. THE UNITED STATES RAILROADS

With less than one-twelfth of the world's population and little more than one-third of its area, North America has nearly one-half of the world's railway mileage and far more than one-half of the aggregate railway capacity to move passengers and freight. The United States leads the countries of North America with about five-sixths of the railway mileage of the grand division. Per 100 sq.m. of land area, the United States has 20·8 m. of railway line while the rest of North America has 1·3 m. and the world (exclusive of North America) 1·1 miles. Compared with population, the world, not including North America, has 2.7 m. of railway line per 10,000 inhabitants; North America, excluding the United States, has 17·1 miles; the United States has 23.6 miles. The whole of Europe has 5·1 m. of railway per 10,000 inhabitants and 5·6 m. per 100 sq.m. of area.

The modern railroad, wherever it exists, is a result of the progressive development and reciprocal adaptation of the roadway, or track, and the motive power, under the stimulus of expanding demand for transportation. Historically, an expanding and effective demand has been generated only by rapidly diminishing charges for the services sought and this diminution has been obtainable only by improvements in methods and mechanism producing commensurate reductions in unit costs of rendering service.

John Stevens (*q.v.*), called in the United States "the father of the railroads," and his associates, received the first American railroad charter from the State of New Jersey on February 6, 1815. At that time approximately eight-tenths of the total population of 8,350,000 resided in New England and in States adjacent to the Atlantic ocean. Most of the balance were situated in Ohio, Kentucky or Tennessee, but scattering and growing settlements were to be found in the Mississippi valley. Within this last named region and in the South there were great areas occupied solely by Indians organized in tribes which were treated as sovereign within their localities.

The War of 1812, the Napoleonic wars, and the Tariff of 1816, had given an impulse to domestic manufactures and to internal trade and had created aspirations towards an economic progress that would require transportation facilities far in excess of any then existing. The conditions creating, in the United States, an exceptional demand for transportation, as they existed on the eve of railway development, can obviousiy be described oniy in very general terms. The picture is that of a growing number of economically detached communities; increasing rapidly in population and industrial importance-each possessing the foundation for profitable commercial ,interchanges, if only the machinery for interchange could be created; and united under one flag. Territorial division of labor had commenced, promising an enormous expansion of internal commerce. Machinery, iron products and textiles for use west of the Allegheny mountains were being manufactured in the Atlantic states; western farms produced grain and food supplies for the South. The East, owing to the increased population of industrial centers following a flood of foreign immigration, had become dependent upon the West for food supplies; the Southern states were experiencing a rapid expansion of the cotton growing industry, and their exports made up two-thirds of the total exports of the United States. The great obstacle to interstate trade and internal development with resulting prosperity was slow and costly transportation. The routes of movement had assumed sharply defined lines. At first following natural waterways, sections not served by such channels had demanded facilities to enable them to compete with their more fortunate neighbors. Turnpikes and canals had been constructed, but the services of these two agencies were sharply restricted by geographic and climatic conditions.

The First Railroads.—The Delaware and Hudson's gravity railroad, in Pennsylvania, was not only the first on which a locomotive was ever operated in the Western Hemisphere but was also the first that was constructed with locomotive operation in view. It began operation in 1829 and only a few months after, tracklaying began, in February, 1829, on the Charleston and Hamburg, later the South Carolina, railroad, the first railroad intended both for general public transportation and for locomotive operation. Prior to 1829, however, there was considerable use of tracks of wood, stone or iron over which cars were drawn by horses or stationary engines, the latter used principally in the operation of inclined planes. Probably, the first of such tramways was an inclined plane in use in Boston in 1795, and operated for moving brick. The next tramway, constructed by Silas Whitney. was also in Boston. It was formerly supposed that the line built by Thomas Lieper, in Delaware county, Pennsylvania, preceded Whitney's, but investigation has disclosed that it was not until 1809 that Lieper constructed an experimental road which was soon followed by another used for transporting stone. The fourth railroad was, apparently, one constructed soon after 1810, at Fallings Creek, Virginia. It was about a mile long and extended from a powder magazine to a mill. These roads were followed by a wooden-rail tramway at Bear Creek, Pennsylvania, in 1818; a short road at Nashua, New Hampshire, in 1825, and the Quincy railroad, in Massachusetts, constructed in 1826. The latter was used to move stone for the construction of Bunker Hill monument from the quarries to the wharf on the Neponset river, about four miles.

In 1827, the Mauch Chunk railroad, in Pennsylvania, 9 mi. long, was built and used in the transportation of anthracite. It was then the longest and most important railroad operating in the United States. Another short road, half a mile long, was constructed in 1827 to connect coal mines with the Schuylkill canal. The Mill Creek Railroad, extending from Port Carbon to the present site of the town of St. Clair, a distance of 3 mi., was also built in 1829. The Delaware and Hudson Company was chartered on April 23, 1823, and its gravity railroad, from Carbondale to Honesdale, connecting its mines with its canal, was actually operated from August 8, 1829, when over it the first locomotive test ever attempted in the United States was made. The use of steam locomotives on this railroad was first advocated by John B. Jervis. Except for the Charleston and Hamburg, none of these early railroads was intended for passenger traffic. The other railways were built to transport freight and natural products in a single direction to a place of trans-shipment, manufacture or use.

The Charleston and Hamburg.—In February, 1829, 150 ft of track, the beginning of the Charleston and Hamburg, were laid on Wentworth street, in Charleston, South Carolina. This railroad was completed to Hamburg, South Carolina, across the Savannah river from Augusta, Georgia, in 1833, and was then the longest in the World, having a length of 135 miles.

The Baltimore and Ohio, the first railrpad built in the United States for the general transportation of passengers and freight, but not projected specifically as a locomotive railroad, was chartered by the State of Maryland, and construction was commenced on July 4, 1828. On May 24, 1830, 13 mi were opened to Ellicott's Mills; on Dec. 1, 1831, it was extended to Frederick City; in 1832 to Point of Rocks, Maryland, in 1834 to Harper's Ferry; to Cumberland in 1852, and to Wheeling in 1853. The branch from Relay to Bladensburg (near Washington) was opened on August 25, 1834.

The Mohawk and Hudson Railroad Company was chartered by the legislature of New York on April 17, 1826, to build a railroad between the Hudson and Mohawk rivers, and after legal delays construction began in July, 1830. Operation began on August 10, 1831, the travel between the termini, Albany and Schenectady, amounting at the outset to from 200 to 300 passengers per day Other sections of the present New York Central were later incorporated and opened for operation: the Utica and Schenectady, opened in 1836, the Syracuse and Utica, in 1839; the Auburn and Syracuse, in 1838; the Auburn and Rochester, opened from Rochester to Canandaigua, in 1840, to Seneca Falls, in 1841, to Cayuga, in 1841, and to Auburn in 1841; the Rochester and Syracuse, in 1853; the Tonawanda Railroad, to Batavia in 1837, and to Attica in 1842; the Attica and Buffalo, to Darien, and to Attica in 1842. These eight railroads together constituted the first railroad connecting the Atlantic ocean or any of its tributary waters with the Great Lakes or rivers flowing to them or into the Mississippi river.

Boston and Albany were also connected by railroads completed in 1842; New York and Boston, in 1849, by the completion of the New York and New Haven; Ogdensburg and Lake Champlain, in 1850; Boston and the Saint Lawrence river, by the building of the Vermont Central and the Vermont and Canada, in 1851. Also, in 1851, the Erie Railroad was completed from Weehawken, New Jersey, on New York tidewater, to Lake Erie, and the Hudson River Railroad, paralleling the Hudson river to Troy was opened in 1852, but the west shore of the Hudson river was not occupied by a trunk line until the construction of the West Shore Railroad, which was opened in 1883. The New York, Westchester and Putnam Railway, now the fourth line of the New York Central to New York City and tidewater was opened in 1880.

Several independent railways formed a line from the Ohio river to Lake Erie in 1848. These lines, with the road from Toledo to Buffalo, the last section of which was finished in 1853, opened practically the whole State of Ohio to railroad transportation. Chicago was reached by rail in 1852 and in 1854 the Chicago and Rock Island Railroad was extended to the Mississippi river. As a result of these extensions much of the trade of the west bank of the Mississippi and of that part of Illinois which is contiguous to the navigable portion of the Illinois river was diverted from New Orleans which had been its only outlet. By 1856 two more lines were built from Chicago to the Mississippi river, in addition to the Illinois Central which was completed to the junction of the Mississippi with the Ohio in the same year. In 1859, the railway system of the country was carried to the Missouri river, by the completion of the Hannibal and Saint Joseph Railroad; in 1866 the Galena and Chicago Railroad was extended to Council Bluffs.

A railway journey across the continent first became possible in 1869 when the Union Pacific, building from the Missouri river at Omaha, met the Central Pacific, built from San Francisco, making a line 1,848 mi. long. Construction was started in 1864 by the Central Pacific. In the following year the Union Pacific began its progress westward. Many hardships and difficulties were encountered in completing this feat of railroad engineering and with its achievement the general outline of the railway system of the United States was formulated. Filling in this outline has been the task of the extensive construction work that has ensued, reaching regions that were left intermediate or at one side, by building cross lines, branches and additional trunk lines. Plans for the Northern Pacific were first developed in 1864, but work was not begun until 1870; it was completed to Portland in 1883. Work on the Atchison, Topeka and Santa Fe was commenced in 1869 and by 1873 450 mi. were in operation. The Southern Pacific, originally intended to join the Texas and Pacific at the Colorado river, had built 102 mi. by 1869, and, in the subsequent four years 172 additional miles were constructed; the year 1881 marked its completion from San Francisco to New Orleans, 2,489 miles. The Atchison's line, from Kansas City to San Diego, and that of the Great Northern, from Saint Paul to Seattle were finished in 1893. Other transcontinental lines, subsequently built, are the Chicago, Milwaukee and Saint Paul; San Pedro, and Western Pacific.

Construction of railways, considering the limited capital resources of the earlier periods, became rapid throughout the more developed portions of the country after the close of the decade that ended with 1830. In that year the total length of railway lines was just under 40 miles; in 1831, it had increased to 98.7 miles; in 1832, to 229 miles; and by 1835, to 1,098 miles. The growth of mileage, by sections, from 1840 to the latest date for which data are available is shown in Table I.

TABLE I. ***Length** of Railway Lines in 1927.*

Year	New England	Middle Atlantic	North Central	South, East of Missis-sippi river*	West of Missis-sippi river†	**Total length of line at end of each decade**
1840	517	1,566	80	636	None	2,799
1850	2,507	3,105	1,272	1,799	None	8,683
1860	3,660	6,353	9,592	8,838	1,840	30,283
1870	4,494	10,991	14,701	11,501	12,191	53,878
1880	5,997	15,949	26,382	14,908	31,435	94,671
1890	6,718	19,842	36,923	29,492	70,622	163,597
1900	7,521	24,691	41,006	35,546	84,582	193,346
1910	7,922	27,379	44,929	47,025	113,184	240,439
1920	7,941	28,096	44,905	49,556	122,347	252,845
1927	7,636	27,741	43,684	48,392	121,678	249,131

*Includes Louisiana †Includes Minnesota. (H. T. N.)

Railroad Consolidation.— The processes of consolidation have acted upon railroads from their earliest days with the result that the thousands of independent companies have been reduced to less than 100 unified systems. As a single and not unusual example, the present New Haven Railroad is composed of what were once about 200 separate enterprises. The decision of the Supreme Court of the United States, in the Northern Securities Case (1904), that the Sherman Anti-Trust Act applied to railroad consolidation, retarded such projects, especially those motivated by the desire to reduce competition.

After two years of war-time operation of all railroads as a single system by the government, the properties were returned to independent operation under the Transportation Act of 1920. That act, among other things, promulgated a new rule of rate-making which directed the Interstate Commerce Commission to set rates so that railroads as a whole might earn a fair return on property value. Congress recognized the fact that, under uniform rates on competitive traffic, a scale which would yield a fair return to railroads collectively would yield more than that return to the strong and less to the weak.

To solve the problem of the weak road the act directed the Commission to prepare a plan under which the many roads would, without undue reduction in competition, be consolidated into a limited number of large systems of fairly equal earning power, so that, under uniform rates on competitive traffic, each would earn approximately the same rate of return.

The tentative plan, published in 1921, had prolonged discussion and the final plan was not published until December, 1929. It called for 21 consolidated systems. The depression was then in its first stages and diverted attention from the plan, and the severity of the losses in earnings through 1931–1935 threw many properties into the hands of receivers or trustees. In the meantime, in 1933, Congress changed the rule of rate-making by eliminating any reference to fair return on value.

It now appears that there is little likelihood of a revival of interest in a country-wide, comprehensive plan of consolidation, but consolidations, along natural lines, will be made here and there as in the past, whenever the proposal is found by the Commission to be sound and in public interest.

Railroad Electrification. — The predictions of 25 years ago, that electricity would soon displace steam as railroad motive power, have not been fulfilled. The miles of electrified railroads (2,686) are now, 40 years after the first installation, little more than one percent of the total.

Because of the elimination of smoke, electrification is especially suitable in tunnels. A serious accident in the smoke-filled Park Avenue tunnel forced the electrification of the Grand Central Terminal in New York. Electrification has been found well suited also to suburban rail service and on heavy mountain grades, and experience has indicated that it brings substantial increases in capacity where traffic is unusually heavy. The factor of increased capacity was given much weight in the decision of the Pennsylvania Railroad, to extend its electrification from New York to Philadelphia and Washington.

There are, however, few railroad divisions which have traffic in volume sufficient to justify the high capital expenditures. When a railroad is electrified the additional capital cost adds as much as or more than 50 percent to the investment in fixed property, and electric locomotives now cost twice as much as steam locomotives of equal power. The economies in locomotive fuel and maintenance are substantial, and there are many other advantages in electrification, but the carrying charges on the additional investment are usually in excess of the economies.

Number of Railways and Mileage. — For statistical purposes the Interstate Commerce Commission divides the railways of the United States into four groups: Classes I, II and III, and Switching and Terminal.

In class I are railways with operating revenues in excess of $1,000,000 annually. In class II are railways earning from $100,000 to $1,000,000. Railways earning less than $100,000 are in class III.

TABLE II. *Number of Railway Companies and Their Classification (1934)*

Item	Class I	Class II	Class III	Switching and Terminal	Total
No. of operating companies	144	206	263	250	863
Road miles operated	238,555	11,821	4,506	*	254,882
% total revenues	96.83	1.10	.24	1.83	100
% total revenue ton-miles	99.42	.52	.06	*	100
% total revenue pass'r-miles	99.80	.18	.02	*	100

*Not reported

While the table shows 144 class I operating companies, many of the separately organized railways are operated as parts of systems under unified managements. The number of unified operating systems and smaller independent railways in class I is about 60.

Because the data for class I railways are much more complete than those pertaining to classes II and III, and because classes II and III are so relatively unimportant, the facts and figures in the following text will, unless otherwise stated, apply to class I railways only.

The road mileage shown in the table does not include multiple running tracks or tracks in yards and sidings. The total miles of trackage of class I railways in 1934 was 402,431, of which 238,555 was first main track, 36,313 second main track, 5,685 other multiple main tracks, and 121,878 yards, sidings and industrial tracks. For every road mile in 1934, therefore, there were 1.68 miles of track, including yards and sidings. The ratio of track miles to road miles has been increasing slightly.

The total railway route miles in recent years has been declining inasmuch as the miles abandoned have exceeded the miles of new railway constructed. The abandoned mileage consisted mainly of unprofitable branch lines, on which the volume of traffic, adversely affected by depletion of natural resources or by competition of motor vehicles, had been so seriously diminished as to yield operating revenues less than the cost of operation. From 1921 to 1934, inclusive, the total road miles constructed were 7,075 and the miles abandoned were 13,866.

Number of Locomotives and Cars. — The numbers of locomotives and cars have recently declined. The increases in the tractive capacity and the efficiency of locomotives, and the increases in capacity of freight cars and their mileage per car day, have enabled the railways to handle a given volume of traffic with a smaller number of units. The decline in number had set in about 1923 and was accelerated during the depression by losses in traffic and earnings, and inability financially to keep up the former programme of replacement of obsolete units.

TABLE III. *Locomotives and Rolling Stock, Class I Railways*

Year	Steam Locomotives: Number in Service	Steam Locomotives: Average Tractive Capacity (lbs.)	Cars: Passenger Train cars	Cars: Freight Train Cars	Cars: Average Capacity per Freight Car (tons)
1935	45,614	48,367	41,584	1,835,736	48.3
1930	55,875	45,225	52,130	2,276,867	46.6
1920	64,368	36,365	53,501	2,322,025	42.4

In addition to the steam locomotives shown in the table for 1935 there were 980 electric and internal combustion locomotives. The comparable figures for 1930 and 1920 were 707 and 364. In addition to the railway-owned freight cars the railways use over 300,000 private freight cars owned by packers, oil companies, coal companies and other large shippers, and the railways own 76,955 company service cars. To the railroad-owned passenger train cars should be added about 8,000 Pullman sleepers and parlor cars owned by the Pullman Company and operated by the railways under contracts.

Investment in Road and Equipment. — The combined balance sheet of all railways on December 31, 1935, shows an investment of $25,500,335,062 in road and equipment. This is the so-called "book value," the integrity of which has frequently been challenged because of a widely held belief that it had been inflated by questionable financial practices in earlier years. The principal purpose of the Valuation Act of 1913 was to determine the validity of the investment account. The figures now available indicate that the book value exceeds the estimated cost of reproduction, less accrued depreciation. The inflation of years ago, when the books did not accurately reflect the facts, had been offset by the many reorganizations of the weak lines and by earnings plowed into the property by the strong lines.

Against this investment there was, on December 31, 1934, an outstanding net capitalization of $18,652,491,252, of which $11,613,527,983 was in bonds or other funded debt, and $7,038,963,269 was in capital stock. The capitalization above noted is that outstanding in the hands of the public and excludes securities held by or for the issuing companies.

While it is true that the actual investment in rail ay properties is slightly in excess of the book value entered as an asset on the balance sheet, and that the capital obligations outstanding in the hands of the public are substantially less than the book value, it does not necessarily follow that the railroads collectively are not overcapitalized, if earning power rather than physical value is taken as the criterion. The book value includes the cost of many facilities not now used, or used in but small degree, and the cost of many locomotives and cars which are so highly obsolescent as to be worth no more than their scrap value. Sooner or later the railways will be forced to recognize that obsolescence, restate their investment account and adjust their capital structure accordingly. No one can now state with authority what that obsolescence amounts to in definite figures.

The weakness in railway financial organization is not so much in the relation between capitalization and investment as in the composition of that capitalization and in inadequate reserves for depreciation and obsolescence. The figures in the preceding paragraph indicate that over 62% of the capitalization is in funded debt and that the stockholders' stake in the enterprise is but 38%. The fixed charges for interest on funded debt are such a burden on net income that substantial losses in gross earnings, as in the period of the depression, result in financial distress. Conservatism demands that the capital raised by the sale of bonds should be no greater than that raised by the sale of stock.

Since 1907, under the regulations of the Interstate Commerce Commission the railways have been required to accrue depreciation reserves on locomotives and rolling stock, but as to such reserves on physical structures there has been no such requirement. Very few railways have made such depreciation charges on physical structures and, moreover, the rates charged on locomotives and rolling stock have been inadequate. The Commission had not, until very recently, specified the rates to be charged. As a consequence the depreciation reserve (in 193j) on roadway and structures was less than 1% of that part of the investment, and the depreciation reserve on locomotives and rolling stock was 45% of the investment in equipment. The total reserve was but 10% of the total investment in road and equipment.

TABLE IV. Condensed Income *Account*, Class *I* Railways (in millions)

Item	1926	1933	1935
1. Operating revenues:			
Freight	$4,809.6	$2,492.7	$2,790.6
Passenger	1,043.1	329.3	357.9
Other	530.2	273.4	303.4
Total	6,382.9	3,095.4	3,451.9
2. Operating expenses:			
Maintenance of ways & structures	866.8	322.3	394.0
Maintenance of equipment	1,283.1	598.7	681.9
Transportation	2,181.5	1,078.0	1,253.1
Other	337.9	250.2	263.7
Total	4,669.3	2,249.2	2,592.7
3. Net operating revenue	1,713.6	846.2	859.2
4. Taxes	388.9	249.6	236.9
5. Uncollectable railway revenues	1.9	1.2	1.2
6. Hire of equipment—net Dr.	82.9	85.0	85.7
7. Joint facility rents—net Dr.	26.8	36.0	35.6
8. Net railway operating income	1,213.1	474.3	499.8
9. Other (non-operating) income	297.9	211.0	187.7
10. Gross income	1,511.0	685.3	687.5
11. Deductions from income:			
Rent for leased roads	166.5	150.2	149.3
Interest on funded debt	496.5	498.3	476.5
Interest on unfunded debt	12.1	26.2	32.5
Other deductions	26.9	16.5	21.7
Total deductions	702.0	691.2	680.0
12. Net corporate income	809.0	Deficit 5.9	7.5
13. Dividend appropriations:			
From income	224.4	28.0	38.2
From surplus	174.8	67.7	88.1
Total	399.2	95.7	126.3
14. Investment in road & equipment	23,204.2	25,345.9	25,025.7
15. Return on investment (per cent) (Item 8 ÷ Item 14)	5.23	1.87	2.00

Similar in principle is the failure of railways, except in isolated instances, to provide sinking funds for the retirement of bonds. As such bonds matured they were refunded, with no reduction in funded debt. The Interstate Commerce Commission has recently advocated that the railways provide for sinking funds on new or refunding issues with a view to the gradual liquidation of debt. The failure to make such provision heretofore has been justified by the theory that investment in railroad physical structures and equipment, if properly maintained, is more or less permanent. This view had force in the earlier days, when railroads had a virtual monopoly of inland transportation, but is not sound today when alternative methods of transportation are available and there is a substantial surplus in transportation facilities.

Revenues, Expenses and Net Income. — The gross earnings and net income of railways may be indicated by the returns for the years 1926, 1933 and 1935. The first was the year of greatest gross earnings. The low spot during the depression was reached in 1933. In 1935 better business conditions brought an upturn which continued in 1936.

The apparent inconsistency in an excess of dividends over income in 1933 and 1935 is explained by the fact that these figures in Table IV. are the aggregates of all railways, some of which earned much more than the dividends paid and some of which failed to earn enough to pay all of their deductions from income.

Volume of Traffic. — The tonnage and passengers carried and the ton-miles and passenger-miles produced by railways during 1926, 1933 and 1935 are given in Table V.

TABLE V. *Traffic* Statistics—Class I Railways

Item	1926	1933	1935
Revenue tons originated: (*thousands*)			
Products of agriculture	111,787	81,702	76,338
Animals and products	26,243	17,651	15,125
Products of mines	757,703	395,065	445,136
Products of forests	104,850	33,165	42,483
Manufactures and miscellaneous	296,068	157,009	196,506
Less than carload	39,491	14,351	14,039
Total	1,336,142	698,943	789,627
Revenue tons transported (inc. tons from connections)	2,465,369	1,258,823	1,427,042
Revenue ton-miles (millions)	443,746	249,223	282,037
Revenue passengers (*thousands*)	862,361	432,980	445,872
Revenue passenger-miles (millions)	35,478	16,341	18,476
Miles per ton per railway	180	198	198
Miles per passenger per railway	41	38	41
Revenue per ton-mile (cents)	1.081	0.999	0.988
Revenue per passenger-mile (cents)	2.936	2.013	1.940

The decline in the volume of railway freight traffic since 1929 was due in by far the greater part to the depression but the competition of other agencies of transportation was a contributing factor. The motor truck began to make inroads on rail tonnage shortly after the service effectiveness of the truck had been demonstrated during the war-time congestion in railway service, and during the depression the trucks' share of the total freight traffic increased while the railway share diminished. The continuing expansion in the national system of improved waterways resulted in further diversions from the rails and a substantial part of rail traffic in carloads of oil and gasolene was lost to the extended system of pipe lines. High-tension power lines displaced coal or oil formerly carried by rail to power plants. In addition to these losses the railways suffered from the growing tendency of shippers to provide their own transportation by operating their own trucks on the improved highways and their own vessels on the improved waterways. The effect of these forms of competition was to cause a shrinkage in the railway share of the total traffic, and at the same time influences were at work which caused a slowing up in the total transportation demand by all agencies. These influences were (a) no new territories to develop; (b) slower growth in population; (c) shrinkage in exports and imports; (d) relocation of factories and warehouses nearer to the sources of raw materials and markets; and (e) technological advances which reduce the amount of raw materials needed for a unit of finished product.

In the field of passenger service the loss to the railways was even greater than that in the freight service. The greater use of the private automobile was the principal cause, but in addition thereto the bus (motor coach) and the aeroplane have taken many passengers from the railways.

The competition of highway, pipe line, waterway and airway services has had the effect of reducing railway rates in both freight and passenger services. Table V. shows that the average revenue per ton-mile fell from 1·081 cents in 1926 to 0.988 cents in 1935. The revenue per passenger-mile was reduced from 2.936 cents in 1926 to 1·940 cents in 1935.

This competition has also had the effect of shifting the emphasis in rail rate-making from the "value of service" principle to that of "cost of service." Railway rates traditionally were built on the principle that low-grade commodities, which would move only under low freight rates, could properly be charged less than the total cost. so long as the charge was more than the direct or "out-of-pocket" cost, and that the indirect or overhead costs not borne by the low-grade commodities could be assessed against the commodities of high value which could bear a charge in excess of total cost. The "value of service" theory has but slight recognition in the tariffs of the truckmen and since their lower charges have appealed especially to the shippers of high-grade commodities, on which the railway rates are high, the railways have been forced to depart in substantial degree from the value principle and meet competition on a cost basis. To the shipper that basis is controlling, as he will not now pay more for carrier service than the cost to him of providing his own transportation in his own trucks, vessels or pipe lines.

Having lost their ability to charge abnormal rates on high-grade commodities to offset the deficiencies in revenue on low-grade freight carried at sub-normal rates, the railways have had even greater incentive than ever before to hold down their costs, increase their operating efficiency, and improve the quality of their service. That they were fairly successful in their efforts is indicated by the fact that the 45·9% decrease in revenues, 1935 under 1926, was met by a 44.5% decrease in operating expenses. This is noteworthy in view of the fact that something like one-half of operating expenses are normally fairly constant and fluctuate but slightly with moderate variations in volume of traffic.

Number of Employees. — Inasmuch as labour costs make up nearly 60% of total operating expenses, the recent heavy reductions in such expenses have meant drastic cuts in number of employees, employee-hours and wages. The data for 1926, 1933 and 1935 are shown in Table VI.

TABLE VI. *Employees and Their Compensation, Class I Railways*

Item	1926	1933	1935
Number of employees	1,779,275	971,196	994,371
Employee-hours (thousands)	4,671,736	2,233,045	2,397,353
Hours per employee	2,626	2,299	2,411
Aggregate compensation (thousands)	$2,946,114	$1,403,841	$1,643,879
Average compensation:			
Per employee-hour	$0.631	$0.629	$0.686
Per employee-year	$1,656	$1,445	$1,653

The railway "brotherhoods," often referred to as the "Big Four," are among the oldest and strongest of labour unions. In the order of seniority in date of organization they are the Brotherhood of Locomotive Engineers, the Order of Railroad Conductors, the Brotherhood of Locomotive Enginemen and Firemen, and the Brotherhood of Railroad Trainmen. Practically all of the eligible employees are members of their respective unions, which are more or less knit together by common ties and working agreements. They are not affiliated with the American Federation of Labor.

In addition to the train and yard service brotherhoods there are many other unions of railway workers, comprising the railway department of the American Federation of Labor. The employees in the locomotive and car shops have several separate unions acting together in matters of common interest as the Federated Shops Crafts. The telegraph and telephone operators belong to the Order of Railroad Telegraphers. The section foremen and labourers have their Maintenance of Way Brotherhood. The clerical forces are represented by the Brotherhood of Railway Clerks.

For a time many railway companies had so-called company unions embracing several classes of employees other than those in train and yard service but very few of those unions have survived the opposition of the national unions. Every union has its contract or working agreement, covering wage rates and rules, with each individual railroad, and for each brotherhood or craft there is substantial standardization as between railways in rates of pay and other conditions of employment.

TABLE VII. *Number of Officers and Employees, Class I Railways, August 15, 1936*

Class	Number
Executives, officials and staif assistants	12,053
Professional, clerical and general:	
Clerks	88,631
Others	80,061
Total	168,692
Maintenance of way and structures:	
Bridge and building workers	18,086
Gang and section foremen	26,021
Section men and extragangs	163,669
Others	40,207
Total	247,983
Maintenance of equipment:	
Skilled craftsmen	202,776
Unskilled labourers	54,597
Others	37,500
Total	294,873
Transportation:	
Stationmen (other than labourers)	39,370
Station labourers	23,752
Yardmasters, switch tenders and hostlers	12,921
Yardconductorsand brakemen	52,641
Yardenginemen and firemen	29,220
Roadconductorsand trainmen	79,724
Road enginemenand firemen	63,004
Others	66,252
Total	366,884
Grand total	1,090,485

Official Organization. — In addition to the officers which are common to any corporate organization — the president, the treasurer and the secretary — a railway corporation has an official organization peculiar to its needs. Below the board of directors. which is elected by the stockholders at the annual meeting, and the president, who is selected by the board, there are several departments, each in charge of a general officer who may also hold the rank of vice-president. To the operating department, headed by a vice-president and general manager, is entrusted the maintenance of way, structures and equipment, and the operation of stations, yards and trains. The traffic department, in charge of a vice-president and traffic manager, makes rates and solicits traffic. The legal department, whose head is the vice-president and general counsel, furnishes legal advice to the board, the president, and to all other officers who may need it, supervises the execution of contracts and agreements, deals in general with the regulatory authorities, institutes legal proceedings, protects the company against suits, and handles all claims for personal injury and damage to property. The department of accounting and finance is headed by a vice-president, assisted by a general auditor or comptroller and a treasurer. The former takes care of the accounting and auditing; the latter is the custodian of funds and makes disbursements on vouchers drawn by the authorized officers and approved by the comptroller.

Besides these general officers there are other departmental heads. The purchasing agent is a specialist in the markets and purchases materials on requisitions drawn by the departmental officers and approved by the general manager. To him, may report the general storekeeper who has charge of the materials and supplies and disburses them to the using departments, but he may report instead to the general manager or to the comptroller. The chief engineer usually confines his attention to construction and to the formulation of standards and instructions governing maintenance of way and structures. He is usually assisted by a bridge engineer, a signal engineer, and other staff officers. The chief of motive power or chief mechanical engineer reports to the general manager and is in charge of general repair shops for locomotives and cars, decides upon standards, and outlines the practices to be followed at engine houses or divisional car repair points. He is assisted by an engineer of tests and other staff officers.

The secretary of an American railway is essentially the keeper of the corporate records and performs the duties legally required in attending meetings of the board or its committees and the annual meeting of the company.

Beyond the officers hereinbefore mentioned there may be others, depending upon the size or complexity of the railway and the individual views of the president. Sometimes there is a vice-president in charge of personnel work, or there may be an executive assistant in charge of public relations, but ordinarily these functions are left to officers with other duties as well. An examination of the charts of several railroads will reveal wide differences, not only in detail but also in the fundamental conception of good organization.

For operating purposes a large railway is divided into districts and each district is partitioned into divisions. The districts. ordinarily, are in charge of general superintendents and the divisions are headed by the division superintendents. The typical railroad uses what is known as the divisional system under which the superintendent is in charge of maintaining way, structures, loco-' motives and cars, as well as of operating stations, yards and trains. To him report a division engineer, controlling maintenance of way and structures, a division master mechanic, responsible for locomotive and car running repairs, and a train-master, who supervises station agents, and yardmasters as well as train and engine crews. The division engineer and the division master mechanic are told by the division superintendent what to do and they do it according to standards promulgated by the chief engineer and chief mechanical officer, who are staff officers.

Governmental Regulation.—Railway companies are incorporated under the laws of a state or states. With few exceptions class I railways operate in more than one state. From the beginnings of railways in the late 1820s until the end of the Civil War period, railways were subjected to little governmental regulation and were given substantial land grants and other forms of financial aid by the Federal Government, states, counties and cities. The building of railways was publicly encouraged and there was keen competition between localities in securing railway service. But as the economic importance of the new form of transportation became apparent, and abuse of power and disregard of broad public interest by railway managers became common, the need of effective regulation in public interest was realized. The initial steps were taken by the individual states, first by .enacting general statutes for the incorporation of railway companies and next by the creation of railway commissions with supervisory powers. In the early 1870s this tendency received an impetus in the central western states in what was known as the Granger Movement to curb undue discrimination in rates and service, and the newly created state commissions were clothed with extensive powers over railway management. Experience indicated, however, that regulation by individual states, over operations which were preponderately interstate in character, was ineffective, and the demand for interstate regulation was met in 1887 by the Federal enactment of the Interstate Commerce Act, based on the constitutional power of Congress to regulate commerce between states. The original act was found by experience to be defective and several amendments were adopted, notably the Elkins Act of 1903, the Hepburn Act of 1906, the Mann-Elkins Act of 1910, the Panama Canal Act of 1912, the Valuation Act of 1913, the Clayton Anti-Trust Act of 1914, the Transportation Act of 1920, the Railway Labor Act of 1926 and the Emergency Transportation Act of 1933. In addition several laws, generally designated as the Safety Appliances Acts, were from time to time enacted in the interest of safety of employees.

The nature and degree of regulation by the Interstate Commerce Commission and the commissions of the several states may be indicated by a summary of present conditions. No railway may be constructed or operated without a certificate of public convenience and necessity, nor may any railway or any part of a railway be abandoned without the permission of the regulatory authority. Inasmuch as all but a small fraction of railway mileage carries traffic which in some degree is interstate in character, the Interstate Commerce Commission is virtually the supreme regulatory authority but its functions are shared or duplicated in certain respects by the individual states.

Existing railways may not issue new securities nor borrow money for longer than two years without the approval of regulatory authority. A certificate of public convenience and necessity will not be issued unless, in the judgment of regulatory authority, the proposed line will meet a real public need not already met reasonably by existing transportation service, and unless the proposed line will not unduly injure existing service to the detriment of public interest. The promoters of the project must satisfy the regulatory authority that it is bona *fide* in nature, that it is likely to earn enough to be self-supporting and give reasonably adequate service, and that the promoters have sufficient financial capacity to complete and operate the railway.

Railways are obliged to furnish transportation upon reasonable request therefor, to provide reasonably adequate facilities, and to furnish safe and adequate car service.

Rates and rules affecting public service must be just and reasonable, and must not be unduly discriminatory as between persons, localities and commodities. The rate for a shorter distance may not be more than that for a longer distance over the same route in the same direction. Rebates or similar devices are prohibited. Rates proposed by a carrier must be publicly filed. They may not become effective in less than thirty days, except under special authority. If objection is made the proposed rate may be suspended for months and the burden of proof placed upon the railway to justify the rate at public hearings. All tariffs must be available at stations for public inspection and the rates must be strictly adhered to. Railways are prohibited from transporting commodities (except lumber) which they themselves produce.

Prior to 1920 the regulatory authority, in its control over rates, was specifically instructed to consider only the factors of justness, reasonableness and freedom from undue discrimination. The Interstate Commerce Act said nothing about protecting the railway against the imposition of rates which might be confiscatory. In the Transportation Act of 1920 a new rule of rate making was enacted. Under it the Commission was directed to set rates so that the railways, as a whole or in territorial groups, should be able, under honest, efficient and economical operation, to earn a fair return on the value of property devoted to public service, such value to be determined by the Commission. The fair return originally set at 6% was, in 1922, reduced to $5\frac{3}{4}$%, but the railways as a whole actually earned considerably less, even in the prosperous years 1926–1929. The rule might have been workable if railways had continued to hold their former virtual monopoly of inland transportation, but since 1920 that monopoly has been lost as a result of the intensive development of competitors by highway, inland waterway, pipe line and air. Railway rates, since 1920, therefore, have had to take account of competition of other agencies, and the return on investment has ceased to be controlling.

The futility of the 1920 rule of rate making was recognized in the Emergency Transportation Act of 1933 when a new and somewhat vague substitute was adopted. Under it, rates are to be set so that traffic may move freely and so that the railways may earn enough, under efficient management and reasonable expenditures for maintenance, to keep their properties in such condition as reasonably to meet public demands for transportation. The new rule, adopted during the depression. has not (1937) had a fair trial and has yet to meet the test of normal business conditions.

All railways are required to keep their accounts and to make periodical and special reports in form and manner prescribed by regulatory authority. All accounts and all correspondence and other files may be inspected at any time by representatives of the regulatory authority and that body is required to publish the accounting and statistical returns in such detail as it may deem expedient. The monthly and annual reports of the carriers to the regulatory authority are available for public inspection.

The regulatory authority has power to inquire into any phase of management and to pass judgment on the degree of honesty, efficiency and economy in administration. It may prohibit a director or officer of one railway from serving in similar capacity with another company. Railways are required under certain conditions to advertise for bids on materials to be purchased and there are restrictions upon purchasing materials from a concern in which a director or officer of the railway has an interest.

The regulatory authority has power to require one railway to permit another railway to use its terminal facilities, under reasonable terms, when the company owning the facilities can grant such use without undue detriment to its own business. The regulatory authority has power also to determine the division of through rates between railways participating in interline traffic.

Railways are prohibited from unduly stifling competition by pooling of traffic, by restricting the free interchange with competitors, by controlling water lines with which they compete, by refusing to make physical connection with other railways or water lines, and by any form of undue discrimination; provided, however, that when the regulatory authority believes that public interest will be served, pooling may be authorized. The regulatory authority may require a railway to join with other railways in the establishment of through routes and publication of through rates.

The Railroad Labor Act of 1926 sets up a procedure that must be followed in disputes with employees as to wages or conditions of employment. Under the Hours of Service law an 8-hour basic day has been established, with a limitation of 16 hours during which certain employees may be continuously employed. Under the Safety Appliances Acts, and other requirements of regulatory authority, certain devices, such as automatic train control apparatus, cab curtains, power reverse gears, and automatic fire-box doors, must be installed and maintained. Locomotive boilers must conform to prescribed standards and be inspected periodically. Car equipment, in such things as couplers, ladders, hand holds, running boards and brake apparatus, must conform to specified standards and the adequacy of the maintenance of such equipment is checked by governmental inspection.

The degree of public regulation of railways is much greater than that applying to competing forms of transportation, especially by water and air. Commercial motor carriers by highway have been subjected for several years to varying degrees of state regulation of intrastate traffic and since 1935 their interstate operations have been regulated by federal law. (W. J. C.)

ROADBEDS AND STRUCTURES

Of the two major classifications of railway property, stationary or fixed property (including roadway and structures) and rolling stock (cars and locomotives), the former comprises somewhat more than 75% of the total investment. Comprehended under the subject of roadway and its construction are the important topics of clearance, roadbed design and construction, culverts, and the ballast bed. Track structure and special trackwork embracing ties, rails, fastenings, etc., are also here treated with relation to present and future design. Signs, fences, crossings, labour-saving equipment, railway timbers, water stations, are likewise discussed briefly as integral parts of the subject of stationary property. (*See* also BRIDGES.)

An increasing concentration of traffic, greater individual axle loads, and the higher speeds of freight trains have imposed heavier burdens upon the roadway and track structure. The ton miles per mile of road were 100% more in 1928 than in 1903 on American railroads. Driving axle loads, which in 1900 did not average more than 30,000 lb., are now in excess of 70,000 lb. in some cases.

The development of a more stable roadbed structure bas been dictated by necessity as well as to reduce track maintenance cost, to increase the margin of safety for anticipated heavier driving axle loads, and to effect a decrease in train resistance. Practically all American railroads have strengthened the roadway by widening it, increased the depth of the ballast, the number of ties in a panel, the weights of rail, as well as making greater use of tie plates, anti-creepers and other auxiliary fastenings.

Clearance.—Since 1918 changes have been made in the dimensions and types of equipment, in the sizes and weights of shipments, and in the clearances fixed by legislative acts in many of the States. The magnitude of the problems involved has led to the standardization of clearances for new (single) track construction, for bridges and tunnels, and for the third rail of electrical tracks; and a minimum distance between tracks has also been established. Consideration has likewise been given to structures placed along side tracks, a minimum distance being established from the gauge line of the rail on tangents.

Roadbed Design.—Roadbed design includes both the roadbed and ballast sections, which together form the foundation of the track, made up of the ties, rails and required fastenings. While the improvement of the roadbed with its cushion of ballast has been in progress since the beginning of railways, its most marked developments have taken place since the beginning of the present century. The minimum width (1929) for both excavations and embankments is 20 ft., with the added provision that a roadbed shoulder of not less than 18 in. be maintained outside of the toe of the ballast slope. Crowning of the roadway is a common practice to facilitate drainage; while the making of fills of clay or other impervious materials is avoided. Ditches have been deepened to provide for sub-draining the roadbed, as well as for discharging the storm water. Intercepting ditches are coming more into use for diverting from cuts water which is collected over a considerable drainage area, and for conveying it along the foot of embankments, avoiding in the first case the deposit of material which may interfere with traffic, and, in the second case, erosion which may endanger the stability of the roadway. Sub-drainage of cuts, by means of vitrified pipes laid with open joints and fed by perforated transverse pipes, small tiles or cinder-filled trenches, is being more generally employed as a means of effecting large savings in track surfacing costs.

Culverts.—While the original box culvert still finds use, its construction is no longer of rubble stone or wood, but is now almost always of concrete, either mass or reinforced. Where the extent of the openings is not prohibitive, pipes of concrete, cast iron or corrugated metal have largely replaced the box culvert, their cost being comparatively low and their service life practically unlimited. The majority of culverts are being provided with both a headwall and an apron at the discharge end, each serving the double purpose of preventing erosion and holding the embankment against sliding. Cast iron pipes (*see* PIPE), have been improved in design as well as in the method of casting and production so that they may be employed for openings of a diameter as great as 90 inches. Pipes fabricated of corrugated corrosion-resisting metal, which provide light and easily installed structures, are being employed frequently.

Ballast Section.—Standard ballast sections have been adopted in recent years which provide a greatly increased depth of material beneath the ties. For the heaviest service this depth is now no less than 24 in., which is based on the principle that a roadbed material subject to deformation by the application of a live load should have a depth sufficient to produce approximately uniform pressure on the roadbed, which is thus the maximum spacing between ties. The heavy expense for ballast of this depth is avoided by the use of a sub-ballast of a material superior to that of the roadbed, and often equally efficient with the ballast in its two functions of drainage and distribution of the lead. Crushed stone and gravel are the materials most generally employed for ballast. The former is regarded as superior to all other materials for this purpose, since its angular fragments bind together so as to distribute the load over the largest area, and it affords the best drainage for the longest period without cleaning or renewing. Washed gravel is nearly as effective for ballast as crushed stone, and is much cheaper where it is available. Burnt clay, slag and cinders are materials in common use for ballasting the less important tracks. The cleaning of ballast, which was formerly done by hand labour with ballast forks, is frequently done with mechanical equipment.

Track Structure. Ties.—While the general design of the track has not changed materially since the early days of railroads, the size and spacing of the ties, the weight and length of the rails, the strength and rigidity of the rail fastenings, and the designs of standard and special trackwork, have undergone a progressive development. Among the earlier expedients for strengthening the track structure was a closer spacing of the ties and, more recently, the specifying of wider ties than those standard in previous years. Whereas 7 in. ties were considered adequate 25 years ago (although doubtless many wider ones were used) present practice favours an 8 or 9 in. width for heavy-traffic main tracks. Similarly, a spacing of 16 ties to the 33 ft. panel was then customary, while 20 ties to 33 ft. is now nearly universal. These two features have increased by about 50% the extent of the rail directly supported on the ties. Probably no fact regarding ties is more striking than the attention which is being given to their conservation by an increasing use of tie plates to protect them against mechanical wear and by a more extensive use of chemical preservatives, approximately three-fourths of all ties used by steam railroads now being so treated. These protective measures have also conserved timber (see TIMBER PRESERVATION) by enabling the faster-growing woods to be used for ties.

Rail and Fastenings.—Development in this field has been outstanding in recent years. The weight of rail, which about 1900 was frequently no heavier than 60 lb., has been more than doubled. Recent studies have shown the trend on the part of the railways toward heavier sections for their main-line tracks. The 136 lb. rail is the heaviest section used in any main-line American track. Important changes have also taken place in the design of the rail section, as well as in the composition of the steel from which the rails are rolled. In American Railway Association sections, developed in 1905, the height was generally one-tenth greater than the base, with the sides sloped on an angle of 1 in 16, which slope is retained in the designs recently adopted by the American Railway Association and known as the R. E. sections. By reason of the uniformity now possible in its manufacture, rail steel has tended toward a generally higher carbon content than formerly, the specifications adopted by the American Railway Association permitting as high as 0·89%. (See IRON AND STEEL for a discussion of manufacture.) The standard length of rails, which formerly was 30 ft., is now 39 feet. While rails as long as 60 ft. were laid 25 years ago, the practicability of the longer rails has only been possible through the development of an improved joint structure, together with devices for restraining the creeping of the rails, along with a higher standard of roadway design and better maintenance of the roadbed structure. Joint fastenings, which formerly were of light angle bars, with fish plates not uncommon in certain tracks, have had their section greatly increased, while a number of designs have been developed looking to a closer approach of the joint to the strength of the unbroken rail. The general use of heat-treated or high-tensile bolts, and of spring washers of the higher tensions, has also contributed greatly to the rigidity of the joint structure. Auxiliary track fastenings, such as tie plates and anti-creepers, are being made in heavier designs and used more plentifully in all classes of railway tracks.

Trackwork.—An outstanding development has been the consideration given to the distribution of metal in switches, frogs and crossings to provide uniform strength throughout. Heat-treated and high-tensile bolts are frequently specified for the assembly of frogs and crossings. Heavier track structures are being laid in terminal yards, while increased attention is being given to the selection of frogs and switches of smaller angles, so as to provide a greater margin of safety.

Wooden signs are fast being replaced with those made of concrete or iron and of more attractive appearance, while stronger types of woven wire fencing, with treated wood, steel or concrete posts, are being used to fence the right of way. Many wooden plank crossings are being relaid with other more lasting materials.

Water Stations.—The increased number of locomotives, and their greater size and power, the extending use of larger engine tanks as a means of accelerating train movement—these frequently having capacities of from 16,000 to 21,000 gal.—and the growing recognition of the value of improved quality of feed waters in promoting increased locomotive efficiency, has made the water an important factor among the other items of the fixed property. Railway water supply has become a highly specialized branch of operation, including at many plants treatment of the waters. The greater quantity of water required has made necessary the installation of larger pumps and pumping combinations, while the need for uninterrupted service has shown the desirability of ample storage capacity, with duplicate pumping units in some instances. Increased interest has been shown in the turbine, among other deep wells and systems. While the steam plant predominates, the use of oil engines has grown greatly, and electric drive for pumps is advancing rapidly wherever current is available, particularly by reason of the advantages obtained through float switches, pressure gauges and remote control. Tanks for the storage of water, which are of wood, steel and sometimes concrete, are of greater capacities, commonly as high as 100,000 gallons. Where track tanks are used to avoid delays due to stops for water, they are being lengthened to supply double-headed trains or those following each other at close intervals. While the essential features of the exterior treatment of locomotive waters has not changed greatly in recent years, and the precipitating and neutralizing of the harmful solids by lime and soda ash remain accepted practice, increasing use is being made of other chemicals to supplement this basic treatment. Definite progress has also been made in interior treatments by the development of new chemical compounds for introduction into the tender or directly into the locomotive boiler.

Passenger and freight stations, engine terminals, shops and powerhouses are essential to the operation of railways. (See the sections on Freight, Passenger and Water terminals for a discussion of these subjects.)

The present design of track will continue substantially unchanged for many years, although the economic advantages of heavy track construction will be increasingly appreciated and utilized. Advances will continue to be made in rails. Although the general use of the 150 lb. section is far in the future, its ultimate adoption is inevitable as wheel loads continue to increase. Mill practice in the manufacture of rail will be further improved, providing enhanced wearing qualities with a reduction in failures. (E. T. H.)

RAILWAY FREIGHT TERMINALS

According to the definition agreed upon by the American Railway Engineering Association, a railway terminal is, "An assemblage of facilities provided by a railway at a terminus or at intermediate points on its line for the purpose of assembling, assorting, classifying and relaying trains." In its larger usage the word is sometimes applied to an entire district or zone, such as Chicago, St. Louis or New York.

Importance of Terminals.—The importance of terminal tracks for classifying, switching and assembling freight may be judged by the statistics published by the Interstate Commerce commission, Dec. 31, 1937, which showed that out of 414,572 m. of track in the United States, 122,411 m. consisted of yard track and sidings.

The importance of terminal operation may also be measured in the use of freight equipment. Studies of the St. Louis Engineers Committee in 1922 showed that the average time in handling a car between an industry and the beginning of the road-haul in St. Louis was four days, and that this terminal-handling time was quite frequently six and seven days, and in extreme instances 30 days.

Costs of acquiring and operating terminals are perhaps the most important elements of railway expense. The Erie railroad estimated the terminal cost of handling its trans-continental fruit traffic at New York in 1922 to be $40 or 30% of the total revenue derived from the 1,000 m. haul east of Chicago. Costs of handling import, export and intercoastal freight at the port of New York were calculated in 1924 by the railroads at $2.75 per ton, exclusive of rail switching.

Types of Railroad Terminals. — Railroad terminals may be generally classified into two groups: (a) intermediate or division yards, primarily for the purpose of classifying and forwarding freight to destination beyond, and (b) delivery terminals serving local areas. The nucleus of an intermediate railroad freight terminal is a receiving yard, classification yard and departure yard. In the receiving yard, road engines and cabooses are detached and trains made ready for classification. In the classification yard are the tracks upon which most of the actual switching takes place. The departure yard contains the tracks where cars are reassembled after classification and made up into road trains for further dispatch. These intermediate terminals are located at strategic junction points for the purpose of maintaining full train loads en route. A feature of many such yards is a transfer platform for handling less than carload freight from local or "ferry" cars to "destination" cars.

Classification Yards. — The classification yards of the intermediate terminals are of two main types; flat and hump switching. Flat switching is accomplished by engine power, either by steam or Diesel switch engines, with the latter in favour because of their faster and more economical operation. Gravity switching is done by pushing cars over a summit or hump to achieve the necessary velocity for movement down into the tracks beyond.

Construction of a hump yard in place of a flat switching yard is economically justified when the volume of cars handled amounts to 800 daily, and when 20 classifications are necessary among every 100 cars handled. The grades upon which hump switching is conducted vary somewhat with the type of traffic handled, and the climatic conditions. The usual grade for the first 100 to 200 ft. from the summit is 3 to 4 per cent. Beyond that the grades to the classification track switches are 1 to 2 per cent. Cars attain a speed of 15 to 20 m. an hour and must be controlled by brakemen, car riders or automatic retarding equipment.

In a typical classification yard, tracks are laid out parallel to each other and are connected by diagonal "ladder" tracks at each end leading to a throat at the hump. In addition, there are running tracks reserved for through movement through the yard. The operation of classification in the hump yard involves pushing the road train over the hump, uncoupling each "cut" of cars in accordance with classification instructions, riding these cars by brakemen down into the designated track and braking the car to a stop at that point. Prior to the actual humping, the yard master lays out separate tracks in the classification yard for each destination or division into which the cars will be segregated for movement beyond the terminal. In addition to the classification tracks themselves there are special service tracks for caboose storage, repair of cars in bad order, coaling and ash dumping. Special icing tracks for replenishing bunkers of refrigerator cars, feed tracks and stock tracks for animals are set aside in the classification yard.

Some of the mechanical devices which have been introduced for more efficient handling and classifying of freight cars are automatic switch control, car retarders and flood lighting. In some yards complete systems of centrally operated switches are used. These are electro-pneumatic, air being admitted hy electrically controlled valves to a cylinder which throws the point of the switch. An operator in a tower throws the switches by pushing a button. An indicator in circuit with the rails of the switch shows on the operating board when a car has cleared the switch. Further progress in classification yard design and practice has been achieved by the installation of car retarders which eliminate the car riders, reduce car damage and speed up operation. Car retarders are often castiron shoes placed along both sides of each rail which when operated by electro-pneumatic valves grip the car wheels and reduce speed.

Studies of car retarder operations indicate that the classification track grades should be decreased to between ·2% and ·3% so that cars entering the tracks will proceed at a speed of from three to five m.p.h. without accelerating or decelerating, and continue at this speed to the end of the track.

Flood lighting permits operation without headlights and switch lamps. The primary benefits are safety to employees, reduction of damage to equipment, and decrease of theft.

Less-than-carload Transfer Houses. — Freight loaded at smaller shipping stations or for less important destinations is stowed in local peddler or ferry cars, as they are known, and hauled to transfer stations at strategic junctions. At these intermediate transfer stations the package freight is sorted and consolidated into destination cars or cars for transfer stations at more distant division points. Such transfer stations are maintained at important division points by all carriers handling any considerable volume of less-than-carload freight.

Delivery Terminals. — Yards serving a terminus are often located near important intermediate yards but have facilities for delivering freight which are not found in the intermediate yards. Delivery terminals are made up of team track yards, freight houses, and specialized freight facilities such as live stock yards, produce terminals and grain elevators.

Team Track Yards. — The ordinary method of delivering carload freight is at team track yards. Such yards are of various designs depending upon the size of the property available. They consist of stub-end tracks laid out in pairs with paved roadways between. Most team track yards are equipped with scales and with cranes for lifting heavy freight.

Freight Houses. — Numerous freight houses are maintained in important terminal centres for the handling of package freight in less-than-carload lots and sometimes in carloads as well. Freight houses have a driveway on one side accessible to trucks of shippers and consignees, and rails on the other side. Often the inbound and outbound platforms face on separate driveways with four or five tracks between them. Many modern freight houses are constructed in two levels or more. In many stations the freight is unloaded by the shipper's teamster straight into wheeled trucks, manually operated or hauled by tractors. Where the volume of package freight is sufficient, cars are loaded to destination, otherwise they are sent to the division transfer houses for reclassification.

Produce *Terminals*.—Perishable freight, particularly the fresh fruit and vegetable traffic, has reached such a volume that special handling facilities have been provided in important delivery yards. In 1927 over one million cars of fresh fruits and vegetables alone were originated by the railroads of the United States. A typical produce terminal consists of a special section in the classification yard for the purpose of holding and re-icing cars for consignee's order; a team track yard where cars are spotted alongside narrow platforms permitting inspection of contents and reconsignment or local distribution after sale; and a heated freight house where display and sale of produce and consolidation of buyers' truck loads takes place. The newer terminals in New York, Philadelphia, Boston and Chicago provide space for auction rooms within the freight house.

Live Stock Yards. — The movement of live stock is an important feature of railroad operation, particularly in the territory of Chicago and west. In the Kansas City, Mo., stock yards 7,000,000 head of live stock are handled in a single year; at Chicago 15,000,000. The Union stock yards at Chicago cover 500 ac. and 13,000 enclosures. Chutes and runways are provided for the unloading of the live stock into pens. The Federal law passed in 1906 provides that live stock must not be confined for longer than 28 consecutive hours without unloading for rest, water and feeding. Therefore pens must be maintained en route at intermediate yards for accommodation of the cattle on long runs. In addition to the pens and corrals, facilities for watering and feeding, including storage tanks, troughs and hose connections, are maintained.

Grain Elevators. — Grain elevators are maintained at shipping points, primary markets and at lake and ocean ports. Few local shipping point elevators are owned or operated by railroads. However, in a primary market such as Chicago or St. Louis, the railroads maintain large elevators for the storage, cleaning and drying of grain. (See GRANARIES AND GRAIN ELEVATORS.)

Waterfront Terminals.—A number of important terminal areas, notably New York, Baltimore, Norfolk and San Francisco, are so divided by waterways that a considerable part of the delivery even of local freight is most economically accomplished by marine equipment.

Belt Lines.—Belt lines connecting the terminal yards of two or more railroads and local industries in the terminal area are frequently found in the important terminal districts of the United States. Belt lines are utilized for two purposes; first, to accomplish interchange between the railroads themselves on through traffic; and second, to make delivery to industrial sidings, team tracks and piers not reached by the rails of the delivering carrier itself.

In the Chicago district the Belt railway is the inner belt line used primarily for reaching industries. This line is 25 m. long and is owned jointly by a number of the important railways serving Chicago.

The Indiana Harbor Belt railway, 120 m. long, and owned by the New York Central lines, is an outer belt line extending from Indiana Harbor, Ind., to Franklin Park, Ill. This line forms a connection with virtually all the lines serving Chicago, and constitutes the principal interchange route between the eastern and western lines.

In some cities public belt line railways have been built and operated municipally or leased to railroad operators. The best known example of this type in the United States is the New Orleans Public Belt railroad. owned and operated by the City of New Orleans. Outer belt lines have been instrumental in diverting large amounts of through or overhead traffic away from congested terminal centres. The inner type of belt line is an important factor in linking up industrial districts into a common unit for freight operation.

Off-track Stations and the Use of Motor Truck Equipment.—Interchange of package freight requiring rapid service has in several instances been accomplished more satisfactorily by motor equipment than by rail switching.

The use of motor equipment as an auxiliary to the railroads in terminal operation has been further extended to the pickup and delivery of local package freight.

The direct delivery of freight by truck to the consignee's door was practised during the early part of the 20th century, especially in Washington and Baltimore, but was abandoned in 1911 after litigation before the Interstate Commerce commission concerning the permissible extent of this service without extra charge. After 1930 the practice was revived throughout the U.S. and extended to include "pick-up" service from the consignor. Carloading companies also introduced the practice of picking up less-than-carload freight, consolidating it into "merchandise" or "package" cars with a number of individual containers, and separating it for delivery at the various terminating points.

Freight Terminals and City Planning.—The integration of terminal facilities into a comprehensive plan, particularly in the metropolitan districts surrounding such large centres of population as New York, Chicago and St. Louis, commands the greatest ability not only of railroad engineers but of city planning experts as well. A few of the common problems faced by both parties are electrified operation, separation of grade crossings, capitalization of air rights and joint use of trackage and terminals. The railroads entering the heart of large communities are beginning to electrify both freight and passenger operations, either voluntarily or under mandate of law.

The increasing activity of public authorities in requiring separation of grade crossings to eliminate the chances of accident in highway traffic is exemplified by recent amendment to the New York State Constitution. Under this amendment, voted in Nov. 1925, a State bond issue of $300,000,000 was authorized to finance grade crossing elimination. The capitalization of air rights by construction of massive buildings over passenger tracks and terminals in large cities has become a well-established practice. As grade separation and electrification extend to freight trackage and the cost of land occupied by freight terminals rises, vertical development of multiple-storey stations and lease of upper floors to manufacturing and warehousing tenants follow.

The establishment of adequate railway terminals is no longer regarded purely as a railroad function. Public authorities have found it necessary to persuade or force carriers into joint use of terminal facilities, and to provide public belt lines to insure industrial and pier siding connection with all trunk lines serving a terminal area. Public interest in efficient use of terminal facilities may compel proprietary monopolies to give way to a greater degree of common or joint operation,

RAILWAY PASSENGER TERMINALS

Most large passenger stations are popularly referred to as "terminals," even though, strictly speaking, they actually are not terminals, that is, the end or terminus of the railroad. Specifically, a passenger station consists of the group of tracks, platforms, buildings, etc., which furnish the means of contact between the railroad and the public for the purposes of travel. Where more than one railroad is so served the term "union station" is often used. In addition to the building for the waiting room and other station facilities, the platforms also are housed. This housing in many earlier stations was a high shed covering both tracks and platforms. Later this type was practically abandoned in favour of a low shed over each platform. Many large passenger stations are constructed in combination with office buildings or hotels—an arrangement which increases the station's concession business.

Classification into Types.—The types resulting from the arrangement of the tracks and from the manner of operation or working are as follows:—Through type is that where the tracks and trains run and are operated through the station to points beyond. Most stations are of this type. Stub type is that where the tracks terminate in or near the station. Loop.—At stations which would be normally of the stub type, a loop arrangement of one or more tracks is sometimes made, thus permitting a train, by running around the loop either before or after entering the station, to move forward at all times. This operation results in the conversion of the stub type into the through type, in principle, so that suburban or other trains carrying passengers only, can proceed through the station with the same despatch that would obtain in a normal through station. But for through or long distance trains made up of passenger cars and cars carrying other kinds of traffic, it is found that the advantages of the train being moved in one direction are largely offset by the delay occasioned in handling the traffic other than passengers (mail and express) on the platforms and in shifting and classifying the cars containing the non-passenger traffic. Composite.—As most stations where the loop principle is applied must handle a mixture of suburban and through traffic, the composite type which is a combination of the stub and through, is used. The suburban part of the traffic is handled around the loop and the through traffic largely on stub tracks. Where suburban and through traffic are handled together, and the suburban business is large, there is a tendency to handicap seriously the through traffic; this fact suggests the desirability of their segregation either in the same or separate stations.

Types resulting from the topography or the relative levels of the track and streets, are: *Single* Leuel.—This type, representative of the early stations built when low costs were vital and grade crossings permissible, has the tracks and adjoining streets at the same level. Double *Level.*—This type has the tracks and adjoining streets at different levels. The gradual elimination of grade crossings increases the number of this type. The better arrangement is afforded with the streets below rather than above the track level *Multi-level.*—The multi-level type is a combination of three or more levels and usually results either from the topography or from the area available being limited by physical conditions or high land values. This type lends itself to the segregation of suburban traffic.

The types based on the arrangement of the principal station facilities are: — Waiting Room Type. — A general waiting room is made the focus of the station traffic, the major facilities opening therefrom. Concourse Type. — A general concourse is made the focus of the station traffic and facilities, the ticket offices, train gates and major facilities opening therefrom. Composite Type. — A service lobby is provided for sale of tickets, checking baggage, etc., with waiting rooms and passenger train concourse separate therefrom.

Conditions Influencing Location. — The features or conditions which influence the choice of the site are: — (I) The location of existing trackage and working or operating necessities of the railroad. (2) Consolidation with other railroads or the establishment of a "union station." **(3)** Co-ordination with the city street plan. (4) Off line passenger stations. — These are local stations for the assemblage and distribution of passengers to be transported to and from a principal large station by motor bus as a part of the contract service rendered by the railroad. This subordinate service permits the location of the main station beyond the business centre or, if the main station is at the business centre, it provides contact with outlying centres of population. (5) Location and adequacy of the urban and suburban transit facilities. — If these outside agencies of transportation are developed or may be developed and relied upon to collect and distribute passengers locally, they have weight in fixing the station site. (6) Motive power, *i.e.*, steam or electric, used to work or operate the line. — Electric operation usually permits a location nearer the business centre than would be possible with steam.

Parking facilities are an important consideration in the location of a passenger station, not only for the convenience of the railways' patrons but also for that of employees. Complete garages are installed in some stations.

Size of Facilities — The size of facilities is related to the volume of business handled. In rebuilding or enlarging existing stations, due weight should be given to obtainable facts and records of actual performance in the old stations.

The elements influencing the size of the station facilities are: — Methods of operation. — The length and frequency of the trains generally determines the length of station platforms and the number of tracks. Single trains of from 12 to 16 cars (1,000 to 1,300 ft.) are now usual, with a tendency to greater length. The placing of sleeping cars for the reception of passengers in advance of leaving time is an important item in determining the number of station tracks required. Volume of future business. — The ultimate number of trains and passengers determines the size of most of the facilities to be provided.

