PONTIVY, a town of W. France, capital of an arrondissement in the department of Morbihan. Pop. (1936) 7,109 A monastery was founded there in the 7th century by St. Ivy of Lindisfarne. The town, at the confluence of the Blavet with the Nantes-Brest canal, has distinct parts—the old town and that to the south known as Napoléonville and built by Napoleon I as military headquarters for Brittany The ancient castle (1385) of the dukes of Rohan, whose capital the town was, is a museum. The chief industry is the manufacture of agricultural implements.

PONT-L'ABBÉ, a tonn of western France in the department of Finistère, 13 mi. S.W. of Quimper by rail. Pop (1936) 5.578. The town stands on the right bank of the estuary of Pont-l'Abbé, 2 mi. from the sea Its port carries on fishing, imports timber. coal, etc., and exports mine-props and the cereals and vegetables of the neighbourhood. There is a church of the 14th, 15th and 16th centuries, once attached to a Carmelite convent; an old castle is occupied by the *hôtel* de *ville.* The local costumes, trimmed with the bright-coloured embroideries for which the town is noted, are among the most striking in Brittany; the *bigouden* or headdress of the women has given its name to the female inhabitants.

PONTOISE, a town of northern France, capital of an arrondissement of the department of Seine-et-Oise, 18 mi N.W. of Paris on the railway to Dieppe. Pop. (1936) 11,959. Pontoise existed in the time of the Gauls as *Briva* Zsarae (Bridge of the Oise). It was destroyed by the Normans in the 9th century, united with Normandy in 1032, and acquired by Philip I. in 1064. Capital of the French Vexin, it played a conspicuous part in the wars between the French and the dukes of Normandy and in the Hundred Years' War. The English took it in 1419, and again in 1437. In 1441 Charles VII. took it by storm after a three months' siege. After belonging to the count of Charolais down to the Treaty of Conflans, it was given as a dowry to Jeanne of France when she was divorced by Louis XII. The parlement of Paris several times met in the town; and in 1561 the states-general convoked at Orléans removed thither after the death of Francis II. During the Fronde it offered a refuge to Louis XIV. and Mazarin. Henry III. made it an apanage for his brother the duke of Anjou. Later it passed to the duke of Conti. Down to the Revolution it remained a monastic town.

Two churches alone remain: St. Maclou, a 12th century church, restored in the 1 jth and 16th centuries, and containing a fine holy sepulchre of the 16th century; and Notre-Dame, of the close of the 16th century, with the tomb of St. Gautier, abbot of Meulan in the 12th century. Trade is in grain and in flour ground by numerous water-mills on the Viosne; a well-known fair is held in November. At Mériel, near Pontoise, there are remains of the 12th century Cistercian abbey of Le Val.

PONTOPPIDAN, ERIK (1698–1764), Danish author, was born at Aarhus on Aug. 24, 1698. He studied divinity at the University of Copenhagen, and for some time acted as a travelling tutor. In 1735 he became one of the chaplains of the king. In 1738 he was made professor extraordinary of theology at Copenhagen, and in 1745 bishop of Bergen. He died on Dec. 20, 1764.

His principal works are: *Theatrum* Daniae *veteris* et modernae (4to, 1730), a description of the geography, natural history, antiquities, etc, of Denmark; Gesta et *vestigia danorum* extra Daniam (3 vols. 8vo, 1740), a laborious but uncritical work; Annales *ecclesiae danicae* (3 vols., 1741–1747); *Marmora danica* selectiora (2 vols. fol, 1739–41); *Glossarium* norvegicum (1749); Det forste *forsög Norges* naturlige *historie* (4to, 1752–54); Eng. trans., Natural History *of* Norway (2 vols., 17jg), containing curious accounts, often referred to, of the Kraaken, sea-serpent, and the like; Origines *hafnienses* (1760); *Menoza* (3 vols., 1742–43), a religious novel. His Danske Atlas (7 vols. 4to), is an historical and topographical account of Denmark.

See S. M. Gjellerup in Dansk *Biografisk* Lexikon (vol. xiii., 1899).

PONTOPPIDAN, HENRIK (1857–1943), Danish author, was born at Fredericia on July 24, 1857. He studied at the university of Copenhagen, and when he was 18 travelled on foot through Germany and Switzerland. His novels show an intimate acquaintance with peasant life and character, the earlier ones showing clear evidence of the influence of Kjelland. An excellent example of his work is the trilogy dealing with the history of Emanuel Ransted, a theorizing radical parson who marries a peasant wife These three stories, *Muld* ("Soil," 1891), Det *Forjaettede Land* ("The Promised Land," 1892) and *Dommens Dag* (1895) are marked by fine discrimination and great narrative power. Among his other works are Fra Hytterne (1887), *Folkelivsskildringer* (2 parts, 1888–90) and Skyer (1890). He began in 1898 a new series in Lykke Per, the story of a typical Jutlander, completed in 1904. In 1912–16 appeared his trilogy, *De Dodes Rige,* dealing with the first decade of the 20th century. In 1917 he shared with Gjellerup the Nobel prize for literature. He died Aug. 21, 1943, in Charlottenlund, Denmark.

See an article of Niels Möller in Dansk *Biografisk* Lenikon (vol. xiii., 1899); also V. Andersen, *Henrik* Pontoppidan (Copenhagen, 1917).

PONTORMO, JACOPO DA (1494–1556), was one of the leading representatives of the late Florentine school of painting, which, though nearing exhaustion. still reflected the traditions of the great age. He was born at Pontormo, near Empoli, on May 24, 1494, and was the son of Bartolommeo Carucci, a painter. He was apprenticed to Leonardo da Vinci, and afterwards to Albertinelli and Piero di Cosimo. At the age of 18 he entered the workshop of Andrea del Sarto and was remarked as a young man of exceptional promise. One of his earliest works extant, painted in 1516, is the fresco in the vestibule of S. Annunziata, Florence, representing the "Visitation." Two years later he completed the altarpiece in the church of S. Michele Visdomini. From this early period of the master date three small pictures painted for the mansion of Piero Franceschi Borgherini of Florence. One of these, representing "Joseph and his Kindred in Egypt," is now in the National Gallery, London. It was regarded by Vasari as Pontormo's best picture. The other two panels, also of the story of Joseph, are with Lady Desborough at Panshanger. In 1521 he was employed on decorative work in the Medicean villa at Poggio a Caiano. He was then at the height of his powers, and a fresco painted in a large lunette with mythological figures may be regarded as one of his most successful achievements. He then took to imitating Durer, whose engravings and woodcuts were circulating in Italy. In 1522 he executed at the Certosa di Val d'Erna a series of frescoes founded on the Passion subjects of the German master. Pontormo's last works were a series of frescoes for the church of S. Lorenzo, Florence. He had then fallen under the dangerous influence of Michelangelo's style. After working on these for 11 years he left them incomplete. He died in Florence on Jan. 2, 1556.

See Vasari, Vite, edit. Milanesi.

PONTREMOLI, a town and bishop's see in Tuscany, Italy, in the upper valley of the Magra, 843 ft. above sea-level. Pop. (1936), 3,801 (town); 14,537 (commune). The town has a castle and walls, with the church of the Annunziata and its Augustinian monastery.

PONTRESINA (5,915 ft.), a village of the upper Engadine in the canton of Graubunden (Grisons), Switzerland, a station on the Rhaetic railway which goes over the Bernina pass. It is an important health resort and winter sport centre at the foot of the Bernina alps. Its 984 inhabitants are German-speaking.

PONTUS, a district in the north-east of Asia Minor bordering on the Euxine (Black Sea). About 301 B.C. Mithradates I., Ktistes, founded a kingdom beyond the Halys ruled by a succession of kings, mostly bearing the same name, till 64 B.C. As the greater part of this kingdom lay within Cappadocia, which extended from the borders of Cilicia to the Euxine, the kingdom was at first called "Cappadocia towards the Pontos" (πρὸς τῷ Πόντῳ), but afterwards simply "Pontus." Under the last king, Mithradates the Great, the realm of Pontus included not only Pontic Cappadocia but also the seaboard from the Bithynian frontier to Colchis, part of inland Paphlagonia, and Lesser Armenia (see MITHRADATES). After Pompey's conquest part of the kingdom was annexed to the Roman empire, being united with Bithynia in a double province called "Pontus and Bithynia"; this part included the seaboard between Heracleia (Eregli) and Amisus (Samsun), the Ora pontica. Hereafter the simple name Pontus was employed to denote the half of this dual province.

Its native population was of the same stock as that of Cappadocia, an oriental race called by the Greeks Leucosyri or White Syrians, but their precise ethnological relations are uncertain. It is a table-land, forming the north-east corner of the great plateau of Asia Minor, edged on the north by a lofty mountain rim, along the foot of which runs a fringe of coast-land. The table-land consists of a series of fertile plains, drained almost entirely by the river Iris (*Yeshil Irmak*) and its tributaries. Between the Halys and the Iris the mountain rim is comparatively low and broken, but east of the Iris it is a continuous lofty ridge, the rugged northern slopes of which are furrowed by torrent beds. These inaccessible slopes were inhabited in Strabo's time by wild, half-barbarous tribes, of whose ethnical relations we are ignorant — the Chalybes, Tibareni. Mosynoeci, 'and Macrones, on whose manners and condition some light is thrown by Xenophon (*Anab.* V.). But the fringe of coast-land from Trebizond westward is one of the most beautiful parts of Asia Minor.

The seacoast was studded with Greek colonies founded from the 6th century onwards: Amisus, a colony of Miletus, Cotyora, Cerasus, and Trapezus (Trebizond), a famous city from Xenophon's time until the end of the middle ages. The last three were colonies of Sinope, itself a Milesian colony. The chief towns in the interior were Amasia, on the Iris, the birthplace of Strabo, the capital of Mithradates the Great, and the burial place of the earlier kings, whose tombs still exist; Comana, higher up the river, a famous centre of the worship of the goddess Ma (Cybele, *q.v.*); and Zela, a religious centre, refounded by Pompey, now Zileh.

Christianity was introduced into the province Pontus (the Ora pontica) by way of the sea in the 1st century after Christ and was deeply rooted when Pliny governed the province (A.D. 111–113). But the Christianization of the inland Pontic districts began only about the middle of the 3rd century and was largely due to the zeal of Gregory Thaumaturgus, bishop of Neocaesarea.

See Ramsay, *Histor.* Geogr. of Asia *Minor* (1890); Anderson and Cumont, Studia pontica (1903 et seq.); Babelon and Reinach, Recueil des *monnaies d'Asie min.,* t.i. (1904); Cambridge Ancient History, vol. iii. ch. xxv. (bibliography).

PONTUS DE TYARD (1521?–1605), French poet and member of the Pléiade (see DAURAT), was seigneur of Bissy in Burgundy, where he was born in or about 1521. He belonged to the Lyons group of poets and was a friend of Antoine Héroet (*q.v.*) and Maurice Scève. His *Erreurs amoureuses,* originally published in 1549, was augmented with other poems in successive editions till 1573. He translated (1551) the *Dialoghi d'amore* of Léon Hébrieu, the breviary of philosophic lovers of that day. Two of his *Discours philosophiques* (1552) have what may fairly be called parallel statements of the *Défense* et illustration *de* la *langue française* of Du Bellay. Pontus was one of the first to write sonnets in French (the actual priority belongs to Melin de St. Gelais). It is also said that he introduced the sestine into France, or rather re-introduced it, for it was originally a Provencal invention. In 1578 he became bishop of Châlons-sur-Saône. He resigned in 1594, and died Sept. 23, 1605.

See the *Pléiade française* (1875) of M. Ch. Marty-Laveaux.

PONTYPOOL, an urban district of Monmouthshire, England, $9\frac{1}{4}$ mi. N. of Newport, served by the G.W.R. and L.M.S.R. Pop. (est. 1938) 40,200. Area, 24 9 sq.mi. It is at the base of Mynydd Maen on the right bank of the Avon Lewyd, a tributary of the Usk. Its growth is due to its situation on the eastern edge of the great south Wales coalfield. The earliest record of trade in iron is in 1588, but it was developed chiefly in the beginning of the 18th century by the Hanbury family. Tin plate was first made there by Andrew Yarranton in 1670. There are tin and iron works in the neighbourhood. Water communication is with Newport by the Monmouthshire canal. The urban district included after 193j the former urban districts of Abersychan and Panteg. The rapid growth of the Abersychan population caused the town to expand along the main valley and its tributaries. At Panteg are large steel and galvanized iron works. This whole district suffered greatly in the depression of the 1930s.

PONTYPRIDD, an urban district of Glamorganshire, Wales, situated on the Taff at its junction with the Rhondda, on the G.W.R. and on the Glamorganshire canal, 12 mi. N.W. from Cardiff. Pop. (est. 1938) 38.610. Area, 12.7 sq.mi. It receives its name from a remarkable one-arch bridge spanning the Taff, erected in 1755. It was an insignificant village till the opening of the Taff Vale railway into the town in 1840, and it owes its progress chiefly to the development of the coal areas of the Taff-Rhondda valleys. It also possesses chain and cable works, chemical works, and iron and brass foundries. It became a sort of gathering focus for the coal before being sent to Cardiff and Barry for export. Depression following World War I seriously affected this area, 60 8% of insured men being unemployed in May 1934. A trading estate in the district afforded some relief.

PONY, a horse of a small breed (see HORSE).

PONY EXPRESS, THE, an establishment **of** the United States government to carry mail on horseback from St. Joseph, Mo. to the Pacific before railways or telegraph It was started in 1860, when an impending crisis made the rapid communication of news between the older States and far-distant California a national necessity, and it had a brief existence of but 16 months before it was supplanted by a telegraph line. The animals used were, of course, not ponies but fleet American horses. They were stationed at "stages" from 10 to 15 miles apart and each rider rode three animals successively, covering not less than 33 miles before he passed the pouch to his successor. The fastest trip made was in 7 days and 17 hours when Lincoln's first inaugural address was carried, but the schedule was 10 days, about 24 days faster than the schedule of Butterfield's Overland Stage line travelling on the southern route. The maintenance of this schedule in all kinds of weather and in the face of Indian dangers and other hazards won for the service a fame which time has not diminished.

PONZA (anc. *Pontia)*, the principal of a small group of islands belonging to Italy. Pop. (1936), 2,787 (town), 6,457 (commune). The group is of volcanic origin, and includes Palmarola (anc. Palmaria), Zannone (Sinonia), Ventotene (Pandateria) and Santo Stefano. It is about 20 mi. S. of Monte Circeo and 70 mi. W. of Naples. There is regular communication with Naples by steamer, and in summer with Gaeta. The islands rise to a height of about 70 ft. above sea-level. Ventotene has a convict prison, and the islands were a place of banishment in ancient times. Under fascism, Ponza became again a place of banishment for Italians opposed to Mussolini, like Gen. Bencivenga and others.

POOD, a Russian weight, equivalent to 40 lb. Russian and about 36 lb. avoirdupois. A little more than 62 poods go to the ton. The word is an adaptation of the Norse *pund*, pound.

POOLE, REGINALD STUART (1832–1895), English archaeologist and orientalist, was born in London on Jan. 27, 1832, the son of Edward Poole and his wife *née* Sophia Lane. Poole acquired his taste for antiquities during a stay (1842–49) with his uncle, R. S. Poole, in Cairo. In 1852 he became an assistant in the British Museum, and was assigned to the department of coins and medals. of which in 1870 he became keeper. In 1882 he helped to found the Egypt Exploration Fund, and in 1884 the Society of English Medallists. He retired in 1893, and died on Feb. 8, 1895.

His elder brother, EDWARD STANLEY POOLE (1830–1867), who was chief clerk in the science and art department at South Kensington, was an Arabic scholar, whose early death cut short a promising career. His two sons, Stanley Lane-Poole (*q.v.*) and Reginald Lane-Poole (b. 1857), keeper of the archives at Oxford (1909–27), lecturer in diplomatic, and author of various historical works, carried on the family tradition of scholarship.

POOLE, WILLIAM FREDERICK (1821–1894), American bibliographer and historian, was born in Salem, Mass., on Dec. 24, 1821. He graduated at Yale college in 1849 and in the previous year had already compiled an *Index* to *Periodicals,* which was published anew in 1853 and 1882. Later editions were prepared in collaboration and rendered great service to scholars. He was one of the founders of the American Library Association.

His writings include: *The Battle of the Dictionaries* (1856); *Websterian Orthography* (1857); *Cotton Mather and Salem Witchcraft* (1869); *The Popham Colony* (1886); *Anti-Slavery Before 1800* (1887); and *Columbus and the Finding of the New World* (1892).

POOLE, a municipal borough and county, market town and seaport in Dorsetshire, England, 113½ mi. S.W. by W. from London by the S.R. Pop. (est. 1938) 68,860. Area 24.4 sq.mi. Poole is not mentioned till after the Domesday survey. The manor, part of that of Canford, belonged in 1086 to Edward of Salisbury, and passed to William Longespée, earl of Salisbury, thence to Edmund de Lacy, earl of Lincoln, and with his heiress to Thomas, earl of Lancaster, and so to the crown. It is uncertain when the burgesses obtained their town at the fee-farm rent of £8 13*s.* 4*d.* mentioned in 1312. In 1372 they obtained assize of bread and ale. and right to hold the courts of the lord of the manor. Elizabeth incorporated Poole in 1569 and made it a separate county. Poole, as headquarters of the Parliamentary forces in Dorset during the Civil War, escaped the siege that crippled so many of its neighbours. It is on a peninsula between Holes Bay and the shallow irregular inlet of Poole Harbour, one of the best on the south coast, extending inland 6 mi., with a general breadth of 4 mi. The harbour has a narrow entrance, and is studded with low islands, on the largest of which, Brownsea or Branksea, is a castle originally erected as a defense of the harbour in Tudor times, and strengthened by Charles I. A bridge across the harbour entrance, forming a link for road transport to Bournemouth, was opened in 1927. Clay is exported and shipbuilding and the making of ship fittings are carried on.

POOLS, IN INDUSTRY. Rival manufacturers or traders who, while still ostensibly in competition with each other, either allocate among themselves by agreement the amount or proportion of business each shall do, or agree as to who shall put in the lowest tender for a contract, frequently set up, as a part of their agreement machinery, a pooling system. One type is that adopted by those associations of manufacturers in the same industry which allot to each member a percentage of the output of the whole group, and require that each member who exceeds his "quota" shall pay an appropriate sum into a pool and that each member who does not reach his quota shall receive an appropriate sum from it. In associations concerned with work for which tenders are asked, three kinds of pooling are known. In one the tenders prepared by members of the group are confidentially examined by the secretary of the association and a percentage added to each, to be subsequently paid by the successful tenderer into a pool and divided among the rest. In another a uniform tender price is decided upon which all shall quote on the understanding that the firm receiving the contract shall pay an agreed percentage into the pool. In another the tenderers are informed of the order in which the sums quoted run, from highest to lowest, in order that the lowest tenderer may hold out for his price: in which case also the successful tenderer pays an agreed percentage of his contract into a pool. Another arrangement is the profit pooling agreement in which the future profits of two or more businesses are for a specified period paid into a common fund and divided out in agreed proportions. *See* ASSOCIATIONS, INDUSTRIAL; COMPETITION and TRUSTS. (J. H.)

Finance and Commerce — A pool on the stock exchange would work in some such way as follows, although the actual details naturally vary: —

(1.) Its members would consist of the holders of a certain share, and while the pool organizers would not attempt to bring in every shareholder, the members of the pool would between them have to hold a substantial block of the total shares issued for the formation of the pool to be worth while.

(2.) The pool members would authorize the pool organizers to sell their shares on their behalf, and would agree not to sell them themselves.

(3.) The pool organizers would agree not to sell these shares at less than a certain price. Thus the first third of the shares in the pool might be sold at a minimum of 21s., the next third at 22s., and the remainder at 23s. 6d. The proceeds of the sale as effected, less the charge for the pool's expenses, would be paid over to the pool members in proportion to the shares each held.

(4.) After six months from its date of formation, the pool would break up, and any shares still unsold would be re-transferred to the members, to deal with as best they could.

The whole object of a pool is to control and regulate the supply of a certain share to the market. For a pool to be effective, it must have a big holding of the share, or it will be faced with competitive selling from outsiders, and will be unable to obtain its minimum price.

If a new issue meets with an immediately unfavourable reception so that the bulk of it has to be taken up by the underwriters, it often happens that the underwriters form a pool.

A commercial pool in a commodity would work in very much the same way; it might be a buyer's pool—as the American rubber pool—or a seller's pool, such as the Canadian wheat pool, a great non-profit, co-operative marketing association in Canada. In either case, the buying and selling is done by the pool for its members, who agree to operate only through the pool. The object is to obtain by combined effort a reasonable price. (N. E. C.)

United States. — Pools among railway companies became widely prevalent throughout the United States between 1870 and 1887 and aroused so much opposition on the part of the public that the Interstate Commerce Act was passed in 1887 making them illegal as regards interstate traffic. The act was not altogether successful for division of traffic, especially in the shipping of cotton, fruit and grain, persisted without the usual pooling machinery being in evidence. Such agreements, however, being non-enforceable, were seldom of long duration. The wisdom of the Interstate Commerce Act has been often called into question, and recommendations favouring legalization under government supervision have been made both in presidential messages and in the reports of the interstate commerce commission itself. A decision of the Supreme Court in 1911 making contracts not illegal unless in "unreasonable restraint of trade" eased the situation somewhat, while the modern tendency toward combination also tends to eliminate the conditions which cause pooling arrangements to be made.

POONA, a city and district of British India, in the Central division of Bombay. The city is at the confluence of the Mutha and Mula rivers, 1,850 ft. above sea-level and 119 m. S.E. from Bombay on the Great Indian Peninsula railway. Pop. (1931), 214,380 (including Kirkee). It is pleasantly situated amid extensive gardens, with a large number of modern public buildings, and also temples and palaces dating from the 16th to the 19th century. The palace of the peshwas is a ruin, having been destroyed by fire in 1827. From its healthy situation Poona has been chosen not only as the headquarters of the Southern Command, but also as the residence of the governor of Bombay during the rainy season, from June to September. The cantonment is at Kirkee, 4 m. N.W. (pop. 16,302), where there is also a large ammunition factory. The waterworks were constructed mainly by the munificence of Sir Jamsetjee Jeejeebhoy. There are cotton, paper, rice and sugar mills, ice, and iron works, distilleries and a tannery. It was proposed in 1927 to bring electric power to the city from the Tata power company's installation at Nila-Mula. Educational institutions include the government Deccan college; Fergusson college; the government colleges of science, engineering and agriculture; training schools for masters and mistresses; medical school; and municipal technical school.

The DISTRICT OF POONA has an area of 5,332 sq.m. Population (1931), 1,169,798. Towards the west the country is undulating, and numerous spurs from the Western Ghats enter the district; to the east it opens out into plains. The district is liable to drought. The two most important irrigation works are the Mutha canal, with which the Poona waterworks are connected, and the Nira canal. The district is traversed by the Great Indian Peninsula railway, and also by the Madras and Southern Mahratta line, which starts from Poona city towards Satara.

In the 17th century the district formed part of the Mohammedan kingdom of Ahmadnagar, and was the early centre of the Mahratta power and the seat of government.

POORE (or POOR), **RICHARD** (d. 1237), English bishop, was a son of Richard of Ilchester, bishop of Winchester. About 1197 he was chosen dean of Sarum and, after being an unsuccessful candidate for the bishoprics of Winchester and of Durham, he became bishop of Chichester in 1214. In 1217 he was translated to Salisbury, where he succeeded his elder brother, Herbert Poore, and in 1228 to Durham. He died at Tarrant Monkton, Dorset, said by some to be his birthplace, on April 15, 1237. Poore took some part in public affairs, under Henry III., but the great work of his life was done at Salisbury. Having in 1219 removed his see from Old to New Sarum, or Salisbury, he began the building of the magnificent cathedral there. He laid the foundation stone in April 1220, and during his episcopate he found money and forwarded the work in other ways. For the city the bishop secured a charter from Henry III. and he was responsible for the plan on which it was built.

POOR LAW. The term "poor law" in British usage denotes a peculiar system of giving public relief to the destitute. (See PAUPER.) The principles are laid down in statutes and worked out in detail in "orders" and "circulars" of a central department of State, the Ministry of Health or the Scottish Board of Health. The administration is in the hands of a special local authority, known as the board of guardians in England and Wales, and the parish council in Scotland. The modern system began in 1834, when the "New Poor Law" replaced the "Old Poor Law" which after nearly two and a half centuries of existence had become an intolerable scandal. The machinery set up then has not undergone much change, nor, in theory at least, have the methods of relief, though there have been considerable modifications in practice, which will be referred to presently. The whole of the Statute law was consolidated in the Poor Law Act, 1927, which together with the Poor Law Institutions Order, 1913, and the Relief Regulation Order, 1911, contains a full outline of the system.

Central Authority.—The Ministry of Health took over the functions of the Local Government Board in 1919. (The first central authority was the Poor Law Commissioners of 1834. These were replaced in 1847 by the Poor Law Board, which in turn was abolished on the creation of the Local Government Board in 1871.) The Ministry of Health exercises a close control over the local authorities, through its poor law "orders," which they must obey, its inspectors, its systematic audit of local accounts, and its power of sanctioning loans. And, by the Boards of Guardians (Default) Act, 1926, the minister has power to supersede any board of guardians, which he considers unable to discharge its functions properly, by persons appointed by himself.

Local Authorities.—The board of guardians is a popularly elected body in each of the 600 odd Poor Law Unions in England and Wales, whose members hold office for three years. It has a limited power of co-opting. The board acts, like other local authorities, through committees dealing with separate departments of its work, and through its permanent officials. The most important of these are the clerk, the master and the matron of the workhouse, the relieving officer and the medical officers. In addition there are officials in charge of various institutions, such as children's homes and schools and casual wards, as well as teachers, infirmary nurses, etc. The guardians' expenses are met mainly out of the local rates, by precepting on the rating authority, the town or district council. But they also receive considerable grants-in-aid from the national exchequer. In London the expenditure of the boards of guardians is largely equalized through a pool system known as the Metropolitan Common Poor Fund, into which the richer Unions pay, and out of which the poorer Unions receive, large sums. Thus in 1925–6 Bermondsey drew £248,469 from the fund, Stepney £308,386, and Poplar £520,095.

Powers **and** Duties.—The principal duty of the board of guardians is the relief of destitution. It has besides one or two minor functions; *e.g.,* it enforces the vaccination acts and appoints registrars of births and deaths. The relief to the destitute may be either "indoor" or "outdoor." Indoor relief is closely regulated by the Poor Law Institutions Order, 1913, and is given in workhouses, infirmaries and other institutions such as casual wards, district sick asylums, poor law schools, training-ships, "cottage" and other homes for children, homes for the aged, county and county borough asylums, licensed houses for lunatics, schools for the blind, deaf and dumb. Outdoor relief includes allowances in money or kind, medical attendance and drugs, the payment of funeral expenses, and the provision of work for able-bodied men. Outdoor relief is not normally given to the able-bodied; but the Relief Regulation Order, 1911, permits the guardians to depart from the rule when they consider that special circumstances warrant it, and report to, and get the sanction of, the Ministry. For the administration of medical out-relief the whole country is divided into districts more or less equal in area and population, for each of which a medical officer is appointed. Relief may, if the guardians choose, be given on loan, and the cost is then recoverable in a county court. The guardians also have power to recover the cost of relief either wholly or in part from certain persons who are legally liable for the maintenance of relatives. Thus a husband is bound to maintain his wife. Parents are bound to maintain their children under 16 (or over 16 if unable to support themselves), and grandparents their grand-children under 16. Legitimate children are bound to maintain parents who are unable to support themselves. A married womak having a separate estate is bound to maintain her husband, her children under 16 and her parents. A single woman is bound to maintain her illegitimate children under 16.