Classes of *traffic* served, such as through or *suburban* passenger, baggage, mail and express. — Station facilities for all through passenger service or all suburban service can be made more compact when treated separately than when combined. The handling of baggage, mail and express traffic combined with the passenger business also affects the size. As the volume of each class of traffic increases, the tendency to provide separate facilities therefor becomes stronger. Daily and yearly *traffic distribution.* — Suburban traffic has hourly fluctuations with morning and afternoon peaks, and some seasonal variations. Through traffic has some hourly and seasonal variations. Mail and express show considerable seasonal variations. All such variations influence the size of facilities required. Facilities, once tentatively determined in size, are co-ordinated or balanced one against the other to avoid over or under capacity in any particular.

Necessary Facilities. — Perhaps the most important feature of a large modern station is the concourse. It is the place where most of the services and conveniences required by the traveller are found. It gives access to the train platforms and communication from one platform to another. It is usually the station thoroughfare. When enclosed on all sides it becomes in effect an auxiliary waiting room. Where the concourse is either in whole or part a passenger bridge or a subway, a generous width may be provided permitting the placing of seating facilities. The floor areas involved are usually large.

Waiting Rooms. — The sizes and accessories of waiting rooms are influenced by local traffic necessities, such as the proportion of passengers changing from one train to another, the relative volume of suburban or long-distance traffic. The reliability of local transportation to and from terminals has had its effect in reducing the size of these rooms. The tendency is to more compact waiting rooms, concourses, toilets, and other facilities.

Ticket *Office.* — This feature is the salesroom of the station's chief commodity, "transport." It should front on the maximum channel of traffic through the station. The ticket windows and counters should be set back from the main current of traffic affording room for lines at windows so that they do not interfere with the general circulation. In the earlier stations the ticket office was segregated into separate selling units for the various classes of tickets, and in many stations entirely separate rooms were so used. The modern tendency is towards general selling, that is, all tickets at all windows.

Tracks. — The through station yard has switching ladders at both ends. The stub station yard has a single throat, the tracks of the approach iadders being used in both directions. The stub end tracks terminate at the station end of platforms and are often provided with run-around switches near the dead end so that locomotives and cars on inbound trains can be released. In some cases trains are turned on "Y" tracks before entering the station for the same reason or to proceed further. The loop station yard is a stub yard converted in principle into a through yard by the looping of some or all of the dead end tracks. The composite station yard is any combination of the above types, with the tracks on one or more levels.

Train Platforms and Shelter Sheds. — The platforms vary in height from rail to car floor level. Where rapid exit of passengers from cars is required, the high or car floor level platform is used. Elsewhere the lower level platform is found. Usually one platform serves two tracks, one at either side, the passenger, baggage, mail and express traffic, all being handled thereon. At some stations separate baggage platforms are provided. The train platforms are usually protected from the weather by a continuous roof or by so-called umbrella sheds over each platform, which sometimes extend over the adjacent tracks.

Stairways, Elevators and *Ramps.* — When the tracks are at a different level from the station and streets, stairways are generally used to connect them. In addition, elevators or lifts and escalators are used, and in recent stations the incline or ramp has been introduced. Passenger and Baggage Bridges or Subways. — These features are required to eliminate the necessity of passengers, baggage, mail and express traffic crossing the tracks at grade. The bridges and subways also furnish the means of intercommunication and interchange between the several train platforms. At stub stations, this interchange is secured through an intercommunicating platform or "midway" placed between the ends of the stub tracks and the train gates of the concourse. *Offices,* Railroad and Station Staff. — Adequate office space conveniently located and arranged is provided for the station and railroad staff.

Baggage. — Baggage is handled in space accessible to passengers and in communicating contact with the train platform. In large modern stations the rooms for checking hand baggage, inbound and outbound, and for baggage transfer are located in contact with the station proper rather than the baggage room. Checks and pieces of baggage are handled between the checking rooms and the baggage rooms by pneumatic tubes and mechanical conveyors.

Mail. — This traffic is handled in three ways according to its volume: in small lots occupying a portion of a baggage car and the station baggage room; by car ioad lots in mail cars and in separate mail rooms at stations; and by solid train lots and in separate buildings. In large stations all three ways are used.

Express. — This traffic is classified and handled in essentially the same way as the mail. Toilets. — These are provided usually adjacent to women's rest rooms and men's smoking rooms. The tendency is to place these services on a revenue basis. Baths and dressing rooms are sometimes made a part of the revenue toilet facilities. *Information.*—In order to relieve the ticket sellers of the miscellaneous inquiries, separate bureaux of information are provided. At some of the largest stations, in addition to the ordinary service a travel or touring bureau is maintained.

(A. FE.; X.)

WATER TERMINALS

In the United States adequate water terminal facilities are of great economic importance in railroad transportation. The proper co-ordination of rail and water facilities to insure the rapid transport of freight and passengers, both inland and on the high seas, is a problem of increasing importance. A water terminal can be defined by the single word "Port," a port being a harbour properly equipped with the terminal facilities necessary to handle the freight passing through the port as well as the passenger traffic.

Handling of Freight and Merchandise.—Originally the ship's tackle alone was used, later this was supplemented by movable derricks and cranes.

The freight is discharged to the dock or directly on trucks or cars; at times it is loaded on lighters and carfloats lying alongside the ship.

For handling abnormal weights, floating derricks of large capacity are available.

Small electric motor trucks are used in many terminals for hauling the freight to the warehouses and are very efficient. They can haul several trailers at about 10 m.p.h. and can be driven into the car and there loaded or unloaded.

Overhead conveyors, either the telfer type or belt, facilitate the moving of cargoes such as bales of cotton, chests of tea, leaving the deck of the pier clear to be used by trucks and railroad cars.

Sea-trains.— Train-ferries have been operated for many years between Italy and Sicily, Hamburg and Denmark, and Denmark and Sweden. In the U.S.A. sea-trains operate between New York city and Cuba. Other such ferries are primarily for passengers.

The transporting of freight trains over the ocean was inaugurated by the Sea-train Lines about seven years ago. The steamers are regular deepsea ships and not just glorified car-floats.

They have a capacity of one hundred freight cars and when fully loaded each ship carries 26 cars in the hold, 26 between deck, 30 on the main deck, and 18 on the super-structure.

In order to load and unload the cars to and from the vessel, a 125-car elevator is used.

The car is run onto a cradle which is raised and moved over one of the ship's hatches, then lowered to its proper deck, then moved forward or aft as the ship's plan may call for; once in place the car is securely bolted down.

Bulk Freight.—Ore is a very important freight carried on the water routes of the Great Lakes. The operating season is comparatively short and it is imperative that the ore carriers make as many trips as possible each year. Therefore a ship must remain in port as short a time as possible. This has led to loading by gravity and emptying by special machinery. The ore-carrying trains are hauled on top of a trestle pier with numerous pockets or hoppers. The cars dump directly into these. The ore ship is run alongside of the pier and its hold is filled by gravity, the ore flowing into the ship through chutes. Ten thousand tons of ore are often loaded into a ship in about 90 minutes, and unloaded in about 4 hours. Large installations like this are found at Duluth and Two Harbors, Minn. At Erie, Conneaut, Ashtabula, Cleveland and many other unloading points, the ship is run under a series of ore-unloaders which dredge the ship out. These ore-unloaders, without the aid of shovellers, have an efficiency of about 98%.

Coal.—Coal piers are very similar to those handling ore—a trestle, and ramp hoppers into which the coal is dumped directly from the cars, or into which the coal is unloaded from the ship. The emptying of the hoppers is done by gravity. Installations are found at Chicago, St Louis, Philadelphia, Newport News, New York and numerous other points. Coal car dumpers are used at various places. This apparatus lifts the car up and turns it over through an angle of 160°, dumping the load into a pan from which it is allowed to run into the coal barge. The machinery is placed on top of a trestle. At such places where it is necessary to have a large supply of coal, it is often stored on the ground.

Grain.—Large grain elevators have been erected at many points. Among these are Buffalo, Quebec, Montreal, New York, New Orleans. In fact, most of the American ports are equipped with such reservoirs. The grain is sucked out of the ship or cars and deposited on conveyors, passing through the drier to the bins. The loading of ships or cars is done by gravity, the grain flowing through chutes leading to the hold or car. Floating elevators are used in many harbours to transfer the grain directly from the barges to ships. The airveyor installed in many terminals handles certain bulk cargoes most efficiently and economically. Suction produced by a partial vacuum raises the material from the ship to receiver and separator, whence it is deposited in the bins

Oil.—The storage of oil, crude or manufactured, is of extreme importance. Increasing use of oil-burning ships and internal combustion engines necessitates the establishment of oil terminals. These are usually located in some outlying district where a fire will do little to shipping. Huge tanks containing 55,000 bbl. and more are erected, leaving sufficient space between them to erect a fire wall around each unit to prevent the spread of the burning oil. In case of a fire, adjoining tanks are immediately pumped out into others further away, and the oil in the burning tank is transferred as far as possibte to minimize the loss. The fire hazard is great and at times considerable losses are experienced although they are not as great as one might expect. The oil is pumped from the wells directly to the oil plant on the seaboard or brought in tankers. It is distributed to the ships by means of steam barges, to the factories in oil trucks or cars.

Connecting Railroads and Belt Lines.—Direct connection with the railroads is essential to a modern water terminal; a belt line connecting the various water front units is required Such connecting links have been installed in many cities. In New York, the Bush Terminal, American Dock Company and Pouch Terminal have installed tracks as part of their systems. These local tracks have direct connections with the railroad feeding that part of the harbour. The belt lines are used to collect freight, which is then hauled to the classification yard and there made up into trains. As it is frequently required to handle heavy pieces and other bulky freight, locomotive cranes of various types are used to load the cars. For a discussion of Air Terminals *see* TRANSPORT BY AIR; AERODROME, AIR PORT OR AIR STATION.

(CH. D.; X.)

ROLLING STOCK

To furnish transportation and to provide for all the requirements governing the handling of traffic it is necessary, among other things, for railroads to maintain various and distinct designs of freight and passenger cars for revenue-producing service and equipment for its own use. The prosperity of a railroad depends to a great extent upon the efficiency and condition of its rolling stock. Regular service is dependent upon the number and types of cars and the proper maintenance of this equipment.

The outstanding developments in railway rolling stock during the past few years have been the increased size of cars, both freight and passenger, the gradual substitution of steel and aluminium for wood as the chief material of construction, the use of roller-bearing journals, air-conditioning, the rapid advances made in the use of high-speed light-weight streamlined trains and container cars.

In America the long hauls and the interstate commerce require for most economical service that freight be moved in large units, making it necessary to provide cars of large cubical capacity. Modern cars range in load capacity up to 70 tons or more. This increase in size and weight of freight cars with an accompanying increase in the size and weight of passenger cars and of the locomotives required to haul them, has called for heavier construction.

Heavy rolling stock has also required improvements in the construction and maintenance of road bed, track and bridges.

Passenger Train Cars.—Passenger train equipment is defined as rolling stock suitably constructed to operate at high speeds in passenger trains; its general characteristics being passenger type of truck, passenger type of brake, air signal, steam heat equipment and interior arrangement to suit the class of traffic for which it is intended. Passenger train car equipment in America includes coaches, observation, sleeping, dining, buffet, cafe, club, parlor and business cars for carrying passengers and baggage, express and postal cars for handling baggage, merchandise and mail in passenger trains. At the end of 1936 there were over 70,000 passenger train cars owned by the railways of the United States, Canada and Mexico. This includes over 8,500 Pullman owned cars and a number of privately owned cars.

Construction and Equipment.—Railroad passenger train cars are designed according to the various kinds of service for which they are to be used. With the exception of Pullman cars, and a small number of express-baggage cars, few passenger cars enter into general interchange traffic. As a consequence, on American railroads, there is less uniformity in the design of passenger train cars than in that of freight cars. Pullman cars enter into general interchange traffic in order to permit the operation of through sleeping car lines between large cities.

During the three years 1933–36 there were some spectacular developments in new railway passenger car equipment by the railroads and car builders, one of the most important being high-speed light-weight streamlined trains with every possible passenger convenience. Some of these trains have been of the articulated type and others of the individual car type. Several railroads have modernized and streamlined some of their existing passenger car equipment. The new light-weight trains have been constructed of stainless steel and aluminium alloys, and the railroads and car builders are striving to reduce weight throughout their passenger equipment. These new high-speed trains have reached speeds as high as 120 miles an hour at times and have made non-stop test runs of over 1,000 miles.

The construction, finish and equipment of passenger train cars have been steadily modified. In 1929 few passenger cars were built which were not of all-steel construction. The substitution of steel for wood has meant the replacement of wood trimming and cabinet work by sheet steel doors, windows and interior finish. Plainness, neatness and sanitary conditions are now sought, while much has also been done to add to convenience and comfort. A typical modern passenger coach is about 70 ft. long, over the body, seats from 60 to 84 passengers, weighs from 100,000 to 140,000 lb., is of steel construction, has vestibuled platforms, is carried on 4 or 6 wheel roller-bearing trucks, and is lighted by electricity, heated by steam and air-conditioned. The future will doubtless see better insulation and weight ratio. Practically all sleeping cars now in use on the railroads of the United States are owned and operated by the Pullman company. For the operation of the Pullman-owned cars over 2,800 conductors and 12,000 porters are required. Annually the cars have a car mileage of 1,140,476,000 m. to carry over 31,000,000 passengers, which means that every night more than 55,000 people sleep in the Pullman berths. There are various types of Pullman sleeping cars, among those in most common use being the following: 16 section car, each with an upper and a lower berth; 12 section car, with drawing room and compartment; 10 section car, with two drawing rooms; 8 section car, with four compartments; 10 section car, with an observation parlor; 10 section car, with drawing room and two compartments; 10 section car, with three compartments; drawing room and compartment cars containing three drawing rooms and six compartments, arid cars with various other combinations of drawing rooms and compartments, and cars containing compartments only. The latest Pullman car, known as the "overnight car," contains 14 rooms, each equipped with a bed and complete toilet and lavatory facilities. The Pullman Company is now putting new light-weight cars in service.

Observation cars are a distinctive feature of American railroading. They are of various types. Some contain a number of rooms, others a few sections, others smoking rooms, ladies' lounges, refreshment stands, baths for men and women, but in each case the rear of the car is a commodious lounge room with seats, sofas, radios, telephones for use at terminals, writing tables, and other conveniences, with a commodious rear platform equipped with chairs. Smoking cars are used on practically all passenger trains and may be devoted entirely to passenger service or be built with an express or baggage compartment. Club smoking cars on limited trains usually have card tables, writing desk, reading matter and an attendant.

Buffet or cafe cars are provided with facilities for serving a simpler class of meal than that affordedin dining cars. The business or private car is provided with sleeping and dining accommodations and also desks, tables and stationery. Business cars are used to a great extent by railroad officialsin transacting railroad business on the lines. Private cars are sometimes used by persons of prominence and wealth. Baggage, mail and express cars are designed to carry the commodities indicated by the classification of the cars themselves. Special postal cars for carrying mail are designed and equipped for operation in passenger trains. These cars are provided with interior fittings especially arranged to facilitate the handlixg of mail. Some cars are provided with facilities for sorting mail en route; other cars are designed only for the transporting of mail and express in bulk. Various other special types of passenger train cars are used.

Air-Conditioning.—Air-conditioning has been one of the most outstanding railway developments during recent years and has increased materially railroad passenger travel. Air-conditioning directly affects the passengers and adds much to their comfort, both in summer and winter.

It is the function of an air-conditioning system to control scientifically the temperature and humidity of a car in winter as well as in summer, and the heating control is a very important part of an air-conditioning system, thereby differing from a strictly cooling system for use in hot weather only. Ideal air-conditioning for railway cars is the simultaneous control of the factors affecting both the physical and chemical conditions of the atmosphere within the railway car. These factors include temperature, humidity, air motion, air distribution. ionization and elimination of dust, bacteria, odours and toxicity. A dependable power supply is necessary to provide for the equipment involved in the proper air-conditioning of a railway car. This equipment controls the ventilation, filtering, heating, cooling and humidity.

The principal methods of air-conditioning railway passenger cars are mechanical (both electro and direct), steam ejector and ice activated. The refrigerant most commonly used in the mechanical type of cooling system is "dichlorodifluoromethane." There are several types of drive mechanisms through which power is transmitted from the car axle to the cooling equipment. These comprise the gear type of drive using either hypoid, spur or bevel gears; the belt and gear type of drive using a V-belt and bevelled gear; the belt type of drive using a "V" or flat belt without a gear, and the friction type of drive. Generators where used with an electro-mechanical system will range upwards from 5-kw. There is also one system using an internal combustion engine driving a directly connected compressor.

The insulation of railway cars is very important when considering air-conditioning. To maintain a differenceof 20° between the outside and inside temperature of a car with 3″ of insulation and double windows will require about 1·3 tons of refrigeration, whereas a car with only ½″ of insulation and single windows will require 3·1 tons of refrigeration. An air-conditioned car will use from 100,000 to 125,000 cu. ft. of air per hour. This will approximate 25% fresh air and 75% re-circulated air. It is important that proper ducts be provided to permit the intake of fresh air and control the escape of air to the outside atmosphere. The Association of American Railroads has determined by tests that the minimum air change required in an air-conditioned railway car is 10 cu. ft. of air per minute, per passenger. Therefore, an air-conditioning installation on a 60-passenger car should be so designed as to deliver not less than 600 cubic feet of air per minute. The total cost of air-conditioning consists of four items; namely,

(1) cost of installation; (2) cost of terminal facilities; (3) cost of maintenance and (4) cost of operation.

The economics of air-conditioning from an operating standpoint is affected by a number of factors; namely, the length of the cooling period and the atmospheric conditions prevailing during that period, the average speed in miles per hour and the total car miles per year. These factors must be considered in order to select a system from the standpoint of economy.

Rolling Stock Prices.—During the year 1927 the average purchase prices for freight cars were $1,800.00 to $2,200.00. During 1926 the average price of all steel freight cars averaged 4.734 a pound, and composite wood and steel freight cars averaged 4.93¢ a pound. Seventy ton all steel hopper cars cost from $2,200.00 to $2,500 00, while a 50 ton box car cost $2,200.00. The price of an ordinary coach with 6-wheel trucks ranged from $27,000.00 to $33,000.00. Dining cars ranged from $43,000.00 to $51,000.00, depending upon the interior furnishings. Baggage cars ranged from $18,000.00 to $20,000.00.

Weight of Passenger Train Equipment.—Main line passenger equipment cars in America weigh from 100,000 to 150,000 pounds. The average Pullman car varies between 150,000 and 160,000 pounds. Suburban cars weigh between 80,000 and 120,000 pounds. Dining cars on American railroads weigh between 160,000 and 175,000 pounds. The American railroads have to haul twice as many pounds of equipment per Pullman passenger as per day coach passenger. In the United States this condition has been brought about by demands of the travelling public for a more luxurious and convenient mode of transportation. The limits seem to have been reached as far as dead weight and size are concerned and the trend is now to reduce weight. What seems to be excessive weight is also the outcome of the desire on the part of railroad officials to provide as safe a means of transportation as possible. Any reduction in weight should not be made at the sacrifice of strength and safety. Some experiments have been made with the use of aluminium in car construction. Designers have tried to produce double deck cars in order to decrease the dead weight per passenger. Alloy steel is also coming into general use in car construction.

Roller Bearings.—A large number of passenger train cars were in 1928 equipped with roller bearings and all modern cars are now roller bearing equipped. Practically all of the new designs of the electric cars are fully roller bearing equipped. These applications exist not only on the journals but also on the armature shafts of the motors and in the speed reduction units. Roller bearings have also been applied to freight cars, locomotive tenders, driving axles, engine trucks and trailing axles. A roller bearing equipped train can be started with one-eighth the power required to start a train equipped with plain journals.

For a discussion of Electric Motor Cars and Self Propelled Equipment see ELECTRIC TRACTION; LOCOMOTIVES.

Articulated Cars.—An articulated car consists of two or more car bodies flexibly coupled together and operating as a single unit by necessity of its truck arrangement. Each articulation or joint in the car is supported by only one truck. The number of trucks is one more than the number of bodies permanently coupled. The use of articulated cars in America is limited mainly to elevated and subway service in cities, to electric railway cars and to self-propelled rail motor cars, as the articulated principle must be used in trains kept as one unit during their entire trip.

Freight Train Cars.—Rolling stock for use in handling freight in America are termed "freight cars" and are divided into several general classes. The cars generally in use are of either the enclosed type, which includes box, refrigerator, stock and other house cars; or of the open type which include flat cars, gondolas, both high and low side, hopper and other cars of open construction. Tank cars for conveying oil and other liquids in bulk are used; as are also many types of special cars.

Design.—The operation of freight cars on American railroads has resulted in the adoption of certain fundamentals of design which experience has shown to be the most practicable. (See "Standards and Recommended Practices" and "Supplement," American Railway Association.) The materials that are used in the construction and maintenance of freight and passenger train cars may with few exceptions be divided into four general classes, as follows: (1) metal materials; (2) lumber; (3) paints and varnishes; (4) various complete devices or specialties. The requirements to be met in the design of freight rolling stock are protection of the contents (when required) from weather; facilities for loading, packing and unloading; strength of underframe and body to withstand severe service, and the largest available capacity consistent with requirements of construction.

In the early days of development freight cars were constructed more strongly than passenger cars and a freight car 28 ft. long with a capacity of g ton, weighed 6 ton. In existing designs of open top cars the ratio of dead weight to pay load is approximately 1 to 3. The types of cars now in use on American railroads are developments from the early crude forms. Wooden freight cars are being rapidly replaced by all steel or steel underframe cars.

Nearly all coal cars, either gondola or hopper, are now being made of steel. After Jan. 1, 1931, no wooden cars were accepted in interchange on American railroads. Early in this century the combination of pressed steel and structural steel was used in car construction and this is the type of construction most commonly used today. The 70 ton hopper cars have come into general use and also 90 ton, 100 ton and 120 ton capacity coal cars are in operation. The largest freight car in commercial use at present is the 120 ton capacity steel coal car. This is a type of gondola of which the most novel feature is its size.

A large number of "automobile" or box cars with large cubical capacity are in use in the United States. Many have end doors and all have wide side doors.

The number of freight train cars in service (1935) on railroads in the United States was as follows: (1) railroad owned or leased 1,596,711; (2) privately owned 295,664; total 1,892,375. Freight train cars installed in major steam railways during the year 1935 totalled 18,496, a very low figure due to the depression.

The average mileage made by a freight car in America is approximately 30 m. in 24 hours. The railroads of America are constantly speeding up train operation. It is predicted that in a few years freight trains will be operated at passenger train speeds. In America the percentage of empty to loaded car miles has run about 30% during the past few years. Freight car heavy repairs become due in periods of about once every 8 or 10 years, whereas running repairs and inspections are a continuous necessity.

The average freight car earnings per year in America are approximately $2,200. The average life of a freight car is from 20 to 25

FIG. 15.—UNDERFRAME OF STANDARD AMERICAN FREIGHT CAR VIEW OF UNDERSIDE

years. To whatever extent the unproductive weight of a train can be diminished, to that extent the productive weight may be increased by the absorption of the same amount of energy of locomotive tractive power without reduction of the rate of speed. The expenditure of fuel in hauling a ton is about the same whether or not it is paying freight. The smaller the percentage of non-paying or dead weight to total weight moved, the smaller will be the cost of hauling the paying freight

On American class 1 railroads the cost of hauling one ton of dead weight 1 mile varies from $0 004 to $0.007. The cost of hauling a ton of weight is not directly proportional to the weight carried but rather the relation of the full tonnage possibilities to actual tonnage hauled. A railroad having full tonnage trains will have a lower cost per ton-mile than one with variable loads of less than full tonnage.

Great progress has been made by American railroads in the standardization of freight equipment. The following table shows a comparison of a few representative car parts necessary to keep on hand at railway shops for repairs and represents the progress made in standardization in 41 years.

	1882	1923
Axles, different kinds	56	5
Journal boxes, different kinds	58	5
Couplers, different kinds	26	1
Brake shoes, different kinds	20	1
Brake heads, different kinds	27	1

Car Trucks.—Car trucks in use on American railways are built in accordance with general requirements specified by the American Railway Association. The cast iron wheel 33 in. diameter, with a chilled tread, is in use under freight cars of a capacity of 50 ton and under. On nearly all passenger equipment and on a few freight cars of high capacity steel wheels are used. For 1929 the side frames of all new freight car trucks are commonly of cast steel. Pedestal type trucks are used for passenger equipment and to a limited extent for freight equipment.

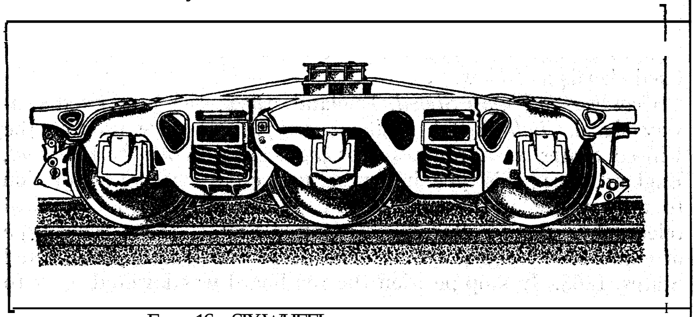

FIG. 16.—SIX-WHEEL FREIGHT CAR TRUCK

Tractive Resistance of freight and passenger cars is very important because of its relation to tonnage ratings of locomotives and to questions of economies of operation. The resistance of a car to movement on a straight level track may be divided into the following components: (a) journal friction, (b) rolling of the wheel on the rail; track resistance due to compression of the track, concussions, and miscellaneous losses due to oscillation and vibration that absorb energy from which no return can be obtained; (c) flange friction due to the pressure of the wheel flange against the rail; (d) atmospheric resistance; still air and wind. Plain bearing friction varies within certain limitations of speed while roller bearing friction is fairly constant from zero up to high speeds. Rolling of the wheel on the rail and the flange friction increase with the speed and also vary materially with the condition of the track and stiffness of the rail. The atmospheric resistance increases as the square of the speed. Rolling of the wheel and flange friction are reduced to a minimum by the use of heavy rails well supported and with proper alignment.

Container Car.—The container car system is now coming into popular use on American railroads. This system provides that portable containers shall be loaded and locked at the shipper's own plant, conveyed by motor truck to the railroad yard and lifted by crane aboard the container car where steel bulkheads and sides form absolute protection against opening the container in transit. At its destination the locked container is unloaded by crane and carried by motor truck directly to the warehouse or consignee's door to be unloaded at his convenience. One of the principal advantages of the container car system is the greatly increased use of container car rolling stock in moving service which is particularly important when traffic expands to its "peak" and the prime need is to shorten lay-overs of cars in yards and stations for loading and unloading and to limit their idleness and obstruction through misuse for storage purposes. (*See* American Society Mechanical Engineers, paper by Walter C. Sanders presented at annual meeting, New York, Dec. 6, 1921.)

Refrigerator and Heater Cars.—The need for protection in transit against all ranges of temperature of such commodities as meat, milk, fruit and vegetables, has led to the design of various types of refrigerator and heater cars. A large number of refrigerator cars are designed for both passenger and freight train operation. Some cars used for transporting semi-perishable commodities not requiring refrigeration or heating are insulated and ventilated to protect the loading against extreme outside temperatures and the heat of the product itself. The principal means of obtaining refrigeration in transit is by circulated air, cooled by contact with ice, or mixtures of ice and salt. Some modifications of this system and others differing radically such as mechanical refrigeration or iceless cars are in use to a small extent and may be more generally adopted in the future.

All refrigerator cars are insulated. One type is equipped with brine tanks at each end and used for carrying eggs, butter, vegetables and fruits. Some refrigerator cars are equipped so that they may be converted into heater cars during the winter. Heating systems employing coal, charcoal, alcohol and kerosene as well as steam have been developed.

Tank Cars.—Tank cars are used to transport gasoline and other inflammables, acids, alcohol, ammonia, oils, paints, milk, vinegar, pickles and other liquid and semi-liquid products. The most common design is the tank car for general oil or liquid service. It consists of a steel tank mounted on a frame, or mounted directly on cradles over truck bolsters. Safety release valves are provided and it is emptied by valves at the bottom. At the top is a dome, with or without manhole, and the openings through which the tank may be filled. Milk in bulk is transported in cars equipped with glass lined tanks.

Railway Service Cars.—Many types of special cars for maintenance of the track, and general construction work in connection with railroad operations are necessary. These include dump cars, motor and hand cars, locomotive cranes, steam shovels, pile drivers, ditchers, dangers, snow plows, sweepers, supply cars, air-brake instruction cars. This rolling stock is known as non-revenue equipment. Wrecking, instruction and dynamometer cars are included in the non-revenue group. Section or inspection cars are used to convey the section men to and from their work and to conserve the time of other maintenance employees.

Passenger Car Lighting.—Three general systems of electric car lighting are in service as follows: Axle-generator system, head-end system, storage battery system. The axle-generator system is the most commonly used, and provides for lighting each individual car by means of a storage battery charged by a generator under the car, and driven by a belt from one of the axles. The head-end system requires a generator located in a car at the head of the train where it may receive steam from the locomotive. The generator may also be driven by an internal combustion engine. This generator furnishes current for lighting the entire train. In some cases the generator may be driven by a belt from the axle or it may be mounted on the locomotive. The straight storage battery system has a storage battery under each car as an individual unit or one battery for lighting several cars. The batteries are charged at terminals during a lay-over period.

Passenger Train Heating.—Heating is accomplished by steam or electric heating apparatus. On steam operated railways vapor heating systems are usually used. Other systems employed are direct steam or pressure and combination vapor and pressure. At terminals when a locomotive is not available until leaving time cars are heated from a central heating plant. The heating elements of a steam heated car consist of iron pipes placed along each side wall near the floor and protected by a grill. Live steam is supplied by the locomotive. Where cars are subject to isolation, a coal fired heater is installed in each car. Electrically operated cars are usually heated by resistors taking current from the power source.

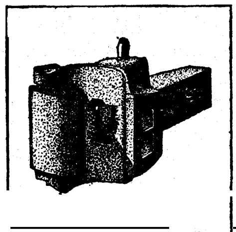
Car Ventilation.—Until the recent improvements in air-conditioning, explained above, nearly all types of car ventilators in passenger cars were (and, in many cars in use in 1937, are) located either in the deck sash or in the main roof of the car. Their action was to admit or exhaust air to or from the car and depended upon the motion of the car for full action. This was later helped by the action of electric fans. Freight cars employed in handling certain commodities used a simpler system of ventilation consisting usually of a series of slots at each end of the car and sometimes of ventilator side doors. For Air-Conditioning, see above.

Inspection. — To facilitate the economical movement of traffic in America the railroads have for many years permitted car load freight to be shipped from consignor to consignee without the expense and inconvenience of trans-shipment at junction points. This has resulted in a vast interchange of traffic between the various railroad systems and in the gradual formation of the restrictions or rules under which this traffic interchange is conducted. One railroad will repair the rolling stock of another railroad under a code of rules which governs this practice.

Draft Gear. — A draft gear is an apparatus which connects the coupler to the car sills or underframe of the car. Its function is to receive the shocks transmitted by the coupler and to dissipate them without damage to the rolling stock. The friction type of draft gear is gradually superseding the spring type on American railways. Draft gear yokes, arms and various attachments are necessary to connect the draft gear to the coupler, and then to the car. The constant increase in the length of the trains and in the size and weight of rolling stock in America has made it extremely difficult for draft gear development to keep pace with these conditions.

No standard design of draft gear has been established except for certain limitations of space in the car underframe into which the draft gear must be assembled.

Couplers. — Couplers are the mechanisms by which cars are connected together. The standard American Railway Association (Master Car Builders) "D" coupler is in general use on American and Canadian railroads and also a few foreign railroads. Before the advent of the M.C.B. type coupler in the United States the connection between the cars of a train and locomotive were made with the "link and pin." This was a very hazardous practice and resulted in many injuries and automatic Master Car Builders Association couplers were subsequently developed, and are now required by law.



BY COURTESY OF SIMMONS-BOARDMAN PUB CO.
FIG. 17.—STANDARD COUPLER WITH KNUCKLE CLOSED

Buffers. — Buffers are applied to the ends of passenger train equipment to provide smoothness of handling. This additional cushioning is obtained by the use of buffers in addition to the ordinary draft gear. Buffers are of both the spring type and friction type design.

All American railway rolling stock is equipped with safety appliances in accordance with instructions and specifications from the Interstate Commerce Commission of the United States Government.

Air Brakes. — The air brake is a brake operated by compressed air which was invented in its first form by George Westinghouse in 1869. In an air brake, the air is compressed by some form of a pump on the steam locomotive or by a motor compressor on electric or internal combustion locomotives or cars, and is conveyed by pipes and flexible hose between the cars to cylinders and pistons under each car, by which the pressure is transmitted by brake levers and thence to the brake shoes against the wheels. The adhesion of the wheels to the rails governs the amount of pressure that may be applied by the brake shoes.

A combination of straight air and automatic air brake has also come into use and is known as the automatic straight air brake. Other types of brakes are: the quick action automatic air brake, high speed brake, empty and load brake, vacuum brake, electro-pneumatic brake and the traction air brake. The automatic air brake is in general service under American rolling stock. This system is designed so that the brakes will be applied automatically in case air escapes from the system or the train breaks in two.

Industrial Rolling Stock. — Industrial cars are used in almost every branch of industrial activity; in manufacturing plants, mines, lumber operations, sugar cane plantations, and in construction work. They are also used in quarries, sand and gravel plants, brick and clay works, steel mills, smelters, foundries, machine shops and in many other places for handling all classes of loose or package materials. (*See* LOCOMOTIVE; ELECTRIC TRACTION.)

RAILWAY SIGNALLING

Railway Signalling has passed through a long period of development and is to-day an efficient means for safeguarding and expediting the movement of railway trains. This article traces this development from a crude type of fixed signal in use in the early days of railways to the perfected systems of to-day.

Fixed Signals are signals of fixed location used to govern trains by displaying aspects whose indications show when, where and how to go and when and where to stop. The principal types of fixed signals as follows:

Crossbar-and-lamp Signal, England, 1834; the first fixed railway signal. *Ball Signal,* England, 1837; type once used in the United States as a railway crossing signal. *Semaphore Signal,* England, 1841; this type, in general use to-day, was an adaptation to railway use of the Chappe semaphore, 1793, used in optical telegraphy. *Banner Box Signal,* United States, 1863; early type of manual block signal. *"Smashboard" Drawbridge Signal,* United States, 1868. In stop position the red board was lowered so as to strike the locomotive stack should the signal be overrun. *"Banjo" Signal,* United States, 1871, type of first electrically operated automatic block signal. *Clockwork Signal,* United States, 1879, mechanically operated automatic block signal with electric control. *Semaphore Signals: Electro-pneumatic* type, United States, 1881, the first power operated semaphore; *Electric* type, United States, 1893, the forerunner of present day electric motor semaphore signals; *Upper Quadrant* type, United States, 1908, for both manual and power operation. Previous types operated in lower quadrant.

Light Signals displaying coloured electric lights for both day and night indications: *Colour Light* type, United States, 1908; *Position Light* type, United States, 1915; *Colour-position Light* type, United States, 1921.

Train Dispatching in the United States is a highly developed method of directing train movement by the use of general rules time-tables (with special instructions), train orders, or by signals in place of written train orders.

Rules and time-tables are the plans for directing train movement. Train orders are to meet conditions which cannot always be anticipated. If train operation could be conducted by time-tables without delay, train orders would not be necessary. Such precision being impossible, train orders are used to supplement the time-table.

Train dispatching has reached the third stage of its development. The first, when the time-table was the sole authority for train movement, was the "time-table" stage. The second or "train order" stage began in 1851 when the electric telegraph was first used for sending train orders. The written train order is now being superseded by the unmistakable indication of the signal, and train dispatching is entering the third or "signal indication" stage. (*See* the section on *Train Operation* by *Signal Indication* on p. 951.)

Block Systems were developed in England to provide for safe travel by rail. At first the signals were used in much the same way that signals are used to-day by policemen for controlling street traffic. Signalmen known as policemen, stationed along the railroad at hazardous locations (stations, tunnels, etc.) warned the trains by signals of danger ahead. As trains increased in number, signals were next used in an effort to maintain a *time* interval between trains; protection from rear collisions depending

5. Automatic block system, block section **B** to B' unoccupied. Track circuit current flows from track battery through rail **R** to track relay and back through rail R' to track battery. Track relay is closed, closing circuit to signal battery and holding signal **S** at "clear"
6. Automatic block system, block section B to B' occupied. Track circuit current by-passed by wheels of train. Track relay is opened, opening circuit to signal battery, and moving signal S to "stop"
7. Electro-pneumatic interlocking, Union Station, Cincinnati, Ohio. Switches and signals operated from an electro-pneumatic interlocking machine
8. Electric interlocking, Buffalo Central Terminal, Buffalo, N. Y. Looking west toward Tower **48,** New York Central Railroad. Signals and switches are operated from an electric interlocking machine

on the continuous maintenance of this time interval between moving trains and the use and observance of red flags, lanterns, torpedoes and fusees for the protection of standing trains; protection from head-on collisions (on single-track lines) depending on the exercise by enginemen and conductors of most intelligent and unceasing vigilance in the observance of rules and written orders and on the exercise of the utmost care by the train dispatcher. As it is not always possible to move trains on schedule time, this method fails to prevent occasional collisions.

The third step provides a *space* interval between trains moving on the same track by dividing the track into a series of consecutive block sections by the use of fixed signals to govern the movement of trains, no train being permitted to enter an occupied block section except under certain restrictions.

Manual Block is a system in which the block signals are operated manually upon information by electric communication: first used in England, 1839 and in the United States, 1863.

Controlled Manual Block is a manual block system with an electric control of the signals, used to increase the safety of their operation: first used in England, 1875.

Automatic Rlork is a system, developed in the United States. defined by the American Railway Association as "a series of consecutive blocks governed by block signals operated by electric, pneumatic or other agency actuated by a train, or by certain conditions affecting the use of a block." When a train enters a block section the signals governing the block automatically move to and remain in the stop position until the train leaves the section controlling the signals. The signals are thus actuated not by human agency but automatically by the train through the medium of a closed track circuit.

The Interstate Commerce Commission has said: "Perhaps no single invention in the history of the development of railway transportation has contributed more toward safety and despatch in that field than the track circuit." The closed track circuit, invented by Dr. William Robinson, was first put in use in the United States in 1872.

The automatic block system is in general use on the railroads of the United States. Its value as a means for protecting and expediting the movement of trains received world-wide recognition.

Interlocking is an arrangement of switch and signal appliances so interconnected that their movements must succeed each other in a predetermined order. Its purpose is to provide a safe path for the movement of trains through switches. junctions, railroad grade crossings, stations and over drawbridges.

Mechanical Interlocking is a manually operated system which had its inception in the crude machine put in use at Bricklayer's Arms Junction, England, 1843. Thirteen years later a mechanical machine was put in use in England by John Saxby that included the essential principles of the later interlocking systems. This type of machine was put in use in the United States at Trenton, N J., 1870. Mechanical interlocking is in extensive use on the railways of Great Britain. In the United States the tendency is toward the use of power interlocking.

Electro-pneumatic Interlocking is a power system, the switches and signals operated by pneumatic power with electrical control of the valves of the pneumatic cylinders: first used in the United States, 1891, and invented by George Westinghouse. the inventor of the air brake.

Electric Interlocking is also a power system. the switches and signals operated by electric motors with electrical control. The system now in general use and first used in the United States, 1889, was invented by John D. Taylor.

Power Interlocking is used for the operation, as one plant, of what would otherwise require two or more mechanical interlocking plants. The principal terminal stations in the United States are all equipped with power interlocking.

Electro-mechanical Interlocking is a system that was developed for use with automatic block signalling; the switches are operated by mechanical interlocking and the signals by power interlocking: first put in use in the United States in 1906.

Remote Power Switch Machines are used for the operation of outlying main track switches located at too great a distance from either train order, block or interlocking stations to permit of their operation from these stations by mechanical or power interlocking. The operation of switches that would otherwise be hand-thrown by trainmen eliminates making train stops for trainmen to throw switches. Eliminating train stops decreases train delay.

Automatic Interlocking is a power operated system for junctions and grade crossings, automatically actuated by a train and not by operators as in other systems of interlocking.

Train Operation by **Signal Indication** was first put in use in the United States, 1882, at Louisville, Ky. Train movement was directed without the use of written train orders by signal indications given under the instructions of the dispatcher. A large number of installations of train operation by signal indication without train orders were placed in use in the United States on single-track lines and for "either-direction" operation on multiple-track lines.

Later, an improved system was developed that further simplified the work of the train dispatcher and enabled him to increase substantially the output of transportation, especially on single-track lines. The signals and switches of a district are operated and controlled from a central point by a dispatcher solely by the use of electric actuating devices and without the aid of operators. The dispatcher directs the movement of trains by operating the signals and by direct operation of the switches, also sets up the routes.

Train Orders and signal indications differ greatly as a means for directing train movements. Train orders are written instructions that must be delivered to the conductor and engineman of the train. They must be correctly prepared. transmitted, delivered and understood. They must not be forgotten. On roads not equipped with modern signalling systems, safety of operation depends entirely upon the human element, for there is no check either electrical or mechanical to prevent an improper train movement should an error occur in the preparation, transmittal or delivery of the order, or should the order be misunderstood or forgotten.

Signal Indications are simplified instructions for directing train movement given by the aspects of fixed wayside or cab signals. The train order calls for deferred action, whereas the signal indication, conveying instructions at the points where they are to be executed, calls for immediate action. Hence there is no lapse of time in which to forget the instructions.

Operation by train orders requires delivery of the order to the train. If in motion, the train must slacken speed or stop to receive the train order instructions as to how to proceed. As train orders are for the ultimate purpose of keeping trains moving, this slowing down or stopping for the delivery of orders in a measure defeats this purpose. Train orders when they retard the movement of trains cause loss of time. To produce transportation, trains must be kept moving; hence when train orders unnecessarily retard or stop the movement of trains, they tend to limit the production of transportation.

Train operation by signal indication on the contrary does not require the train to stop for proceed instructions and therefore tends to increase the production of transportation.

Classification Yards located at important freight centres are for sorting and grouping cars for their respective destinations and for making up trains with the cars in destination order to expedite the road movement. These yards consist of a number of parallel tracks each assigned to a particular destination. The cars are sorted by switching them into these tracks. In flat or level yards, switch engines switch the cars. In modern yards, built on an inclined grade, hump or gravity type, cars are pushed to the top of the hump or incline and then move down by gravity into their respective tracks. Hand operated switches acd switchmen have been replaced by power operated switches using either compressed air or electric motor-switch machines controlled by operators from central towers. These operators also control the power operated car retarders or track brakes which control the speed of cars moving by gravity into the classification tracks.

Prior to the use of car retarders, speed of the cars was controlled by hand brakes operated by car riders.

Classification yards equipped with power switches and car retarders are worked at maximum capacity with minimum labour costs as switchmen and car riders are not required.

Highway Grade Crossing Signals are for the protection of highway traffic crossing railway tracks at grades. The Interstate Commerce Commission lists for 1927 a total of 236,283 grade crossings in the United States: 12% of these crossings equipped with watchmen, gates or signals, 86% equipped with "railroad crossing" signs only and 2% not so equipped. The signals are largely of two types: a swinging disc and a red light or two flashing red lights.

The remarkable increase in motor-car traffic and the expanding net work of improved highways in the United States has made highway grade crossing protection a most pressing safety problem. (H. M. SP.)

AUTOMATIC TRAIN CONTROL

Automatic train control is a term commonly used to describe a method of stopping or reducing the speed of a train without the intervention of the engineman, and, as generally employed, covers either an automatic train stop or a speed control system. In the first instance the brakes are applied until the train is brought to a stop; in the second, the brakes are applied if the speed of the train exceeds a certain designated limit, but may be released by the engineman after the speed has been reduced. These actions may take place at a designated point or at any point on the equipped territory depending on whether an intermittent or a continuous type is in use.

These devices provide means for transferring to the locomotive an indication of conditions existing on the track and furnish the connecting link between the track circuit and the air brake system of the train. The track circuit is really the block system or "train spacing" feature and the cab signals, train control, or roadside signals are merely the means of indicating to the engineman the conditions of the track as to occupancy by trains, open switches, broken rails, or some other obstruction.

There must be, therefore, apparatus, on the roadside to co-act with the locomotive apparatus, which may be a special adjunct, or the contact may be through the running rails. The locomotive must be provided not only with some device for receiving the indication from the track by electrical means or by mechanical contact, but also some method must be employed for exhausting the brake pipe air to atmosphere, and so causing the brake (or triple) valves on each car to function and apply the brakes. This is done either by a special valve opening directly to the atmosphere, or by apparatus which automatically operates the engineer's brake valve Special appliances must be provided for the release of the brakes after the stop has been made. A "forestalling" device is also used except with speed control, which permits an alert engineman to prevent an automatic brake application

The Intermittent Type — Automatic train stop and train control devices have been classified according to the type of communication between the track and the engine. The simplest form, the plain automatic trip, consists of a contact member, or trip, along the track which is brought into a position, when a stop is desired, to make contact with a trigger or projecting arm on the locomotive which, when moved, will open the air brake pipe and cause the brakes to be set; the trip may be set electrically or mechanically. This type is in use on elevated roads and subways.

The ramp type has for its roadside element a length of iron of "L" or "T" section placed parallel to and outside the rail on the end of the ties and extending 5 or 6 inches above the top of the rail at its highest point in the centre of its length. Electric energy from a roadside source is supplied to it, controlled by connections to the signal system. The engine carries a shoe adjusted to engage the ramp through a vertically moving member that, to secure proper electrical contact, is held down by air pressure or spring. As the engine circuits are opened every time a ramp is engaged, thus producing a potential stop condition, means must be provided for holding closed the engine circuit by energy collected from the ramp, if a stop is not intended. This is accomplished through electrical contacts, or switches, attached to the moving member of the shoe.

The devices just described are known as the intermittent contact type, that is, physical contact is required between the track and engine elements, but to avoid this, the non-contact type has been developed. One form of this type uses permanent magnets located in the track between the rails, and associated with large coils which are designed, when carrying an electric current, to neutralize or deflect the magnetic field of the permanent magnets normally extending above the road bed to such a height that the engine apparatus will pass through it. During this passage, the lines of force either neutralize the lines of force of a small magnet carried on the engine or open contacts which control the electric circuits, thus initiating a brake application.

Another form is known as the inductor type, and so far as the track element is concerned, consists of specially wound coils in a non-magnetic casing secured to the ends of the ties. These coils are connected to the signal system in such a way that a complete electric circuit is formed when the signal is in a "proceed" position. The engine apparatus or receiver consists of coils in a casing usually attached to the tender truck and adjusted to register with the track inductors but with a clearance of abut two inches. When passing over an inductor with a closed circuit there is no effect, but if the circuit is open, the current flow through the engine apparatus is so reduced as to permit the opening of a special valve, directly resulting in an application of the brakes. Nearly all of the intermittent train stop devices now in service are of the inductor type.

The Continuous System.——In this type a flow of alternating current through the rails is provided, resulting in an electrical field being produced around each rail. Collecting coils on the engine are so designed as to be sensitive to this field, and when passing through or near it the action is somewhat similar to that of a transformer, the rails being the primary, resulting in a flow of current from the receiver coils to the locomotive apparatus. This is amplified by means similar to that used in radio, and sufficient current is produced to operate a relay, which, in turn, controls the circuits of the engine apparatus. A notable development, the code system provides for the use of interrupted currents of varying frequencies in the rails, which, when picked up by the receiver coils and passed through selective apparatus on the locomotive, permit a number of indications to be transmitted.

Continuous train stop and speed control systems include audible and visible cab signals, the latter usually taking the form of coloured lights or rows of small white lights simulating the position of the wayside signal. Cab signals provide a continuous indication of the track ahead and afford protection at all times against a switch being opened or a car or train fouling the main track even after the automatic signal has been passed. They increase the safety of train operation during fogs and storms when the wayside signals cannot readily be observed and permit regular schedules with full knowledge of the signal indications. Some railroads have installed two cab signals, one for the engineman and'fireman, and an acknowledger, these in lieu of automatic train control devices. A failure to observe a restrictive cab signal results in a whistle sounding until acknowledged.

Speed control devices are used to require definite speeds as a maximum under certain conditions. These generally are in the form of a centrifugal device, attached to one of the locomotive wheels, and are capable of application to most of the systems in use. By means of electrical contacts closed or open at certain speeds, the brake controlling apparatus may be operated.

Automatic train stop devices are not new, but the first permanent installation in the United States was on the Boston Elevated in 1899. In 1906, an investigation of this subject was started by a special board appointed by Congress, which work was carried on later under the Interstate Commerce Commission. This Commission issued orders in 1922 and 1924, requiring 80 passenger divisions on certain railroads to be installed. Some voluntary installations have been made with the result that over 10,250 miles of road and 9.120 locomotives have been equipped with automatic train control or continuous cab signal devices. (*G. E. E.*)

RAILWAYS, TUBE. The term "Tube Railways" is applied generally in Britain to deep-level underground railways constructed with a metallic lining and usually of round section. For the construction and the ventilation of the tube, see the article TUNNEL. The Tube Railway is a form of Subway. The latter is discussed under TUNNEL and ELECTRIC TRACTION. (See also TRAMWAYS.)

Stations are constructed, as a rule, by building a tunnel of twice the dimensions of the running tunnels. The station tunnel is sufficiently large to accommodate the platform as well as the track. Tube railways are generally operated at about 600 volts, direct current being fed to the conductor rails from substations. The substations are usually of the rotary converter type. High tension current is supplied from a central power station. From the substations also run cables sgpplying current for station lighting, lifts, escalators, and pumps.

In the London area. Metrooolitan and District lines are shallow sub-surface railways; the other underground lines, also owned by the London Passenger Transport Board, and the Southern Railway's line from Waterloo to the city, are tube railways proper.

RAIN: see RAINFALL; METEOROLOGY.

RAINBOW, formerly known as the iris, the coloured rings seen in the heavens when the light from the sun or moon shines on falling rain; on a smaller scale they may be observed when sunshine falls on the spray of a waterfall or fountain. The bows assume the form of concentric circular arcs, having their common centre on the line joining the eye of the observer to the sun. Generally only one bow is clearly seen; this is known as the *primary* rainbow; it has an angular radius of about 42°, and exhibits a fine display of the colours of the spectrum, being red on the outside and violet on the inside. Sometimes an outer bow, the secondary rainbow, is observed; this is much fainter than the primary bow, and it exhibits the same play of colours, with the important distinction that the order is reversed, the red being inside and the violet outside. Its angular radius is about 54°.

Among the Greeks and Romans various speculations as to the cause of the bow were indulged in; Aristotle, in his Meteors, erroneously ascribes it to the reflection of the sun's rays by the rain; Seneca adopted the same view. The introduction of the idea that the phenomenon was caused by refraction is to be assigned to Vitellio.

The most valuable of all the earlier contributions to the scientific explanation of rainbows is undoubtedly a treatise by Marco Antonio de Dominis (1566–1624), archbishop of Spalato. This work, De *radiis visus* et *lucis* in *vitris perspectivis* et *iride,* published at Venice in 1611 by J. Bartolus, although written some twenty years previously, contains a chapter entitled "Vera iridis tota generatio explicatur," in which it is shown how the primary bow is formed by two refractions and one reflection, and the secondary bow by two refractions and two reflections. Descartes strengthened these views, both by experiments and geometrical investigations, in his Meteors (Leyden, 1637). Descartes could advance no satisfactory explanation of the chromatic displays; this was effected by Sir Isaac Newton. (See Newton's *Opticks,* book i. part 2, prop. 9.)

The geometrical theory, which formed the basis of the investigations of Descartes and Newton, afforded no explanation of the supernumerary bows, and about a century elapsed before an explanation was forthcoming. This was given by Thomas Young, who, in the Bakerian lecture delivered before the Royal Society on the 24th of November 1803, applied his principle of the interference of light to this phenomenon. His not wholly satisfactory explanation was mathematically examined in 1835 by Richard Potter (*Camb. Phil.* Trans., 1838, 6, 141), who, while improving the theory, left a more complete solution to be made in 1838 by Sir George Biddell Airy (*Camb. Phil.* Trans., 1838, 6, 379).

Geometrical Theory.—The geometrical theory first requires a consideration of the path of a ray of light falling upon a transparent sphere. Of the total amount of light falling on such a sphere, part is reflected or scattered at the incident surface, so rendering the drop visible, while a part will enter the drop. Confining our attention to a ray entering in a principal plane, we will determine its deviation, *i.e.,* the angle between its directions of incidence and emergence, after one, two, three or more internal reflections. Let EA be a ray incident at an angle i (fig. 1); let AD be the refracted ray, and r the angle of refraction. Then the deviation experienced by the ray at A is $i-r$. If the ray suffers one internal reflection at D, then it is readily seen that, if DB be the path of the reflected ray, the angle ADB equals $2r$, *i.e.,* the deviation of the ray at D is $\pi-2r$. At B, where the ray leaves the drop, the deviation is the same as at A, viz., $i-r$. The total deviation of the ray is consequently $D=2(i-r)+\pi-2r$.

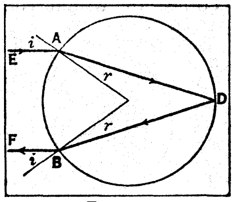

FIG. 1

Similarly it may be shown that each internal reflection introduces a supplementary deviation of $\pi-2r$; hence, if the ray be reflected n times, the total deviation will be $D=2(i-r)+n(\pi-2r)$.

The deviation is thus seen to vary with the angle of incidence; and by considering a set of parallel rays passing through the same principal plane of the sphere and incident at all angles, it can be readily shown that more rays will pass in the neighbourhood of the position of minimum deviation than in any other position. (See REFRACTION.) The drop will consequently be more intensely illuminated when viewed along these directions of minimum deviation, and since it is these rays with which we are primarily concerned, we shall proceed to the determination of these directions.

Since the angles of incidence and refraction are connected by the relation $\sin i=\mu \sin r$ (Snell's Law), μ being the index of refraction of the medium, then the problem may be stated as follows; to determine the value of the angle i which makes $D=2(i-r)+n(\pi-2r)$ a maximum or minimum, in which i and r are connected by the relation $\sin i=\mu \sin r$, μ being a constant. By applying the method of the differential calculus, we obtain $\cos i=\sqrt{\{(\mu^2-1)/(n^2+2n)\}}$ as the required value; it may be readily shown either geometrically or analytically that this is a minimum. For the angle i to be real, $\cos i$ must be a fraction; that is, $n^2+2n>\mu^2-1$, or $(n+1)^2>\mu^2$. Since the value of μ for water is about $\frac{4}{3}$, it follows that n must be at least unity for a rainbow to be formed; there is obviously no theoretical limit to the value of n, and hence rainbows of higher orders are possible.

So far we have only considered rays of homogeneous light, and it remains to investigate how lights of varying refrangibilities will be transmitted. It can be shown, by the methods of the differential calculus or geometrically, that the deviation increases with the refractive index, the angle of incidence remaining constant, Taking the refractive index of water for the red rays as $\frac{108}{81}$ and for the violet rays as $\frac{109}{81}$ we can calculate the following values for the minimum deviations corresponding to certain assigned values of n.

n	Red	Violet
1	$\pi-42°\cdot1$	$\pi-40°\cdot22$
2	$2\pi-129°\cdot2$	$2\pi-125°\cdot48$
3	$3\pi-231°\cdot4$	$3\pi-227°\cdot08$
4	$4\pi-317°\cdot07$	$4\pi-310°\cdot07$

To this point we have only considered rays passing through a principal section of the drop; in nature, however, the rays impinge at every point of the surface facing the sun. It may be readily deduced that the directions of minimum deviation for a pencil of parallel rays lie on the surface of cones, the semi-vertical angles of which are equal to the values given in the above table. Thus, rays suffering one internal reflection will all lie within a cone of about 42°; in this direction the illumination will be most intense; within the cone the illumination will be fainter, while, outside of it, no light will be transmitted to the eye.

Fig. 2 represents sections of the drop and the cones containing the minimum deviation rays after 1, 2, 3 and 4 reflections; the order of the colours is shown by the letters R (red) and V (violet). It is apparent, therefore, that all drops transmitting intense light after one internal reflection to the eye will lie on the surfaces of cones having the eye for their common vertex, the line joining the eye to the sun for their axis, and their semi-vertical angles equal to about 41° for the violet rays and 43° for the red rays. The observer will, therefore, see a coloured band, about 2" in width, and coloured violet inside and red outside. Within the band, the illumination will be faint; outside the band there will be perceptible darkening until the second bow comes into view. Similarly, drops transmitting rays after two internal reflections will be situated on covertical and coaxial cones, of which the

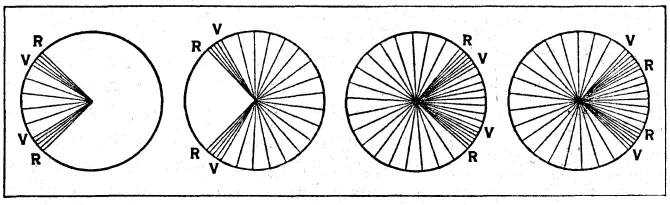

FIG. 2

semi-vertical angles are 51° for the red rays and 54° for the violet. Outside the cone of 54° there will be faint illumination; within it, no secondary rays will be transmitted to the eye. We thus see that the order of colours in the secondary bow is the reverse of that in the primary; the secondary is half as broad again (3°), and is much fainter, owing to the longer path of the ray in the drop, and the increased dispersion.

Similarly, the third, fourth and higher orders of bows may be investigated. The third and fourth bows are situated between the observer and the sun, and hence, to see them, the observer must face the sun when looking at the water drops which produce the bows. But the illumination of the bow is so weakened by the repeated reflections, and the light of the sun is generally so bright, that these bows are rarely, if ever, observed except in artificial rainbows. The same remarks apply to the fifth bow, which differs from the third and fourth in being situated in the same part of the sky as the primary and secondary bows, being just above the secondary.

Physical Theory.—Usually the most conspicuous colour in the principal rainbow is the red; but wide variations are noted from one bow to another not only in the brightness and purity of the different colours, but also in their angular width. This is not in accordance with the elementary theory, which would require all rainbows to be similar in the distribution of colours as well as in their relative intensity. The fuller treatment of the theory which is based on the undulatory theory of light will be found in Pernter-Exner's *Meteorologische Optik*, or in Humphreys' *Physics of the Air.* It can be shown that the phenomena depend in a very marked way on the size of the water drops, and that the width of the coloured bands increases as the size of the drop decreases. The elementary theory leads to the result that there is a direction of maximum illumination along the direction of minimum deviation, but the more detailed theory leads to the result that there are other directions along which there is considerable illumination. The subsidiary maxima account for the *spurious* bows, whose distance from the main bow is greater for small drops than for larger drops. The actual primary rainbow observed is thus the effect of the superposition of a number of bows. If the red of the second bow falls upon the green of the first, the result is to give a bow with an abnormally wide yellow band, since red and green lights when mixed form yellow. This is a very common type of bow, one showing mainly red and yellow, with little or no green or blue. If the drops are smaller the red of the second bow may fall within the blue of the first bow, so that we should then see a second bow (spurious bow) within the first. The phenomena are further complicated by the variation in the size of raindrops within the cloud. Since the smaller drops occur in the upper levels, the spurious bow is generally observable only near the top of the bow.

With very small drops, whose diameter is 0·1 mm. or less, the colours become superimposed, and the rainbow becomes almost a pure white. This type of rainbow, sometimes known as Ulloa's Ring or as a fog-bow, is only seen distinctly when the observer is very near the cloud which produces it.

The centre of a rainbow is at the same angular distance below the horizon as the sun is above the horizon. Rainbows can be formed by light coming from the reflection of sunlight in a water surface. The observer then sees more than a semicircle of this rainbow, the centre being above the horizon; and he will at the same time see the rainbow formed in the usual way by direct rays from the sun. The two rainbows intersect, and are commonly referred to as *intersecting rainbows.*

Rainbows can also be formed by moonlight, but the colours are then very faint, and difficult to distinguish.

The physical theory of rainbows is given in R. W. Wood's Optics; Preston's *Theory of Light;* Humphreys' *Physics of the Air;* and Pernter-Exner's *Meteorologiche Optik.* (D. Bru.)

RAINBOW TROUT (*Salmo irideus*): *see* **Trout.**

RAINER, ARCHDUKE OF AUSTRIA (1827–1913), was born on Jan. 11, 1827. His father, Rainer, the eighth son of the Emperor Leopold II. and of his consort Maria Luisa of Spain, was born in Florence in 1783, and from 1818–48 was viceroy of the kingdom of Lombardo-Venetia; his mother was the Princess Elizabeth, sister of Charles Albert, King of Sardinia. The Archduke was in 1857 placed at the head of the permanent Imperial Council organized in 1851, which stood immediately under the Emperor and had among its functions the preparation of laws, and his experience in this office convinced him that the transition to a constitutional form of government on a liberal and centralized basis was necessary. In 1860 he conducted the negotiations for a strengthened Imperial Council; in 1861 he was associated with the promulgation of the charter of the Constitution of Feb. 26, 1861, elaborated by the liberal Schmerling administration. In the same year he became curator of the Academy of Sciences. In 1865 he retired from public affairs. In 1872 he was appointed to the supreme command of the newly established Austrian *Landwehr,* to the organization of which he devoted many years. The archduke purchased the papyrus discovered at Fayum, which was called, after him, the "Rainer Papyrus." He married in 1852 Marie Caroline, daughter of the Archduke Charles, the victor of Aspern, but died childless on Feb. 27, 1913.

RAINFALL is produced when damp air rises, and cools as it expands. The ascent may be due to (a) simple convection due to surface heating, (b) the effect of upward sloping ground in causing the air motion to follow the slope, or (c) the action at a front, where a warm current is forced to ascend over a wedge of cold air. Most rain in middle latitudes is due to the third of these causes, but the amount of rainfall is increased where the air is forced to rise over ground. Heavy rain due to the forced ascent of damp air over high ground is most strongly exemplified by the rain of the south-west monsoon of India, and that of the western slopes of the Rocky mountains. The rainfall on the lee slopes of the mountains is very much less than that on the windward slopes. Similar, but less marked effects are shown by lower hills, such as the Pennine Range in Northern England.

Rainfall is slight in the central regions of the sub-tropical anticyclones, which are therefore the desert regions of the earth. In parts of the deserts no appreciable rain has ever been observed. Over most of Europe the annual rainfall exceeds 20 inches, while over most of Asia, excluding India, Tibet, and China, the annual rainfall is less than 20 inches, being less than 10 inches in a long tongue extending from Arabia across to N.E. Mongolia. The central regions of Australia, a part of S.W. Africa, and a small area of Arizona, U.S.A., also have less than 10 inches of rain in the year. Portions. of the West coast of Africa, between the equator and 10° N., a strip of the West coast of India, parts of Assam, and a coastal strip of Burma all have more than 100 inches of rain in the year.

The following are some of the heaviest rainfalls recorded within 24 hours:

Berlin, Apr. 14, 1902, 6·6in.; Alexandria, Dec. 9, 1888, 9·6in.; Bruton, England, June 28, 1917, 9·7in., Cherrapunji, June 14, 1876, 41·4in.; Baguio, Philippines, July 14–15, 1911, 46·7in.; Fiji, Aug. 8, 1906, 37·6in.

In still shorter periods, rainfall at heavier rates has been observed. Campo, U.S.A., Aug. 12, 1891, 11·7in. in 80 minutes. Rumania, July 7, 1889, 8·2in. in 20 minutes. Portobello, Panama, Nov. 29,1911, 2·5in. in 3 minutes. Norwich, England, July 14, 1917, 0·48 in. in 2 min. Kew observatory, 0·2 in. in 1 min.

Possibly the wettest part of the globe is Mount Waialeale in Hawaii, where the average annual rainfall, 1928–39, was 505 in. At Cherrapunji, Assam, the annual rainfall has averaged 428 in., while at Mavijuram, in Assam, 270 in. of rain fell in the month of August 1841. The average rainfall or rainfall plus snow melted to water of each month, and of the year, is given in the following table for some of the chief cities of the world, together with the average number of days in the year on which snow or measurable rain fell. where such data are available. Further data for other places will be found in any standard textbook on climatology, such as Kendrew's Climates *of* the *Continents* (Oxford, 1936).

RAINIER, MOUNT, a peak of the Cascade Range in Pierce county, Washington, about 60m. from Seattle, and 50m. from Tacoma. It is about 14,408ft. above sea-level, the third highest peak in the United States, excluding Alaska. Rainier, as are the other peaks of the Cascade Range, was built up by successive layers of material (chiefly andesite) thrown out of its crater. The volcano has long been extinct, but small craters still give forth steam and sulphurous fumes. Its base is set in the green of the wonderful Puget Sound forest and its snowy cone rises 10,000ft. Along its sides are 28 glaciers and a number of permanent ice-fields, the largest in the United States, which extend down the scarred slopes to the forests, below which they give rise to dashing streams. Beautiful sub-alpine wild-flower fields follow the receding snow in summer.

Mt. Rainier was first discovered by Vancouver, who, disregarding the Indian name "Tacoma," named the peak in honour of Rear Admiral Rainier of the British Navy. The first successful ascent was made in 1870 by Gen. Hazard Stevens and P. V. van Trump.

Mt. Rainier national park (325 sq.m. in area) was set aside by the U.S. Government to preserve the wild mountain scenery in its natural beauties and to make the mountain accessible to the public. Entrances to the park can be reached from Seattle or Tacoma in a few hours by automobile or railway.

See F. W. Schmoe, *Our Greatest Mountain; Mount Rainier* (1925); E. S. Meany, *Mount Rainier,* a *Record of Exploration* (1916); and *Information Circulars* issued by the US. Dept. of the Interior.

RAINIS, JÓZSEF, see Plieksans, Jan.

RAIN-PROOF FABRICS. Rain-proof fabrics can be divided into two general classes — apparel fabrics and non-apparel fabrics. Included in the first group are fabrics used in raincoats, slickers, umbrellas, etc. Among those in the second group are fabrics employed in making tents, tarpaulins and automobile tops. Rain-proof fabrics may be actually waterproof or merely water-repellent. Waterproof fabrics are impervious to water, the interstices or pores in the cloth being completely covered or filled by the waterproofing agent or sufficiently stopped up that water will not pass through them at the maximum pressure to which the fabric is exposed under conditions of use.

Water-repellent fabrics, on the other hand, are not impervious to water, the repellent effect being obtained not by closing or materially reducing the size of the interstices or pores, but by treating the cloth with a compound which increases the surface tension between the fibres and the mater and thus makes it more difficult for the water to penetrate into and through the fabric.

Thus, a raincoat made from a lightweight water-repellent fabric may withstand a light shower, but not a heavy, driving rain. The degree of water-repellency depends on the type and twist of yarn, weight and closeness of weave, and efficacy of the water-repellent compound.

In general, heavy, closely woven fabrics are more water-repellent than are light, loosely woven fabrics.

Other important applications of waterproof and water-repellent fabrics, in addition to those mentioned above, include shower-bath curtains, spot-proof table covers, and sheetings for hospital use. Fabrics which are both waterproof and chemical-resistant find use in such applications as protective clothing for workers engaged in the handling of chemicals.

Fabrics which are both waterproof and gasproof or air-tight are employed in the aeronautical industry and as a protection againstnoxiousgases.

Many different processes are employed for rendering fabrics waterproof or water-repellent. In general, truly waterproof fabrics are obtained by impregnating or coating the cloth with rubber, synthetic rubber, pyroxylin (cellulose nitrate solution), cellulose acetate, linseed oil, tar, or synthetic resins. Various degrees of water-repellency can be imparted to fabrics by treating them with such materials as aluminium acetate, paraffin wax emulsions, metallic soaps, cuprammonium solution, or quaternary ammonium compounds.

Raincoats are made from cotton, silk, rayon, or wool fabrics which have been rendered rain-proof or showerproof by any one of several processes. One of the earliest methods employed was that invented by Charles Macintosh, which made use of rubber as a waterproofing agent; raincoats made from cloth treated in this way were known as macintoshes. Oilskins are made by applying boiled linseed oil, together with a suitable drier and pigments to give the desired colour, to light- or medium-weight cotton fabrics. Silk fabrics treated in a similar manner, and known as oiled-silk fabrics, are being rapidly superseded for use as raincoats by silk or rayon fabrics which have been waterproofed by treatment with a vinyl resin lacquer or another synthetic resin. Another type of waterproof raincoating is made by rubberizing cotton fabrics.

Water-repellent fabrics employed for raincoats are usually made from cotton or wool. One of the best known methods is to treat the fabric in solution of aluminium acetate and then in a soap solution or an emulsion containing soap and paraffin or Japan wax. A newer method makes use of a water-repellent agent consisting essentially of a solution of aluminium acetate containing paraffin wax in colloidal dispersion.

A still newer process employs long-chain quaternary ammonium compounds that actually combine with the fibre to form a durable, water-repellent coating.

Mixtures of various materials are employed for coating canvas, duck, and other heavy cotton fabrics used for tents, tarpaulins, etc. Among these are included asphalt, paraffin, tar, beeswax, and lead oleate. An effective method for waterproofing cotton fabrics, which also renders the fabric mildew-resistant, makes use of cuprammonium solution.

Bibliography.—Herbert P. Pearson, *Waterproofing Textile Fabrics;* and S. Mierzinski, *The Waterproofing of Fabrics.* (W. W. Ch.)

RAIN-TREE (Pithecellobiurn saman), a tropical South American tree, so called from the fact that the ejection of juice by cicadas (*q.v.*) upon it causes it to appear to be always raining under its branches. *Andira inermis,* which belongs to the same family (Leguminosae), is also called rain-tree for the same reason.

RAIPUR, a town and district of British India in the Chhattisgarh division (*q.v.*) of the Central Provinces. The town is 188m. E. of Nagpur and has a station on the Bengal-Nagpur railway. There are ruins of an immense fort with many tanks and old temples. The town and civil station is situated on a red laterite plain and the climate is extremely hot. Besides the usual institutions at the headquarters of a division and district, there is the Rajkumar college, where the sons of the chiefs of Chhattisgarh, as well as of chiefs of Orissa, are educated under a European principal. The college also admits sons of the greater landholders.

The DISTRICT OF RAIPUR (area 9,717 sq.m.; pop. [1931], 1,527,573) occupies the south and centre of the Chhattisgarh rice plain (*see* CHHATTISGARH, DIVISION). The district is traversed by the Bengal-Nagpur railway from Bombay to Calcutta, and numerous roads were constructed in the famines. Raipur will now shortly be connected by rail with Vizianagram on the east coast section of the Bengal-Nagpur railway and from there with the port of Vizagapatam.

RAIS (or RETZ), **GILLES** DE (1404–1440), marshal of France, the central figure of a 15th-century *cause célèbre,* was the son of Guy de Montmorency-Laval, the adopted son and heir of Jeanne de Rais, and of Marie de Craon. He was born at Machecoul in September or October 1404, and was brought up by his grandfather, Jean de Craon. Chief among his great possessions was the barony of Rais (erected in the 16th century into the peerage-duchy of Retz), south of the Loire, on the marches of Brittany. He joined the Montforts, supporting Jean V. of Brittany against the house of Penthikvre. He helped to release Duke John from Olivier de Blois, count of Penthibvre, and was rewarded by extensive grants of land, subsequently commuted by the Breton parliament for money payments. In 1420 he married Katherine of Thouars, a great heiress in Brittany, La Vendée and Poitou. In 1426 he raised seven companies of men-at-arms, and began active warfare against the English under Artus de Richemont. He accompanied Joan of Arc to Orleans, fighting by her side at Orleans, and afterwards at Jargeau and Patay. He had advocated further measures against the English on the Loire before carrying out the coronation of Charles VII. at Reims. On July 17 he was made marshal of France at Reims. In the winter he was in Normandy at Louviers whether with a view to the release of Joan, then a prisoner at Rouen, cannot be stated. He expended great sums in the king's service and maintained a court more suited to royal than baronial rank. He was a munificent patron of literature and of music, and his library contained many valuable works, he himself being a skilled illuminator and binder. At the chief festivals he gave performances of mysteries and moralities, and it has been asserted that the *Mystkre de* la *Passion,* acted at Angers in 1420, was staged by him in honour of his own marriage. The original draft of the *Mystery* of *Orleans* was probably written under his direction. In his financial difficulties he began to alienate his lands, selling his estates for small sums, providing his heirs with material for many lawsuits. Among those who profited by his prodigality were the duke of Brittany, and his chancellor, Jean de Malestroit, bishop of Nantes, but in 1436 his kinsfolk appealed to Charles VII., who proclaimed further sales to be illegal. Jean V. refused to acknowledge the king's right to promulgate a decree of this kind in Brittany, and replied by making Gilles de Rais lieutenant of Brittany and by acknowledging him as a brother-in-arms.

Gilles hoped to redeem his fortunes by alchemy, and also spent large sums on necromancers, seeking to guarantee himself from evil consequences by extravagant charity and a splendid celebration of the rites of the church. The abominable practices of which he was really guilty seem to have escaped the notice of his equals or superiors, though suspected by the peasantry. His wife left him in 1434–35; and when his brother René de la Suze seized Champtocé, family considerations no doubt imposed silence. His servants kidnapped children, generally boys, whom he tortured and murdered. The number of his victims was stated in the ecclesiastical trial to have been 140. In 1440 he came into conflict with the church by an act of violence which involved sacrilege and infringement of clerical immunity, and in the autumn he was arrested and cited before the bishop of Nantes on various charges, the chief of which were heresy and murder. With the latter count the ecclesiastical court was incompetent to deal, and Gilles refused to accept its jurisdiction (Oet. 8). Terrified by excommunication, however, he secured absolution by confession.

A parallel inquiry was made by Pierre de l'Hôpital, president of the Breton parliament, by whose sentence he was hanged (not burned alive as is sometimes stated), on Oct. 26, 1440, with two of his accomplices. In view of his confessions his guilt seems certain, but the irregularities of the proceedings, the fact that his chief accomplices went unpunished, taken together with the financial interest of Jean V. in his ruin, have left a certain mystery over a trial, which, with the exception of the process of Joan of Arc, was the most famous in 15th-century France. His name is connected with the tale of Bluebeard (*q.v.*) in local tradition at Machecoul, Tiffauges, Pornic and Chéméré. The records of the trial are preserved in the Bibliothkque Nationale in Paris, at Nantes and elsewhere.

RAISIN, the name given to the dried fruits of certain varieties of the grape vine, which grow principally in the warm climate of central California and the Mediterranean coasts. Leading countries of production are the United States, Turkey, Australia, Persia, Greece, and Spain. Dried grapes, or raisins, are rich in fruit sugar, which acts as a natural preservative of the product, and are of great antiquity as a human food (Num. vi. 3; I Sam. xxv. 18). "Raisins of the sun" are obtained by letting the fruit remain on the vines after it has come to maturity, where there is sufficient sunshine and heat in the autumn, till the clusters dry on the stalks. The more usual process, however, is to cut the fully ripened clusters and expose them, spread out, for several days in the rays of the sun. In unfavourable weather, they may be dried in a heated chamber, but are then inferior in quality. Sun-drying may be hastened by first dipping the grapes in a soda or lye bath to puncture the skin, but this process is not generally followed in growing areas that afford a drying season free from rainfall, such as the interior valleys of California. Some varieties are dried and retained on their stems and sent into the market as clusters for table use; but the greater part are separated from their stems in the process of drying and cleaning.

Raisins are of three types: (1) large seeded raisins made from the Muscat of Alexandria variety of grape, or Gordo Blanco, called Malagas in general world commerce and muscats in California; (2) small seedless raisins made from the Sultanina grape, called sultanas in most parts of Europe and Thompson seedless in California; (3) very small seedless raisins made from a black grape known in most countries as the Black Corinth. In commerce they appear as Zante currants or Greek currants. There are also miscellaneous varieties of grapes dried in some countries, especially in those bordering on the eastern end of the Mediterranean, which are inferior as raisins and are termed "dried grapes."

Malaga type raisins of commerce come chiefly from the provinces of Malaga, Valencia, and Alicante, in Spain, and from California and Australia. The variety grown in California, called the muscat, is sweet and extensively used in desserts. It is packed for household purposes by the removal of seeds by automatic machinery, and so processed that the raisins can be separated easily as they come from the box.

Sultana type raisins are cultivated extensively in California, Smyrna, and Australia. Those grown in Smyrna are soda-dipped in the curing process, having a golden-yellow colour, and a thin, translucent skin. Those grown in Australia are also usually dipped in the curing process; but those grown in California are exclusively sun-dried except for a limited quantity intended principally for certain portions of the export market. Zante currants are grown in small quantities in a number of countries, but the principal world supply comes from Greece and Australia.

After 1918, world demand for raisins shifted from seeded to seedless varieties. Seedless varieties are successfully cultivated in California and in Australia, and the United States and Australia are large exporters. Practically all of the raisins grown in the United States are produced in the San Joaquin valley of California within a radius of roo mi. of the city of Fresno. Approximately 10.000 growers are engaged in the production of raisins in this district and the processing of these raisins centres in Fresno, where there is the largest dried fruit plant in the world. (W.N.K.)

RAJAH, a Hindu title for a chief, or prince, derived from the same root as the Latin *rex.* Other forms are rao, rana and rawal, while chiefs of high rank are styled maharaja, maharao and maharana. The Hindustani form is rai, and the title of the Hindu emperor of Vijayanagar in South India was raya.

RAJAHMUNDRY, a town of British India, in the Godavari district of Madras. Pop. (1931) 63,526. It is a growing place on the left bank of the river Godavari, at the head of the delta, 360 m. N. of Madras, and has a station on the East Coast railway, which is here carried across the river by a bridge of 56 spans.

Tradition divides the merit of founding Rajahmundry between the Orissa and Chalukya princes. In 1470 it was wrested from Orissa by the Mohammedans, but early in the 16th century it was retaken by Krishna Raja. It continued under Hindu rule till 1572, when it yielded to the Mohammedans of the Deccan under Rafat Khan. It passed into the possession of the French in 1753, but they were driven out by the British in 1758.

RAJASTHANI LANGUAGE, the language of Rājasthān of Rajputana, an Indo-Aryan vernacular closely related to Gujarati (*q.v.*). It is spoken in Rajputana and the adjoining parts of central India, and has several dialects, the principal of which are Jaipuri, Mārwāṛī, Mēwātī and Mālvī. Hāṛautī, an important variety of Jaipuri, is spoken in the states of Kota and Bundi.

See vol. *IX.* of the ***Linguistic Survey of India*** for a full account, *s.v.* GUJARATI.

RAJGARH, an Indian State in the Bhopal agency of central India. Area, 962 sq. miles. Pop. (1931), 134,891. The chief, who has the title of rajah and a salute of 11 guns, is a Rajput of the Ponwar clan. This State and Narsingarh were the result of a partition in the 17th century. It afterwards became tributary to Scindia, but fell under the general settlement of Malwa in 1818. The town of Rajgarh had a population of 6,759 in 1931.

RAJGIR HILLS, a range of hills in British India, in the south of the Patna district of Behar and Orissa. They form part of a range, extending N.E. from near Bodh-Gaya for 40 miles, and at one place rise to 1,472 ft, but elsewhere seldom exceed 1,000 ft. in height. The hills in Patna district consist of two parallel ridges. In the valley between, south of the village of Rajgir, was built the old city of Rajagriha, "the royal residence." Legend ascribes it to Jarasandha, king of Magadha (south Behar), who had his capital at Giribraja, "the city of hills." The outer fortifications can be traced on the crests of the hills over a distance of more than 25 miles; they are 17½ ft. thick, built of massive undressed stones without mortar. According to Sir John Marshall, we can assign these ruins only to "some uncertain age before the dawn of history and rank them, as their stupendousness entitles them to be ranked, among the greatest wonders which primeval man has bequeathed to us." The remains of New Rajagriha, the reputed capital of Bimbisara (*c.* 520–490 B.C.), lie two-thirds of a mile N. of the valley.

The Rajgir hills are associated with the life of Buddha, who often taught here. Chhatagiri is the old Gridhrakuta, or vulture's peak, which was one of his favourite resorts. One of the towers on the Baibhar hill (Vaibhargiri) has been identified as the Pipara stone house in which Buddha lived. The Sattapanni, the cave in which after his death the council of his disciples was held to record the tenets of the faith, has been identified with different sites on this hill and with the Soubhandar cave at its foot: the latter is now believed to have been excavated by Jains in the 3rd or 4th century A.D. A brick mound, topped by a Jain shrine, stands in the centre of the valley. Rajgir is a place of pilgrimage. There are modern Jain temples built on the hills round the valley. There are also hot springs in the valleys surrounded by Hindu shrines.

See M. A. Stein, "Notes on an Archaeological Tour in South Bihar and Hazaribagh," ***Indian Antiquary,*** 1901; Sir J. Marshall, "Rajagriha and its Remains," ***Report Arch. Surv. India,*** 1905–06; V. H. Jackson, "Notes on old Rajagriha," ***Report Arch. Surv. India,*** 1913–14; ***District Gazetteer of Patna*** (Patna, 1924).

RAJKOT, a town in India, capital of a native state, the western India States Agency, in Bombay, and headquarters of the western division of the political agent of Kathiawar. Pop. (1931) 47 485. It is situated in the middle of the peninsula of Kathiawar, is the centre of the railway system, and a civil and military station. The town contains the Rajkumar college, for the education of the sons of princes, on the lines of an English public school, two hospitals, a library and museum. It is the chief educational centre of Kathiawar. In the civil station are the Jubilee gardens and Memorial institute. There are waterworks for the civil station and irrigation works for the town. The state of Rajkot has an area of 282 sq.m. Pop. (1931) 75,540.

RAJMAHAL, a former capital of Bengal, India, now a village in the district of the Santal Parganas, situated on the right bank of the Ganges, where that river makes a turn to the south. Pop. (1921), 3,454. It was chosen for his capital by Man Singh, Akbar's governor, in 1595–96, but in 1608 the seat of government was transferred to Dacca. It was again made the seat of government by prince Shah Shuja in 1639, and was a second time superseded by Dacca 20 years later. Even in 1665 Manucci found that it had fallen into ruin, being full of dilapidated palaces, great fallen mansions and neglected gardens. A pavilion called the Sangi Dalan is all that survives of Shah Shuja's palace. Rajmahal has given its name to a range of hills, comprising an area of some 2,000 sq.m. which rise to a height of about 2,000 feet. They are inhabited by an aboriginal race known as Maler (the Malli of Megasthenes) or Sauria Paharias, *i.e.,* "hill-men." The approach to their villages often consists merely of great boulders piled one upon another. The valleys are inhabited and cultivated by the Santals, a different aboriginal race, who have immigrated in large numbers.

RAJPIPLA, a native state of India, in the Rewa Kantha agency, Bombay, occupying a hilly tract between the rivers Narbada and Tapti; area, 1,518 sq.m. Pop. (1931) 206,114; tribute (to Gaekwar of Baroda), £3,300. The chief, whose title is maharana, is a Gohel Rajput, of the same family as the thakor sahib of Bhavnagar. The soil is fertile, cotton being the chief crop, and there are teak forests in the hills. A light railway, constructed at the cost of the state, connects Nandod with Anklesvar in Broach district. The old fort of Rajpipla, in the hills, is now deserted. The modern capital is Nandod, situated on the river Karjan, 32 m. from Surat. Pop. (1931) 13,302.

RAJPUT, the generic term for a number of castes, which gives Rājpūtāna (*q.v.*) its name, and is widely spread over the rest of northern India. Claiming to have replaced the ancient Kshattriyas (*q.v.*), the Rajputs are a dominant, fighting, landowning class. Of Indo-Aryan type, they have been also recruited from earlier ethnic elements which rose to power and from invading races, notably the Huns. As a body they are physically robust, brave and chivalrous, cherishing the feudal spirit and traditions. Pride of birth makes them punctilious in questions of honour, but poor cultivators when in reduced circumstances. They still hold somewhat aloof from the civil professions, regarding military service as their proper *métier.* Rājpūt history is a bardic adaptation of myth to courtly adulation. It asserts that to their two original races, the Solar and the Lunar, were added four, the Agnikula, "Fire-sprung," purified by Brahmans in the great agnikunda, "fire-pit" on Mt. Abu to fight the Daityas, "Titans." Being interpreted, this must mean that the four clans were Brahmanised, or Hinduised, to suppress some anti-Brahmanical people or foreign foes. The four were the Chalukya, modern Solanki, a Sanskritized patronymic of Chalkya, a dynasty in the Deccan, but immigrant from Kashmir and probably Gurjara by race: the Pratihāra, now Parihār, "durward," known to be Gurjaras: the Pramāra, now Panwār; and Chāhamāna, now Chauhān. These became eponyms of leading Rājpūt tribes, and the legend traced their origin to Rudra, Brahma, Indra and Vishnu. Folketymology also derived Chāhamāna from Chatur-

A RAJPUT PEASANT

bhuja, "four-armed." From these, by some incoherent process, were derived 36 "royal races," never the same in any two versions of their names, but in some including the Jāt, Hun, Ahir and Bar-Giijar clans. To these must be added clans like Chandēl, doubtless of Gond origin. Below them were ranged the 84 mercantile tribes, chiefly of Rājpūt origin, in whom we may see the Bhātias and recall the ancient Vaisyas.

RAJPUTANA, a collection of Indian states, under the political charge of an agent to the governor-general. It lies between 23" and 30° N. and between 69° 30' and 75° 15′ E., and includes 18 states, 2 chiefships and the small estate of Lawa. For political purposes the agent to the governor-general, with his headquarters at Ajmere and Mount Abu, is himself in charge of Sirohi and Bikaner. Then there are three residencies and four agencies. These are as follows: (1) Mewar residency, with headquarters at Udaipur, comprising the state of Udaipur (Mewar); (2) Jaipur residency, with headquarters at Jaipur, comprising the states of Jaipur and Kishangarh, with the estate of Lawa; (3) Western Rajputana states residency, with headquarters at Jodhpur, comprising the states of Jodhpur and Jaisalmer; (4) Eastern Rajputana states agency, with headquarters at Bharatpur, comprising the states of Alwar, Bharatpur, Dholpur, and Karauli; (5) Haraoti-Tonk agency, with headquarters at Dcoli, comprising the states of Tonk and Bundi, with the estate of Shahpura; (6) Kotah agency, with headquarters at Kotah, comprising the states of Kotah and Jhalawar; and (7) Southern Rajputana states agency, comprising Dungarpur, Banswara, Partabgarh and Kushalgarh. All of these states are under Rajput rulers, except Tonk, which is Mohammedan, and Bharatpur and Dholpur, which are Jat. The small British province of Ajmere-Merwara is also included within the geographical area of Rajputana.

Physical Features.—The total area of Rajputana is about 129,059 sq.m. It is bounded on the west by Sind, and on the north-west by the Punjab state of Bahawalpur. Thence its northern and north-eastern frontier marches with the Punjab and the United Provinces until it touches the river Chambal, where it turns south-eastward for about 200 m. The southern boundary runs in a very irregular line across the central region of India. The Aravalli range of mountains intersects the country in a line running from south-west to north-east. About three-fifths of Rajputana lies north-west of the range, and comprises the states of Bikaner, Jaisalmer and Jodhpur. With the exception of the districts of Jodhpur which lie immediately below the Aravallis, this division is sandy, ill-watered and unproductive, improving gradually from a desert in the north-west and west to comparatively fertile land in the east. The country to the east and south-east of the Aravallis is blessed with fertile lands, hill-ranges and long stretches of forest, where fuel and fodder are abundant.

The chief rivers are the Luni, the Chambal and the Banas. The Chambal rises in the highlands of the Vindhyas, anddischarges itself into the Jumna after a course of 560 m. There are several important artificial lakes, constructed for storing water. The only basin of any extent is the Sambhar salt lake, of about 50 m. in circuit.

Geology.—Geologically considered, the country may be divided into three regions—the central, and largest, comprising the whole width of the Aravalli system, formed of very old sub-metamorphic and gneissic rocks; an eastern region, with sharply defined boundary, along which the most ancient formations are abruptly replaced by the great basin of the Vindhyan strata, or are overlaid by the still more extensive spread of the Deccan trap, forming the plateau of Malwa; and a western region, of very ill-defined margin, in which, besides some rocks of undetermined age, it is more or less known or suspected that Tertiary and Secondary strata stretch across from Sind, beneath the sands of the desert, towards the flanks of the Aravallis. Rajputana produces a variety of metals. Ore of cobalt and zinc blende are peculiar to it. Copper and lead are found in several parts of the Aravalli range and of the minor ridges in Alwar and Shaikhawati, and iron ores abound in several states. Alum and blue vitriol (sulphate of copper) are manufactured from decomposed schists at Khetri in Shaikhawati.

Climate.--The climate throughout Rajputana is very dry and hot during the summer; while in the winter it is much colder in the north than in the lower districts, with hard frost and ice on the Bikaner borders. The rainfall is very unequally distributed: but on the whole Rajputana is reckoned one of the healthiest countries in India.

Population.—In 1931 the population was 11,225,712. The territory is called Rajputana because it is politically possessed by Rajputs. The whole number of this race is only 620,229, and nowhere do they form a majority of the whole population in a state; but they are strongest, numerically, in the northern states and in Udaipur. The Brahmans rank first; with them may be classed the Bhats, the keepers of secular tradition and of the genealogies. Next come the mercantile castes, mostly belonging to the Jain sect; these are followed by the powerful cultivating tribes, such as the Jats and Gujars, and then come the so-called aboriginal tribes, chief of whom are the Minas, Bhils and Meos. Rajasthani is the chief language of the country, one or other of its dialects being spoken by more than 70% of the total population.

BY COURTESY OF DR. COOMARASWAMY

MOHAMMEDAN WOMEN OF RAJPUTANA TERRITORY CARRYING WATER JARS ON THEIR HEADS

The mass of the people are occupied in agriculture. The chief manufactures are cotton and woollen goods, carvings in ivory and working in metals, etc., all of which handicrafts are chiefly carried on in the eastern states. The system of agriculture is very simple; in the country west of the Aravallis only one crop is raised in the year, while in other parts south and east of the Aravallis two crops are raised annually, and various kinds of cereals, pulses and fibres are grown. Jaipur had 144,179 pop.

History.—Previous to the invasion of Upper India by the Mohammedans, Rajputana was subject for the most part to two or three powerful tribal dynasties. Chief of these were the Rahtors, who ruled at Kanauj; the Chauhans of Ajmere; the Solankis of Anhilwara, in Gujarat; the Gehlots with the Sisodhyia sept, still in Mewar or Udaipur; and the Kachwaha clan, still in Jaipur. These tribal dynasties of Rajputs were gradually supplanted by the Moslem invaders of the 11th century and weakened by internal feuds. The clans were finally either conquered, overawed or conciliated by Akbar—all except the distant Sisodhyia clan, which, however, submitted to Jehangir in 1616. The Mahrattas, having been called in by the Rahtors to aid them, took possession of Ajmere about 1756; thenceforward Rajputana became involved in the general disorganization of India. By the end of the century nearly the whole of Rajputana had been virtually subdued by the Mahrattas. On the outbreak of the Pindari War in 1817 the British government offered its protection. The Pindaris were put down, Amir Khan submitting and signing a treaty which constituted him the first ruler of the existing state of Tonk. By the end of 1818 similar treaties had been executed by the other Rajput states with the paramount power. Since then the political history of Rajputana has been comparatively uneventful. The great storm of the Mutiny of 1857, though dangerous while it lasted, was short, as most of the rajas remained loyal.

Rajputana is of great archaeological interest, possessing some fine religious buildings in ruins and others in excellent preservation Among the latter are the mosques at Ajmere and the temples on Abu. But the most characteristic features of architecture in the country are shown in the forts and palaces of the chiefs.

RAJSHAHI, a district and division of British India. in the Province of Bengal. The administrative headquarters are at Rampur Boalia. Area 2,609 sq.m.; pop. (1931) 1,429,013. Rajshahi comprises an alluvial plain seamed with old river-beds and studded with marshes, but on the north and west a slightly elevated country is found in the Barind Rice is the staple crop, with pulses, oilseeds and jute. Indigo has disappeared and the silk industry is moribund. The hemp grown on a small tract in the north of the district supplies all the *ganja* that is consumed in Bengal. The district is traversed from south to north by the main line of the Eastern Bengal state railway.

The DIVISION OF RAJSHAHI is coextensive with northern Bengal, from the Ganges to the mountains It comprises the eight districts of Rajshahi, Dinajpur, Jalpaiguri, Malda, Darjeeling, Rangpur, Bogra and Pabna. Total area, 19,163 sq. miles. Pop. (1931) 10,668,066.

RÁKÓCZY, the name of a noble Hungarian family, which in the 10th century was settled in the county of Zemplén, members of which played an important part in the history of Hungary during the 17th century.

GEORGE I., prince of Transylvania (1591–1648), who began his career as governor of Onod, was the youngest son of Sigismund Rákóczy (1544–1608), who was for a short time prince of Transylvania. He took a leading part in the rebellion of Bethlen Garbo, who made him commandant of Kassa, and was elected prince of Transylvania by the diet of Segesvár on Nov 26, 1630. He followed Bethlen's national Hungarian policy, allied himself with Gustavus Adolphus of Sweden and on Feb 2, 1644, with the consent of the Pope, declared war on the Emperor Ferdinand III., drove him out of most of Hungary, and forced him to conclude the Peace of Linz (Sept. 16, 1645), which accorded full religious liberty to the Magyars, and ceded to Rákóczy the fortress of Regéc and the Tokaj district. On the death of Wladislaus IV. (1648) Rákóczy aimed at the Polish throne also, but died before he could accomplish his design. His capital, Gyula Fehérvár, was a great Protestant resort and asylum.

See Sándor Szilagyi, ***The Rdkdczy Family in the 18th Century*** (Hung) (Pest, 1861).

GEORGE II., prince of Transylvania (1621–1660), was the eldest son of George I. and Susannah Lorántffy. He was elected prince of Transylvania during his father's lifetime (Feb. 19, 1642), and married (Feb 3, 1643), Sophia Báthory. On ascending the throne (Oct. 11, 1648), he hoped to realize his father's Polish ambitions, and he allied himself, in 1649, with the Cossack hetman, Bogdan Chmielnicki, and the hospodars of Moldavia and Wallachia In 1657, as the ally of Gustavus Adolphus, he led his allies against the Polish king, John Casimir, took Cracow and entered Warsaw with the Swedes; but the moment his allies withdrew the whole scheme collapsed, and it was only on the most humiliating terms that the Poles finally allowed him to return to Transylvania. Here (Nov. 3, 1657) the diet, at the command of the Porte, deposed him for undertaking an unauthorized war, but in January 1658 he was reinstated by the Medgyes Diet. Again he was deposed by the grand vizier, and again reinstated. The Turks again invaded Transylvania, and Rákóczy died at Nagyvárad of the wounds received at the battle of Gyula (May 1660).

See ***Imre*** Bethlen, ***Life and Times of George Rákóczy II.*** (Hung.) (Nagy-Enyed, 1829); ***Life*** (Hung.) in SQndor Szilagyi's ***Hungarian Historical Biographies*** (Budapest, 1891).

FRANCIS I., prince of Transylvania (1645–1676), was the only son of George Rákóczy II. and Sophia Báthory. He was elected prince of Transylvania during his father's lifetime (Feb. 18, 1652), but lost both crown and father at the same time, and withdrew to the family estates, where, at Patak and Makovica, he kept a splendid court. His mother converted him to Catholicism, and on March 1, 1666 he married Helen Zrinyi. In 1670 he was implicated in the Zrinyi-Frangepán conspiracy, and only saved his life by the interposition of the Jesuits on the payment of an enormous ransom.

See Sándor Szilagyi, ***The Rdkdczy Family in the 17th Century*** (Hung.) (Pest, 1861).

FRANCIS II., prince of Transylvania (1676–1735), was born at Borsi, Zemplén, on March 2, 1676. Having lost his father during infancy, he was educated under the guardianship of his mother, Helen Zrinyi, in an ultra-patriotic Magyar environment, though the Emperor Leopold I. claimed a share in his tutelage. In 1682 his mother married Imre Thokoly, through whose speculations Rákóczy lost the greater part of his estates. As a child of eleven he witnessed the heroic defence by his mother of his ancestral castle of Munkács against Count Antonio Caraffa (d 1693). On its surrender (Jan. 7, 1688) the child was transferred to Vienna that he might be isolated from the Hungarian nation and brought up as an Austrian magnate Cardinal Kollonics, the sworn enemy of Magyar separatism, now became his governor, and sent him to the Jesuit college at Neuhaus in Bohemia. In 1690 he completed his course at Prague, and in 1694 he married Maria Amelia of Hesse-Rheinfels, and lived for the next few years on his Hungarian estates. Rákóczy's birth, rank, wealth and brilliant qualities made him the natural leader of the Magyar nation. On the eve of the war of the Spanish Succession Rákóczy, with some other magnates, entered into correspondence with Louis XIV. for assistance through one Longueval, a Belgian general in the Austrian service. Longueval betrayed his trust, and Rákóczy was arrested and imprisoned at Eperjes. His wife saved him from certain death by enabling him to escape to Poland in the uniform of a dragoon officer. On June 18, 1703 he openly took up arms against the emperor; but the Magyar gentry stood aloof, and his ill-supported peasant levies (the Kuruczes) were repeatedly scattered. He had, indeed, some initial success; but the battle of Blenheim made any direct help from France impossible, and on June 13, 1704 his little army of 7,000 men was routed by the imperialists at Koronco and subsequently at Nagyszombat Want of arms, money, native officers and infantry, made, indeed, any permanent success in the open field impossible; yet he drilled his army into some degree of efficiency, and even after the rout of Pudmerics (Aug. 11, 1705), disposed of 100,000 men.

Rákóczy, who had already been elected Prince of Transylvania (July 6, 1704), now surrounded himself with a council of state of 24 members. But his efforts to secure toleration for his Calvinist followers alienated the pope, who dissuaded Louis XIV. from assisting him. Peace negotiations with the emperor during 1705 came to nothing, the latter refusing to acknowledge the independence of Transylvania, while France would not recognize the rebels officially till they had formally proclaimed the deposition of the Habsburgs, which last desperate measure was actually accomplished by the Onod diet on June 13, 1707. This measure, however, alienated both the emperor's foreign allies and the majority of the Magyar gentry, while, after all, Louis XIV sent no effective help. On Aug. 3, 1708 Rákóczy was heavily defeated at Trencsen (Trenčin), and again at Romhány (Jan. 22, 1710). A desperate effort to secure the help of Peter the Great also failing, Rákóczy quitted his country for ever on Feb. 21, 1711, refusing to accept the general amnesty conceded after the peace of Szatmár. (See HUNGARY, *History*) He lived for a time in France on the bounty of Louis XIV, finally entering the Carmelite Order. In 1717, with forty comrades, he volunteered to assist the Turks against the Austrians, but his services were not utilized. He lived for the rest of his life at Rodostó, where he died on April 8, 1735.

(Hung.) (Beszterczebánya, 1903); S. Endrödi, *Kurucz Notes, 1700–1720* (Hung.) (Budapest, 1897).

RAKOVSKY, CHRISTIAN GEORGIEVICH (1873–), Russian politician and diplomat, of Bulgarian descent and Rumanian nationality, was born on Aug. 13, 1873 at Kotel, Bulgaria. His father's home in the Dobruja passed after the Russo-Turkish war to Rumania, and the family became Rumanian. Rakovsky's Bulgarian ancestors, especially his grandfather, had organized risings against the Turkish rule, and the revolutionary traditions of the family were revived in Christian Rakovsky. In 1890 on account of his socialist activities all appointments in Bulgarian schools were closed to him. He therefore went to Geneva, where he joined the international social democratic student movement, and came in contact with Plekhanov and other Russian social democrats; and also to Germany, where he met Liebknecht. He was expelled from Prussia in 1894; went to France, where he graduated as a doctor of medicine at Montpellier, and wrote his thesis on *The Etiology of Criminality and Degeneration* (1897). Returning to Bulgaria, he recommenced revolutionary activities, and in *Russia in the East* (1898) denounced Tsarist politics. In 1900 he served as an officer in the Rumanian army. During the peasant riots of 1907 he was expelled from Rumania, his title to Rumanian citizenship not being considered adequate, and his civil rights were only restored in 1912. The five years of Rakovsky's exile were interrupted by illicit homecomings and consequent labour troubles.

After Rumania entered the World War Rakovsky was arrested and imprisoned in various places, and finally at Jassy, whence he was released by the Russians on May 1, 1917. After the Soviets came into power in November he became a member of the central executive committee of the Union, and in 1919 he became a member of the central committee of the Communist party. Rakovsky was well known as a writer on political and economic subjects under the pen name of "Insarov," and a number of his books were written and published in Russia *(Modern France,* 1900; *Metternich and His Time,* etc.).

Rakovsky's diplomatic career began with his appointment as head of the delegation entrusted with the peace negotiations with the Ukrainian central rada. In 1919 he was appointed president of the soviet of people's commissars of the Ukraine, and in 1922 represented Russia at the conference of Genoa. In 1924 he was the Soviet chargé d'affaires in London. and in 1926–27 he was Soviet ambassador to France. His support of Trotsky led, in 1928, to his expulsion from the Communist party and exile to Stalingrad. He was re-admitted in 1934, and was a departmental chief in the Commissariat of Health until 1937, when he was dismissed. He was among the 21 members of the "Right Trotskyist bloc" arrested in Feb. and tried in March 1938. Rakovsky was sentenced to 20 years' imprisonment.

RALEIGH, SIR WALTER (c. 1552–1618), British explorer, was born about 1552, the son of Walter Raleigh, of Fardell, and Catherine, daughter of Sir Philip Champernown of Modbury. He was born at the farmhouse of Hayes near Budleigh Salterton Bay. In 1568 he was entered as a commoner of Oriel College, Oxford. In 1569 he followed his cousin Henry Champernown, who took over a body of English volunteers to serve with the French Huguenots and was perhaps present at the battle of Jarnac (Mar. 13, 1569) Nothing is known with certainty of his life until February, 1575, when he was resident in the Temple. In June 1578 his half-brother Sir Humphrey Gilbert obtained a patent for six years authorizing him to take possession of "any remote barbarous and heathen lands not possessed by any Christian prince or people." During 1578 Gilbert led a piratical expedition against the Spaniards. Raleigh accompanied his half-brother as captain of the "Falcon," and was perhaps with him in an unsuccessful voyage in 1579. In 1580 Raleigh was twice arrested for duels, and he attached himself to the earl of Leicester, and to the earl of Oxford. Late in 1580 he was serving as captain of a company of foot in Munster. He took an active part in suppressing the rebellion of the Desmonds; he advocated a ruthless policy against the Irish, and recommended assassination as a means of getting rid of their leaders.

In December 1581 he was sent home with despatches and his great fortune dates from his arrival at court, where he was already known through his correspondence with Walsingham. He had corresponded with Walsingham for some time. It is possible that Raleigh did throw his mantle on the ground to help the queen to walk dry-shod over a puddle, and that he scribbled verses with a diamond on a pane of glass to attract her attention. His tall and handsome person, his caressing manners and his quick wit certainly pleased the queen, and the stories in Sir Robert Naunton's *Fragmenta Regalia* and in Fuller's *Worthies* represent at least the mythical truth as to his rise into favour. The rewards showered on him were out of all proportion to his services in Ireland. In February 1583 he accompanied the duke of Anjou to Flanders. In 1583 he received the grant of Durham House, Strand, and in the same year the queen's influence secured him two beneficial leases from All Souls, Oxford, which he sold to his advantage, and a patent to grant licences to "vintners" — that is, tavern keepers, which he subleased. In 1584 he had a licence for exporting woollen cloths. He was knighted in 1584. In 1585 he succeeded the earl of Bedford as Warden of the Stannaries. Raleigh made a good use of his new powers in the mining districts of the west. He reduced the old customs to order, and showed himself fair to the workers. In 1586 he was given 40,000 acres of the forfeited lands of the Desmonds, on the Blackwater in Ireland. He planted English settlers, and introduced the potato and tobacco. In 1587 he received a grant of part of Babington's forfeited land.

Raleigh was now at the height of his favour; Queen Elizabeth always had several favourites at once, lest any one might be supposed to influence her. She treated Raleigh exclusively as a court favourite, but never gave him any great office, nor admitted him to the council. Even his post of captain of the Guard, given in 1587, was mainly ornamental. The patent given to his half-brother Sir Humphrey Gilbert ran out in 1584. To avert this loss Raleigh, partly out of his own pocket, provided the means for the expedition to Newfoundland in 1583, in which Gilbert died. The patent was renewed in Raleigh's favour in March 1584.

Raleigh now began the series of ventures in the colonization of Virginia. His patent gave him and his heirs the proprietary right over all territory they occupied on payment of one-fifth of the produce of all mines of precious metals to the crown. In April 1584 Raleigh sent out two captains, Philip Amadas and Arthur Barlowe, on a voyage of exploration. They sailed by the Canaries to Florida, and followed the coast of North America as far as the inlet between Albemarle and Pamlico sounds in modern North Carolina. The name of Virginia was given to a vast and undefined territory, but none of Raleigh's captains or settlers reached the state of Virginia. In the same year he became M.P. for Devonshire. His first body of settlers, sent out in 1585 under Sir Richard Grenville, landed on what is now Roanoke Island in North Carolina. The settlers got on bad terms with the natives, and deserted the colony when Drake visited the coast in 1586. Attempts at colonization at the same place in 1586 and 1587 failed *(see* NORTH CAROLINA), and in 1589 Raleigh resigned his rights to a company of merchants, preserving to himself a rent, and a fifth of whatever gold might be discovered.

After 1587 Sir Walter Raleigh's position as favourite was challenged by the earl of Essex. *(See* ESSEX, 2nd *EARL* OF.) In 1588 he was in eclipse. He was in Ireland for part of the year with Sir R. Grenville, and as vice-admiral of Devon looked after the coast-defences and militia levy of the county. In 1589 he was again in Ireland, visiting Edmund Spenser at Kilcolman. It was by Raleigh's help that Spenser obtained a pension, and royal aid to publish the first three books of the *Faerie Queen.* In 1589 Raleigh accompanied the expedition to the coast of Portugal which failed to raise a revolt against Philip II. In 1591 he was at the last moment forbidden to take part in the voyage to the Azores, being replaced by his cousin Sir R. Grenville. In 1592 he was again at sea with an expedition to intercept the Spanish trade, but was recalled by the queen, having seduced one of her maids of honour, Elizabeth Thtogmorton Raleigh denied the stories in a letter to Robert Cecil. On his return he was put into the Tower, and if he was not already married was married there. To placate the queen he made a fantastic display of despair at the loss of her favour. The maids of honour could not marry without the queen's consent, which Elizabeth was always reluctant to give and would be particularly unwilling to give when the husband was an old favourite of her own. Raleigh proved a good husband and his wife was devoted to him through life. He superintencied the distribution of the booty from the Portuguese carrack "Madre de Dios." He had provided large sums for the expedition, but the queen left him barely enough to cover his expenses.

Raleigh now retired to an estate at Sherborne in Dorsetshire, which he had extorted from the bishop of Salisbury by unscrupulous use of the royal influence. A son was born to him here in 1593. But a retired life did not suit Raleigh, and in 1595 he sailed on a voyage of exploration to the coast of South America. The object was undoubtedly to find gold mines, and Raleigh had heard the wild stories of El Dorado. His account of his voyage, *The Discoverie of Guiana,* published on his return, is brilliant, but contains much manifest romance and was received with incredulity. He was now the most unpopular man in England for his greed, arrogance and scepticism in religion. In 1590 he was named with Marlowe and others as an atheist. The share he took in the capture of Cadiz in 1596, where he was wounded, was followed by a return to favour, and he was apparently reconciled to Essex, whom he accompanied to the Azores in 1597. This co-operation led to a renewal of the quarrel, and Raleigh became still more unpopular. In 1600 he obtained the governorship of Jersey, and in 1601 took a part in suppressing the rebellion of Essex, at whose execution he presided as captain of the Guard. In 1600 he sat as member for Penzance in Elizabeth's last parliament. He was a steady friend of religious toleration, and a bold critic of the fiscal and agrarian legislation of the time.

James I., who regarded Essex as his partisan, had been prejudiced, and Raleigh's desire for war with Spain was against James's peace policy. Raleigh sold his Irish estates to Richard Boyle in 1602. He was expelled from Durham House, which was reclaimed by the bishop, dismissed from the captaincy of the Guard, deprived of his monopolies and of the government of Jersey. He was concerned in the complication of conspiracies of the first months of James's reign, and was committed to the Tower on July 19, 1603. Here he tried to stab himself, but only inflicted a small wound. His trial at Winchester, November 1603, was conducted with outrageous unfairness, and his gallant bearing in face of the brutality of the Attorney-General, Sir Edward Coke, turned public opinion in his favour. Raleigh was probably cognizant of the conspiracies, though the evidence against him was insufficient to prove his guilt. Much was kept back by the council, and the jury was influenced by knowing that the council thought him guilty.

The sentence of death passed on Raleigh was not carried out, but he was sent to the Tower, where he remained till March 19, 1616. His estate of Sherborne, which he had transferred to his son, was taken by the king. A sum of £8,000 offered in compensation was only paid in part. Raleigh's confinement was easy, and he turned to chemical experiments and literature. He had been known as a minor poet, and in prison he composed the only volume of his vast *History of the World* published. He invented an elixir, a very formidable quack stimulant. Hope of release never deserted him, and he secured his freedom in a way discreditable to all concerned. He promised the king to find a gold mine in Guiana without entrenching on a Spanish possession. It must have been obvious that this was impossible, and the Spanish ambassador, Gondomar, warned the king that the Spaniards had settlements on the coast. The king, who was in need of money, replied that if Raleigh was guilty of piracy he should be executed on his return. Raleigh gave promises he obviously knew he could not keep and sailed on March 17, 1617, relying on the chapter of accidents, and on vague intrigues he had entered into in Savoy and France. The ill-equipped expedition reached the mouth of the Orinoco on Dec. 31, 1617. Raleigh was ill with fever, and remained at Trinidad. He sent five small vessels up the Orinoco under Lawrence Keymis, with whom went his son Walter and a nephew. The expedition found a Spanish settlement on the way to the supposed mine, and a fight ensued in which Sir Walter's son and several Spaniards were killed. Keymis returned to Sir Walter with the news of his son's death and his own utter ruin, and killed himself as a result of Raleigh's reproaches. After a miserable scene of recriminations and mutiny, the expedition returned home. Raleigh was arrested, and in pursuance of the king's promise to Gondomar was executed under his old sentence on Oct. 29, 1618. When he knew his end to be inevitable he died with serenity and dignity. His wife survived him, and he left a son, Carew Raleigh. His enmity to Spain made him a popular hero.

AUTHORITIES.—An edition of his *Works* in eight volumes was published in London in 1829. It contains a *Life* by Oldys and Birch, written with all the knowledge then available. *A Life of Sir Walter Raleigh* (1806, 2nd ed.) was much used by Southey in his biography of Sir Walter Raleigh in vol. iv. of *The British Admirals* in the *Cabinet Cyclopaedia* (1837). Two biographies appeared simultaneously, *Life of Sir Walter Raleigh* by J. A. Saint John, and *Life of Sir Walter Raleigh* by E. Edwards (1868). E. Edwards's work is in two volumes, of which the second contains the correspondence, and is still the best authority. Smaller lives, which in some cases contain new matter, are those by E. W. Gosse, "Raleigh" in *English Worthies* (1886); W. Stebbing, *Sir W. Raleigh* (1891 and 1899); Martin Hume, *Sir Walter Raleigh* (1897); H. de Selincourt, *Great Ralegh* (1908); and M. Waldman, *Sir Walter Raleigh* (1928). For special episodes *see* Sir John Pope Hennessy, *Sir Walter Raleigh in Ireland* (1883), and T. N. Brushfield, *Raleghana* (Ashburton, 1896). Two separate editions of Raleigh's poems have been published, *Poems, with biography and critical introduction* by Sir F. Brydges (London, 1813), and *Poems of Raleigh with those of Sir H. Wotton, etc.*, edited by J. Hannah (London, 1892). S. R. Gardiner made a careful examination of the events of Raleigh's life after 1603 in his *History of England from the Accession of James I. to the Outbreak of the Civil War* (1883–84). *See* also C. H. Firth, *Sir Walter Raleigh's History of the World* (1918); and L. Cust, *Portraits of Sir Walter Raleigh* (1920).

RALEIGH (raw'lĭ), **SIR WALTER** (1861–1922), English man of letters, born on Sept. 6, 1861, in London, was educated at University college, London, and King's college, Cambridge. He was professor of modern literature at University college, Liverpool, and professor of English literature at Glasgow. In 1904 he was appointed professor of English literature at Oxford. He was knighted in 1911, and elected to a fellowship at Merton college in 1914. He died on May 13, 1922.

Raleigh was a good critic, and a stimulating teacher. He was not bound by the accepted judgments on individual writers, but brought a fresh and original mind to bear on literature. He did as much as any man of his time to break with what may be called the "dry-as-dust" school. His publications include *The English Novel* (1894), *Style* (1897), *Wordsworth* (1903), *The English Voyagers* (1904), *Shakespeare* (1907), Six *Essays on Johnson* (1910), *Romance* (1917), and many essays on literary subjects.

RALEIGH, the capital of North Carolina, U.S.A., and also the county seat of Wake county; in the heart of the eastern part of the State, on Federal highways 1 and 70, and served by the Norfolk Southern, the Seaboard Air Line, and the Southern railways. Pop. 22,418 in 1920 (35% Negroes); 46,897 in 1940 by the Federal census. The city has an altitude of 360 ft. and an area of 7 sq.mi. In the centre, on the highest ground, is the beautiful Capitol park of 4 ac., from which lead four broad streets, named for earlier capitals of the State. The present capitol building (completed 1840) of granite from a near-by quarry owned by the State, has a Doric portico and an octagonal dome. In the immediate neighbourhood are the State supreme court, the State Office building, the Justice building, the State Law library, the State museum, the Administration building, the Agricultural building, and the Highway Commission; and not far away is the Governor's mansion (1889), set in 4 ac. of grounds. In Pullen park is the house in which Andrew Johnson was born. Among the numerous antebellum mansions still standing is that of Joel Lane (built in 1760), from whom in 1792 the State purchased the site of the city. Most of the State institutions are located at Raleigh: the hospital for the insane and epileptics (established in 1856, through the efforts of Dorothea Lynde Dix), the prison (1869), the schools for the white blind (1845) and the coioured deaf and blind (1867), the Confederate soldiers' home (1891), and the laboratory of hygiene. Raleigh is an important educational centre, with some 5,000 students in the colleges and other schools under private auspices. The North Carolina State College of Agriculture and Engineering (1889) with the affiliated experimental farms, occupies 486 ac. in the western part of the city. Meredith college for women (Baptist; chartered 1891) moved in 1924 to a suburban campus of 130 acres. Shaw university (Baptist; 1865) and St. Augustine's college (Protestant Episcopal; 1868) are two of the oldest institutions in the South for the higher education of negroes. Seventeen miles north is Wake Forest college (Baptist) opened as an institute in 1834 and chartered as a college in 1838. Raleigh has a large wholesale and retail trade. Hydro-electric power (60,000 h.p.) is available from three sources. The diversified manufacturing industries (with an output valued at $6,500,000 in 1940) include railway shops of two roads, with an annual payroll of $800,000, and printing and publishing plants employing 500 persons. Five insurance companies have their home offices here. The assessed valuation of property for 1940 was about $51,000,000.

In 1787 the State convention decreed that there should be a "fixed and unalterable seat of government," and that it should be named in honour of Sir Walter Raleigh; in 1788 the site (Wake Court House) was chosen; in 1792 the land was bought and the city was laid out, with wide streets and large public squares; and in 1793 it was incorporated. Sherman's army passed through Raleigh on April 13, 1865.

RALPH (d. 1122), archbishop of Canterbury, called Ralph de Turbine, or Ralph d'Escures from his father's estate of Escures, near Séez in Normandy, entered the abbey of St. Martin at Séez in 1079, and ten years later became abbot of this house. After Anselm's death in April 1109 Ralph acted as administrator of the see of Canterbury until April 1114, when he himself was chosen archbishop at Windsor. Claiming authority in Wales and Scotland, he refused to consecrate Thurstan as archbishop of York because the latter prelate declined to profess obedience to the archbishop of Canterbury. This step involved him in a quarrel with the papacy, and he visited Rome, but was unable to obtain an interview with pope Paschal II., who had left the city. In spite of peremptory orders from Paschal's successors, Gelasius II. and Calixtus II., the archbishop still refused to consecrate Thurstan, and the dispute was unsettled when he died on Oct. 20, 1122.

RALPH OF COGGESHALL (d. after 1227), English chronicler, was at first a monk and afterwards sixth abbot (1207–1218) of Coggeshall, an Essex foundation of the Cistercian order. Ralph himself tells us these facts; and that his resignation of the abbacy was made against the wishes of the brethren, in consequence of his bad health. He took up and continued a Chronicon Anglicanum belonging to his house; the original work begins at 1066, his own share at 1187. He hoped to reach the year 1227, but his autograph copy breaks off three years earlier. The tone of the chronicle is usually dispassionate; but the original text contained some personal strictures upon Prince John, which are reproduced in Roger of Wendover. He wrote a continuation of Niger's chronicle, extending from 1162 to 1178 (printed in R. Anstruther's edition of Niger, London, 1851), and short annals from 1066 to 1223.

The autograph manuscript of the Chronicon *Anglicanum* is to be found in the British Museum (Cotton, Vespasian D. X.). The same volume contains the continuation of Ralph Niger. The *Chronicon* Terrae Sanctae, formerly attributed to Ralph, is by another hand; it was among the sources on which he drew for the Chronicon *Anglicanum*. The so-called *Libellus* de *motibus* anglicanis sub *rege Johanne* (printed by Martene and Durand, *Ampl. Collectio,* v. pp. 871–882) is merely an excerpt from the *Chronicon Anglicanum.* This latter work was edited for the Rolls series in 1875 by J. Stevenson.

RAM. A male sheep, one kept for breeding purposes in domestication and not castrated, as opposed to the castrated wether. (*See* SHEEP.) For the ram as one of the signs of the zodiac, see ARIES. The word may be connected with O.Nor. *ramme,* strong, or with Skt. ram, to sport. The butting propensities of the ram have given rise to the many transferred senses of the word, chief and earliest of which is that of a battering implement used before the days of cannon for beating in the gates and breaching the walls of fortified places. (See BATTERING RAM.) Many technical uses of the term have been developed from this, *e.g.,* the weight of a pile-driving machine, the piston ot a hydraulic press and other machines or portions of machines worked by water power. (See HYDRAULICS.) The ancient war-vessels were fitted with a beak (Lat. rostrum, Gr. ἔκβολον), projecting from the bows, and used to ram or crush in the sides of an opposing vessel; for the development of this in the modern battleship see SHIP.

RAMA, an almost extinct Indian tribe who live on Rama key in Bluefields lagoon on the east coast of Nicaragua. Formerly they occupied the north bank of the San Juan river. Linguistically the Rama are allied to the Chibchan peoples of South America. Their material culture suggests a South American connection.

See C. de Kalb, Bibliography of the Mosquito Coast of Nicaragua (Bulletin of the American Geographical Society, vol. xxvi. No. 2, 1894); D. E. Harrower, *Rama, Mosquito,* and *Sumu* of *Nicaragua* (Indian Notes, vol. ii., 1925).

RAMADAN (rah-mah-dahn'), the Muslim month in which absolute fasting from dawn to sunset is required. The law is based on Qur'ān ii. 179–184, and is as follows: A fast has always been a part of religion. In Islām it falls in this month because in it the Qur'ān was revealed, and it is holier than the others. It begins when the new moon is actually seen, and lasts until sight of the next new moon; it extends each day from the time when a white thread can be distinguished from a black one and until nightfall; it is absolute in that time as to food, drink, women. The sick and those on a journey may be excused, but should fast thereafter an equivalent number of days. The last ten days of the month are regarded as especially sacred; in the course of them falls the "Night of Decree," or "of Power" (Qur'ān xc. 1), but its exact date is not known. Fasting in Ramadān is reckoned one of the five pillars, or absolute requirements, of Islam. It is followed by the Lesser Festival, the first three days of the month Shawwāl (see BAIRAM).

BIBLIOGRAPHY.—T. P. Hughes, Dictionary of *Islam, s.v.* (1885); Snouck Hurgronje, Mekka, 51, 77 ff. (1889); E. W. Lane, *The* manners *and customs of the* modern Egyptians, chap. xxv.; Th. W. Juynboll, *Handbuch* des islamischen *Gesetzes,* chap. iii. (1910).

RAMADI, a town in Iraq in 33° 30' N. 43° 30' E. about 80 m. by road from Baghdad. The town lies on both sides of the Euphrates, which is here crossed by a bridge of boats, and in the 20th century became of some importance as an airport and as the point at which the overland mail leaves the cultivated area and starts its journey over the desert.

RAMAN EFFECT. When a beam of monochromatic light passes through a transparent substance a certain amount of light is scattered from the path of the original beam which is of greater wave-length than the incident light. This effect was discovered by Raman in 1928, and is known by his name. It must be distinguished from the Tyndall effect and from ordinary fluorescence. In the Tyndall cone (see COLLOIDS) the scattered light is of exactly the same wave-length as the primary beam, supposing monochromatic light to be used: if mixed light is used each wave-length is scattered without change of frequency, but the fact that the short wave-lengths are scattered in greater intensity than the longer wave-lengths leads to an apparent modification of colour. With fluorescence the light scattered in all directions is, except in a few exceptional cases, of wave-length greater than that of the primary beam (*see* FLUORESCENCE AND PHOSPHORESCENCE, where the exceptions to Stokes' law are discussed), but this wave-length is characteristic of the particular fluorescent substance, and does not change with the wave-length of the incident light, so long as this is short enough to excite fluorescence at all. The Raman effect is distinguished by the fact that the frequency of the scattered light changes with that of the primary beam, the difference of frequency between the primary beam and the scattered light being independent of the frequency of the primary beam. Thus, with the light from a mercury arc as the exciting radiation, each strong line is accompanied by a group of scattered lines, the frequency intervals from the primary line being the same within each group. Further, certain classes of chemical substances, such as different organic liquids each containing the same chemical group (*e.g.,* the CH group), give in the scattered light groups of lines whose frequency intervals from the primary line are the same for all substances of the class, but these intervals vary from substance to substance in other cases. The Raman radiation resembles the Tyndall scattered light in that it is, in general, strongly polarised.

The effect is observed by illuminating pure dust-free liquids with an intense beam of light containing approximately monochromatic radiations, *e.g.*, the light from a mercury vapour lamp, and photographing the scattered light from a direction more or less at right angles to the original beam. The magnitude of the shift is of the order of 100 Angstrom units: it is not a question of a minute modification of frequency. The scattered light always contains the original frequency in comparatively great intensity, the modified lines often requiring a long exposure.

The interpretation of the effect is a matter of great theoretical importance. On the quantum theory of radiation (see QUANTUM THEORY) a certain quantum of energy $h\nu$ is to be attributed to the incident radiation, and a quantum of energy $h\nu'$ to the scattered radiation, h being Planck's constant and ν and ν' the respective frequencies. The difference $h(\nu-\nu')$ must be absorbed by the molecule in sume quantum change, and the order of magnitude of this difference corresponds to an infra-red frequency. There is strong support for the view that the energy communicated to the molecule appears as energy of vibration of the nuclei of certain atoms in it, that is, the distance between the nuclei of these atoms varies periodically, the energy of the oscillations being governed by quantum conditions. Thus, associated with the strong mercury line 4,358A in the incident light, there is a scattered line at 5,000A with organic compounds containing the CH group: the difference of wave-number is $10^8\left(\frac{1}{4358}-\frac{1}{5000}\right)=2946\text{cm.}^{-1}$, which corresponds to an infra-red line at $3{\cdot}4\mu$. Such a line is present in the infra-red spectra of these compounds, and is attributed to nuclear oscillation. (*See* BAND SPECTRUM.) Other scattered lines lead to other infra-red frequencies characteristic of the molecules in question. The Raman effect thus furnishes spectroscopy with a new and very powerful weapon for investigating the infra-red spectra of determined molecules without the very troublesome technique of infra-red measurements. In the case of complicated molecules the vibrations can be traced to simple groups within them, as exemplified by the CH group.

Besides the lines of lower frequency than the exciting light a few lines are found in the scattered light which have a higher frequency, and thus correspond to a contribution of energy by the molecule to the quantum of energy of the incident light. Such lines find a natural explanation in the existence of molecules which, as regards the nuclear vibrations, are in one of the excited quantum states of higher energy: a quantum jump to a state of lower energy occurring in conjunction with the scattering process provides the necessary increment of energy to the scattered quant.

The Raman effect shows an interesting similarity to the Compton effect (*q.v.*). In the Compton effect the incident light-quant communicates part of its energy to a free, or loosely bound, electron, which energy appears as kinetic energy of this electron, the light quant of diminished energy being scattered as radiation of greater wave-length than that of the incident quant. The Compton effect is observed with hard X-rays, the magnitude to be anticipated for the effect with optical frequencies being too small for experimental observation. In the Raman effect the incident radiation sacrifices part of its energy in an interaction with matter, and reappears as a radiation of diminished frequency, just as in the Compton effect, but the energy lost as radiation appears as energy of molecular vibration instead of as kinetic energy of an electron.

BIBLIOGRAPHY.—The discovery of the effect was first announced by C. V. Raman in the *Indian Journal of Physics*, ii., 387, 1928, and by Raman and K. S. Krishnan in *Nature*, CXXI., 501, 1928. Other papers on the subject are: Raman and Krishnan, *Indian Joural of Physics*, II., 399, 1928; Cabannes and Daure, *Comptes Rendus de l'Académie des Sciences*, CLXXXVI. 1533, 1928; G. Rogard, *Comptes Rendus*, CLXXXVI., 1107, 1928; P. Pringsheim, *Die Naturwissenschaften*, XVI., 597, 1928; R. W. Wood, *Philosophical Magazine*, VI., 729, 1928.

(E. N. DA C. A.)

RAMANUJAN, SRINIVASA (1887–1920), Indian mathematician, whose correct name was Srinivasa Ramanuja Tyengar, was born at Erode, southern India, on Dec. 22, 1887. He was educated at the Town High school and at the Government college at Kumbakonan. He obtained a scholarship from the University of Madras, but after his marriage, in 1909, became a clerk in the Madras Port Trust. Correspondence with Prof. G. H. Hardy, of Cambridge, led to his obtaining a further scholarship from Madras university, and an exhibition from Trinity college, Cambridge. In spite of religious difficulties arising from the fact that he was a Brahmin, he came to England in April 1914, where Hardy, by private teaching, helped to provide the necessary mathematical background for his original work. His mathematical work is on the theory of numbers, theory of partitions and the theory of continued fractions. He became ill in 1917, returned to India in 1919, when he resumed some of his mathematical work, but died on April 26, 1920, at Kumbakonan. He was elected F.R.S. in 1918 and fellow of Trinity college later in the same year.