Except in the case of vagrants, relief is normally given to a person only in his own parish, *i.e.*, the parish in which he is legally "settled." Settlement is acquired by birth, marriage, ownership or occupation of property, apprenticeship, or residence. Residence for three years constitutes a full settlement; but one year's residence gives a status of "irremovability." The harsh settlement laws that caused so much mischief in the old days have been very greatly modified; but paupers can be, and still are, removed from one Union to another. Removal orders must be signed by two justices of the peace. Of course relief is not withheld because of a doubt or dispute about a person's settlement. It is given, and the questions of chargeability and removal are decided subsequently between the Unions concerned.

Vagrancy.—The treatment of vagrancy has certain peculiarities. The casual ward is subject to the strict regulations of the central authority in respect of tasks, dietary, sleeping accommodation, bathing and conditions of admission and discharge. Normally the casual cannot leave before the morning of the second day following his admission, nor till he has finished the task which is the price of his food and lodging. But if he satisfies the superintendent that he is definitely seeking work, he may be discharged after one night. The casual's task may be stone-breaking, digging, pumping, wood-cutting or grinding, and for women, washing, scrubbing, or cleaning. Oakum-picking was abolished in 1925. Since the report of the royal commission in 1909, some reforms have been introduced in the administration. In the provinces there are county vagrancy committees, representing the boards of guardians within the county, or sometimes a larger area. Through these committees a more or less uniform treatment is secured, the cost of relief of the casual paupers is pooled, and arrangements are made for mid-day meals and other forms of assistance to men on the tramp for work. Boards of guardians are not compelled to come into these combinations, and many refuse to. Some of the independent casual wards are very unsatisfactory. The majority of the boards, however, have come in, and in 1927 the vagrancy committees represented 480 Unions. In London all the' casual wards have been managed since 1912 by one central body, the Metropolitan Asylums Board. The majority of the members of the M.A.B. are representatives of the 25 London boards of guardians, the rest are nominated by the Ministry of Health. Besides the management of the casual wards it has a number of other duties; *e.g.*, it maintains isolation hospitals (for non-pauper as well as pauper cases), asylums for the mentally defective, a colony for sane epileptics, and the *Exmouth* training-ship for poor-law boys.

Scotland.—The Scottish system closely resembles the English. It begins with an Act of 1579, entitled "For Punishment of the Strong and Idle Beggars, and Relief of the Poor and Impotent," which corresponds to the English act of 1601. The Poor Law Amendment (Scotland) Act, 1845, corresponding to the English act of 1834, established poorhouses and local authorities known as parochial boards. These were replaced in 1894 by parish councils, whose duties in regard to the relief of destitution are very much the same as those of the boards of guardians, and which are under the supervision of the Scottish Board of Health. One peculiar feature of the Scottish poor law may be noted, however; an able-bodied person, until 1921, had no legal right to relief of any kind. An act of that year, the Poor Law Emergency Provisions (Scotland) Act, supplemented by another in 1927, gave the right, but only for a limited period (till the end of 1928).

The Old Poor Law.—The Old Poor Law was the creation of Tudor statesmen, and was forced upon them by the necessities of their age. After the Reformation the Church was no longer equal to the task of relieving the needs of the poor, and the social and economic changes of the 15th and 16th centuries had multiplied the numbers of the vagrants and the "idle and disorderly." Various measures were passed for dealing with the mischief, and these were eventually codified in the famous statute of the 43rd year of Elizabeth (1601). Every parish was required to appoint overseers, whose duty it was to levy rates for the relief of the poor. The rates were to be expended for the apprenticeship of children whose parents could not maintain them; for providing work for the able-bodied unemployed; and for assisting those who were unable to work owing to sickness, age or other infirmity. The Elizabethan system was fairly successful for a generation or so, but with the Civil War decay set in. After 1662 the difficulties were aggravated by the law of settlement (under which any person who came to live in a parish not his own might, if he seemed likely to become a charge on the rates, be turned out, and sent back to the place where he "belonged") and abuses rapidly increased. Experiments in reform were tried at intervals throughout the 18th century—workhouses, the farming-out of the poor to contractors, and various forms of outdoor relief, ranging from the payment of unconditional doles to the hiring of paupers to farmers at nominal wages which were supplemented out of the rates. Finally the "Speenhamland system" spread far and wide. This developed out of a rule made in 1795 by the Berkshire magistrates, meeting at the Pelican inn, Speenhamland, that allowances of money should be given on a sliding scale regulated by the price of bread. In the early part of the 19th century pauperism was a canker in the body politic, and its cost a crippling burden. In 1818 poor law expenditure reached the figure of nearly £8,000,000, or 13/3d. per head of the population, and though it fell a little in the following years, it stood at £7,000,000, or 10/– per head of the population, in 1832 In that year a royal commission was appointed to enquire into the whole system, and its recommendations were the basis of the reforms which were embodied in the Poor Law Amendment Act of 1834.

The New Poor Law.—The New Poor Law made a clean sweep of the old practice of unrestricted out-relief. It grouped hitherto independent parishes into Unions, each under an elected board of guardians, with a strong central authority to enforce a uniform policy. And it laid down the cardinal principle that relief should only be given to the able-bodied poor and their dependants in a well-regulated workhouse under conditions inferior to those of the humblest labourer outside. This drastic measure of deterrence naturally provoked widespread popular discontent, and was indeed one of the grievances which played a part in the Chartist agitation. But it went far to reduce the volume and the cost of pauperism As time wore on, however, its strict application became more and more difficult. The developnient of democracy, the growth of humanitarian feeling, and the discovery of more scientific methods of dealing with destitution, all helped to mitigate the harshness of poor law administration. There were improvements in the treatment of different classes of paupers, and many boards of guardians adopted a more generous—or, as their critics said, a more lax—policy both in the granting of outdoor relief and in the management of the workhouse. But no one who looked below the surface could be satisfied with the poor law at the beginning of this century. Its abuses were not those of a hundred years earlier, but they were serious enough to call for public investigation. A royal commission "on the poor laws and the relief of distress" was appointed in 1905, and its reports, issued in 1909, exposed the whole system to a searching criticism, The failure of the poor law was seen in almost every department. "Well-regulated workhouses" were the exception rather than the rule. Here and there the deterrent principle was maintained, and "able-bodied tests" were applied in the shape of stone-breaking or other tasks set to the unemployed workman, which were not only brutal but uneconomic. More often, however, the workhouse had an able-bodied ward, in which all and sundry were left to twiddle their thumbs in a demoralizing idleness. For the tramps there were casual wards run on methods that were cruel to the honest work-seeker, and utterly useless from the point of view of reforming the "work-shy." Nor was the condition of the non-able-bodied less deplorable. The general workhouses contained a great host of children, in constant contact with the adult paupers, often ill-tended and improperly educated. The treatment of the patients in many of the infirmaries and sick-wards, and of the idiots, imbeciles and lunatics, was a scandal. In the granting of outdoor relief there was no uniformity at all In some Unions the allowances were fairly generous, in others they were utterly inadequate. There were boards of guardians which gave a widow 1s. or 1/6d. a week for her child, with nothing for herself. And despite the strenuous efforts of many of the guardians to humanize the administration and of others to keep down the cost of pauperism, the poor law was detested by the poor and a growing burden on the rates.

Reports of Royal Commission, 1909.—The royal commission demanded drastic reforms. The majority recommended that the boards of guardians should be replaced by statutory committees of the county and county borough councils, to be known as "public assistance authorities," with a number of minor bodies (public assistance committees) working under them in sub-areas. The general workhouses should be abolished, and different classes of the destitute relieved in properly specialized institutions. The able-bodied should as far as possible be provided for by other methods. Outdoor relief, or "home assistance," should be adequate, but should be given only after strict inquiry, under supervision, and on a uniform basis. The minority were not content with this; they proposed the complete abolition of the poor law—the thing as well as the name. They argued that the system was fundamentally bad. It was the business of the community to try to prevent destitution, and not merely to palliate it when it occurred. This had long been recognized in the case of other public authorities which had to deal with different classes of the poor—the aged, the children, the sick and the feeble-minded. And these authorities, it was pointed out, were not only working on the right principle; they were better equipped than were the guardians for giving the appropriate treatment in each case, they were free of the "stigma of the poor law," and parliament was steadily extending their functions. But, while this was satisfactory in itself, it involved in practically every department a deplorable amount of administrative disorder, overlapping, duplication of machinery and waste. In the case of each class of the poor, infants, children of school age, the sick, the feeble-minded, the aged, the able-bodied, there was at least one, and often more than one, other authority set up as a rival to the board of guardians. On administrative as well as humanitarian grounds, therefore, the minority report recommended the break-up of the poor law, and the distribution of the functions of the guardians (or the parish councils in Scotland) among the appropriate local authorities, save in the case of the able-bodied, who it was proposed should be made the charge of a national unemployment authority.

This policy received strong support throughout the country and there was an active agitation for poor law reform during the next two or three years. The Government, however, was not disposed to introduce the necessary legislation, and John Burns, the president of the Local Government Board. undertook what he called "revolution by administration." All that he did in fact, was to abate certain of the most crying scandals; in essentials the poor law was left intact. When the war broke out in 1914, the problem was naturally shelved; the volume of pauperism rapidly diminished, and in any case no large reform was possible under war-time conditions. In 1917, however, the whole question was re-examined by a committee appointed by the Ministry of Reconstruction, and presided over by Sir Donald Maclean, M.P.

The Maclean Report.—The Maclean committee was important, because it included representatives of both the majority and the minority of the old royal commission, and it produced a unanimous report which reconciled their differences. The report in fact confirmed the sentence of death passed on the guardians eight years before, and made detailed recommendations for the break-up of the poor law. Its main proposals were:—

1. The transfer of all the functions of the boards of guardians to the councils of counties, county boroughs, and boroughs or urban districts with populations exceeding 50,000.

2. Provision for all the sick and infirm (including the aged requiring institutional care, and maternity cases and infants) should be made by these authorities under the Public Health Acts, suitably extended.

3. The Ministry of Health should have power to put any borough with a population over 10,000, or any urban district with over 20,000, in the position of an autonomous health authority, with such reservations as might be desirable.

4. The children should be dealt with by the local education authorities, the mentally deficient by the local lunacy authorities.

5. Every county or county borough (or borough or urban district council with a population over 50,000) should set up: (1) a prevention of unemployment and training committee (on the lines of the education committee, and including representatives of employers and trade unions); (2) a home assistance committee (on the lines of the education committee) to enquire into the economic circumstances of all applicants for public assistance, to supervise them, to administer all relief given in the home, to recover expenses of maintenance, treatment, etc., and to keep a private register of all such applicants and their families and of the assistance given.

6. County councils should appoint committees for districts or combinations of districts, to which various functions of the home assistance committee and the prevention of unemployment committee would be delegated. Such district committees would consist of: (a) members of the county council; (b) borough or district councillors; (c) persons experienced in the work to be done.

7. London should have a special scheme, in which the functions would be divided between the L.C.C. and the metropolitan borough councils. The borough councils would appoint home assistance committees, and would also be responsible for vaccination and registration of births and deaths. The L.C.C. would, through its appropriate committees, exercise the rest of the functions transferred. It would also appoint a central assistance committee, which would lay down a policy and rules of local administration for the home assistance committees in the metropolitan boroughs.

8. Poor law officials should be transferred to the local authorities (provided both they and the local authorities agreed), and compensated for any pecuniary loss incurred by the change.

9. The cost of all functions transferred should fall on the new authority (the county, county borough, borough or urban district, and in London mainly on the county, but partly on the metropolitan borough).

Scotland was outside the committee's terms of reference. But the matter was referred for consideration to the Scottish consultative council on local health administration. The council issued majority and minority reports, the majority declaring in favour of a Scottish scheme on the general lines of the Maclean report. This scheme was approved by the government of the day, and pledges were given that a bill to reform the poor law would be introduced as soon as opportunity offered. Nothing was done, however, either by that government or by its successors, until Neville Chamberlain, the Conservative minister of health, began to move in the matter in 1925.

In the meantime the poor law entered on a new and alarming phase. The industrial depression, which began in 1920, resulted in a rapid and unprecedented increase of unemployment. Trade union funds and such private savings as the workpeople had were soon exhausted, and the Unemployment Insurance Act and relief works were inadequate to meet the widespread distress. Unless the government was prepared with some heroic policy, it was evident that nothing remained save the poor law. The government refused to be heroic; it actually encouraged recourse to the poor law, in order, as its critics said, to shift as much of the cost as possible from the taxes to the rates. Before long the boards of guardians in all the most heavily stricken areas were flooded with applicants. At the end of 1920 there were just over half a million persons in receipt of poor relief in England and Wales. By the following October the figure was nearly a million and a half, and in the middle of June, 1922, it reached the record of 1,837,980, or 1 in 21 of the whole population. In certain districts the position was even worse than this. No less than thirty Unions had 1 in 10, and several had 1 in 5, of their inhabitants registered as paupers. There was presently a gradual decrease, but the total in June, 1923, was still 1,270,000. In Dec., 1925, it rose again to 1,324,000, and in Aug., 1926, as a result of the great coal dispute, to over 2,250,000. In this month there were eight Unions with a third, and fourteen others with a quarter of their population in receipt of relief. In two Unions in particular weeks more than 50% of the population were paupers. The vast majority of those relieved in the mining areas were the wives and children of the miners, since the "Merthyr judgment" forbade relief to the men themselves. (In the case of Attorney-General v. Merthyr *Tydfil Union* [1900, 1 Ch. 516], the court of Appeal decided that poor relief may not legally be given to an able-bodied person who, by reason of a strike or otherwise, refuses work which is available for him, unless he is so reduced by privation as to be physically incapable of work; but that it may be given to his dependants.) In 78 Unions (covering 85% of the mining population of the country) there were approximately 1,507,600 persons receiving out-relief on Oct. 30, 1926—or about three-fifths of the whole number of miners' dependants in those areas. And for the period of the general strike and the coal dispute, *i.e.*, from May 1 to Nov. 27, these 78 boards of guardians spent spme £63 million more than they would have done if the April rate of expenditure had continued. Scotland had much the same experience. The total number of poor of all classes relieved by the Scottish parish councils was 138,071 on September 15, 1921, and 261,408 a year later. The peak figure of 382,970 was reached on Sept. 15, 1926.

All this, of course, meant an appalling rise of the rates in the crowded industrial districts, which were hit by the trade slump in the earlier part of the period, and hit again by the general strike and the coal stoppage. On Tyneside in 1926–27 the rates were 17/5 in the £ in Wallsend, 17/6 in Tynemouth, 19/11 in Jarrow, 23/9 in Gateshead, 24/8 in Felling, 27/8 in Blaydon. The poor rate formed a large proportion of all these: in Gateshead it was 11/–, which represented an increase of over 600% over the poor rate of 1913–14. Among the metropolitan boroughs Bermondsey had a rate of 18/7, Stepney 19/–, Bethnal Green 22/–, and Poplar 25/–. Other highly rated places were Sheffield (18/2), Middlesbrough (19/8), West Ham (24/6), Pontypridd (20/8), Merthyr Tydfil (24/4). In some cases the ratepayers were unable to meet the strain. The guardians were compelled to borrow and thus saddle the' rates with a heavy burden for the future. In 1923 the actual total indebtedness of the Unions that had raised loans was about £5¼ millions. By March, 1926, it stood at over £7 millions, and in March, 1927, at nearly £12¾ millions. The bulk of the new borrowing in this last year was in the mining districts.

Breakdown of "Principles of 1834."—The task thus thrust an the poor law was clearly one for which it was neither intended nor equipped. And the inevitable result was confusion worse confounded, and a widespread abandonment of what was left of the principles of 1834. The prohibition of outdoor relief to the able-bodied unemployed, save with the express sanction of the Minister of Health in particular cases, still remained on paper. But it became virtually a dead letter in Unions where there was serious unemployment. Outdoor relief was given wholesale, and as a matter of course, to able-bodied men simply because they were out of work, and often not even the names of the recipients, but only the number of cases, were reported to the Ministry for its formal approval. The guardians of course could not fairly be blamed for this; in the circumstances there was nothing else they could do. And the central authority was equally helpless; it could not adhere to the letter of the law without provoking a general upheaval. It could, and indeed did, grumble and remonstrate, but in the last resort it was bound to sanction departure from the regulations. And it could not prevent the use of "scales" of relief adopted by boards of guardians and applied mechanically or in a slipshod fashion. It strove to keep the amount given in outdoor relief below the level of the wage earned by regular full-time employment, but even in this it was only partially successful. In the annual report of the Ministry of Health for 1923–24, the complaint is made that "it is still the fact that the scale on which relief is given is such as, in a number of Unions, to make the income of the person relieved compare very favourably with the wages of an employed person." And again in the 1926 report the warning is repeated that a scale of relief "should not be such as to challenge comparison with the earnings of the workers who are called upon, directly or indirectly, to contribute to the relief so granted." A common scale at this period was 36/– a week for a man, wife and four children. There were maximum scales in 1924–25 of 44/– in Cardiff, 45/6 in Burnley, 46/– in Leeds, 51/– in Poplar, 55/– in West Ham. In Scotland the Board of Health was a little more successful in its attempts to keep down the relief to the unemployed. In view of the critical financial position in 1926 it recommended a maximum scale (23/– a week for man and wife; 2/– for a child under 16; 7/6d. for an adult son or daughter living in the family; 15/– for a single man or woman; and all household income to be deducted), and it refused to sanction loans or overdrafts to parish councils which did not keep within the scale. This had the effect generally of stopping poor law relief in supplement of unemployment benefit, which had become a common practice. Nevertheless the burden was immense. In two big parishes, Glasgow and Govan, the 1926 expenditure was double that of the previous year, and in some smaller parishes it rose by over 300%.

"Poplarism."—To return to England, however—what appeared serious in this development was that it was not merely the result of carelessness or fluster in the guardians. On the contrary, certain boards quite deliberately adopted the policy of giving out-relief on such a generous scale that there could be no pretence of making the lot of the pauper less desirable than that of the independent labourer. This policy was not entirely new; the Poplar board, dominated by a Socialist majority, had long favoured the giving of what it regarded as adequate, and its critics as extravagant, relief. But with the increase of distress that was now facing many of the poor law authorities the burden on the ratepayers became formidable, and a struggle presently began over what was known as "Poplarism." Efforts were at first made to get the Ministry of Health to devise means for alleviating this burden in the poorer districts, but in vain. The Poplar borough council (which also had a Socialist majority) then took the desperate course of refusing to collect the rates for the London county council and certain other central bodies. Legal proceedings were taken, and the high court ordered the collection of the rates. The borough council ignored the order and 29 of its members were imprisoned for contempt of court. Their imprisonment put the Government in an uncomfortable position, and forced it to concede the legislation which Poplar had been demanding. The Local Authorities (Financial Provisions) Act, 1921, provided for a large measure of equalisation of poor rates in London; in particular it laid down that the cost of outdoor relief should be borne by the Metropolitan common poor fund within the limits of a scale to be fixed by the minister of health.

The minister, Sir Alfred Mond, issued his scale in Jan. 1922. It did not satisfy the Poplar guardians, who now pressed for a loan to tide them over their immediate difficulties. A special inquiry was then instituted by the minister into the circumstances of Poplar. The report was unfavourable to the guardians, and declared that by more economical methods they could save £100,000 a year. This they hotly denied; they still demanded their loan, and insisted on their right to administer relief at their discretion. The minister thereupon played his trump card. He issued a "peremptory order," applicable to the Poplar Union alone, providing that no relief in excess of the "Mond scale" to an able. bodied person or any member of his family should be legal, unless specially sanctioned by the minister. The guardians, however, persisted in defying this order, and so laid themselves open to surcharge. After a few months a curious complication was introduced by the Local Authorities (Emergency Provisions) Act, 1923, which apparently revoked automatically the "Mond scale," but left the Poplar order intact, though the two had been closely bound up together. This anomaly lasted till Feb. 1924. The guardians meanwhile were regularly surcharged by the auditor, but successive ministers of health shut their eyes to the matter, until at length John Wheatley in 1924 rescinded the order, and announced that no action would be taken to enforce surcharges in respect of the "illegal relief" given before its rescission. That was the end of this particular battle, though it was not the end of high relief scales. Other boards of guardians continued to favour "Poplarism" and pursued a guerrilla warfare with the Ministry of Health.

There was, of course, a division of opinion over "Poplarism." The one side insisted that it was not only the right, but the duty of the guardians to give adequate relief; the other retorted that the Poplar conception of adequacy was preposterous. But the division was not, as is sometimes supposed, simply one between Socialists and anti-Socialists. The critics included many supporters of the Labour party who not only looked askance at law-breaking tactics, but foresaw disastrous results if the policy of lavish and unconditional relief were to become general. At the same time they appreciated the difficulties of Poplar and similarly placed unions, and argued that the mischief could only be remedied by the reform or the abolition of the poor law. In this view the "Poplarists" themselves concurred, and, indeed, it was realised on all sides that the poor law guardians were not and could never be a satisfactory unemployment authority. But nothing was done to relieve them of their burden, and fresh trouble soon developed.

The Battle of West Ham.—The West Ham board of guardians had for some time been paying out in poor relief a sum far exceeding what could normally be raised by way of rates, and were in fact financed by loans advanced by the Ministry of Health on the recommendation of a Treasury committee. By the autumn of 1925 the outstanding balance of these loans had reached nearly £2,000,000, or 57% of the rateable value of the Union, and the guardians were asking for another £350,000 in respect of current expenditure. The Treasury and the Ministry of Health made a stand at this point and insisted on certain restrictions of expenditure as a condition of the loan. The guardians refused to accept the conditions, and so found themselves with no funds out of which to pay their outdoor relief, their officers' salaries or the other expenses of the Union. The minister thereupon took the unprecedented step of guaranteeing payment of tradesmen's bills for outdoor relief supplied in kind on orders made by the guardians and marked with a special stamp. The amount of the relief was not, however, to exceed three-quarters of the amount which would have been granted under the guardians' scale. This plan worked for four weeks, and then, as the guardians were still obstinate, the minister threatened that he himself would take over the whole business of administration in the West Ham Union. He had (at that date) no legal power to do this, but he would, of course, have got an indemnity from parliament. The threat brought the guardians to heel; they accepted the conditions and got their loan. But this was only the first round. In the summer of 1926 there was a renewal of the contest. At the beginning of May some 70,000 persons in the Union were in receipt of relief; by the middle of the month the general strike had brought the number up to 165,000, or 21% of the population. The board of guardians now applied for another loan of £425,000. The minister pointed out that the district auditor had held their expenditure to be in many cases entirely unjustifiable, and certain members of the board agreed with this view. Their scale of weekly relief was 24/– for a man and wife, and 4/– for each child, up to a maximum of 49/–, plus 1/6d. for coal. He once more insisted upon drastic economies, as a condition of the loan; but the guardians refused to amend their scale, and he administered a knockout blow. Under the bill that was passed into law as the Boards of Guardians (Default) Act, 1926, he superseded the West Ham guardians and handed over their functions on July 20 to three paid administrators, two civil servants and one ex-civil servant, nominated by himself. Under the new régime the number of outdoor paupers rapidly fell (it was 60,000 on July 17, 1926, and 41,000 on March 26, 1927), and the expenditure was substantially reduced.

The Guardians (Default) Act.—But West Ham was not the only Union in which the act was applied. In August the Chester-le-Street, and in the following February the Bedwellty, guardians were removed. In both cases an acute crisis had developed during the coal stoppage. Liberal relief was being given, and it was being given to unmarried miners, which was contrary to the law as laid down by the judges in the Merthyr Tydfil case. In Chester-le-Street the total of outdoor paupers rose from 10,547 on March 27, 1926, to 37,643 on August 28, and in Bedwellty from 15,293 on March 27 to 59,565 on July 17. The minister admitted that the guardians were in an exceedingly difficult position; but he declined to sanction further loans, and put in his appointed guardians. They at once revolutionised the administration by cutting down the relief scales, by refusing to supplement unemployment benefit except by medical extras, and by discontinuing all subsidies to wage-earners, and so effected a reduction of rates, if not of distress.

The passage and the application of the Default Act naturally caused much heartburning. Nor did the criticism come only from whole-hearted champions of "Poplarism." Many who deprecated the policy pursued in these three Unions held that the act was a dangerous infringement of the principles of local government. It put excessive power in the hands of a central department, which might be used quite arbitrarily to undermine democracy up and down the land. Even if Neville Chamberlain could be acquitted of any such intention, there was no guarantee that others would not cherish it, and there were actually, it was pointed out, influential persons in his party who were clamorous for tightening the grip of parliament and Whitehall on the local authorities throughout the country. On the other hand it was contended that the true interests of democracy were not served by letting it run into excesses; the example of West Ham and Chester-le-Street and Bedwellty, if it were generally imitated, would mean an immense demoralisation and in the end violent reaction. Both sides undoubtedly had a case in this controversy. though it was often exaggerated or obscured by party bias. But the real moral of the whole episode was not the danger of "Socialism" or of "Fascism." It was the folly of putting new wine into old bottles.

The Guardians **and Unemployment.**—Neither the Elizabethan nor the 19th century poor law was framed to deal with unemployment in its modern form. It is true that the duty of "setting to work all such persons having no means to maintain them" was laid upon the overseers in 1601, and the duty of "offering the workhouse" upon the guardians in 1834. But the prime objects of both the Old and the New poor law were the repression of the idle who could work and the succouring of the sick and the aged and the young, who could not work. Relief to an able-bodied adult was to be regarded as exceptional (in Scotland it was not allowed at all until 1921), and under the New poor law, at least, was given on repellent terms. How could the ancient machinery of the poor law be expected to adapt itself to the very different conditions and mind of the 20th century? Boards of guardians cannot set to work a million men of all sorts, nor can they "test" them, even if they wished to. Some, perhaps most, do not wish to "test" the unemployed workman who has lost his job through no fault of his own and is unable, either privately or through the employment exchange, to find another. That feeling of compunction, as has already been mentioned, was growing fast in the early years of this century. It was expressed in legislation for making provision for the unemployed otherwise than through the poor law; it was expressed by poor law administrators themselves in the relaxing of restrictions on relief to the able-bodied. After the war the idea of the "test" became still more unpopular, and finally the flood of unemployment made the "offer of the house" an impossibility in the most seriously affected areas. And thus it was that the poor law reverted to a condition very like that of a hundred years earlier, save that then the bulk of the pauperism had been rural, and now it was urban. The minister of health in his 1927 report mentions one remarkable similarity. "During the past six years," he says, "numbers of young men, without employment and maintained on poor law relief, have married, securing thereby an increase in their income from relief, and have had families, each addition to the family bringing its addition to the family income. In this respect it may be doubted whether the present position can be paralleled since 1834." It was inevitable that such abuses should occur. The guardians were compelled to be a dole disbursing agency, filling the "gaps" of the Unemployment Insurance Act, supplementing its benefits, or feeding those who fell outside its provisions. They had not then, and never had, the power to deal with unemployment as a whole, or to organise any proper palliative, let alone preventive, measures. In all the circumstances it is not surprising that there were muddles, fraud and extravagance, involuntary or deliberate, or that when a whole population was workless and political passions were running high, the law was defied. There might easily have been a hundred West Hams and Chester-le-Streets. As it was, there were only three; and the guardians and their officials, as a whole, might fairly claim to have struggled honestly and courageously with their herculean task.