Most of his papers, edited by G. H. Hardy, P. V. Seshu Aiyar and B. M. Wilson, were published under the title of *Collected Papers of Srinivasa Ramanujan* (1927). *See* also obituary notice, with a list of Ramanujan's papers, by G. H. Hardy, in *Proceedings of the Royal Society*, vol. xcix. (1921).

RAMANUJAS, followers of Ramanuja, a southern Brahmin of the 12th century. Sri Vaishnavas, as they are usually called, worship Vishnu (Narayana) with his consort Sri or Lakshmi (the goddess of beauty and fortune), or their incarnations Rama with Sita and Krishna with Rukmini. Ramanuja's doctrine is essentially based on the tenets of an old Vaishnava sect, the Bhagavatas or Pancharatras, who worshipped the Supreme Being under the name of Vasudeva (later identified with Krishna, as the son of Vasudeva). They have shrines at Srirangam near Trichinopoly, Mailkote in Mysore, Dvaraka (the city of Krishna) on the Kathiawar coast, and Jagannath in Orissa; all of them decorated with Vishnu's emblems, the tulasi plant and salagram stone. Whilst Sankara's mendicant followers were prohibited to touch fire and had to subsist entirely on the charity of Brahman householders, Ramanuja, on the contrary, not only allowed his followers to use fire, but strictly forbade their eating any food cooked, or even seen, by a stranger. On the speculative side, Ramanuja met Sankara's strictly monistic theory by another, recognizing Vishnu as identical with Brahma, the Supreme Spirit animating the material world as well as the individual souls which have become estranged from God through unbelief, and can only attain again conscious union with him through devotion or love (bhakti). His tenets are expounded in various works, especially in his commentaries on the Vedantasutras and the Bhagavadgita. The followers of Ramanuja have split into two sects, a northern one, recognizing the Vedas as their chief authority, and a southern one, basing their tenets on the Nalayir, a Tamil work of the Upanishad order. (*See* RAMATS.)

See E. Thurston, *Tribes and Castes of India*, s.v.

RAMATS, a numerous north Indian sect (*Ramanandis* or *Ramavats*). Its founder, Ramananda, flourished in the latter part of the 14th century, according to tradition.

He was originally a Sri-Vaishnava monk, who, having come under the suspicion of laxity in observing the strict rules of food during his peregrinations, and having been ordered by his superior (Mahant) to take his meals apart from his brethren, left the monastery in a huff and set up a schismatic math of his own at Benares. The main distinctive features of their creed consist in their making Rama and Sita, either singly or conjointly, the chief objects of their adoration, instead of Vishnu and Lakshmi, and their attaching little or no importance to the observance of privacy in the cooking and eating of their food. Their mendicant members, usually known as Vairagis, are, like the general body of the sect, drawn from all castes without distinction. Thus, the founder's twelve chief disciples include, besides Brahmans, a weaver, a currier, a Rajput, a Jat and a barber —for, they argue, seeing that Bhagavan, the Holy One (Vishnu), became incarnate even in animal form, a Bhakta (believer) may be born even in the lowest of castes. Ramananda's teaching was thus of a popular character. The Bhakta-malā and other authoritative writings of the sect are composed in the popular dialects.

A follower of this creed was the poet Tulsidas, the author of the Hindi version of the Ramayana. *(See* RAMANUJAS.)

RAMBAUD, ALFRED NICOLAS (1842–1905), French historian, was born at Besançon on July 2, 1842. After studying at the Bcole normale supérieure, he completed his studies in Germany. He was appointed *répétiteur* at the École des Hautes Études on its foundation in 1868. His earlier historical work was done in Byzantine and Russian history. Probably his study of Russia was motived partly by his sense of the desirability of a Franco-Russian entente. Rambaud was *chef de cabinet* to Jules Ferry (1879–81), and in 1883 became professor of contemporary history at the Sorbonne.

He now wrote his *Histoire de la civilisation française* (2 vols., 1885, 1887; 9th ed., 1901) and his *Histoire de la civilisation contemporaine en France* (1888; new ed. entirely revised, 1906), and undertook the general editorship of the *Histoire générale du IVe siècle jusqu'à nos jours.* The plan of this great work had been drawn up with the aid of Ernest Lavisse, but the entire supervision of its execution was carried out by Rambaud. Rambaud held the position of minisler of Public Instruction from 1896 to 1898, and sought to carry on the educational work of Jules Ferry. He died in Paris on Nov. 10, 1905.

See the notices by E. Lavisse in the *Revue de Paris* for January 15th, 1906, and G. Monod in the *Revue historique* (vol. xc., pp. 344–348).

RAMBOUILLET, CATHERINE DE VIVONNE, MARQUISE DE (1588–1665), French *salonnière,* was the daughter and heiress of Jean de Vivonne, marquis of Pisani, and Giulia Savelli. She was married at twelve to Charles d'Angennes, vidame of Le Mans, and afterwards marquis of Rambouillet. The young marquise found the coarseness and intrigue that then reigned in the French court little to her taste, and after the birth of her eldest daughter, Julie d'Angennes, in 1607, she began to gather round her the circle afterwards so famous. She established herself at the HBtel Pisani, called later the HBtel de Rambouillet. Almost all the more remarkable personages in French society and French literature frequented it, especially during the second quarter of the 17th century. Madame de Rambouillet's natural abilities had been carefully trained, but were not extraordinary. She had genuine kindness and a lack of prejudice that enabled her to entertain on the same footing princes and princesses of the blood royal, and men of letters, while among her intimate friends was the beautiful Angélique Paulet. The respect paid to ability in her salon effected a great advancement in the position of French men of letters. The almost uniform excellence of the memoirs and letters of the period may be traced largely to the development of conversation as a fine art at the HBtel de Rambouillet, and the consequent establishment of a standard of clear and adequate expression. Mme. de Rambouillet was known as the "incomparable Arthénice," the name being an anagram for Catherine, devised by Malherbe and Racan. Among the famous incidents in the story of the Hôtel are the sonnet war between the Uranistes and the Jobistes—partisans of two famous sonnets by Voiture and Benserade—and the composition by all the famous poets of the day of the *Guirlande de Julie,* a collection of poems on different flowers, addressed in 1641 to Julie d'Angennes, afterwards duchesse de Montausier. Julie herself was responsible for a good deal of the preciosity for which the Hôtel was later ridiculed.

The *Prkcieuses,* who are usually associated with Molière's avowed caricatures and with the extravagances of Mlle. de Scudéry, but whose name, it must be remembered, Madame de Sévigné herself was proud to bear—insisted on a ceremonious gallantry from their suitors and friends, though it seems from the account given by Tallemant des Réaux that practical jokes of a mild kind were by no means excluded from the HBtel de Rambouillet. They especially favoured an elaborate and quintessenced kind of colloquial and literary expression, imitated from Marini and Gongora, and then fashionable throughout Europe. Molière's attack was probably levelled not at the Hôtel de Rambouillet itself, but at the numerous coteries which in the course of years had sprung up in imitation of it. But the satire did in truth touch the originators as well as the imitators,—the former more closely perhaps than they perceived. The HBtel de Rambouillet continued open till the death of its mistress, on Dec. 2, 1665, but the troubles of the Fronde diminished its influence.

The chief original authorities respecting Madame de Rambouillet and her set are Tallemant des Réaux in his *Historiettes,* and Antoine Baudeau de Somaize in his *Grand Dictionnazre des Précieuses* (1660). Many modern writers have treated the subject, notably Victor Cousin, *La Société française au xviie siècle* (2 vols., 1856), and C. L. Livet, *Précieux et Précieuses . . .* (1859). There is an admirable edition (1875) of the *Guirlande de Julie* by O. Uzanne.

RAMBOUILLET, a town of France, capital of an arrondissement in the department of Seine-et-Oise, 30 m. S.W. of Paris on the railway to Chartres. Pop. (1936) 6,908. Rambouillet derives its interest from the associations connected with the ancient château. Originally a royal domain, the lands of Rambouillet passed in the 14th century to the D'Angennes family, who held them for 300 years and built the château. Francis I died there in 1547; and Charles IX and Catherine de Medici found a refuge there in the Wars of Religion, as Henry III did after them. The title became a marquisate in 1612, and a dukedom under Louis XIV. It was here that in 1830 Charles X signed his abdication. The shooting of the famous coverts of Rambouillet was reserved for French presidents. There is a military preparatory school.

RAMEAU, JEAN PHILIPPE (1683–1764), French musical theorist and composer, was born at Dijon, the son of an organist, on Oct. 23, 1683. His father wished him to study law, but the boy's head was full of music, which he could only pursue in haphazard fashion. In 1701 his father sent him to Milan to break off a foolish love-match. But he learned little in Italy, and soon returned in company with a wandering theatrical manager, for whom he played the second violin. He next settled in Paris, where he published his *Premier livre de pièces de clavecin,* in 1706. He succeeded his father as organist of Notre Dame, Dijon, in 1709, and in 1714 removed to Lyons, where he was organist at the Jacobins. In 1715 he was organist at Clermont-Ferrand and working on his *Traité de l'harmonie.* There he remained until 1722. He studied the writings of Zarlino, Descartes and other theorists.

Rameau's keen insight into the constitution of certain chords, which in early life he had studied only by ear, enabled him to propound a series of hypotheses, many of which are now accepted. While the older contrapuntists were perfectly satisfied with the laws which regulated the melodious involutions of their vocal and instrumental parts, Rameau demonstrated the possibility of building up a natural harmony upon a fundamental bass, and of using that harmony as an authority for the enactment of whatever laws might be considered necessary for the guidance either of the contrapuntist or the less ambitious general composer. And in this he first explained the distinction between two styles, which have been called the "horizontal and vertical systems," the "horizontal system" being that by which the older contrapuntists regulated the onward motion of their several parts, and the "vertical system" being that which is built up perpendicularly from the bass. From fundamental harmonies he passed to inverted chords, to which he was the first to call attention; and the value of this discovery fully compensates for his erroneous theory concerning the chords of the eleventh and the great (Angl. "added") sixth. *(See* HARMONY.)

Rameau first set forth his new theory in his *Traité de l'harmonie* (Paris, 1722), and followed it up in his *Nouveau systkme* (1726), *Génération harmonique* (1737), *Démonstration* (1750) and *Nouvelles réflexions* (1752). After his return to Paris in 1722 he produced some light dramatic pieces, and then showed his real powers in his opera, *Hippolyte et Aricie,* founded on Racine's *Phèdre* and produced at the Acadkmie in 1733. He wrote more than twenty operas, the most successful of which were *Dardanus, Castor et Pollux, Les Indes galantes* and *La princesse de Navarre.* Honours were showered upon him. He died in Paris on Sept. 12, 1764. Rameau was undoubtedly the greatest French musician of his day.

See biographies by Charles Poisset (1864), Nisard (1867), Pougin (1876), and L. de la Laurencie (1908); also Chabanon, *Eloge* (1764); Paul-Marie Masson, *L'Opéra de Rameau* (1926). His *Oeuvres complètes,* ed. Saint-Saëns *(1894 seq.),* had reached the 18th vol. in 1924.

RAMEK, RUDOLF (1881–   ), Austrian statesman, was born at Teschen on April 12, 1881, and served in the Austrian army in World War I. In the Renner cabinet of 1919 he was state secretary for justice, and in 1921 minister of the interior in the Mayr cabinet. Dr. Ramek, a member of the Christian Socialist party, formed a coalition government in Nov. 1924. The chief problems before the chancellor were the strengthening of the federal principle of the constitution and the completion of the Austrian reconstruction scheme under the League of Nations. With the re-establishment of Austrian finance the League of Nations control was withdrawn, and at the end of 1925 the chancellor found it necessary to reconstruct his ministry. He kept foreign affairs in his own hands and appointed Kollmann as finance minister. Involved in controversy with Mussolini over the latter's reference to "carrying the Italian standard if necessary beyond the Brenner," an explanation was given and the incident regarded as closed, but in Austria the chancellor was criticized as having been too lukewarm in his defense of Tyrolese interests. The fall of his government (Oct. 15, 1926) was immediately due to his refusal of any increase of pay to civil servants. He was succeeded by Dr. Ignaz Seipel (*q.v.*).

RAMESES or **RAMESSES** (Gen. xlvii, 11; Exod. xii, 37; Num. xxxiii, 3), or, with a slight change in the vowel points, RAAMSES (Exod. i, 11), the name of a district and town in Lower Egypt, is notable as affording the mainstay of the current theory that King Rameses II was the Pharaoh of the oppression and his successor Merneptah the Pharaoh of the exodus. The first three passages cited above are all by the priestly (post-exile) author and go together. Jacob is settled by his son Joseph in the land of Rameses and from the same Rameses the exodus naturally takes place. The older narrative speaks not of the land of Rameses but of the land of Goshen; it seems probable, therefore, that the later author interprets an obsolete term by one current in his own day, just as the Septuagint in Gen. xlvi, 28 names instead of Goshen Heroopolis and the land of Rameses. Heroopolis lay on the canal connecting the Nile and the Red sea, and not far from the head of the latter, so that the land of Rameses must be sought in Wādi Tūmīlāt near the line of the modern fresh-water canal. In Exod. i, 11, again, the store-cities or arsenals which the Hebrews built for Pharaoh are specified as Pithom and Raamses, to which the Septuagint adds Heliopolis. Pithom also takes us to the Wādi Tūmīlāt. It is possible that these names were added by a writer who knew what fortified places were in his own time to be seen in Wādi Tūmīlāt; for the form of the story of the Hebrews in Egypt is throughout deficient in precise geographical data. The post-exile or priestly author indeed gives a detailed route for the exodus (which is lacking in the older story), but he, we know, was a student of geography and might supplement tradition by what he could gather from traders as to the caravan routes.

It appears, however, from remains and inscriptions that Rameses II did build in Wadi Tūmīlāt, especially at Tell Maskhūta, which Lepsius therefore identified with the Raamses of Exodus. But Naville's excavations found that the ruins were those of Pithom and that Pithom was identical with the later Heroopolis. Petrie found sculptures of the age of Rameses II at Tel Rotāb, in the Wadi Tūmīlāt west of Pithom, and concludes that this was Rameses. The Biblical city is probably one of those named Prameses, "House of Ramesses," in the Egyptian texts.

RAMESWARAM, a town of British India, in the Madura district of Madras, on an island in Palk straits and on the line of the South Indian railway from Madura. It has one of the most venerable Hindu shrines, founded, according to tradition, by Rama himself, and the resort of thousands of pilgrims.

RAMIE, RHEA or CHINA-GRASS, the product of species of the genus Boehmeria, a member of the family Urticaceae and nearly allied to the stinging nettle genus (*Urtica*), from which, however, it differs in absence of stinging hairs. Some confusion has arisen in the use of the various terms Ramie, Rhea, and China-grass. Ramie is generally used by English speaking people to designate the plant Boehmeria *nivea,* with leaves snow white on the under surface, and also the fibre obtained from this plant. The name is of East Indian or Malay origin and is said to have been used originally to designate *Boehmeria nivea tenacissima,* a tropical form with thin leaves, green on both surfaces. Rhea is used in India to designate both forms, but more especially the introduced form with leaves white on the under side, known elsewhere as ramie. Formerly in the London fibre market the name ramie was used to designate the fibre from China and Japan, and the name rhea for the fibre from all other sources. China-grass is the hand-cleaned but not degummed fibre as it comes on the market. The name has been incorrectly used to designate the plant.

B. nivea is a shrubby plant with the growth of the common nettle but without stinging hairs, sending up each season a number of straight shoots from a perennial underground rootstock. The plant leaves remind one of the nettle in their shape and serrated margin, but their backs are clothed with a downy substance and have a silvery appearance. The minute greenish-brown flowers are closely arranged along a slender axis. This variety has been cultivated by the Chinese for many years, and the fibre has been used more or less as a substitute for linen. Ramie is grown commercially in China, Formosa, Japan and the Philippine Islands. It has been grown experimentally in most temperate and subtropical countries throughout the world. About 1855, ramie was first introduced into the United States, and shortly thereafter it found its way into a number of Central American countries. A number of attempts have been made to start a ramie industry in the United States, Central America and South America, but no industry has developed.

In the United States experiments have been conducted along the South Atlantic coast, the Gulf of Mexico coast, and in California by individuals, by state agricultural experiment stations and by the United States department of agriculture. The most extensive plantings have been made by companies interested in testing new machines and methods of preparation. Between 1935 and 1943 the acreage of ramie in the U.S. has varied from approximately 100 to 300 ac. but only a few tons of ramie fibre have been prepared. It is questionable if ramie can be grown and prepared in countries having high labour wage scales to compete with fibre prepared with the cheap labour of the orient.

Cultivation.—The plant, which attains a height of from 3 to 8 ft., is grown from seed, cuttings or layers, or by division of the roots. From two to four crops per season may be obtained on suitable ground, each crop yielding up to four tons or more of green moist stems per acre. The yield of crude China-grass fibre is approximately $2\frac{1}{2}\%$ of the green plant material as cut in harvesting. When proper attention is given to the choice of ground, and to planting, there is not much difficulty in raising a good crop: the trouble arises in the extraction of the fibre.

The stems when ripe are cut down, and after the leaves and small branches have been removed, the outer cover and the layers of fibre are stripped off in the form of ribbons. These ribbons contain the bark, the fibre and a quantity of very adhesive gum. The Chinese remove this bark and as much of the gum as possible before the plant has dried. When it has dried this fibre is called China-grass. This hand-process is naturally slow and tedious.

Properties.—The fibre possesses some very valuable properties; it is not only much stronger than any other known fibre, but almost equals some kinds of silk in its brilliance. Its lustre is about equal to that of mercerized cotton but much inferior to that of artificial silk. Ramie successfully resists atmospheric changes, is easily dyed and is affected but little by moisture. On the other hand, articles manufactured from it on account of their hairy character have not the same smart appearance as those made from flax. Although the fibre is in some cases 12 in. long, it varies considerably in length, and this handicaps the operations of preparing and spinning. It is impossible to make perfect yarns from fibres of various lengths; hence it is necessary either to separate the fibres into reasonable groups, or to cut them into satisfactory lengths.

Manufacture.—In general, after decortication, the first process is that of degumming. This is usually done by immersing the fibre in a hot caustic soda or patented chemical solution. After the gum is removed, the material is lifted out, the alkali or chemical neutralized, and the fibre thoroughly washed. The bulk of the water may be removed by a hydro-extractor, and the fibre is then dried. To facilitate the subsequent process, the fibre may be softened by passing it through a machine fitted with fluted rollers. Then follow the operations of dressing, roving, wet spinning and doubling, and finally the twisted thread may be passed through a flame to remove superfluous hairs.

Ramie has been in the past used for gas mantles, for which it is particularly well adapted, for paper-making, ropes, linens, nets, underwear, and for canvas and several other fabrics. If only a good dependable supply of clean uniform low valued fibre could be obtained, there is not much doubt but that manufacturers and machine-makers would quickly provide means for utilizing it on an extensive scale. (B. B. R.)

RAMILLIES, a village of Belgium, in the province of Brabant, 13 miles N. by E. of Namur, between the sources of the Little Gheete and of the Mehaigne. It is famous for the victory of the Allies under the duke of Marlborough over the French commanded by Marshal Villeroi on May 12–23, 1706 in the War of the Spanish Succession (*q.v.*). The position of the French on the high ground about Ramillies was marked by the villages of Autréglise (Anderkirch) on the left, Offuz on the left centre, Ramillies on the right centre and Taviers on the right close to the river Mehaigne. In front of the last was a smaller village, Franquenay, which was held as an advanced post. Between these *points d'appui* the ground was mostly open upland, and the position as a whole was defective in so far that the villages were barely within cannon-shot of each other. It was particularly strong on the flanks, which were protected by the marshy beds of the Mehaigne and the Little Gheete. Ramillies stands almost on the watershed of these adjacent valleys, and here Marlborough decided to deliver his main attack. The forces were about equal, and were at first equally distributed along the whole line of each army. Marlborough's local concentration of force at the spot where the attack was to be pressed home was made not before, but after the action had opened (cf NEERWINDEN). Villeroi's left wing of cavalry and infantry was secure — and at the same time immobilized — behind the upper course of the Little Gheete, and the French commander allowed himself to be imposed upon by a demonstration in this quarter, convinced perhaps by the presence of the British contingent that a serious attack was intended. The morning was spent in arraying the lines of battle, and it was about 1·30 when the cannonade opened. Soon the first lines of infantry of the Allied centre and left (Dutch) opened the attacks on Franquenay and Taviers and on Ramillies, and, when after a severe struggle Taviers fell into the hands of the Dutch, their commander, Marshal Overkirk, led forward the whole of the left wing cavalry and fiercely engaged the French cavalry opposed to it. The ground was open, both parties had placed the greater part of their horse on this side, and it was only after a severe and prolonged engagement (in which Marlborough himself took part like a trooper and was unhorsed) that the Allies were definitely victorious, thanks to the arrival of a force of cavalry brought over from the Allied right wing. Meanwhile the principal attack on Ramillies had been successfully pressed home, the necessary concentration of force being secured by secretly and skilfully withdrawing some British battalions from the right wing. While Villeroi was trying to bring up supports from the left to take part in the cavalry battle, the French in Ramillies were driven out into the open, where the Allied cavalry, having now gained the upper hand, rode down many battalions. Most of the French cavalry from the other wing, having to force its way through the baggage trains of the army (these had been placed too near the fighting lines), arrived too late, and once Ramillies had fallen the whole line of the Allies gradually took up the offensive. It was not long before the French line was rolled up from right to left, and the retreat of the French was only effected in considerable confusion. Then followed for once a relentless pursuit, carried on by the British cavalry (which had scarcely been engaged) to Louvain, 20m. from the field of battle. Marlborough's unequalled tactical skill and judgment thus sufficed not merely to win the battle, but to win it with so large a margin of force unexpended that the fruits of his victory could be gathered. The French army lost, in killed, wounded and missing, some 15,000 men, the Allies (amongst whom the Dutch had borne the brunt of the fighting) scarcely one-third as many.

RAM MOHAN ROY (1774–1833), Indian religious reformer, and founder of the Brahma Samaj (*q.v.*) or Theistic Church, was born at Radhanagar, in the district of Hugli, Bengal, in May 1774. He was the son of a small landowner, and in his early life acquired a knowledge of Persian, Arabic and Sanskrit, besides his own vernacular, Bengali. At the age of sixteen he first assailed idolatry in his Bengali work, entitled *The* Idolatrous *Religious* System of the *Hindus*. This gave offence to his orthodox father, and Ram Mohan left home and spent some years in travel. He was a clerk in the British service from 1800 to 1814, when he settled in Calcutta to devote himself to religious reform. Ram Mohan wrote Bengali works on the Vedanta philosophy, translated some of the *Upanishads,* and on Jan. 23, 1830. definitely established the Brahma Samaj "for the worship and adoration of the Eternal, Unsearchable, Immutable Being who is the Author and Preserver of the Universe." In 1830 the emperor of Delhi bestowed on Ram Mohan the title of raja, and sent him to England as his agent. He presented petitions to the House of Commons in support of the abolition of the suttee rite. He died on Sept. 27, 1833.

RAMNAD, a town and district of Madras, British India, at the base of the spit of land that projects towards the island of Pamban in Palk strait. The town (pop. 1931, 16,817) is the residence of a raja of old family, head of the Maravar caste, whose title is setupathi, or lord of Adam's Bridge. It is a desolate and generally barren tract, traversed by the South Indian railway. The district has an area of 4,819 sq.m., and a pop. (1931) of 1,838,95j. Fishing is carried on.

RÂMNICU SARAT, the capital of the department of Râmnicu Sărat, Rumania; on the railway from Buzau to Focşani, and on the left bank of the Râmnicu, a tributary of the Sereth. Pop. (1930) 15,013, about 1,500 being Jews. The town rises from a marshy plain, east of the Carpathians, and west of the cornlands of southern Moldavia. Râmnicu Sărat was the scene of battles between the Moldavians and the Walachians in 1434 and 1573, and between the Walachians and Turks in 1634. Here also, in 1789, an Austro-Russian army defeated the Turks. In 1854 the town was almost destroyed by fire and was rebuilt.

RÂMNICU-VÂLCEA, an episcopal city and the capital of the department of Vâlcea, Rumania; situated at the foot of the Carpathians, on the right bank of the river Olt, and on the railway from Caracal to Sibin. Pop. (1930) 15,162, including many "Saxons." The district contains the famous monasteries of Arnota, Bistrita, Cotia and Moret. Besides wine, fruit, grain and timber, the surrounding uplands yield petroleum and salt. Within a few miles are the thermal springs of Olănestzi and Calimanesti and the salt mines of Ocnele Mari, with deposits estimated at 330 million tons. The city is said to be the ancient Castra Traiana.

RAMON Y CAJAL SANTIAGO (1852–1934), Spanish histologist, was born May 1, 1852, at Petilla de Aragon (Pamplona). He graduated at the University of Saragossa, and went in 1881 as professor to the University of Valencia, and in 1886 to Barcelona, publishing in 1889 his first important work (*Elementos* de Histologia normal y de *Técnica Micrográfica*). In that year he discovered "the laws which govern the morphology and the connections of the nerve cells in the grey substance." In 1890 and 1891 he discovered the primary changes of the neurin, and the genetic unity of the nerve fibres and the protoplasmic appendices. During this period also he discovered the axis cylinder of the fibres of the cerebellum and their continuity with the parallel fibrillae of the molecular covering, formulated the principle of the dynamic polarisation of the neurins, aided by Van Gehuchten, and worked upon the analysis of the sympathetic ganglia. In 1892 he took the chair of normal histology and pathological anatomy in the University of Madrid. In 1894, on the invitation of the Royal Society of London, he developed systematically his views on morphology and connections of the nervous cells of the spinal medulla, ganglions, cerebellum, retina and olfactory bulb. He was called upon by the Clark University (Worcester) in 1899 to give an exposition of his investigations regarding the cerebral tegumen, and in 1900 the International Congress of Medicine, which met in Paris, gave him the Moscow International Award. He was awarded half the Nobel Prize for medicine in 1906. His work in three volumes, *Histologia del Sistema Nervioso de Hombre y de los Vertebrados,* appeared between the years 1897 and 1904. In May 1922 he was exempted, on account of long service, from his duties in connection with the chair which he held, and, on the initiative of the Government, he founded the Cajal Institute in Madrid.

RAMPION, the name given to herbs of the genus *Phyteuma,* belonging to the family Campanulaceae. There are 45 species, which inhabit Europe, Asia and the Mediterranean region; two are native to the British Isles. The flowers are small, usually blue, and are massed together in heads. The pollen is driven out of the narrow tube, formed by the corolla, by the elongation of the style, and is thereby exposed to visiting insects.

RAMPOLLA, COUNT MARIANO DEL TINDARO (1843–1913), Italian cardinal, was born on Aug. 17, 1843, at Polizzi, in the Sicilian diocese of Cefalù. Having completed his studies in the Capranica College at Rome, and having taken holy orders, he studied diplomacy at the College of Ecclesiastical Nobles, and in 1875 was appointed councillor to the papal nunciature at Madrid. Two years later he was recalled to Rome and received high office. After another brief stay in Madrid as nuncio he was created cardinal, and became papal secretary of State. New to the Sacred College and free from traditional preconceptions, he was admirably fitted to carry out the papal policy under Leo XIII. (*See* PAPACY.) Rightly or wrongly, he was held personally responsible for the *rapprochement* with France and Russia and the opposition to the Powers of the Triple Alliance; and this attitude had its effect on his career when Leo XIII. died. Rampolla was not selected as pope owing to the veto of Austria, and resigned his office as secretary of State. He died in Rome on Dec. 17, 1913.

RAMPUR, an Indian state, lying within the United Provinces, between the British districts of Moradabad and Pilibhit. Area, 893 sq.m. The country is level and generally fertile; being watered in the north by the rivers Kosila and Nahul, and in the south by the Ramganga. The chief crops are wheat, barley, maize, rice and sugar cane. Pop. (1931) 465,225. The chief, whose title is nawab and who enjoys a salute of 15 guns, is a Rohilla Pathan, representing the family which established their power over this part of the country in the 18th century. When the Rohillas were subjugated by the nawab of Oudh, with the assistance of a force lent by Warren Hastings, one of their number, Faiz-ullah Khan, from whom the present nawab traces his descent, was permitted to retain possession of Rampur. During the Mutiny of 1857 the n & ~ & of Rampur rendered important services to the British. The town of Rampur is on the left bank of the river Kosila. Pop. (1931) 74,216. There are manufactures of damask, pottery, sword-blades and sugar. It was once completely surrounded by a broad bamboo hedge, which formed a strong defence. In addition to a modern fort and several fine buildings, it contains an Arabic college, which attracts students from all parts of India.

RAMPUR BOALIA, a town of British India, the administrative headquarters of Rajshahi district in Bengal, on the left bank of the Ganges. Pop. (1931), 27,064. It is 28 m. by road from the Nator station of the Eastern Bengal State railway and has a steamer station on the Ganges. The town contains a Government college, and the museum of the Varendra Research Society.

RAMSAY, ALLAN (1686–1758), Scottish poet, was born at Leadhills, Lanarkshire, on Oct. 15, 1686. He was educated at the parish school of Crawford, and in 1701 was apprenticed to a wig-maker in Edinburgh. He married Christian Ross in 1712; a few years after he had established himself as a wig-maker (not as a barber, as has been often said) in the High Street, and soon found himself in comfortable circumstances. His first efforts in verse-making were inspired by the meetings of the Easy Club (founded in 1712), of which he was an original member; and in 1715 he became the Club Laureate. In the society of the members he assumed the name of "Isaac Bickerstaff," and later of "Gawin Douglas." By 1718 he had some reputation for occasional verse, which he published in broadsheets, and then (or a year earlier) he turned bookseller. A rough transcript (1716) of *Christ's Kirk 072 the Green* from the Bannatyne ms., with some additions of his own, was followed in 1718 by a new edition with supplementary verses. In the following year he printed a collection of *Scots Songs.* The success of these ventures prompted him to collect his poems in 1722. The volume was issued by subscription, and brought in the sum of 400 guineas. He then opened a circulating library (the first in Scotland) in new premises, and extended his business as a bookseller.

Meanwhile he had issued the first instalments of *The Tea-Table Miscellany* and *The Ever Green* (both 1724–27). *The Tea-Table Miscellany* is "A Collection of Choice Songs Scots and English," containing some of Ramsay's own, some by his friends, several well-known ballads and songs, and some Caroline verse. In *The Ever Green, being a Collection of Scots Poems wrote by the Ingenious before 1600,* Ramsay sought to reawaken an interest in the older national literature. He produced, in 1725, his dramatic pastoral *The Gentle Shepherd,* which passed through several editions, and was performed at the theatre in Edinburgh; its title is still known in every corner of Scotland, even if it be no longer read. Ramsay wrote little afterwards, though he published a few shorter poems, and new editions of his earlier work. A complete edition of his *Poems* appeared in London in 1731 and in Dublin in 1733. In 1736 he set about the erection of a new theatre, "at vast expense," in Carrubber's Close, Edinburgh, but the opposition was too strong, and the new house was closed in 1737. In 1755 he retired from his shop to the house on the Castle Rock, still known as Ramsay lodge where he died on Jan. 7, 1758.

The Tea-Table Miscellany was reprinted in 1871; *The Ever Green* in 1875; *The Poems of Allan Ramsay* in 1877. A selection of the *Poems* appeared in 1887. There are many popular reprints of *The Gentle Shepherd.*

RAMSAY, ALLAN (1713–1784), Scotch portrait-painter, the eldest son of the author of *The Gentle Shepherd,* was born in Edinburgh in 1713. He studied in London under the Swedish painter Hans Huyssing, and at the St. Martin's Lane Academy; and in 1736 he left for Rome, where he worked for three years under Solimena and Imperiali (Fernandi). In 1767 he succeeded Shakelton as principal painter to the king; and he painted the royal portraits which the king presented to ambassadors and colonial governors, employing a number of assistants—of whom David Martin and Philip Reinagle are the best known. But this prosperous career came to an end through an accidental dislocation of his right arm. He died at Dover on Aug. 10, 1784.

His bust-portraits of Scottish gentlemen and their ladies, which he executed before settling in London, are full of grace and individuality; the features show excellent draughtsmanship, and the flesh-painting is firm and sound in method, though frequently tending a little to hardness and opacity. His work is seen at its best in the portrait of his wife, in the Scottish National Gallery.

RAMSAY, SIR ANDREW CROMBIE, knighted 1881 (1814–1891), British geologist, was born at Glasgow on Jan. 31, 1814, the son of William Ramsay, manufacturing chemist. He served for forty years (1841–81) on the geological survey. To the first volume of the *Memoirs of the Geological Survey* (1846) he contributed a now classic essay, "On the Denudation of South Wales and the Adjacent Counties of England," in which he advocated the power of the sea to form great plains of denudation. In 1866 he published *The Geology of North Wales.* He became professor of geology at University College, London, in 1848, and lecturer in the same subject at the School of Mines in 1851. In 1872 he succeeded Murchison as director-general of the geological survey.

His best known work was his *Physical Geology and Geography of Great Britain* (5th ed., 1878). He became F.R.S. in 1862. He died at Beaumaris on Dec. 9, 1891.

His publications include: *The Old Glaciers of Switzerland and North Wales* (1860); *The Red Rocks of England* (1871); *The River Courses of England and Wales* (1872).

See *Memoir* by Sir. A. Geikie (1895).

RAMSAY, ANDREW MICHAEL (1686–1743), French writer, of Scottish birth, commonly called the "Chevalier Ramsay," was born at Ayr on Jan, g, 1686. Ramsay served with the English auxiliaries in the Netherlands, and in 1710 visited Fénelon, who converted him to Roman Catholicism. He remained in France until 1724, when he was sent to Rome as tutor to the Stuart princes, Charles Edward and Henry, the future cardinal of York. He was driven by intrigue from this post, and returned to Paris. He died at St. Germain-en-Laye (Seine-et-Oise) on May 6, 1743. The best known of Ramsay's many works is *Les voyages de Cyrus* (London, 1728; Paris, 1727), written in imitation of *Télémaque.*

RAMSAY, SIR WILLIAM (1852–1916), British chemist, was born in Glasgow on Oct. 2, 1852. From 1866 to 1870 he studied in his native city, and in 1871 went to work under R. Fittig at Tiibingen. In 1872 he became assistant in the Young laboratory of technical chemistry at Anderson's college, Glasgow, and from 1874 was tutorial assistant in the university. In 1880 he was appointed to the chair of chemistry at University college, Bristol, and made principal in the following year. In 1887 he succeeded A. W. Williamson as professor at University college, London, a position which he resigned in 1913. He was awarded the Davy medal of the Royal Society in 1895 and the Nobel prize for chemistry in 1904. He was made a K.C.B. in 1902 and died at High Wycombe, Eucks, on July 23, 1916.

Ramsay's earliest investigations covered a wide field—from a new bismuth mineral to the physiological action of certain alkaloids —in the course of which he showed that the alkaloids are related to pyridine; later he specialized definitely on inorganic and physical chemistry. With S. Young and others, he investigated the critical state, the relationship between vapour pressure and temperature and other properties of liquids. With J. Shields he verified the Eotvos law of the constancy of the rate of change of molecular surface energy with temperature, and obtained evidence concerning the molecular complexity of certain liquids. In 1892 Lord Rayleigh had asked for suggestions from chemists to account for the difference between the densities of chemical and atmospheric nitrogen, and Ramsay became interested in the problem. He devised methods for removing oxygen and nitrogen completely from air, and found that there was present in addition a small quantity of an hitherto unknown gas; in Aug. 1894 Ramsay and Rayleigh announced the discovery of this new gas, afterwards called "argon," present to the extent of almost 1% in the atmosphere. The high density of this gas accounted for the atmospheric nitrogen having a greater density than the chemical variety. In 1895, whilst searching for new sources of argon, Ramsay heated the mineral cleveite with acid and obtained a gas which gave a spectrum identical with that of helium, detected in the sun by Sir J. N. Lockyer and Sir E. Frankland in 1868; in this way helium was first obtained, but it was later found to be present in the air to the extent of about one part in 250,000.

Both helium and argon were found to be absolutely inactive chemically, and so were called the "inert gases." A study of their position in the periodic table led to the belief that at least three more such gases should exist, and Ramsay, with M. Travers, found them in 1898 in the liquid air residues from which oxygen and nitrogen had been removed; they were called neon, krypton and xenon, and were found to be present in the air only to an extremely minute extent (*e.g.,* xenon, one part in 170 million). Ramsay next turned to radioactivity since he noted the association of helium with radioactive minerals, and with F. Soddy (*q.v.*) he found in 1903 that helium was continuously produced as a disintegration product of radium emanation; this discovery led to the transmutation theory and its important consequences. In 1910 Ramsay obtained a small quantity of radium, and with D. Whytlaw Gray he was able, as a result of a wonderful piece of experimental work, to determine the density, and incidentally the atomic weight, of about one three-millionth part of a cubic inch of radium emanation. The atomic weight showed that this gas was the last of the "inert gas" series and it was called "niton."

Ramsay's eminence, and his interest in educational matters, resulted in his being asked by the Indian Government to advise on the best way to utilize the Tata bequest; as a consequence the Indian Institute of Science was founded at Bangalore, During World War I he was an active member of the Royal Society Committee for the pooling of scientific knowledge, to be placed at the command of the Government. He made strong representations on the necessity of preventing cotton and fats from reaching central Europe. Ramsay was an inspiring teacher as well as a brilliant researcher; he had remarkable skill as a manipulator, and this, as well as his spirit of enthusiasm for research, contributed to his success as an investigator.

Sir W. Ramsay's works include: *A System of Chemistry* (1891); *The Gases of the Atmosphere* (1896); *Modern Chemistry* (2 vols,, 1901); and *Essays Biographical* and *Chemical* (1908).

See Sir William Tilden, *Sir William Ramsay: Memorials of his Life and Work* (1918), and *Famous Chemists* (1921); Obituary notice, *Proceedings Royal Soc.* (1916–17).

RAMSBOTTOM, urban district, Lancashire, England, 4 mi. N. of Bury on L.M.S.R. Pop. (1938) 14,940. Area 14.9 sq.mi. It has iron and brass foundries, machine factories and textile establishments. Municipal transport connects it with Bury and Rawtenstall.

RAMSDEN, JESSE (1735–1800), English astronomical instrument maker, was born at Salterhebble near Halifax, Yorkshire, on Oct. 6, 1735. After serving his apprenticeship with a cloth-worker in Halifax, he went in 1755 to London, where in 1758 he was apprenticed to a mathematical instrument maker. About four years afterwards he started business on his own account and secured a great reputation with his products. He died at Brighton on Nov. 5, 1800. Ramsden's speciality was divided circles, which began to supersede the quadrants in observatories towards the end of the 18th century. His most celebrated work was a 5-foot vertical circle, which was finished in 1789 and was used by G. Piazzi at Palermo in constructing his well-known catalogue of stars.

RAMSEY, a market-town in Huntingdonshire, England, on the south-western border of the Fen country, on branch lines of the L.N.E. railway, 13 mi. S.S.E. of Peterborough. Pop. of urban district (est. 1938) 5,219. Area 27 sq.mi. According to a 12th century chronicle of one of the monks, the name Ramsey is derived from "ram," referring to the tradition of a solitary ram's having taken up its abode here, and "ey" meaning an island. Ramsey, however, was not completely insulated. The abbey was founded by Ailwin, earl of the East Angles, in 969, and a charter of King Edgar granted lands and privileges for the purpose. Ramsey abbey was noted for the school established within its walls and for its library of Hebrew works. Its abbot was mitred. The lands were granted after the dissolution to Sir Richard Cromwell. The church of St. Thomas à Becket is transitional between Norman and Early English, and has a Norman east end. The tower was built in 1672 of stone from Ramsey abbey. An oak lectern, dating from the 15th century, carries a chained copy, in a Tudor binding of brass, of Dean Comber's (1655–99) book on the Common Prayer, and a black-letter copy of Erasmus' Paraphrase of the Gospels. There are many interesting tombs in the churchyard, and the church register contains several entries relating to the Cromwell family, who removed to Ramsey from Huntingdon and owned the abbey estates till 1674. Of the ancient Benedictine abbey, the only remains are a part of a gateway, a lodge and some buttresses, while some broken stone arches and walls remain of the conventual buildings. Ramsey has a market for agricultural produce, potatoes being the chief product of the district, and Ramsey mere, now entirely drained, forms excellent wheat land.

RAMSGATE, a municipal borough, watering-place, seaport and member of the Cinque Port of Sandwich, in the Isle of Thanet parliamentary division of Kent, England, 79 mi. S.E. of London by the S.R. Pop. (est. 1938) 34,390. Area, 5.7 sq.mi. Ramsgate (Ramesgate) was originally a small but comparatively prosperous place united until 1827 to the parish of St. Lawrence. The charter of Charles II mentions it as a member of Sandwich. In 1884 it was incorporated by royal charter, and a commission of the peace was granted in 1893. The jurisdiction of the Cinque Ports' justices thereupon ceased within its limits, which include the parishes of Ramsgate and St. Lawrence Intra. Under Elizabeth, Ramsgate was still unimportant, though possessed of a fair before the reign of Henry VIII. After 1668 the growth of trade increased its prosperity, and at the beginning of the reign of George I the pier was enlarged and pier-wardens appointed to collect the *droits*. In 1749, having been selected as a harbour of refuge for the Downs, it underwent great improvements, and henceforward paid £200 yearly to Sandwich out of the *droits* for clearing the Channel and repairing the banks of the river Stour within the Liberty; but by 1790 the harbour was of small account. During World War I, a large aerodrome was established at Manston, two miles from Ramsgate and considerable damage was done by bombs dropped on the town. In World War II 8,500 houses were damaged in the German raids of 1940–41. The conversion of $3\frac{3}{4}$ mi. of abandoned railway tunnels provided an air-raid shelter with accommodation for 60,000 persons. Ramsgate is practically contiguous with Broadstairs to the north. Before World War II the corporation, to improve the town as a seaside resort, undertook large works, including a new bathing pool (1935), tennis courts, bowling and putting greens, and ornamental gardens. The cliff promenades were extended by about a mile. The harbour, of 42 ac., was acquired by the town in 1934. During the season steamers connect it with London and the intermediate watering-places on the north coast, and with Calais and Boulogne. A fair coasting and fishing trade is carried on. Pegwell bay, famed for its shrimps, is supposed to have been the scene of the landing of Hengest and Horsa, and at Cliff's End (Ebbs Fleet) a monolithic cross marks the landing-place of St. Augustine in 596.

RAMUS, PETRUS or **PIERRE DE LA RAMEE** (1515–1572), French humanist, was born at the village of Cuth in Picardy in 1515, a member of a noble but impoverished family; his father was a charcoal-burner. Having gained admission, in a menial capacity, to the college of Navarre, he worked with his hands by day and carried on his studies at night. The reaction against scholasticism was still in full tide, and Ramus outdid his predecessors in the impetuosity of his revolt. On the occasion of taking his degree (1536) he actually took as his thesis "Everything that Aristotle taught is false." This *tour de force* was followed up by the publication in 1543 of *Aristotelicae Animadversiones* and *Dialecticae Partitiones,* the former a criticism on the old logic and the latter a new textbook of the science. What are substantially fresh editions of the *Partitiones* appeared in 1547 as *Institutiones Dialecticae,* and in 1548 as *Scholae Dialecticae;* his *Dialectique* (1555), a French version of his system, is the earliest work on the subject in French. Meanwhile Ramus had opened courses of lectures, but was interdicted (1544) on the ground of undermining the foundations of philosophy and religion. The decree against him was presently cancelled, and in 1551 Henry II. made him professor of philosophy and rhetoric at the Collège de France. But in 1561 he embraced Protestantism, and was compelled to flee from Paris, and in 1568 from France. But he returned before the massacre of St. Bartholomew (1572), of which he was one of the victims.

The logic of Ramus enjoyed a great celebrity for a time, and there existed a school of Ramists boasting numerous adherents in France, Germany and Holland. There is even a little treatise from the hand of Milton, published two years before his death, called *Artis Logicae Plenior Institutio ad Petri Rami Methodum concinnata.*

See Waddington-Kastus, *De Petri Rami vita, scriptis, philosophia* (1848), and *Ramus, sa vie, ses écrits et ses opinions* (1855), in which a list of 50 writings by Ramus is given; C. Desmaze, *Petrus Ramus, professeur au Collège de France, sa vie, ses tcrits, sa mort* (1864); P. Lobstein, *P. Ramus als Theolog* (Strasbourg, 1878); E. Saisset, *Les précurseurs de Descartes* (1862); J Owen, *French Skeptics of the Renaissance* (1893); Voigt, *Über den Ramismus der Universität Leipzig* (Leipzig, 1888); F. P. Graves, *Peter Ramus and tke Educational Reformation of the 16th Century* (1912).

RAMUSIO, GIAN BATTISTA (1485–1557), geographer, was born at Treviso in 1485 (June 20), the son of Paolo the Elder (c. 1443–1506). Gian Battista was educated at Venice and at Padua and entered the public service (1505), becoming in 1515 secretary of the senate and in 1533 secretary of the Council of Ten. He served the republic in various missions to foreign states, *e.g.,* Rome, Switzerland and France. He died on July 10, 1557.

Ramusio had witnessed from his boyhood the unrolling of that great series of discoveries by Portugal and Spain in East and West, and geography was his chief study and delight. It appears from a letter addressed to him by his friend Andrea Navagero, that as early as 1523 the preparation of material for his great work, *Navigationi e Viaggi,* had already begun. The task had been suggested by Girolamo Fracastoro, his lifelong friend. Among Ramusio's correspondents were Cardinal Pietro Bembo, Damiano de Goez and Sebastian Cabot; among lesser lights, Vettor Fausto, Daniel Barbaro, Paolo Manuzio, Andrea Navagero, the cardinals Gasparo Contarini and Gregorio Cortese, and the printer Tommaso Giunti, editor after Ramusio's death of the *Navigationi.*

Two volumes only of the *Navigationi e Viaggi* were published during his lifetime, vol. i. in 1550, vol. iii. in 1556; vol. ii. did not appear till 1559, two years after his death. Ramusio had intended to publish a fourth volume, containing, as he mentions himself, documents relating to the Andes, and, as appears from one of the prefaces of Giunti, others relating to explorations towards the Antarctic. Ramusio ransacked Italy and the Spanish peninsula for contributions, and translated them when needful into the racy Italian of his day. The invaluable travels of Barbosa and Pigafetta's account of Magellan's voyage were not publicly known in complete form till the present century. Of two important articles at least the originals have never been otherwise printed or discovered; one of these is the *Summary of all the Kingdoms, Cities, and Nations from the Red Sea to China,* a work translated from the Portuguese, and dating apparently from about 1535; the other, the remarkable Ramusian redaction of Marco Polo (*q.v.*). The *Prefatione, Espositione* and *Dichiarazione,* which precede this version of Marco Polo's book, are the best and amplest examples of Ramusio's own style.

There were several editions of the *Navigationi e Viaggi,* and its bibliography is extremely complicated and the contents of the editions vary. It must suffice here to say that a set of Ramusio, to be as complete as possible, should embrace—for vol. i., 1563 or any subsequent edition; for vol. ii., 1583 or 1606; for vol. iii., 1606.

Besides the circumstances to be gathered from the *Navigationi* regarding the Ramusio family, *see* the *Iscrizioni Venete* of Emanuele Cigogna. There is also in the British Museum *Monografia letta il 14 Marzo 1883 . . .* by Guglielmo Carradori (Rimini, 1883); but little has been found in this.

RAMUZ, CHARLES FERDINAND (1878–), French-Swiss author, born at Cully, in the canton of Vaud. In the opening years of the 20th century he gained a well-merited reputation in a restricted circle; but nearly 25 years were to pass before proper appreciation was accorded by foreign critics to a writer of rare talent with a purely original style owing nothing to the "Latin" and "Classical" tradition. In his numerous works (from *Aline,* 1903, to *La Beautk sur la Terre,* 1927, including *Samuel Belet, Aimk Pache, Le Règne de l'esprit malin, La Guérison des .maladies, Passage du poète,* etc.) Ramuz gives, with broad and simple strokes, a picture of primitive human sentiments in language, the rhythm and phrasing of which intimately recall a definite district—namely, the Leman basin above Lausanne—a narrow strip of vineyard country backed by mountains and looking out over the Rhone and the luminous expanse of Lake Geneva. Though his outlook on the world and mankind is restricted to and conditioned by the influences of this district. Ramuz is the very opposite of a regionalist. In a country where so many others have abused the facile picturesque and have used "local colour" without distinction, his originality is the more striking. No one has approached him in his humble self-subjection to the spirit of the country; he is completely under the spell of nature seen at close quarters and under its daily changing aspects. His own thoughts and aspirations are expressed in his characters; nevertheless his work is a most varied and representative picture gallery of a well-defined race, universal in its appeal though in appearance exclusively *Vaudois.* (C. CL.)

RANADE, MAHADEO GOVIND (1842–1901), Indian lawyer, reformer and author, was born on Jan. 16, 1842, at Niphad, in Nasik district, of a Chitpavan Brahman family. When his father was minister at Kolhapur he attended the Anglovernacular school in that town, and joined the Elphinstone Institute in Bombay at the age of fourteen. He was one of the first graduates of the Bombay University, taking the B.A. in 1862 and the LL.B. in 1866. Having entered government service he became presidency magistrate and then fourth judge of the small cause court at Bombay in 1871, first-class sub-judge at Poona in 1873, and judge of the Poona small cause court in 1884, after which, as special judge under the Deccan Agriculturists' Relief Act from 1887, he came into close contact with the difficulties of the agrarian classes. In 1886 he was a member of the finance committee appointed to report on the expenditure, both imperial and provincial, with a view to retrenchment. This service won him the decoration of C.I.E. He became a member of the legislative council of Bombay in 1885, and occupied that position until raised to the high court in 1893. Being an energetic social reformer, he directed his efforts against infant marriages, the shaving of widows, the heavy cost of marriages and other social functions, and the caste restrictions on travelling abroad. He strenuously advocated widow remarriage and female education. He was the founder of the social conference movement, which he supported till his death. In the political sphere he founded the Poona Sarvajanik Sabha, through which he frequently helped the government with sound advice. He was also one of the originators of the Indian National Congress.

In Bombay University, where he held the offices of syndic and dean in arts, he displayed much organizing power and great intimacy with the needs of the student class. Himself a thorough Mahratti scholar, he encouraged the translation of standard English works, and tried, with some success, to introduce vernacular languages into the university curriculum. He joined with his friends, Dr. Atmaram Pandurang, Bal Mangesh Wagle and Vaman Abaji Modak, in founding a new sect in Bombay known as the "Parthana Samaj." This community resembles, in all essential points, the Brahma Samaj of Bengal. He died on Jan. 16, 1901.

See G. A. Mankar, Justice M. G. Ranade (Bombay, 1902).

RANAVALO (RANAVALONA) **III.** (1864–1917), the last queen of Madagascar. She succeeded to the throne of Madagascar after the death of Queen Ranavalo II., on July 14, 1883. Although nominally queen, she took no share in the government, which her prime minister, Rainilaiarivony, had controlled since 1864. After placing her on the throne, he married her before the close of the year. For the events which resulted in the establishment of a strict French protectorate see MADAGASCAR, History. General Gallieni abolished the sovereignty by proclamation in Feb. 1897, and exiled Ranavalo to Réunion. In March 1899 she was removed to Algiers. She died May 23, 1917.

RANC, ARTHUR (1831–1908), French politician and writer, was born at Poitiers on Dec. 20, 1831, and studied law. His anti-imperialist activities led to his deportation to Algeria in 1855, but he returned to Paris at the amnesty of 1859. He sat in the Commune, and in 1873 was returned to the National Assembly, where he sat on the extreme left. A threatened prosecution for his share in the Commune obliged him to escape to Belgium, where he remained until the amnesty of 1879, continuing his collaboration on La *République française*. He succeeded Clémenceau as editor of the Aurore. In 1903 he became senator for Corsica, and died on Aug. 10, 1908.

In addition to his political writings, Arthur Ranc published political novels of the Second Empire, *Sous l'empire* (1872) and Le roman d'une *conspiration* (1868).

RANCÉ, ARMAND JEAN LE BOUTHILLIER DE (1626–1700), founder of the Trappist Cistercians. He was ordained in 1651, and embarked on the ambitious and worldly career of a court abbé in the days of Louis XIV. But after a few years he underwent a complete change of life, and in 1662 he retired to his abbey of La Trappe, of which he became regular abbot in 1664 and introduced an austere reform. (See TRAPPISTS.) The best known episode of his subsequent life was the "Contestation" with Mabillon on the lawfulness of monks devoting themselves to study, which De Rancé denied. He resigned his abbacy in 1695, owing to declining health, and died in 1700.

The best of the early lives is that of P. le Nain, his sub-prior (1715); see also M. Serrant, *L'Abbé* de Ranct et Bossuet (1903).

RANCHI, a town and district of British India, in the Chota Nagpur division of Bihar and Orissa. The town, which is situated about 2,100 ft. above sea-level, is the headquarters not only of the division and the district, but also of the provincial Government during the hot weather months. Pop. (1931), 50,517. The town contains a cantonment, a radium institute, and two mental hospitals, one for European patients from the whole of northern India, the other, which can accommodate 1,378 patients, for Indians of Bengal as well as Bihar and Orissa.

THE DISTRICT OF RANCHI, formerly called Lohardaga, after the town which was its headquarters, has an area of 7,102 sq.m. and a population (1931) of 1,567,149. It consists of two tablelands, of which the higher rises to about 2,000 feet. The whole area is broken by hills and undulations, which are terraced for rice. The steep slopes are covered with forest, where wild animals still abound. The principal rivers are the Subarnarekha and the North and South Koel. Rice is the staple crop. Tea cultivation has been introduced, but there are only 21 gardens, with an output (1921) of 172,000 pounds. The only industry on a large scale is the manufacture of shellac. Myrobalans are also exported. Deposits of bauxite have been found and await exploitation. Ranchi is connected with Purubia and the main system of the Bengal-Nagpur railway by a narrow gauge railway, which has been extended through the district to Lohardaga. The most numerous and characteristic races are the aboriginal Mundas and Oraono. Nearly 200,000 persons returned themselves as Christians at the census of 1921.

RAND, a Dutch word, in use in South Africa, meaning rim, edge, ridge of hills; specifically, it is an abbreviated form of Witwatersrand, an elevated ridge in south Transvaal, forming the water-parting between the Vaal river and the Olifants river. The Rand is famous for its auriferous reefs (see GOLD), and the word is often used as a synonym for the extensive gold mining industry of this area, or for Johannesburg (*q.v.*), the city which the industry created.

RANDALL, JAMES RYDER (1839–1908), American journalist and poet, born at Baltimore, Md., Jan. 1, 1839. His academic education was received at Georgetown College, after which he travelled in South America and then became professor of English literature at Poydras College at Pointe-Coupée, La., where he was when the Civil War broke out. The attack made by citizens of Baltimore upon Massachusetts and Pennsylvania troops as they passed through the city was the occasion of his writing "Maryland! My Maryland!" first published in the New Orleans Delta. The poem was widely copied and a few days later came to the attention of Baltimore people. There it was first sung by Miss Hetty Cary to the classic melody of "Lauriger Horatius." Words and music were happily united and from that time forth the song was heard in all the homes and camps of the South and in time became a national favourite. After the war Randall became the editor of the Georgia *Constitutionalist*. He was later Washington correspondent for a number of Southern papers. He died at Augusta, Ga., Jan. 15, 1908.

See The Poems of James Ryder *Randall* (1910), with introduction.

RANDALL, SAMUEL JACKSON (1828–1890), American politician, was born in Philadelphia, Pa., on Oct. 10, 1828. He was educated in the public schools and in the University academy, Philadelphia. In 1858–59 he was a Democratic member of the State senate. During the Civil War he served in the Union army, rising to the rank of captain and playing an important part in the Gettysburg campaign. From 1863 until his death he was a Democratic representative in Congress. During the session of 1874–75 he first gained a national reputation by the masterful manner in which he prevented the Republican majority from passing the Force Bill or Federal Election Law. Under his leadership discipline and party harmony were established among the Democrats for the first time after the Civil War. He was speaker of the House from Dec. 1876 to March 1881, during a period marked by rancorous debates concerning the disputed Hayes-Tilden presidential election. He was noted for his work as chairman of the committee on appropriations and as a member of the committee on banking currency and retrenchment. He was a leader of the Protectionist wing of the party. He died in Washington, D.C., on April 13, 1890.

RANDAZZO, a town of Sicily, in the province of Catania, at the north foot of Mount Etna, 43 mi. N.W. of Catania by rail, and 26 mi. direct. Pop. (1936) 12,558 (town); 13,684 (commune). Remains of architecture of the 13th and 14th centuries include three Norman churches and some interesting palaces. The former contain some fine sculptures and goldsmith's work, while the Museo Vagliasindi has interesting objects from a Greek necropolis in the neighbourhood. It is the nearest town to the summit of Etna (9 m.).

RANDEGGER, ALBERTO (1832–1911), Italian musical composer and conductor, was born in Trieste April 13, 1832. He settled in London in 1854. He became professor of singing at the Royal Academy of Music in 1868 and at the Royal College of Music in 1896. He was conductor of the Carl Rosa Company from 1879 to 1885 and conducted the Norwich Festivals 1881–1905. Randegger, who died in London on Dec 18, 1911, assisted the popular revival of opera in England. His works include *Bianca Capello* (1854), and other operas, also *Primer on Singing*.

RANDERS, a town of Denmark, capital of the *amt* (county) of its name in Jutland, on the Gudenaa at the point where it begins to widen into Randers Fjord, an inlet of the Cattegat. Pop. (1940) 32,928. Randers is best known in history as the scene of the assassination of Count Gerhard by Niels Ebbesin in 1340. Though a place of considerable antiquity—being mentioned in 1086 as the meeting-place of insurgents against Knud, the saint—Randers has few remains of old buildings and bears the stamp of a compact, modern manufacturing town that owes its importance to its distilleries, manufactories of gloves, railway carriages, etc. St. Marten's church dates from the 14th century. The high school is housed in a mediaeval monastery. The town is 15 m. from the open Cattegat and the harbour is 15 ft. deep.

RANDOLPH, EDMUND [JENNINGS] (1753–1813), American statesman, was born on Aug. 10, 1753, at Tazewell Hall, Williamshurg, Va., the family seat of his grandfather, Sir John Randolph (1693–1737), and his father, John Randolph (1727–84), who (like his uncle Peyton Randolph) were king's attorneys for Virginia. Edmund graduated at the College of William and Mary, and studied law with his father, who felt bound by his oath to the king and went to England in 1775. In Aug.–Oct. 1775 Edmund was aide-de-camp to Gen. Washington. In 1776 he was a member of the Virginia convention, and was on its .committee to draft a constitution. In the same year he became the first attorney general of the State (serving until 1786). He served in the Continental Congress in 1779 and again in 1780–82. He had a large private practice, including much legal business for Gen. Washington. In 1786 he was a delegate to the "Annapolis convention," and in 1787–88 was governor of Virginia. He was a delegate to the constitutional convention of 1787, and on May 29 presented the "Virginia plan" (sometimes called the "Randolph plan"). In the convention Randolph advocated a strongly centralized Government, the prohibition of the importation of slaves, and a plural executive, suggesting that there should be three executives from different parts of the country, and refused to sign the Constitution because too much power over commerce was granted to a mere majority in Congress, and because no provision was made for a second convention to act after the present instrument had been referred to the States. In Oct. 1787 he published an attack on the Constitution; but in the Virginia convention he urged its ratification, arguing that it was too late to attempt to amend it without endangering the Union, and thinking that Virginia's assent would be that of the necessary ninth State. In 1788 he refused re-election as governor, and entered the house of delegates to work on the revision and codification of the State laws (published in 1794).

Service in Cabinet.—In Sept. 1789 he was appointed by President Washington first attorney general of the United States. He worked for a revision of Ellsworth's judiciary act of 1789, and especially to relieve justices of the supreme court of the duties of circuit judges, and advocated a Federal code; in 1791 he considered Hamilton's scheme for a national bank unconstitutional; and in 1792–93, in the case *Chisolm* v. *Georgia* before the supreme court, argued that a State might be sued by a citizen of another State.

On Jan. 2, 1794 he succeeded Thomas Jefferson as secretary of State. In 1795 he wrote 13 letters (signed "Germanicus") defending the president in his attack on the American Jacobin or democratic societies. He was the only cabinet member who opposed the ratification of the Jay treaty. Before it was ratified the delicate task of keeping up friendly diplomatic relations with France fell to him. Home despatches of the French minister, Joseph Fauchet, intercepted by a British man-of-war and sent to the British minister to the United States, accused Randolph of asking for money from France to influence the administration against Great Britain. Although this charge was demonstrably false, Randolph when confronted with it immediately resigned, and subsequently secured a retraction from Fauchet; he published *A Vindication of Mr. Randolph's Resignation* (1795) and *Political Truth, or Animadversions on the Past and Present State of Public Affairs* (1796). He died at Carter hall, Millwood, Clarke county, Va, on Sept. 12, 1813.

See M. D. Conway, in his *Omitted Chapters of History disclosed in the Life and Papers of Edmund Randolph* (1888; 2nd ed., 1889).

RANDOLPH, JOHN, of Roanoke (1773–1833), American statesman and orator, was born at Cawsons, Va., on June 2, 1773. Through his father, John Randolph, and his mother, Frances Bland, he was related to the Randolphs of Turkey Island and the Blands of Westover, two of the most conspicuous families of colonial Virginia; and, through an ancestress, Jane Bolling, he was a descendant of the Indian princess, Pocahontas. He received his collegiate education at Princeton, Columbia and William and Mary colleges. In 1799, he was elected to the House of Representatives, after an historic debate with Patrick Henry. In the House, his rise was so rapid that, after the election, in 1801, of Jefferson to the presidency, he was made chairman of the House committee on ways and means, and became the leader of the House Republicans. Soon, however, he drifted away from Jefferson, and lost both chairmanship and leadership. Afterwards he was, for many years, a mere free-lance; but, in 1820, his resolute resistance to the Missouri Compromise made him again a truly powerful figure in the House. After his first election in 1799, he was re-elected to the House, every two years, until 1829 except in 1813, when his opposition to the War of 1812 resulted in his defeat by John W. Eppes, and in 1817, when he declined to be a candidate. After re-election to the House in 1825, he was elected to the U.S. Senate; but he was defeated for re-election by John Tyler In 1807, he was the foreman of the grand jury which indicted Aaron Burr for treason; and he was a prominent member of the famous Virginia Constitutional Convention of 1829–30. In 1830, he was sent by Andrew Jackson on a special mission to Russia. In the succeeding year, he returned, and later denounced, in a series of speeches, the nullification proclamation of Andrew Jackson. He died at Philadelphia on May 24, 1833. Randolph was a passionate partisan of State sovereignty; and, therefore, opposed to a national bank, protection, and Federal internal improvements and interference with slavery; but he disliked slavery, and freed his slaves by his will. He filled with admirable efficiency the chairmanship of the House committee on ways and means. Jefferson said that his "popular eloquence gave him such advantages as to place him unrivalled as the leader of the House."

At the time of the Missouri Compromise, his influence was so great that Henry Clay afterwards declared in a speech: "His acts came near shaking this Union to the centre, and desolating this fair land." After his return to the House in 1827, it was again so great that the failure of John Quincy Adams to be re-elected to the presidency was largely due to it. "Wit and genius *all* allowed him," Thomas H. Benton tells us. "He has probably," declared Horace Binney, "spoken to more listeners than any other man of his day; having been unrivalled in the power of riveting the attention by the force and pungency of his language, the facility and beauty of his enunciation, and the point and emphasis of his most striking manner." Some of Randolph's speeches in Congress are found in every anthology of American eloquence. One of the most brilliant and disinterested, though by no means one of the most useful, of American public men; a captivating talker; a delightful letter-writer; a ripe scholar; a devotee of the horse, the dog and the gun; the scion of old and distinguished family stocks; the lonely occupant, when at Roanoke, of two rude dwellings, in the heart of a primaeval forest, and yet the possessor of a vast landed estate, a numerous retinue of slaves, a splendid stud of thoroughbreds, and a choice library; marked by startling peculiarities of voice, face and form which, once heard or seen, were never forgotten; always eccentric and sick, sometimes actually demented; a party to two duels and many quarrels; dauntlessly intrepid; intensely malignant at times, and yet susceptible also to the tenderest impulses of love and pity, it is not surprising that John Randolph of Roanoke should occupy, in American history, a place that is likely forever to remain unique.

See Lemuel Sawyer, *Biography of Randolph* (1844); Hugh A. Garland, *Life of Randolph* (1850); Henry Adams, *John Randolph* (1882); William Cabell Bruce, *John Randolph* (1922); G. W. Johnston, *Randolph of Roanoke* (1929). (W. C. BE.)

RANDOLPH, PEYTON (1721–1775), American politician, was born at Tazewell Hall, Williamsburg, Virginia, in 1721, a son of Sir John Randolph (1693–1737), the king's attorney for Virginia. He graduated at the College of William and Mary, studied law at the Inner Temple, London, and in 1748 was appointed the king's attorney for Virginia. Randolph wrote the address of remonstrance to the king on behalf of the burgesses against the suggested stamp duties in 1764. His policy was conservative and moderate, and in May, 1765, he opposed Patrick Henry's radical "Stamp Act Resolutions." In 1766 he resigned as king's attorney and was succeeded by his brother John (1727–84). In 1769 he acted as moderator of the privately convened assembly which entered into the non-importation agreement, and in May, 1773, he became chairman of the first Virginia intercolonial committee of correspondence. He presided over the provincial convention of Aug., 1774; was a member of the first Continental Congress, of which he was president from Sept. 5 to Oct. 22, 1774, and was re-elected to Congress in March, 1775. Randolph died of apoplexy in Philadelphia on Oct. 22, 1775. He was provincial grand master of the Masons of Virginia, and was an intimate friend of Washington.

RANDOLPH, THOMAS (1523–1590), English diplomatist, son of Avery Randolph, a Kentish gentleman, was educated at Christ Church, Oxford, and in 1549 became principal of Pembroke College, Oxford, then known as Broadgates Hall. During the reign of Mary, Randolph, who was a zealous Protestant, sought refuge in Paris, where he cultivated the society of scholars. Returning to England after the accession of Elizabeth, he was employed as a confidential diplomatic agent of the English queen in Scotland. Randolph's despatches from Scotland between 1560 and 1585 supply important materials for the history of the political intrigues of that period. In 1568 he undertook a mission to Russia which resulted in the concession by Ivan the Terrible of certain privileges to English merchants; and in 1570 he returned to Scotland. After carrying through certain diplomatic business in France in 1573 and 1576, Randolph returned in January 1581 to Scotland, where the earl of Morton, the regent, had been arrested a few days previously. Randolph, acting on Elizabeth's instructions, intrigued with Angus and the Douglases in favour of a plot to seize the person of the young King James, and to save Morton by laying violent hands on the earl of Lennox. Douglas of Whittingham made revelations which imperilled Randolph, who withdrew to Berwick before the execution of Morton in June 1581. In 1585, when he next visited Scotland, he helped to arrange a treaty between England and Scotland. For the next four years he was chancellor of the exchequer in England, and he died in London in June 1590.

See *Calendar of State Papers relating to Scotland* (1509–1603), 2 vols., ed. M J. Thorpe.

RANDOLPH, THOMAS (1605–1635), English poet and dramatist, was born near Daventry in Northamptonshire, and was baptized on June 15, 1605, Ben Jonson adopted him as one of his "sons." He addressed three poems to Jonson, one on the occasion of his formal "adoption," another on the failure of *The New Inn*, and the third an eclogue, describing his own studies at Cambridge. He was buried in Blatherwick church on March 17, 1634–35.

Randolph's earliest printed work is *Aristippus, Or, The Joviall Philosopher. Presented in a private shew, To which is added, The Conceited Pedlar* (1630). It is a gay interlude burlesquing a lecture in philosophy, the whole piece being an argument to support the claims of sack against small beer. His other authenticated works are: *The Jealous Lovers* (1632); *The Muse's Looking-Glass*; and *Amyntas, or The Impossible Dowry*, a pastoral printed in 1638; and some Latin and English poems. *Hey for Honesty, down with Knavery*, a comedy, is doubtfully assigned to him.

His works were edited by W. C. Hazlitt in 1875

RANDOLPH, a town of Norfolk county, Massachusetts, U.S.A., 16 mi. S. of Boston, on state highway 28, 5 mi. N. of Brockton. Pop. 1930, 6,553; 1940, by the federal census, 7,634. The town was set off from Braintree and incorporated in 1793.

RANDOM, an adjective originally meaning impetuous, hasty, hence done without purpose or aim, haphazard. The term "random work" is used, in architecture, by the rag-stone masons, for stones fitted together at random without any attempt at laying them in courses. (*See* MASONRY.)

RANELAGH, formerly a resort by the Thames in Chelsea, London, England. About 1690 the land lying east of Chelsea Hospital, and bordering the river about the point where Chelsea Bridge now stands, was acquired by Richard, Viscount Ranelagh, later earl of Ranelagh. He built a mansion and laid out gardens, which, in 1742, were thrown open as a proprietary place of entertainment. A building called the Rotunda was erected for concerts, and the gardens became a resort of fashionable society. By the close of the 18th century Ranelagh was ceasing to attract the public, and in 1803 the Rotunda was closed. The buildings were removed, and the grounds passed to Chelsea Hospital.

RANGABÉ, ALEXANDROS-RIZOS (1810–1892), Greek poet, archaeologist and statesman, born at Constantinople in 1810, was the son of Jean-Rizos Rangabé, a celebrated poet and scholar. In 1829, Alexandros entered the ranks of the Bavarian army, but after the establishment of the Greek republic, he returned to his native country, where he became successively minister of education (1833) and director of the royal printing press (1841). In 1844 he became professor of archaeology at the University of Athens, and for the next 12 years, in company with Dr. Bursian, he investigated the ruins of the temple of Juno, near Argos, bringing to light many statues and bas-reliefs, and discovering the entire formation of the building. He died at Athens on Jan. 28, 1892.

Rangabé advocated a revival of the ancient Greek language, and wrote poetry and dramas in Greek, including *Phrosyne*, *The Vigil*, and *The Thirty Tyrants*. He also wrote various archaeological works in French, notably *Antiquités helléniques* (1842–55) and *Antiquités troyennes* (1874).

RANGE: *see* STOVES.

RANGE-FINDERS are used to enable the fire of guns and rifles to be directed with maximum effect. They are indispensable to warships (*see* GUNNERY: *Naval*), coast forts and anti-aircraft guns. Artillery in the field generally relies on accurate maps when such are available, but in open and unmapped country a range-finder is very useful. Infantry require a small and light instrument. In ships weight is unimportant, there are limits to size, while ranges may be 20 miles or more. Coast fort ranges are similar to those of ships, but practically unlimited space is available.

The instruments which have been designed to meet these varied conditions may be divided into three types: (*a*) the self-contained or monostatic. also called short-base or one-man; (*b*) the long horizontal base system, consisting of two azimuth (horizontal angle measuring) instruments and a plotter; and (*c*) the depression range-finder, a single instrument depending for base on its height above the sea.

In each type the base is the base of a triangle, of which the apex is the target. Adjustment of one or both of the angles at the base solves the triangle and usually sets the indicator of the range scale. In type (a) one base angle is a right angle and, since an exceedingly delicate means of adjusting the other is possible, the base may be small. In type (b) adjustment is necessarily coarse, hence a very long base is required, but there are great advantages. In type (c) one angle is again a right angle, while the depression angle can be adjusted with an accuracy intermediate between the other two types. Ships and field army artillery and infantry use only monostatic range-finders, while coast forts may have all three types. Anti-aircraft guns use height-finders which will be described later. (K. F. D.)

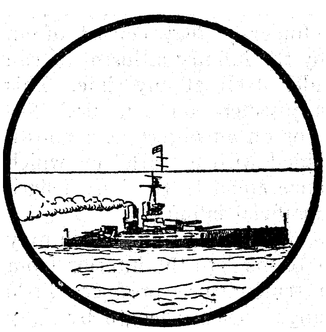
(a) MONOSTATIC RANGE-FINDERS

Short-base or monostatic range-finders are those which are entirely self-contained, the instrument itself constituting the base. From a scientific point of view they are perhaps the most interesting of the three types and have been brought very near to human limits of perfection. This is largely due to the work of the British inventors, Messrs. Barr and Stroud, from 1888 onwards. Range-finders vary in length from about 2-ft. to the 100-ft. coast defence range-finders.

In the earliest engagements of the World War the largest in use in the British navy had a base length of only 9 ft., but range-finders up to 30-ft. base and more had been made by Messrs. Barr & Stroud and were in use before the war. One of 15-ft. base was in the Russian navy from 1908. The 9-ft. range-finders were called upon to measure ranges up to 20,000 yards (11 or 12 miles) though originally designed to meet the requirements when the maximum range contemplated was very much less. Modern naval range-finders meeting increased range requirements vary from $4\frac{1}{2}$ ft. to 40-ft. bases.

Many forms of monostatic range-finders have been constructed, commencing with Magellan, an optician, in 1775. The next in importance was Adie, 1860. In 1888, Professors Barr and Stroud produced the first of the long series of range-finding instruments that bear their name.[1]

Two types only are in general use, the "coincidence" and the "stereoscopic." The best known as those of Barr and Stroud, Zeiss and Goerz. The two types are distinguished chiefly by the mode of presentation of the images of the target to the eyes of the observer. As usually constructed the range-finder consists externally of a tube carrying internally at each end a reflector in the form of an "optical square." This is either a "pentagonal" prism or a pair of mirrors inclined to each other at an angle of 45°. The advantage of this type of reflector over a single mirror is that an incident ray is always reflected (within narrow limits) through a constant angle; in this case 90°. The optical distance between the end reflectors constitutes the base length. The end reflectors receive rays of light from the target and reflect them towards the centre of the base, where "eyepiece prisms" are placed to direct them outwards through a single eyepiece, in the coincidence type, or through two separate eyepieces, in the stereoscopic type. Between the end reflectors and the eyepiece prisms are placed object glasses which, with the eyepiece or eyepieces constitute the range-finder telescopes. In addition, there is an optical device to enable the range to be ascertained and provision is made for effecting adjustments.



BY COURTESY OF MESSRS. BARR & STROUD
FIG. 1

In the coincidence type two partial views of the target are seen by one eye in juxtaposition, one above and the other below a fine "separating line," as in fig. 1. The process of "taking a range" consists of operating a device that brings the two partial images into alignment; the range scale then indicates the range.

In a stereoscopic range-finder the two images are presented separately to the two eyes of the range-taker so that the target is seen as in a stereoscope. In the field of view of each eye-piece there is a mark, the two marks being also seen stereoscopically as one. The range is taken by operating an optical device which alters the apparent distance of either the target or the mark until the target and the mark appear to be at the same distance, when the range may be read from the range scale.

Coincidence Range-finders.—As the base is so very small compared with the ranges to be measured, great refinement is essential in the means adopted. If partial images of an object such as a mast are presented to the eye above and below a fine separating line, a want of alignment due to 12 seconds of angle may be detected under ordinary conditions by the unaided eye. In a laboratory this might be reduced to 3 seconds. In this type of observation "the resolving power," as usually defined with regard to telescopic observations, does not apply, nor does the physiological limit of acuity of vision, stated to be 60 seconds.

If the telescopic magnification be 24, a parallax angle of $\frac{1}{2}$ second between the entering beams is detectable. Fig. 2.

If B be the base length and R the range, both in yards, and θ be the apex angle in radians, then, for the small angle concerned

$$\theta = \frac{B}{R} \quad \ldots \quad (1) \quad \text{and} \quad d\theta = -\frac{B}{R^2}\,dR \quad \ldots \quad (2)$$

If then $d\theta$ be taken as $\frac{1}{2}$ second,

$$dR = -\frac{R^2}{400{,}000\,B} \quad \text{approximately} \quad \ldots \quad (3$$

Formula (3) enables us to find the minimum error that is just detectable under good conditions at any range R, with a coincidence range-finder of base B and magnification 24.

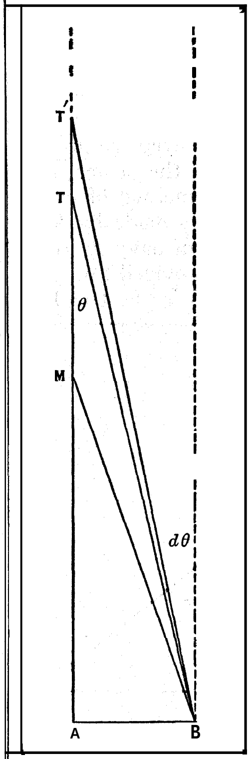


FIG. 2

Equation (3) shows that ranges may be determined within 100 yards with a 9-ft. base up to those of 11,000 yards range, with 15-ft. base up to 14,000 yards and with 30-ft. base up to 20,000 yards and with 100-ft. base up to 36,000 yards.

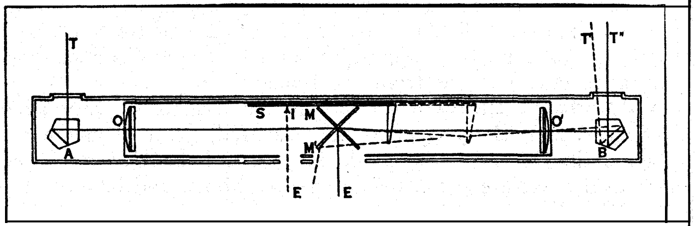
For the 9-ft. range-finder, if 3,000 yards is the shortest range to be measured, then the largest apex angle is $\frac{3}{3{,}000}$ radian, about 3 minutes of $\frac{1}{20}$, which comprises the whole of the scale corresponding with ranges from 3,000 yards to infinity. At 20,000 yards the apex angle is $\frac{3}{20{,}000}$ radian, about 30 seconds or $\frac{1}{120}$. The difference in angle between 20,000 yards and 20,500 yards is $\frac{3}{4}$ second or the angle subtended by a halfpenny at 43 miles. This will indicate the accuracy of the optical devices to be used.

The optical devices used for effecting coincidence are usually the translational deflecting prism system invented by Barr and Stroud in 1888 or the rotating pair of prisms used by Barr and Stroud in some early types, but chiefly adopted by the continental makers. Other devices have been used, but only these two have survived. Fig. 3 shows the essential parts of a coincidence range-finder.

The eyepiece prisms are shown as crossed mirrors for simplicity. Assuming that the left-hand ray enters the left window at right angles to the base and is directed by the optical system so as to appear in the centre of the field of view, the right-hand ray will enter the right-hand window at an angle depending on the range and the base length. After passing through the object glass the convergent beam of rays is bent through a constant angle by the thin deflecting prism. By sliding the prism longitudinally the

[1]See Proceedings of Institute of Mechanical Engineers, January 1896 and the Dictionary of Applied *Physics*, vol. iv.

image formed by this beam may be so displaced that the eye will see the upper and lower images in alignment. The range may then be read from the range scale, which is rigidly attached to and moves with the prism. Equation (1) shows that the scale is a reciprocal one. The scale may be read through a second eyepiece, or through a special window, or may even be made visible in the main eyepiece at one side of the field of view. It may be



BY COURTESY OF MESSRS. BARR & STROUD

FIG. 3

noted that there can be no backlash in this arrangement.

The translational prism must be placed in the convergent rays of the telescopic system. The rotating prisms may be placed outside it in the parallel beam. The rotating prisms are mounted in two rings, geared together so as to rotate in opposite directions.

If these prisms have their thin edges vertical and similarly directed, they produce a maximum deviation in the horizontal plane in one sense, and when each is rotated 180° they produce a maximum deviation in the other sense, in neither case producing any deviation in the vertical plane. If they are of equal angle of deviation they produce no deviation in any direction when each is rotated go° from the original position, and it will be evident that as the prisms are rotated equally and in (opposite directions from their original positions they produce a variable deviation in the horizontal plane, while they produce no deviation in the vertical plane. The rotations of such a pair of prisms in a range-finder comprising object glasses and eyepiece prisms, as illustrated in figure 3, therefore provides a means of measuring the angle θ, and a scale of ranges may be associated with the mechanism producing the equal and opposite rotations of the prisms. With suitable modifications such a pair of prisms may be inserted between one of the objectives and the eyepiece prisms, or one of the prisms may be inserted in each of the beams, say, before they enter the end reflectors. This latter method of working was adopted in the first 15-foot range-finders made by Barr and Stroud for the Russian navy and the Italian navy in 1908.

Adjustments. — Two main adjustments are provided for. The *halving* adjustment is to ensure that the images in the two half

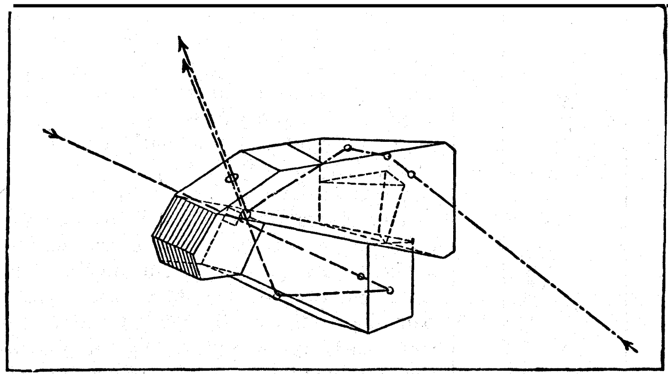


FIG. 4

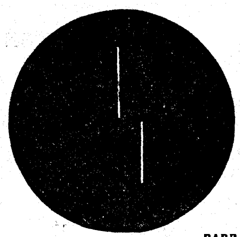
fields are neither duplicated nor that any part is missing at the separating line. This may be effected by suitably swinging about a horizontal axis a parallel plate of glass placed between one object glass and the eyepiece prism. The *infinity* adjustment is provided to permit of any small index error being removed. For this purpose the images of an infinitely distant object such as the moon or a star are set in coincidence and the scale is then set independently to read infinity. During ordinary range-taking the scale and prism are moved together.

Eyepiece prisms or "centre-prism-combinations" of many different varieties have been produced so as to present various effects in the field of view. (*See* Barr and Stroud's *Patent Specifications* from 1888 onwards.) For instance, both partial images may be erect, as shown in fig. 3, or the lower image may be erect and the upper image inverted. The latter type is often used in field range-finders. Again one side of the range-finder may produce nearly the whole field of view, while the other side is made to produce a narrow strip across the centre. Again, in this narrow strip, the view may be inverted. One type of eyepiece prisms from a German range-finder is shown in fig. 4. It gives an inverted strip field and shows the range scale at the side of the field of view. In all coincidence range-finders the fineness of the dividing line is important.

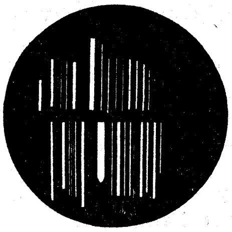
Stereoscopic Range-finders. — Externally these resemble the coincidence type very closely. The complicated eyepiece prism system is, however, replaced by two fairly simple prisms, each with, its own eyepiece. The adjustments provided are also, in general, similar: but an additional adjustment is required to ensure that the stereoscopic marks are in register with each other. The optical devices for producing stereoscopic movement may be similar to those in the coincidence type. For example, the Levallois stereoscopic height-finder, an instrument of French make, makes use of one fixed and also of one translational prism.



BY COURTESY OF MESSRS BARR & STROUD

FIG. 5

There does not seem to be much difference between the accuracy of the two types when used by experts in each. The chief disadvantages of the stereoscopic range-finder in service use are that fewer men can be found with a sufficiently acute stereoscopic sense and that this stereoscopic sense is liable to occasional large errors and to complete derangement if the operator be subjected to fatigue or mental strain. For these reasons they have always been regarded with suspicion in the British service.



BY COURTESY OF MESSRS. BARR & STROUD

FIG. 6

Other adjuncts to monostatic range-finders are *astigmatisers* and *internal adjusters.* Astigmatisers as used in coincidence range-finders are thin cylindrical lenses which may be inserted in the telescopic systems at will. Their effect is to draw the images into vertical streaks.

They are useful for taking the range of ill-defined objects, very small objects and of lights. Fig. 5 shows the effect on a star and fig. 6 the effect on a group of lights.

Internal adjusters, of which there are several types, are provided in some of the larger range-finders. They consist of an arrangement of optical parts whereby the infinity adjustment can be carried out within the range-finder itself at any time. This method cannot, however, replace adjustment on a natural "infinity," such as a star or the moon, or on an object at a known range. Small range-finders are provided with a "lath" on which are two marks separated by a distance equal to the base length of the range-finder, constituting an artificial infinity.

General Construction. — The main body is a tube, which may be double with an air space in order to insulate the interior from heat. A general expansion due to temperature produces little effect. A change of 50° F may change the base length by $\frac{1}{30}\%$ and can be detected by a go-foot range-finder only at ranges below 3,000 yards. Differential expansion due to the use of different materials in the various parts is taken into account in the design of the details. As the end reflectors are optical squares a very slight bend of the main tube will produce little or no effect on the range adjustment due to angular movement of the reflectors.

The object glasses, halving and coincidence adjusters, astigmatisers, eyepiece prisms and translational prism are carried in an "inner frame" "geometrically" supported within the main tube, which carries the eyepieces, end reflectors and, when used, rotational prisms. The main tube may be carried on a mounting designed to facilitate the use of the range-finder.

Uses.—In the field small range-finders up to one metre base length are in use. They are handled by one man and are carried either by the man or on a horse or in a vehicle. In the case of the instruments used in ships and forts, which are much larger and are mounted on pedestals or in turrets, although one man is sufficient to "take the range," he is assisted by others in directing the instrument and reading the scale. In battleships and cruisers a range-finder is usually carried in each gun turret, where it is subject to severe shocks.

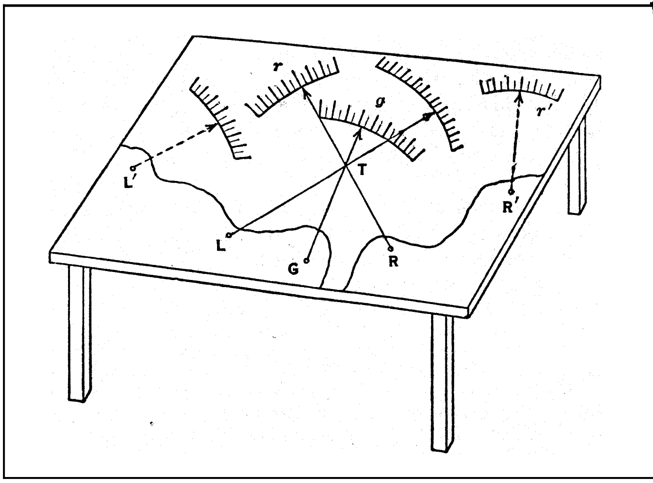


FIG. 7.—PLOTTING TABLE FOR LONG BASE RANGE-FINDING SYSTEM

For descriptions of the various details see publications mentioned in the bibliography. (X.)

(b) THE LONG HORIZONTAL BASE SYSTEM

While details of the long horizontal base range-finding system are usually secret, the principle may be indicated. Fig. 7 shows a simple plotting table or plotter, covered with a chart. R and L represent two azimuth observing instruments at distant posts. The observers lay their telescopes on the target and telephone the angles to the plotter. Arms RT and LT, provided with suitable arcs *r* and I, are set to these angles. Then their intersection T is the position of the target. If G is a gun position, a graduated arm GT with arc *g* will give the range and bearing of the target from the gun G. If the target moves, T will trace its course on the chart, the speed can be ascertained,

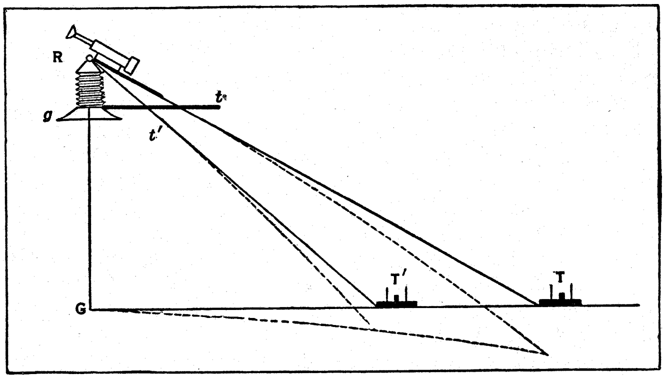

FIG. 8.— PRINCIPLE OF DEPRESSION RANGE-FINDER

and data can be sent to the gun continuously. Thus the gun can be fired at a target which may be invisible from the gun position. Other observing stations such as R′ and L′ may be used alternatively to either R or L, if either or both of these cannot see the target or if the apex angle RTL becomes less than about 10°. Thus the system is very flexible. Disadvantages are the necessary communications and the difficulty of ensuring that both observers are on the same target if several targets are close together; but great accuracy is possible. A simplification is to mount a telescope on one of the arms and use the plotter as an azimuth observing instrument.

The triangle RTL has been solved electrically by employing the logarithmic sine formula (*e.g.,* Pollak, J. E., Br. Pat. 218548). The azimuth instruments actuate rheostats to give the apex angle. Other rheostats then solve the logarithmic sine formula to give the range LT or RT. The plotting board system in various forms is in universal use.

(c) DEPRESSION RANGE-FINDER

In fig. 8 TT' are targets on the sea GT'T. Rgt represents the range-finder on a cliff *g*G The bar gt't is levelled and represents the sea. The height screw Rg represents the height RG and can also allow for tide, while the arm Rt is pivoted at R and carries a

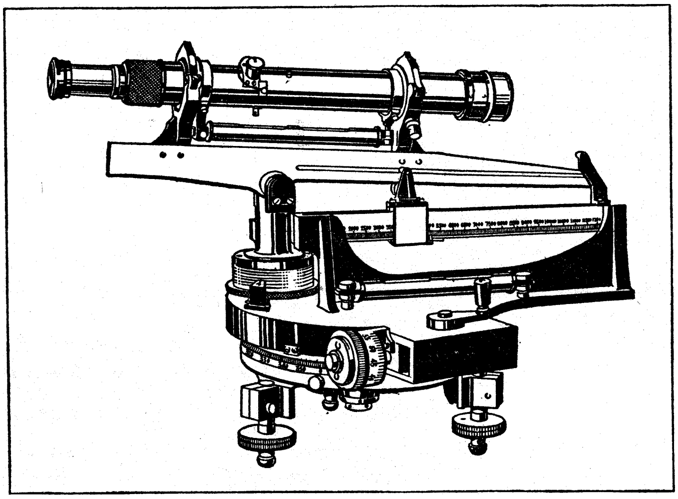

FIG. 9.— DEPRESSION RANGE-FINDER

telescope which can be directed at the water-line of a target by moving a slider along *gt*. The triangles RGT′T and R*gt′t* are then similar and so the bar *gt′t* may be graduated in ranges. curvature of the earth and atmospheric refraction, indicated by dotted lines, may be compensated for by suitably curving the telescope arm R*t*. The pivot R may be displaced laterally from *g* to represent the distance of the range-finder from the gun. The triangle RGT of fig. 8 (*q.v.*) is then reproduced, and the range indicated will be that from the gun. If a chart is placed under the bar *gt′t,* the position of T can be plotted and the instrument becomes a depression position finder. The useful limits of depression instruments are 4,000 to 5,000 yards for every 100 ft. of height above the sea, the accuracy of the "lay" being 10–15 seconds of arc.

The type *(b)* and *(c)* instruments used in the British service, together with their electrical operating devices, and certain field range-finders now replaced by type (*a*) were invented by Col

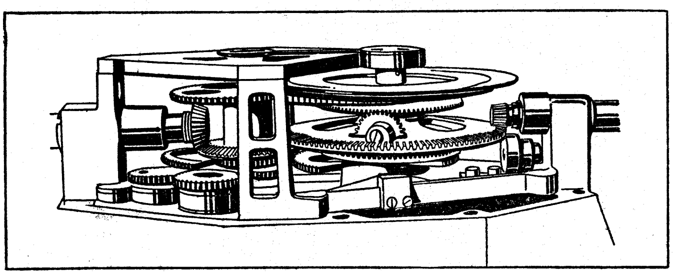

FIG. 10.— HEIGHT CONVERSION GEAR OF BARR & STROUD RANGE-FINDER

H. S. S. Watkin between 1886 and 1899. This was a stupendous achievement at a time when no good range-finder existed.

Height-finders.— The factor which is liable to least alteration in the flight of an aeroplane is its height. Anti-aircraft guns therefore base their calculations on height and angle of sight (elevation) instead of range, and so require height-finders. These are of the types (a) and *(b)*, *q.v.*

Monostatic Height-finders are actually range-finders with the addition of computing gear, based on some form of the equation, height = range × sin. angle of sight (or elevation). The Barr and Stroud is a coincidence range-finder with a beautiful logarithmic toothed cam gear. The French Lavallois is stereoscopic with a triangular link gear. Both these gears are so arranged that adjustment is only lost when the height alters, the necessary movement of the translational prism for range being effected automatically by that part of the computing gear which is controlled by the elevation movement of the main tube. This principle is essential for all height-finders.

In an optical solution, Rottenburg and Willans (Br. Pat. 125164, 1916) split the Barr and Stroud prism into two halves, rotating them in opposite directions through the angle of sight. The translational movement was then a measure of height, not range.

Long Base Height-finders. — These depend on the Bennett-Pleydell or "roof" principle. In fig. 11, T is an aerial object. LA*ar* and RA*ar* are two planes (Bennett planes) capable of being rocked about horizontal axes Ll and Rr (Bennett axes) at the ends of a measured base LR, at right angles to it and parallel to each other. The planes can be rocked about their axes so that their intersection A*a* (the ridge of the "roof") passes through it. If LAR is a vertical plane cutting the roof, then the perpendicular AP is the height of the ridge and therefore of T, wherever T may be along the ridge. If the base LR is b, then the height $h = \dfrac{b}{\cot L + \cot R}$. The angles ART and ALT are known as "sweep" angles. In practice the instruments at L and R have telescopes mounted on universal

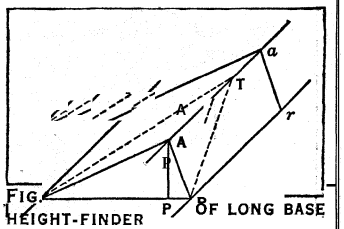

FIG. 11. — HEIGHT-FINDER ... OF LONG BASE

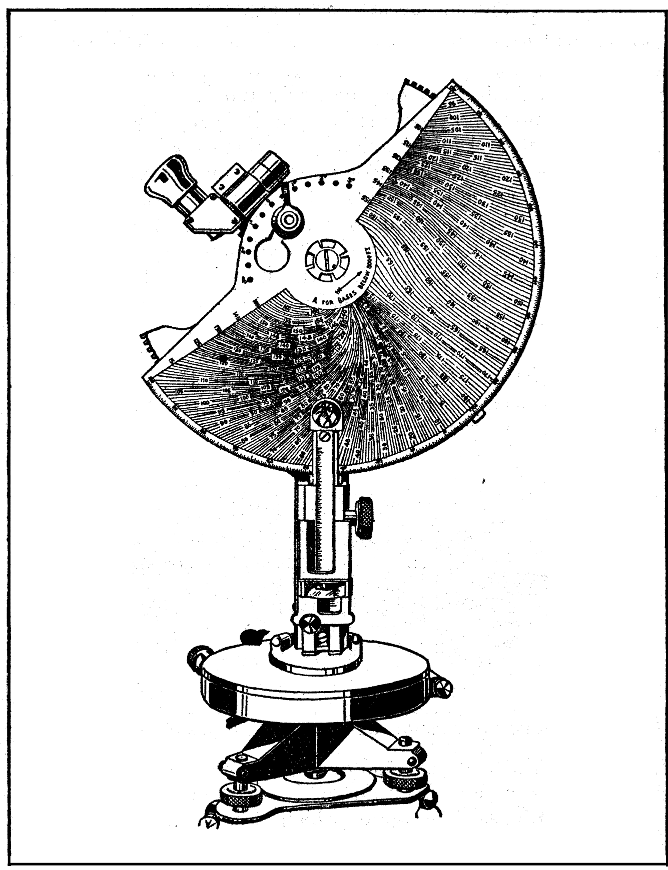

FIG. 12. — LONG BASE HEIGHT-FINDER INSTRUMENT

joints, of which the main (Bennett) axes are horizontal and set at right angles to LR. Movement about these registers the Bennett angles, while movement about the sweep axes allows the telescopes to be swept along the ridge without affecting the Bennett angles,

The formula can be solved in various ways to give the height. The latest British instruments are a copy of the French Puteaux, Modèle 1917. A semicircular plate, covered with curves of Bennett angles is attached to the telescope so as to swing with it about the Bennett axis. A vertically sliding pointer, engraved with a scale of heights, is carried on the body of the instrument and can be moved up or down to touch any curve on the plate. When L and R have laid their telescopes on the target, L telephones his Bennett angle to R, who then moves the pointer to that curve and reads the height opposite the indicator of the height scale. Further if L telephones his angles continuously, R will find that his disc brings the corresponding curves to the height pointer as L calls them through; if not, the height has altered. Cf. constant height constant coincidence of monostatic type.

The disadvantages of this system are similar to those of type (b) range-finders (*q.v.*). Hence, though this type has its uses, the monostatic is more generally relied on; as it is quicker in operation, speed being essential, and there is no confusion of targets.

RANGER, a city of Eastland county, Texas, U.S.A., 100 m. W. by S. of Fort Worth, at an altitude of 1,429 ft.; on federal highway 80, and served by the Texas and Pacific and the Wichita Falls and Southern railways. Pop. 6,208 in 1930; in 1940, 4,553 (95% native white) by the federal census. Oil was discovered on Oct. 21, 1917, and within a few weeks the town of 500 inhabitants was transformed into a camp of 30,000 living in tents and shacks, half of this number becoming permanent residents when the first boom was over. It is the field headquarters of several large refining companies and manufacturers of casinghead gasoline, shipping over 5,000,000 gal. in a month. The city is surrounded by a rich farming and poultry-raising region, and has the largest rock-crusher in the state. Ranger was the site of an old fort which was headquarters of the Texas Rangers. It was chartered as a city in 1919.

RANGOON, the capital of Burma, situated on the left bank of the Hlaing or Rangoon river, 21 m. from the sea, in 16° 47' N. and 96° 13' E. In 1880 the city was detached from the main district, called Hanthawaddy, and formed into a separate district, with an area of 19 sq.m. This has since been continually increased; the census area of Rangoon town district in 1931 was 77 sq.m. with a population of 400,000. Since Aug. 1, 1926, the district has formed part of the Pegu division. Rangoon, from being a comparatively insignificant place, rose in less' than half a century to be the third seaport in British India, being surpassed only by Calcutta and Bombay in the volume of its trade. During the busy season of rice-export, which lasts from the end of December to the middle of May, the pool forming the port of Rangoon presents almost as crowded a scene as the Hugli at Calcutta. Rangoon has the double advantage of being situated near the sea and in easy communication with a great river navigable for 900 m. behind it. It is, in addition, the centre of the Burmese railway system. In the broad and deep river is concentrated the whole of the rich trade of the delta of the Irrawaddy. Great part of the river frontage is occupied with rice-mills, teak wharves and similar buildings. The need for wharfage accommodation has resulted in recent years in the majority of the mills being removed to the opposite or Dalla shore of the Rangoon river, or along the banks of the Pegu river east of Rangoon. The rice exported from Rangoon in the years 1922–3 to 1926–7 averaged nearly 2,000,000 tons.

Architecture and History. — The city is dominated by the great golden pile of the Shwe Dagôn pagoda, the centre of Burmese religious life. Rising to a height of 368 ft., this magnificent building is loftier than St. Paul's cathedral in London, and its size is greatly enhanced by the fact that it stands on an eminence that is itself 168 ft. above the level of the city. It is covered with pure gold from base to summit, and once in every generation this gold is renewed by public subscription. The pagoda is a solid stupa of brick, in the form of a cone, raised over a relic chamber; and the place of worship is the surrounding platform with a perimeter of nearly 1,400 ft.

Though traditionally a site of great sanctity, Rangoon owes its first importance to its rebuilding in 1753 by Alompra, the founder of the Burmese monarchy, who gave it the name of Yan *Kon,* "the end of the war." The present Burmese designation of the town is Yandoon. An English factory was opened here about 1790. On the outbreak of the first Burmese War, in 1824, the city was taken by the British, but subsequently restored. It was captured a second time in 1852, and passed with the province of Pegu into the hands of the British. It was destroyed by fire in 1850, and serious conflagrations occurred again in 1853 and 1855.

Administration and Improvements. — Until 1874, when the existing municipality was constituted, the administration was in the hands of the local government, which devoted itself to raising the centre of the town above the river level, providing land fit for building purposes from the original swamp, which was flooded at spring-tides, and making roads, bridges, culverts and surface drains. In 1892 was introduced the sewage system, and now Rangoon has an excellent drainage system. The water supply, drawn at first from the Victoria lake, 5 m. distant, is now mainly from a large reservoir lake 17 m. distant. The city proper of Rangoon with the Kernmendine suburb is laid out on the block system, each block being 800 by 860 ft., intersected with regular streets. The city is now well lit with electric light, and has an extensive electric tramway system, recently supplemented by motor bus services. Rangoon has many fine public buildings including the Secretariat, the Law Courts, Post Office and General Hospital.

There are two large maidans, or commons, which are used as military parade grounds and for sport, the larger being used as a golf links. There are spacious and well kept zoological gardens, botanical gardens and an extremely pretty and well-kept garden in the cantonments under the pagoda. Beyond these lie the Royal Lake and Dalhousie park, with 160 acres of water and well-laid out and well-timbered park land, indeed, quite the finest in the East. There are two cathedrals, Church of England and Roman Catholic, a Presbyterian church, and churches of most denominations with services in English, Burmese and the principal Indian languages. Buddhists, Hindus, Mussulmans, Parsees, Armenians and Jews all own lands and pagodas, temples, mosques, churches and synagogues.

The chief educational institution is the University of Rangoon, constituted in 1920 and embracing two colleges. One, University college, was formerly known as Rangoon college and was affiliated to Calcutta university. The other, Judson college, is run in connection with the American Baptist Mission organization. The university has recently (1928) been moved to magnificent new buildings overlooking the Victoria or Great lakes. In 1926–27 there were 1,068 regular students in University college and 315 in Judson college. There are also numerous secondary and high schools in Rangoon.

Rangoon can now boast most of the amenities of a western city, including several excellent hotels, a number of cinemas, the largest of which are used for stage plays by travelling companies, fine shops and a number of clubs notably the Gymkhana, Pegu, Golf and Boat clubs. The European residences are mainly on the outskirts of the city to the north-west in what is still called the cantonments. The military lines have, however, recently been moved, in the main, to new cantonments at Mingalodon, 12 m. to the north of Rangoon. At Mingalodon is one of the finest 18 hole golf courses in the East. The development of Rangoon is now in the hands of the Rangoon Development Trust which administers the Rangoon Government Estate on behalf of the Government. The Trust develops the land, and then hands over the completed roads, etc., for maintenance by the Rangoon corporation. A magnificent race course at Kyaikasan was completed in 1926.

The affairs of the port are administered by the Rangoon port commissioners, and Rangoon handles about 85 or 86 per cent of the total trade of the province. Rangoon town is the business centre of Burma, but the rice-milling (at Dalla), ore-refining (at Syriam) and teak working, which form the staple industries, are carried on outside the town proper. The chief exports of Rangoon, with quantities in tons in 1926–27 are rice (1,734,565), bran and pollard (196,152), mineral oils (666,426), timber (215,577), oil cake (71,115), pulse (55,430), lead (51,859), zinc ore (46,452), wax, candles, cotton, oilseed and tobacco. The leading imports are noted under Burma. The port is visited yearly by about 1,650 vessels (1,450 steamers), with a total gross tonnage of between 6,000,000 and 7,000,000 tons.

Most of the labour in the port and the town is immigrant Indian labour; much of the skilled labour, especially in the building trades, is supplied by Chinese. The traders and clerical communities are also mainly Indians. Rangoon is by no means a Burmese city, and out of a population of 341,962 in 1921 there were only 112,000 Burmese, compared with 125,000 Hindus, 62,000 Muslims, 25,000 Christians (mainly Europeans and half-castes, officially styled Anglo-Indians) and 12,000 Chinese.

See references under Burma *see* also *Administration Report of the Commissioners for the Port of Rangoon* (annual), *Report of the Rangoon Development Trust* (annual) and *Report on the Municipal Administration of the City of Rangoon* (annual).

RANGPUR, a town and district of British India, in the Rajshahi division of Bengal. The town is situated on the little river Ghaghat. Pop. (1931) 20,749. It is a long straggling town, with a railway station at one end and the public offices 3 m. away at the other.

The DISTRICT OF RANGPUR, with an area of 3,496 sq m. and a population (1931) of 2,594,785, is one vast plain. The greater part of it, particularly towards the east, is inundated during the rains, and the remainder is traversed by a network of streams. The river system is constituted by the Brahmaputra and its tributaries, chief of which are the Tista, Dharla, Sankosh and Dudhkumar. About three-fourths of the district is under continuous cultivation. The staple crops are rice, oil-seeds, jute and tobacco. The east district is well served by railways. Saidpur (pop. 16,519), with the workshops of the metre-gauge system of the E. Bengal State railway, is an important railway town.

RANJIT SINGH, MAHARAJA (1780–1839), native Indian ruler, was born on Nov. 2, 1780, the son of Sirdar Mahan Singh, whom he succeeded in 1792 as head of the Sukarchakia branch of the Sikh confederacy. By birth he was only one of many Sikh barons and owed his rapid rise entirely to force of character and will. At the age of 20 he obtained from Zaman Shah, the king of Afghanistan, a grant of Lahore, which he seized by force of arms in 1799. Subsequently he attacked and annexed Amritsar in 1802, thus becoming master of the two Sikh capitals. When Jaswant Rao Holkar took refuge in the Punjab in 1805, Ranjit Singh made a treaty with the British, excluding Holkar from his territory. Shortly afterwards acute difficulties arose between him and the British as to the Cis-Sutlej portion of the Punjab. It was Ranjit Singh's ambition to weld the whole of the Punjab into a single Sikh empire, while the British claimed the territory south of the Sutlej by right of conquest from the Mahrattas. The difference proceeded almost to the point of war; but at the last moment Ranjit Singh yielded. In 1808 Charles Metcalfe was sent to settle this question with Ranjit Singh, and a treaty was concluded at Amritsar on April 15, 1809.

The Maharajah organized a powerful force, which was trained by French and Italian officers such as Generals Ventura, Allard and Avitabile, and thus forged the formidable fighting instrument of the Khalsa army, which afterwards gave the British their hardest battles in India in the two Sikh wars. In 1810 he captured Multan after many assaults and a long siege, and in 1820 had consolidated the whole of the Punjab between the Sutlej and the Indus under his dominion. In 1823 the city and province of Peshawar became tributary to him, In 1833 when Shah Shuja, flying from Afghanistan, sought refuge at his court, he took from him the Koh-i-noor diamond, which subsequently came into the possession of the British crown. Though he disapproved of Lord Auckland's policy of substituting Shah Shuja for Dost Mohamed, he loyally supported the British in their advance on Afghanistan. He was known as "The Lion of the Punjab." Ranjit Singh died of paralysis on June 27, 1839. *(See* also PUNJAB: *History.)*

See Sir Lepel Griffin, *Ranjit Singh* (Rulers of India Series), 1892; General Sir John Gordon, *The Sikhs,* 1904; and S. S. Thorburn, *The Punjab in Peace and War,* 1904.

RANJITSLNHJI, KUMAR SHRI (1872–1933), maharajah of Nawanagar, was born at Sarodar in Kathiawar, India, on Sept. 10, 1872. By race a Rajput, he was educated first at Rajkumar college, Rajkot, and afterwards at Trinity college, Cambridge. He did not get his "blue" until his last year, 1893, but thereafter leaped at once into the highest place in English cricket. From 1895–1904 he played for Sussex, and was captain from 1899–1903. He also played occasionally afterwards, his last appearance being in 1920. He went to Australia with Stoddart's team in 1897–98, and took a team to America in 1899. He made in all 14 scores of over 200, and in 1900, his greatest year, made over 3,000 runs for an average of 87, and over 200 five times. His greatest feat was at Hove against Middlesex. On the last day of the match, on a bad wicket, he made 202, when Vine (17) was the only other man on the side to get into double figures.

On his cousin's death in 1907 he succeeded as chief of the State of Nawanagar, and has proved an enlightened ruler. He provided troops for the Allies in the World War, and himself served at the front. He represented the Indian States at the League of Nations Assembly in 1920, and became vice-chancellor of the Indian Chamber of Princes. He died April 2, 1933.

He wrote *The Jubilee Book of Cricket* (1897); *With. Stoddart's Team in Australia* (1898); *How to Play Cricket* (1906).

See P. C. Standing, *Ranjitsinhji, Prince of Cricket* (1903); Beldam and Fry, *Great Batsmen* (1905); *Scores and Biographies,* vol. xv. (1925).

RANKE, LEOPOLD VON (1795–1886), German historian, was born on Dec. 20 or 21, 1795, at Wiehe, in Thuringia. He studied classics and theology at Halle and Berlin. In 1818 he began to teach history in a school at Frankfort-on-the-Oder, thereby entering the service of the Prussian Government.

With the scholar's dislike of textbooks. he rapidly acquired a thorough knowledge of the ancient historians, quickly passed on to mediaeval times, and determined to make a study of universal history. At Frankfort he wrote his first work, *Geschichte der romanischen und germanischen Völker 1494–1514* (1824), which included a critical dissertation on the historians of this period *(Zur Kritik neuerer Geschichtschreiber),* exposing the untrustworthiness of much traditional history. This dissertation was as important for modern history as the critical work of Niebuhr had been in ancient history. A copy of the book was sent to the Prussian minister of education, K. A. Kamptz, and Ranke was appointed supernumerary professor in the University of Berlin, and began his 50 years' connection with the university. His *Fürsten und Völker von Südeuropa im* 16 *und* 17 *Jahrhundert* (1827) was based on the study of ms. records in the Berlin library. In later editions the book was called *Die Osmanen und die spanische Monarchie.* The Prussian Government now provided him with means to prosecute his researches abroad. He visited Vienna, where the friendship of Gentz and the protection of Metternich opened to him the Venetian archives, of which many were preserved in that city—then a virgin field. He wrote a short book on *Die serbische Revolution* (1829), afterwards expanded into *Serbien und die Türkei im* 19 *Jahrhundert* (1879), from material supplied to him by Wuk Stephanovich, a Serbian who had himself been witness of the scenes he related. He spent three Years (1828–31) in Italy. The recommendations of Metternich opened to him almost every library except the Vatican.

For a time Ranke was editor of a periodical in which Friedrich Perthes sought to defend the Prussian Government against the democratic press. He failed; men desired not the scientific treatment of politics, but satire and invective. He earned the hatred and suspicion of the liberals and did not satisfy the Prussian conservatives, and after four years the *Historisch-Politische Zeitschrift* came to an end. Two-thirds of the matter had been contributed by the editor, and the two stout volumes in which the numbers were collected contained the best political thought which had for long appeared in Germany. For Ranke the failure was not to be regretted; the rest of his life was to be wholly devoted to history proper. *Die römischen Päpste, ihre Kirche und ihr Staat im* 16 *und* 17 *Jahrhundert* (3 vols., 1834–36, and many other editions), in form, as in matter, the greatest of his works, contains the results of his studies in Italy. The English translation by Mrs. Austin was the occasion of one of Macaulay's most brilliant essays. Before it was completed Ranke had already begun the researches for the second of his masterpieces, his *Deutsche Geschichte im Zeitalter der Reformation* (1839–47), a necessary pendant to his book on the popes. In 1837 he became full Professor at Berlin; in 1841 Frederick William IV. appointed him Prussian historiographer. In this capacity he wrote the *Neun Bücher preussischer Geschichte* (1847–48), a work which makes severe demands on the attention of the reader—he is the "Dryasdust" of Carlyle's Frederick; but in it he laid the foundation for the modern appreciation of the founders of the Prussian State. The nine books were subsequently expanded to 12 (Leipzig, 1874). His *Französische Geschichte, vornehmlich im 16 und 17 Jahrhundert* (Stuttgart, 1852–61) was followed by his *Englische Geschichte, vornehmlich im* 16 *und* 17 *Jahrhundert* (1859–68). This, the longest of his works, lacked something of the freshness of his earlier books; he was over 70 when it was completed, and he was never quite at home in dealing with the foundations of English public life. In his 81st year he began to write the *Weltgeschichte* (9 vols., Leipzig, 1883–88). Drawing on the knowledge accumulated during 60 years, he had brought it down to the end of the 15th century before his death in Berlin on May 23, 1886.

Ranke's other writings include *Zur deutschen Geschichte vom Religionsfrieden bis zum 30-jährigen Kriege* (Leipzig, 1868); *Geschichte Wallensteins* (Leipzig, 1869; 5th ed., 1896); *Abhandlungen und Versuche* (Leipzig, 1877; a new collection of these writings was edited by A. Dove and T. Wiedemann, 1888); *Aus dem Briefwechsel Friedrich Wilhelms IV. mit Bunsen* (Leipzig, 1873); *Die deutschen Mächte und der Fürstenbund. Deutsche Geschichte 1780–90* (1871–72); *Historisch-biographische Studien* (Leipzig, 1878); *Ursprung und Beginn der Revolutionskriege 1791–92* (Leipzig, 1875); and *Zur Geschichte von Oesterreich und Preussen zwischen den Friedensschlüssen zu Aachen und Hubertusberg* (Leipzig, 1875). He also wrote biographies of Frederick the Great and Frederick William IV. for the *Allgemeine Deutsche Biographie.*

Ranke married, at Windermere, in 1843, Miss Clara Graves, daughter of an Irish barrister. She died in 1870, leaving two sons and one daughter.

At the time of his death Ranke was generally regarded as the first of modern historians. His reputation was due, in part, to his success as a teacher. In his more private classes, where he dealt with the technical work of a historian, he trained generations of scholars. No one since Heyne has had so great an influence on German academical life, and for a whole generation the Berlin school had no rival. Ranke's example and training has made it impossible for any one to attempt to write modern history except on the "narratives of eye-witnesses and the most genuine immediate documents" preserved in the archives. He was determined never to allow himself to be misled, in his search for truth, by those theories and prejudices by which nearly every other historian was influenced—Hegelianism, Liberalism, Romanticism, religious and patriotic prejudice.

Many of Ranke's works have been translated into English. Among these are *Civil Wars and Monarchy in France,* by M. A. Garvey (1852); *History of England, principally in the 17th Century* (1875); *History of the Latin and Teutonic Nations,* 1494–1514, by P. A. Ashworth (1887) and again by S. R. Dennis (1909); *History of the Reformation in Germany,* by S. Austin (1845–47); *History of Servia and the Servian Revolution,* by Mrs. A. Kerr (1847); *Ferdinand I. and Maximilian II. of Austria; State of Germany after the Reformation,* by Lady Duff Gordon (1853); *Memoirs of the House of Brandenburg and History of Prussia during the 17th and 18th Centuries,* by Sir Alexander and Lady Duff Gordon (1849); and *History of the Popes during the 16th and 17th Centuries,* by S. Austin (1840; new eds., 1841 and 1847), by W. K. Kelly (1843), and by E. Foster (1847–

53). A collected edition of Ranke's works in 54 volumes was issued at Leipzig (1868–90), but this does not contain the *Weltgeschichte.*

For details of Ranke's life and work *see* his own *Zur eigenen Lebensgeschichte*, edited by A. Dove (Leipzig, 1890); and the article by Dove in the *Allgemeine deutsche Biographie*. *See* also Guglia, *Leopold von Rankes Leben und Werke* (Leipzig, 1893); M. Ritter, *Leopold von Kanke* (Stuttgart, 1895); H. F. Helmolt, L. *Rankes Leben und Wirken* (Leipzig, 1921) and H. Oncken, *Aus Rankes Frühzeit* (Gotha, 1922).

RANKIN, a borough of Allegheny county, Pennsylvania, U.S.A., on the Monongahela river, 9 mi. S.E. of the centre of Pittsburgh, adjoining Braddock and North Braddock (*qq.v.*). It is served by the Baltimore and Ohio, the Pittsburgh and Lake Erie, the Pennsylvania and the Union railways. Pop. (1920) 7,301 (36% foreign-born white and 12% Negroes); in 1940, 7,470. Rankin, Braddock and North Braddock form one community.

RANKINE, WILLIAM JOHN MACQUORN (1820–1872), Scottish engineer and physicist, was born at Edinburgh on July 5, 1820, and completed his education in its university. He was trained as an engineer under Sir J. B. Macneill, working chiefly on surveys, harbours and railroads, and was appointed in 1855 to the chair of civil engineering in Glasgow. Rankine was the earliest of the three founders of the modern science of thermodynamics (*q.v.*) on the bases laid by Sadi Carnot and J. P. Joule respectively, and the author of the first formal treatise on the subject; 150 scientific papers are credited to him in the Royal Society's Catalogue. The more important of these were collected and reprinted in Rankine's Scientific Papers (1881), which contains a memoir of the author by Prof. P. G. Tait. Rankine died at Glasgow on Dec. 24, 1872.

See also his *Civil Engineering, The Steam-Engine and other Prime Movers, Machinery and Millwork,* and *Applied Mechanics.*

RANNOCH, district of north-west Perthshire, Scotland, partly extending into Argyllshire. It measures 32 m. E. and W. and from 10 to 12 m. N. and S. and is surrounded by the districts of Badenoch, Atholl, Breadalbane, Lorne and Lochaber. Dugald Buchanan (1716–68), the Gaelic poet, was schoolmaster of the village, and a granite obelisk has been erected to his memory.

RANSOM, the price for which a captive in war redeemed his life or his freedom, a town secured immunity from sack and a ship was repurchased from her captors. The customs of feudal warfare recognized that captives of knightly rank had the right of buying their liberty from their captors. It was the duty of a feudal tenant to contribute towards his lord's ransom, and a king would often show his appreciation of a knight's services by redeeming him from captivity. The practice introduced a commercial element into mediaeval warfare, which became very prominent in the Hundred Years War between England and France and in the internal wars of Italy in the 15th century. In the former war, the ransom paid by John, king of France, and David II., king of Scotland. sensibly relieved the finances of Edward III.'s administration and at an earlier date the ransom paid by Richard I. to the emperor led to the introduction of new financial devices which are important in the history of English taxation.

RANTERS, an antinomian and spiritualistic English sect in the time of the Commonwealth, who may be described as the dregs of the Seeker movement. Their central idea was pantheistic.

See Rufus M. Jones, *Studies in Mystical Religion,* 1909, ch. xix.

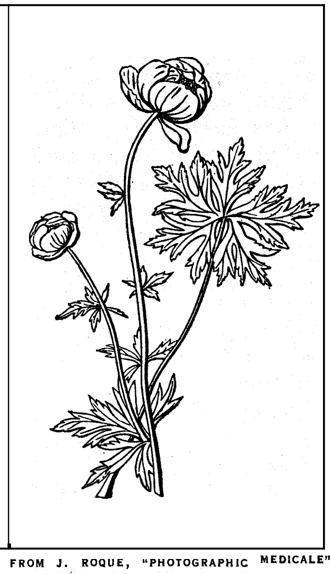
RANUNCULACEAE, a family of Dicotyledons belonging to the series Ranales, and containing 40 genera with about 700 species, which are distributed through temperate and cold regions but occur more especially in the northern hemisphere.

It is generally regarded as a genetic family which gave rise to the higher Dicotyledons, as well as the Monocotyledons. It contains many well known forms, such as buttercup, larkspur, anemone, columbine, clematis, marsh marigold, peony, etc. It is well represented in Britain, where 12 genera are native. In North America there are about 25 genera. The plants are mostly herbs, rarely shrubby, as in Clematis, which climbs by means of the leaf-stalks, with alternate leaves, opposite in Clematis, generally without stipules. The flowers, which show considerable variation in the number and development of parts, are characterized by free hypogynous sepals and petals, numerous free stamens, usually many free one-celled carpels and small seeds containing a minute straight embryo embedded in a copious endosperm. The parts of the flower are generally arranged spirally on a convex receptacle. The fruit is one-seeded, an achene or a many-seeded follicle, rarely, as in *Actaea,* a berry.

The family falls into several well-defined tribes which are distinguished by characters of the flower and fruit.

Tribe I. Paeonieae, peony group, are mostly herbs with deeply cut leaves and large solitary showy flowers in which the parts are spirally arranged, the sepals, generally five in number, passing gradually into the large coloured petals. There are 2–5 free carpels which bear a double row of ovules along the ventral suture. There are no honey-leaves (nectaries) but honey is secreted by a ring-like swelling round the base of the carpels, which become fleshy in the fruit and dehisce along the ventral suture. There are only three genera, the largest of which, *Paeonia,* occurs in Europe, temperate Asia and western North America. P. *officinalis* is the common peony. *P. suffruticosa* is the so-called tree peony, native of China.

Tribe *II.* Helleboreae are almost exclusively north temperate or subarctic. The plants are herbs, either annual, *e.g.,* Nigella (love-in-a-mist), or perennial hy means of a rhizome, as in *Aconitum* or *Eranthis* (winter aconite). The leaves are simple, as in *Caltha,* but more often palmately divided as in hellebore, aconite and larkspur. The flowers are solitary (Eranthis) or in cymes or racemes, and are generally regular as in Caltha (king-cup, marsh marigold), *Trollius* (globe-flower), *Helleborus* (hellebore), Aquilegia (columbine); sometimes markedly irregular as in *Aconitum* (aconite) and *Delphinium* (larkspur). The carpels, generally three to five in number, form in the fruit a many-seeded follicle, except in Actaea (baneberry), where the single carpel develops to form a many-seeded berry, and in *Nigella,* where the five carpels unite to form a five-chambered ovary. There is considerable variety in the form of the floral envelopes and the arrangement of the parts. The outer series, or sepals, generally five in number, is generally white or bright-coloured. Thus in *Caltha* and *Trollius* the sepals form a brilliant golden-yellow cup or globe, and in *Eranthis* a pale yellow star which contrasts with the green involucre of bracts immediately below it; in *Nigella* they are blue or yellow, and also coloured in *Aquilegia.* In Helleborus the greenish sepals persist till the fruit is ripe. *Aconitum* and *Delphinium* differ in the irregular development of the sepals, the posterior sepal being distinguished from the remaining four by its helmet-shape (*Aconitum*) or spur-shape (*Delphinium*). In Caltha there are no petals, but in the other genera there are honey-secreting and storing structures varying in number and in form in the different genera. In *Trollius* they are long and narrow with a honey-secreting pit at the base, in Nigella and Helleborus they form short-stalked pitchers, in *Aquilegia,* they are large and coloured with a showy petal-like upper portion and a long basal spur in the tip of which is the nectary. In Delphinium they are also spurred, and in *Aconitum* form a spur-like sac on a long stalk. The parts of the flower are generally arranged in a spiral (acyclic), but are sometimes hemicyclic, the perianth forming a whorl as in winter aconite; rarely is the flower cyclic, as in Aquilegia, in which case the parts throughout are arranged in alternating whorls. In *Caltha,* where there are no petals, honey is secreted by two shallow depressions situated on the side of each carpel.



FROM J. ROQUE, "PHOTOGRAPHIC MEDICALE" (B. GORMAN & CO)

GLOBE FLOWER (TROLLIUS EUROPAEUS)

Tribe *III. Anemoneae,* are chiefly north temperate, arctic and alpine plants, but also pass beyond the tropics to the southern hemisphere. They differ from the two preceding tribes in the numerous carpels, each with only one ovule, forming a fruit of numerous achenes. They are annual or perennial herbs, erect as in *Anemone, Thalictrurn* (meadow-rue) and many buttercups, or creeping as in *Ranunculus repens*; the section *Batrachium* of the genius *Ranunculus* (*q.v.*) contains aquatic plants with submerged or floating stems and leaves. The flowers are solitary, as in *Anemone pulsatilla* (Pasque flower), or cymose as in species of *Ranunculus,* or in racemes or panicles as in *Thalictrum.* The parts are spirally arranged throughout as in *Myosurus* (mouse-tail), where the very numerous carpels are borne on a much elongated receptacle, *Adonis* (pheasant's eye), or the perianth is whorled as in *Anemone* and *Ranunculus.* In *Anemone* and *Thalictrum* there is only one series of perianth leaves, which are petaloid and attractive in *Anemone* where honey is secreted by modified stamens, as in *A. Pulsatilla,* or, as in A. *nemorosa* (wood anemone), there is no honey and the flower is visited by insects for the sake of the pollen; in *Thalictrum* the perianth is greenish or slightly coloured, and the flower is wind-pollinated (*T. minus)* or visited for its pollen. In *Ranunculus* and *Adonis* a calyx of green protective sepals is succeeded by a corolla of showy petals; in *Ranunculus* there is a basal honey-secreting gland which is absent in *Adonis.* In *Anemone* the achenes bear the persistent naked or bearded style which aids in dissemination; the same purpose is served by the prickles on the achenes of *Ranunculus arvensis. Clematis* (*q.v.*), is characterized by its shrubby, often climbing habit, opposite leaves and the valvate, not imbricate as in the other tribes, aestivation of the sepals. The usually four sepals are whorled and petaloid, the numerous stamens and carpels are spirally arranged; the flowers are visited by insects for the sake of the abundant pollen. The fruit consists of numerous achenes which are generally prolonged into the long feathery style, whence the popular name of the British species, old man's beard *(Clematis vitalba).*

Special articles will be found on the more important genera of Ranunculaceae, *e.g.,* ACONITE, ADONIS, ANEMONE, BANEBERRY, CLEMATIS, COLUMBINE, HELLEBORE, RANUNCULUS. For further details *see* Enpler and *K.* Prantl, *Die natürlichen Pflanzenfamilien* (Leipzig, 1887–1908); **A. B.** Rendle, *Classification* of *Flowering Plants* (Cambridge. 1925).

RANUNCULUS, familiarly known as "buttercup," or crowfoot, a characteristic genus of the botanical family Ranunculaceae. The Latin name, which means a little frog or tadpole (dim. of *rana,* frog), was also given to a medicinal plant, which has been identified by some with the crowfoot. The members of the genus *Ranunculus* are more or less acrid herbs, sometimes with fleshy root-fibres, or with the base of the stem dilated into a kind of tuber *(R. bulbosus).* They have tufted or alternate leaves, dilated into a sheath at the base, and very generally, but not universally, deeply divided above. The flowers are solitary, or in loose cymes, and are remarkable for the number and separation (freedom from union) of their parts. Thus there are five sepals, as many petals, and numerous spirally arranged stamens and carpels. The petals have a little pit or honey-gland at the base, which is interesting as foreshadowing the more fully developed tubular corollas of the nearly allied genera *Aconitum* and *Helleborus.* The fruit is a head of "achenes"—dry, one-seeded fruits.