But if the poor law managed somehow to weather the worst of the storm, that does not prove that the ship was, or can ever be made, seaworthy. What was done in the years of distress from 1921 onwards was done at a fearful cost, financial and moral. The burden of the rates lay heaviest where it could least be borne—on struggling industries and small householders and shopkeepers, in districts whose rateable value was low and in which public expenditure was bound to be high. The guardians could only ease its present weight by borrowings which spread it over the future. And the distribution of these vast sums was, and could only be, for the most part a dangerous form of charitable relief. Such a system might be justified as a temporary necessity in an emergency like that of the mining dispute of 1926. But as a settled policy it must lead to a pauperisation which would be none the less deplorable because the old "pauper stigma" was not attached to it. The experience of these "seven lean years," in short, confirmed only too plainly the conclusions of those who had insisted, before the war and after it, that local boards of guardians could not do the work of a national unemployment authority. And the vast majority of the guardians themselves, however much they might object to other proposed reforms of the poor law, were converted at least to this.

The Poor Law in 1927–28.—The following figures give some indication of the effect of the "seven lean years" on the extent and the cost of pauperism.

(A) Total number of persons in receipt of poor relief in England and Wales on January 1, and in Scotland on January 15, 1928, 1920 and 1914.

	England & Wales	Scotland
1928	1,236,000	240,580
1920	576,418	85,678
1914	761,578	105,245

(B) Total numbers in receipt of indoor and outdoor relief in 31 chief urban areas of Great Britain in Jan., 1928. (From Ministry of Labour Gazette.)

Area	No. in receipt of relief: Indoor	Outdoor	Total	Rate per 10,000 of estimated population
England and Wales:				
Metropolis:—				
West District	9,498	7,317	16,815	202
North District	10,873	18,580	29,453	286
Central District	2,399	2,578	4,977	371
East District	10,097	59,834	69,931	1,072
South District	19,647	71,936	91,583	466

Total for above 31 Districts in Jan., 1928	132,784	645,012	777,796	435

(C) Unemployed persons (excluding the sick) who were in receipt of outdoor relief in England and Wales, June, 1927. (These figures are based on a return of the Ministry of Health [Cmd. 3006].)

	Men having no wife or child dependent	Men having wife or child dependent	Women	Total
Number of persons in each class who had been in receipt of poor-law relief in the same union continuously for—				
Less than one year	12,069	43,051	1,962	57,082
One year, but less than three years	9,900	27,356	1,712	38,968
Three years, but less than four years	1,934	6,795	536	9,265
Four years or more	1,963	8,528	536	11,027
Total number of persons in each class included in the returns	25,866	85,730	4,746	116,342

Of the total 82% were in 50 large unions, which contain 35% of the population of England and Wales. Over 44% of the men, and over 32% of the women were aged between 30 and 50. $2\frac{1}{2}$% of the men and $15\frac{1}{2}$% of the women were under 21. About 5% of both sexes were over 65.

(D) This table shows the total number of vagrants who were relieved in the casual wards (average on Friday nights throughout the year).

1910–11	11,801	1923–24	8,505
1913–14	7,794	1924–25	7,915
1919–20	1,870	1925–26	8,475

(E) Numbers on outdoor relief in certain London Unions in September, 1927.

Poplar	22,906	Greenwich	11,147
Bermondsey	13,206	Bethnal Green	10,851
Stepney	13,769		

(F) Proportionate increase of outdoor relief in certain London Unions (March 26, 1927, compared with December 25, 1920).

Union	*Increase* per cent.
Paddington, Hammersmith, St. Pancras, Hackney, Southwark, Lewisham	over 200
Poplar	,, 300
Greenwich	,, 500
St. Marylebone	,, 600
Stepney, Bermondsey, Woolwich	,, 700
Bethnal Green	,, 4,000

(G) Total poor law expenditure* (in round figures).

Year	England & Wales	Scotland
1926–27	£49,500,000	£5,171,000
1925–26	40,000,000	4,400,000
1919–20	23,500,000	2,100,000
1913–14	15,000,000	1,600,000

(H) Total cost of outdoor relief* (in round figures).

Year	England & Wales	Scotland
1926–27	£23,600,000	£3,947,000
1925–26	15,300,000	2,800,000
1919–20	4,109,000	963,000
1913–14	2,215,000	594,000

(*N.B. In making comparisons between the figures for different years, regard should be had to changes in the value of money. £1 in 1913–14 was equal roughly to 9/- in 1919–20, and 11/8 in 1926–27.)

(I) Cost of outdoor relief, per head of "ordinary outdoor poor," in 1926–27.

	Per week
England & Wales (average)	$6/7\frac{3}{4}$d.
Bishopsthorpe	9/-
Berwick-on-Tweed	9/9d.
London (average)	7/4d.
Bethnal Green	8/3d.
Poplar	9/6d.
Scotland (average) (1925–26):	
Other than able-bodied	$6/10\frac{3}{4}$d.
Able-bodied unemployed	$4/6\frac{1}{2}$d.

(J) Cost of indoor relief per head in 1925–26.

England & Wales (average).

(a) Provinces:

	Per week
In workhouse	from $8/11\frac{3}{4}$d. to $10/11\frac{3}{4}$d.
,, hospitals and asylums	,, $9/11\frac{1}{4}$d. to $16/8\frac{1}{2}$d.
,, separate institutions for children	,, $7/10\frac{3}{4}$d. to $9/0\frac{1}{4}$d.

(b) London:

	Per week
In workhouse	9/4d.
,, hospitals and asylums	$15/4\frac{3}{4}$d.
,, separate institutions for children	$9/7\frac{3}{4}$d.

Scotland.

"Sane indoor poor"	$19/2\frac{1}{4}$d.

Neville Chamberlain began to move in the matter of poor law reform soon after he took office as minister of health in 192; . He carried through a measure which, though its prime object was to amend the rating system, was an important preliminary step towards the abolition of the guardians. Under the Rating and Valuation Act, 1925, the parish disappears as the valuation area, the board of guardians no longer appoints the assessment committee, and all the rating functions of the overseers of the poor are transferred to the town and district councils. The Rating (Scotland) Act, 1926, was framed on similar lines; the parish councils are replaced as rating authorities by the town and county councils, and the poor rates are raised by requisition on these. This legislation was followed towards the end of 1925 by detailed plans for the break up of the poor law. The main points were:—

(1) Boards of guardians to be abolished.

(2) Registration of births, deaths and marriages to be transferred to electoral registration officers acting for counties and county boroughs.

(3) The rest of their functions, and their property (including institutions), liabilities and staffs to be transferred to the county and county borough councils.

(4) County borough councils to provide at their own discretion for the carrying out of the transferred duties.

(5) The county council to be the supervising and controlling authority for all health purposes and to have complete responsibility for "home assistance" throughout the administrative county. The transferred duties to be carried out "through existing or new committees of the council, assisted where necessary by local sub-committees consisting of county councillors, or partly of county councillors and partly of representatives of the borough and district councils of the localities" (or of the metropolitan borough councils in London). But delegation to be allowed to borough and district councils (or metropolitan borough councils in London) of "any transferred service identical in kind with a service already administered by the borough or district council" (*e.g.*, care of infancy and expectant or nursing mothers).

(6) Relief to able-bodied persons to be limited and correlated with unemployment insurance.

(7) The assigned revenue system to he abolished. Block grants, fixed for a term of years, to be paid in aid of transferred and existing health services and distributed to county borough councils on a basis of population qualified by a factor representing low ability to pay. The cost of delegated services to be borne by the borough or district councils to which they are delegated.

This scheme, it will be seen, was based in principle on the Maclean report. But it had certain differences of detail, some of them important. In particular, it gave greater power to the counties, allowing no such autonomy as the Maclean report recommended to the larger non-county boroughs and urban districts. It also contemplated some special system of dealing with the able-bodied unemployed, though what that system was could not be discovered from the brief and obscure statement *(see* point [6] above) in which it was adumbrated. The whole scheme, however, was, Chamberlain said, provisional; it was issued primarily for consideration and criticism by the local authorities and others concerned. It had a mixed reception. Root and branch reformers welcomed it, though they were critical of certain details. The county and borough and district councils raised various technical objections. The guardians, who did not want to be done away with, and their friends, who carried weight with the Conservative Government, denounced it. In these circumstances it was evident that the proposals would have to be considerably modified before they could be made the basis of a Government bill. A new scheme emerged from the melting pot in the summer of 1927. It was largely an attempt to meet the criticisms of the Conservatives in the rural areas, and it represented a dubious compromise between the demand for reform and the claims of vested interests. Its principal features are:—

(1) The administration of the poor law is to be transferred from the existing boards of guardians to (a) the councils of the county boroughs, and (b) the councils of the non-county boroughs and the districts.

(2) The area of each county borough will be a single Union and the council will exercise all the poor law functions within its area.

(3) Elsewhere there is to be a division of powers. The town or district council will become the board of guardians for its area and will have the same powers and duties as the former guardians in regard to domiciliary relief.

(4) The provision of institutional relief will be the business of the county council, and all poor law institutions — workhouses, hospitals, casual wards, etc.—will be transferred to it. The new boards of guardians (save, as stated above, in the county boroughs) will not be allowed to own or lease any institution or building, except their own offices.

(5) Schemes for the reorganisation and administration of the institutions are to be prepared by the counties and county boroughs for the approval of the Ministry of Health. And these schemes are to include proposals not merely for the institutional treatment of paupers, but for the co-ordination of the public health service generally.

(6) The expenses of running the institutions will fall on the county or county borough, but the county council may recover from each board of guardians the cost of maintenance of its cases in an institution (except vagrants, who will be wholly a county charge).

There was little public discussion of the scheme, however, and in 1928 the Government abandoned it and reverted to the original plan.

Transfer of Functions of Poor Law Authorzties in England and Wales, Report of Local Government Committee of the Ministry of Reconstruction, 1918* (Maclean report). *Memorandum on the Rescission of the Poplar Order* (Cmd. 2052, 1924). *Provisional Proposals for Poor Law Reform, prepared in the Ministry of Health for circulation to the London County Council, Associations of Local Authorities*, etc. (1925). *Annual Reports* of Local Government Board, and of Local Government Board for Scotland, down to 1919. *Annual Reports* of Ministry of Health, and of Scottish Board of Health, from 1920 onwards. *Annual Local Taxation Returns*. The "Orders" of the Ministry of Health are printed in the annual volumes of *Statutory Rules and Ouders*. Some current statistics of pauperism are given each month in the *Ministuy of Labour Gazette*. (*B*) *Unofficial*. The most comprehensive and up-to-date account of the poor law, from the earliest times down to 1927, is Sidney and Beatrice Webb, *English Poor Law History* (2 vols., 1927 & 1928). Other books on the early poor law are: F. R. Salter, *Some Early Tracts on Poor Relief* (1926); *E*. M. Leonard, *The Early History of English Poor Relief* (1900); Dorothy Marshall, *The English Poor in the XVIII. Century* (1926). Of older books the two most important are *The State of the Poor*, by Sir *F*. M. Eden (1797), and *A History of the English Poor Law*, vols. *1* and *2*, by Sir Geo. Nicholls (1854), vol. 3 by T. Mackay (1899). (C. M. L.)

The Local Government Act, 1929.—The whole machinery of Poor Law administration was changed by this Act which replaced the Boards of Guardians by Public Assistance Committees acting under the Ministry of Health. Two-thirds of the members of these Committees are required to be members of a County or County Borough Council. This law, together with previous legislation, was consolidated in the Poor Law Act, 1930.

UNITED STATES

Any discussion of the laws which relate to the relief of the poor in the United States is much complicated by the wide variety of law and practice among the 48 States, the many laws within States covering the different types of public assistance, and the present involvement of the three levels of government—Federal, State, and local. Prior to 1933, there was no Federal agency where comprehensive data could be secured covering State relief laws, their administration, or relief expenditures and the number of persons assisted. Since 1933, progress has been made in the collection of data covering the country generally on various types of outdoor relief. In addition, there have been many important special studies on phases of public welfare made by various Federal agencies.

I. HISTORY PRIOR TO 1930

State Laws.—Few States had a "Poor Law" in the sense of a comprehensive statute regulating relief to the poor and its administration. In many States the subject was dealt with briefly and fragmentarily in sections scattered through the general statutes. In some States, local provisions so modified State law that it was difficult to know what the law really was.

State laws were based largely on the early English Poor Law. They had been only slightly altered since enactment, with no reflection of changing social conditions and increasing understanding of social problems. The most important changes had been effected by taking away certain functions from poor relief officials, and not by reorganizing and improving the poor relief system. Under laws largely concerned with the control of vagrancy and able-bodied pauperism, officials attempted to care for the sick, aged, infirm, dependent children, destitute families, and in some cases the insane and mental defectives.

Responsibility for Care of the Poor.—The principle of responsibility for the care of the poor by some governmental unit was found in the laws of all States. The legislation tended to be permissive, leaving to the responsible authorities the decision as to whether almshouses should be erected and whether outdoor relief should be granted.

Administrative Systems.—In the New England States the townships, through their selectmen, cared for the poor. Later, when the duties became heavier, a special poor relief official, the overseer of the poor, was substituted for the selectman. Cities usually had the same responsibilities as the towns. In Southern States, the county was the governmental unit and poor relief was on a county basis, with the governing board of the county as the administrative authority. These two systems, or some combination of them, formed the basis for the administrative systems of all the States, the governmental form adopted in the States depending largely on the system in vogue in the State from which most of the settlers came. In about half of the States all poor relief was administered on a county basis. In States having a mixed administrative system, the relation of the city and town to the county was complicated and varied greatly from State to State. City charters usually placed the responsibility for the care of the poor on a special official or board, either elected or appointed.

Authorized Relief.—The laws of every State except New Mexico authorized the establishment of almshouses by some governmental unit, either the town, city, or county. The law, with the exception of two States, was permissive. Outdoor relief was authorized at the discretion of the poor law authorities, either by specific statement or by implication. As a rule, the laws dealt briefly with outdoor relief, regarding it as a temporary expedient, and tended to place greater emphasis on almshouse care. Medical care was authorized at the discretion of the poor law officials as a form of poor relief.

Eligibility for Relief.—Practically all laws had some definition of what sort of persons were to be cared for by public relief In about three-quarters of the States, care was to be given to "persons unable to support themselves" or "all poor, indigent, and incapacitated persons." The laws of most of the States established the liability of the community for support of a needy person on the basis of "settlement,"—a required length of residence in the community. As a rule, legal settlement was acquired by a residence for a stated time in the particular governmental unit without receipt of relief. The usual requirement was for residence of one year, though some States required as much as five or seven years. Settlement was generally considered to have been lost in a State by absence for one year from that State.

Liability of Relatives.—The laws of most of the States were based on the principle that relief should be given only when there were no close relatives liable and able to support their dependents. Occasionally the grandparents and grandchildren were made liable, but usually only parents and children.

State Supervision.—While 43 States had some central board or department with some degree of administrative or supervisory responsibility relating to some phases of the care of the dependent classes, comparatively few such State bodies had definite responsibilities in regard to the supervision of poor relief. In about one-quarter of the States, State authorities inspected almshouses, received financial reports, and made recommendations to local authorities. The recommendations, however, could seldom be enforced. There was even less supervision of outdoor relief, and comparatively few States had accurate figures as to the amount expended for this purpose by local authorities.

Development of Poor Relief.—At first, the poor were cared for by outdoor relief, by indenture of adults or children, or by boarding out. As the number of poor increased, the practice grew of auctioning the care of the poor as individuals or as a group. The first almshouse was established in Massachusetts in 1660, but it was not until after 1700 that any great number were established. During the 18th century and the first half of the 19th century the almshouse came to be looked upon as the best method of correcting the abuses inherent in the earlier systems of aiding the poor at home. It soon became a catch-all for all types of people for whom no other care was available, such as the sick, the aged, infirm, children, insane, feeble-minded, vagrants, etc. The period from 1870 was characterized by a growing realization of the failure of the almshouse to care adequately for its varied type of inmates. By steady effort, specialized care was secured for many of these cases. In particular, laws were enacted forbidding the care of children in almshouses and requiring the removal of the insane and feeble-minded.

A report of the United States census on Jan. 1, 1923, showed that there were 78,090 inmates in almshouses, showing a decrease since 1910 when there had been 84,198 inmates. In 1923, 47 States had 2,183 publicly owned almshouses, representing an investment of $150,485,230. The annual maintenance cost of the publicly owned institutions was $28,740,523. About 88% of the publicly owned almshouses were directly operated by public officials. The other 12% operated under a contract system whereby the public institution and care of the inmates was given to a private individual on various terms. As to public outdoor relief, very little was known prior to 1930, since no general study had ever been made and few States had even accurate information as to the amount expended by local officials for this purpose. From figures available from a few States, it was evident that many more people were being aided by outdoor relief than through almshouse care The administration of outdoor relief was subject to great criticism which certain special studies justified.

Children. — Poor relief officials were originally responsible for all public care given to dependent children, but this function was taken away from them in all but a few States, chiefly during the years following 1900. The inefficiency of almshouse care and the inadequate care given by poor law officials to children, resulted in the establishment of new agencies for the care of dependent children, such as county boards of child welfare, boards of children's guardians, county children's courts, county children's homes, or a State institution. In all except a few States, the poor relief officials came to have practically no responsibility for children cared for away from their families.

Special Types of Assistance. — The inadequacies of the poor relief system also gave rise to statutory provision for special types of assistance, now commonly called categorical assistance, usually administered by other than poor law officials. These types included assistance to veterans, widows' pensions or mother's aid, and assistance to the blind and the aged. Relief to war veterans was the earliest type of special assistance. The first State statute providing mother's aid, now known as aid to dependent children, was passed in 1911. Major development in the field of assistance to the blind began in 1910. A law providing for old age assistance was passed in 1914, but was declared unconstitutional; the next such statute was enacted in 1923. By 1930, there had been substantial growth in all of the special types of assistance.

Poor Law Administration. — Faulty administration was undoubtedly the chief weakness of the poor relief system in every State. In only a few States was there any evidence of public interest in poor law reform. Instead, the tendency had been to transfer poor relief functions to agencies caring for special groups of dependents. Some changes made in State laws were in the direction of establishing the county as the unit of administration, as for example, the new poor law passed in Pennsylvania in 1925 and the public welfare law passed in New York State in 1929. The New York public welfare law, replacing a statute which had not been significantly changed for a hundred years, embodied the modern philosophy which was to mark later legislation in the relief field.

II. HISTORY SINCE 1930

Great changes in the relief structure of the United States occurred in the decade following 1930. The depression beginning in 1929, and the ensuing unemployment, brought on a volume of relief need with which existing poor law systems were utterly unable to cope. Not only was this magnitude of need entirely beyond the possibility of local units of Government to finance, the nature of the problem itself had significantly changed. Previously the group aided by poor officials comprised mainly the unemployable; the new group, on the other hand, was constituted principally of people out of work who were able and wanted to work. New administrative systems and procedures had to be established, and the deterrent philosophy underlying the poor law had to give way to a more constructive method of public assistance. This is strikingly apparent in the relief field, but other forms of care such as almshouse care and care of children away from their own homes have continued with relatively little change during this period.

Emergency Unemployment Relief and Federal Participation in Relief. — Beginning in 1931, States enacted emergency unemployment relief laws usually with the purpose of providing State funds for relief. In general, these laws supplemented and broadened poor laws, or temporarily superseded them. In some States, the emergency unemployment relief program was separate from the established outdoor relief system; in other States, the two programs were integrated from the outset. By 1933, legislation had been enacted in nearly three-quarters of the States which provided some system for emergency unemployment relief. In many States the systems included a program of work relief whereby needy persons were provided for by wages earned on relief projects.

A major step in the public welfare history of the country was taken with the entrance of the Federal Government as a participant in the relief problem. This occurred first in 1932, when funds were loaned to States and local governmental units for the relief of the unemployed. It continued, more significantly and on a wider scale, with the establishment of the Federal Emergency Relief Administration in 1933, authorized to make outright grants to States for relief purposes. Work programs financed by Federal, State, and local funds came to play a large part in the general relief program, and it was roughly calculated that about 50% of persons in need were cared for through work relief. Relief standards were quite generally raised through financial participation of the Federal Government and some degree of Federal supervision or control.

The FERA was discontinued in 1935, with the Federal Government then embarking on what it regarded as a sounder method of assisting in the emergency relief problem. It established a federally administered and financed work program, the Works Progress Administration. At the same time, under the Social Security Act, it provided grants in aid to States for the care of the aged, blind, and children at home. The cessation of Federal grants to States for direct unemployment relief had an adverse effect particularly serious in poorer States. In some States, though some meagre provision for assistance was available, no relief was provided to employahles for whom there was no place on WPA.

Special Types of Assistance. — The Social Security Act established the principle of Federal assistance to States in special forms of relief. It provides grants-in-aid to States for old age assistance, aid to the blind and aid to dependent children, with requirements for State financial participation and certain standards in State plans as a condition for receiving Federal grants. Prior to the Social Security Act, there had been considerable development of these special forms of relief. In 1934, all except three States had mother's aid laws; 28 States had laws providing assistance for the aged; ahd in 1935, 26 States had laws providing assistance to the blind. The Federal act stimulated greatly the enactment of more such lams, and revision of existing laws. In 1939 all but a very few States had legislative provision for all of these types of assistance.

Provisions for Care and Eligibility. — Persons in need are cared for chiefly in three ways: general home relief, special types of assistance, work relief. General home relief cares for those not eligible for the special types of assistance or for WPA, and for those eligible for but not receiving these forms of aid. Established need and settlement are the usual prerequisites for receiving general home relief. Certain additional qualifications are necessary for the special types of assistance. WPA takes care of the major number of employable unemployed who are certified as to need by relief agencies in the majority of States, but occasionally by WPA itself. In addition, hospital care, institutional care and care of children away from their own homes are provided, though these types of care are overshadowed by the magnitude of the outdoor relief programs.

Administration of Outdoor Relief. — The Federal Government directly administers WPA and establishes the standards for the special types of assistance which States must meet to receive Federal aid. The State governments either administer or supervise the local administration of the special types of assistance. About two-thirds of the States also have either administrative or supervisory responsibility for general home relief. The local governments in many States directly administer the special types of assistance, and in all except ten States are administratively responsible for general home relief. There has been a trend toward integration of State supervisory or administrative departments to cover the different types of assistance. In 1939, 45 States had State agencies administering or supervising at least three types of assistance, 22 of them administering or supervising five types of assistance. Several State agencies administered or supervised a completely integrated program. It may be said in general that the administration of special types of assistance is more controlled and on a more permanent basis than the administration of general home relief which remains quite largely the responsibility of local governmental units. Extremely significant changes, however, have occurred or are occurring, as follows: (1) a decided increase in the strengthening of State supervision of local administration; (2) an assumption by the State of direct administrative responsibility; and (3) a tendency toward integration in one central State body of supervisory or administrative responsibility. The degree to which these changes have occurred vary, of course, from State to State.

Financing of Relief.—Prior to 1930, the cost of relief with minor exceptions was borne by local units of government. This applied in the majority of instances to the special types of assistance as well as to general home relief. Beginning in 1931, there was an increase in State financial participation in general home relief; and after 1935, a similar increase for the special types of assistance. In 1939, some State funds for general home relief were provided in two-thirds of the States; all States provided funds for old age assistance; all but two States provided funds for blind assistance; and all but four States provided funds for aid to dependent children. Usually when financial responsibility is divided between States and local units, the amounts to be contributed by each are determined by a fixed percentage of the total. Some States allow administrative discretion for the distribution of State funds, with various criteria used for such distribution. The trend in the financing of relief generally parallels the trends in relief administration and supervision, with more and more responsibilities assumed by the States. For general home relief, the major financial responsibility, if not the exclusive responsibility, remains with the local units of government in most States.

Statistics on Expenditures and Caseloads.—Before 1933 there were no figures on relief expenditures for recipients even approximately complete, though special studies had shown a slight but steady trend upward before 1929, and a sharp upward trend after that year. The Social Security board has collected figures on outdoor relief with relative completeness covering the period from 1933, though the general relief figures rely partially on estimates. These figures show an increase in expenditures for all forms of outdoor relief from $1,358,159,000 in 1933 to $3,485,757,000 in 1938. Monthly expenditures in the early months of 1939 amounted to more than $300,000,000. As of 1938, WPA accounted for about 50% of the expenditures, the special types of assistance about 15%, general relief about 14%, and miscellaneous programs about 21%. It was estimated that in December of 1938, 6,500,000 households representing 20,900,000 persons, or between one-sixth and one-seventh of the total population, received some sort of assistance during the month.

Status of Relief Legislation.—Legislation in the relief field is in a transitional stage. Beginning with the enactment of emergency unemployment relief laws and later with the increase in laws covering special types of assistance, the past decade has been particularly marked by the diminishing importance of the old "poor laws" which now play a relatively small part in the total public welfare structure. The status of relief legislation varies greatly from State to State. Some States have passed unified statutes covering all types of relief; other States still operate under a combination of poor laws, laws covering special types of assistance, and emergency unemployment relief laws. The trend is toward unification, with the elimination of the poor laws and emergency laws and the enactment of comprehensive public welfare laws covering all forms of public assistance. In States where this has occurred, the new laws show marked improvement both in substance and spirit over the old laws, even though they embody some of the characteristics of the poor laws, particularly the requirements of settlement and responsibility of legally liable relatives to support dependents. In general, there has been astonishing progress made in the decade since 1930, and the coming years should show further progress toward a sound public welfare structure.

POOR PERSONS: *see* PRACTICE AND PROCEDURE.

POOR-WILL, the name (from its cry) of a North American bird (*Phalaenoptilus nuttalli*), allied to the whip-poor-will, nightjar and nighthawk (*qq.v.*), which it resembles in habits. It is about 8 in. long, the smallest of the family; the primaries are rusty, barred with black. It breeds west of the Mississippi north to British Columbia, and south to southern California. There are two subspecies, the frosted poor-will (*P. n. nitidus*) in Texas and Arizona, and the California poor-will (*P. n. Californicus*) in the coast region of California.

POPAYAN, a city of Colombia, capital of the department of Cauca, about 240 mi. S.W. of Bogotá, on the old trade route between that city and Quito, in 2° 26' N., 76° 49' W. Pop. (1938) 18,292. Popayán is built on a great plain sloping north-west from the foot of the volcano Puracé, near the source of the Cauca and on one of its small tributaries, 5,712 ft. above the sea. Its situation is singularly picturesque, the Puracé rising to an elevation of 15,420 ft. about 20 m. south-east of the city, the Sotara volcano to approximately the same height about the same distance south by east, and behind these at a greater distance the Pan de Azúcar, 15,978 ft. high. It has rail connection with Cali. Earthquakes have caused much damage to Popayán, especially those of 1827 and 1834.