The genus contains a large number of species (about 300) and occurs in most temperate countries in the northern and southern hemispheres, extending into arctic and antarctic regions, and appearing on the higher mountains in the tropics. About 15 species are found in Great Britain. *R. acris, R. repens, R. bulbosus,* are the common buttercups. *R. arvensis,* which is found in cornfields, has smaller pale yellow flowers and the achenes covered with stout spines. *R. lingua,* and *R. flammula,* the spearwort, grow in marshes ditches and wet places. R. *ficaria* is the pilewort or lesser celandine, an early spring flower in pastures and waste places, characterized by having heart-shaped entire leaves and clusters of club-shaped roots. The section *Batrachium* comprises the water-buttercups, denizens of pools and streams, which vary greatly in the character of the foliage according as it is submerged, floating or aerial, and when submerged varying in accordance with the depth and strength of the current.

Inclusive of the water-buttercups, some 70 native species of *Ranunculus* occur in North America, widely distributed throughout the continent. Representative species are R. *septentrionalis, R. abortivus* and *R. recurvatus,* of the eastern States, and *R. californicus,* of the Pacific coast.

The ranunculus of the florist is a cultivated form of *R. asiaticus,* a native of the Levant, remarkable for the range of colour of the flowers (yellow to purplish black) and for the regularity with which the stamens and pistils are replaced by petals forming double flowers.

RAOUL DE CAMBRAI, the name of a French *chanson* de *geste.* The existing romance is a 13th-century recension of a poem by a trouvère of Laon called Bertholais, who professed to have witnessed the events he described. Raoul de Cambrai, the posthumous son of Raoul Taillefer, count of Cambrai, by his wife Alais, sister of King Louis (d'Outre-Mer), demanded the fief of Vermandois, which was the natural inheritance of the four sons of Herbert, lord of Vermandois. On King Louis's refusal, he proceeded to war. Bernier, a grandson of Count Herbert, eventually slew the terrible Raoul in single fight, but in his turn was slain, after an apparent reconciliation, and the blood-feud descended to his sons. The date of these events is exactly ascertainable. Flodoard (*Annales, Anno* 943) states that Count Herbert died in that year, and was buried by his sons at St. Quentin; that when they learnt that Raoul, son of Raoul de Gouy, was about to invade their father's territory, they attacked him and put him to death.

See Li *Romans de Raoul de Cambrai et de Bernier,* ed. *E.* le Glay (1840); "Raoul de Cambrai," ed. P. Meyer and *A.* Longnon (*Soc. des anc. textes fr.,* **1882**); **J.** M. Ludlow, *Popular Epics of the Middle* **Ages (1865)**; **G.** Grober, *Grundriss d. roman. Phil.* (ii. *pp.* **567** *seq.).*

RAOULT, FRANÇOIS MARIE (1830–1901), French chemist, was born at Fournes (Nord), on May 10, 1830. In 1862 he became professor of chemistry in Sens lycée, where he prepared the thesis on electromotive force which gained him his doctor's degree at Paris in the following year. In 1867 he was put in charge of the chemistry classes at Grenoble, and three years later he succeeded to the chair of chemistry, which he held until his death on April 1, 1901. His name is best known in connection with the work on solutions (*q.v.*). His first paper on the depression of the freezing-points of liquids by the presence of substances dissolved in them was published in 1878, Another conclusion was that the diminution in the vapour-pressure of a solvent, caused by dissolving a substance in it, is proportional to the molecular weight of the substance dissolved—at least when the solution is dilute. These two generalizations not only afforded a new method of determining the molecular weights of substances, but were also used by J. H. van't Hoff, S. Arrhenius, and others, in working out the theory of solutions.

RAPALLO, a seaport and winter resort of Liguria, Italy, in the province of Genoa. Pop. (1936) 6,766, town; 13,947, commune. It occupies a beautiful and well-sheltered situation on' the east side of the Gulf of Rapallo, 18½ m. E. by S. from Genoa by rail. The bridge, known as "Hannibal's Bridge," is mediaeval. To the south lies the small seaport of Portofino (the Roman *Portus Delphini*) under the south-east extremity of the promontory of Portofino (2,010 ft.) crowned by the remains of a castle. On the way from S. Margherita to Portofino is the suppressed monastery of Cervara, in which Francis I. of France was confined after the battle of Pavia on his way to Madrid. At all these places are beautiful villas. On the S. side of the promontory is the small village of S. Fruttuoso, with the tombs of some of the Doria family of Genoa (1275–1305).

RAPALLO, TREATY OF (April 16 1922). During the Conference of Genoa *(see* GENOA, CONFERENCE OF), at which it was designed to consider the economic relations of the participating Powers with Russia, the Russian delegates showed no great desire to resume relations with the Allied and Associated Powers, but to the consternation of the latter signed an agreement with Germany, after secret negotiations. The treaty was initialled on April 16 1922 by M. Chicherin and M. Rathenau. Germany and Russia renounced reciprocally all claims to war indemnities of any sort, including payment for the maintenance of prisoners of war.

Germany renounced any compensation for losses incurred by German subjects in consequence of Russian socialisation of private property "provided that the Soviet Government does not satisfy similar claims of other States." Diplomatic and consular relations were resumed, the principle of the most favoured nation was to be mutually applied, with a Russian reservation in favour of States formerly belonging to the Russian empire. Economic relations were to be regulated "with mutual feelings of goodwill." The treaty was made public immediately on signature. On Nov. 5, 1922, the treaty was extended to the Ukraine, White Russia, the Transcaucasian republics and the Far Eastern republic.

RAPE, a territorial division of the county of Sussex, formerly used for various administrative purposes. There are now six of these divisions: Hastings, Pevensey, Lewes, Bramber, Arundel and Chichestcr.

See the Victoria County History, *Sussex,* vol. i.; *New* English Dictionary; and M. A. Lower, *History of Sussex* (Lewes, 1870).

RAPE, in botany. Several forms of plants included in the genus Brassica are known as rape and cultivated instead of a turnip crop or as a "catch crop" for food for sheep or for their oil-yielding seeds. The nomenclature and relationship of these forms of Brassica are not clear as crosses are frequent. B. *Rapa* is grown in Great Britain as a green crop while B. *Napus* var. *oleifera* known as colza rape or coleseed is grown on the continent of Europe for oil. Its seeds contain from 30 to 45% of oil

For further details see W. W. Robbins, Botany of Crop Plants (Philadelphia, 1924); R. Percival, *Agricultural* Botany (1926).

RAPE, in law, the crime of having carnal knowledge of a woman by a man, not her husband, forcibly and unlawfully, against her will. A felony at common law, it was reduced in England to a misdemeanour in 1275, but in 1285 was again declared a felony, with benefit of clergy. This was the state of the law until 1575, when the punishment was made more severe. Formerly a capital offence, by the Offences against the Person Act 1861, it is punishable by penal servitude for life.

The law of England regards as immaterial whether the woman is chaste or unchaste, married or single, provided the offence has been committed forcibly and without her consent. The offence is complete if consent is extorted by means of threats of death or immediate bodily harm, by fraud or by false pretences or representation. (Criminal Law Amendment Act 1885.)

In the United States the elements of the crime under statute are similar to those at common law. The age when effective consent can be given by the female has commonly been set by the various States between 14 and 18 years. Want of age on the part of the male is not a defence, as at common law, but simply presumptive evidence of lack of physical capacity. Many States require the testimony of the female to be corroborated by other evidence as well as requiring the prosecution to be initiated within a year or less after the commission of the offense. The punishment is imprisonment though a few southern States prescribe death as the penalty.

RAPE OIL, an important fatty oil, known also as "sweet oil," either expressed or extracted from the crushed seeds of cultivated varieties of the cruciferous genus Brassica, the parent form of the whole apparently being the wild navew, B. *campestris.* Under the general name "rape oil" is included the produce of several plants having distinct and fairly constant characters, and one of these oils—colza (*q.v.*)—is a very well-known commercial variety. In Germany, where the production of rape oil centres. two principal oil-seeds—rape and Riibsen—are recognized. (See RAPE.)

The oil yielded by these seeds is, in physical and chemical properties, practically the same, the range of fluctuations not being greater than would be found in the oil of any specific seed under similar varying conditions of production; the winter varieties of all the seeds are more productive than the summer varieties. Newly pressed rape oil has a dark sherry colour with, at first, scarcely any perceptible smell; but after resting a short time the oil deposits an abundant mucilaginous slime, and by taking up oxygen it acquires a peculiar disagreeable odour and an acrid taste. Refined by the ordinary processes (see OILS), the oil assumes a clear golden yellow colour. In specific gravity it ranges between 0·9112 and 0·9117 (raw), and from 0·9127 to 0·9136 (refined); the solidifying point is from $-4°$ to $-6°$ Centigrade.

The principal uses of rape oil are for lubrication and lighting; but since the introduction of mineral oils for both these purposes the importance of rape has considerably decreased. It is but little employed in soap-making, as it saponifies with difficulty and yields only an indifferent product. In Germany it is very considerably used as a salad oil under the name of *Schmalzöl,* being for that purpose freed from its biting taste by being mixed with starch, heated till the starch is carbonized, and filtered after the oil has cooled. The offensive taste of rape oil may also be removed by treatment with a small proportion of sweet spirits of nitre (nitrous ether). In the East Indies rape oil and its equivalents, known under various names, are the most important of oils for native use. They are largely consumed as food instead of ghi under the name of "metah" or sweet oil, but for all other purposes the same substance is known as "kurwah" or bitter oil. Most natives prefer it for the preparation of their curries, and other hot dishes. Rape oil is the subject of extensive adulteration, principally with the cheaper hemp oil, rosin oil and mineral oils. These sophistications can be most conveniently detected, first by taste and next by saponification, rosin oil and mineral oil remaining unsaponified, hemp oil giving a greenish soap, while rape oil yields a soap with a yellow tinge. Rape oil and the other cruciferous oils are characterized by the presence of the unsaturated fatty acid erucic acid, $C_{21}H_{41}COOH$, the identification of which affords a means of detecting rape oil in admixture with other oils. Lead plaster (*Emplastrum* lithargyri) boiled in rape oil dissolves, and, sulphide of lead being formed, the oil becomes brown or black. Other lead compounds give the same black coloration from the formation of sulphide.

RAPHAEL, in the Apocryphal Book of Tobit, the name of the angel who in human disguise and under the name of Azarias ("Yahweh helps") accompanied Tobias in his adventurous journey and conquered the demon Asmodaeus (see TOBIT). He is said to be "one of the seven holy angels [archangels] which present the prayers of the saints and go in before the glory of the Holy One" (Tob. xii. 15). In the Book of Enoch (ch. xx.) Raphael is "the angel of the spirits of men," and it is his business to "heal the earth which the angels have defiled." His name means "God heals."

RAPHAEL SANZIO (1483–1520), the great Italian painter, was the son of Giovanni Sanzio or Santi, a painter in the ducal city of Urbino. The house of Giovanni Santi, where Raphael was born (April 6, 1483) still exists at Urbino in the Contrada del Monte, and is now the property of the municipality. For many years both before and after the birth of Raphael (April 6, 1483) Urbino was one of the chief centres in Italy of intellectual and artistic activity, thanks to its highly cultured rulers, Duke Federigo II. of Montefeltro and his son Guidobaldo, who succeeded him in 1482. Giovanni Santi was a welcome guest at this miniature but splendid court, and the rich treasures which the palace contained, familiar to Raphael from his earliest years, helped to form and foster his early love for art. Raphael's boyish admiration of the oil-paintings of Jan Van Eyck and Justus of Ghent may have had something to do with the miniature-like care and delicacy with which some of his earliest works, such as the "Apollo and Marsyas," were executed.

Though Raphael lost his father at the age of eleven, he certainly owed to him a great part of his early training. The altarpiece painted by Giovanni for the church of Gradara, and a fresco, now preserved in the Santi house at Urbino, are clearly prototypes of some of Raphael's most graceful paintings of the Madonna and Child. On the death of his father in 1494 Raphael was left in the care of his stepmother (his mother, Magia Ciarla, died in 1491) and of his uncle, a priest called Bartolomeo.

First or Perugian **Period.**—Vasari's statement that Raphael was sent to Perugia during his father's lifetime is certainly a mistake. He probably did not enter Perugino's studio till the end of 1499. Of the thirty drawings contained in the so called Sketch Book of Raphael in the Venice Academy but two can be ascribed to the master. (See G. Morelli, Italian Masters in German Gal*leries,* 1882.)

Before long Raphael appears to have shared in the execution of paintings by his master; and his touch may perhaps be traced in some of Perugino's panels which were executed about 1502; examples are the Resurrection of Christ in the Vatican and the Diotalevi Madonna in the Berlin Museum.

About 1500 Raphael began to execute independent works. The portrait of Tangino in the Borghese Gallery, Rome, was probably painted about 1500. Four pictures for churches at Citti di Castello appear to have been painted in the years 1502–04. The first is a gild-banner painted on one side with the Trinity, and below, kneeling figures of S. Sebastian and S. Rocco; on the reverse is a Creation of Eve, very like Perugino in style, but possessing more grace and breadth of treatment. These are still in the church of S. Triniti. Also for Città di Castello were the coronation of S. Niccolo Tolentino, now destroyed, though studies fcr it exist at Oxford and Lille (Gaz. d. B. Arts, 1878, i. p. 48), and the Crucifixion, now in the National Gallery (Mond collection), painted for the church of S. Domenico and signed RAPHAEL VRBINAS P. It is a panel 8 ft. 6 in. high by 5 ft. 5 in. wide, and contains noble figures of the Virgin, St. John, St. Jerome and St. Mary Magdalene. The fourth painting executed for this town, for the church of S. Francesco, is the exquisitely beautiful and highly finished Sposalizio, now in the Brera at Milan, signed and dated RAPHAEL VRBINAS MDIIII. This is closely copied both in composition and detail from Perugino's painting of the same subject now at Caen, but is far superior to it in sweetness of expression and grace of attitude. The Temple of Jerusalem, a domed octagon with outer ambulatory in Perugino's picture, is reproduced with slight alterations by Raphael, and the attitudes and grouping of the figures are almost exactly the same in both. The Connestabile Madonna (sold to the tsar of Russia in 1871) is one of Raphael's finest works, painted during his Perugian period; it is a round panel. The motive, the Virgin reading a book of hours, is a favourite one with him, as it was with his father Giovanni.

Second or Florentine Period, 1504–1508.—In the first half of 1504 Raphael visited Urbino, where he painted two small panels for Duke Guidobaldo, the St. George and the St. Michael of the Louvre. His first visit to Florence was made towards the end of 1504, when he presented himself with a warm letter of recommendation from his patroness Joanna della Rovere to the gonfaloniere Pier Soderini. At the time of his arrival in Florence artistic Italy was excited over the cartoons of the battle of Anghiari and the war with Pisa, to which Leonardo da Vinci and Michelangelo were then devoting their energies. With astonishing rapidity Raphael shook off the mannerisms of Perugino and put one great artist in painting or sculpture after another under contribution for some special power of drawing, beauty of colour, or grace of composition in which each happened to excel. The Carmine frescoes of Masaccio and Masolino taught this eager student long-remembered lessons of methods of dramatic expression. (See his cartoon of St. Paul preaching at Athens [Victoria and Albert Museum].) Among his contemporaries it was especially Signorelli and Michelangelo who taught him the necessity of a thorough knowledge of the human form. From da Vinci he learnt subtleties of modelling and soft beauty of expression (see the portrait of Maddalena Doni in the Pitti), from Fra Bartolommeo nobility of composition and skilful treatment of drapery in dignified folds. (See the Madonna del Baldacchino in the Pitti.) The friendship between Raphael and the last of these was very close. The architect Baccio d'Agnolo was another of his friends, at whose house the young painter enjoyed social intercourse with the chief artists of Florence, and probably learnt from him much that was afterwards useful in his practice as an architect.

The transition in Raphael's style from his first or Perugian to his second or Florentine manner is shown in the large picture of the Coronation of the Virgin painted for Maddalena degli Oddi, now in the Vatican, one of the most beautiful that he ever produced, and especially remarkable for its strong religious sentiment—in this respect a great contrast to the paintings of his last or Roman manner which hang near it. The exquisite grace of the angel musicians shows signs of his short visit to Florence, while the formality of the composition and certain details, such as the fluttering ribands of the angels, recall peculiarities of Perugino and of Pinturicchio, with whose fine picture of the same subject hung close by it is interesting to compare it. The predella of this masterpiece of Raphael is also in the Vatican; some of its small paintings, especially that of the Annunciation to the Virgin, display his careful study of the rules of perspective. Preparatory sketches for this picture exist at Lille and elsewhere. The Lille study is drawn from two youths in the ordinary dress of the time; and it is interesting to compare it with his later studies from the nude, many of which are for figures which in the future picture were to be draped. It was at Florence, as Vasari says, that Raphael began serious life studies, not only from nude models but also by making careful anatomical drawings from dissected corpses and from skeletons.

His first visit to Florence lasted only a few months; in 1505 he was again in Perugia painting his first fresco, the Trinity and Saints, for the Camaldoli monks of San Severo, now a mere wreck from injury and restorations. The date MDV and the signature were added later, probably in 1521. Pgrt of this work was left incomplete by the painter, and the fresco was finished in 1521 (after his death) by his old master Perugino. It was probably earlier than this that Raphael visited Siena and assisted Pinturicchio with sketches for his Piccolomini frescoes. He probably had no hand in the actual execution of the paintings. The Madonna of S. Antonio (Metropolitan Museum of Art, New York) was also finished in 1505, but was probably begun before the Florentine visit. A record of his visit to Siena exists in a sketch of the antique marble group of the Three Graces, then in the cathedral library, from which, not long afterwards, he painted the small panel of the same subject now at Chantilly.

In 1506 Raphael was again in Urbino, where he painted for the duke another picture of St. George, which was borne to England as a present to Henry VII. by Guidobaldo's ambassador, the accomplished Baldassare Castiglione (*q.v.*), a friend of Raphael, whose noble portrait of him is in the Louvre. At the court of Duke Guidobaldo the painter's ideas appear to have been led into a more secular direction, and to this stay in Urbino probably belong the Chantilly Graces and the miniature "Knight's Dream of Duty and Pleasure" in the National Gallery (London), which also possesses its cartoon in brown ink, pricked for transference.

Towards the end of 1506 Raphael returned to Florence, and there (before 1508) produced a large number of his finest works, carefully finished, and for the most part wholly the work of his own hand. The following is a list of some of his chief paintings of this period: the "Madonna del Gran Duca" (Pitti); "Madonna del Giardino," 1506 (Vienna); "Holy Family with the Lamb," 1506 or 1507 (Madrid); the "Ansidei Madonna," 1506 or 1507 (National Gallery); the Borghese "Entombment," 1507; The Panshanger "Madonna" (now in America), 1508; "La bella Giardiniera," 1508 (Louvre); the "Eszterhazy Madonna," probably the same year, as well as the "Madonna del Cardellino" (Uffizi), the "Tempi Madonna" (Munich), the "Colonna Madonna" (Berlin), the "Bridgewater Madonna" (Bridgewater House), and the "Orleans Madonna" (Chantilly). The "Ansidei Madonna" was bought in 1884 for the National Gallery from the duke of Marlborough. It was painted for the Ansidei family of Perugia as an altar-piece in the church of S. Fiorenzo, and is a work of the highest beauty in colour, well preserved. The Virgin with veiled head is seated on a throne, supporting the Infant with one hand and holding a book in the other. Below stands S. Niccolo Tolentino, for whose altar it was painted; he holds a book and a crozier, and is clad in jewelled mitre and green cope, under which appear the alb and cassock. On the other side is the Baptist, in red mantle and camel's-hair tunic, holding a crystal cross. The rich jewellery in this picture is painted with Flemish-like minuteness. A favourite method of grouping his Holy Families is that seen in the "Madonna del

Cardellino" and the "Bella Giardiniera," in which the main lines form a pyramid. This arrangement is also used in the "Madonna del Giardino" and in the larger group, including St. Joseph and St. Elizabeth, known as the "Canigiani Holy Family," now at Munich. The "Entombment of Christ," now in the Galleria Borghese in Rome, was painted during a visit to Perugia in 1507 for Lady Atalanta Baglioni, in memory of the death of her brave and handsome but treacherous son Grifonetto, who was killed in 1500 by his enemies the Oddi party. (See Symonds, Sketches *in* Italy, the chapter on Perugia, mainly taken from the contemporary chronicle of Matarazzo.) The many studies and preliminary sketches for this important picture which exist in various collections show that it cost Raphael an unusual amount of thought and labour in its composition. It is, however, much injured by repainting. The "Madonna del Baldacchino," owing much to Fra Bartolommeo, is also unsatisfactory in execution; being left unfinished by Raphael, it was completed by Ridolfo Ghirlandajo. It was painted for the Dei family as an altar-piece for their chapel in S. Spirito, Florence. The "St. Catherine" of the National Gallery was probably painted in 1507; its cartoon, pricked for transference, is in the Louvre. To the Florentine period belong some of his finest portraits, and it is especially in these that da Vinci's influence appears. The portraits of Angelo Doni and his wife Maddalena (Pitti) are vivid and carefully executed paintings, and the unknown lady with hard features (now in the Uffizi) is a masterpiece of noble realism and conscientious finish. A fine but much-restored portrait of Raphael by himself, painted at Florence, exists in the Uffizi; it represents him at a very early age, and was probably painted during the early part of his stay in Florence.

Third or Roman Period, 1508–1520.—In 1508 Raphael was painting several important pictures in Florence; in September of that year we find him settled in Rome, from a letter addressed in the warmest terms of affectionate admiration to Francia, to whom he sent a sketch for his "Adoration of the Shepherds," and promised to send his own portrait in return for that whish Francia had given him. Raphael was invited to Rome by his fellow-citizen Bramante, who was then occupied in the erection of the new church of St. Peter, the foundation-stone of which had been laid by Julius II. on the 18th of April 1506. At this time the love of the popes for art had already attracted to Rome Michelangelo, Signorelli, Perugino, Pinturicchio, Lorenzo Lotto, Peruzzi, Sodoma and many others, and it was among this brilliant assembly that Raphael, almost at once, took a leading position. Thanks to Bramante's friendly intervention, Julius II. (Della Rovere) soon became Raphael's most zealous patron and friend, as did also the rich bankers Agostino Chigi and Bindo Altoviti, of whom a portrait, by Giulio Romano, is now in Munich.

A series of rooms in the Vatican, over the Appartamenti Borgia, were already decorated with frescoes by Bonfigli, Perugino, Piero della Francesca, Andrea del Castagno, Signorelli and Sodoma; but so rapidly had the taste of the time changed that Julius II. decided to re-cover the walls with paintings in the more developed style of Raphael. It was not without regret that Raphael saw the destruction of this noble series of frescoes. One vault, that of the Stanza dell' Incendio, painted by his master Perugino, he saved from obliteration; it still exists, well preserved, a most skilful piece of decorative work; and he also set his pupils to copy a number of portrait-heads in the frescoes of Piero della Francesca before they were destroyed.

The Stanza della Segnatura (papal signature room) was painted in 1509–11. The first painting executed by Raphael in this room was the so-called Disputa, finished in 1509. In its religious sentiment it far excels any of the later stanze paintings, retaining much of the sacred character of earlier Florentine and Umbrian art. As a scheme of decoration it appears to have been suggested by some of the early apsidal mosaics. Gold is largely used, while the later purely pictorial frescoes have little or none. The subject is the hierarchy of the church on earth and its glory in heaven.

The painting on the vault of this room is the next in date, and shows further transition towards the "Roman manner." In his treatment of the whole Raphael has been partly guided by the painting of Perugino's vault in the next room (the Stanza dell' Incendio). The pictures are kept subordinate to the lines of the vault. A great part of the ground is gilt, marked with mosaic-like squares, a common practice with decorative painters. The principal medallions in each cell of this quadripartite vault are very graceful female figures, representing Theology, Science, Justice and Poetry. Smaller subjects are arranged in the intermediate spaces, and each has some special meaning in reference to the medallion it adjoins; some of these are painted in warm monochrome to suggest bas-reliefs. The fine painting of the "Flaying of Marsyas" is interesting as showing Raphael's study of antique sculpture: the figure of Marsyas is a copy of a Roman statue. The very beautiful little picture of the "Temptation of Eve" recalls Albert Dürer's treatment of that subject, though only vaguely. Much mutual admiration existed between Raphael and Dürer: in 1515 Raphael sent the German artist a most masterly life study of two nude male figures (now at Vienna); on it is written in Albert Dürer's beautiful hand the date and a record of its being a gift from Raphael. It is executed in red chalk, and was a study for two figures in the "Battle of Ostia."

On the wall opposite the Disputa is the so-called School of Athens. The subject of this noble fresco, in contrast to that opposite, is "Earthly Knowledge," represented by an assembly of the great philosophers, poets and men of science of ancient Greece. The central figures are Plato and Aristotle, while below and on each side are groups arranged with the most consummate skill, including the whole "filosofica famiglia" of Dante (Infer. iv. 133–144), and a number of other leaders of thought, selected in a way that shows no slight acquaintance with the history of philosophy and science among the ancient Greeks. Many interesting portraits are introduced—Bramante as the aged Archimedes, stooping over a geometrical diagram; a beautiful fair-haired youth on the left is Francesco Maria della Rovere, duke of Urbino; and on the extreme right figures of Raphael himself and Sodoma are introduced. The stately building in which these groups are arranged is taken with modifications from Bramante's first design for St. Peter's.

Over one window is a group of poets and musicians on Mount Parnassus, round a central figure of Apollo; it contains many heads of great beauty and fine portraits of Dante and Petrarch. Over the opposite window are graceful figures of the three chief Virtues, and at one side Gregory IX. (a portrait of Julius II.) presenting his volume of decretals to a jurist; on the other Justinian presents his code to Trebonianus.

The next room, the Stanza d'Eliodoro, was painted in 1511–14. The room is so called from the fresco representing the expulsion of Heliodorus from the Temple (2 Macc. iii.), which is an allusion to the struggles between Louis XII. of France and Julius II. Its chief motive is the glorification of the pontificate, with insistence on the temporal power. The main incident of this picture is the angel visitant on the horse. The group of women and children on the left is very beautiful, and the figures of Julius II. and his attendants are nobly designed. This picture was completed in 1512. Over one window is shown the scene of the Miracle at Bolsena of 1264, when the real presence was proved to a doubting priest by the appearance of blood-stains on the Corporal. (See Orvieto.) Julius II. is introduced kneeling before the altar; and the lower spaces on each side of the windows are filled with two groups, that on the left with women, that on the right with officers of the papal guard. The last group is one of the most masterly of all throughout the stanze: each face is a marvel of expression and power, and of technical skill. The next fresco in date is that of the Repulse of Attila from the walls of Rome by Leo I., miraculously aided by the apparitions of St. Peter and St. Paul; it contains another allusion to the papal quarrels with France. It was begun in the lifetime of Julius II., but was only half finished at the time of his death in 1513; thus it happens that the portrait of his successor, the Medici pope Leo X., appears twice over, first as a cardinal riding behind the pope, painted before the death of Julius II., and again in the character of S. Leo, instead of the portrait of Julius which Raphael was about to paint. A pen sketch in the Louvre by Raphael shows Julius II. in the place afterwards occupied by Leo X. In 1514 he painted the "Deliverance of St. Peter from Prison," with a further political allusion. It is skilfully arranged to fit the awkward space round the window, and is remarkable for an attempt to combine and contrast the three different qualities of light coming from the room, the glory round the angel, and the torches of the sentinels.

For the so-called Stanza dell' Incendio Raphael designed and partly painted the "Incendio del Borgo," a fire in the Borgo or Leonine City, which was miraculously stopped by Leo IV. appearing and making the sign of the cross at a window in the Vatican. On the background is shown the façade of the old basilica of St. Peter, not yet destroyed when this fresco was painted. One group on the left, in the foreground, is remarkable for its vigour and powerful drawing; the motive is taken from the burning of Troy; a fine nude figure of Aeneas issues from the burning houses bearing on his back the old Anchises and leading the boy Ascanius by the hand. Many studies for this picture exist. This is the last of the stanze frescoes on which Raphael himself worked. Others in this room designed by him and painted by Giulio Romano and other pupils were the "Battle of Ostia," and the "Oath of Leo III. before Charlemagne." The enormous fresco of the "Defeat of Maxentuis by Constantine," in the Saladi Constantino, was painted by Giulio Romano, soon after Raphael's death, from a sketch by the latter.

The paintings in the stanze were only a small part of Raphael's work between 1509 and 1513. To this period belong the Madonna of Foligno (Vatican), painted in 1511 for Sigismondo Conti. Of about the same date are the gem-like Garvagh Madonna (National Gallery, once in the possession of the Aldobrandini family), the Diademed Virgin of the Louvre, and the Madonna del Pesce at Madrid. The last was executed in 1513 for S. Domenico in Naples. In addition to other easel pictures a number of his finest portraits belong to this period—that of Julius II. the original of which is lost (copies in the Uffizi and National Gallery, London); the Tommaso Inghirami in the Gardner Collection, Boston; the Baldassare Castiglione of the Louvre; and the portrait of a cardinal in the Prado, Madrid.

When Giovanni de' Medici became pope as Leo X., a period of splendour and magnificence succeeded the sterner rule of Julius II. Agostino Chigi, the Sienese financier, was the chief of those whose lavish expenditure contributed to enrich Rome with works of art. For him Raphael painted, in 1513–14, the very beautiful fresco of the Triumph of Galatea in his new palace by the Tiber, the Villa Farnesina, and also made a large series of magnificent designs from Apuleius's romance of Cupid and Psyche, which were carried out by a number of his pupils.[1] For the same patron he painted (also in 1513) his celebrated Sibyls in S. Maria della Pace—figures of exquisite grace, arranged with perfect skill over an arch in the nave. It is not without reason that Vasari gives these the highest position among his fresco-paintings. Agostino Chigi also employed Raphael to build for him a private chapel in S. Maria del Popolo, and to make a series of cartoons to be executed in mosaic on the inner dome. The central medallion has a figure of God among clouds and angel boys, surrounded by eight planets, each with its pagan deity and directing angel in accordance with Dante's scheme in the Paradiso. The execution of these brilliant mosaics was carried out in 1516 by the Venetian Luigi della Pace. Probably in the early years of Leo X.'s reign were painted the Madonna della Sedia (Pitti), the S. Cecilia at Bologna (not completed till 1516), the miniature Vision of Ezekiel (Pitti) and two important pictures at Madrid. The latest of these, known as Lo Spasimo, from the church at Palermo, for which it was painted, represents Christ bearing His Cross. The Madonna called Della Perla, "the pearl" of the Spanish royal collection, was originally painted for Bishop Louis of Canossa; it was sold by Cromwell with the greater part of Charles I.'s collection at Hampton Court. The portrait of Leo X. with Cardinals de' Rossi and de' Medici, in the Pitti, is one of his finest portrait-pictures. Little is known about the Madonna di S. Sisto, the glory of the Dresden Gallery; no studies or sketches for it exist,

One of Raphael's latest works is the large "St. Michael and the Devil," in the Louvre, signed "Raphael Urbinas pingebat. MDXVIII."

The tapestry cartoons, seven of which are in the Victoria and Albert Museum, were painted by pupils from Raphael's designs. They are part of a set of ten, with scenes from the Acts of the Apostles, intended, when copied in tapestry, to adorn the lower part of the walls of the Sistine chapel. The tapestries themselves, worked at Brussels, are now, after many vicissitudes, hung in a gallery in the Vatican; the set is complete, thus preserving the design of the three lost cartoons ("The Martyrdom of St. Stephen," "St. Paul's Conversion" and "St. Paul in Prison"). The existing seven, after being cut up into strips for use on the looms, were bought by Rubens for Charles I. The tapestry copies are executed with wonderful skill. The designs are reversed, and the colours far more brilliant than those of the cartoons, much gold and silver being introduced. The rich framework designed by Raphael's pupils, probably by Penni and Giovanni da Udine, exists in the tapestries and adds greatly to their decorative effect. The cartoons were executed in 1515 and 1516, and the finished tapestries were first exhibited in their place in the Sistine chapel on Dec. 26, 1519.

The **"Transfiguration."**—In 1519 Cardinal Giuliano de' Medici (afterwards Clement VII.), as bishop of Narbonne, ordered two altar-pieces for his cathedral—the one by Raphael, the other by Raphael's Venetian rival Sebastiano del Piombo. That by the latter painter is the Resurrection of Lazarus, now in the National Gallery. Several studies for Raphael's picture exist, showing that he at first intended to paint a Resurrection of Christ as a pendant to Sebastiano's subject, but soon altered his scheme into the Transfiguration. The eight or nine existing studies are scattered through the Oxford, Lille, Windsor and some private collections. A great part of the lower group was unfinished at the time of the painter's sudden death in 1520, and the heavy colouring of Giulio Romano is visible in it. On the death of Raphael the picture became too precious to send out of Rome, and Cardinal de' Medici contented himself with sending the Resurrection of Lazarus to Narbonne The Transfiguration was bequeathed by him to the monks of S. Pietro in Montorio, in whose church it remained till it was stolen by Napoleon I. It now hangs in the Vatican Gallery.

Architectural Work.—Bramante, before his death in March 1514, requested that Raphael should be made his successor as chief architect of St. Peter's. To this important post he was appointed by Leo X., Aug. 1, 1514. The progress of St. Peter's was, however, too slow for him to leave much mark on its design. Another work of Bramante's, completed by Raphael, was the graceful Cortile di S. Damaso in the Vatican, including the loggie, which were decorated with stucco-reliefs and paintings of sacred subjects by his pupils under his own supervision, but only very partially from his designs. The Palazzo dell' Aquila, built for Giovanni Battista Branconio, and destroyed in the 17th century during the extension of St. Peter's, was one of Raphael's chief works as an architect. He also designed the little cross church, domed at the intersection like a miniature St. Peter's, called S. Eligio degli Orefici, which still exists near the Tiber, almost opposite the Farnesina gardens. According to M. Geymiiller, *Raffaello come Architetto* (Milan, 1883), the Villa Farnesina of Agostino Chigi, usually attributed to Peruzzi, was, as well as its palace-like stables, designed by Raphael; but internal evidence makes this very difficult to believe. It has too much of the delicate and refined character of the 15th century for Raphael. whose taste seems to have been strongly inclined to the more developed classic style, of which Palladio afterwards became the chief exponent. Villa Madama, on the slopes of Monte Mario above Rome, was designed by Raphael, though its actual carrying out, and the unrivalled stucco-reliefs, are due to Giulio Romano and Giovanni da Udine, as mentioned in Vasari's life of the latter.[2] The original design for this villa made by Raphael himself has been discovered by Sf. Geymüller. Another architectural work was the little Chigi chapel

[1]Chiefly by Giulio Romano. Gianfrancesco Penni and Giovanni da Udine; much injury has been done to these frescoes by repainting.

[2]*See* Gruner, *Fresco Decorations, etc.* (London, 1854), pls. 6–12, and Kaffaelle Santi, *Ornati della Villa Madama, etc* {Rome, 1875).

in S. Maria del Popolo, built in 1516. At the time of his death, Raphael was preparing to build himself a handsome palace near the church of S. Eligio; the deed for the purchase of its site was signed by him only a few days before his last short illness. Though not completed till 1530, the Palazzo Pandolfini at Florence was also designed by him.

Sculpture. — That Vasari is right in attributing to him the model for the beautiful statue of Jonah which is in the Chigi chapel is borne witness to by two important documents, though there is no evidence to show that he ever worked in marble. One of these is a letter written to Michelangelo to warn him that Raphael had been invading his province as a sculptor by modelling a boy, which had been executed in marble by a pupil, and was a work of much beauty. Again, after his death his friend Baldassare Castiglione, in a letter dated the 8th of May 1523, asks his steward in Rome "if Giulio Romano still possesses a certain boy in marble by Raphael and what his lowest price for it would be." The statue of Jonah was executed in marble by Lorenzetto, a Florentine; and it remained in his studio for many years after Raphael's death. The Victoria and Albert Museum possesses a small clay sketch for this beautiful group, slightly different from the marble; it is probably the original design by the master's own hand. The whole feeling of the group — a beautiful youth seated on a sea-monster — is classical, and the motive is probably taken from some antique statue representing Arion or Taras on a dolphin.

A large number of Raphael's designs were engraved by his pupils Marcantonio Raimondi and Agostino Veneziano. These valuable engravings are from Raphael's sketches, not from his finished pictures, and in some cases they show alterations made in the execution of the picture. Raimondi's engraving of the S. Cecilia of Bologna in design is very inferior to that of the actual painting. Several of Raphael's most important compositions are known to us only by these early engravings, *e.g.,* the Massacre of the Innocents (engraved by Raimondi), which is one of his finest works. Another magnificent design is the Judgment of Paris, containing a large number of figures; the nude figure of Minerva is a work of especial force and beauty. A standing figure of Lucretia about to stab herself is also one of his most lovely figures. Many of Raphael's studies for Marcantonio's engravings still exist.

Archaeology. — Raphael's report to Leo X. in 1518 is an eloquent plea for the preservation of ancient buildings. In 1515 he had been appointed by Leo X. inspector of all excavations in Rome and within 10 miles round. His study of the antique is clearly shown in many of his frescoes, and especially in the graceful stucco reliefs and painted grotteschi, in the Vatican loggia, the Villa Madama and elsewhere.

Raphael's Fame. — Among all the painters of the world, none has been so universally popular as Raphael, or has so steadily maintained his pre-eminent reputation throughout the many changes in taste which have taken place in the last three and a half centuries. In the seventeen or eighteen years which composed his short working life he passed through stages of development for which a century would not have seemed too long, while other painters lived through the same changeful time with but little alteration in their manner of work. Perugino, who outlived his wonderful pupil, completed in 1521 Raphael's San Severo fresco in a style differing but little from his paintings executed in the previous century.

In versatility of power Raphael remains almost without a rival; whether painting an altar-piece for a church, a large historical fresco, a portrait or decorative scenes from classical mythology, he seems to excel equally in each; and the widely different methods of painting in tempera, oil or fresco are employed by him with apparently equal facility. His range of scale is no less remarkable, varying from a miniature, finished like an illuminated ms., to colossal figures in fresco dashed in with breadth and vigour.

His personal beauty, charm of manner and kindliness of heart endeared him to all who knew him. He was as an equal to the princes of the church, the distinguished scholars and the world-famed men who formed the courts of Julius II. and Leo X. In accordance with the spirit of the age he lived with considerable display and luxury. His pupils formed round him a sort of royal retinue, numbering about fifty youths, each talented in some branch of the arts. Giulio Romano and Gianfrancesco Penni, his two favourite pupils, lived with him in the Palazzo di Bramante, a house (now destroyed) near St. Peter's, where he resided during the greater part of his life in Rome.

Raphael died on Good Friday, April 6,1520, at the age of thirty-seven, after an attack of fever which lasted only ten days. His body was laid out in state in his studio, by the side of the unfinished Transfiguration, and all Rome flocked to the place for a last sight of the "divino pittore." His drawings and mss. he left to Giulio Romano and Gianfrancesco Penni, his newly bought land to Cardinal Bibbiena, the uncle of the lady to whom he had been betrothed. He desired to be buried in the Pantheon. His body is laid beside an altar, which he endowed with an annual chantry, and on the wall over it is a plain slab, with an inscription written by his friend Cardinal Bembo. See PAINTING.

RAPID CITY, a city of South Dakota, U.S.A., beautifully situated in the western part of the state, on Rapid river, at the foot of the Black Hills, 3,229 ft. above sea level; the county seat of Pennington county. It is on federal highways 14 and 16, and is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific and the Rapid City, Black Hills and Western railways. Pop. 1940 federal census, 13,844. It is the centre of a wide agricultural and grazing region and of the mining district of the Black Hills, which produces gold, silver, lead, copper, tin, antimony, tungsten and mica. Its manufactures include flour, lumber, meat, brick, stucco, cement, boxes and foundry and machine shop products. The State School of Mines was established here by the Territorial Legislature of Dakota in 1885. Its museum contains, besides minerals, a fine collection of fossils from the Bad Lands, 30 mi. to the southeast. The state game lodge, in the state park near Custer, 30 mi. S.W. of Rapid City, was occupied by President Coolidge as the summer White House in 1927, and the executive offices were housed in Rapid City. The city was founded in 1876 and incorporated in 1878.

RAPIER, the name given to two distinct types of sword. Originally the "rapier" (Fr. *rapière)* was a long two-edged and pointed weapon with a wide cup hilt, used together with the dagger in fencing and duelling chiefly as a thrusting weapon, the cut taking a secondary position. This was the typical duelling sword of the 16th and 17th centuries. In the 18th century the "small-sword" took its place; this was a pointed weapon only, the "cut" having entirely dropped out, and the dagger being discarded. (See FENCING and ***SWORD.)***

RAPPOLTSWEILER: see RIBEAUVILLÉ.

RARE EARTHS, in chemistry, the name given to a group of metallic oxides originally called by this title since they resemble the substances then known as earths (lime, magnesia, etc.). The corresponding elements are unique in that they are all very similar in their chemical properties. The group has been roughly sub-divided into three portions more for convenience than from theoretical considerations. The elements, together with their main characteristics, are given in the sub-groups shown below. The atomic number precedes the name and the atomic weight is given after the symbol. For details *see* separate article on each element.

SUB-GROUP 1

(57) *Lanthanum* (La 138.9). Colourless salts; solutions show no absorption spectrum. White, strongly basic oxide, La_2O_3, which is diamagnetic.

(58) *Cerium* (Ce 140·2). Forms two series of salts, cerous and ceric, derived from the oxides Ce_2O_3 and CeO_2. Cerous salts are colourless and show no absorption spectrum. Ceric salts are yellow or orange-red, and are rapidly hydrolyzed by water. The stable oxide, CeO_2, is insoluble in hydrochloric and nitric acids when pure.

(59) *Praseodymium* (Pr 140·9). Forms leek-green coloured salts whose solutions show a very characteristic and intense absorption spectrum. The stable oxide (Pr_4O_7) is black.

(60) *Neodymium* ((Nd 144·3). Amethyst-coloured salts, the solutions of which give a characteristic and intense absorption spectrum. The oxide, Nd_2O_3, is blue when carefully ignited.

(61) *Illinium* (I1 ?). Solutions said to give an absorption spectrum which is obliterated by the presence of neodymium or samarium. Also called florentium.

(62) *Samarium* (Sa 150·4). Very pale yellowish oxide, Sa_2O_3, giving topaz-yellow salts, showing a characteristic absorption spectrum.

SUB-GROUP 2

(63) *Europium* (Eu 152·0). Pale pink oxide, Eu_2O_3, and pale rose-tinted salts; solutions give weak but characteristic absorption spectrum and brilliant and very strong spark spectrum.

(64) *Gadolinium* (Gd 157·3). White oxide, colourless salts; solutions show absorption spectrum in the ultra-violet only.

(65) *Terbium* (Tb 159.2). Stable oxide, Tb_4O_7, almost black. Salts and solutions almost colourless, giving one absorption band in the blue.

SUB-GROUP 3

(66) *Dysprosium* (Dy 162·5). Oxide, Dy_2O_3, white, forms greenish-yellow salts; solutions characterized by an absorption spectrum. Compounds possess a very high magnetic susceptibility.

(67) *Holmium* (Ho 163.5). Oxide, Ho_2O_3, yellow, giving orange-yellow salts; solutions show characteristic absorption spectrum.

(39) *Yttrium* (Y 89·0). This element is placed here for convenience. Its atomic weight is out of order, and many do not consider it a true member of the series. Oxide, Y_2O_3, white and diamagnetic, gives colourless salts whose solutions give no absorption.

(68) *Erbium* (Er 167.7). Oxide, Er_2O_3, rose, gives rose-coloured salts showing very characteristic absorption spectrum.

(69) *Thulium* (Tm 169·4). Oxide, Tm_2O_3, greenish-white, forms pale bluish-green salts. Solution characterized by both absorption and bright line spectra.

(70) *Ytterbium* (Yb 173·5). Oxide, Yb_2O_3, white, gives colourless salts and solutions showing no absorption spectrum. Spark spectrum, however, is very characteristic. Differs from La_2O_3 and Y_2O_3 since the oxide is a much weaker base and is paramagnetic.

(71) *Lutecium* (Lu 175·0). Oxide, Lu_2O_3, white; almost identical in its properties with the preceding element except that it has a lower magnetic susceptibility and a characteristic spark spectrum.

Of the elements listed above, cerium, lanthanum and neodymium are comparatively common, while europium, terbium and thulium are very rare. While it is true that certain minerals are richer in one sub-group than in others, nevertheless if a sufficient amount of any mineral is examined, the presence of every member of the series can be detected. Monazite, cerite, allanite, etc., are the best sources for the elements of sub-group 1; samarskite and certain varieties of xenotime for sub-group 2; gadolinite, xenotime, euxenite, fergusonite, etc., for sub-group 3. These minerals are found chiefly in Norway, U.S A., Brazil, India and Australia.

In 1794 Gaaolin separated a new earth yttria from a black mineral found at Ytterby in Sweden, and in 1804 Berzelius and Hisinger (Klaproth independently) found another new earth in a mineral from Bastnäs which they named ceria. In 1839 Mosander showed that ceria consisted of ceria and a new oxide—lanthana. A little later the same worker showed that lanthana was composed of lanthana and another oxide didymia. Again, in 1843 Mosander showed that yttria was composed of the oxides, viz., yttria, terbia (rose) and a dark oxide, erbia. Berlin and other chemists in 1860 found only two oxides, viz., yttria and the rose-coloured oxide which they now called erbia.

Delafontain and Marignac independently showed that Mosander's three oxides really existed, and, since the name erbia had been given to terbia, the latter was used to designate erbia. In 1879 de Boisbaudran claimed the discovery of a new element in didymium oxide which he called samarium. Marignac found another element in samarium which he later named gadolinium. In 1885 von Welsbach split didymium into praseodymium and neodymium, and in 1896 Demarcey separated europium from samarium. In 1926 Hopkins announced the discovery of element 61—illinium. In the same year Corke, James and Fogg obtained "61" independently and measured the lines of the X-ray spectrum. These discoveries may be represented graphically as in scheme (I.)

$$\text{(I.)}\qquad \text{Ce}\begin{cases}\text{Ce}\\ \text{La}\begin{cases}\text{La}\\ \text{Di}\begin{cases}\text{Di}\begin{cases}\text{Nd}\begin{cases}\text{Nd}\\ \text{Il}\end{cases}\\ \text{Pr}\end{cases}\\ \text{Sa}\begin{cases}\text{Sa}\begin{cases}\text{Sa}\\ \text{Eu}\end{cases}\\ \text{Gd}\end{cases}\end{cases}\end{cases}\end{cases}$$

In 1878 Marignac divided erbia into erbia and a new oxide ytterbia. In 1878 and 1879 Soret and Cleve separated erbia into three oxides, erbia, holmia and thulia; de Boisbaudran, in 1886, obtained a new oxide, dysprosia, from holmia. In 1906 Urbain claimed the discovery of lutecia in ytterbia. Thus we have scheme (II.).

$$\text{(II.)}\qquad \text{Y}\begin{cases}\text{Y}\\ \text{Er}-\text{Tb}\ \{\ \text{Yb}\begin{cases}\text{Yb}\\ \text{Lu}\end{cases}\\ \text{Tb}-\text{Er}\ \{\ \text{Er}\begin{cases}\text{Er}\\ \text{Ho}\begin{cases}\text{Ho}\\ \text{Dy}\end{cases}\\ \text{Tm}\end{cases}\end{cases}$$

The rare earths possess a valence of three, and with the exception of cerium, do not form salts higher than the type RX_3. A few, like samarium, form a lower chloride RCl_2.

The position of these elements in the periodic system presented a great difficulty, which has been solved by N. Bohr's work. Further, it is clear from Moseley's work on the atomic number (*q.v.*) that all the elements of this series are now accounted for.

For the extraction and separation of the individual members of the group the reader is referred to the following: J. F. Spencer, *The Metals of the Rare Earths* (1911); *J. N.* Friend, *Text-book of Inorganic Chemistry,* vol. iv. (1914, etc.); S. I. Levy, *The Rare Earths* (1915, 1924); J. W. Mellor, *Treatise on Inorganic and Theoretical Chemistry,* vol. v. (1922). (C. J.)

RASCHIG, FRIEDRICH AUGUST (1863–1928), German chemist, was born at Brandenburg on June 8, 1863. He studied at Berlin and Heidelberg, and became assistant in the chemical laboratories at the University of Berlin (1885–87). He became chemist to the Badische Anilin und Soda Fabrik in 1887, and in 1891 started a factory for the manufacture of phenol. He carried out researches on the reactions involved in the lead chamber process of producing sulphuric acid. Raschig discovered a technical method of preparing hydroxylamine, and his researches on chloramine led to his well known process for the manufacture of hydrazine. He was an authority on the distillation of coal tar and the manufacture of synthetic phenol. He died on Feb. 4. 1928.

RASHI (1040–1105), Jewish scholar. RABBI SOLOMON IZHAQI (son of Isaac), usually cited as Rashi from the initials of those words, was born at Troyes in 1040 and died in the same town in 1105. He seems to have passed the decade beginning with 1055 in Worms, where a niche in a wall, where his mother was miraculously saved from death was long shown. Within this, it is said, Rashi was wont to teach. A small edifice on the east of the synagogue is called the "Rashi Chapel," and the "Rashi Chair," raised on three steps in the niche, is one of the objects of the pious admiration of pilgrims. At Worms Rashi worked under Jacob ben Yaqar, and at Mainz under Isaac ben Judah, perhaps combining at the same time the functions of teacher and student.

Rashi was twenty-five years of age when he returned to Troyes, which became a recognized centre of Jewish learning. Here he acted as rabbi and judge; he and his family worked in the vines of Troyes. His learning and character raised him to a position of high respect among the Jewries of Europe, though Spain and the East were long outside the range of his influence. As was said of him soon after his death: "His lips were the seat of wisdom, and thanks to him the Lam, which he examined and interpreted, has come to life again." The latter part of his life was saddened by the massacres in the Rhineland at the time of the first Crusade. Rashi died in Troyes in 1105.

Besides minor works, such as a recension of the Prayer-Book *(Siddur)*, the *Pardes* and *ha-Orah,* Rashi wrote two great commentaries on the whole of the Hebrew Bible and on about thirty treatises of the Talmud. His commentary on the Pentateuch, in particular, has been printed in hundreds of editions; it is still to Jews the most beloved of all commentaries on the Mosaic books. More than a hundred supercommentaries have been written on it. His influence in Christian circles was great, especially because of the use made of the commentary by Nicolaus de Lyra (*q.v.*), who in his turn was one of the main sources of Luther's version. Even more important was his commentary on the Talmud, which became so much the definitive interpretation that Rashi is cited simply as "the Commentator."

BIBLIOGRAPHY.—M. Liber, *Rashi* (1906), published as a memorial of Rashi on the 800th anniversary of his death. Rashi's commentary on the Bible has been iranslated into Latin by Breithaupt (1710–14); and into German (Pentateuch) by Dukes (1833–38) and others. The foundation of recent investigation into Rashi's life is Zunz's *Salomon b. Isaac* (1823), to which I. H. Weiss added much in his (Hebrew) biography (in *Bet Talmud* ii., Nos. 2–10). *See* also Graetz, *History of the Jews* (Engl. trans., vol. iii. ch. ix.). A critical edition of Rashi's Pentateuch commentary was published by A. Berliner (2nd ed., 1905).

RASHTRAKUTA, an Indian dynasty which ruled in the Deccan (*q.v.*) from about A.D. 750 to 973. The Rashtrakuta or Ratta clan are supposed to have held power during the historical blank before the 6th century; but they came to the front in A.D. 750, when Dantidurga overthrew the Chalukya dynasty and made himself ruler of the Deccan. He was succeeded by his uncle Krishna I. (*c.* 760), who completed his conquests, and whose reign is memorable for the execution of the Kailasa, the rock-cut temple at Ellora. His grandson Govinda III. (780–81 j) extended the power of the family from the Vindhya Mountains and Malwa on the north to Kanchi on the south. The next king, Amogavarsha, reigned for sixty-two years. The reign of Krishna III. was remarkable for a war with the Cholas, in which the Chola king was killed on the field of battle in 949. The last of the Rashtrakuta kings was Karka II., who was overthrown by the Chalukyas in 973.

See R. G. Bhandarkar, *Early History of the Deccan* (Bombay, 1884).

RAŠIN, ALOIS (1867–1923), Czechoslovak statesman, was born at Nechanice. While at the university he took an active part in politics, and his abilities as an orator, journalist and organizer brought him into the forefront of the Czech progressive movement. His anti-Austrian activities brought him into conflict with the authorities; he was tried in connection with the "Omladina" affair in 1893 and condemned to two years' imprisonment and the loss of his doctorate. After serving his sentence he gained a prominent position in the Czech Liberal ("Young Czech") party, which he represented both in the provincial diet of Bohemia and in the Austrian Reichsrath. During the anti-Czech persecution in the World War period, Rašin, together with Kramár, was arrested in 1915, charged with treason and condemned to death. The sentence, however, was not carried out, and after the accession of the emperor Karl, Rašin, with other political prisoners, was amnestied. He then took part in the preparations for the revolutionary coup in 1918, which, as a member of the National Committee, he helped to bring about. In the first Czechoslovak Government he became finance minister and rendered inestimable services to his country by freeing the Czechoslovak currency from that of Austria and inaugurating a financial policy which led to the stabilization of the Czechoslovak crown. He described his achievement in a book entitled *Financial Policy of Czechoslovakia During the First Year of its History* (1921, Eng. trans., 1923). In Jan. 1923 he was attacked by a demented youth and died of his injuries six weeks afterwards, on Feb. 16, 1923.

RASK, RASMUS CHRISTIAN (1787–1832), Danish scholar and philologist, was born at Brandekilde, Fiinen, on Nov. 22, 1787. He studied at the university of Copenhagen, and in 1808 was appointed assistant keeper of the university library, and later professor of literary history. In 1811 he published, in Danish, his *Introduction to the Grammar of the Icelandic and other Ancient Northern Languages,* from printed and ms. materials accumulated by his predecessors in the same field of research. The Arna-Magnaean Institution then commissioned him to edit the ms. of the Icelandic *Lexicon* (1814) of Bjorn Haldorson. Rask spent ten years in Iceland, mastering the language and familiarizing himself with the literature, manners and customs of the natives. He was the first president of the Icelandic Literary society, established at Copenhagen early in 1816. In October 1816 Rask left Denmark on a literary expedition, at the cost of the king, to prosecute inquiries into the languages of the East, and collect manuscripts for the university library at Copenhagen. He went first to Sweden, making an excursion into Finland to study the language. Here he published, in Swedish, his *Anglo-Saxon Grammar* in 1817. In his *Essay on the Origin of the Ancient Scandinavian or Icelandic Tongue* (Copenhagen, 1818) he traced the affinity of Icelandic to the other European languages, particularly Latin and Greek. In the same year he brought out the first complete editions of Snorro's *Edda* and Saemund's *Edda.* From Stockholm he went in 1819 to St. Petersburg, and thence through Tartary into Persia, and resided for some time at Tabriz, Teheran, Persepolis and Shiraz. From Persia he went to India and Ceylon. Rask returned to Copenhagen in May 1823, bringing a considerable number of Oriental manuscripts, Persian, Zend, Pali, Sinhalese and others, with which he enriched the collections of the Danish capital. He died at Copenhagen on Nov. 14, 1832.

During the period between his return from the East and his death Rask published in his native language a *Spanish Grammar* (1824), a *Frisic Grammar* (1825), an *Essay on Danish Orthography* (1826), a *Treatise respecting the Ancient Egyptian Chronology* and an *Italian Grammar* (1827), and the *Ancient Jewish Chronology previous to Moses* (1828). Rask's *Anglo-Saxon, Danish* and *Icelandic Grammars* were brought out in English editions by Thorpe, Repp and Dasent respectively.

See his collected essays, *Samlade Afhandlinger* (Copenhagen, 3 vols., 1834–38).

RASLE, SEBASTIEN (1658–1724), French missionary, born at Dôle, studied at Dijon, and for some time taught Greek at Nimes in the seminary of the Jesuit order, of which he was a member. He went out to Canada as a missionary in 1689, and was placed in charge of the station at Norridgewock. He used his great influence with the Indians in the interest of France against England, came into collision with the colonial authorities in New England, and a price was placed on his head. He escaped capture for a long period, but was eventually captured at Fcrt Richmond and was shot. He compiled a dictionary of the Abenaki language.

RASMUSSEN, KNUD JOHAN VICTOR (1879–1933), Danish explorer, was born at Jakobshavn, Greenland, on June 7, 1879. In 1902 he made the first of several expeditions to Greenland and the northern polar regions. Between 1905 and 1924 Rasmussen visited all the extant Eskimo tribes and ascertained that they were originally Red Indian tribes which had wandered east and west from the coast. Rasmussen, whose ancestors in the maternal line were Eskimos, gained a thorough knowledge of arctic peoples and customs and made them the subject of numerous tracts and publications, including *Nye Mennesker* (1905); *Myter og Sagn fra Gronland* (1921) and *Gronland Langs Polhavet* (1919; Eng. trans., *Greenland by the Polar Sea,* 1921).

RASPBERRY, an old and well-known fruit-bearing bush, was known to classic writers and was mentioned by Pliny as a wild fruit called *Idea* from Mt. Ida in Asia Minor on which it grew. Parkinson *(Paradisus,* 1629) speaks of red, white and thornless varieties of raspberries, and its culture began about this time. The raspberries (of the genus *Rubus*) bear juicy red or black (rarely orange, amber or pale yellow) berries which pull off the plant, leaving the receptacle on the stem. This characteristic differentiates the raspberry from the blackberry in which the receptacle picks off the plant.

The raspberry section of *Rubus* probably evolved in eastern Asia, where upward-of zoo species of raspberries are known. In Great Britain and throughout Europe only one species, R. *idaeus*, is known, from which the European cultivated varieties are derived. In the United States and Canada, three species *(R. strigosus,* the red raspberry; *R. occidentalis*, the eastern black raspberry; and *R. leucodermis*, the western black raspberry) are found. American red varieties are derived from *R. strigosus* and hybrids of it with *R. idaeus*. They are much hardier and less prickly than European varieties. Black varieties came from R. *occidentalis*, purple varieties are hybrids of the black and red.

Related edible berries often called raspberries are the two flowering raspberries of the northern woodlands, *Rubus odomtus* and *R. parviflorus;* the Rocky Mountain flowering raspberry, *R. deliciosus;* the salmonberry, *R. spectabilis,* of the Pacific northwest; and the baked-apple berry, R. *chamaemorus,* of the northern bogs, a circumpolar species.

Three other raspberries are grown slightly for their fruit in other parts of the world — the Andes black raspberry, R. *glaucus,* in northern South America, the Southern Asian black raspberry, *R. niveus,* and the wineberry, R. *phoenicolasius*, introduced from northeastern Asia. R. *kuntzeanus* from China has been hybridized with the Cuthbert to give the Van Fleet, and *Rubus biflorus,* also from China, has been hybridized with Latham to give the Dixie, both of these. being varieties adapted to southern U.S.A.

The acreage of red raspberries in Great Britain was reported as 5,401 in 1937. In Scotland the Blairgowrie district is the centre of production; in England, Kent, the eastern counties and Worcestershire are important centres. It is grown in mixed plantings with other fruits, the plants being set 18 in. apart in rows 6 or 7 ft. distant. Lloyd George is the chief variety — having very large berries which are excellent for canning and jam. Red Cross and Pynes Royal are other good varieties.

The acreage of raspberries in the United States was 59,000 in 1939 with a crop value of $7,416,000. Black raspberries are nearly as important as the red. The acreage of purple varieties is small. Important red-raspberry sections are western Maryland, southern New Jersey, the Hudson river valley, western Michigan, near Minneapolis, Minn., the Puyallup valley of Washington, the Willamette valley of Oregon, and the Santa Clara valley of California. The largest acreage of black raspberries is in western Michigan. Smaller sections are in western Maryland, western New York, and the Willamette valley of Oregon. Few plantings in the United States, except in the Hudson river valley, are mixed with other fruits. Good red varieties are Cuthbert and Washington in the Pacific northwest, Ranere in California, Latham for eastern states, except for Sunrise for very early crop in New Jersey and southward, and Taylor and Milton in New York and New England. The Cumberland is the chief black variety. In eastern Canada, Viking and Newman red varieties are widely grown. Sodus and Potomac are desirable purple varieties. Ranere and Indian Summer are red sorts that also bear fruit on the young canes in late summer and fall.

Red raspberries are propagated by suckers which come from the roots of the parent plant. Root cuttings about? in. long are also used for rapid increase of new varieties. Black and purple varieties have arched canes and are propagated by tip layers, the tips of the shoots being buried about 2 in. deep in August and the rooted tips being dug in early spring. Leaf-bud cuttings may be used for the rapid propagation of new black varieties. Red raspberries are usually planted 2½ ft. apart in rows 6 to 9 ft. distant; the black and purple being planted about 4 ft. apart in rows also 6 to 8 ft. distant. Shoots are produced by these plants in spring and summer which bear fruit the following year and then die. These old canes are cut away each year just after the harvest to make room for the new shoots. The new shoots of the black varieties are tipped or cut off at 12 in. to induce branching; those of the purple are cut at 18 to 24 in. These branches are shortened the following winter to about 8 in. for the black and 12 in. for the purple. The canes of the red raspberries are either not pruned or are shortened to 3 to 5½ ft., depending on the variety and vigour. However, surplus suckers should be cut away early in the summer, leaving 7 or 8 of the strongest canes per plant or per 30 in. of row. The stouter the canes of both black and red varieties the more productive they are. Stakes or trellises are commonly used to support the canes of the red raspberry. Two wire trellises with a wire each side of the row about 3 ft. high or with one wire above the other at 30 in. and 54 in. are common types.

Virus diseases, leaf spot, anthracnose, crown gall, wilt and yellow rust are serious diseases, while the red spider mite, crown borer and fruit worms are serious insect pests. (G. M. D.)

RASPE, RUDOLF ERICH (1737–1794), the original author of the *Adventures* of *Baron Munchausen (see* MUNCHAUSEN), was born in Hanover in 1737, and studied at Gottingen and Leipzig. In 1767 he was appointed professor in Cassel, and subsequently librarian. In 1775 he went to Italy to buy curios for the landgrave of Hesse, to whom he was keeper of the gems, and sold the landgrave's valuables for his own profit. On orders being issued for his arrest, he decamped to England. Later he found a patron in Sir John Sinclair of Ulbster, whom he deceived by pretending to discover valuable and workable veins on his estates; but Raspe had "salted" the ground himself, and on the verge of exposure he absconded. He betook himself to Ireland and died at Muckross in 1794. His authorship of *Munchausen* was only revealed in 1824, by the biographer of its translator Burger.