Popayán was founded by Sebastibn Benalcbzar in 1538 on the site of an Indian settlement, whose chief, Payán, had the unusual honour of having his name given to the usurping town. It is noted as the birthplace of Caldas, the Colombian naturalist, and of Mosquera, the geographer.

POPE, an ecclesiastical title now used in the West exclusively to designate the head of the Roman Catholic church. In the 4th and 5th centuries it was frequently used by any bishop (Du Cange, *s.v.*); but it gradually came to be reserved to the bishop of Rome, becoming official. In the East, the title became restricted to the patriarchs of Alexandria, Antioch, Jerusalem and Constantinople, but is still given by popular usage to priests. Even in the case of the sovereign pontiff the word pope is officially only used as a less solemn style: though the ordinary signature and heading of briefs is, *e.g.*, "Pius P.P.X.," the signature of bulls is *Pius episcopus ecclesiae catholicae*, and the heading, *Pius episcopus, servus servorum Dei*, this latter formula going back to the time of St. Gregory the Great. Other styles met with in official documents are *Pontifex*, *Summus pontifex*, *Romanus pontifex*, *Sanctissimus*, *Sanctissimus pater*, *Sanctissimus dominus noster*, *Sanctitas sua*, *Beatissimus pater*, *Beatitudo sua;* while the pope is addressed in speaking as *"Sanctitas vestra,"* or *"Beatissime pater."*

Jurisdiction.—The pope is pre-eminently, as successor of St. Peter, bishop of Rome. Writers are fond of viewing him as representing all the degrees of the ecclesiastical hierarchy; they say that he is bishop of Rome, metropolitan of the Roman province, primate of Italy, patriarch of the Western Church and head of the universal Church. This is strictly correct, but with the exception of the first and last, these titles are seldom to be found in documents. And if these terms were intended to indicate so many degrees in the exercise of jurisdiction they would not be correct. As a matter of fact, from the earliest centuries (*cf.* can. 6 of Nicaea, in 325), we see that the popes exercised a special metropolitan jurisdiction not only over the bishops nearest to Rome, the future cardinal bishops, but also over all those of central and southern Italy, including Sicily (*cf.* Duchesne, *Origines du culte*, ch. 1), all of whom received their ordination at his hands. Northern Italy and the rest of the western Church, still more the eastern Church, did not depend upon him so closely for their administration. His influence was exercised, however, not only in dogmatic questions but in matters of discipline, by means of appeals, petitions and consultations, not forgetting to mention spontaneous intervention.

Primacy.—The primacy of the pope, a primacy of honour and jurisdiction, involving the plenitude of power over the teaching, the worship, the discipline and administration of the Church, is received by the pope as part of the succession of St. Peter, together with the episcopate of Rome. The whole episcopal body, with the pope at its head, should be considered as succeeding to the apostolic college, presided over by St. Peter; and the head of it, now as then, as personally invested with all the powers enjoyed by the whole body, including the head. Hence the pope, as supreme in matters of doctrine, possesses the same authority and the same infallibility as the whole Church; as legislator and judge he possesses the same power as the episcopal body gathered around and with him in oecumenical council. Such are the two essential prerogatives of the papal primacy: infallibility in his supreme pronouncements in matters of doctrine *(see* INFALLIBILITY); and immediate and sovereign jurisdiction, under all its aspects, over all the pastors and the faithful. These two privileges, having been claimed and enjoyed by the popes in the course of centuries, were solemnly defined at the Vatican Council by the constitution *Pastor aeternus* of the 18th of July 1870. For the history of the papacy, and associated questions *see* PAPACY, CONCLAVE, CURIA ROMANA, CARDINAL, VESTMENTS. For restoration of the temporal power, *see* VATICAN. For particulars regarding the lives of the different popes, *see* the separate articles.

POPE, ALEXANDER (1688–1744), English poet, was born in Lombard street, London, on May 21, 1688. His father, Alexander Pope, a Roman Catholic, was a linen-draper who afterwards retired from business with a small fortune and fixed his residence about 1700 at Binfield in Windsor forest. Pope's education was desultory. Before he was 12 he had obtained a smattering of Latin and Greek from various masters; by his 17th year excessive study had undermined his health and he had developed the personal deformity which later on largely distorted his view of life. Under the treatment, however, of the famous physician John Radcliffe, he recovered his health and continued his studies.

Pope was early an eager aspirant to the highest honours in poetry, and his connections with neighbouring Roman Catholic families of influence in the literary world gave direction to his ambitions. Pope was thus brought under the notice of Sir William Trumbull, a retired diplomatist, living at Easthampstead. Thomas Dancastle, lord of the manor of Binfield, took an active interest in his writings, and at Whiteknights, near Reading, lived another Roman Catholic, Anthony Englefield, "a great lover of poets and poetry." Through him Pope made the acquaintance of Wycherley and of Henry Cromwell, the former introducing him to William Walsh, then of great renown as a critic. Before the poet was 17 he was admitted in this way to the society of London "wits" and men of fashion, and was cordially encouraged as a prodigy.

Pope recognized soon that a long course of preparation was needed for the translation of *Homer* into English verse, on which he had decided. He learnt most, as he acknowledged, from Dryden, but the harmony of his verse also owed something to an earlier writer, George Sandys, the translator of Ovid. At the beginning of the 18th century Dryden's success had given great vogue to translations and modernizations. Dryden had rewritten three of the *Canterbury Tales;* Pope tried his hand at the *Merchant's Tale, Prologue to the Wife of Bath's Tale,* the *House of Fame,* and further experimented with translations from some Latin authors and the *Odyssey.*

Precocious Pope was, but he was also industrious; and he spent nine years in arduous discipline, before anything of his appeared in print. His first publication was his "Pastorals"; they appeared in May 1709 at the end of the sixth volume of Tonson's *Poetical Miscellanies,* containing contributions from Ambrose Philips, Sheffield, Garth and Rowe, with "January and May," Pope's version of Chaucer's "Merchant's Tale."

Pope's next publication was the *Essay on Criticism* (1711), written two years earlier, and printed without the author's name. The sales were slow until Pope caused copies to be sent to Lord Lansdowne and others, but its success was none the less brilliant for the delay. The town was fairly dazzled by the young poet's learning, judgment, and felicity of expressions, and Pope gained credit for much that might have been found where he found it, in the *Institutes* of Quintilian, in the numerous critical writings of RenC Rapin, and in RenC le Bossu's treatise on epic poetry. Addison has been made responsible for the exaggerated value once set on the essay, but Addison's paper *(Spectator,* No. 253) was not unmixed praise. He and Pope became acquainted and Pope's sacred eclogue, "Messiah," was printed as No. 378 of the *Spectator.* In the *Essay on Criticism* Pope provoked one bitter personal enemy in John Dennis, the critic, by describing him as Appius, who "stares, tremendous, with a threat'ning eye." Dennis retorted in *Reflections . . . upon a late Rhapsody . . .* (1711), abusing Pope among other things for his personal deformity; and Pope never forgot this brutal attack.

The *Rape of the Lock,* in its first form, appeared in 1712 in *Lintot's Miscellanies;* the "machinery" of sylphs and gnomes was an afterthought, and the poem was republished as we now have it early in 1714. William, 4th Baron Petre, had surreptitiously cut off a lock of Miss Arabella Fermor's hair, and the liberty had been resented; Pope hearing of this, caught at the hint, and treated the subject in mock heroic vein—the result being a poem which is generally admitted to be a masterpiece of airiness, ingenuity, and exquisite finish. It was followed by the publication in March, 1713, of *Windsor Forest,* which was begun, according to Pope, when he was 16 or 17. Hitherto, Pope had avoided politics, but this work appeared with a flattering dedication to the secretary for war, George Granville, Lord Lansdowne, and an opportune allusion to the Treaty of Utrecht. When the poem appeared, it was made the subject of an insidious attack by the Addison coterie, who about this time became estranged from Pope. Addison disavowed connivance of this coarse attack, but a coolness between the two friends ensued.

The attacks upon *Windsor Forest* appeared in a series of papers on "Pastorals" which were published in the *Guardian* (Nos. 22, 23, 28, 30 and 32). No mention was made of the poem, but everyone knew to whom the general principles referred. In the articles the introduction of Greek names, customs and deities was ridiculed and as *Windsor Forest* was fairly open to criticism on this ground, the real subject of the papers was manifest. The real sting of the criticisms, however, lay in their extravagant praise of the second-rate poet Ambrose Philips and the implied comparison with Pope. The latter characteristically succeeded in revenging himself. He secured the publication in the *Guardian* of an anonymous article which ostensibly attacked his own poems, but which actually, by quotation, disposed of the pretensions of Ambrose Philips, and ridiculed the *Guardian's* principles.

The links that attached Pope to the Tory party were strengthened by a new friendship. His first letter to Swift, who became warmly attached to him, is dated Dec. 8, 1713. Swift had been a leading member of the Brothers' Club, from which the famous Scriblerus Club seems to have been an offshoot. The leading members of this informal literary society were Swift, Arbuthnot, Congreve, Bishop Atterbury, Pope, Gay and Thomas Parnell. Their chief object was a general war against the dunces, waged with great spirit by Arbuthnot, Swift and Pope.

The estrangement from Addison was completed in connection with Pope's translation of Homer, which was definitely undertaken in 1713, and was published by subscription. Men of all parties subscribed, their unanimity being a striking proof of the position Pope had attained at the age of 25. But the unanimity was broken by a discordant note. A member of the Addison clique, Tickell, attempted to run a rival version. Pope suspected Addison's instigation; Tickell had at least Addison's encouragement. Pope's famous character of Addison as "Atticus" in the *Epistle to Dr. Arbuthnot* (ii. 193–215) was, however, inspired by resentment at insults that existed chiefly in his own imagination.

The translation of Homer was Pope's chief employment for 12 years. The new pieces in the miscellanies published in 1717, his "Elegy on an Unfortunate Lady," and his "Eloisa to Abelard," were probably written some years before their publication. The *Iliad* was delivered to the subscribers in instalments in 171j, 1717, 1718 and 1720. Pope's own defective scholarship made help necessary. William Broome and John Jortin supplied the bulk of the notes, and Thomas Parnell the preface. For the translation of the *Odyssey* he took Elijah Fenton and Broome as coadjutors, who between them translated 12 out of the 24 books. (1, 4, 19 and 20 are by Fenton; 2, 6, 8, 11, 12, 16, 18, 23, with notes to all the books, by Broome.) It was completed in 172j. Opinions have varied on the purely literary merits of the poem, but with regard to it as a translation few have differed from Bentley's criticism, "A fine poem, Mr. Pope. but you must not call it Homer." In 1722 he edited the poems of Thomas Parnell, and in 1725 made a considerable sum by an unsatisfactory edition of Shakespeare, in which he had the assistance of Fenton and Gay.

Pope, who cleared £8,000 by the two translations, was thus rendered independent and enabled to live near London. The estate at Binfield was sold, and he removed with his parents to Mawson's buildings, Chiswick, in 1716, and in 1719 to Twickenham, to the house with which his name is associated. Here he practised elaborate gardening on a small scale, and built his famous grotto, which was really a tunnel under the road connecting the garden with the lawn on the Thames. He was constantly visited at Twickenham by his intimates, Dr. John Arbuthnot, John Gay, Bolingbroke (after his return in 1723), and Swift (during his brief visits to England in 1726 and 1727), and by many other friends of the Tory party. With Atterbury, bishop of Rochester, he was on terms of affectionate intimacy, but he blundered in his evidence when he was called as a witness on his behalf in 1723.

In 1717 his father died, and he appears to have turned to the Blounts for sympathy in what was to him a very serious bereavement. He had early made the acquaintance of Martha and Teresa Blount, having probably met them first at the house of his neighbour, Englefield of Whiteknights, who was their grandfather. Their home was at Mapledurham, near Reading. He began to correspond with Martha Blount in 1712, and after 1717, the letters are much more serious in tone. He quarrelled with Teresa, who had apparently injured or prevented his suit to her sister, but his friendship with Martha lasted all his life. So long as his mother lived he was unwearying in his attendance on her, but after her death in 1733 his association with Martha Blount was more constant. His earlier attachment to Lady Mary Wortley Montague was apparently a literary passion, which perished under Lady Mary's ridicule.

The year 1725 may be taken as the beginning of the third period of Pope's career, when he made his fame as a moralist and a satirist. Edward Young's satire, *The Universal Passion,* had just appeared, and been received with more enthusiasm than any thing published since Pope's own early successes. Swift was finishing Gulliver's *Travels,* and the survivors of the Scriblerus Club resumed their old amusement of parodying and otherwise ridiculing bad writers, especially bad writers in the Whig interest; four volumes of their *Miscellanies in Prose and Verse* were published from 1727 to 1732. According to Pope's own history of the *Dunciad, an Heroic Poem in Three Books,* which first appeared on May 28, 1728, the idea of it grew out of this. Among the Miscellanies was a "Treatise of the Bathos or the Art of Sinking in Poetry," which gave rise to a torrent of abusive falsehoods and scurrilities from those who thought themselves injured by it.

The *Dunciad* was Pope's answer to them, and among the most prominent objects of his satire were Lewis Theobald, Colley Cibber, John Dennis, Richard Bentley, Aaron Hill and Bernard Lintot, who, in spite of his former relations with Pope, was now classed with the piratical Edmund Curll. The book was published anonymously with the greatest precautions. When the success of the poem was assured, it was republished in 1729, and a copy was presented to the king by Sir Robert Walpole. Names took the place of initials, and a defence of the satire, written by Pope himself, but signed by his friend William Cleland, was printed as "A letter to the Publisher." Various indexes, notes and particulars of the attacks on Pope made by the different authors satirized were added. To avoid any danger of prosecution, the copyright was assigned to Lord Oxford, Lord Bathurst and Lord Burlington, whose position made them practically unassailable. The most unprovoked assault was on Richard Bentley, whom he satirized in the reconstruction and enlargement of the *Dunciad* made in the last years of his life at the instigation, it is said, of William Warburton. In the earlier editions the place of hero had been occupied by Lewis Theobald, who had ventured to criticize Pope's *Shakespeare.* In the edition which appeared in Pope's *Works* (1742), he was dethroned in favour of Colley Cibber; Warburton's name is attached to many new notes, and one of the preliminary dissertations by Ricardus Aristarchus on the hero of the poem seems to be by him.

The four epistles of the *Essay on Man* (1733) were also intimately connected with passing controversies. The subject was suggesled to him by Henry St. John, Lord Bolingbroke, who had returned from exile in 1723 and was a fellow-member of the Scriblerus Club. Bolingbroke is said—and the statement is supported by the contents of his posthumous works—to have furnished most of the arguments. In this didactic work, as in his *Essay on Criticism,* Pope put together on a sufficiently simple plan a series of happy sayings, separately elaborated, picking up the thoughts as he found them in miscellaneous reading and conversation and trying only to fit them with perfect expression. His readers were too dazzled by the verse to be severely critical of the sense. Pope himself had not comprehended the drift of the arguments he had adopted from Bolingbroke, and was alarmed when he found that his poem was generally interpreted as an apology for the freethinkers. Warburton is said to have qualified its doctrines as "rank atheism," and asserted that it was put together from the "worst passages from the worst authors." The essay was soon translated into the chief European languages, and in 1737 its orthodoxy was assailed by a Swiss professor, Jean Pierre de Crousaz, in an *Examen de l'essay de M. Pope sur l'homme.* Warburton now saw fit to revise his opinion of Pope's abilities and principles—for what reason does not appear. In any case he now became as enthusiastic in his praise of Pope's orthodoxy and his genius as he had before been scornful, and pro. ceeded to employ his unrivalled powers of sophistry in a defence of the orthodoxy of the conflicting and inconsequent positions adopted in the *Essay on Man.* Pope was wise enough to accept with all gratitude an ally who was so useful a friend and so dangerous an enemy, and from that time onward Warburton was the authorized commentator of his works.

The *Essay on Man* was to have formed part of a series of philosophic poems on a systematic plan. The other pieces were to treat of human reason, of the use of learning, wit, education and riches, of civil and ecclesiastical polity, of the character of women, etc. Of the ten epistles of the *Moral Essays,* the first four, written between 1731 and 1735, are connected with this scheme, which was never completed.

There was much bitter, and sometimes unjust, satire in the *Moral Essays* and the *Imitations of Horace.* In these epistles and satires, which appeared at intervals, Pope was often the mouthpiece of his political friends, who were all of them in opposition to Walpole, then at the height of his power, and Pope chose the objects of his attacks from among the minister's adherents. Epistle III., "Of the Use of Riches," addressed to Allen Bathurst, Lord Bathurst in 1732, is a direct attack on Walpole's methods of corruption and on his financial policy in general; and the two dialogues (1738) known as the "Epilogue to the Satires," professedly a defence of satire, form an eloquent attack on the court. Pope was attached to the prince of Wales's party and he did not forget to insinuate, what was indeed the truth, that the queen had refused the prince her pardon on her death-bed. The "Epistle to Dr. Arbuthnot" contains a description of his personal attitude towards the Scriblerus and is made to serve as a "prologue to the satires." The gross and unpardonable insults bestowed on Lord Hervey and on Lady Mary Wortley Montague in the first satire "to Mr. Fortescue" provoked angry retaliation from both. The descriptions of Timon's ostentatious villa in Epistle IV., addressed to the earl of Burlington, was generally taken as a picture of Canons, the seat of John Brydges. duke of Chandos, one of Pope's patrons. Epistle II., addressed to Martha Blount, contained the picture of Atossa, which was taken to be a portrait of Sarah Jennings, duchess of Marlborough.

One of the worst imputations on Pope's character was that he left this passage to lie published when he had in effect received a bribe of £1.000 from the duchess of Marlborough for its suppression through the agency of Nathanael Hooke (d. 1763). As the passage eventually stood, it might be applied to Katherine, duchess of Buckingham, a natural daughter of James II. Pope may have altered it with the intention of diverting the satire from the original object. To appreciate fully the point of his allusions requires an intimate acquaintance with the political and social gossip of the time, but apart from their value as a brilliant strongly-coloured picture of the period, Pope's satires have a permanent value as literature. It is justly remarked by Mark

Pattison (in his edition of the *Satires and Epistles*, 1866), that "these *Imitations* are among the most original of his writings." The vigour and terseness of the diction is still unsurpassed in English verse.

Pope's wit had won for him the friendship of many distinguished men, and his small fortune enabled him to meet them on a footing of independence. He paid long visits at many great houses, especially at Stanton Harcourt, the home of his friend Lord Chancellor Harcourt; at Oakley, the seat of Lord Bathurst; and at Prior Park, Bath, where his host was Ralph Allen. He died on May 30, 1744, and was buried in the parish church of Twickenham. He left the income from his property to Martha Blount till her death, after which it was to go to his half-sister Magdalen Rackett and her children. His unpublished mss. were left at the discretion of Lord Bolingbroke, and his copyrights to Warburton.

If we are to judge Pope fairly there are two features of his times that must be kept steadily in view—the character of political strife in those days and the political relations of men of letters. The age of Queen Anne was pre-eminently an age of intrigue. The Government was almost as unsettled as in the early days of personal monarchy, but it was policy rather than force upon which men depended for keeping their position. Secondly, men of letters were admitted to the inner circles of intrigue as they had never been before and as they have never been since; and Queen Anne's statesmen paid their principal literary champions with social privileges and honourable public appointments. Hence men of letters were directly infected by the low political morality of the unsettled time.

Pope's own ruling passion was the love of fame, and he had no scruples where this was concerned. His vanity and his childish love of intrigue are seen at their worst in his petty manoeuvres to secure the publication of his letters during his lifetime. These intricate proceedings were unravelled with great patience and ingenuity by Charles Wentworth Dilke, when the false picture of his relations with his contemporaries which Pope had imposed on the public had been practically accepted for a century. After manipulating his correspondence so as to place his own character in the best light, Pope deposited a copy in the library of Edward, second earl of Oxford, and then had it printed. The sheets were offered to Curll by a person calling himself P.T., who professed a desire to injure Pope, but was no other than Pope himself. The copy was delivered to Curll in 1735 after long negotiations by an agent who called himself R. Smythe, with a few originals to vouch for their authenticity. P.T. had drawn up an advertisement stating that the book was to contain certain answers from various peers. Curll was summoned before the House of Lords for breach of privilege, but was acquitted, as the letters from peers were not in fact forthcoming. Difficulties then arose between Curll and P.T., and Pope induced a bookseller named Cooper to publish a *Narrative of the Method by which Mr. Pope's Private Letters were procured by Edmund Curll, Bookseller* (1735). These preliminaries cleared the way for a show of indignation against piratical publishers and a "genuine" edition of the *Letters of Mr. Alexander Pope* (1737, fol. and 4to).

Unhappily for Pope's reputation, his friend Caryll, who died before the publication, had taken a copy of Pope's letters before returning them. This letter-book came to light in the middle of the 19th century, and showed the freedom which Pope permitted himself in editing. The correspondence with Lord Oxford, preserved at Longleat, afforded further evidence of his tortuous dealings. But against Pope's petulance and "general love of secrecy and cunning" have to be set, in any fair judgment of his character, his exemplary conduct as a son, the affection with which he was regarded in his own circle of intimates, and many well-authenticated instances of genuine and continued kindliness to persons in distress.

BIBLIOGRAPHY.—Various collected editions of Pope's *Works* appeared during his lifetime, and in 1751 an edition in nine volumes was published by a syndicate of booksellers "with the commentaries of Mr. Warburton." In 1769–1807 an edition was issued which included Owen Ruffhead's *Life of Alexander Pope* (1769), which was largely inspired by Warburton. The notes of many commentators, with some letters and a memoir, were included in the *Works of Alexander Pope,* ed. W. L. Bowles (10 vols., 1806). His *Poetical Works* were edited by Alexander Dyce (1856); by R. Carruthers (1858) for Bohn's Library; by A. W. Ward *(Globe Edition*, 1869), etc. Materials for a definitive edition were collected by John Wilson Croker, and formed the basis of what has become the standard version, *The Works of Alexander Pope* (10 vols., 1871–98), including unpublished letters and other new material, with introduction and notes by W. Elwin and W. J. Courthope. The life of Pope in vol. v. was contributed by Prof. Courthope. The chief original authnrity besides Pope's correspondence and Ruffhead's *Life* is Joseph Spence's *Anecdotes,* published by S. W. Singer in 1820. Samuel Johnson gives a good estimate of Pope in his *Lives of the Poets.* The best modern lives are that by Prof. Courthope already mentioned; and *Alexander Pope,* by Sir L. Stephen, in the *English Men of Letters* series (1880). *See* also George Paston, *Mr. Pope: his Life and Times* (1909). The first check to the admiration that prevailed during Pope's lifetime was given by the publication of Joseph Warton's *Essay on the Genius and Writings of Pope* (vol. i., 1757; vol. ii., 1782). Thomas Campbell's criticism in his *Specimens of the British Poets* provoked a controversy to which William Hazlitt, Byron and W. L. Boules contributed. For a discussion of Pope's position as one of the great men of letters in the 18th century who emancipated themselves from patronage, *see* A. Beljame, *Le Public et les hommes de lettres en Angleterre au dix-huitième siècle* (1881); a section of Isaac D'Israeli's *Quarrels of Authors* is devoted to Pope's literary animosities; and most important contributions to many vexed questions in the biography of Pope, especially the publication of his letters, were made by C. W. Dilke in *Notes and Queries* and the *Athenaeum.* These articles were reprinted by his grandson, Sir Charles Dilke, in 1875, as *The Papers of a Critic.*

POPE, JOHN (1822–1892), American soldier, was born at Louisville, Ky., on March 16, 1822. He graduated at the United States military academy in 1842 and was assigned to the engineers. He served in the Mexican War, subsequently engaged in engineering and exploring work, and was commissioned captain in 1856. Early in the Civil War he was placed, as a brigadier general U.S.V., in charge of the district of Missouri, which by vigorous campaigning against guerrilla bands he quickly reduced to order. In 1862, along with the gunboat flotilla (commanded by Commodore A. H. Foote) on the Mississippi, Pope obtained a great success by the capture of the defences of New Madrid and Island No. 10, with nearly 7,000 prisoners. Pope subsequently joined Halleck, and in command of the Army of the Mississippi took part in the siege of Corinth. He was now a major general (U.S.V.). The reputation he had thus gained as an energetic leader quickly placed him in a high command, to which he proved to be quite unequal. The "Army of Virginia," as his new forces were styled, had but a brief career. At the very outset of his Virginian campaign Pope, by a most ill-advised order, in which he contrasted the performances of the western troops with the failures of the troops in Virginia, forfeited the confidence of his officers and men. The feeling of the Army of the Potomac (which was ordered to his support) was equally hostile, and the short operations culminated in the disastrous defeat of the second battle of Bull Run. Pope was soon compelled to realize the impossibility of retrieving his position, and resigned the command. Later, in command of the department of the North-West, he showed his former skill and vigour in dealing with Indian risings. In 1882 he was promoted to the full rank of major general, U.S. army. He died at Sandusky, O., on Sept. 23, 1892.

He was the author of various works and papers, including railway reports *(Pacific Railroad Reports* vol. iii.) and *The Campaign of Virginia* (Washington, 1865).

POPE, JOHN RUSSELL (1874–1937), American architect, was born in New York city on April 24, 1874. In 1895 he was fellow of the American Academy at Rome and in 1896–97 held the Schermerhorn travelling fellowship in architecture. In 1900, after attending the École des Beaux Arts in Paris, he began practice in New York city. In addition to many private residences he designed the Scottish Rite Temple, Washington (D.C.); Plattsburg (N.Y.) city hall; the Terminal station, Richmond (Va.); the McDonough memorial at Plattsburg; and the Lincoln memorial at Hodgenville (Ky.). He was chosen architect for the Roosevelt memorial and the Mellon art gallery in Washington (D.C.) and the Roosevelt memorial in New York city.

POPE, SIR THOMAS (*c.* 1507–1559), founder of Trinity College, Oxford, was born at Deddington, Oxfordshire, probably in 1507, and educated at Eton college, where he entered the court of chancery. As clerk of briefs in the star chamber, warden of the mint (1534–1536), clerk of the Crown in chancery (1537), and second officer and treasurer of the court for the settlement of the confiscated property of the smaller religious foundations he obtained wealth and influence. In this last office he was superseded in 1541, but from 1547 to 1553 he was again employed as fourth officer, and was enriched by grants of monastic lands. In 1537 he was knighted. The changes made by Edward VI. were repugnant to him, but at the beginning of Mary's reign he became a member of the privy council, and he retained the royal favour under Elizabeth.

As early as 1555 Pope had begun to arrange for the endowment of a college at Oxford, for which he bought the site and buildings of Durham College, the Oxford house of the abbey of Durham, from Dr. George Owen and William Martyn. He received a royal charter for the establishment and endowment of a college of the "Holy and Undivided Trinity" on March 8, 1556. The foundation provided for a president, twelve fellows and eight scholars, with a schoolhouse at Hooknorton. The number of scholars was subsequently increased to twelve, the schoolhouse being given up. On March 28, the members of the college were put in possession of the site, and they were formally admitted on May 29, 1556. Pope died at Clerkenwell on Jan. 29, 1559, and was buried at St. Stephen's, Walbrook; but his remains were removed to Trinity College, where his widow erected a monument to his memory.