RASPUTIN, GREGORY EFIMOVITCH (1871–1916), Russian monk, was born in 1871 in the village of Pokrovskoe. near Tyumen, in the province of Tobolsk, Siberia. He was the son of a poor peasant whose disorderly behaviour resulted in his being given the name of Rasputin, meaning "debauchee." He received no education, and till the end of his life was unable to write properly. He spent the first part of his life till the age of 33 in his native village; he married in 1895 a well-to-do girl, Olga Chanigoff, and they had two daughters and a son. In 1904 Rasputin resolved to change his mode of living. He left his family and devoted himself to religious exercises, declaring to his people that he was inspired by God. His passionate nature, his great physical strength and the superstitious atmosphere in which he had been brought up, gave an unexpected direction to his religious exaltation. He adopted the views of the sect known under the name of "Khlysty," the leading idea of whose teaching was that salvation could be achieved only by repentance.

"Sin in order that you may obtain forgiveness" — was the practical rule which he drew from this doctrine. "A particle of the Supreme Being is incarnated in me" — he told his hearers. "Only through me you can hope to be saved; and the manner of your salvation is this: you must be united with me in soul and body. The virtue that goes out from me is the source of light, the destruction of sin" (E. J. Dillon, *The Eclipse of Russia).* This extravagant and dangerous teaching, which resulted in practice in the wildest orgies, not only created for Rasputin immense popularity and the reputation of a holy man among his fellow-peasants, but opened before him the doors of some of the most fashionable Russian houses and even those of the Imperial palace. Looking for new experiences Rasputin left his native village, and made long pilgrimages to various holy places, and even went to Mount Athos and Jerusalem. He spent some time in different monasteries and applied himself to the study of holy books, but his lack of elementary education reduced the results of his labours almost to nothing. He only retained by heart some incomprehensible passages, and often used them in his prophecies. He had, however, a strong magnetic power, the influence of which was recognized by his bitterest opponents.

In 1907, during a stay in St. Petersburg (Leningrad), Rasputin was introduced to the archimandrite Feofan, rector of the theological academy and confessor to the empress, who took an interest in the story of his conversion. The archimandrite, with the assistance of the grand duchesses Militza and Anastasia, presented Rasputin at court, and he produced a deep impression on the empress and emperor. The mystic atmosphere which always prevailed at the Russian court and the constant fear for the health of the tsarevich created a favourable background for the appearance of such a man. The eventual improvement in the health of the grand duke Alexis procured for Rasputin a commanding influence over the empress.

For some time Rasputin was satisfied by his social success, and at first he did not interfere in politics. But his activity was felt in church questions. His friendship with the famous monk, Heliodor, and the bishop of Saratov, Hermogen, which resulted in a complete rupture between them and in a series of scandals, had a painful echo in the country. The appointment of Varnava, an illiterate peasant and a friend of Rasputin, to be bishop of Tobolsk in 1911, and the servility with which the Holy Synod followed the wishes of the favourite, provoked a strong opposition among all classes of society. An unsuccessful attempt to kill him, made by a certain Guseva in 1914, incited by the monk Heliodor, only strengthened his influence. No important nomination was made without his approval, and the most unexpected people rose to the highest offices as the result of his influence. Rasputin was t o ignorant to have any opinion on political questions: he was in most cases a mere instrument of the reactionaries. Numberless stories of the debauchery practised at the court, in which the name of Rasputin was coupled not only with some of the court ladies but even with that of the empress herself, became a common topic of conversation in all classes of Russian society. At length a small group of men of the highest social position, which included the grand duke Dimitri Pavlovich, Prince Yussupoff and Purichkevich determined to end the empire of Rasputin. He was invited to a supper at the Yussupoff palace on Dec. 17, 1916, and shot dead, after an attempt at poisoning him with a strong dose of potassium cyanide mixed with wine had not produced the desired effect. The empress had the body transferred to the park of Tsarskoe Selo, where a special chapel was erected, and she went every night to pray on his grave.

See *Letters of the Tsaritsa to the Tsar 1914–16* (1923); and further letters published in *The Manchester Guardian*, Jan. 9 and Feb. 7, 1924; also Prince Yussupoff, *Rasputin: His Malignant Influence* and *his Assassination* (*Eng.* ed. 1927); M. V. Rodzianko, *Reign of Rasputin* (1927); *R.* Fülöp-Miller, *Rasputin, the holy devil* (1928).

RASSAM, HORMUZD (1826–1910), Assyriologist and traveller, was born at Mosul of native Christian parents. His first work was done as assistant to Sir A. H. Layard in his first expedition (1845–47). He then studied at Oxford, and was again sent by the British Museum trustees to accompany Layard in his second expedition (1849–51). Rassam continued the work (1852–54) in Assyria under the direction of the British Museum and Sir Henry Rawlinson at Nimrud and Kuyunjik. In 1866 he was sent by the British government to Abyssinia, where, however, he was imprisoned for two years until freed by the victory of Sir Robert Napier. From 1876 to 1882 he was again in Assyria conducting important investigations, especially at Nineveh, and during the Russo-Turkish War he was sent on a mission of inquiry to report on the condition of the Christian communities of Asia Minor and Armenia. His archaeological work resulted in many important discoveries and the collection of valuable epigraphical evidence.

See *The Times*, Sept. 17, 1910.

RASSKAZOVO (formerly Byelaya Polyana and Arzhenka), the name of two settlements in the Russian S.F.S.R., on the river Arzhenka, a tributary of the Tambov, and on the road and railway between Kirsanov and Tambov, in 52° 42' N., 41° 46' E. Population 25,168. One settlement, formerly called Byelaya Polyana, was noted for its fair in June. Both have cloth factories.

RAS TAFARI MAKONNEN: *see* MAKONNEN, RAS TAFARI.

RASTATT, a town of Germany, in the *Land* of Baden, on the Murg, 15 mi. by rail S.W. of Karlsruhe. Pop. (1939) 17,-503. The old palace of the margraves of Baden, a Renaissance edifice in red sandstone, contains a collection of pictures, antiquities and trophies from the Turkish wars. The chief manufactures are stoves, beer, paper, sugar, furniture and tobacco.

Rastatt has been the scene of two congresses. The first congress culminated in the treaty of Rastatt between France and Austria, signed on March 7, 1714. The second congress, opened in Dec. 1797, was intended to rearrange the map of Germany by providing compensation for those princes whose lands on the left bank of the Rhine had been seized by France but it had no result.

RASTELL (or RASTALL), **JOHN** (*c.* 1475–1536), an English printer and author, belonged to a Coventry family, and was educated for the law. He succeeded his father as coroner at Coventry in 1506. He was also M P. for Dunheved, Cornwall, from 1529 to the time of his death. He began his printing business some time before 1516, for in his preface to the undated *Liber Assisarum* he announced the forthcoming publication of Sir A. Fitzherbert's *Abbreviamentum librorum legum Anglorum,* dated 1516. In that year he undertook an expedition to America, but got no further than Ireland when his sailors left him. Among the works issued from the "sygne of the meremayd at Powlysgate," where he lived and worked from 1520 onwards, are *The XII. Mery Gestys of the Wydow Edyth* (1525), and *A Dyaloge of Syr Thomas More* (1529). The last of his dated publications was *Fabyl's Ghoste* (1533), a poem. In 1530 he wrote, in defence of the Roman doctrine of Purgatory, *A New Boke of Purgatory* (1530), dialogues on the subject between "Comyngs and Almayn a Christen man, and one Gyngemyn a Turke." This was answered by John Frith in *A Disputacion of Purgatorie.* Rastell replied with an *Apology against John Fryth,* also answered by the latter. Rastell had married, at some time before 1504, Elizabeth, sister of Sir Thomas More, with whose Catholic theology and political views he was in sympathy. More had begun the controversy with John Frith, and Rastell joined him in attacking the Protestant writer, who, says Foxe (*Actes and Monuments,* ed. G. Townsend, vol. v. p. 9), did so "overthrow and confound" his adversaries that he converted Rastell to his side. Separated from his Catholic friends, Rastell does not seem to have been fully trusted by the opposite party, for in a letter to Cromwell, written probably in 1536, he says that he had spent his time in upholding the king's cause and opposing the pope, with the result that he had lost both his printing business and his legal practice, and was reduced to poverty. He was imprisoned in 1536, perhaps because he had written against the payment of tithes. He probably died in prison, and his will was proved on July 18, 1536.

Rastell's best-known work is *The Pastyme of People, the Chronycles of dyvers Realmys and most specially of the Realme of England* (1529), a chronicle dealing with English history from the earliest times to the reign of Richard III., ed. T. F. Dibdin (1811). His *Expositiones terminorum legum Angliae* (in French, trans, into English, 1527; reprinted 1629, 1636, 1641, etc., as *Les Termes de la Ley*), and *The Abbreviacion of Statutis* (1519), of which 15 editions appeared before 1625, are the best known of his legal works.

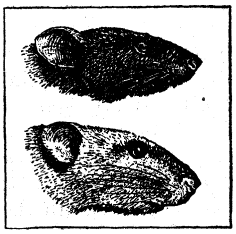
To Rastell is generally attributed the morality play, *A new Interlude and a Mery of the IIII Elements* (*c.* 1519). The fullest details available on John Rastell's life are in A. W. Reed, *Early Tudor Drama* (1926). For the books issued from his press *see* a catalogue by R. Proctor, in *Hand-Lists of English Printers* (Bibliographical Soc., 1896).

RASTELL, WILLIAM (*c.* 1508–1565), English printer and judge, son of the preceding, was born in London about 1508. At the age of 17 he went to the university of Oxford, but did not take a degree, being probably called home to superintend his father's business. The first work which bears his own imprint was *A Dyaloge of Sir Thomas More* (1531), a reprint of the edition published by his father in 1529. He also brought out a few law-books, some interludes ascribed to John Heywood (*q.v.*), an edition of *Fabyan's Cronycle* (1533), and *The Apologye* (1533) and *The Supplycacyon of Soulys* of his uncle Sir Thomas More. He became a student at Lincoln's Inn on Sept. 12, 1532, and gave up the printing business two years later. In 1547 he was appointed reader. On account of his Catholic convictions he left England for Louvain; but upon the accession of Mary he returned, and was made serjeant-at-law and treasurer of Lincoln's Inn in 1555. His patent as judge of the Queen's Bench was granted on Oct. 27,1558. Rastell continued on the bench until 1562, when he retired to Louvain where he died on Aug. 27, 1565.

It is difficult to distinguish between the books written by William and those by his father. The following are believed to be his: *A Colleccion of all the Statutes* (1559), *A Table collected of the Yeares of the Kynges of Englande* (1561), both frequently reprinted with continuations, and *A Colleccion of Entrees, of Declarations, etc.* (1566), also frequently reprinted.

RASTENBURG, a town in the province of East Prussia, Germany, on the Guber, 64 mi. S.E. of Konigsberg by the railway to Lyck. Pop. (1939) 19,494. Its principal manufactures are flour, sugar, oil, beer and machinery.

RAT, probably in its original sense the designation of the British rodent known as the black rat (*Mus rattus*), but also applied to the brown or Norway rat (*M. norvegicus*), and in a wider sense to all the larger representatives of the family Muridae.



ABOVE: BLACK RAT (MUS RATTUS); BELOW: BROWN RAT (MUS NORVEGICUS)

Rats have more rows of scales on the tail (reaching to 210 or more) than mice, in which the number does not exceed 180. For the distinctive characteristics of the family Muridae *see* RODENTIA. Of the two British species the brown or Norway rat (M. *norvegicus*) is distinguished by its large size, brownish grey colour, short tail and ears, stout skull, and the possession of from 10 to 12 teats. It is fierce and cunning, and overcomes all allied species with which it is brought in contact. Its original home would seem to have been some part of Central Asia. Thence it has spread to all parts of the world, driving out the house-haunting species everywhere, as it has in England all but exterminated the black rat. The brown rat migrated westwards from Central Asia early in the 18th century, and is believed to have first reached Great Britain about 1730. Its already evil reputation has been increased of late years by the fact that it is a disseminator of bubonic plague. Black phases are not uncommon. The black rat (M. *rattus*) is distinguishable from the brown rat by its smaller size, longer ears and tail, and glossy black colour. It shares the roving habits of the latter, frequenting ships and by these means reaching various parts of the world. On this account it is common in many places to which the brown species has not yet penetrated, for instance in South America. This long-tailed rat, originally a native of India, would seem to have first penetrated to all parts of the world and to have nearly exterminated the indigenous rats. After this followed the advance of the more powerful brown rat. The black rat first reached Europe in the 13th century. The Isle of Dogs and Yarmouth, in Norfolk, are the chief of the English strongholds of the black rat. Both species agree in their predaceous habits, omnivorous diet and great fecundity. They bear, four or five times in the year, from four to ten blind and naked young, which are in their turn able to breed at an age of about six months; the time of gestation being about twenty days.

See J. G. Millais, "The True Position of *Mus rattus* and its Allies," *Zoologist*, June 1905; M. A. C. Hinton "Rats and Mice; Enemies of Mankind," *Brit. Mus. Pamphlets.*

RATAFIA. A liqueur or cordial flavoured with peach or cherry kernels, bitter almonds, or other fruits; many different varieties are made. The same name is given to a flavouring essence resembling bitter almonds, and also to a light biscuit.

RATCHET AND PAWL is an important mechanical device in a great many machines and appliances, enabling a movement to be effected in one direction, with slip or freedom in the opposite direction. The mechanism is used to lock something so that it cannot slip or reverse, to hold a load as in a winch, or to give a positive feed. Some ratchets are straight, or with a moderate curve, but the majority are circular. The teeth are usually V-shaped, and the pawl is pivoted so that it drops against any tooth and remains without danger of jumping out. Where a continuous movement is desired. the objectionable clicking of the pawl may be checked by a leather facing, or by the use of a ball or roller, or a set of these, to catch in the teeth, with gravity or spring action to ensure engagement. In the case of a silent ratchet, the wheel has no teeth but an eccentrically-pivoted pawl works frictionally against the periphery.

Various drives and brake mechanisms are made safe by ratchet mechanism, the ship's capstan being one of the oldest examples. Screwdrivers and wrenches are operated by ratchet for access in difficult situations, or to help the worker in manipulative power. Braces and metal drills are actuated by ratchet when it is not possible to make the complete revolution of a handle. So also are jack screws for lifting loads rapidly. Ratchet feed, by which an arm holding the pawl is moved over, and the ratchet-wheel and a feed screw are turned, is utilized in many types of machines and is usually automatic in action. The finest example occurs in cylindrical grinding machines, in which by means of an automatic feed the grinding-wheel travels along a shaft or spindle, the ratchet mechanism setting the wheel to cut a very little smaller before each traverse takes place, this process being repeated as often as is necessary to bring the shaft to size.

RATE. In England the term is specially applied to the levying of public money contributions for local purposes, as distinguished from the "taxes" raised for what are treated as general State purposes. By the Rating and Valuation Acts of 1925 and 1928 the English system of rating has been amended and the law partially consolidated as also for Scotland by the Rating Act, 1926, and the Rating (Scotland) Amendment Act, 1928. In the United States the term "rate" does not signify a form of taxation, but is used to indicate the assessment percentage. (*See* further POOR *LAWS*; UNITED KINGDOM: *Local Government*; TAXATION.)

RATEL or **HONEY-BADGER,** the name of certain Indian and African small clumsy-looking creatures of the size and appearance of badgers, representing the genus *Mellivora* in the family Mustelidae (*see* CARNIVORA). Two species of ratel are commonly recognized — the Indian (M. *indica)* and the African (*M. ratel*), which ranges over Africa; but a black ratel from the Ituri forest has been separated as M. *cottoni*. Both the two former are iron-grey on the upper parts and black below, a style of colouration rare among mammals. The body is stout and thickly built; the legs are short and strong, and armed, especially the anterior pair, with long curved claws; the tail is short; and the ears are reduced to rudiments. The Indian ratel is found throughout India, chiefly in hilly districts, but also in the north of India in alluvial plains. It lives usually in pairs, and eats rats, birds, frogs, white ants, and various insects. Like its Cape congener it occasionally partakes of honey and is often destructive to poultry. In confinement the Indian ratel becomes tame and even playful.

THE RATEL (MELLIVORA INDICA), OR HONEY BADGER

RATHENAU, WALTHER (1867–1922), German statesman and industrialist, was born in Berlin on Sept. 29, 1867, the son of Emil Rathenau, the founder of the Allgemeine Elektrizitats-Gesellschaft. After studying philosophy, physics and chemistry at Berlin and Strasbourg he graduated in 1889, and spent a year studying machine structure and chemistry at Munich. He was then engaged as a civil engineer by the Aluminium Industrie A.-G. of Neuhausen, Switzerland.

In 1893 he became a director of the Electrochemische Werke (Limited) at Bitterfeld for the utilization of a process for making chlorine and alkalis by electrolysis. He also built large works at Rheinfelden, in Russian Poland, and in France, and elaborated processes for the production of ferrosilicate, chrome, soda and magnesia. In 1899 Rathenau became a director of the Allgemeine Elektrizitats-Gesellschaft, and built central stations at Manchester, Amsterdam, Buenos Aires and Baku. In 1902 he belonged to the board of directors of about 100 enterprises. During 1907 Rathenau accompanied Dernburg, the Secretary of State of the Imperial Colonial Office, to German East and West Africa, and also visited the British Colonies in Africa. His *Reflexionen* (1908) contain his two final reports on those visits.

Even at the beginning of the World War Rathenau foresaw the threat to the German supply of raw materials involved by the British blockade. In an astoundingly short time, with the acquiescence of the War Minister von Falkenhayn, he established a huge organization for the administration of the war raw materials then at Germany's disposal. This Board of the War Ministry, called the *Kriegsrohstoff-Abteilung,* which he left in splendid working order to his successor on March 31, 1915, alone made it possible for Germany to hold out with raw material.

After his father's death in the summer of 1915 Rathenau was made president of the Allgemeine Elektrizitats-Gesellschaft. He published *Von Kommenden Dingen* (Eng. trans. *In Days to Come),Eine Streitschrift vom Glauben* and *Vom Aktienwesen.* In 1918 his collected works were published. After the War Rathenau endeavoured to found a middle-class Democratic Party which should bridge the gulf between the middle classes and labour caused by the revolution, and in this way to restore national unity. In 1919 he participated in the preliminary preparations in Berlin for the Conference of Versailles. From April 1920 to May 30, 1921 Rathenau was a member of the so-called "Socializing Commission" convoked by the newly founded *Reichswirtschaftsrat* to discuss the question of nationalizing the coal-mines.

He was government expert at the Spa conference of July 1920, and in the spring of 1921 took part in the preliminaries to the London Conference. At the end of May 1921 he was asked by the chancellor Wirth to join the Government. The two leading men of the Cabinet thus formed, Wirth and Rathenau, were united by trust and friendship. The combination of the chancellor's original and impulsive nature, his courage and love of responsibility, was a happy blend with Rathenau's far-sighted and extraordinary capability. Rathenau co-operated in the final conclusion of the Peace Treaty with the United States of America in Aug. 1921. As Minister of Reconstruction he concluded with Loucheur, the French Minister of the Liberated Regions, the Wiesbaden agreement, securing to France the privileged supply of deliveries in kind as reparation payment, which helped to relax the tension between France and Germany. But the disruption of the Upper Silesian coal and iron district, quite contrary to the German reading of the Versailles Treaty and to the result of the plebiscite, provoked Rathenau to resign from the Cabinet by way of protest. He did not withdraw his support from the Cabinet, however, and went, in Nov. and Dec. 1921 to London, to enlist England's interest and understanding, and to secure a British loan for the next reparation instalment. This loan was refused on technical grounds But in England Rathenau came in touch with members of the British Government. Under his influence arose the famous Lloyd George "Chequers scheme," which gave a practical form to the idea of a "United States of Europe" by proposing the reconstruction of Russia through the united economic forces of the other great European Powers, including Germany. The ideas underlying the later Pact of Locarno (1925) were also discussed. In Paris Rathenau found less support. Nevertheless, the project discussed at Chequers led to the conference of Cannes (Jan. 1922), where Rathenau, in an eloquent speech, exposed the impossibility of the London reparation demands and secured an essential diminution of the reparation payment of 1922.

Meanwhile, at the wish of the chancellor, Wirth, Rathenau had re-entered the Cabinet, this time as Minister for Foreign Affairs. The Genoa negctiaticns did not, unfortunately, lead to a united European work of reconstruction. But separate negotiations between British and French representatives took place with Russia to the exclusion of Germany. Rathenau, fearing that German interests would suffer, accepted on April 16, 1922 at Rapallo the Treaty of Peace and Friendship offered by the Russians, cancelling all reciprocal demands which had accrued from the War.

The climax of his endeavour to replace blind hatred by reason was shown in his great speech in Genoa on May 19, 1922, which ended with the cry of Petrarch: *"Pace—Pace—Pace!"* The question of the alleged War guilt of Germany was one that Rathenau had greatly at heart. He furthered the publication of the pre-War documents.

The effects of the inflation of the currency on the impoverished middle classes caused him the greatest anxiety, and he secured many relief measures. Yet he fully realized that German industry, when inflation ceased, would be faced with extraordinary dangers; but that the development of reparation payment in kind and the treaty with Russia would at least ensure some work for industry in the impending hard times of recovery.

Rathenau, however, was not to see the fulfilment of his plans. On his usual morning drive from his house to the Foreign Office on June 24, 1922 he fell a victim to the bullets and hand-grenades of misguided young Germans, who by this deed robbed their country, not only of a great philosopher and industrialist, but of one of their most fervent patriots and of the best Foreign Minister of that time.

In philosophy Rathenau was an idealist. Adopting the evolutionary theories of Leibniz and Darwin, he saw the development of man's purpose in three stages — first, prehistoric man wholly guided by instinct, then historical man led by intellect and conscious purpose, and lastly the man of the future whose fulfilment will be in the kingdom of the soul. "The soul is no weapon," says Rathenau. It thus stands in contrast to the whole spiritual world of instinct and purpose resulting from the struggle of life. In the social world, whilst believing in an aristocracy of the mind, he realized that democracy was necessary to consolidate the crumbling foundations of the society of his day. A capitalist by birth and training, he held without repudiating his creed, that in countries like Germany, carrying the burden of a dense population, "Consumption, like all enormous activities, is not an individual but a communal affair"; "The equalization of property and income is prescribed both by ethics and by economics"; "The extant sources of wealth are: monopolies in the widest sense, speculation and inheritance"; "The restriction of the right of inheritance, in conjunction with the equalization of popular education at a higher level, will throw down the barriers which now separate the economic classes of society, and will put an end to the hereditary enslavement of the lower classes."

Rathenau's collected works (5 vol.) were published in 1925. The following were not included and appeared separately *Die Neue Wirtschaft* (1918); *An Deutschlands Jugend* (1918); *Zeitliches* (1918); *Nach der Flut* (1919); *Der Kaiser* (1919); *Der Neue Staat* (1919) (Eng. trans. *The New Society*); *Krit. der dreifachen Revolution* (1919); *Die neue Gesellschaft* (1919); *Autonome Wirtschaft* (1919); *Was wird werden?* (1920); *Demokr. Entwicklung* (1920); *Albert Kollmann* (1921); *Reden* (1924); *Briefe* (1926); H. Kessler, *Walther Rathenau, sein Leben und sein Werk* (1928, English trans. *Walther Rathenau*, 1929) The *Rathenau Stiftung* (Berlin), founded after his death, collects all bibliographical material. (F. SI.)

RATHENOW, a town in the Prussian province of Brandenburg, Germany, on the Havel, 45 mi. W.N.W. of Berlin. Pop (1939) 33,531. Rathenow was incorporated as a town in 1295. In 1394 it was taken and partly destroyed by the archbishop of Magdeburg. It suffered much from the ravages of the Thirty Years' War. The Protestant church of St. Mary and St. Andrew, originally a basilica, was transformed to the Gothic style in 1517–89.

RATIBOR (Polish *Raciborz*), a town of Germany, in the Prussian province of Silesia, situated on the left bank of the Oder at the point where the river becomes navigable, 97 mi. S.E. of Breslau by rail, on the main line to Oderberg. Pop. (1939) 49,085. Ratibor, which received municipal privileges in 1217, was formerly the capital of an independent duchy, 380 sq.m. in extent, which existed from 1288 to 1532, and afterwards passed successively into the hands of Austria and Prussia. In 1821 a small mediate principality was formed and was conferred upon the landgrave of Hesse-Rotenburg, as compensation for some Hessian territory absorbed by Prussia. In the partition of Upper Silesia between Germany and Poland in 1921 (*see* SILESIA) Ratibor was retained by Germany. The most prominent buildings are the law-courts and the chbteau on the right bank of the Oder.

RATIOCINATION, a term used in logic and psychology for those processes by which the mind proceeds from general to particular truths. The steps involved in ratiocination may perhaps be most clearly seen in the form of reasoning followed in the syllogism. (*See* SYLLOGISM.)

RATIONALISM is that trend of philosophy which intercedes for the rights of "natural reason" and sees in it the source of all truth. Common to all the historical forms of rationalism is the belief in the "autonomy of thought," *i.e.,* the view that thought can discover by its own strength, without support from a supernatural revelation and without appeal to sense perception, a system of "eternal truths," a system presented to thought within its own realm and comprehended by thought as necessary.

In the theoretical field there are certain "innate ideas" which form the basis of all certainty and from which all specific proofs are derivable by logical inference. The same is true also of practical consciousness. Beside the theoretical, especially logical and mathematical, truths, there are ethical truths which can be comprehended with certainty as unconditional obligations or imperatives of action.

Early History. — This fundamental conviction found its clearest expression in the Stoic doctrine of the κοιναὶ ἔννοιαι (notitiae communes), as it is developed in the writings of Cicero. From here it exercised a lasting influence. In modern philosophy this influence first appears within the religious sphere, in which also the terms "rationalism" and "rationalist" seem to have originated, and where they designate the assumption that there cannot be an insurmountable conflict between the "natural" cognition of reason and the "supernatural" truth of revelation.

Thus, in English religious philosophy of the 16th and 17th centuries, for instance, those are called "rationalists" who consider reason the highest authority not only in science but also in matters relating to religion and society. (Cf. Lechler, *Geschichte des englischen Deismus,* p. 61.) Also in the Netherlands it was customary at that period to distinguish between "rational" and "non-rational" theologians. (*Cf.* Bayle, *Dictionnaire historique et critique.*) In the introduction to his *Théodicée,* in the "Discours de la conformité de la foi avec la raison," Leibniz gave an outline of the development and significance of "theological rationalism."

It was especially in England and through Herbert of Cherbury (1581–1648) that religious rationalism received its complete foundation and its clear formulation. In his two works *De veritate* (1624) and *De religione gentilium* (1645), Herbert of Cherbury starts from the assumption that reason possesses in itself the capacity for all truths, including religious and moral ones. Beside reason, there is no other higher authority; for even revelation can claim validity only because its content harmonizes with the principles of rational knowledge. The dogma of original sin, or the corruption of reason through the fall of man, is unconditionally rejected by Herbert. In every healthy and reasonable person there are universal and innate truths, by which our earthly mind, implanted as it were, from heaven, is enabled to participate in the recognition of things of God and of moral good. From the sphere of religion this doctrine passes to the science of law (doctrine of "natural law"); to the theory of the State (doctrine of "raison d'état," of the foundations of international law, etc.), to ethics ("autonomy" of morals). In its totality it represents the new "natural system of the sciences of mind" which, since the Renaissance, unfolds itself steadily and supercedes the mediaeval view of the world, which was theological and hierarchic.

Modern Science.—The strongest support was given to this movement by the new achievements of natural knowledge through the great scientists of the 17th century, Copernicus, Galilei, Kepler and Descartes. The new science rests on the basis of mathematics, and it recognizes as "clear and distinct" only what can be expressed in mathematical form. All such cognitions have this in common: that they go back to certain major premises, to "axioms" and "principles" which can be comprehended by reason as universal and necessary, as a priori propositions. Thus, according to Galilei, Truth is written in the great book of Nature, but only he can read it who can decipher the letters in which it is written. These letters, however, are the terms of mathematics, especially of geometry: the concepts of the straight line, the circle, the sphere, etc. None of these concepts is derived from experience; the mind rather takes them "from itself" in order to apply them to sense-perceptions. In the same way, Kepler considers the ideas of number and magnitude as "innate ideas," not drawn from experience but required for the scientific investigation of nature. (Cf. Cassirer, *Das Erkenntnisproblem,* 3rd ed., I., p. 328 sqq.) Descartes enlarges this view by setting forth a system of universal concepts of reason which are obtained by mental analysis from a contemplation of certain fundamental, logical and mathematical, relationships, and which can be applied to all empirical data. These concepts are valid—as he expounds in Le *monde*—not alone for the actual world but for all possible worlds, so that, in understanding by means of them every effect from its cause, we can obtain a priori knowledge of the universe as a whole. As instances of such fundamental concepts, Descartes cites primarily the concept of *Being,* then also the ideas of *Number* and *Time,* of Space, Figure and Motion (Oeuvres, ed. Adam-Tannery, III., 665).

As a middle term for making the transition from the rational to the empirical, from the "possible" to the "actual," a metaphysical idea is used by Descartes as well as by Kepler. The actual world must correspond to the supreme laws of reason, because it is the work of an infinite mind, because it is a creation of the divine intellect. The applicability of pure mathematics to physics, to the concrete phenomena of nature, seems explainable only on this presupposition. It is valid because nature itself is the product of a "divine mathematics": *cum* Deus *calculat, fit mundus.*

For Leibniz, too, there is a continuous harmony between "truths of reason" and "truths of fact," between the empirical and the rational world. The pure laws of thought as exhibited in logic, arithmetic, geometry and abstract dynamics, apply to all objects in nature, and to all changes taking place therein.

This metaphysical rationalism is further developed by Leibniz so that the eternal truths of reason constitute the essence of the divine mind, and God, therefore, cannot desert them in his activity, in his creation. Creation consists in transition from "essence" to "existence," from the "possible" to the "actual."

Leibniz developed this view of rationalism in two directions. It determines, first of all, the entire structure of his metaphysics; it forms the logical and methodical basis of his *monadology.* The system of "monads," *i.e.,* of perceiving minds, is graded, according to Leibniz, in such a way that each monad resembles the others as regards the content of its perception; for each of them represents and reflects the total universe from a definite angle. Accordingly, the difference between the various minds can consist in nothing other than the form of perception, the greater or lesser degree of clarity. Hence a gradation from the dim and confused mode of perception, such as we must assume, for instance, in plant or animal consciousness, up to the divine cognition which consists in completely distinct and adequate ideas. Human knowledge lies in the middle between the two extremes; it knows "confused" ideas, *e.g.,* those of sense-qualities, as well as "distinct" ideas, *e.g.,* those of logic and mathematics.

However, its specific task consists in referring progressively the former to the latter, in transforming all data into pure objects of thought, all merely factual presentations into notions continuously connected by proof and thus conceived by reason. This task can be accomplished in detail only by presupposing a general system of the possible forms of thought and of the universal laws of connection which those forms obey. Leibniz attempted to satisfy this demand in the grandiose outline of his "general characteristique" in which the primary elements of all cognition were to be set forth in conjunction with the demonstration of a method by which all truths, however complex, could be exhibited as combinations of those primary elements. Through this outline of his "general characteristique," Leibniz became the founder of that "symbolic logic" which reached its complete development only in the nineteenth century through the works of Boole and Schroder, of Peirce and Peano, of Whitehead, Frege and Russell. (Cf. Couturat, La Logique de Leibniz, 1901.)

In the eighteenth century, on the other hand, philosophical rationalism became dominant only in that more limited form which it had received in the system of Christian Wolff (1679–1754). Wolff's doctrine, too, rests entirely on the distinction between contingent "truths of fact" and necessary "truths of reason": he, too. contends that the specific task of cognition, especially the task of philosophical knowledge, consists in transforming all contingent elements into rational ones by understanding them according to the principle of sufficient reason.

Consequently, we cannot claim a philosophic insight into a region of facts unless we succeed in bringing the factual details into a rational order so that each member can be completely understood from the context and from the necessary laws which determine this context. Accordingly, Wolff supplements each form of empirical cognition by a corresponding "rational" form. The propositions, for instance, which in the field of physics result directly from observation and from experiments, must be raised to the rank of genuine cognitions of reason by being deduced from the principles of general ontology and general cosmology. Specifically, Wolff's system is subdivided into Logic as the doctrine of the operations of the understanding in general, into Ontology as the doctrine of Being and its most universal determinations, Cosmology as the doctrine of the world, of the simple substances and their combination, Psychology, Theology, and, finally, universal Teleology, the doctrine of ends in general and of the end of human action in particular.

Kant.—It is against this rationalism of Wolff that the attack of Kant is directed in the Critique of Pure Reason. In the section on the "transcendental dialectic," he demonstrates the fact that, and the reason why, a rational psychology, a rational cosmology, a rational theology, such as Wolff had planned and developed, are impossible. The decisive ground for this impossibility lies, according to Kant, in the fact that mere reason does not suffice for the cognition of absolute Being, of God, Soul and World. Soul, God and World are transcendental "ideas"; but reason becomes involved in insoluble contradictions as soon as it tries to "hypostasize" these ideas; *i.e.,* as soon as it takes them for transcendent objects, for objects beyond all possible experience. All that reason can reach, lies within the boundaries of experience itself; it cannot recognize the nature of things in themselves, its sole task in theoretical cognition consists in "spelling phenomena in order to be able to read them as experiences."

The *metaphysical* rationalism of the dogmatic systems, as it is to be found in Descartes and Spinoza, Leibniz and Wolff, is thus opposed by the new attitude of critical rationalism. The latter, too, retains the fundamental idea of the older rationalism; namely, that reason can recognize completely only that which it can produce according to its own design—"that we know a priori only so much of things as we ourselves put into them." (*Critique of Pure Reason*, 2nd. ed.; p. 18.) But this kind of "construction" is possible only in so far as we deal not with things-in-themselves, independently of all possible experience, but with experience itself and the conditions of its possibility. The understanding is able to recognize a priori and, as it were, to anticipate the *form* of experience in so far as it constitutes this form. It is, itself, "the legislation for nature"—but only in so far as we understand by "nature" not the subsistence and constitution of absolute objects, but the order and regularity of empirical phenomena. Thus rational cognition becomes fruitful only where, instead of dwelling in the world of "noumena," it concerns itself with phenomena. The characteristic of these, however, is that they form a spatio-temporal manifold. All efficacy of the "pure concepts of understanding" is, therefore, necessarily confined to space and time, to the forms of "pure intuition." Only in connection with pure intuition does cognition by understanding or cognition by pure reason receive a real content

This fundamental idea of Kant's critical rationalism is more explicitly developed in his doctrine of the "schematism of the pure concepts of understanding." The categories of thought are merely directions for establishing certain relationships; but these directions need to be referred to sensuousness. Thus, the concept of substance, for instance, does not mean the Being-in-itself as *such* (as conceived by Spinoza), but the persistence of an object *in time*, and it immediately loses all possibility of application when we abstract from the order of time. In general, the "schemata" of the pure concepts of understanding are nothing but "determinations a priori of time according to rules," and these schemata are "the true and only conditions for securing for our concepts of understanding a reference to objects, *i.e.*, significance. The categories are, therefore, only of empirical use, inasmuch as they merely serve to subject phenomena to general rules of synthesis and thus make them fit for coherent correlation in experience." (*Critique of Pure Reason*, 2nd ed., p. 185.) Kantian rationalism, in other words, does not aim at the "existence of things," but at the form of experience itself, at the order and connection of phenomena. (*Cf.* TRANSCENDENTALISM.)

The mistake of Empiricism consists in overlooking the intellectual factor which is indispensable for any cognition of objects; the mistake of Rationalism consists in over-estimating this factor, in isolating it from the sensuous conditions upon which its applicability depends. "Leibniz *intellectualized* the phenomena, just as Locke altogether *sensualized* the concepts of understanding, *i.e.*, regarded them as nothing but empirical or abstracted concepts of reflection." (*Critique of Pure Reason*, 2nd ed., p. 327.) In this form of *critical* rationalism, the original problem from which the *scientific* rationalism of the Renaissance had started, is restated; but it is now solved in a new sense. The scientific rationalism of Kepler and Galilei, too, asserted that "experience is possible only through the representation of a necessary connection between perceptions." (*Critique of Pure Reason*, 2nd ed., p. 218.) But it was able to explain this necessity only by founding it on a metaphysical proposition, namely, the contention that the world itself is the work of an infinite intellect. Kant removes this dependence of rationalism upon a proposition of dogmatic metaphysics: he treats the truth of experience as self-sufficient, although its form and order are based on the general orderliness of the understanding, without which they would be impossible.

RATIONALIZATION OF INDUSTRY. This term would appear to have come first into common use in Germany in the post-war years of inflation and economic derangement to denote the type of organization and leadership under which, it was in some quarters contended, German industries must more than ever be arrayed in order to stand firm against threatening dissolution. As post-armistice depression settled upon the great industries of other countries the same idea was thrust to the fore and the term "rationalization" crept into the terminology of industrial re-organization.

World Economic Conference.—In the report of the World Economic Conference of 1927 rationalization is taken to mean "the methods of technique and organization designed to secure the minimum waste of either effort or material." It includes the scientific organization of labour, standardization of both material and products, simplification of processes, and improvements in the system of transport and marketing. The conference considered that one of the principal means of increasing output, improving conditions of labour, and reducing costs of production, was to be found in "rational organization of production and distribution," the judicious and constant application of which was "calculated to secure (1) to the community greater stability and a higher standard in the conditions of life, (2) to the consumer lower prices and goods more carefully adapted to general requirements, (3) to the various classes of producers higher and steadier remuneration to be equitably distributed among them."

If this were all that rationalization implied and entailed nothing would remain but to recognise a new name for a familiar and excellent thing and to continue with redoubled effort the good work that has been going forward for decades past along these salutary lines. But something more revolutionary is involved.

Control of Industry.—Broadly conceived, rationalization is the bringing of the whole of an industry under intelligent direction and administration. It implies a conception of industrial organization and control radically different from that which prevailed in the last century, under which it was regarded as normal that the output, prices, and evolution of an industry should be at the mercy of demand interacting with supply through the machinery of competition between the independent firms of which the industry was comprised. (*See* COMPETITION.) It implies the conception of an industry as an organic body, with each separate establishment a corporate part of the whole, no longer expending energy in internecine conflict, but working together to a common policy and programme laid down by a directorate in whom absolute authority over the industry as a whole has been reposed. Regarded aggressively, it implies an industry presenting a united front to the handlers, carriers and users of its goods. Regarded constructively it implies the organization of an industry as a corporate whole in such manner as to eliminate "friction, waste and slip," to bring the technique and machinery of all establishments to the level of the best; and, most of all, to order the capacity, output, selling activities, and prices of the industry as a whole in accordance with what are deemed to be the present and future needs of the market and the highest interests of the industry itself in the industrial, social and political complex in which it has its being.

Monopoly Aspect.—The bringing together of the disparate units of an industry into such an organization can be effected in three main ways; by the voluntary association of independent firms for policy purposes (*see* ASSOCIATIONS, INDUSTRIAL); by the centralised control of quasi-independent firms under some form of holding company; and by outright amalgamation. Obviously such thorough-going organization and administration as is indicated above cannot be made effective unless the whole, or a predominant part of the whole, industry is ranged under the centralised direction. The organization, in other words, must have a more or less complete monopoly, and one of the major social and political problems that "rationalization" brings in its train is the curbing of the power of monopoly should that power be used to the detriment of consumers and of the public generally.

The conception of "rationalized" industries has much in common with that of industrial guilds, which were the subject of much forceful advocacy during the post-war reconstruction period. The rationalization of industry is also hardly to be distinguished, in many of its promised advantages, from the "nationalization of industries" which has figured for so long on the socialist programme. (*See* SOCIALISM.) But it differs fundamentally from both these on the question of who shall be in control. Rationalization envisages the retention, with no radical change, of the capitalist order. The ultimate control of the industry is vested, not in a democratic electorate of all those engaged in the industry, and not in a Government department, but in the shareholders and other financiers of the combined enterprises. Proposals for associating the workpeople with the internal management and with the fortunes of the separate or combined undertakings by means of works committees, workmen's representatives on the board, and schemes of profit-sharing and co-partnership do not essentially alter this fact; nor does the probability that such organization will find it wise to keep on good terms with the political power shift sensibly the nominal seat of industrial power. From this aspect flows two important considerations; one as to the manner in which the nominal control of the stock-holders and other financiers (including the banks) will find expression in the policy of the central directorate and the type of administrator that will be thrown up; and the other the attitude of the workpeople to the form and policy of the organization.

Attitude of Trade Unions.—From the latter standpoint much interest attaches to the approaches made towards the end of 1927 by Sir Alfred Mond (Lord Melchett) head of the great chemical consolidation, on behalf of a body of employers identified with rationalization aims; to the General Council of the Trades Union Congress, the response of that organization, and the conferences that subsequently took place. The declared view of the Trade Union movement, as expressed in the course of these conferences, is that while rationalization can never prove an alternative to nationalization the movement was prepared to welcome and support such changes in the organization of industry during the period of private ownership as would lead to improvements in the efficiency of industry, and to the raising of the standard of living of the people.

RATIONING, a term of military origin, indicating the apportionment to each member of a population or of an army of his due share of the available supplies. As usually understood, the process of "rationing" is associated with the distribution of commodities in a time of shortage.

A complete and effective system of rationing involved the control of commodities at every stage from the source of supply to the consumer. Rationing proved to be a twofold problem, positive in the securing and conserving of supplies, negative in the prevention of injustice, waste and fraud. The consumer saw only a small part of a complex and far-reaching organization. The economic order of the operations is: (1) Supply; (2) distribution to localities; (3) distribution to consumers or rationing.

During the World War two distinct rationing plans were evolved, by Germany and Great Britain respettively. Other countries adopted one or other of these schemes, with more or less modification.

The Central European Systems.—In September, 1914, the general commanding in Brandenburg assumed control of all cereals, and, before the end of the year, bread cards had appeared in many German cities. By the early days of 1915, all bread cereals in Germany were under official management. The method adopted to deal with supplies and distribution gives the keynote for all the Central European efforts at rationing. The control of bread was quickly followed by that of practically every article of daily consumption. The German scheme was based on the local control of consumption, and this reposed on a supply in the main nationally controlled. Distribution and control were largely conditioned by the existing machinery of local government, with its regular gradation from the Reich to the Commune.

Taking the control of bread cereals as an example, the system may be thus described: The consumer was provided with a card, with dated and numbered sections, and the appropriate section was cancelled by the retailer or official distributor when the ration allotted by the local authority (Kommunalverband) was purchased. Card sections were only valid as dated and numbered. This was to prevent fraud and sudden fluctuations in demand. Bona *fide* travellers used special cards. Supplies were allotted to *Kommunalverbände* on the basis of the amounts available and the number of "men" to be fed. Manual workers received slightly more than a "man's" ration, and women and children less. The Kommunalverband got its supplies either from local producers, or from the authorities of the Kreis. These again indented on the next highest authority, and, step by step, the requisitions went on till they reached the central authority of all. This was a company formed, partly of business representatives, partly of Government nominees, and capitalized partly by subscription and partly by Government funds. Beyond this central company, which controlled only the supplies of its own particular group of products, was the Imperial Food Bureau, with corresponding ministries in most of the Federal States.

The country's supplies were thus centralized, and the requirements of the various subordinate authorities were met in that degree which the national or local food policy made possible.

The central empires had to rely for their food supplies almost exclusively on home production. They had, therefore, to face the problem of obtaining the articles to be distributed from the actual producers. A special ration was allowed to "self-suppliers" (Selbstversorger), which, although small, was generally greater in amount than that allowed to other people. This was inevitably accompanied by evasion of regulations. If the self-supplier could conceal part of his output he could retain more than his official "ration," and this he usually succeeded in doing. As official rations dwindled, the practice of concealing output increased, and an extensive illicit trade (*Schleich-handel*) came into being. The activities of this trade completely upset the calculations of the German and Austrian food controllers, and by the middle of 1917 the rationing authorities themselves were obliged to have recourse to this efficient and wide-spread organization. The German plan for rationing food was beginning to break down.

The British System.—The British control of foodstuffs began to take shape in 1917. This system, as finally organized, depended principally on the fact that the bulk of supplies was sea-borne. Nearly all articles, therefore, came naturally and easily under public control from the moment they entered the country. Since Britain met her problems after Germany had been compelled to deal with similar difficulties, she had the advantage of the German experience. The British authorities had first of all to find out the real incidence of demand. This was accomplished indirectly by the first measures adopted to deal temporarily with the effects of shortage in the supply of sugar.

In August, 1914 a royal commission on sugar supplies was set up. By the end of 1916 sugar began to be in short supply. Each trader, wholesale or retail, was then given 50% of his 1915 supply, and left to share this among his customers as best he could. In June 1917, the cabinet decided upon a rationing scheme, under which each householder was invited to register with a particular retailer, to whom supplies were issued at a given ration per head of registered customers. In order to work this first sugar rationing scheme, some 1,800 food control committees were appointed by local authorities. Their expenditure was met from national funds, and they were supervised by 15 divisional food commissioners. These commissioners were appointed by a special wartime ministry of food, at the head of which was the food controller.

On Jan. 1, 1918, the rationing of individuals began, and as meantime other food supplies (*e.g.*, tea, margarine, bacon, cheese) had begun to run short, and there was no hope of a national rationing scheme being made effective for some months, local food committees had to arrange for the consumers under their charge as they best could. Several of them, that of Birmingham notably, began to use the powers of requisition granted to them by the ministry of food, and to distribute supplies to retailers, with whom consumers had to be registered. General provision for such schemes was made by an order of the food controller, dated Dec. 22, 1917. The same difficulty arose, however, as had been experienced in Germany many months before; different action by the authorities of adjacent districts led to confusion.

A rationing scheme, covering meat and fats, for London and the home counties, came into force on Feb. 25, 1918. Each individual (about 10,000,000 were involved) received two cards, one with detachable coupons for meat, and one with numbered spaces, to be marked by the retailer, for butter and margarine. Each consumer was registered with one retailer, and each retailer was supplied with the appropriate quantity of rationed articles necessary for his registered customers. A short time before the rationing scheme for London and the home counties was put into force, 500,000 people stood in food queues every Saturday in London. A month afterwards the queues had practically disappeared.

Since local authorities could not wholly ensure or control supply, they could not effectively ration meat. A national scheme for meat rationing was therefore introduced on April 7. The success was as great as that of the London scheme. On July 14, 1918, each member of the public received a single book, with coupons for meat, fats, sugar and lard. After May 3, 1919, coupons were abolished; and when sugar was decontrolled, in November 1920, the period of rationing was over. In Ireland, the only rationing was a control over the distribution of sugar.

The Two Systems Contrasted.—In Germany the essential idea was the administrative independence of the local authority, which, within its limits, was jealously guarded. The whole organization of food supply had to turn upon that which lay within the competence of the local power, namely, the actual distribution of the ration. In Britain, and the countries which followed Britain, the primary thought was the assurance of supply, and its control.

In none of the other Allied countries was food rationing so complete or so successful as in Great Britain. Both in France and Italy the system was conditioned mainly by the allocations of the inter-allied programme committees (see CONTROL) and by the fact that the scheme was administered by local bureaucrats acting to a large extent independently, with the natural result of uncoordinated control and public indifference. Among the neutral countries Holland and Sweden had the most efficient organization, built up on German experience.

United States.—Sugar and wheat flour were closely regulated. Towards the end of 1917 the diversion of ships from the Cuban trade made it necessary to reduce the supplies to confectioners and sweet-makers; and from July 1, 1918, shipments of sugar to retailers were made on the authority of certificates issued by the food administration on the basis of the number of their customers. The restrictions placed on the sale of wheat flour were at first voluntary, but compulsory regulations were issued in January 1918. These were dictated solely by the necessity of maintaining export to the European Allies.

RATIONING OF NEUTRALS (BLOCKADE). The rationing of neutral countries contiguous to the enemy was a new departure, and certainly one of the most momentous and far-reaching steps taken in connection with the economic section of the World War. It was also one which, not unnaturally, the United States and the other neutral countries saw in a different light from the British Government.

The British Government, in Aug. 1914, proclaimed that it would abide by the Declaration of London, but it soon became clear that, owing to the exceptional conditions in which the war was being conducted, it would be necessary to apply more vigorous methods to prevent the enemy procuring what he most needed through neutral countries. When the restriction of enemy's supplies committee was appointed by Winston Churchill, first lord of the Admiralty, on Aug. 13, 1914, it was allotted the task of watching all means or routes by which supplies of food or raw material might reach Germany or Austria, and of recommending by what methods such supplies might be restricted or stopped.

Conditions were such, however, that it soon became evident that pressure by means of a rationing policy must be brought to bear on various neutrals, who were rapidly becoming storehouses for enemy purposes.

The first suggestion of the application of a rationing policy was due to the Restriction of Enemy Supplies Committee which in April 1915 called attention to the extraordinary supplies of almost every kind of commodity that Germany was obtaining through Swedish intermediaries since the beginning of the war. It proposed that since the German attacks on British and neutral shipping with a view to laying siege to the United Kingdom should be effectively countered in accordance with the reprisals policy formally announced on March 11, 1915, the Swedish imports should be confined to their normal pre-war proportions having regard to any special circumstances or to any imports that country might lack through failure of supplies from Germany.

For the application of such a rationing, two courses appeared possible (1) that of making arrangements and agreements with responsible bodies in neutral countries for the consignment of imported goods under guarantee, for the purpose of ensuring that such supplies should not be re-exported to the enemy, or (2) rationing by force.

Agreements were made, after prolonged negotiations as follows:

The Netherlands Overseas Trust.—By agreement with this body, goods consigned to it were stored in bonded warehouses, and warrants for these goods were held by the banks who guaranteed the N.O.T. contracts. All private buyers having goods consigned to the N.O.T. were required to make a deposit as a guarantee of good faith, and this was liable to seizure by the N.O.T. in case of fraudulent practices being discovered. It was the custom of the N.O.T. to review the position of trade at the beginning of each month, first as regarded trade from the Dutch East Indies, and secondly, as regarded other countries. If the N.O.T. considered that any import was becoming excessive the trade was stopped and merchants compelled to purchase from accumulated stocks. By the Customs Exportation Restriction Act of June, 1915, further provision was made for the prevention of British goods passing through neutral countries to an enemy destination, the export from the United Kingdom of any goods to Holland, except such as were consigned to the N.O.T., being prohibited. By the Order in Council of June 25, 1915, all free list goods had to go to the N.O.T.

The Societé Suisse de Surveillance Economique.—The proposal to create a responsible body for the control of imports into Switzerland met with violent opposition as being derogatory to Swiss honour; nevertheless, after a long delay and tedious negotiations the S.S.S. was established. The basis of the rationing policy was that of allowing Switzerland her normal imports after deducting the exports to enemy countries.

Sweden.—Negotiations between the British Government and the Swedish authorities were protracted and on the whole unsatisfactory; it was found impossible to establish an authoritative control on the lines of the Netherlands Overseas Trust, but cotton was made subject to an agreement by which only a certain quantity was permitted to be exported monthly to Sweden for her home requirements.

Norway.—No actual agreement was made by the British Government with Norway, though that country was restricted in regard to imports. Legislation was, however, introduced early in 1915, into the *storting* with a view to preventing goods imported into Norway (under a guarantee against re-export) from being re-exported either by the person who had given the guarantee or by third parties.

Denmark.—It was recognized from the beginning that the geographical position of Denmark caused an exceptionally difficult and delicate blockade situation. An agreement was, nevertheless, made by the British Government with a well-organized commercial body which was known as the Danish Merchants Guild. Goods were only allowed to proceed to Denmark under the guarantee of this dependable guild, and further, the British custom house had full powers to insist, whenever it was deemed desirable, on the production of guarantees and to refuse to allow exports (even of free goods) except when covered by guarantees.

See WAR TRADE ADVISORY COMMITTEE; BLOCKADE. (L. C. L.)

RATITAE, the name given to the "flatbreasted," flightless birds, in opposition to the Carinatae, which possess a keeled sternum. Ratitae comprise the genera *Struthio* (see OSTRICH), *Rhea* (*q.v.*), Casuarius (see CASSOWARY), *Dromaeus* (see EMU), Apteryx (see KIWI), and the fossils *Dinornis* and Aepyornis. For their characteristics see ORNITHOLOGY.

The names Ratitae and Carinatae are now generally replaced by Palaeognathae and Neognathae respectively.

RATLAM (or RUTLAM), an Indian state in the Malwa agency of Central India. Area, 693 sq.m. The population in 1931 was 107,321. The chief, whose title is Maharaja, is a Rahtor Rajput of the Jodhpur family.

RATNAGIRI, a town and district of British India, in the southern division of Bombay. The town is on the seacoast, 136 m. S. of Bombay. Pop. (1931) 23,906. There is no railway, but there is steamer connection with Bombay.

The DISTRICT OF RATNAGIRI has an area of 3,989 sq. miles. It forms a strip between the western Ghats and the sea, and its general character is rugged; nearly all the fertile land lies on the banks of the streams which intersect the country. Ratnagiri (pop. [1931] 1,302,527) formed part of the dominions of the Peshwa, and was annexed by the British government in 1818 on the overthrow of Baji Rao. It is the home of the influential class of Chitpavan Brahmans.

RATNAPURA (*i.e.*, "The City of Gems"), the chief town in the province of Sabaragamuwa, Ceylon. It is the centre of a long established industry in digging for precious stones—rubies, sapphires, cat's-eyes, etc. There is also much rice and fruit cultivation and planting of tea in the district. Pop. of town was 8,497; of province (1931) 578,368. It is the railhead with connections to Colombo.

RATON (rah-ton'), a city of northeastern New Mexico, U.S.A., on the Raton range, spur of the Rockies; county seat of Colfax county. It is on federal highways 85, 87 and 64; is served by the Santa Fe railway system and by bus lines. Pop. (1920) 5,544 (89% native white), 7,607 by the federal census in 1940. Its altitude is 6.666 ft., just south of the Raton pass, in the midst of forest and mountain scenery. There are many camps for boys and girls and other vacation resorts in the vicinity. Thirty miles S.E. is the extinct volcano El Capulin; 60 m. S.W., the Eagle's Nest Dam (keystone of an irrigation project) at the head of the Cimarron cañon; and 30 mi. farther west, the Indian pueblo and artists' colony at Taos. The city lies in the richest coal-producing area of New Mexico.

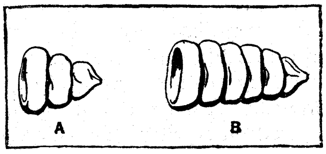
It has a municipal electric power plant and extensive railway shops and is a livestock and jobbing centre. Raton was a stage station on the Santa Fe Trail; was established as a railway station in 1879, and was incorporated in 1891.

RATTAZZI, URBANO (1808–1873), Italian statesman, was born on June 29, 1808, at Alessandria, and from 1838 practised at the bar. In 1848 he was sent to the chamber of deputies in Turin as deputy of his native town. For a short time he held the portfolio of public instruction; afterwards, in the Gioberti cabinet, he became minister of the interior, and on the retirement of Gioberti in 1849 he became practically the head of the Government. The defeat at Novara compelled the resignation of Rattazzi in March 1849. His election as president of the chamber in 1852 was one of the earliest results of the so-called "connubio" with Cavour, *i.e.*, the union of the moderate men of the Right and of the Left. Rattazzi resigned office in 1858, but again entered the cabinet under La Marmora in 1859 as minister of the interior. He again retired in Jan. 1860. He was entrusted with the formation of a new ministry in March 1862, but his policy of repression towards Garibaldi at Aspromonte led to his fall in December. He was again prime minister in 1867, from April to October. He died at Frosinone on June 5, 1873.

See Madame Rattazzi, *Rattazzi et* son *temps* (1881); B, King, History of *Italian Unity* (1899).

RATTLESNAKE, any snake of the genera *Sisturus* and *Crotalus,* American pit-vipers with the tail terminating in a rattle. The "pit" characteristic of this sub-family of the vipers is a deep depression on each side of the snout between eye and nostril.

The rattle is developed as a modification of the single scale which covers the tip of the tail; instead of being a simple, conical sheath, as in ordinary snakes, it has two ring-like constrictions so that it resembles three hollow bulbs, gradually diminishing in size and each one opening into its neighbour; the largest is also open at its free end, where the tail enters. All snakes shed the horny, epidermal covering of their scales periodically, a new one forming beneath the old one before the latter is sloughed; when however, the new covering of the end of the tail is developed in the rattlesnakes, the middle "globe" develops within the largest of the old sheath and, though the rest of the old skin is sloughed, the old tail sheath remains loosely fitting over the new one but prevented from slipping off by its shape. Thus, newly-born rattlesnakes have no rattle but with each succeeding moult a joint is added; the older joints, however, gradually wear away and are lost so that the number of joints on the rattle is not necessarily any criterion of a snake's age.



A.—A SINGLE RATTLE WITH THREE JOINTS. B.—FIVE RATTLES JOINED TOGETHER

The characteristic noise is produced by rapid vibration of the whole tail, when the loosely fitting horny shells produce a shrill noise which may be audible 20 yards away. The majority of the species are dwellers of the plains and open spaces and it has been suggested that the development of the rattle was to give a warning audible at a distance.

The venom of the rattlesnakes is of the same general type as other viperine venoms and all species are large enough to be able to inject sufficient to kill a man. They are, however, not easily provoked and will usually endeavour to escape or, if cornered, to frighten the aggressor by rattling and puffing themselves out as much as possible. In all species the eggs are retained within the body of the mother until the young are ready to emerge.

Sisturus, with only two species and confined to the southern United States and northern Mexico, may be distinguished from *Crotalus* by the presence of large, regularly arranged shields on the top of the head; both species are small, not more than about $2\frac{1}{2}$ ft. long. Crotalus, with small irregular scales on the top of the head, contains about 20 species, most of which occur in North and Central America. The largest and most dangerous species is the diamond back (C. adamanteus) which reaches a length of about 8 ft.; it is confined to the south-eastem United States. Other well known species are the prairie rattler (C. *confluentus*) which occurs all over the Great Plains from Canada to Texas, the timber rattlesnake (C. horridus) of the eastern United States and C. *terrificus* which ranges from Mexico to the Argentine and is the only representative of the genus in South America. The sidewinder (C. cerastes) is a small, desert-dwelling form from south-westem North America and is characterized by the development of a blunt, horn-like process above each eye. (H. W. P.)

RAU, KARL HEINRICH (1792–1870), German political economist, was born on Nov. 29, 1792, at Erlangen, where he studied at the university, of which he subsequently became a professor (1818). In 1822 he was called to the chair of political economy at Heidelberg where the rest of his life was spent in teaching and research. He took some part, however, in public affairs: in 1837 he was nominated a member of the first chamber of the duchy of Baden; in 1845 he became a privy councillor, and in 1851 he was one of the commissioners sent to England on the part of the Zollverein to study the Industrial Exhibition. A result of this mission was his account of the agricultural implements exhibited at London (Die *landwirthschaftlichen Geräthe* der *Londoner Ausstellung,* 1853). He was elected a corresponding member of the French Institute in 1856. He died at Heidelberg on March 18, 1870.

His principal work is the Lehrbuch *der politischen Ökonomie* (1826–37), an encyclopaedia of the economic knowledge of his time, written with a special view to the guidance of practical men. The three volumes are respectively occupied with (1) political economy, properly so called, or the theory of wealth, (2) administrative science (*Volkswirtschaftpolitik*) and (3) finance. The two last he recognizes as admitting of variations in accordance with the special circumstances of different countries, whilst the first is more akin to the exact sciences, and is in many respects capable of being treated, or at least illustrated, mathematically. This threefold division marks his close relation to the older German cameralistic writers. The book has passed through many editions; in that of 1870 by Adolf Wagner it was transformed into a new book.

His most important works are his early prize essay, *Über das Zunftwesen* (1815) ; *Ansichten der Volkswirtschaft* (1821) ; *Malthus und Say* (1821) ; *Grundriss der Kameralwissenschaft* oder *Wirtschaftslehre* (1823) ; *Über die Kameralwissenschaft* (1825) ; *Uber die Landwirtschaft der Rheinpfalz* (1830) ; and *Geschichte des Pfluges* (1845). Rau founded in 1834 the *Archiv der politischen Ökonomie und Polizeiwissenschaft,* in which he wrote a number of articles, afterwards issued in separate form.

RAVAILLAC, FRANÇOIS (1578–1610), the assassin of Henry IV. of France, was born near Angoulême. He began life as a *valet de chambre,* but afterwards became a lawyer and school reacher. He failed to obtain admission either to the recently founded order of Feuillants or to the Society of Jesus. Rumours that the king was intending to make war upon the pope suggested to him the idea of assassination, which he carried out on May 14, 1610.

He was executed on May 27, 1610.

See Jules Loiseleur, *Ravaillac et ses complices* (1873) ; E. Lavisse, *Histoire de France,* tome vi. (1905) ; J. J. Tharand, *Tragkdie de Ravaillac* (1913 and 1920).

RAVAISSON-MOLLIEN, JEAN GASPARD FELIX (1813–1900), French philosopher and archaeologist, was born at Namur on Oct. 23, 1813. He attended the lectures of Schelling at Munich and in 1837 published the first volume of his *Essai sur la me'taphysique d' Aristote,* to which in 1846 he added a supplementary volume. He was professor of philosophy at Rennes (1838), inspector-general of public libraries (1840), inspector-general in the department of higher education (1860), and curator of the Department of Antiquities at the Louvre (from 1870). He died in Paris on May 18, 1900. He belonged to the school of Cousin, with whom, however, he was at issue in many important points. The act of consciousness, according to him, is the basis of all knowledge. Ravaisson's chief philosophical works are: "Les Fragments philosophiques de Hamilton" (in the *Revue des Deux Mondes,* Nov. 1840); *Rapport sur le stoicisme* (1851) ; *La Philosophie en France au dix-neuvième siècle* (1868; 3rd ed., 1889) ; *Morale et métaphysique* (1893).

See Renouvier, in *L'Année philosophique* (1868) ; Dawriac, "Ravaisson philosophe et critique" (*La Critique philosophique,* 1885, vol. ii.).

RAVANASTRON, an Indian stringed instrument played with a bow, used by wandering pilgrims. It consists of half a round gourd, over which is fixed a sound-board of skin or parchment, with strings, either one or four in number, above. It is considered by some to have been the first instrument played with a bow.

THE RAVANASTRON, AN ANCESTOR OF THE VIOLIN

RAVEL, MAURICE (1875–1937), French musical composer, was born at Ciboure, near St. Jean de Luz, Basses-Pyrénées, March 7, 1875. He was the most outstanding figure in modern French music. More than that, he held an assured place in that line of composers beginning with the *clavecinistes* of the 17th century, who had so powerful an influence on French instrumental music. Educated at the Paris Conservatoire, where his master in composition was Gabriel Fauré, Ravel won the second Prix de Rome for composition in 1901. But he was not awarded the Grand Prix de Rome, and the judges were severely criticised for thus refusing to recognise his talent; the resignation of Dubois from the directorship of the Conservatoire was in fact attributed to this cause. When Ravel's piano pieces began to be known, notably *Pavane pour une Infante Ddfunte* and *Jeux d'eau,* played in Paris by Ricardo Vifies in 1902, a comparison was made between him and Debussy, whose *Pelléas et Mélisande* (Opéra-Comique, 1902) was then arousing heated controversy.

It is true that such diverse minds as Fauré, Chabrier, and Erik Satie exercised an influence on Ravel during his formative years, but his personality showed itself from the first. This personality became more clearly defined in his subsequent works, which included the string quartet in F, the three *Schéhérazade* melodies for voice and orchestra or piano (both 1904); the *Histoires Naturelles* (1907); *Introduction and Allegro* (septet for harp, strings, flute and clarinet) and the *Rapsodie Espagnole* for orchestra (1907). For the piano he wrote *Miroirs* and *Sonatine* (1905); *Gaspard de la nuit* (3 pieces) (1909); *Ma Mère l'Oye* (suite of five pieces) (1908); and *Valses nobles et sentimentales* (1911). The last two of these are best known in England as orchestrated by the composer.