The life, by H. E. D. Blakiston, in the *Dict. Nat. Biog.*, corrects many errors in Thomas Warton's *Life of Sir Thomas Pope* (1772). Further notices by the same authority are in his *Trinity College* (1898), in the "College Histories" Series, and in the *English Historical Review* (April, 1896).

POPE, SIR WILLIAM JACKSON (1870–1939), British chemist, was born in London March 31, 1870, and was educated at Finsbury technical college, and the central technical college, London. From 1897 to 1901 he was head of the chemistry department at the Goldsmith's Institute, and in 1901 he became professor of chemistry at the municipal school of technology at Manchester, occupying the chair of chemistry in the university there from 1905 to 1908. In 1908 he was appointed professor of chemistry at Cambridge, where he was later elected a fellow of Sydney Sussex College. Pope carried out much valuable research. His earliest work was in crystallography, but later he turned to pure organic chemistry and made a special study of asymmetric Compounds; he confirmed Le Bel's observation on optically active nitrogen compounds (1899) and also prepared the first sulphur (1900), tin (1900) and selenium (1902) compounds of this type. During the World War he served on Lord Fisher's Admiralty Inventions Board (1915), and was conspicuous for his work on poison gases, and for the active assistance he gave to chemical industries. Some of the results of his experimental work on "mustard-gas" and similar compounds were published in the *Journal* of the Chemical Society after the war. He was knighted in 1919, and was in addition the recipient of many British and foreign awards, including the Davy Medal of the Royal Society, in 1914.

POPERINGHE (pŏp′ur-ĭng′ẹ; popularly pŏp′ŭr-ĭng) is an ancient town in the province of West Flanders, Belgium, 12 mi. west of Ypres. Pop. (1936) 11,564. Its fine 11th century church is dedicated to St. Betin. During World War I it was the railhead, and served for rest billets for the troops in Ypres. It was here that the movement subsequently known as Toc H (*q.v.*) originated. In World War II it was occupied by Germany.

POPHAM, SIR HOME RIGGS (1762–1820), British admiral, entered the navy in 1778, and served with the flag of Rodney till the end of the war. In 1783 he was promoted lieutenant, and was for a time engaged on survey service on the coast of Africa. Between 1787 and 1793 he engaged in the Eastern trade, and undertook several surveys and rendered some services to the East India Company, which were officially acknowledged. For some years during the French Revolutionary wars he cooperated in a naval capacity with the military forces of Great Britain and her allies. He died at Cheltenham on Sept. 10, 1820. Popham was one of the most scientific seamen of his time. He did much useful survey work, and was the author of the code signals adopted by the admiralty in 1803 and used for many years.

POPHAM, SIR JOHN (c. 1531–1607), English judge, was born at Huntworth, in Somerset, about 1531. He was recorder of Bristol, and represented that city in parliament in 1571 and from 1572 to 1583. He was elected Speaker in 1580, and in 1581 became attorney-general, a post which he occupied until his appointment as lord chief justice in 1592. He presided at the trials of Sir Walter Raleigh and Guy Fawkes. Towards the end of his life Popham took a great interest in colonization, and was an advocate of the transportation system. His experiment, the Popham colony on the Kennebec river, was not a success. He died on June 10, 1607.

See Foss, *Lives of the Judges; J.* Winsor, *History of America*, vol. iii. He issued a volume of *Reports*. (1682). E.R. vol. 79.

POPILIA VIA, the name of two ancient roads in Italy. (1) A high road running from the Via Appia at Capua to Rhegium, a distance of 321 m. right along the length of the peninsula, running through the interior, not along the coast. It was built in 159 B.C. by the censor M. Popilius Laenas or in 132 B.C. by the consul P. Popilius. (2) A high road from Ariminum to Aquileia (178 m.) along the Adriatic coast. It came into use when Aquileia was founded as a frontier fortress of Italy in 181 B.C. In 132 it was reconstructed by the consul P. Popilius. It ran along the shore strip (Lido) from Ariminum to Ravenna (33 m.).

POPISH PLOT: see OATES, TITUS.

POPLAR, an eastern metropolitan borough of London, England, bounded north by Hackney, south by the river Thames and west by Stepney and Bethnal Green, and extending east to the boundary of the county of London. Pop. (1938) 134,400. The river Lea is believed to have been crossed towards the north of the modern borough by a Roman road, the existence of which is recalled by the district-name of Old Ford; while Bow (formerly Stratford-le-Bow or Stratford-atte-Bowe) was so named from the "bow" or arched bridge which took the place of the ford in the time of Henry II. South of these districts lies Bromley; in the south-east the borough includes Blackwall; and a deep southward bend of the Thames here embraces the Isle of Dogs. Poplar falls within the great area named "East End." In the north a part of Victoria park is included. In Blackwall and the Isle of Dogs streets give place to the extensive East and West India docks (opened in 1806) and Millwall dock, with shipbuilding, engineering, chemical and other works along the river. Blackwall has been a shipping centre from early times. The West India docks, situated on the northern part of the Isle of Dogs, cover an area of 241 ac., of which 92$ ac. is water. They have large warehouses where the goods are stored, being mainly hardwoods (mahogany, walnut, teak, etc.), grain, sugar, rum and dates. The West India docks include export and import docks covering a water area of $23\frac{3}{5}$ ac. and $26\frac{2}{3}$ ac. respectively, and a quayage length of 1,876 yd. and 1,983 yd., and a maximum depth of 26 ft. The north quays of these have been widened, and large transit sheds have been built there. In addition, West India docks include Blackwall basin with an area of 73 ac. and a depth of 26 ft.; Junction dock, area $1\frac{1}{4}$ ac. and depth of 25 ft.; South dock with an area of 27 ac., maximum depth of 29 ft. and quayage of 1,967 yd.; and South dock basin, area $5\frac{1}{5}$ ac. and a depth of 29 ft. New cuttings connecting West India docks with Millwall docks south of them were nearly completed at the end of 1928.

Another much appreciated improvement scheme included a new entrance lock, 590 ft. long, 80 ft. wide, with a depth of 35 ft. on the sill, which would render the docks able to deal with ships up to 600 ft. in length. The East India docks to the east consist of Import and Export docks and a basin with total water area of $31\frac{1}{4}$ ac. and 2,517 yd. of quay, the depths in the Export and Import docks being 28 ft., and in the basin 32 ft. An impounding station has been built which raises the water in the docks 2 ft. above the tidal high water level. A quarantine station has been built at the East India docks. Millwall docks, situated on the southern portion of the Isle of Dogs, cover an area of 35 ac. and have a maximum depth of 28 ft. Near the East India docks is the settlement of St. Frideswide, supported by Christ Church, Oxford. In Canning Town, which continues this district of poverty across the Lea, and so outside the county of London, are Mansfield house, founded from Mansfield college, Oxford; and a women's settlement, notable for its medical work. The metropolitan borough of Poplar includes the Bow and Bromley and the South Poplar divisions of the parliamentary borough, each returning one member. For "Poplarism" see POOR LAW.

POPLAR (*Populus*), the name of a small group of catkin-bearing trees belonging to the family Salicaceae, which includes the willows. The catkins of the poplars differ from those of willows in the absence of nectar glands; the male flowers contain from 4 to 80 stamens; the female bear a one-celled ovary, surmounted by the deeply cleft stigmas; the two- to four-valved capsule contains several seeds, each furnished with a long tuft of silky or cotton-like hairs. The leaves are generally either deltoid or ovate in shape, often heart-shaped at the base, and frequently with slender, laterally compressed petioles. Many of the species attain a large size, and all are of very rapid growth. The poplars are almost entirely confined to the north temperate zone, but a few approach or even pass its northern limit, and they are widely distributed within that area; they show, like the willows, a partiality for moist ground and often line the riversides in otherwise treeless districts. There are about 30 species, but the number cannot be very accurately defined, since there are many regional varieties and also widely diffused hybrids of uncertain origin. All yield a soft, easily worked timber. Many of the species are used for paper-making.

Of the European forms one of great importance is the white poplar or abele, P. alba, a tree of large size, with rounded spreading head and curved branches which, like the trunk, are covered with a grayish white bark, becoming much furrowed on old stems. The leaves are ovate or nearly round but with deeply waved, more or less lobed and indented margins and heart-shaped bases; the upper side is dark green, but the lower surface is clothed with a dense white down, which likewise covers the young shoots—giving, with the bark, a hoary aspect to the whole tree. A related form, P. *canescens,* the gray poplar of the nurseryman, is distinguished from the true abele by its smaller, less deeply cut leaves, which are gray on the upper side but not so hoary beneath as those of P. alba. Some authorities regard this form as a hybrid (P. alba × *tremula*).

Both trees occasionally attain a height of 90 ft. or more. The wood is very white, uith soft and even grain, and is employed by turners and toy-makers; it is also suitable for the construction of packing cases, etc. The white poplar is an ornamental tree; it has, however, the disadvantage of throwing up numerous suckers for some yards around the trunk.

P. nigru, the black poplar, is a tree of Iarge size, sometimes 100 ft. high, with dark, deeply-furrowed bark on the trunk, and ash-coloured branches; the smooth deltoid leaves, serrated regularly on the margin, are of the deep green tint which has given name to the tree; the petioles, slightly compressed, are only about half the length of the leaves. The black poplar is common in central and southern Europe and in some of the adjacent parts of Asia, but though abundantly planted in Great Britain, is not there indigenous. The wood is of a yellowish tint.

A closely related form is the well-known Lombardy poplar, P. *nigra* var. *italica,* remarkable for its tall, cypress-like shape, caused by the nearly vertical growth of the branches. It is probably a variety of the black poplar, and its native land appears to have been Persia or some neighbouring country; it was unknown in Italy in the days of Pliny, while from remote times it has been an inhabitant of Kashmir, the Punjab and Persia, where it is often planted along roadsides for shade; it was probably brought from these countries to southern Europe, and derives its popular name from its abundance along the rivers of Lombardy, where it is said to spring up naturally from seed, like the indigenous black poplar. It was introduced into Great Britain soon after 1750, if not earlier. The Lombardy poplar is valuable chiefly as an ornamental tree; its tall, erect growth renders it useful to the landscape gardener as a relief to the rounded forms of other trees, or as a contrast to the horizontal lines of the lake or riverbank. Its growth is extremely rapid and it often attains a height of 100 ft.

P. *euphratica,* believed to be the weeping willow of the Scriptures, is a large tree remarkable for the variability in the shape of its leaves, native to north Africa and western and central Asia.

In North America about 13 native species are found, together with some 15 well-marked varieties and some five or more hybrids, widely distributed throughout the continent. Most of these, especially the larger kinds, are generally called cottonwood.

The eastern cottonwood (P. deltoides), a very large, broad-headed tree, with deeply-furrowed, gray or dark brown on the older trunks, which divide into many great arms, and large, ovate, finely toothed leaves, 4 to 7 in. long, longer than broad, occurs only locally and infrequently from Vermont to Mississippi. Its immensely more abundant variety, the common cottonwood or necklace poplar (*P.* deltoides var. *virginiana*), differs chiefly in having smaller triangular or ovate-triangular leaves, about as broad as long. It grows native from Quebec to North Dakota and south to Florida and Texas, sometimes attaining a height of 150 ft. and a trunk diameter of 8 ft. The loosely-flowered fruiting aments form a pendent string, 6 to 10 in. long, of ripening pods, whence the name necklace poplar. The timber is used for lumber and pulpwood, and the tree is often planted for ornament. Numerous forms of this poplar are planted in Europe and America, probably mostly hybrids with forms of the European black poplar (P. *nigra*). Among these are the Carolina poplar (× P. camdensis), widely grown in streets and parks in the eastern states, a vigorous, upright tree, with strongly ascending branches, the trunk continuing through the top, and the Eugene poplar (× P. canadensis var. *eugeni*) which was originated in France in 1832. Both these forms bear only male flowers and hence do not produce the profusion of downy seeds which renders the common cottonwood somewhat objectionable as a street tree. The Norway or "sudden-sawlog" poplar, a very rapid-growing and hardy form, supposedly of Siberian origin, is probably either a variant of the common cottonwood or a hybrid of it. Since its distribution in 1904 from a Norwegian settlement in Minnesota it has been widely planted in the northwestern states. In seven years the "sudden-sawlog" poplar will grow from a small cutting to a height of 50 ft. or more and a trunk diameter of 6 to 8 in., producing quick shade, windbreaks, useful light timber and pulpwood.

As practically the only large tree in many parts of the interior region, where it grew along the watercourses, the cottonwood was utilized by the pioneers in an immense number of ways, but chiefly for soft lumber, fuel and quick shade. Its downy fruits. widely driven by the wind, readily take root in the wet sands of lake and river shores. Around the southern and eastern shores of Lake Michigan the cottonwood, because of this characteristic, is an important factor in the formation of dunes.

The swamp cottonwood or downy poplar (P. *heterophylla*), which is found from Connecticut to southern Illinois and southward to Florida and Louisiana, attains a height of 90 ft. and trunk diameter of 3 ft. It has dark, rough bark and large, broadly ovate Ieaves, 5 to 6 in. long, which are intensely woolly when young. This tree furnishes excellent pulpwood and the lumber known to the trade as black poplar.

The black cottonwood or California poplar (P. *trichocarpa*) together with its northern variety (var. hastata) comprise the largest broad-leaved tree indigenous to the Pacific coast region of North America, attains a height of 200 ft. and a trunk diameter of 8 ft. It grows from Alaska to Lower California and eastward to Idaho and Nevada. It has yellowish fissured bark and large ovate, finely toothed leaves 2 to 11 in. long, lustrous green above and whitish below. The timber is utilized for wooden ware and pulpwood.

The balsam poplar or tacamahac (P. deltoides *missouriensis*), the "liard" of the Canadian voyageurs, is a narrow-topped tree, sometimes 100 ft. high, with a diameter of 7 ft. at the stump. It has smooth gray bark, ovate, pointed, dark-green leaves, which are whitish below, and resinous buds with a pleasing balsamic odour. It is found along the northern border of the United States from Mains westward, southward in mountains to Colorado, Nevada and Oregon, and northward nearly throughout Canada and Alaska to the Arctic circle. Like the cottonwood in the United States, the tacamahac was put to manifold uses by the early settlers in the prairie regions of Canada. The balm-of-gilead poplar *(P. candicans)* is similar to but smaller than the balsam poplar, with broad, heart-shaped leaves and very large, resinous, highly aromatic buds. It is widely planted in the northeastern states and Canada and also occurs as if native. It is thought to be a hybrid of European origin but perhaps partly of North American parentage.

In the Rocky mountain region and adjacent plains are found the lanceleaf cottonwood *(P. angustifolia)* and a foot-hill species (*P. sargenti*).

In the arid districts of the southwestern states there are seven species of cottonwood, all of more or less limited range, among which are the Fremont cottonwood *(P. fremonti)* and the Mexican cottonwood *(P. wislizeni)*.

The white, the black, and the Lombardy poplar are widely planted in the eastern states and Canada, where the two first named have become more or less naturalized.

In 1940 the cut of cottonwood lumber in the U.S.A. was 153,562,000 bd. ft., lumbered chiefly in the Mississippi valley, mostly from the common cottonwood in the north and swamp cottonwood in the south. In 1899, the peak year of production, it was 421,575,000 bd. ft. *(See* ASPEN.)

See C. S. Sargent, *Manual of the Trees of North America* (1905, new ed. 1933); G. B. Sudworth, *Forest Trees of the Pacific Slope* (1908) and *Check List of the Forest Trees of the United States* (1927); L. H. Bailey, *Manual of Cultivated Plants* (1924).

POPLAR BLUFF, a city of south-eastern Missouri, U.S.A., at the head of navigation on the Black river; the county seat of Butler county. It is on federal highways 60 and 67, and is served by the Frisco and the Missouri Pacific railways. Pop. (1940) 11,163. It was named from the tulip poplar trees which grew on the bluff of Black river. It marks the eastern border of the Big Springs country of the Ozark mountains. Wappapello and Clearwater dams provide a mammoth lake resort area, already noted for Keener spring and cave, hideout of the outlaw Jesse James. The industries include railway shops, shoes, lumber, wood handles, staves, tents, awnings, livestock, dairying, cotton and potatoes. It was incorporated as a town in 1870, as a city in 1892.

POPLIN. A fink and plain-ribbed fabric produced from any class of textile material and comprising a variety of different textures and qualities, and containing fine ribs or cords of uniform size extending across the width of the fabric, from selvedge to selvedge, *i.e.,* in the direction of the weft. The ribbed effect in a poplin fabric is obtained by employing a relatively high number of warp threads of fine counts of yarn and interweaving these on the principle of the plain calico weave, with picks of weft of coarse counts. Hence, during weaving, the finer and weaker warp threads bend or interlace quite freely under and over the *coarser* and stronger picks of weft which, therefore, lie in a perfectly straight line across the entire width of the fabric and thus develop the fine ribs or cords that characterize all poplin fabrics. Cotton poplin fabrics are used for making blouses, dresses, shirts and other garments. Irish poplin is composed of silk warp and worsted weft, and used for ties, dresses, coats and many other articles of clothing.

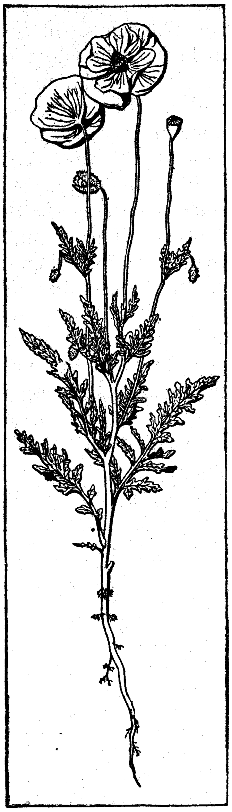
The manufacture is of French origin and was brought to England by the Huguenots.

POPOCATEPETL (Aztec *popoca* "to smoke," *tepetl* "mountain"), a dormant volcano in Mexico 18° 59' 47″ N., 98° 33′ 1″ W., which with the neighbouring Ixtaccihuatl (Aztec "white woman") forms the south-eastern limit of the great basin known as the "Valley of Mexico." As it lies in the State of Puebla and is the dominating feature in the views from the city of that name, it is sometimes called the Puebla Volcano. It is the second highest summit in Mexico, its shapely, snow-covered cone rising to a height of 17,876ft., or 438ft. short of that of Orizaba. This elevation was reported by the Mexican geological survey in 1895, and as the Mexican Geographical society calculated the elevation at 17,888ft., it may be accepted as nearly correct. The bulk of the mountain consists of andesite, with some porphyry, obsidian, trachyte, basalt, and other similar rocks. It has a stratified cone which shows a long period of activity. At the foot of the eastern slope stretches a vast lava field—the "malpays" (*malapais*) of Atlachayacatl—which, according to Humboldt, lies 60 to 80ft. above the plain and extends 18,000ft. east to west with a breadth of 6,000ft. Its formation must be of great antiquity. The ascent of Popocatepetl is made on the north-eastern slope, where rough roads are kept open by sulphur carriers and timber cutters. Describing his ascent in 1904, Hans Gadow states that the forested region begins in the foothills a little above 8,000ft., and continues up the slope to an elevation of over 13,000ft. On the lower slopes the forest is composed in great part of the long-leaved *Pinus liophylla,* accompanied by deciduous oaks and a variety of other trees and shrubs. From about 9,500ft. to 11,500ft. the Mexican "oyamel" (*Abies religiosa*) becomes the principal species interspersed with evergreen oak, arbutus and elder. Above this belt the firs gradually disappear and are succeeded by the short-leaved *Pinus montezumae,* or Mexican "ocote"—one of the largest species of pine in the republic. These continue to the upper tree-line, accompanied by red and purple *Pentstemon* and light blue lupins in the open spaces, some ferns, and occasional masses of alpine flowers. Above the tree-line the vegetation continues only a comparatively short distance, consisting chiefly of tussocks of coarse grass, and occasional flowering plants, the highest noted being a little *Draba.* At about 14,500ft. horses are left behind, though they could be forced farther up through the loose lava and ashes. On the snow-covered cone the heat of the sun is intense, though the thermometer recorded a temperature of 34° in September. The reflection of light from the snow is blinding. The rim of the crater is reached at an elevation of approximately 17,500ft. The crater is elliptical in form, 2,008 by 1,312ft., and has a depth of 1,657ft. below the summit of the highest pinnacle and 673ft. below the lowest part of the rim, which is very irregular in height. The steep, ragged walls of the crater show a great variety of colours, intensified by the light from the deep blue sky above. Huge patches of sulphur, some still smouldering, are everywhere visible, intermingled with the snow and ice that fills the crevices and covers the ledges of the black rocks.

It is believed that Diego de Ordaz was the first European to reach the summit of Popocatepetl, though no proof of this remains further than that Cortés sent a party of ten men in 1519 to ascend a burning mbuntain. In 1522 Francisco Montano made the ascent and had himself let down into the crater a depth of 400 or 500ft. No second ascent is recorded until April and Nov., 1827 *(see* Brantz Mayer, *Mexico,* vol. ii.). Other ascents were made in 1834, 1848 and subsequent years, members of the Mexican geological survey spending two days on the summit in 1895.

POPPY, any plant of the genus *Papaver,* the type of the family Papaveraceae. They are annual and perennial erect herbs containing a milky juice, with lobed or cut leaves and generally long-stalked regular showy flowers, which are nodding in the bud stage. The sepals, which are usually two in number, fall off as the flower opens, the four (very rarely five or six) petals, which are crumpled in the bud stage, also fall readily. The numerous stamens surround the ovary, which is surmounted by a flat or convex rayed disk bearing the stigmas. The ovary develops into a many-seeded short capsule opening by small valves below the upper edge. The valves are hygroscopic, responding to increase in the amount of moisture in the atmosphere by closing the apertures. In dry weather the valves open, and the small seeds escape through the pores when the capsule is shaken by the wind. The genus contains about 140 species, mostly natives of central and south Europe and temperate Asia. Five species occur in Great Britain; *P. rhoeas* is the corn poppy found in fields and waste places. Cultivated forms of this, with exquisite shades of colour and without any blotch at the base of the petals, are known as Shirley poppies. *P. somniferum,* the opium poppy, with large white or blue-purple flowers, is widely cultivated. *(See* OPIUM.)

The Oriental poppy (*P. orientale*) and its several varieties are fine garden plants, having huge bright crimson flowers with black blotches at the base, Many hybrid forms of varying shades of colour have been raised of late years. The Iceland poppy (*P. nudicaule*), is one of the showiest species, having grey-green pinnate leaves and flowers varying in colour from pure white to deep orange-yellow, orange-scarlet, etc. The Welsh poppy belongs to an allied genus, *Meconopsis;* it is a perennial herb with a yellow juice and pale yellow poppy-like flowers. It is found in the southwest and north of England, and in Wales; also in Ireland and western Europe. The prickly poppy belongs to the related, tropical American genus *Argemone.*



COMMON CORN POPPY (PAPAVER RHOEAS) OF "FLANDERS FIELDS"

A. grandiflora is a popular Central American annual with large, white flowers. To the same family belongs the horned poppy, *Glaucium flavum,* found on sandy seashores and characterized by the waxy bloom of its leaves and large golden-yellow short-stalked flowers. The plume poppies *(Macleaya)* are ornamental foliage plants of great beauty. The snow poppy *(Eomecon chionantha)* is a pretty Chinese perennial, having roundish slightly lobed leaves and pure white flowers about 2 in. across The Mexican tulip poppy (*Hunnemannia fumariaefolia*), a perennial usually grown as an annual, has very showy yellow flowers.

The poppy group is well represented in western North America, especially in California, where about 20 native species, together with numerous varieties, are found. The best known is the California poppy (*Eschscholtzia californica*), with brilliant, orange-coloured flowers, widely grown in gardens and extensively naturalized in Australia and India. Other noteworthy Californian species, more or less cultivated, are the tree poppy *(Dendromecon rigida),* a rigid, leafy shrub, 2 to 10 ft. high, with golden-yellow flowers, about 2 in. across; the Matilija poppy *(Romneya coulteri)*, a widely branched sub-shrub, 3 to 8 ft. high, with large, white, fragrant flowers, 6 in. across; the cream-cups (*Platystemon californicus),* a low, delicate annual, with light yellow flowers, 1 in. across; and the flaming poppy or wind poppy *(Meconopsis heterophylla)*, bearing brick-red flowers, 2 in. across. (N. TR.; X.)

POPPY HEADS, in architecture, the finials or other ornaments which terminate the tops of bench ends of pews or stalls. They are sometimes small human heads, richly carved images, knots of foliage or finials and sometimes *fleurs-de-lis* simply cut out of the thickness of the bench end and chamfered. The term is probably derived from the French *poupée,* doll or puppet, rather than from the flower.

POPPY OIL *(Oleum papaveris)*, **a** vegetable oil obtained by pressure from the minute seeds of the garden or opium poppy, *Papaver somniferum.* The white-seeded and black-seeded varieties are both used for oil-pressing; but, when the production of oil is the principal object of the culture, the black seed is usually preferred. The qualities of the oil yielded by both varieties and the proportion they contain (from 50 to 60%) are the same. By cold pressing seeds of fine quality yield from 30 to 40% of virgin or white oil *(huile blanche),* a transparent limpid fluid with a slight yellowish tinge, bland and pleasant to taste, and with almost no perceptible odour. On second pressure with the aid of heat an additional 20 to 25% of inferior oil *(huile de fabrique* or *huile russe*) is obtained, reddish in colour, possessed of a biting taste, and a linseed-like smell. The oil belongs to the linoleic or drying series, having as its principal constituent linolein; and it possesses greater drying power than raw linseed oil. Its specific gravity at 15°C. is 0·925.

Poppy oil is a valuable and much used medium for artistic oil painting. The fine qualities are largely used in the north of France (*huile d'oeillette)* and in Germany as a salad oil, and are less liable than olive oil to rancidity. The absence of taste and characteristic smell in poppy oil also leads to its being much used for adulterating olive oil. The inferior qualities are principally consumed in soap-making and varnish-making, and for burning in lamps. The oil is very extensively used in the valley of the Ganges and other opium regions for food and domestic purposes. By native methods in India about 30% of oil is extracted, and the remaining oleaginous cake is used as food by the poor. Ordinary poppy-oil cake is valuable feeding material, rich in nitrogenous constituents, with an ash showing an unusually large proportion of phosphoric acid. The seed of the yellow horned poppy, *Glaucium luteum,* yields from 30 to 35% of an oil having the same drying and other properties as poppy oil; and from the Mexican poppy, *Argemone mexicana,* is obtained a non-drying oil used as a lubricant and for burning.

POPULATION. About two-thirds of the inhabitants of the world are now periodically enumerated by means of a census. Whenever a census is taken a number of questions is asked concerning each person. Thus with respect to two-thirds of the inhabitants of the world there is a considerable volume of information of a fair degree of accuracy. The questions asked vary considerably from country to country. Information is nearly always required regarding age, sex and marital condition and therefore the inhabitants of different countries of which the population is periodically enumerated can be compared in respect of these matters. But with regard to the asking of questions concerning other matters much variation exists, and comparisons are often rendered impossible. There is no question regarding religion in the English census, for example, and comparisons in this respect between England and other countries where such information is collected are therefore not possible. For the remaining third of the world population it is necessary to rely upon estimates. No great degree of confidence can be placed upon these estimates, and a wide margin of error must be allowed for. Furthermore, estimates can only be made for the total population. It is impossible to estimate the distribution of the population in respect to age or sex, and as to these matters, therefore, for the remaining third of the world population there is no information.

The information obtained by the taking of a census can be analysed and tabulated. The results of so doing can be compared with the results of analysing former censuses. It will almost certainly be found that important changes have occurred since the taking of the last census. The population may have increased or diminished; the sex ratio may have altered. The taking of a census brings such changes to light but does not explain them. A census is, as it were, a snapshot of the population, and for the study of population changes more is required than a series of snapshots taken at different dates. An increase in the population of a country, such as a census may show, might be due to the immigration of people into the country, to an increase in the birth-rate or to a decrease in the death-rate. In those countries where a census is taken, data are also collected regarding births, deaths, marriages, movement into and out of the country and other matters. There is considerable variation in the methods of taking these data as there is in the taking of a census from country to country. These data are not only of interest in themselves but they can be used to throw light upon the changes which occur between one census and another.

These registration statistics of births, marriages and deaths may provide immediate explanations of some of the changes exhibited by the taking of a census. They may show, for instance, that the slackening of the rate of increase of the population of a country is due to a decline in the birth-rate. We are in that case led on to enquire into the causes of the decline of the birth-rate, or it may be in other cases into the causes of an increase in the death-rate or in the immigration rate. It is likely that to some extent an examination of the census figures and of the registration statistics will assist us in any effort we may make to explore these more distant matters. A detailed examination, for instance, of changes in the birth-rate over a number of years will almost certainly contribute towards the solution of the problem of the decline in the birth-rate. But it will seldom be found that the evidence of census and registration figures will be conclusive regarding these more distant problems. Biological questions are frequently involved. It may, for example, be shown that the statistics of the decline in the birth-rate are compatible with the increasing use of contraceptive methods. But before any conclusion can be come to on the point, it is necessary to enquire into the possible influence of diet upon fertility and other purely biological problems. Evidently the pursuit of explanations as to how the population of any country has come to be what it now is can lead us very far afield. It is not possible in this article to follow up these matters further than the point at which census and registration data cease to throw light upon them; nor can more than incidental reference be made to the results of population changes.

(1) WORLD POPULATION AND ITS DISTRIBUTION

(a) **Geographical Distribution.**—The best known estimates of the population of the world are those of the International Statistical Institute. In Table I. are given the estimates of the institute for the world as a whole and for the five continents about the years 1920 and 1926. It never happens that there is up-to-date information for every country in the same year. The data available nearest the year named are used and therefore in the table the word "about" is introduced. To what extent can these estimates be relied upon? There is a certain margin of doubt. The estimate for the institute for 1920 is 1,811 millions, while the independent estimates of the International Institute of Agriculture for 1921 and 1925 are 1,820 and 1,871 millions respectively. Other independent estimates show no very serious divergences and it is not likely that the totals are greatly in error. When we come to examine the estimates for each continent we find that the figures for Europe and North America

TABLE I. *Estimated Area and Population of the World*

Region	Area in thousands of square miles	Population in thousands		Density per square mile
		about 1920	about 1926	in 1926
Europe	3,700	449,727	467,092	126·2
America	16,663	209,409	233,106	13·0
Africa	11,053	132,139	138,249	12·4
Asia	17,008	1,012,122	1,032,381	60·6
Oceania	3,299	7,615	8,767	2.6
Total	56,613*	1,811,012	1,879,595	33·2

*Including 4,890,000 square miles of arctic and antarctic lands.

may be taken as approximately accurate, though some doubt arises concerning Russia and Mexico. The figures for Oceania are probably more accurate than those for any of the other remaining areas. While very considerable progress has been made in the enumeration of the inhabitants of certain South American countries, especially of Brazil, Argentina, Chile and Uruguay, there remains a large measure of doubt concerning the total population of the Southern half of the American Continent. The figures for earlier dates are still more open to suspicion, and the relatively large increase in the total population which would appear to have taken place during the present century is probably in part due to incomplete enumeration at earlier dates.

The figures for Asia are still less trustworthy. For some Asiatic countries there are reliable figures. One of the greatest achievements in the history of the enumeration of peoples has been the taking of a census in India. But important as is India from the point of view of numbers, China is still more important. Until recently, estimates of the population of China differed by more than a hundred millions. They still differ widely but there is a general tendency among those who have given most study to the matter to accept a high rather than a low estimate. In 1921 an estimate of 445,000,000 was made for China, Manchuria and the Chinese dependencies by the Chinese postal administration, and this estimate agrees closely with those made by the Chinese maritime customs for 1922 and by the China Continuation Committee for 1918. Those who accept lower estimates have apparently been influenced by the census of 1910. This was a census of households and not of persons and in order to obtain the number of persons it is necessary to multiply by a factor—a proceeding which leaves the results open to a wide margin of error. The estimate by the International Statistical Institute of the world population in 1926 includes a figure of 433,000,000 for China and this figure is based upon special information furnished by the Chinese Minister of the Interior. It is evident that in view of the uncertainty regarding the population of China and of the tendency to accept higher estimates, no great importance can be attributed to the apparent growth of the population of Asia in recent years which figures generally show. Similarly no confidence can be placed in the figures which seem to show a decrease in the population of Africa during the last half century. The estimates for this continent are less trustworthy than for any other continent. It would seem that in the last century observers tended greatly to overestimate the negro population. These estimates have since been considerably reduced and this reduction accounts for the apparent decrease in the population of the continent. At the same time parts of the continent have been ravaged by sleeping sickness and other diseases in late years and it is thus unlikely that there has been any true increase in the population.

TABLE II. *The Proportion of the Total Population of Europe* (=100) *America* (=100), *Africa* (=100) *and Asia* (=100) *contributed by certain European, American, African and Asiatic countries at various dates*

Europe

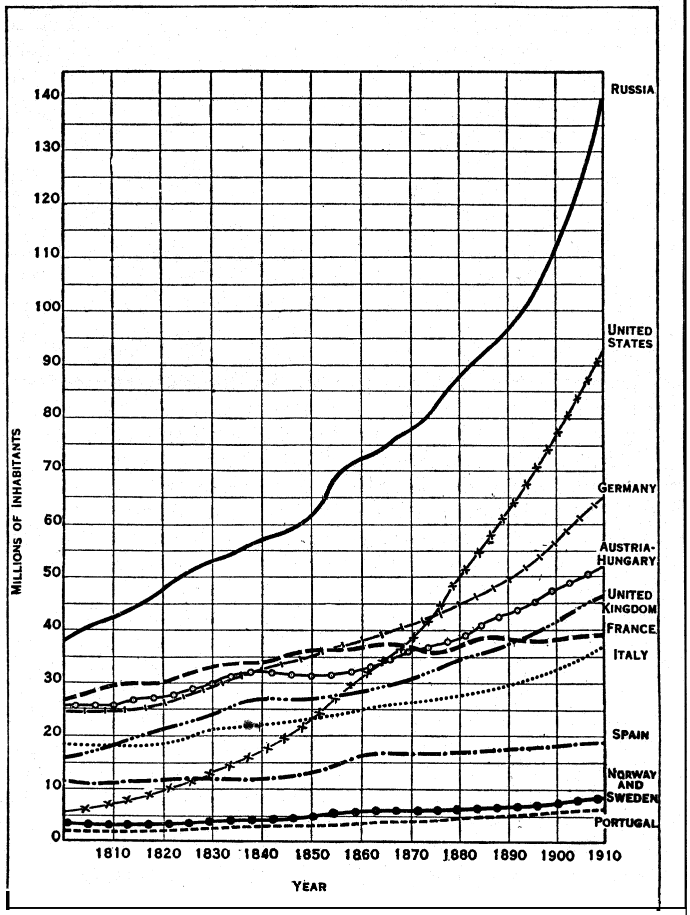
India	31·51	30·89
Japan	5·53	5·79
Russia (in Asia)	2·95	3.66
All other countries	10·14	10·62

(b) Changes in Geographical Distribution.—For the reasons given above it is not possible to obtain any accurate measurement of the proportion of the world population represented by the inhabitants of different countries during the last century and of the changes which have occurred since. But comparisons of this kind can be made for countries in Europe because trustworthy European statistics are available over a long period



FROM DR. EAST, "MANKIND AT THE CROSSROADS" (CHARLES SCRIBNER S SONS)

FIG 1.—GRAPH OF GROWTH OF POPULATION IN VARIOUS COUNTRIES 1800–1910, SHOWING THE RAPID INCREASE IN THE UNITED STATES AND RUSSIA CONTRASTED WITH THE SLOW INCREASE IN FRANCE

of years. In Table II. figures are given showing the proportions which the inhabitants of various European countries formed of the total population of Europe for various dates beginning with 1880. The same table gives similar data for America beginning with 1910 and for Africa and Asia beginning with 1920. Between 1880 and 1910 there were no changes in the frontiers of European countries, and the alterations in the relative positions of the various countries are due to varying rates of increase. The notable features are the decline in the position of France and the advance in the position of Russia. Between 1910 and 1920 there were large losses and large gains of territory in many countries. In addition, many European countries experienced an increased death-rate. Thus, in the case of the 1920 figures the changes due to varying rates of increase are overshadowed by the effects of the War. These effects have been remarkable. It is noticeable that France, in spite of an increase in territory, has not quite maintained her position, and that Germany, in spite of a large decrease in territory, has suffered comparatively little. Austria and Hungary, so greatly changed as political units by the War, now contribute less than 2% each to the population of Europe. The figures for America are interesting in that they show that the various countries tend to maintain their relative positions. The United States have lost slightly; Brazil and Argentina are gaining. The figures for Africa and Asia are chiefly of interest, rather in respect of the present relative importance of the various countries, than of any changes which they reveal. The dominating positions of India and China in Asia are generally recognised but the similarly dominating positions of British and French territories in Africa are not so well known. Looking at the relative world position of different countries and their territorial possessions, not from the point of view of population but of extent of territory, we find that Great Britain comes first with approximately 14·2, Russia second with 9.2, and thereafter France with 4.3, the United States with 3.7, Brazil with 3.2, and China with 3 million square miles.

It is evident that changes in the relative positions of different countries in respect of the proportion which their inhabitants form of the population of the continent in which they live, or of the world, are of the utmost interest and importance. Power and prestige in general go together. Behind the large populations are the big battalions. Therefore we may extend our view and look at the matter in another way. The figures for the total population of the United States and of the principal European countries are known since 1800 and in the accompanying graph (fig. 1) taken from Dr. E. M. East's *Mankind at the Crossroads*, the growth in absolute numbers of the inhabitants of these countries is shown. It is seen that the population of the United States which in 1800 only exceeded three of the European countries for which data are given, grew to surpass in turn the population of all the chief European countries with the exception only of Russia. Looking next at the European countries we find that they did not maintain their relative positions. France began by being second only to Russia but was passed in turn by Germany, Austria Hungary and the United Kingdom. The other changes need no comment. It is evident that these facts are full of significance in connection with international relations.

(c) Racial Distribution.—It is necessary to exercise the greatest caution in the use of the term "race." If by racial groups are meant groups of men exhibiting in common certain inherited character differences, then we may legitimately employ the term. There are groups of men exhibiting in common certain inherited characteristics in respect of hair, pigmentation and other physical features, and it may be asked what proportion of the population of the world falls into each of the larger groups. To this question no satisfactory answer can be returned. Not only in South America, for example, is the total population not accurately known but trustworthy data as to the proportion which each racial group, Caucasian, Negroid and Amerindian, contributes respectively to the estimated total are wholly lacking. The same applies to Asia and Africa.

It is estimated that the white branch of the Caucasian racial group and the Mongoloid group between them account for about two-thirds of the population of the world. In the absence of accurate information as to the constitution of the population of the world to-day it is clearly impossible to discover whether the different racial groups are maintaining their relative positions or whether one or more groups have improved their relative positions since 1900 or 1880. It can only be said that the white element of the Caucasian group, which was during the greater part of the last century considerably improving its position, is in any case not now doing so in the same ratio if indeed it is improving it at all.

(d) Growth of World Population.—The present population of the world is approximately 1,900 millions. Estimates of world population before 1880 are not very trustworthy. Sir George Knibbs, however, considers that Michelot's estimate of 1,009 millions for 1845 is as well founded a guess as can be made. Accepting this estimate it can be calculated that between 1845 and 1914 the average annual increase of the world population was about ·7%. It was in other words increasing at a rate which would double the population in less than 100 years. This rate of increase is considerably less than that found among the more advanced countries which compile registration statistics. Taking 26 such countries and calculating the rate of increase for the period 1906 to 1911 it works out at over 1·1%. These 26 countries were increasing at a rate which would double their populations in about 60 years. Putting the rate of increase at ·628% per annum, which was the rate of increase of the world population between 1901 and

1924, and supposing this rate to continue indefinitely, the world population would number 4,000 millions in 2031, 8,000 millions in 2131 and 16,000 millions in 2231. These calculations suggest certain reflections. Evidently the rate of increase must have been far lower on the average in past times. Knibbs has shown that the progeny of a single pair of human beings increasing at the average rate of 1% would come to equal in numbers the present population of the world in 1,900 years. It is probable that there have been flyctuations of numbers in earlier centuries of civilization. It is certain that disregarding these fluctuations the rate of growth in former times taken over several centuries was very small and that the rate of growth during the last century was wholly abnormal.

The causes of changes in the rate of increase and the prospects for the future will call for mention later when we come to consider birth-rates and death-rates. One aspect of the present situation has received attention lately and may be noticed here. How much more room is there? This question has frequently been put of late years. The answers, as might be expected, differ widely. There is no agreement as to how much food is needed on the average by each person, there are marked differences of opinion regarding the extent of soil available for important crops such as wheat and there is the difficult question of the allowances to be made for improvements in the technique of food production which may be expected. Estimates of the possible maximum world population vary from as little as 3,000 millions to as much as 7,000 millions. It is not possible to say more than that there is a limit and that it lies between these totals on the assumptions commonly made. It is easy to calculate that if the present rate of increase continues there will be no more room after a certain date. If, however, it is grasped that, had the present rate obtained in the past, the earth would have been full up long ago, it will be realized that there is nothing inevitable about the present rate of increase and that no inevitable catastrophe awaits us. For the greater part of human history the population has probably been approximately stable in numbers or has been increasing so slowly that the increase was hardly perceptible. It may well become stable again.

(2) DENSITY AND URBANIZATION

(a) Density of Population. — In Table I. is shown the density per square mile of the population of each continent. The five million square miles of arctic and antarctic lands have not been included in the continents though they are included in the total land area. When they are taken into account the average density for the whole land surface is about 33·2 per square mile. If they were excluded the average density would be perceptibly raised. It should be noticed that no deduction has been made on account of the many large barren and almost uninhabitable tracts that are included within every continent except Europe. Their inclusion somewhat exaggerates the true density of the European population on the one hand and gives a somewhat false impression of the sparseness of population elsewhere on the other hand. The true position of Australia, for instance, does not emerge so long as no account is taken of the presence of the great central deserts, and the same applies to Africa when no account is taken of the Sahara. Taking the figures as they appear in the table it is found that Europe and Asia are the most crowded continents, Europe being twice as crowded as Asia. The remaining continents are, relatively speaking, empty.

Among countries and areas which are regarded as distinct units from the point of view of political organization, Barbados is the most densely populated, having (in 1921) 952 per sq m., while Java comes next with (in 1920) 689 per sq. mile. Belgium is the most densely populated among European countries with 635 per sq.m. (in 1920), while Great Britain has 482 per sq.m. (in 1921). It is worthy of notice that England and Wales have a density of 649 per sq.m. (in 1921) and are therefore more densely peopled than Belgium. Such comparisons can be widely extended and up to a point are informative. It should be remembered that they may also be very misleading. The area of Egypt is, for example, 383,000 sq.m., and the total population amounts to 14,227,000, giving an average density of 37 per sq. mile. But the population of Egypt is almost wholly confined to the valley and delta of the Nile, the areas of which contain 13,616 sq.m., giving a density of 1047 per sq.m. of the inhabited area.

The figures of density given above fail to bring out certain important facts. An examination of a map of the world showing density of population without regard to political boundaries makes it at once apparent that there are three densely populated regions of no great size. The first region is that part of Europe which lies south of the parallel 60° north latitude. The second is that made up of the greater part of India and Ceylon; the third includes Japan, the greater part of Manchuria and China and a strip along the coast of Tonking. It may be roughly estimated that the population of these regions amounts to 440,000,000, 480,000,000 and 300,000,000 and the areas to 2,900,000, 2,000,000 and 1,200,000 sq.m. respectively. We thus find over 1,200 million people living on about 6,000,000 sq.m., or in other words about two-thirds of the world population living on about one-eighth of the habitable area. There are four other very much smaller regions which are densely peopled, the New England area of the United States, the Nile valley, the tip of the Malay Peninsula and Java.

What lies behind density of population? The densely populated areas are of two kinds. There are the rice producing countries such as China, Japan and Java. Rice requires a warm damp climate and, wherever rice has been introduced into lands with such a climate, population has become dense. Rice culture is capable of providing more food per acre than any other type of agriculture. There are also the industrial countries and, as Ellsworth Huntington has pointed out, they mostly lie in regions with a temperate climate, neither too hot nor too cold and at the same time of a stimulating nature. According to Ellsworth Huntington it is climate rather than soil which determines density of population. A stimulating climate is what is required in order that men should engage in industrial activities. Raw materials can be brought from elsewhere. A warm and damp climate is required for rice cultivation and in such a climate even a poor soil under rice will support a relatively dense population. The theory that climate is of predominant importance is probably true though it should not be pushed too far. So far as it is true, it renders open to doubt the view that the tropics are destined to support very dense populations. The enervating climate, the poverty of the food products, the difficulty of preserving not only organic materials such as food but also inorganic materials of which machinery is composed, the destructiveness of pests, are all obstacles.

(b) Urbanization. — The study of urbanization is the study of an aspect of the problem of density. It is a very important aspect and as such has not received the attention it deserves. It is probable that no change of so fundamental a nature has ever occurred in the lives of the mass of the people as that which has converted the greater part of the population of industrial communities from country dwellers to town dwellers during the last century. It is thus desirable to obtain a measure of urbanization but it is not an easy matter to do so. The census returns of most countries classify the population into urban and rural, but while these figures are useful for comparing changes in the same country between two dates, they are of little use when comparing two countries. This is so because the classification is based upon very different methods in different countries. Thus, owing to differences in local government between England and Scotland, the figures giving the percentages of urban dwellers out of the total populations are not comparable. Again, those officially classed as urban dwellers often live under what to most people would appear as rural conditions. English urban dwellers include, for instance, according to the official classification, those who live in the areas of urban district councils and, as is well known, to live in such an area is often regarded as having escaped from a town. The best method is perhaps to note, in Table III., the percentage of the total population living in towns having a population of 100,000 and over.

This table must be interpreted with caution. The method of calculating urbanization here adopted is not perfect. The urbanization of Australia, for example, is exaggerated. The urban population of Australia is concentrated in five large towns and there are few towns of relatively small size. If 50,000 instead of 100,000

TABLE III. *Density of Population and Urbanization: 1926*

Country	Population per square mile	Percentage of population living in towns having 100,000 inhabitants and over
Egypt (cultivated area only) . .	1,047	12·2
England and Wales .	668	39·1
Japan . . .	403	14 6
Italy	338	14·5
Germany . . .	350	26.6
France.	192	15·5
India	177	3·6
China . .	101	4·5
Russia (in Europe) . .	63	5·2
United States . . .	38	26.5
Canada (excluding North West territories) .	4	17·7
Australia	2	45'5

was taken as the lower limit, Australia would come out as relatively less urbanized than under the present method of calculating urbanization. Allowing for its defects, the table does show that there is little association between density of population and urbanization. Densely populated countries may or may not have a high degree of urbanization; Australia is an example of a sparsely peopled country with a high degree of urbanization. Further examination of the table shows that urbanization goes with industrialization rather than with density. In other words, a high degree of density without industrialization does not lead to urbanization, whereas urbanization can go a long way where industrialization prevails, even though the population is sparse. The countries which have a high degree of density without urbanization are those such as China, India and Egypt, where intensive agriculture is practised. Density thus accompanies intensive agriculture and may also be attained under industrial condition.

(3) DISTRIBUTION BY SEX AND AGE

(a) Sex.—Among the questions asked where a census is taken there is always one concerning sex. Therefore for every country where a census exists we know the number of males and females comprised in the population. It is usual to state the facts by giving the number of females to 1,000 males and this number is called the sex ratio. It is well kaown that in most European countries females outnumber males and that in most non-European countries the opposite is the case. The facts are set out in Table IV. for certain European countries and in Table V. for certain non-European countries. For many European countries given, there is information for 1910 as well as for 1920.

TABLE V. *Proportion of the Sexes Living and at Birth in Certain Non-European Countries About 1920*

Country	No. of females to 1,000 males about 1920	No. of male births to 1,000 female births about 1920		
		Born living	Born dead	Total

Australia	968	1062	. .	. .

*Excluding coloured population.

It will be seen that in the case of the countries neutral during the war there has been little change on the whole in the proportion between the sexes, whereas in the case of belligerent countries the former considerable excess of females was increased. Belligerent countries are therefore abnormal in respect of the existing large excess of females, and the increased disparity between the sexes is due to deaths of males during the war. The exceptional case of the lately belligerent countries may be thus left out of account, and the proportions about 1910 taken as more normal for Europe.

The conditions normal for Europe, however, are not those normal for non-European countries where males as a rule preponderate to at least as great an extent as females usually preponderate in Europe. In order to throw light upon this matter it is necessary to anticipate part of the discussion relating to distribution by age and to birth and death rates. This for the sake of convenience we may now do.

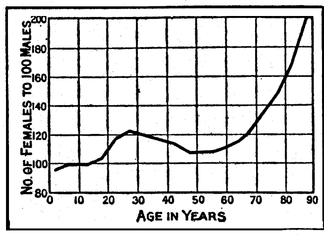
The sex ratio holds for the entire population. It does not necessarily hold for each group in the population. It might be that, while in the population as a whole there was an excess of females, there was at the same time an excess of males among that element of the population which fell between certain ages. This in fact is found to be the case in England and Wales as the following table shows. The figures in this table can be better appreciated when set out in the form of a graph (Graph II.). In England and Wales in 1921 males outnumbered females in the earlier age groups. There were in fact more males than females among those under 15 years of age. Among all those over 1; females were in excess and the older the group the greater in general was the excess of females. Among those 85 years old and over there were more than two women to each man.

TABLE VI. *Sex Ratio: Females to 1,000 Males. England and Wales, 1921*

Age	0–4	5-9	10–14	15–19	20–24	25–29	30–34	35–39	40–44	45–49
Ratio.	976	992	992	1,027	1,176	1,209	1,186	1,156	1,127	1,070
Age	50–54	55–59	60–64	65–69	70–74	75–79	80–84	85–	*All* ages	
Ratio	1,074	1,086	1,132	1,194	1,342	1,476	1,685	2,052	1,096	

These facts set us upon the track of an explanation. Obviously the next step is to investigate the sex ratio at birth. Tables IV. and V. give the number of male births to 1,000 female births for the countries under consideration. In every case there are more male than female births. This fact accounts for the excess of males among the younger age groups. But how does it come about that males lose their preponderance in the higher age groups? An examination of Table VII. gives the answer. Table VII shows that in England and Wales and in the United States registration area during the years 1911–5 females in every age group experienced a lower death-rate than males with the one exception of the age group 10–15 in England and Wales, where the males have the lower death-rate. The answer is that males die off more quickly than females.

It thus comes about that, although in the earliest age groups males outnumber females because more boys are born than girls, females soon come to outnumber males and in fact preponderate in the age group 15–20 in England and Wales and in all succeeding age groups. Thus, taking the population as a whole, females outnumber males. It may then be asked why females have this more favourable experience. There are two reasons which account for this fact. The female sex is more hardy than the male sex, and on the whole resists disease and the wear and tear of daily existence better than does the other sex. Again, females are less exposed to accidents than males. Industrial accidents fall rather upon the latter than upon the former. Men, in fact, lead a more hazardous existence, and more often lose their lives at work or at play than do females. The outbreak of war is only a special case of the extra exposure of males to risk.



FROM CARR-SAUNDERS AND CARADOG JONES, "SOCIAL STRUCTURE OF ENGLAND AND WALES" (CLARENDON PRESS, OXFORD)

FIG. 2.—SEX RATIO IN RELATION TO AGE

Males predominate in the earliest years, females in middle and old age

These facts explain the sex ratio and its distribution by age for such countries as England and Wales but they leave unexplained the situation in such countries as the United States. There also males outnumber females at birth as Table V. shows and there again males die off more rapidly than females as Table VII. makes clear. Why then are there more males than females in the American population as a whole? The explanation is to be found in the fact that large numbers of emigrants from Europe have entered the United States during recent years, and that among these emigrants males preponderate. This tendency for males to migrate more than females accounts also in some degree for the deficiency of males in those European countries from which movement takes place. The excess of males in the United States is found chiefly among the foreign-born whites and not amongst the native-born whites and negroes. Again, in the densely settled regions of that country females outnumber males. The same factor explains the excess of males in the British Dominions. This factor cannot, however, explain the position in India, Japan and Egypt.

There is no gain of males by immigration into these latter countries. If we look into the figures for these countries we find that as in all other countries for which figures are given in the Tables there is an excess of male births. But the death-rate does not as in other countries favour females. Table V. shows that in Japan the female sex experiences a higher mortality than the male sex between the ages of 1 and 40. Therefore males maintain their initial preponderance. It is outside the scope of this article to discuss the determination of sex. The figures in Table IV., however, carry us somewhat further back. So far, reference has only been made to the figures for living births, which show that more males are born alive than females. Reference may now be made to the figures for still births, and it will be observed that males bear a higher proportion to females among still births than they do among living births in every country for which figures are available. Males thus suffer a high mortality at birth, and the original disproportion between the sexes must be higher than the statistics for living births show. Evidence derived from observations upon miscarriages and from other sources goes to show that males suffer a disproportionately heavy mortality at a still earlier stage during pre-natal life. It thus follows that the proportion of males to females must be very much higher at conception than at birth.

(b) Age.—When a census is taken a question about age also is always asked. When populations of different countries are examined it is found that there are remarkable differences in respect to age distribution. These differences are of interest from two points of view. First, the proportion of persons of working age is important because upon their efforts depend the rest of the non-working population, both young and old. Again, only when the age distribution is known can the figures for birth-rates and death-rates be interpreted. It may be known that there are a certain number of births per 1,000 of the population and a certain number of deaths per 1,000 of the population in a certain area during a certain year, but, unless it is also known how many wives of child-bearing age and how many old persons there are in every 1,000 of the population, this information is of little use in enabling comparisons to be undertaken between one country and another or between one town and another. Thus, old people might retire in large numbers to a healthy town and live there until their death, thus causing a high death-rate and giving the appearance of bad conditions in what was in fact a healthy town. To this may be added the fact that age distribution must have an important influence upon the outlook of the population as a whole. Where the young are relatively numerous the outlook will not be the same as where the old are relatively numerous. In Table VIII. is set

TABLE VII. *Death-rate Among Males Expressed as a Percentage of the Death-rate Among Females at Different Age Periods*

Country	under 1	Age periods 1–4	5–9	10–14	15–19	20–24	25–34	35–44	45–54	55–64	65–74	75 and over

All ages	1,000	1,000	1,000	1,000	1,000	1,000	1,000	1,000	1,000	1,000	1,000	1,000	1,000

out the age distribution in certain countries for various dates. Figures such as these are not of a very high order of accuracy. Ignorance and mis-statement vitiate the data to some extent. There seems to be a tendency for persons below a certain age to understate their age and for persons above a certain age to overstate their age. This may be due to vanity. But the figures are of sufficient accuracy to bring out some remarkable differences.