However daring Ravel's harmony may appear, he was never experimental. He had an unerring sense of direction and knew where he was going, even if he sometimes seemed to watch himself going there with a smile of amusement. The cynical wit of his one-act opera, *L'heure Espagnole* (Opéra-Comique, 1911) and the conscious pose of the ballet *Daphnis et Chloe'* (choreography by Fokine and produced by Diaghilev, 1912), emphasize in different ways the detached attitude of Ravel towards his art. His later works include a sonata for violin and violoncello, and a trio for piano and strings (1915); *La Valse* for orchestra (1920) and *Tzigane,* for violin and piano (1924). (H. C. C.)

RAVELLO, a village of Campania, Italy, in Salerno province, 3 mi. N N.E. of Amalfi, 1,227 ft. above sea-level. It commands a magnificent view, especially from the Belvedere of Cimbrone. Pop. (1936) 703 (town), 3,237 (commune). The history of Ravello begins in the 9th century. In the 11th it was called Rebellum, because it rebelled against Amalfi; in the 13th, at the height of its prosperity, it had 36,000 inhabitants. The Palazzo Rufolo, begun in the 11th century, has two lofty towers and beautiful Saracenic decoration in the courtyard. The ex-cathedral of S. Pantaleo has a good campanile, fine bronze doors by Barisanus of Trani (1179) and two pulpits in Cosmatesque work. The larger, supported by six columns resting on the backs of lions, was made in 1272 by Nicolaus of Foggia; the bust over the entrance may be a portrait of Sigilgaita Rufolo, or may symbolise the Church. The smaller (c. 1130) has curious representations of Jonah and the whale. The parish church of S. Giovanni in Toro contains a splendid pulpit in Cosmatesque work, supported on four pillars, and the crypt some 14th-century frescoes. S. Maria Immacolata is another Romanesque church.

RAVEN, the largest bird of the order Passeres, and a member of the Corvidae. Quick-sighted, sagacious and bold, the raven preys on the spoils of fishers and hunters, also on weakly animals among flocks and herds. A sentiment of veneration or superstition has often been attached to it. Superstition has been generally succeeded by persecution, which in many districts has led to extirpation.

The raven breeds early in the year, in England resorting to its nest, which is usually an ancient structure, towards the end of January. Therein are laid from five to seven eggs of the common corvine colouration (*see* CROW), and the young are hatched before the end of February. The young have bright crimson throats. In more northern countries the breeding season is naturally delayed, but everywhere this species is almost if not quite the earliest breeder. The raven measures about 26in. in length, and has an expanse of wing exceeding a yard. It is entirely black, the feathers having a purple iridescence. The common raven (*Corvus corax*) inhabits the whole of Europe, northern Asia and northern America. In Africa its place is taken by allied species, one of which (*Corvus umbrinus*) has a brown neck; farther south are species whose plumage is varied with white.

RAVEN-HILL, LEONARD (1867–1942), English artist and illustrator, was born on March 10, 1867. He studied art at the Lambeth school and afterwards in Paris under A. W. Bouguereau and Aimé Morot. He began to exhibit at the Salon in 1887, and at the Royal Academy in 1889. In 1893 he founded, with Arnold Golsworthy, the humorous and artistic monthly The *Butterfly* (1893–94, revived in 1899–1900). He contributed to many illustrated magazines, and was with *Punch* from 1896 until his retirement in 1935. He illustrated Sir Walter Besant's *East* London (1901) and J. H. Harris's Cornish Saints and Sinners. His impressions of his visit to India on the occasion of the tour of the prince and princess of Wales appeared as An Indian Sketch-Book (1903); other published sketch-books include Our Battalion (1902) and The *Promenaders* (1894). He died March 31, 1942.

RAVENNA, a city and archiepiscopal see of Emilia, Italy, capital of the province of Ravenna, in a marshy plain 13 ft. above sea-level, 6 mi. from the sea and 45 mi. by rail E of Bologna. Pop. (1936) 31,251 (town), 81,086 (commune)—a considerable increase, as the population of 1881 was only 34,270 (commune). The town is a centre for agriculture, which has been much favoured by extensive drainage and reclamation works. There is also a sugar factory at Classe. The town is connected with the sea by the Corsini Canal. Ravenna has railway communication with Bologna (via Castel Bolognese), Ferrara and Rimini, and by steam tram with Forlì. Though the external aspect of the town is not striking, no other in the world offers so many and such splendid examples of the ecclesiastical architecture of the centuries from the 5th to the 8th. The style is commonly called Byzantine; but the colonnades and the mosaics are not so much Byzantine as representative of early Christian art generally.

The cathedral of Ravenna, built by S. Crsus in 370–390, which had a nave and four aisles, was destroyed in 1734–44, only the (inaccessible) crypt and the round campanile remaining from the earlier structure; there are fragments of reliefs from a pulpit erected by Archbishop Agnellus (556–569) in the interior. The present cathedral contains several early Christian marble sarcophagi, a silver cross of the 11th century and the throne of the Archbishop Maximian (546–552), adorned with reliefs in ivory.

The period from the transference of the imperial residence to Ravenna to the death of Valentinian III. (404–455) was the first period of great building activity in Ravenna, when the archiepiscopal see of Ravenna attained great importance. It was to it that we owe the erection of the Basilica Petriana at Classe (396–425), which has entirely disappeared, of the churches of S. Giovanni Evangelista (425), of S. Agata (425–432), of the chapel of S. Pier Crisologo (433–449), of the mausoleum of Galla Placidia (440), the church of S. Pier Maggiore (now S. Francesco) (433–458), the baptistery of Neon (449–458), S. Giovanni Battista and S. Croce.

S. Giovanni Evangelista, erected by Galla Placidia in fulfilment of a vow made on her voyage from Constantinople, has been entirely rebuilt, though the columns are ancient. The Gothic portal is fine, and the church contains a mosaic pavement of 1213 with representations of the 4th Crusade and some frescoes by Giotto, painted during a visit to Dante between 1317 and 1320. S. Agata was almost entirely rebuilt in 1476–94. The chapel of S. Pier Crisologo in the archiepiscopal palace preserves its original mosaics; so also does the mausoleum of Galla Placidia (SS. Nazario e Celso), a small structure in the form of a Latin cross with a dome (in which, as in the baptistery of Neon, the old cathedral, etc., the constructional use of amphorae is noteworthy), with a plain brick exterior, and rich mosaics on a dark blue ground.

S. Francesco has been modernized, except for the crypt and campanile (10th century). The baptistery adjacent to the cathedral was either originally part of the Roman baths, converted to a Christian baptistery by the Archbishop Neon (449–452), or a Christian building dating from before A.D. 396. It is an octagon, with a dome; in the interior are two arcades one above the other. The mosaics of the 5th century, in the dome, are the earliest and perhaps the finest at Ravenna.

Of S. Giovanni Battista, also erected in this period, hardly anything remains after the restoration of 1683, and S. Croce has been overtaken by a similar fate. Honorius and Galla Placidia built a palace about A.D. 402, remains of which have been found under S. Croce.

The reign of Theodoric (493–526) marks another era of magnificence. In the eastern part of the city he built for himself a large palace. There still remains fronting the Corso Garibaldi a high wall built of square Roman bricks, with pillars and arched recesses in the upper portion, which goes by the name of Palazzo di Teodorico, but is a guardhouse erected by the exarchs, recent explorations having made it clear that it was an addition to the palace, while mosaic pavements and a court once surrounded by colonnades and really belonging to the latter were found behind S. Apollinare Nuovo and the so-called Palazzo at a lower level and a different orientation. (See Ghirardini in *Monumenti* dei *Lincei*, xxiv. 737–838.) A mosaic in the church of S. Apollinare Nuovo gives some faint idea of the palace. The massive mausoleum of Theodoric stands still perfect outside the walls near the north-east corner of the city. It is circular internally and decagonal externally, in two storeys, built of marble blocks, and surmounted by an enormous monolith, brought from the quarries of Istria and weighing more than 300 tons. It has been converted into a church dedicated to the Virgin.

S. Apollinare Nuovo, the most important basilica in the town, was built by Theodoric to be the largest of Arian churches. The exterior is uninteresting, and the church lost both atrium and apse in the 16th century. The interior has twenty-four columns of marble, with almost uniform capitals. The walls of the nave are adorned with mosaics of the 6th century; the scenes from the New Testament above the windows date from the time of Theodoric.

The campanile (850–878) is circular, and has perhaps the earliest example of the use of disks of coloured majolica as a decoration. This, like the other campanili of Ravenna, is later than the church to which it belongs. Those of the cathedral of S. Apollinare in Classe, S. Maria Maggiore and S. Agata, also circular, probably belong also to the 9th century, while the two square campanili of S. Giovanni Evangelista and S. Francesco probably belong to the 10th century. The other churches erected by Theodoric are: S. Teodoro (or S. Spirito), erected by Theodoric for the Arian bishops, but entirely modified; the baptistery of this church (afterwards the oratory of S. Maria in Cosmedin), formed out of the octagonal hall of a Roman bath, with mosaics of the 6th century; S. Maria Maggiore, founded by the Archbishop Ecclesius (521–534), but almost entirely rebuilt; and S. Vittore, which has suffered a similar fate. To the same period probably belong a few columns of the so-called Basilica of Heracles in the Piazza Vittorio Emanuele, with capitals like those of S. Apollinare in Classe.

The impulse given by Theodoric was continued by his successors, and during the regency of Amalasuntha and the reigns of Theodatus and Vitiges (526–539), S. Vitale and S. Apollinare in Classe were constructed by Julius Argentarius contemporaneously with S. Lorenzo in Milan and the cathedral of Parenzo—also S. Michele in Africisco, little of the original structure of which now exists; the apse mosaic is in the Berlin museum. The former, well restored by Ricci (except for the dome with its baroque frescoes which has not been altered), is a regular octagon, with a vestibule, originally flanked by two towers on the west, a choir added on the east, triangular outside and circular within: it is surrounded within by two galleries interrupted at the presbytery, and supported by eight large pillars, the intervals between which are occupied by open exedrae. The mosaics of the choir (547) are due to Justinian, and, though inferior in style, are remarkable for their splendour of colouring and the gorgeous dresses of the persons represented, and also for their historical interest, especially the scenes representing the emperor and the empress Theodora presenting offerings. The marble screens of the altar are wonderfully finely carved. The marble mosaic pavement (11th century) is very effective. Remains of the original marble wall lining and stucco decoration also exist.

The architecture of S. Vitale, according to Rivoira, was inspired not by Byzantium, where similar churches—S. Sofia and SS. Sergio and Racco—are slightly later in date, but by the churches of Salonica (A.D. 495), while the plan is derived from a Christian baptistery, or from such a building as the so-called temple of Minerva Medica at Rome.

It has been ascertained that a 5th century building already occupied the site.

S. Apollinare in Classe, erected at the same time outside the walls of Classis, and now standing by itself in the lonely marshes, is the largest basilica existing at Ravenna. It has a nave and aisles with a closed vestibule on the west, and a fine round campanile of the 9th (?) century. The exterior brick walls are divided by shallow arches and pilasters, as in other churches of Ravenna. It has twenty-four columns of Carystian (cipollino) marble, with capitals probably of Byzantine work with swelling acanthus leaves; but the rest of the church is due to native architects. The lofty presbytery and the crypt under it belong to the 12th century. The walls of the interior were stripped of their marble panelling by Sigismondo Malatesta in 1449, for the adornment of his church at Rimini. The apse has mosaics of the 6th and 7th centuries. The 18th-century series of portraits of the archbishops of Ravenna is no doubt copied from an earlier original. There are a number of fine carved sarcophagi in the church (5th to 8th century). The building activity of the Gothic kings was continued by Justinian, to whose time we owe the completion of S. Vitale and S. Apollinare in Classe, and some of the mosaics in S. Apollinare Nuovo.

The buildings of a subsequent period are of minor importance, but the basilica of S. Maria in Portofuori near the ancient harbour (1096 sqq.), a basilica with open roof, with frescoes by masters of the Rimini school, may be noticed. The campanile dates from 1173–87. The tomb of Dante, who died at Ravenna in 1321, is close to S. Francesco; it is a square domed structure, with a relief by Pietro Lombardo (1483) representing the poet, and a sarcophagus below, in an urn within which lie the poet's remains. Close by is a small court with early Christian sarcophagi, containing the remains of the Braccioforte family. The important museum near S. Vitale has Roman and Byzantine antiquities, inscriptions, sculptures, jewelry, etc. The library has rare mss. (including the best extant ms. of Aristophanes), and incunabula. The Accademia has pictures by local masters.

In the Piazza Vittorio Emanuele are two granite columns erected by the Venetians in 1483. The cloisters of S. Maria di Porto erected in the town in the 16th century (owing to malaria, as in the case of those of Classe), and of S. Vitale, are pleasing 16th-century structures, The 15th-century castle in the north-east corner of the town erected by the Venetians is a picturesque brick building. The walls, 3 m. long, which still surround the town, were also built by them.

History.—Strabo mentions a tradition that Ravenna was founded by Thessalians, who afterwards called in the Umbrians and left the city to them. About 191 B.C., by the conquest of the Boii, the whole of this region passed definitely under the dominion of Rome. Under Augustus it rose into importance, when it was made the station for the fleet on "the upper sea." Two hundred and fifty ships could ride at anchor in its harbour. At the same time Augustus conducted a branch of the Po (the fossa Augusta) through the city into the sea. It also became important for the export of timber from the Alps. Strabo gives a description which corresponds closely with modern Venice.

On the other hand, good water was proverbially difficult to obtain at Ravenna—dearer than wine, says Martial. Trajan, however, built an aqueduct nearly 20 miles long, which was restored by Theodoric in 503. Of this some traces still exist in the bed of the Ronco above Ravenna. Flies and frogs were also complained of, and Sidonius, writing in the 5th century, complains bitterly of the "feculent gruel" (*cloacalis puls*) which filled the canals of the city, and gave forth fetid odours when stirred by the poles of the bargemen. The port of Ravenna, situated about 3 miles from the city, was named Classis. A long line of houses called Caesarea connected it with Ravenna, and in process of time there was such a continuous series of buildings that the three towns seemed like one. It had large gilds of fabri (smiths and carpenters) and *centonarii* (firemen).

A pre-historic station was found in 1894 at S. Zaccaria near Ravenna, belonging to a Terramare. Of Roman Ravenna nothing remains above ground. It was connected with Ariminum, 33 miles to the south by the coast road, the Via Popilia, which ran on north to Hatria, and joined the road between Patavium and Altinum at Ad Portum.

Early in the 5th century, Honorius, alarmed by the progress of Alaric in the north of Italy, transferred his court hither. From this date (404) to the fall of the Western Empire in 476 Ravenna was the chief residence of the Roman emperors. Here Stilicho was slain; here Honorius and his sister Placidia caressed and quarrelled; here Valentinian III. spent the greater part of his life; here Majorian was proclaimed; here the little Romulus donned his purple robe; here in the pinewood outside the city his uncle Paulus received his decisive defeat from Odoacer. The great pinewood to the east of the city, which is still one of the great glories of Ravenna, must therefore have been in existence in the 5th century. Odoacer made Ravenna his chief residence. Theodoric's siege of Ravenna lasted for three years (489–492); ten days after his entry into the city he slew his rival at a banquet in the palace of the Laurel Grove (March 15, 493). Ravenna was also Theodoric's chief residence (493–526).

In 535 Justinian sent an army to destroy the Gothic monarchy and restore Italy to the empire. The Goths at length, weary of the feebleness of Vitiges, offered to transfer their allegiance to Belisarius on condition of his assuming the diadem of the Western Empire. Belisarius dallied with the proposal until he had obtained an entrance within the walls of the capital, and proclaimed his inviolable fidelity to Justinian (539). Under the rule of Narses and his successors the exarchs, Ravenna was the seat of Byzantine dominion in Italy. In 728 the Lombard king Luitprand took and destroyed the suburb Classis; about 752 the city itself fell into the hands of his successor Aistulf, from whom a few years after it was wrested by Pippin, king of the Franks.

It formed part of the Frankish king's donation to the pope in the middle of the 8th century, though the archbishops, as a fact, retained almost independent power. It was an independent republic, generally taking the Guelph side in the 13th century, subject to rulers of the house of Polentani in the 14th, Venetian in the 1 jth (1441), and papal again in the 16th. St. Romuald and St. Peter Damian were both natives of Ravenna. From this time (1509) down to our own days, except for the interruptions caused by the wars of the French Revolution, Ravenna continued subject to the papal see and was governed by a cardinal legate. In 1849 Garibaldi's wife Anita, who had accompanied him on his retreat from Rome, succumbed to fatigue in the marshes near Ravenna

Charles the Great carried off the brazen statue of Theodoric and the marble columns of his palace to his own palace at Aix-la-Chapelle. Lord Byron resided at Ravenna for eighteen months in 1820–21, attracted by the charms of the Countess Guiccioli.

AUTHORITIES.—The most important authority for the history of Ravenna is Bishop Agnellus, who wrote, about 840, the Liber *Pontificalis* Ecclesiae Ravennatis. The best edition is that by Holder-Egger in the Monumenta Germaniae Historica (1878). See G. T. Rivoira, *Lombardic* Architecture (London, 1910); C. Ricci, Ravenna (Bergamo, 1902), Ravenna (London, 1913); E. Hutton, The Story of Ravenna (London, 1926). To the careful restorations of Ricci the buildings of Ravenna owe much. (T. H.; T. A.)

BATTLE OF 1512

This battle, one of the principal events of the long Italian wars of Charles VIII., Louis XII. and Francis I. of France, is, like Marignano (*q.v.*), interesting in a tactical sense, from the fact that the feudalism of the past and the expert soldiership of the future were strangely mingled. It arose out of the attempt of the Spanish and Italian forces to relieve Ravenna, besieged by Gaston de Foix, duke of Nemours. The most celebrated captains of these wars were present on either side—under Gaston de Foix were Bayard, Yves d'Allègre, La Palisse; and under Cardona the Spanish viceroy of Naples, Pedro Navarro the great engineer, and Pescara, the originator of the Spanish tactical system. After some preliminary manoeuvres the two armies drew up face ta face on the left bank of the Roneo, the Spanish left and the French right resting on this river. The Spaniards were entrenched, with their heavy artillery distributed along the front, but, thanks to Navarro, they had a more mobile artillery in the shape of 200 arquebuses *à* croc mounted in groups upon carts, after the German fashion. The battle opened with a prolonged cannonade from the Spanish lines. For three hours the professional regiments of all sorts in the French lines rivalled one another in enduring the fire unmoved, the forerunners of the military systems of to-day, landsknechts, Picardie and Piedmont, showing the feudal gendarmerie that they too were men of honour. There was no lying down. The captains placed themselves in the front, and in the centre 38 out of 40 of them were struck down. Molart and Empser, drinking each other's health in the midst of the cannonade, were killed by the same shot. Sheltered behind the entrenchments, the Spaniards scarcely suffered, for they were lithe active troops accustomed to lie down and spring up from the ground. But after three hours, Pescara's light horse having meantime been driven in by the superior light horse of the enemy, the artillery-loving duke of Ferrara conceived the brilliant plan of taking his mobile field-guns to the extreme right of the enemy. This he did, and so came in sight of the prone masses of the Spaniards. Disciplined troops as they were, they resisted the temptation to escape Ferrara's fire by breaking out to the front; but the whole Spanish line was enfiladed, and on the left of it the papal troops, who were by no means of the same quality, filled up the ditch in front of their breastworks and charged forward, followed by all the gendarmerie. Once in the plain they were charged by the French gendarmes under Gaston himself, as well as by the landsknechts, and driven back. The advantage of position being thus lost, the Spanish infantry rose and flung itself on the attackers; the landsknechts and the French bands were disordered by the fury of the counterstroke, being unaccustomed to deal with the swift, leaping and crouching attack of swordsmen with bucklers. But La Palisse's reserve wheeled in upon the rear of the Spaniards, and they retreated to the entrenchments as fast as they had advanced. The papal infantry, the gendarmes, and the light horse had already vanished from the field in disorder; but the Spanish regulars were of different mettle, and it was only after a long struggle that the landsknechts and the French bands broke into the trenches. The conflict continued, but at last La Palisse, with all the gendarmerie still in hand, rode completely round the entrenchments and charged the Spaniards' rear again. This was the end, but the remnant of the Spanish infantry retreated in order along the river causeway, keeping the pursuers at bay with their arquebuses. Gaston de Foix, recklessly charging into the midst of them, was killed.

RAVENNA, a city of northeastern Ohio, U.S.A., 33 mi. S.E. of Cleveland; the county seat of Portage county. It is served by the Baltimore and Ohio, the Erie, the Pennsylvania and electric railways. Pop. 1940, 8,538. It has manufactures of structural steel, iron castings, rubber goods and lumber. It is the site of the Ravenna Ordnance plant, employing about 10,000. Ravenna was founded in 1852 and incorporated as a city in 1912.

RAVENNA, EXARCHATE OF, the official name of that part of Italy which remained in the allegiance of the Roman emperors at Constantinople from the closing years of the 6th to the middle of the 8th century. The civil and military head of these possessions, the exarch (*q.v.*), was stationed at Ravenna. The territory round the town, from the southern border of the modern Venetia to the beginning of the Pentapolis at Rimini, was under his direct administration and formed in a limited sense the exarchate. The other provinces were governed by dukes and *magistri militum,* titles which were generally, but not always, borne by the same person. But as all were subject to his authority, they were included in the exarchate of Ravenna, which was therefore another name for the province of Italy. Sicily formed a separate government. Corsica and Sardinia belonged to the exarchate of Africa. The organization of the exarchate is placed by modern investigators under the reign of the emperor Maurice (582–602), when the imperial Government was confronted by the new problems created by the settlement of the Lombards (*q.v.*). At the end of the 6th century it included Istria; the maritime part of Venetia as distinct from the interior which was in the hands of the Lombard kings at Pavia; the exarchate proper, or territory around Ravenna on the eastern side of the Apennines, to which was added Calabria, which at that period meant the south-east and not the south-west of Italy; the Pentapolis, or coast from Rimini to Ancona with the interior as far as the mountains; the duchy of Rome, or belt of territory connecting the Pentapolis with the western coast, the coast of Naples, with Bruttium, the modern Calabria, and Liguria, or the Riviera of Genoa. Piedmont, Lombardy, the mainland of Venetia, Tuscany and the interior of Naples belonged to the Lombards. The superior organization of the imperial Government enabled it to regain lost territory and delay complete ruin. In 590 it recovered much of Venetia. But these revivals were not permanent. In 640 the Ligurian seacoast fell under the power of the Lombards. About a century later the exarchate had been greatly reduced, though the imperial officials endeavoured to conceal the fact by retaining and transferring names when the reality of possession was lost. About 740 it consisted of Istria, Venetia, Ferrara, Ravenna (the exarchate in the limited sense), Pentapolis, Perusia, Rome, the coast of Naples and the south-west of Italy, which was being overrun by the Lombards of the duchy of Beneventum, which with Spoletum held the interior. In Rome the pope was the real master. These fragments of the "province of Italy" were almost all lost either to the Lombards, who finally conquered Ravenna itself about 750, or by the virtual independence of the papacy. Subsequent Frankish intervention (see ITALY) made a revival of the exarchate impossible. It disappeared, and the small remnants of the imperial possessions on the mainland, Naples and Calabria, passed under the authority of the "patricius" of Sicily, and when Sicily was conquered by the Arabs in the 10th century were erected into the themes of Calabria and Langobardia. Istria was attached to Dalmatia.

In its internal history the exarchate was subject to the influences which were everywhere, in central and western Europe at least, leading to the establishment of feudalism. The great imperial officials gradually became landowners, and conversely the great landowners intruded on the imperial administration. The local militias, organized under imperial authority for defence against the Lombards, tended to become independent. These bodies formed the *exercitus romanae* militiae, who were the forerunners of the free armed burghers of the Italian cities of the middle ages.

See C. Diehl, *Études sur l'administration* Byzantine *dans l'exarchat* de Ravenne (568–751) (1888).

RAVENSBURG, a town in the Land of Wiirttemberg, Germany, on the Schussen, 12 mi. N. of Friedrichshafen on the lake of Constance. Pop. (1939) 32,257. Raverisburg was founded in the 11th century by the Guelphs, and in their castle on the Veitsburg, Henry the Lion was born. In 1180 the town passed to the Hohenstaufens, and a century later it became a free town of the empire. It was ceded to Wiirttemberg in 1810. It retains its walls and nine towers, and its 15th century town hall.

RAVENSCROFT, THOMAS (c. 1590–*c.* 1633), English composer and musical editor, received his B. Mus. at Cambridge in 1607, and from 1618–22 was music master at Christ's hospital. He is best known by his The Whole Booke of *Psalmes* (1621), 48 of the harmonizings being his own. His other works, the first three of which show his appreciation of popular and humorous poems, are Pammelia, a collection of 100 rounds and catches (1609); Deuteromelia, a collection of 31 items, including "Three Blind Mice" (1609) ; *Melismata*, a collection of 21 items, chiefly short madrigals (1611); and *A Briefe* Discourse of *the True* (but Neglected) *use* of *Charact'ring* the Degrees, by *their Perfection,* Imperfection and Diminution in *Measurable Musicke,* etc. (1621).

RAVI, a river of India, one of the "Five Rivers" of the Punjab. It rises in the Kulu subdivision of Kangra district, flows through Chamba state, and enters British territory again in Gurdaspur district. Thence it flows through the plains of the Punjab, passing within a mile of Lahore, and finally falls into the Chenab after a course of about 450 m. Its water is utilized for the Upper and Lower Bari Doab canals, with head works at

Madhupur, and the Sidhrai canal. The Upper Bari Doab canal irrigates some 1,177,000 acres, and the Lower Bari Doab canal (opened 1913) about 345,000 acres. The Upper Chenab canal enters the Ravi at Balloki, where the Lower Bari Doab canal has its head works on the opposite bank, thus providing a level crossing of the Ravi. The Sidhrai canal, which starts a few miles above the Chenab junction, is frequently dry in winter, but the Haveli project, including a dam on the Chenab with a canal delivering water into the Ravi above the Sidhrai weir, will ensure a perennial supply when completed.

RAWALPINDI, a town of British India, which gives its name to a district and a division in the Punjab. The town is situated on the north bank of the little river Leh, 1,726 ft. above the sea, 111 m. E. by S. of Peshawar, and 1,443 m. N.W. of Calcutta. Pop. (1931) 119,284. It is chiefly notable as the largest military station in India, and the key to the British system of defence upon the North-West Frontier. It is also the starting-point of the cart-road to the hill-station of Murree and of the route into Kashmir. It is the headquarters of the northern army with a strong force of all arms, and contains an arsenal. Besides the locomotive works of the North-Western railway, there are gas-works, a tent factory, an iron foundry, an oil refinery and a brewery. An annual horse fair is held in April.

The DISTRICT OF RAWALPINDI has an area of 2,023 sq.m. It contains the Murree hills. The district is traversed by the main line of the North-Western railway, crossing the Indus at Attock, and also by a branch towards the Indus at Kushalgarh. The population in 1931 was 634,357.

RÂWANDIS, a Persian sect (from Rāwand, a town near Isfahan). Its origin is unknown, but its members held ultra-Shiah doctrines (*see* ISLAM). They maintained that the spirit that was in Jesus was in 'Alī, then in the imāms one after the other to Ibrahīm ibn Muhammad, and that thus these were divine. They believed in metempsychosis, or the transmigration of souls, and asserted that the Lord who fed them and gave them drink was Manṣūr. In 759 they came to the palace of Manṣūr in Hashimiya and began to hail him as Lord. The Caliph, however, secured their chiefs and threw them into prison.

See E. G. Browne, *Literary History of Persia* (1902, bibl.)

RAWLINS, a city of southern Wyoming, U.S.A., 6,741 ft. above sea level, on federal highways 30 and 87 and the main line of the Union Pacific railroad; the county seat of Carbon county. Population in 1940 was 5,531. It is the most important shipping point for sheep and wool in the state; a division point on the railroad, which maintains extensive shops and roundhouses here; the supply centre for a mining, stock-raising and oil-producing area, extending 100 mi. on either side of the railroad; and the seat of the State penitentiary (established 1907).

RAWLINSON, SIR HENRY CRESWIGME (1810–1895), English soldier and orientalist, was born at Chadlington, Oxfordshire, on April 11, 1810. In 1827 he went to India as cadet under the East India Company; and after six years as a subaltern he was sent to Persia in company with other English officers to reorganize the Shah's troops. He became interested in the hitherto undeciphered cuneiform character. In two years he transcribed as much as he was able of the great cuneiform inscription at Behistun (*q.v.*); but the friction between the Persian court and the British government ended in the departure of the British officers. He became political agent at Kandahar in 1840. Then, at his own desire, he was sent as political agent to Turkish Arabia; thus he was enabled to settle in Baghdad, where he devoted much time to his cuneiform studies. He was now able to make a complete transcript of the Behistun inscription, which he deciphered and interpreted.

During two years' leave in England (1849–51) he prepared a memoir on the Behistun inscription. He disposed of his valuable collection of Babylonian, Sabaean and Sassanian antiquities to the trustees of the British Museum, who made him a grant to enable him to carry on the Assyrian and Babylonian excavations initiated by Layard. In 1851 he returned to Baghdad. In 1855 he resigned his post in the East India Company and he received the K.C.B. and crown directorship of the East India Company. The remaining forty years of his life were mainly spent in London. In 1858 he was appointed a member of the first India Council, but resigned in 1859 on being sent to Persia as envoy extraordinary and minister plenipotentiary. The latter post he held only for a year. Rawlinson rejoined the Council of India in 1868, and continued to serve upon it until his death. He was a strong advocate of the forward policy in Afghanistan. He died in London on March 5, 1895.

His published works include four volumes of cuneiform inscriptions, published under his direction between 1870 and 1884 by the trustees of the British Museum; *The Persian Cuneiform Inscription at Behistun*, 1846–51, and *Outline of the History of Assyria*, 1852, both reprinted from the Asiatic Society's journals; *A Commentary on the Cuneiform Inscriptions of Babylon and Assyria*, 1850; *Notes on the Early History of Babylonia*, 1854; *England and Russia in the East*, 1875. He contributed to the *Encyclopædia Britannica* (9th edition) the articles on Baghdad, the Euphrates and Kurdistan, and several other articles dealing with the East; and assisted in editing a translation of Herodotus by his brother, Canon George Rawlinson (1812–1902).

See G. Rawlinson, *Memoir of Henry Creswicke Rawlinson* (1898).

RAWLINSON, HENRY SEYMOUR RAWLINSON, 1ST BARON (1864–1925), British soldier, was born on Feb. 20, 1864, son of Maj. Gen. Sir H. Rawlinson, Bart. He joined the army in 1884 and a year later became aide-de-camp to Sir F. Roberts in India on whose staff he served intermittently for some years. He took part in the Burma operations in 1886–87 and on the Nile in 1898; he had succeeded to the baronetcy in 1891. He served throughout the South African War (1899–1902). Some months after his return to England he became commandant of the staff college and from 1910 to May 1914 commanded the 3rd Division. Gen. Rawlinson was in charge of the forces sent to assist Antwerp in 1914, and took part in the first battles of Ypres and in the Neuve Chapelle and the Loos offensives. He commanded the IV. Army during the battle of the Somme (1916) achieving important successes. At the end of 1917 he was transferred temporarily to the command of the II. Army during Gen. Plumer's absence in Italy, and in Feb. and March 1918 he acted for some weeks as British representative on the Supreme War Council. Resuming his command of the IV. Army in April, his troops on Aug. 8, in conjunction with the French, attacked the enemy near Amiens and gained a signal victory, which heralded the general advance of the Allies. After the War he was raised to the peerage as Baron Rawlinson of Trent and received a grant of £30,000. In the latter part of 1919 he mas sent to north Russia to conduct the withdrawal of the Allies from Archangel and Murman, and on his return he commanded at Aldershot for a year. At the end of 1920 he went to India as commander-in-chief. He died at Delhi on March 28, 1925.

See Sir F. Maurice, *Life of Genera2 Lord Rawlinson of Trent, from his Journals and Letters* (1928).

RAWMARSH, an urban district in the West Riding of Yorkshire, England, 74 mi. N.E. of Sheffield on the L.M.S. and L.N.E. railways. Pop. (1938) 18,210. Area 4 1 sq.mi. It is 1½ mi. from the river Don, and is almost continuous with Rotherham. Rawmarsh has large iron-works, steel rolling-mills, and potteries.

RAW MATERIALS include objects, classified with respect to their place in trade and industry, rather than with respect to their physical character. An object that may be classed with raw materials at one time may become a finished product at another, or vice versa. Camphor and indigo were formerly classed as raw materials in the chemical industry. Since the invention of the synthetic processes for their manufacture they have come to be classed as finished products. Coal tar, formerly a finished product of the distillation process, has now come to be the raw material for a great variety of chemical manufactures.

An International Pool.—As modern industry developed in many countries after the middle of the 19th century, notably in the United States and Germany, France, Belgium, Italy and Japan, the principal raw materials became, as it were, an international pool, distributed automatically among the consuming nations in proportions determined by what may be described in general terms as relative power of economic attraction; this power being based on a number of factors of fluctuating value, of which the chief are: (1) facilities for assembling materials in large masses; (2) facilities for distributing the manufactured product; (3) cheapness of fuel, or other sources of power, especially hydro-electric; (4) cheapness and above all efficiency of labour; (5) abundant liquid financial resources for carrying raw material stocks and finished products on their way to the consumer.

Old Versus New Countries.— The predominance of England as a market for raw materials in the first three-quarters of the 19th century rested upon a relative superiority in all these factors. Gradually other nations gained upon England in one factor or another; Germany in fuel and labour, especially the highly trained labour of the chemical industries; the United States in fuel, particular kinds of labour, financial power; Italy and Switzerland in hydro-electric power. In general, it may be said that the tendencies of the 50 years before the outbreak of the World War were in the direction of reducing the lead of the older industrial countries and sections in the power to attract raw materials. The disturbances of trade resulting from the war forced many countries to develop independent manufacturing facilities, with the consequence that the claimants upon the international pool of raw materials have become more numerous and more nearly on an even footing. Under the régime of virtual freedom the trade in raw materials underwent an immense development. The demands of industry produced a great expansion in the production of raw materials, and this expansion, often outrunning demand, reacted upon industry and stimulated its development.

Science Gives New Resources.— In rare instances the progress of science and invention has freed industry from its dependence on the raw materials that figure in world trade. Scientific and industrial progress has steadily increased the number of raw materials in trade and the volume consumed.

At the same time technical progress applied to the production of raw materials themselves has greatly extended the range of possible sources. Prior to the introduction of the flotation process in copper extraction, the minimum paying ore was about 3%; less than 1% is profitable now. Electric concentration has made available magnetic iron ores formerly regarded as too lean for working. The progress of plant-breeding is greatly extending the possibility of supplementing the limited natural production of long-staple cotton. The development of effective systems of plantation management has opened the whole tropical belt to the production of rubber, formerly confined to limited areas in the tropical forests. Moreover, chemical science progresses steadily toward a stage in which an increasing number of raw materials may be produced synthetically.

Increased Consumption.— The growth of industry and wealth has further affected the demand for raw materials by raising the standard of consumption. To this influence must be ascribed not only such striking instances as increase in the demand for raw silk, and the finer grades of wool and cotton, but also the growth in the consumption of a long array of articles of common use.

For a study of the distribution of raw material ***see*** the article PHYSICAL RESOURCES.

Marketing.— It is rarely the case that rich sources of raw materials coincide with the industrial equipment and the consuming power requisite to their utilisation. They must, as a rule, seek distant markets, and therefore assume an important place in international trade. This trade is marked by serious fluctuations in both demand and supply. The production of raw materials of mineral origin is subject to shrinkage from the exhaustion of deposits and to expansion due to the discovery of new deposits. Raw materials of vegetable and animal origin are subject to serious fluctuations under seasonal influences. The demand for many of these products is peculiarly responsive to the alternations of prosperity and depression in the centres of industry and population.

Fluctuations of Brice.—Because of the wide fluctuations in the demand and supply of raw materials, rapid price fluctuations are characteristic of the whole field. In the case of raw materials that are relatively imperishable, like the textile fibres, metals and other minerals, the fluctuations are somewhat evened out by the accumulation of stocks in plethoric times, to be gradually released to trade in times of scarcity. This involves a complicated organisation of finance for carrying the stocks and for distributing the risks of price fluctuations. The physical aspects of the problem involve grading and storage — technically complicated processes, but seldom occasioning serious issues of policy. The financial aspects are more difficult, involving as they do the question of speculation.

In general, it may be said that the carrying of raw material stocks is inherently speculative. Where the producer holds the ramr material until he can dispose of it directly to the manufacturer, he carries the risk of price fluctuations himself. Where the manufacturer accumulates large stocks for future use, the risk rests on him. If speculative markets are well developed, much of the risk may be transferred from the producer of raw materials to a specially trained body of men, whose business it is to study all the possible sources of supply and form forecasts as to the future. Where such markets exist the manufacturer who makes a contract for the future delivery of goods, may safeguard himself against fluctuations in raw material prices through buying "futures"; a manufacturer who is producing for the general market may safeguard himself against a fall resulting from falling prices of material by "hedging," or selling futures for an equivalent volume of raw material.

From time to time the belief gains currency that the speculative markets are themselves responsible for price fluctuations in raw materials, and laws are passed for curbing their operations. While there are numerous instances of price manipulation through "corners," the weight of experience seems to indicate that speculative operations which do not conform with underlying conditions of demand and supply are doomed, as a rule, to disaster. It also indicates that price fluctuations are most disastrous in those materials for which there is no organised speculative market.

The Chief Markets.— The principal markets for dealing in raw materials are situated at the financial centres that were originally most closely related to the points of assembly and primary distribution. London has long been the predominant market for an extensive list of raw materials. Alongside of the London market, independent markets are established wherever the business of handling materials becomes important. The various markets are closely interrelated. No very wide difference can long maintain itself in the prices on the London and the New York copper markets, for example. The initiative toward price changes may arise in either market; it will soon be reflected in the other. Chief influence, however, rests with the market which represents the greater aggregation of trained speculative abilities combined with financial power. For this reason a market might retain its dominant position long after the immediate cause of its establishment, the concentration in the vicinity of material stocks for consumption, has disappeared.

International Control.— The World War brought to the attention of the governments and the public the remarkable dependence of modern industrial countries upon the international movement of raw materials. For the tremendous consumption of war the ordinary supplies of many raw materials were inadequate. Accordingly every belligerent nation adopted measures for conserving, rationing, stimulating the production or importation of, or preventing the exportation of, various raw materials. Raw materials occupied the centre of wartime economic policy (see CONTROL). After the close of hostilities there was a flood of projects for the rationing among nations of the available stocks of raw materials, and for the working out of a permanent policy of international control. All these projects fell to the ground because of the inherent difficulties of the problem. The world's trade in raw materials returned for the most part to the system of automatic distribution under the principle of relative economic attractive power.

Decline of Monopolistic Control.— The idea of controlling raw materials in the nationalistic interest persisted after the war, but under a different form and with different objectives. Thr general impoverishment resulting from the war threw into the foreground policies designed to increase the wealth of governments and their nationals. Possession of the sole or principal source of an important raw material appeared to offer an opportunity for price fixing which should draw to the controlling nation an increased share of the world's wealth. The pre-war control of nitrates by the Chilean Government and the German potash monopoly offered precedents for this policy of price control. For a time it was generally feared that a new régime of nationalistic raw material monopolies might be inaugurated, since it was technically feasible for single governments or two governments acting together to control over twenty important raw materials.

This apprehension proved groundless. Most of the attempted controls failed of their object through increased competition (rubber, Chile nitrates) or through threatened shrinkage of demand (potash). While it is true that most governments to-day are more sensitive to over-production and price depression in raw materials than before the war, the faith in the possibilities of important nationalistic gains through monopolistic methods of price control has greatly weakened.

Restriction of Capital.— A more subtle, and at first glance more justifiable, method of extracting a nationalistic gain from the possession of sources of raw materials consists in reserving their exploitation to national capital. This method has never been employed by the United States. Foreign and native capital have been admitted on equal terms to the development of raw material sources. The policy of most countries of Europe even before the war restricted the operations of foreign capitalists and companies in the raw material field. Since the war this policy has been stiffened rather than relaxed.

So far as concerns the raw materials found within the boundaries of the nation proper, no one questions the morals of a policy of restriction, although there remains a very serious question as to its expediency. A mine opened by foreign capital affords the same employment to domestic labour, gives the same stimulus to trade and transportation as a mine opened by native capital. The only difference consists in the fact that the profits must be remitted abroad, ultimately, however, in the form of commodity exports. If a country is sufficiently supplied with native capital to open up all its raw material resources, the problem of foreign capital will not arise. If it does not have adequate capital, its rate of progress may be greatly accelerated by the active participation of foreign capital in the work of development. The fear that the free admission of foreign capital to the actual work of development may produce a permanent tributary relation is groundless. If the interests of national labour and trade are properly safeguarded, the national enrichment following development will in the end make possible the buying out of foreign interests. Much of the financial power which has enabled the United States to change from the rôle of a debtor to a creditor nation is due in the last instance to the work of foreign capital in developing its resources. There can be no doubt that freedom and security for foreign investment in Russia and Siberia would raise the whole level of national prosperity and in the end produce so great an accumulation of Russian capital as to make foreign capital superfluous.

Exploitation of Colonials.—In the case of colonies and dependencies restrictions upon foreign capital are not only inexpedient, but of doubtful morality. It is an accepted principle of contemporary international ethics that colonies should be administered in the interest of their own inhabitants and of the world at large, not' in the particular interest of the imperial nation. The principle of mandate, as elaborated by President Wilson, is ethically applicable to all colonies. To reserve the exploitation of colonial raw materials to the imperial country, or, if the imperial country has inadequate capital, to hold such resources undeveloped, is injurious to the colony and to the world.

It was the prevalence of the conception of the colony as an exclusive field for imperial capital that led to the nineteenth century scramble for colonies and spheres of influence which, as is now universally admitted, was one of the ulterior causes of the World War. The same policy to-day not only holds back the progress of economic recovery from the war, but is generating throughout the world economic friction which seriously impairs the prospect of a peacefui and harmonious world order.

RAWTENSTALL, municipal borough in the parliamentary borough of Rossendale, Lancashire, England, 18 mi. N. from Manchester by the L.M.S.R. Pop. (1938) 27,070. Area, 14.9 sq.mi. Rawtenstall, which was incorporated in 1891, manufactures cotton and woollen goods and shoes.

RAY (or WRAY, as he wrote his name till 1670), **JOHN** (1628–1705), sometimes called the father of English natural history, was the son of a blacksmith of Black Notley, Essex, where he was born probably on Nov. 29, 1628. Educated at Catherine Hall and Trinity college, Cambridge, Ray became a fellow of Trinity college. He held many college offices.

His first botanical tour was undertaken in 1658, and on being compelled to give up his fellowship (1662), because he could not subscribe to the Act of Uniformity, Ray toured through Europe in 1663 with Francis Willughby (*q.v.*). From this tour Ray and Willughby returned with collections, on which they meant to base complete systematic descriptions of the animal and vegetable kingdoms. Willughby undertook the former part, but, dying in 1672, left only an ornithology and ichthyology, for Ray to edit; while the latter used the botanical collections for the groundwork of his *Methodus plantarum nova* (1682), and his great *Historia generalis plantarum* (3 vols., 1686, 1688, 1704). The plants gathered on his British tours had already been described in his *Catalogus plantarum Angliae* (1670), which work is the basis of all later English floras. He published an account of his foreign travel in 1673, entitled *Observations topographical, moral, and physiological, made on a Journey through part of the Low Countries, Germany, Italy, and France.*

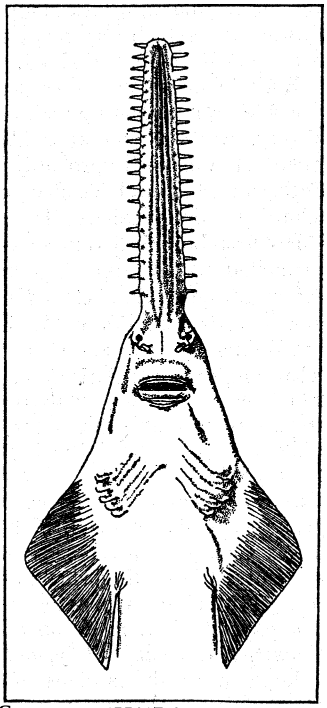
Ray's work shows signs of indebtedness to Joachim Jung of Hamburg and others. In his early work he classified his plants alphabetically but later he used the number of cotyledons as the basis of his classification. Ray also classified according to the fruit but eventually he used the flower for purposes of classification. He distinguished several natural groups such as the grasses, Labiatae, Umbelliferae and Papilionaceae. He was involved in a controversy with Rivinus upon Ray's indefensible separation of ligneous and herbaceous plants. In conjunction with Willughby Ray wrote a paper on his experiments on the motion of sap in trees. In 1667 Ray was elected F.R.S. He died on Jan. 17, 1705. The Ray Society, for the publication of works on natural history, was founded in his honour in 1844.

Ray was also the author of *Catalogus plantarum circa Cantabrigium* (1660, appendices in 1663 and 1685), this was written in conjunction with John Nid; *Catalogus plantarum Angliae* (1670, 1677); *Synopsis stirpium Britannicarum* (1690, etc.); *Stirpium Europaearum extra Britannias nascentium Sylloge* (1694); *Synopsis methodica Animalium Quadrupedum et Serpentini Generis* (1693), *Synopsis methodica Avium et Piscium* (1713) and *Historia Insectorum* (1710).

AUTHORITIES.—*Memorials of Ray* (with the addition of a complete catalogue of his works) edited by Dr. Edwin Lankester (Ray Society, 1846); *Correspondence* (with Willughby, Martin Lister, Dr. Robinson, Petiver, Derham, Sir Hans Sloane and others), edited by Dr. Derham (1718); *Selections*, with additions, edited by Lankester (Ray Society, 1848). Sci.*, iii. p. 332 (ed. 1847), and Wood, art. "Classification" in Rees's *Cyclopaedia.*

RAY, the name given to the short-snouted fish of the genus *Raia*, the skates and rays, and in a more general sense used for all the Selachians (*q.v.*) of the order Hypotremi, which are distinguished from sharks by their depressed form, and by the large pectoral fins, produced forwards and attached to the sides of the head above the gill-openings, which are ventral in position. Generally the nostrils and the transverse mouth are placed on the flat under surface of the head. On the upper surface of the head, behind the eyes, are large holes leading to the pharynx; these are termed spiracles, and serve for the intake of water for respiration. Rays are fitted, by their structure, for life at the bottom of the sea; most are viviparous, but the Raiidae have eggs enclosed in oblong horny cases similar to those of dog-fishes.

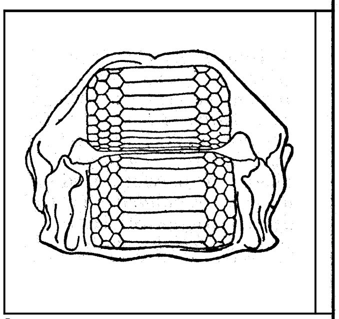
The l'orpedinidae, or electric rays, form an isolated family, distinguished by possessing large paired electric organs, formed of vertical hexagonal columns, placed between the pectoral fins and the head, and capable of giving powerful shocks, either for defensive purposes or to kill prey. The electric rays have a smooth and naked skin; the head and trunk, with the pectoral fins, form a circular disc; the tail is short and stout. About 20 species are known from warm seas, some reaching a weight of 200 lb.; one or two species of Torpedo occur in British waters.



SAW-FISH (PRISTIS PERROTTETI). THE SAW MAY REACH A LENGTH OF SIX FEET AND IS A FORMIDABLE WEAPON

The other rays, without electric organs, generally have a rough skin, often bearing strong spines. The most shark-like are the Rhinobatidae, of which about 20 species are known, from tropical and sub-tropical seas; in most of them the pectoral fins are relatively small, and the trunk passes gradually into the tail. The saw-fishes, or saw-rays (*Pristis*) differ from them in that the snout is produced into a long blade armed with a series of strong teeth on each side; five species are known from warm seas, frequenting sandy shores and estuaries. Some attain a length of 20 feet; such large specimens are dangerous, the saw being a formidable weapon.

In the Raiidae the large pectoral fins extend to the snout, and form a disc distinct from the slender tail. Numerous species of the cosmopolitan genus Raia are known, some living at considerable depths; some species reach a weight of 500 lb. These rays swim by undulating or flapping movements of the pectoral fins; their teeth are small, and blunt in some species, pointed in others; their food consists of molluscs, crustaceans and fishes. One of the largest British species is the common skate (R. *batis*), with long, pointed snout and greyish belly; the commonest ray in British waters is the thornback (R. clavata). Numbers of skates and rays are trawled; the pectoral fins are cut off and used as food.



JAWS OF AN EAGLE-RAY. THE PAVEMENT-LIKE TEETH ARE USED FOR CRUSHING SHELLS

The remaining rays are collectively termed "whip-tailed," the tail being long and slender and bearing a strong barbed spine connected with a poison gland; this spine is capable of inflicting noxious wounds, and is a dangerous weapon when the tail is lashed. All the whip-tailed rays are inhabitants of warm seas, except a few kinds of sting-ray in the rivers of South America. In the sting-rays (Trygon, etc.), as in most of the rays previously described, the teeth are numerous, small and blunt, but in the eagle rays (*Myliobatis*), they are relatively few in number, hexagonal, forming a flat pavement, and in the spotted eagle-rays (Aefobatus) are reduced to a single series of broad flat teeth, used by these large rays to crush the shells of oysters and other molluscs. Largest of all the rays are the devil-fishes, Manta and Mobula, which may measure 20 ft. across the disc. These rays are peculiar in that the anterior ends of the pectoral fins arc free, projecting forwards, when rolled up looking like a pair of horns, but when unrolled meeting below the mouth to form a scoop; a part of these devil fishes have been observed in a shallow bay pursuing the shoals of small fishes and scooping them into their mouths. (See SELACHIANS, SHARK.)

(C. T. R.)

RAYAH, the name given to the non-Muslim subjects of a Mohammedan ruler; all who pay the haraj or poll-tax levied on unbelievers (Arabic *ra'iyah,* peasants). Five classes of rayahs existed under Turkish rule until the system was destroyed by the revolution following the World War. These were: (1) the Greek, or *Roum* milleti; (2) the Armenian, or *Emeni milleti;* (3) the Catholic Armenians—Eremeni gatoliki milleti; (4) the Latin Christians, or *Roum* gatoliki milleti; and (5) the Jews, or *Ichondi* milleti. The name rayah was most commonly used of the peasants, but did not apply only to the agricultural populations. It depended on the status of the non-Muslim subject; this was fixed by religious faith.

RAYLEIGH, JOHN WILLIAM STRUTT, 3RD BARON (1842–1919), English physicist, was born in Essex on Nov. 12, 1842, and educated at Trinity college, Cambridge. He succeeded to his father's title in 1873. From 1879 to 1884 he was Cavendish professor of experimental physics in the University of Cambridge, and from 1887 to 1905, professor of natural philosophy at the Royal Institution of Great Britain. In 1896 he became scientific adviser to Trinity House, and in 1901 chief gas examiner. His early papers were mainly mathematical, including two on electromagnetic phenomena considered in connection with dynamical theory, and one on the stationary thermal conditions of a sphere exposed to radiation from distant sources. His paper on resonance was the first of a series of memoirs which culminated in his standard work, *A* Treatise on *Sound.* Other papers on sound dealt with the vibrations of a gas contained in a rigid spherical envelope, disturbances produced in sound waves by a spherical obstacle, general theorems relating to vibrations, absolute pitch and the resultant of a large number of vibrations of the same pitch and of arbitrary phase. He carried out experiments on the amplitude of the sound wave near the limit of audibility and on the direction of sound. Rayleigh also carried out investigations in optics and experiments in colour vision. He wrote on polarization, the scattering of light by particles, and the colour of the sky. Great experimental skill was shown in his reproductions of gratings by photographic methods. A series of four papers entitled "Investigations in Optics, with special reference to the Spectroscope," were published in the *Philosophical* Magazine in 1879 and 1880. These dealt with the general question of the resolving power of optical instruments. Later he dealt more particularly with the microscope. His contributions to hydrodynamics were important; he dealt with problems connected with the propagation of waves, showing how the wave velocity depends on the period. He applied this to the case of deep sea water waves and showed the part played by waves in earthquakes. Rayleigh's experiments on the instability of water jets led him to work on surface tension. While at the Cavendish laboratory he carried out his determination of the ohm. Rayleigh also worked out a formula for the distribution of energy in black-body radiation which holds for long wave-lengths. His interest in Prout's hypothesis as to atomic weights led him to a series of experiments to determine the densities of gases. While working on nitrogen Rayleigh made observations which led to the discovery of argon. Sir William Ramsay co-operated with him in the latter stages of the work. Lord Rayleigh had an interest in abnormal psychological investigations, and became a member and vice-president of the Society for Psychical Research. He was one of the original members of the Order of Merit, instituted in connection with the coronation of King Edward VII. In 1904 he was awarded a Nobel prize, and at the end of 1905 he became president of the Royal Society, of which he had been elected a fellow in 1873, and had acted as secretary from 1885 to 1896. He remained president till 1908, in which year he succeeded the 8th duke of Devonshire as chancellor of Cambridge university. In 1909 the prime minister, Asquith, set up a committee of aeronautics, of which Rayleigh was president. Rayleigh was the recipient of many academic and other honours. He died at Witham, Essex, on June 30, 1919

Rayleigh's papers are collected in four volumes. An account of his life, by his son, was published in 1924. *See* obituary notice by Sir A. Schuster in *Proceedings of the Royal Society* (vol. 98, 1920–21).

RAYMOND, HENRY JARVPS (1820–1869), American journalist, was born near the village of Lima, Livingston county, (N.Y.), Jan. 24, 1820. He graduated from the University of Vermont in 1840. After teaching, acting as correspondent for various papers, assisting Horace Greeley (*q.v.*) on the *New Yorker* and the *Tribune,* and serving on the *Courier and Enquirer,* Raymond obtained backing for a venture of his own, and the first issue of the New York *Times* appeared Sept. 18, 1851. Of this journal Raymond was editor and chief proprietor until his death. Raymond was a member of the New York Assembly in 1850 and speaker in 1851 and again in 1862. He supported the views of the radical anti-slavery wing of the Whig Party in the North. His nomination over Greeley on the Whig ticket for lieutenant-governor and his election in 1854 led to the dissolution of the famous political "firm" of Seward, Weed and Greeley. He took a prominent part in the formation of the Republican Party, and drafted the famous "Address to the People" adopted by the Republican convention which met in Pittsburgh in Feb. 1856. He was a member of the National House of Representatives in 1865–67. He retired from public life in 1867 and devoted his time to newspaper work until his death in New York city, June 18, 1869. Raymond was an able and polished public speaker; but his great work was in elevating the style and general tone of American journalism. He published several books, including a biography of President Lincoln, which in substance originally appeared as *A History of the Administration of President Lincoln* (1864), and which with additions has been republished under varying titles.

See Augustus Maverick, *Henry J. Raymond and the New York Press for Thirty Years* (1870), which includes in the appendix an autobiographical fragment, various addresses by Raymond, etc., and "Extracts from the Journal of Henry J. Raymond," edited by his son, Henry H. Raymond, in *Scribner's Monthly* (1879–80).

RAYMOND, a city of Pacific county, Washington, U.S.A., on Willapa Harbor, at the mouth of the Willapa river, 15 m. from the ocean and about 30 m. N. of the estuary of the Columbia river. It is on the Roosevelt Pacific highway, and is served by the Chicago, Milwaukee, St. Paul and Pacific and the Northern Pacific railways and by steamship lines. Pop. (1940) 4,045. The traffic of the harbour amounted in 1939 to 352,921 gross tons of vessel cargo, valued at $5,274,680 (largely shipments of lumber) and floated timbers valued at $6,942,806.

RAYMUND, prince of Antioch (1099–1149), was the son of William VI., count of Poitou. On the death of Bohemund II. of Antioch (*q.v.*), the principality devolved upon his daughter, Constance, a child of less than 10 years of age (1130). Fulk, the king of Jerusalem, and, as such, guardian of Antioch, sent envoys to England to offer her hand t~ Raymund, who was then at the court of Henry I. Raymund reached Antioch in 1135. Here he was married to Constance by the patriarch of Antioch, but not until he had done him homage. The marriage excited the indignation of Alice, the mother of Constance, who had been led by the patriarch to think that it was she whom Raymund desired to wed; and the new prince had thus to face the enmity of the princess dowager and her party. In 1137 he had also to face the advent of the eastern emperor, John Comnenus, who had come south partly to recover Cilicia from Leo, the prince of Armenia, but partly, also, to assert his rights over Antioch. Raymund was forced to do homage, and even to promise to cede his principality as soon as he was recompensed by a new fief, which John promised to carve for him in the Mohammedan territory to the east of Antioch. The expedition of 1138, in which Raymund joined with John, and which was to conquer this territory, failed. New disputes arose, and in 1142 John ravaged the neighbourhood of Antioch, but was unable to attain any effective decision. When, however, Raymund demanded from Manuel, who had succeeded John in 1143, the cession of some of the Cilician towns, he found that he had met his match. Manuel forced him to a humiliating visit to Constantinople, during which he renewed his oath of homage and promised to receive a Greek patriarch. In 1149 he fell in battle during an expedition against Nureddin.

For his career see Rey, in the *Revue de l'orient latin,* vol. iv.

(E. B.)

RAYMUND OF TOULOUSE (d. 1105) (called also Raymund of St, Gilles, after a town near Nimes), count of P'rovence, one of the leaders of the first Crusade. According to an Armenian authority, he had lost an eye on a pilgrimage to Jerusalem before the first Crusade; but the statement probably rests on the fact that he was one-eyed, *vir monoculus.* He is also recorded to have fought against the Moors in Spain before 1096; and he was the first of the princes of the West to take the cross after Pope Urban's sermon at Clermont. The oldest and the richest of the crusading princes, the count of Provence started, in October 1096, with a large company, which included his wife, his son, and Adhemar, bishop of Puy, the Papal Legate. His march lay by Ragusa and Scutari to Durazzo, whence he struck eastward, along the route also used by Bohemund, to Constantinople. At the end of April 1097 he was with difficulty induced to take a somewhat negative oath of fealty to Alexius. He was present at Nicaea and Dorylaeum; but he first showed his hand in October 1097, when, as the army neared Antioch, and a rumour was spread that Antioch had been deserted by the Turks. he sent a detachment in advance to occupy the city—an action which presaged his future difficulties with Bohemund (*q.v.*), the would-be prince of Antioch. In the siege of Antioch (which was far from having been deserted) Raymund played his part. When the city was taken by Bohemund (June 1098), the count garrisoned the *palatium Cassiani* (the palace of the emir, Yagi Sian) and the tower over the Bridge Gate. He lay ill during the second siege of Antioch by Kerbogha; but in his camp a great spiritualistic activity culminated in the discovery of the Holy Lance by the Provençals. The miracle stimulated the crusaders to defeat Kerbogha: the Lance itself, discovered by the Provençals and carried henceforward by their count, became a valuable asset in Raymund's favour. A struggle arose between the Provencals and the Normans, partly with regard to the genuineness of the Lance, and partly with regard to the possession of Antioch. Raymund moved southward in the autumn of 1098 to the siege of Marra, leaving a detachment of his troops in Antioch. With Bohemund left in Antioch; with the Holy Lance to give him prestige; and with the wealth which he had at his disposal, the count of Provence began to figure as the leader of the Crusade. But he delayed the advance to Jerusalem to besiege Arca with the intention of founding a principality to check the extension of Bohemund's kingdom. A wave of indignation in the ranks, and the inducements which the emir of Tripoli offered to the other princes, forced Raymund to desist from the siege (May 1098), and to march southwards to Jerusalem. He hampered Godfrey in the campaigns which followed.

Going north in the winter of 1099–1100 Raymund began hostilities against Bohemund, from whom he hoped to wrest Laodicea. From Laodicea he went to Constantinople, where he fraternized with Alexius, the great enemy of Bohemund. Joining in the ill-fated crusade which followed the first, he escaped from the *débâcle,* and returned to Constantinople. In 1102 he went by sea from Constantinople to Antioch, where he was imprisoned by Tancred, regent of Antioch during the captivity of Bohemund, and only dismissed upon promising not to attempt any conquests in the country between Antioch and Acre. He broke his promise, attacking and capturing Tortosa, and beginning to build a castle for the reduction of Tripoli (on the *Mons Peregrinus*). In this policy he was aided by Alexius. In 1105 Raymund died. He was succeeded by his nephew William, who in 1109, with the aid of Baldwin I., captured the town and definitely established the county of Tripoli. William was ousted in the same year by Raymund's eldest son Bertrand; and the county continued in the possession of his house during the 12th century[1].

Raymund of Toulouse represents the Provencal element in the first Crusade, as Bohemund represents the Norman, and Godfrey and Baldwin the Lotharingian. If in temperament he is the least attractive among the princes of the first Crusade, he was yet one of its foremost leaders, and he left his mark upon

[1]For the future history of the county, *see* under RAYMUND OF TRIPOLI and BOHEMUND IV.

history in the foundation of the county of Tripoli.

Raymund of Agiles, a clerk in the Provencal army, gives the history of the first Crusade from his master's point of view. For a modern account of Count Raymund's part in the crusading movement, one may refer to Rohricht's works. *(See* CRUSADES.)

RAYMUND OF TRIPOLI, the most famous of the descendants of Raymund of Toulouse, was a great-grandson of his eldest son Bertrand: his mother was Hodierna, a daughter of Baldwin II., and through her he was closely connected with the kings of Jerusalem. He became count of Tripoli in 1152, on the assassination of his father. In 1164 he was captured by Nureddin, and was only released in 1172 after a captivity of eight years. In 1174 he claimed the regency on behalf of Baldwin IV. (at once a minor and a leper), in virtue of his close relationship, and the claim was acknowledged. After two years the regency seems to have passed to Reginald of Chbtillon; but Raymund, who had married the heiress of the county of Tiberias, continued to figure in the affairs of the kingdom. His great ability procured him enemies; for two years, 1180–1182, Baldwin IV. was induced by evil advisers to exclude him from his territories, But as Saladin grew more threatening, Raymund grew more indispensable; and in 1184 he became regent for Baldwin V., on condition that, if the king died before his majority, his successor should be determined by the great powers of the West. Raymund conducted the regency with skill, securing a truce from Saladin in 1185; but when Baldwin V. died, in 1186, the supporters of Guy de Lusignan (the husband of Baldwin IV.'s sister, Sibylla) had him crowned, in defiance of the stipulation under which Raymund had become regent. Raymund, left in isolation, retired to Tiberias, and negotiated a truce for himself with Saladin. His ambiguous position led contemporaries to accuse him of treasonable correspondence with Saladin; but his loyalty to the Christian cause was nobly shown in 1187, when he reconciled himself to Guy, and aided him in the battle of Hattin, which was engaged, however, in the teeth of his earnest advice. He escaped from the battle wounded, and ultimately retired to Tripoli, where he died (1187). Raymund was as free from venality as any other man of his period and more capable than most of his contemporaries.