When these figures are examined it is found that the conditions represented in different countries and in the same country at different dates form a graded series. At one extreme the young are relatively numerous and at the other the old are relatively numerous. Taking the latter case first we find that France in 1911, Prussia in 1920, England and Wales in 1920 and Scotland in 1920, show conditions where the old are numerous and the young relatively deficient. The opposite case is illustrated by England and Wales in 1881 and Japan in 1920. An intermediate position is represented by England and Wales in 1911, Scotland in 1911, the United States in 1911 and 1920, Australia in 1911 and 1920 and Germany in 1911.

Figures such as these give the age distribution in the most summary manner possible. A more elaborate analysis of age distribution is not without its uses as Table IX., giving the age distribution of males in Great Britain and in the United States for a 40-year period shows. We may regard boys under 15 and men over 65 as constituting the dependent section of the population. They depend for their living upon the efforts of others—those between 15 and 64. In 1891 the dependent section of the male population constituted 41% in Great Britain and 39·5% in the Cnited States. In 1926 the proportions were 34% and 36·5%. Thus the working section had relatively increased. But this is not the full story. There were during these years important changes in the constitutions both of the dependent section and of the working section. The dependent section came to consist to a greater extent of old men than of children. The working section is thus to an increasing extent labouring to support the pensioners rather than the coming recruits to industry. Further, the increase in the working section is confined to those between 45 and 64. Those in the age of full vigour, *i.e.*, between 15 and 45, represent approximately the same proportion of the community as before.

Table IX. Age distribution of males: Great Britain and United States

Age last birthday	Great Britain					United States				
	Numbers	Percentage of year's total				Numbers	Percentage of year's total			
	1921	1921	1911	1901	1891	1920	1920	1910	1900	1890
0–4	1,920,000	9	11	12	13	11,573,000	10·9	11·6	12·1	12·2
5–14	4,091,000	20	21	22	24	22,039,000	20.9	20·5	22·3	23·3
15-44	9,359,000	46	47	48	45	49,986,000	47·3	48·9	47·6	47·4
45-64	3,950,000	20	16	14	14	17,030,000	16·2	14·6	13·7	13·1
65 and over	1,103,000	5	5	4	4	4,933,000	4·6	4·1	4·0	3·7
0–14	6,011,000	29	32	34	36	33,612,000	31·8	32·1	34'4	35'5
15-64	13,309,000	65	63	62	59	67,016,000	63.5	63·5	61·3	60·5

We are now led to enquire into the reasons for these changes in age distribution. It is obvious that if in any area over a long period of years the birth-rate and the death-rate remained the same and there was no migration a particular age distribution would be brought about and would remain constant. It follows that it is to changes in the birth rate, the death rate and to migration that we must look for the reasons for changes in the age distribution. Since it is the young for the most part who migrate, the effect of migration is to raise the proportion of the young in countries who receive immigrants and to lower this proportion in the countries who send them. Migration thus in part explains the differences in age distribution which now exist between Great Britain on the one hand and Australia and the United States on the other hand. A decrease in the birth-rate will tend to diminish the proportion of young and a decreasing death-rate will tend to raise the proportion of old. The birth-rate and the death-rate have both been decreasing in England and Wales for fifty years and this explains the remarkable change in the age distribution between 1881 and 1920 which the table shows. As an illustration of this it may be mentioned that the number of children under 15 years of age in 1921 was much the same as in 1891 though the total population had increased by nearly ten millions during these 30 years. It may be added that the number of scholars on the books of Public Elementary Schools in England and Wales reached its highest point in 1915 when it stood at over six millions. Since that date it has steadily declined. Japan, it may be observed, now shows approximately the age distribution of England and Wales 60 years ago. At that time England and Wales had high birth and death-rates as Japan now has.

It still remains to draw out the full significance of a peculiar age distribution such as now exists in Great Britain, though to do so involves to some extent an anticipation of the subject matter of the concluding section of the article. The significance in question is that relating to the probable trend of the population in the future. The census of 1921 disclosed a certain age distribution due to half a century of decline in both birth and death-rates. Starting with this age distribution as a basis and assuming that the annual number of births remains the same as in 1921–23, that the death-rates are the same as in 1910–12 and that there is no migration, Professor Bowley has calculated the future population of Great Britain and its age distribution, as shown in Table X.

Table X. *The Population of Great Britain*

(On the hypotheses that the annual number of births is the same as in 1921–23, that death-rates are as in 1910–12, and there is no migration)

Ages	1921	1931	1941	1951	1971	1991	2011
Thousands

Females							
0–15	5,929	5,585	5,713	5,713	5,713	5,713	5,713
15–45	10,657	11,125	10,974	10,683	10,515	10,515	10,515
45-65	4,279	5,125	5,595	5,949	5,797	5,676	5,676
65–	1,480	1,790	2,247	2,602	2,991	2,860	2,836
Total	22,345	23,625	24,529	24,947	25,016	24,764	24,740
15-65	14,936	16,250	16,569	16,632	16,312	16,191	16,191
20–45	8,643	9,182	9,138	8,847	8,679	8,679	8,679
Total M. & F.	42,766	45,381	47,282	48,277	48,859	48,696	48,704
Percentages of Total Population							
0–15 M. & F.	28	25	24½	24	23½	23½	23½
15–65 M.	31	32	32	32½	32½	32¾	32¾
15–65 F.	35	36	35	34½	33½	33¼	33¼
65–M. & F.	6	7	8½	9	10½	10½	10½

It appears that on these assumptions we may anticipate a slow increase in the population of Great Britain up to the middle of the century where it will stabilize at between 48 and 49 millions. The disproportion between the sexes will diminish. The age distribution will change in that there will be a shift from the youngest to the oldest class. It is anticipated that in 1971 those between 15 and 65 will form 66% of the total population as they did in 1921 and that those under 15 will form 23½% as against 28% and those over 65 10½% as against 6%. When the assumptions made are borne in mind and it is remembered that at the beginning of the period the population was increasing by nearly half a million annually, these results are at first sight very surprising. The explanation lies in the peculiar age distribution. It is assumed that the annual number of births remains the same. It is not assumed that the annual number of deaths remains the same. It is merely assumed that the average number of persons per 1,000 in any age group who die in a year remains constant. Now this number is higher, the older the age group. Further the older age groups will become relatively more populous. That this will be so is evident if we remember that when those now over 60 years were born the population of the country was little more than half its present size. We have with us little more than half the number of persons over 65 that is, so to speak, proper for a population of the size of the present. It follows that, though the death-rate remains the same, the number of deaths will increase and it appears that they will increase until they balance the assumed number of births. The importance of a peculiar age distribution and of the factors leading up to it is thus well brought out.

Before leaving this matter it is important to realize that Professor Bowley's calculation was made some five years ago. We now (1928) know that the annual number of births in Great Britain is not keeping constant but is decreasing year by year. There were 895,209 births in 1922 in Great Britain, 870,033 in 1923, 836,833 in 1924, 814,719 in 1925, 797,347 in 1926 and 778,337 in 1927. The decline in the annual number of births will tend to bring nearer the date at which the number of births and number of deaths will be the same and at which the population will cease to increase. On the other hand the death rate has not been declining during these five years in such a fashion as to counterbalance the effect of a diminishing number of births. It may also be stated that Professor Bowley takes no account of loss by emigration. The net loss by emigration is not inconsiderable. In 1926 it amounted to more than 100,000. Therefore we must anticipate that the population of Great Britain will cease to increase at an earlier date than that given in the above table and that it might thereafter begin to decline if the number of births continues to fall.

(4) REGISTRATION STATISTICS

It now remains to consider registration statistics. In the first place, marriage, birth and death rates demand separate attention, and, in the second place, the bearing of these rates upon the building up of the population must be reviewed.

(a) Marriage Rate. — The simplest method of measuring the amount of marriage is to record the annual number of marriages per 10,000 of the population. This rate is open to the objection excluding all those who are married. The annual number of marriages per 10,000 of the marriageable section thus defined is then calculated. This latter method is to be preferred though it is applicable only to countries with European standards and habits. It is not applicable, for instance, to India where marriages often take place at an early age. In India in 1921 there were 110,684 boys and 218,463 girls married under five years of age and 757,405 boys and 2,016,687 girls married between the ages of five and ten. Further, there were over two million boys and six million girls married between the ages of ten and fourteen.

In Table XI. there are set out the marriage rates for a number of European countries for two different periods. It appears in the first place that the countries included in the table fall roughly into two groups. There is a group of western European countries where the rate runs to about 500 and a group of eastern European countries where it approaches and sometimes exceeds 1,000. Secondly, a comparison of the rates in each country for the two periods shows that there has been no great change in the amount of marriage during the thirty to forty years which separate the periods. A closer inspection of the course of the marriage rate

TABLE XI. *Mean Annual Number of Marriages per 10,000 Marriageable Persons*

Country	Period	Proportion	Period	Proportion

shows the following: It has been demonstrated for certain countries, Great Britain for instance, that the rate fluctuates with economic conditions as represented by the state of the export trade, the amount of employment and amount cleared at the bankers' clearing house. Apart from these well-known fluctuations there has been in many European countries a decline in the marriage rate during the last fifty years. In Great Britain and Holland the decline amounts to about 10%. Unlike the decline in the birth-rate, however, to which reference is made in what follows, the decline in the marriage rate has not been general. The rate has increased in certain countries — notably in Belgium.

TABLE XII. *Mean Age at Marriage of Those Not Previously Married*

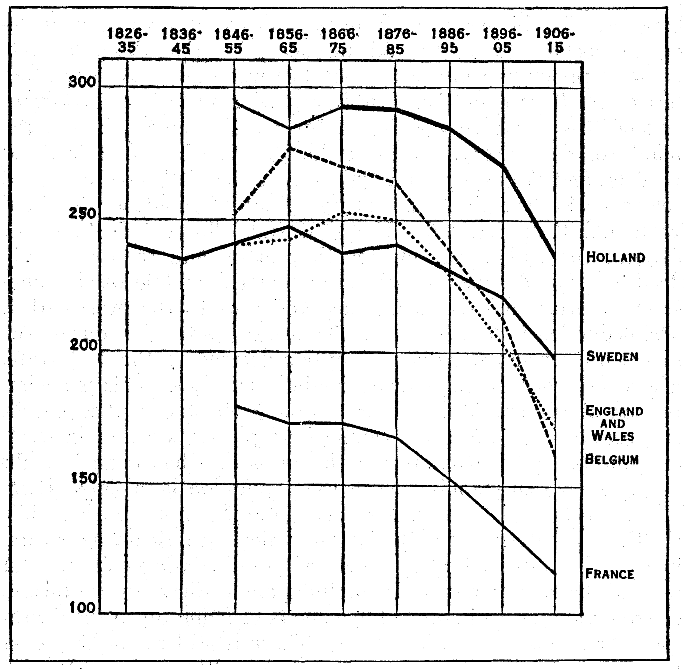
Switzerland	..	..	28·5	26·1	28·4	26·0	28·3	25·8	..	..

that in the same country at different times and in different countries at the same time the proportion which the marriageable persons form of the whole population may vary. This is so because, as we have seen, the age distribution may change. It is more satisfactory to refer the number of marriages to the number of marriageable persons in the population. The marriageable section of the population may be taken as consisting of the males 18 years of age and over and of the females 15 years of age and over

Another matter of considerable importance is the mean age at marriage. In giving figures for the mean age at marriage it is best to omit marriages of widowed and divorced persons. It is the age at marriage of bachelors and spinsters that is of importance, and the facts as to the age at marriage of these persons are obscured if other marriages are taken into account. The mean age at marriage is of course not the same as the most usual age at marriage. Thus, the mean age at marriage in England and Wales in 1920 was not far from 28 for bachelors and 26 for spinsters, whereas the most common ages at marriage in the same year were 24 for men and 21 for women.

Table XII. shows that the mean age at marriage is very similar in all countries for which figures are given. The age for men is a little over 27, while that for women varies from 23–26. Furthermore, there has been but little change in the mean age for fifty years: in France it has remained practically the same; in England and Wales there has been a tendency towards postponement; whereas in Holland the tendency has been the other way.

(b) Birth-rate and Death-rate. — The figure most usually given to represent the birth-rate is the number of births per 1,000 of the population in a year. This may be called the crude birth-rate. As a measure of the true fertility of the population it is inadequate and may be seriously misleading. The reason is the same as that which renders the crude marriage rate inadequate. Just as in order to obtain a true measurement of the amount of marriage it is necessary to refer the number of marriages to the number of marriageable persons, so in order to obtain a true measurement of fertility it is necessary to refer the number of births to the wives of child-bearing age. When this reference is made the crude birth ratio is said to be "corrected." Newsholme gives the following example of using this method of correction. In Ireland, the crude birth-rate was 24.5 in 1881 as compared with 33.9 in England and Wales, and 23·1 in 1901 as compared with 28.4. When these crude rates are corrected they become for Ireland 35·2 in 1881 and 36.1 in 1901, and for England and Wales 34.7 in 1881 and 28.4 in 1901. Thus, the true fertility in Ireland was in fact as high as that in England and Wales in 1881 and much higher in 1901. The explanation of the remarkable differences between the two countries lies in the fact that, whereas in England in 1901 the number of females aged 15 to 45 per 1,000 of the total population was 250 and in Ireland 235, the wives at ages 15 to 45 in England formed 46.8% and in Ireland only 32·5%



FROM "ECONOMICA," BY COURTESY OF SIR WILLIAM BEVERIDGE

FIG. 3.— FALL OF HUMAN FERTILITY IN EUROPE
All countries illustrated show a fall, beginning at about the same date

of the females at the same age. The crude birth-rate, however, does represent an important fact, It represents the additions by birth during the year to every 1,000 of the population. Similarly the crude death-rate represents the losses by death during the year to every 1,000 of population. In other words they represent additions to, and subtractions from, every 1,000 of the population. When the additions exceed the subtractions we may speak of "natural increase," and the problem of natural increase will occupy us later. For the present, however, we have to deal with changes in the birth and death-rates. We may consider the birth-rate first. It is well known that during the last half century the crude birth-rate of every European country has declined. In most cases the decline has been very marked. The crude birth-rate for England and Wales was 33.5 for the period 1871–75 and had declined to 18·8 in 1924. To what has this remarkable decline been due? In those countries where the amount of marriage has decreased the decline of the birth-rate is in part due to the decline in the marriage rate. But in no country has the decline in the marriage rate played a large part. Other causes overshadow it. Thus the decline in the crude birth-rate has been as marked in Belgium where the marriage rate has increased as it has been in England where the latter rate has decreased. If we consider, not the crude birth-rate, but the births per 1,000 married women age 15 to 49, we eliminate the influence of the amount of marriage and also to a certain extent of changes in age distribution. In the accompanying graph (Fig. 3, taken from a paper by Sir William Beveridge) the legitimate birth-rate per 1,000 married women aged 15 to 49 is plotted for five European countries for the last 60 years. In each of the five countries the fall has been marked.

Evidently there has been a decrease in the fertility of married women and this fact, and not the decline (if any) of the proportion which married women form of the whole population, has been the chief factor in bringing about the decrease in the crude birth-rate. It is still possible that changes in the ages of wives may have something to do with the decline. It is well known that women under 45 are not equally fertile and that the older the wife the less chance of bearing a child. Let us put this matter to the test for one of the countries which figures in the graph, namely England and Wales. We find that the number of wives under 45 years of age per 1,000 of the total population has not sensibly changed. It was 115 in 1871 and 121 in 1921. But out of 1,000 wives under 45 the proportion under 35 has decreased, being 607 in 1871 and 538 in 1921. Clearly the increasing age of wives is in part responsible for the decline in the number of children born to wives in England and Wales. How far it is so responsible can be ascertained and is shown in Table XIII.

TABLE XIII. *Indices Showing the Effect on the Birth-rate (Births per 1,000 Married Women Aged 15–45)* Not allowing *for the Ages of Mothers* Birth-rate Index age Rate= 100)

Year	Not allowing for age	Allowing for age
	166	
	162	150
1891	150	148
1901	134	125
1911	112	110
1921	100	100

From this table it is to be deduced that part of the decline, but a small part only, is due to the increasing age of wives. The greater part of the decline in England and Wales, and in other countries also, remains to be explained. This Important matter cannot be thoroughly explored here. It may be pointed out that in the opinion of many authorities the facts when closely examined are not merely concordant with an explanation based on deliberate family limitation but demand such an explanation. (See BIRTH CONTROL.) Those who look to this explanation lay stress on such facts as the following. (a) The birth-rate began to fall at the time when a widespread propaganda was begun in favour of family limitation. (b) The decline has been greatest in those classes—namely the higher social grades—most likely to be influenced by the propaganda. *(c)* The decline has been least in Roman Catholic countries where family limitation is discouraged This has been well brought out by the investigations of Sir William Beveridge who has shown that the fall has been least in those Dutch provinces where the proportion of Catholics in the population is highest. (d) Several minor details concerning the English birth-rate are strongly suggestive of such an explanation. It has been shown by the English census authorities that "the fertility of non-domestic coachmen, grooms, motor car drivers and gardeners is in all cases definitely higher than that of those following domestic employ." It is well known that the possession of a large family is a drawback to those desirous of obtaining and keeping domestic employment and it is reasonable to suppose that the lower fertility of domestic employees is due to deliberate limitation of the size of the family. Evidence of this kind can be multiplied. It is claimed that no explanation founded on a supposed lessening of reproductive power is either itself probable or can be made to fit the facts. On the other hand there are persons whose opinion cannot be disregarded, Dr. Raymond Pearl, for instance, who are not convinced that the whole explanation lies here.

The study of the death-rate contains no problems of such general interest as does that of the birth-rate. The crude death-rate is reckoned by calculating the number of deaths per 1,000 of the population in any year. The crude death-rate is important, just as the crude birth-rate is important, and we shall presently use both of them in connection with the study of increase. In order to judge of the health of any group it is necessary to bring the number of deaths into relation with the sex and age contribution of the population. When corrected it is in general found that the death-rate has markedly decreased in all civilized countries during the last century. The improvement first affected adults and later children and infants. The infantile death-rate for England and Wales dropped from 146 per 1,000 in 1900–02 to 75 per 1,000 in 1925. The reason for this improvement is not mysterious. It is obviously the result of improvement in hygiene, sanitation, medical knowledge and medical services.

(c) Natural Increase.—When the crude birth-rate exceeds the crude death-rate the difference is known as the natural increase. Natural increase is obviously a matter of great practical importance. Table XIV. shows the natural increase for various countries in recent years.

TABLE X'IV. Birth-Rates, Death-Rates and Natural Increase

	Year	Birth rate	Death rate	Natural increase
Australia . . .	1926	22·0	10·5	11·5
Austria . . .	1926	19·2	14·9	4'3
Belgium . . .	1926	18·9	12·8	6·1
Bulgaria . . .	1925	37·0	19·2	17·8
Canada . . .	1926	24·2	11·3	12·9
Ceylon . . .	1925	38.6	23·5	15·1
Chili	1926	40·1	27·2	12·9
Denmark . . .	1926	20·5	11·0	9'5
England and Wales	1926	17·8	11·6	6.2
Egypt . . .	1926	44·0	26.6	17·4
France . . .	1926	18·8	17·5	1·3
Germany . . .	1926	19·5	11·7	7·8
Greenland. . .	1925	45·2	39·7	5·5
Holland . . .	1926	23.8	9·8	14·0
Hungary . . .	1926	27·3	16·6	10·7
Italy	1926	27·2	16·8	10·4
Japan . . .	1925	34'9	20·3	14·7
New Zealand . .	1926	21·2	8·8	12·4
Norway . . .	1926	19·7	10·6	9·0
Philippines . .	1925	34·0	18·1	15·9
Rumania . . .	1925	35·2	21·0	14·2
Scotland . . .	1926	20·9	13·0	7'9
South Africa (European population) . . .	1925	26.5	9·4	17·1
Spain . . .	1926	29·7	19·1	10·6
Sweden . .	1926	16·9	11·8	5·1
Switzerland . .	1926	18·2	11·7	6·5
United States (Registration area)	1926	20·6	12·2	8·4
Uruguay . . .	1925	25·4	11·7	13·8

It will be seen that the crude birth-rates varied from 37·0 in Bulgaria to 18.2 in Switzerland during the period under review. The crude death-rates varied from 39.7 in Greenland to 8.8 in New Zealand. The highest natural increase was in Bulgaria and the lowest in France. While it so happens that Bulgaria had the highest crude birth-rate and the highest natural increase, a glance at the table will show that there is in general no correspondence between a high birth-rate and a large natural increase. Thus Greenland, with a birth-rate nearly as high as Bulgaria, had, next to France and Austria, the lowest natural increase. The table shows that countries with a high birth-rate often have a high death-rate and thus do not exhibit a large natural increase. The association of a high birth-rate with a high death-rate has been much discussed. What the precise nature of the association may be is not clear; to some extent, no doubt, a high birth-rate renders the care of children by the mother more difficult, and to this extent a high birth-rate may be said to cause a high death-rate. At the same time, however, a high death-rate tends to call forth the birth of more children to fill the vacant places, and to this extent the relation is reversed and a high death-rate is the cause of a high birth-rate. It is worthy of note that, as a comparison of Table XI. with Table XIV. shows, those countries with a high birth-rate are in general also those with a high marriage rate.

But the most interesting and important fact which emerges from Table XIV. is that the same natural increase is found in countries which have widely divergent birth and death-rates. Thus, the United States and Japan had both the same natural increase for the periods under review, but, whereas the former had relatively low birth and death-rates, the latter had high rates. The contrast is even more striking between New Zealand, with its low rates and natural increase and such a country as Ceylon, with a death-rate nearly as high as its high birth-rate and in consequence a low natural increase. Apart from the question whether increase is desirable and if so to what extent, it is clear that, if there is to be increase at all in any country, those conditions are to be preferred by which it is attained by a margin between a low birth-rate and a low death-rate rather than between a high birth-rate and a high death-rate.

In the earlier part of this article reference was made to the increase of the world population. It was pointed out that the rapid increase which took place during the last century was altogether exceptional. In other words natural increase, which in previous centuries has been non-existent or small, then became large. Apart from migration a population which is neither increasing nor decreasing can only begin to increase if either one of two things happens. The birth-rate may increase or the death-rate may decrease. There is a widespread misconception that the great outburst of population in the last century was due to an increasing birth-rate. This is not so. Our information regarding birth-rates and death-rates is very deficient for most countries before the middle of the century. So far as the facts can be ascertained for England and Wales it would appear that the birth-rate increased somewhat in the eighteenth century, remained steady up to about 1876 and then declined. The death-rate fluctuated somewhat towards the end of the eighteenth century and then markedly declined. The decline was arrested about the middle of the nineteenth century and then continued and lasts to the present day. The deduction is that the great increase of population during the nineteenth century was due mainly to a decrease in the death-rate. The same probably holds true of other countries. This is an important result and it has bearings on problems of the present and future. The death-rate cannot be rapidly decreased in western Europe and in that region the birth-rate has been brought down so low that stabilization of the population is in sight. Eastern European countries are further behind in the same path while the United States and the British Dominions are, so far as natural increase is concerned, in a somewhat intermediate position. But what of the great communities of India and China? In the former country in any case improved hygiene is bringing down the death-rate. The population is increasing. There is still room for a vast improvement in sanitary conditions and health services. If such an improvement comes about, it will in all probability cause a huge increase in the population because there is no reason to anticipate that a sensible diminution of the birth-rate will occur for a long time to come. This is a development to be feared both in the interests of these countries themselves and of the world in general. This expression of opinion requires a few words of explanation.

(d) Migration.—It does not follow that, because within a given period in a country there has been a certain excess of births over deaths, the population of the country will have increased by that amount. Migration movements have to be taken into account. A country might lose its whole natural increase through migration. What is important to know is the net movement inward or outward for any country and until recently migration statistics have been so defective that there has been little precise information on the subject. The general importance of migration can be shown by the estimate that between 1820 and 1925, 33,000,000 persons left Europe and settled in the United States. Its particular relevance in this discussion is twofold. The white races are still very unevenly distributed over the territories which are fitted for them to inhabit. There are powerful motives leading the more crowded peoples to desire to go to these half empty countries and at the same time there are motives leading those in possession of the latter territories to restrict entrance. Here is a cause of possible international friction. Again for the peoples of India and China among whom increase is to be anticipated there is little opportunity of relief by migration. Attempts by Indians and Chinese to migrate are likely to lead to resistance on the part of those powers who control the territories where Indians and Chinese are likely to want to go.

(e) Economic Problems.—The mention of possible increase led us to refer to migration; and migration was found to raise political problems of the first magnitude. The question of increase also raises economic problems. When speaking of India and China it was said that increase of population might raise internal difficulties for those countries quite apart from troubles arising from external friction. The reference was to the possibility of over-population. A country is over-populated when the number of its inhabitants exceeds the "optimum number" (*q.v.*) and it is an indispensable condition of economic welfare that the population should approximate to the optimum. But relatively simple as is the conception of the optimum, no method of testing by statistics the situation of a country with reference to the optimum is known. The position of any country can only be guessed at after a survey of the conditions. It is generally held that large tracts of India and China are over-populated now, and thus there are grounds for anticipating that any further increase would seriously embarrass them internally. Here, however, the discussion passes into economics just as it was above tending to pass into politics; and the restrictions deliberately imposed upon the scope of the article bring it to an end. (See also BIRTH-RATE, DEATH-RATE, MARRIAGE-RATE, SEX-RATIO AT BIRTH AND DEATH, ILLEGITIMACY, MIGRATION, CENSUS, RURAL DEPOPULATION and URBANIZATION. See UNITED STATES: Population and Social Conditions for population problems in the U.S.)

POPULONIA, an ancient seaport town of Etruria, Italy (Etruscan *Pupluna*), at the north end of the peninsula of Monte Massoncello, at the south end of which is situated the town of Piombino (*q.v.*). The place, almost the only Etruscan town built directly on the sea, was situated on a lofty hill now crowned by a conspicuous mediaeval castle and a poor modern village (Populonia). It commands a fine view, and Corsica is sometimes visible, though not Sardinia, as Strabo (and following him, Lord Macaulay) erroneously state. Considerable remains of its town walls, of large irregular, roughly rectangular blocks (the form is that of the natural splitting of the schistose sandstone), still exist, enclosing a circuit of about 1½ m. The remains existing within them are entirely Roman—a row of vaulted substructions, a water reservoir and a mosaic with representations of fishes. Strabo mentions the existence here of a look-out tower for the shoals of tunny-fish. There are numerous tombs outside the town, from the Villanova period (9th century B.C.) to the middle of the 3rd century B.C. Under heaps of ancient slag removed for resmelting at the present day, a considerable number of chambered inhumation tombs of the 8th–7th century B.C. have been discovered; all were originally covered by circular mounds of earth; the roof was a false dome, formed by the projection of each course of stones beyond the one below it. The remains of a temple, devastated in ancient times, were also found. The iron mines of Elba, and the tin and copper of the mainland, were owned and smelted by the people of Populonia; hot springs too lay some 6 m. to the E. (Aquae Populaniae) on the high road—Via Aurelia—along the coast. At this point a road branched off to Saena (Siena). According to Virgil the town sent a contingent to the help of Aeneas, and it furnished Scipio with iron in 205 B.C. It offered considerable resistance to Sulla, who took it by siege; and from this dates its decline, which Strabo, who describes it well, already notes as beginning, while four centuries later Rutilius describes it as in ruins. The harbour, however, continued to be of some importance, and the place was still an episcopal see under Gregory the Great.

See A. Minto, *Populonia* (Florence, 1922) for a full description.

PORBANDAR, a native state of India, in the Western India States Agency, Bombay, extending along the south-west coast of the peninsula of Kathiawar. Area, 636 sq.m.; pop. (1931) 115,673. Tribute, to the British Government, Baroda and Junagadh, £2,232. The chief is a Jethwa Rajput. Limestone is largely produced, and ghi exported. The town of PORBANDAR is the maritime terminus of the Kathiawar railway system. Pop. (1931), 33,383. A large trade is conducted with coastal ports, the Persian gulf, and the east coast of Africa. There are manufactures of silk and cotton, cement; and cotton ginning and pressing factories.

PORBEAGLE (*Lamna cornubica*), a species of shark, belonging to the Selachians (*q.v.*). The body is short and stout and contrasts strikingly with its much attenuated tail which is strengthened by a keel on each side and terminates in a powerful caudal fin. Its dentition differs from other sharks, and it is not dangerous to man. The porbeagle attains a length of 10 to 12 ft. and is a pelagic fish chiefly of warm seas but not rare in the North Atlantic and Mediterranean and frequently wandering to British and more rarely to North American shores as far as Cape Cod. See SHARK.

PORCELAIN: *see* POTTERY AND PORCELAIN.

PORCELAIN ENAMELLING. A porcelain enamel is a ceramic enamel. It is a thin layer of glass fused to a metal to enhance its beauty, to prevent corrosion, or both. Porcelain enamelled iron is used extensively for both domestic and industrial articles. In addition to its use for kitchen ware, bathtubs and sinks, it is used extensively for table tops, refrigerators, washing machine tubs, and stoves. Industrially it is used for advertising signs, chemical and food tanks of large sizes, for hospital furniture, meat market, grocery, and restaurant equipment, and has found extensive application in architecture for the facing of the outsides of buildings.

A porcelain enamel, being a glass, has the properties of glass; namely, its hard glossy surface and resistance to solution, corrosion, and scratching. The metal backing and design greatly influence its strength and resistance to damage.

The quality of porcelain enamels varies greatly, depending upon the glass used, the design, and the manufacturing technique. (See also ENAMEL; GLASS.)

History.—Although the term "porcelain enamel" did not come into common use until about 1929, porcelain enamelling, vitreous enamelling, or enamelling, as it was sometimes called, actually dates back to a very early period in history. No date can be set concerning the beginning, but the first enamelling was in the form of glass beads fused to copper, gold, and silver decorative ware. This type of ware was classed as jewellery and highly prized.

Later, a type of ware called Cloisonné was gradually developed. Cloisonné was made by first outlining areas on a gold surface by soldering tiny gold wires in place. A finely milled paste made from powdered glass and water was spread into the area between these wires. This was dried and then the ware was placed in a furnace at a temperature sufficient to melt the glass to a smooth layer. Several applications were generally made to give sufficient thickness, and various colours were used in the different areas, thus producing elaborate designs. After the final application of the enamel, the ware was polished off smooth with an abrasive so that the gold wires appeared as uniform boundaries between the different areas of enamel.

Champlevé was made by a modification of this process in which the metal was gouged out, leaving ridges between the areas to be enamelled.

Another interesting early development was that of miniature painting in which the powdered glass suspended in water was used by artists for painting small pictures.

Manufacture. — Although these early developments took many years, the transition from an art to an industry in the early part of the 19th century proceeded very rapidly. Cast iron dry process enamels were the first to be used on a large scale. In this process, the castings, such as bathtubs, were first sand blasted to give them a clean surface. The grip or ground coat was then applied. This ground coat consisted of a powdered glass, clay, water suspension with a consistency about like that of cream. This was dipped, slushed, or sprayed on the cool casting and allowed to dry. The ware was then introduced into a furnace at about 900° C. and allowed to come to the temperature of the furnace. The hot ware was withdrawn from the furnace and powdered glass dusted through a screen over it. This powdered glass melted as it fell on the hot ware and formed a continuous layer of enamel.

Several applications were generally applied, returning the ware to the furnace for reheating before each application. This process is particularly applicable to the manufacture of heavy castings.

Another process which has come into common use is that of wet process cast iron enamelling. This is used on light weight or thin castings and has been adopted extensively in the stove industry. In this process, the ground coat is generally applied, as a suspension of the glass with clay in water, dried, and then fired in a furnace at about 750° C. The ware is removed from the furnace, cooled, the second coat applied, and then refired.

This process is sometimes known as the American process for enamelling cast iron.

Sheet steel enamelling has become the most extensive process used for porcelain enamels. In this process, the sheet steel is fabricated and put through a cleaning and pickling process which prepares the surface for enamelling. Sheet steel enamelling requires a ground coat containing a small percentage of cobalt to give it adherence. This ground coat is applied by the wet process, dried, and then fired in a furnace at about 830° C. After the ware has been removed from the furnace and cooled, a second coat of cover enamel is applied by the wet process. This cover coat may be of any desired colour and may have very special properties depending upon the use to which the ware is to be put. It is commonly sprayed or dipped onto the ware, allowed to dry, and then fired at about 830° C. Additional coats of enamel are sometimes applied, and finally the decoration is applied and fired into the last coat.

Although enamelling is an important industry in most countries, the use of automatic equipment, technical control, and mass production is outstanding in the United States.

PORCH, originally a roofed structure, usually open at the sides, to protect the entrance of a building; loosely used of any projecting portico, or even of any colonnade, and, in America, of any roofed structure open at the sides and front, attached to a house or other building; synonymous with veranda or piazza. Thus a sleeping porch is such a structure usually opening from an upper storey, arranged for sleeping in the open air.

Of the porch proper there are few extant remains prior to the classic period, although Egyptian wall paintings seem to indicate their occasional use with houses. The most important Greek porches are those of the Tower of the Winds at Athens (1st century B.C.), in which two columns of a simple Corinthian order carried a pediment. A similar porch exists in the so-called villa of Diomed at Pompeii. Houses in Rome sometimes had long colonnades facing the street which served as porches. During the Romanesque period simple projecting porches covering the western doors of churches gradually replaced the earlier basilican colonnaded narthices. Especially interesting are the projecting porches of the Italian Romanesque, such as are found in Zeno Maggiore at Verona (12th century), in which the columns are carried on marble lions (as frequently in Lombard work) and at Modena (12th century) and Parma (13th century). In Apulia there are many similar porches of distinct Lombard character.

In France, especially in Burgundy, an even greater development of the porch occurred, in which it became a vaulted structure of great height and importance, two or more bays long, and sometimes as wide as the entire church. The great porch of the abbey church at Vezelay (1132–40), sometimes termed an ante-church, is the largest and most rich. In Norman work in England church porches are more frequently at the sides of the nave than at the west end. An interesting example is that at Southwell minster (early 12th century).

The English love of picturesqueness sometimes developed the porch to such an extent that it became almost a separate building which was called a "galilee," like that at Durham (1175). Galilees in mediaeval churches are supposed to have been used sometimes as a court of law, or a place where corpses were placed before interment, but the galilee probably served chiefly as a chapel for penitents before their admission to the body of the church. Many fantastically rich projecting porches occur in French flamboyant churches, such as that of the church of Notre Dame at Alençon (c. 1500); the pentagonal porch of S. Maclou at Rouen (c. 1520) and the little side entrance of the cathedral at Albi (early 16th century).

The same richness of porch design is not found in English Gothic churches, where western doors are often small and unimportant; an exception, all the more remarkable for its unique character, is the west front of Peterborough cathedral (*c.* 1220), in which the doors are deeply recessed within great arches, 81 ft. high, forming a most impressive porch. The other type of porch, the small projecting gabled feature projecting from the north or south walls of the nave, was, however, highly developed throughout the course of English Gothic. In small examples, in parish churches, the porches are usually of wood, with a richly decorated bargeboard, running up the gable, and often panels of intricate tracery at the sides. In the larger city churches there was frequently a room over the porch, sometimes known as a porch chamber, and sometimes incorrectly termed a parvis (*q.v.*). These seem to have been used sometimes as vestries, sometimes as treasuries and sometimes as chantry chapels. Similar porches, with chambers above, occur occasionally in Tudor mansions, as in the house of Compton Winyates (c. 1520).

In Germany churches of the Flamboyant Gothic period are frequently decorated with western porches of the most fantastic richness, with a great use of cusping, pierced tracery and canopy work. Such is the double arched entrance of the cathedral at Ulm (*c.* 1390), by von Ensingen, and the triangular porch of the cathedral at Regensburg, by M. Roritzer (1482–86).

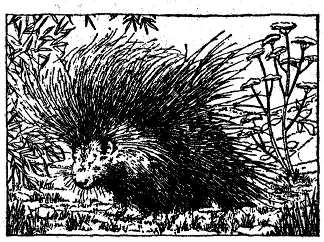
During the Renaissance the porch was usually treated as a portico (*q.v.*), but simple porches of two or four columns were exceedingly common features of the late 18th century houses of England and America. (T. F. H.)

PORCHER, FRANCIS PEYRE (1825–1895), American physician and botanist, was born in St. John's, S.C., on Dec. 14, 1825, and was graduated with a bachelor's degree from South Carolina college in 1844. He took his medical degree three years later from the Medical College of the State of South Carolina and studied in France and Italy for two years thereafter. In 1849 he began practice in Charleston, S.C., and in that year also he published *Sketch of the Medical Botany of South Carolina.* In Charleston he was one of the founders of the city's preparatory medical school and was surgeon at the marine and municipal hospitals; he was also professor at the Medical College of the State of South Carolina. In 1855 he organized a hospital for Negroes.

Dr. Porcher served the Confederacy throughout the Civil War, as surgeon to the Holcombe legion, to the Naval hospital at Ft. Nelson, Norfolk harbour, and to the South Carolina hospital at Petersburg, Virginia. In 1863 he published his monumental *Resources of the Southern Fields and Forests,* which was intended as an inventory of the Confederate States' botanical resources for war, and which became an authoritative reference work. It was revised in 1869.

Among the offices held by Dr. Porcher were the presidency of the South Carolina Medical Association and the vice-presidency of the American Medical Association. He was also one of the editors of The Charleston Medical *Journal* and Review for several years. He died Nov. 19, 1895.

PORCUPINE, the name of the largest European terrestrial rodent, distinguished by the spiny covering from which it takes its name. The European porcupine (*Hystrix cristata*) is the typical representative of a family of Old World rodents, the *Hystricidae*, all the members of which have the same protective covering. They range over the south of Europe, the whole of Africa, India and the Malay Archipelago as far east as Borneo. They are all stout, heavily-built animals, with blunt rounded heads, fleshy mobile snouts, and coats of thick cylindrical or flattened spines, which form the whole covering of their body, and are not intermingled with ordinary hairs. Their habits are strictly terrestrial. The common porcupine, which occurs throughout the south of Europe and North and West Africa, is replaced in South Africa by H. *africaeaustralis* and in India by the hairy-nosed porcupine (Acanthion *leucura*).



BY COURTESY OF THE LONDON ZOOLOGICAL SOCIETY
CRESTED PORCUPINE (HYSTRIX CRISTATA)

There are several smaller species with long tails in north-east India, the Malay region and Africa. In the New World the porcupines are represented by the family *Erethizontidae*. The spines are mixed with long soft hairs. They are less nocturnal in their habits; and with one exception live entirely in trees, having in correspondence with this long prehensile tails. They include three genera, of which the first is represented by the Canadian porcupine (*Erethizon* dorsatum), a stout, heavily-built animal, with long hairs almost or quite hiding its spines, four front- and five hind-toes, and a short, stumpy tail. It is a native of the greater part of Canada and the United States, wherever there is any remnant of the original forest left. *Synetheres* contains some eight or ten species, known as tree-porcupines, found throughout tropical South America, with one extending into Mexico. They are of a lighter build than the ground-porcupines, with short, close spines, often mixed with hairs, and prehensile tails. The hind-feet have only four toes, owing to the suppression of the first.

PORDENONE, IL (1483–1539), Italian painter of the Venetian school. He was born at Corticelli, near Pordenone, in Friuli. His real name was Giovanni Antonio de Sacchi. Vasari's statement that his family name was Licinio has been disproved. In 1535 King John of Hungary knighted him, and thenceforth he called himself Regillo. Il Pordenone was a pupil of Pellegrino di S. Daniele, of the Friulian school of painting, but the leading influence which formed his style was that of Giorgione, and in his early works, such as his fine altarpiece at Susegana and the frescoes in the Palace chapel of S. Salvatore, this influence is very apparent. His later work displays the influence of Correggio and Michelangelo. He executed many works at Pordenone, Spilimbergo, and elsewhere in Friuli. He worked in Treviso, Mantua, Genoa and Cremona. He was asked to execute large mural designs in Venetian palaces, and was so popular in Venice that he seems to have fancied himself the equal of Titian. On one occasion the senate gave him a commission in preference to the great master of Cadore. Unfortunately, his fresco work in Venice has perished. In 1529 he worked in Piacenza, where is one of his most celebrated pictures "St. Catherine disputing with the Doctors of Alexandria." By Hercules II. of Ferrara he was commissioned to execute a series of designs for tapestry illustrating the Odyssey. These were described in detail by Ridolfi but are no longer extant. That duke invited him to Ferrara, in 1538, to execute some work in perspective, but Pordenone died there soon after his arrival and was buried on Jan. 14, 1539. Of his pictures in the Venetian academy "The Glory of S. Lorenzo Giustiniani" is the most notable.

See C. Ridolfi, Le *Meraviglie dell' Arte* (edit. v. Hadeln, 1914–24).

PORDENONE, a town of the province of Udine, Venetia, Italy, 30 m. W. by S. of Udine on the railway to Treviso. Pop. (1936) 12,179 (town); 22,174 (commune). It was the birthplace of the painter generally known as Il Pordenone (*q.v.*). Paintings from his brush adorn the cathedral (which has a fine brick campanile), and others are preserved in the Gothic town hall. Cotton industries are active, also silk and pottery.

PORFIRIUS, PUBLILIUS OPTATIANUS, Latin poet, possibly a native of Africa, flourished during the 4th century A.D. He has been identified with Publilius Optatianus, who was *praefectus urbi* (329 and 333), and may have been a Christian. For some reason he had been banished, but having addressed a panegyric to the Emperor Constantine the Great, he was allowed to return. Twenty-eight poems are extant under his name, of which 20 were included in the panegyric. They have no value except as curiosities and specimens of perverted ingenuity. Some of them are squares, others represent in their shape a syrinx, an organ or an altar; while the 28th poem (the versus anacyclici) may be read backwards without any effect upon sense or metre. The best edition of the poem is by L. Müller (1877).

See O. Seeck, "Das Leben des Dichters Porphyrius," *Rhein. Mus.* (1908).

PORI, formerly Björneborg, a seaport of Finland in 61° 29' N., 21° 43' E., on the Kumo river, 18 m. from its harbours, Reposaari and Mantyluoto. Pop. (est. 1939) 21,201. It imports coal, coke and flour, and exports timber and timber products. The river is 9 ft. deep. The town has ship-repairing yards, but vessels larger than 300 or 400 tons have to be careened. Reposaari, the "town harbour," used only for local traffic, is usually icebound from December to March, Mantyluoto is the new harbour, equipped with cranes, railroad tracks, and quays for five large steamers, being ice-free until January.

PORIFERA, a phylum and class of the animal kingdom comprising the sponges (*q.v.*).

PORISM. *Porisms* is the title of a lost treatise by Euclid, the author of the Elements, for our knowledge of which we are indebted to the Collection of Pappus of Alexandria, who mentions it and gives a number of lemmas necessary for understanding it. Pappus states that the porisms of Euclid are neither theorems nor problems, but are in some sort intermediate; and they were regarded accordingly by many geometers, who looked merely at the form of the enunciation, as being actually theorems or problems, though the definitions given by the older writers showed that they better understood the distinction between the three classes of propositions. They regarded a theorem as directed to *proving* what is proposed, a problem as directed to constructing what is proposed and finally a porism as directed to finding what is proposed (εἰς πορισμὸν αὐτοῦ τοῦ προτεινομένου). Pappus goes on to say that this last definition was changed by certain later geometers, who defined a porism on the ground of an accidental characteristic as τὸ λεῖπον ὑποθέσει τοπικοῦ θεωρήματος, that which falls short of a locus-theorem by a (or in its) hypothesis.

Proclus points out that the word was used in two senses. One sense is that of corollary, a result unsought, but seen to follow from a theorem. On the *porism* in the other sense he adds nothing to the definition of the older geometers except to say that the finding of the centre of a circle and the finding of the greatest common measure are porisms (Proclus, ed. Friedlein, p. 301).

Pappus gives a complete enunciation of a porism derived from Euclid, and an extension of it to a more general case. This porism, expressed in modern language, asserts that—given four straight lines of which three turn about the points in which they meet the fourth, if two of the points of intersection of the three lines lie each on a fixed straight line, the remaining point of intersection will also lie on another straight line. The general enunciation applies to any number of straight lines, say $(n+1)$, of which n can turn about as many points fixed on the $(n+1)$th. These n straight lines cut, two and two, in $\frac{1}{2}n(n-1)$ points, $\frac{1}{2}n(n-1)$ being a triangular number whose side is $(n-1)$. If, then, they are made to turn about the n fixed points so that any $(n-1)$ of their $\frac{1}{2}n(n-1)$

points of intersection, chosen subject to a certain limitation, lie on (n—1) given fixed straight lines, then each of the remaining points of intersection, $\frac{1}{2}$ (n—1) (n—2) in number, describes a straight line. Pappus gives also a complete enunciation of one porism of the first book of Euclid's treatise. This may be expressed thus: If about two fixed points P, Q we make turn two straight lines meeting on a given straight line L, and if one of them cut off a segment AM from a fixed straight line AX, given in position, we can determine another fixed straight line BY, and a point B fixed on it, such that the segment BM' made by the second moving line on this second fixed line measured from B has a given ratio λ to the first segment AM. The rest of the enunciations given by Pappus are incomplete, and he merely says that he gives thirty-eight lemmas for the three books of porisms; and that these include 171 theorems.

The lemmas which Pappus gives in connection with the porisms are interesting historically, because he gives (1) the fundamental theorem that the cross or anharmonic ratio of a pencil of four straight lines meeting in a point is constant for all transversals; (2) the proof of the harmonic properties of a complete quadrilateral; (3) the theorem that, if the six vertices of a hexagon lie three and three on two straight lines, the three points of concourse of opposite sides lie on a straight line.

During the last three centuries many geometers have attempted to restore the lost porisms. The geometer P. de Fermat (1601–65) wrote a short work under the title *Porismatum euclidaeorum* renovata doctrina et sub *forma* isagoges recentioribus geometris exhibita (see Oeuvres de Fermat, i., 1891); but two at least of the five examples of porisms which he gives do not fall within the classes indicated by Pappus. Robert Simson was the first to throw real light upon the subject. He first succeeded in explaining the only three propositions which Pappus indicates with any completeness (Phil. Trans., 1723). Later he investigated the subject of porisms generally in a work entitled De *porismatibus tractatus;* quo doctrinam *porismatum satis* explicatam, et in *posterum* ab *oblivione* tutam fore *sperat auctor*, and published after his death in a volume, *Roberti Simson opera quaedam reliqua* (Glasgow, 1776). Simson's treatise, De *porismatibus,* begins with definitions of theorem, problem, datum, porism and locus.

Respecting the porism Simson says that Pappus's definition is too general, and therefore he will substitute for it the following: "Porisma est propositio in qua proponitur demonstrare rem aliquam vel plures datas esse, cui vel quibus, ut et cuilibet ex rebus innumeris non quidem datis, sed quae ad ea quae data sunt eandem habent relationem, convenire ostendendum est affectionem quandam communem in propositione descriptam. Porisma etiam in forma problematis enuntiari potest, si nimirum ea quae data demonstranda sunt, invenienda proponantur." A locus (says Simson) is a species of porism. Then follows a Latin translation of Pappus's note on the porisms, and the propositions which form the bulk of the treatise. These are Pappus's thirty-eight lemmas relating to the porisms, ten cases of the proposition concerning four straight lines, twenty-nine porisms, two problems in illustration and some preliminary lemmas.

John Playfair's memoir (*Trans. Roy. Soc. Edin.,* 1794), a sort of sequel to Simson's treatise, had for its special object the inquiry into the probable origin of porisms. Playfair remarked that the careful investigation of all possible particular cases of a proposition would show that (1) under certain conditions a problem becomes impossible, (2) under certain other conditions, indeterminate or capable of an infinite number of solutions. These cases could be enunciated separately, were in a manner intermediate between theorems and problems and were called "porisms." Playfair accordingly defined a porism thus: "A proposition affirming the possibility of finding such conditions as will render a certain problem indeterminate or capable of innumerable solutions." Though this definition of a porism appears to be most favoured in England, Simson's view has been most generally accepted abroad, and has the support of the great authority of Michel Chasles.

In *Liouville's* Journal *de mathématiques pures* et *appliquées* (1855), P. Breton published Recherches nouvelles sur les porismes *d'Euclide,* in which he gave a new translation of the text of Pappus, and sought to base thereon a view of the nature of a porism more closely conforming to the definitions in Pappus. This was followed in the same journal and in La Science by a controversy between Breton and A. J. H. Vincent, who disputed the interpretation given by the former of the text of Pappus, and declared himself in favour of the idea of F. van Schooten, put forward in his *Mathematicae exercitationes* (1657), in which he gives the name of "porism" to one section. According to Schooten, if the various relations between straight lines in a figure are written down in the form of equations or proportions, then the combination of these equations in all possible ways, and of new equations thus derived from them, leads to the discovery of innumerable new properties of the figure, and here we have porisms. These discussions, however, did not carry forward the work of restoring Euclid's Porisms, which was left ior Chasles. His work (Les Trois *livres* de porismes *d'Euclide,* 1860) makes full use of all the material found in Pappus, but we may doubt its being a successful reproduction of Euclid's actual work. An interesting hypothesis as to the Porisms was put forward by H. G. Zeuthen (Die Lehre von den Kegelschnitten im Alterturn, 18863. Observing, *e.g.,* that the intercept-Porism is still true if the two fixed points are points on a conic, and the straight lines drawn through them intersect on the conic instead of on a fixed straight line, Zeuthen conjectures that the Porisms were a by-product of a fully developed projective geometry of conics. It is a fact that Pappus's Lemma 31 (though it makes no mention of a conic) corresponds exactly to Apollonius's method of determining the foci of a central conic (Conics, iii. 45–47 with 42).

The three porisms stated by Diophantus in his *Arithmetica* are propositions in the theory of numbers which can all be enunciated in the form "we can find numbers satisfying such and such conditions"; they are sufficiently analogous therefore to the geometrical porism as defined in Pappus and Proclus.

(T. L. H.)

PORK is the flesh of swine, fresh or salted, used for food. Although a large proportion of pig-meat is consumed in the form of bacon or ham, a greater proportion is consumed in an uncured state, as pork (*see* BACON).

POROS or PORO ("the Ford"), Greece, an island off the east coast of the Morea, separated at its western end by a narrow channel from the mainland at Troezen, and consisting of masses of limestone and trachyte connected by a sandy isthmus. The harbour town faces S. toward the mainland. The English, French, and Russian plenipotentiaries met at Poros in 1828 to discuss the basis of the Greek government.

The ancient Calauria, with which Poros is identified, was traditionally given by Apollo to Poseidon in exchange for Delos; and in historic times was famous for a temple of the latter, the centre of an amphictyony of maritime states—Hermione, Epidaurus, Aegina, Athens, Prasiae, Nauplia, and Orchomenus, the distribution and legends of which suggest that their association goes back to Minoan times. Here Demosthenes took sanctuary with "gracious Poseidon," and, when this threatened to fail him, sought death. The temple of Doric architecture, excavated in 1894, lay on a ridge commanding a view of Athens and the Saronic Gulf. Traces also of porticoes and other buildings remain.

PORPHYRIO, POMPONIUS, Latin grammarian and commentator on Horace, possibly a native of Africa, flourished during the 2nd century A.D. (according to others, much later). His scholia on Horace, which are still extant, mainly consist of rhetorical and grammatical explanations. It is probable that the *scholia* have been much altered by copyists.

See edition of the *Scholia* by A. Holder (1894). *See* also C. F. Urba, *Meletemata porphyrionea* (1885); E. Schweikert, *De Porphyrionis . . . scholiis Horatianis* (1865); F. Pauly, *Quaestiones criticae* de . . . *Porphyrionis commentariis Horatianis* (1858).

PORPHYRY (Πορφύριος) (A.D. 233–*c.* 304), Greek scholar, historian, and Neoplatonist, was born at Tyre, or Batanaea in Syria. He studied grammar and rhetoric under Cassius Longinus (*q.v.*). His original name was Malchus (king), which was changed by his tutor into Porphyrius (clad in purple), a jesting allusion to the colour of the imperial robes. In 262 he went to Rome, attracted by the reputation of Plotinus, and for six years devoted himself to the study of Neoplatonism. Having injured his health by overwork, he went to live in Sicily for five years. On his return to Rome, he lectured on philosophy and endeavoured to render the doctrines of Plotinus intelligible to the ordinary understanding. His most distinguished pupil was Iamblichus. When advanced in years he married Marcella, a widow with seven children and an enthusiastic student of philosophy. Nothing more is known of his life, and the date of his death is uncertain.

Of his numerous works on a great variety of subjects the following are extant: *Life of Plotinus* and an exposition of his teaching in the Ἀφορμαὶ πρὸς τὰ νοητά (*Sententiae ad intelligibilia ducentes,* Aids to the study of the Intelligibles). The *Life of Pythagoras,* which is incomplete, probably formed part of a larger history of philosophy down to Plato. His work on Aristotle is represented by the *Introduction* (εἰσαγωγή) to and *Commentary* (ἐξήγησις, in the form of questions and answers) on the *Categories.* The first, translated into Latin by Boetius, was extensively used in the middle ages as a compendium of Aristotelian logic; of the second only fragments have been preserved. His Χρονικά, a chronological work, extended from the taking of Troy down to A.D. 270. Other grammatical and literary works are Ὁμηρικὰ ζητήματα (*Quaestiones homericae*); and *De antro nympharum,* in which the description in the *Odyssey* (xiii. 102–112) is explained as an allegory of the universe. The Περὶ ἀποχῆς ἐμψύχων (*De abstinentia*), on abstinence from animal food, is especially valuable as having preserved numerous original statements of the old philosophers and the essence of Theophrastus' Περὶ εὐσεβείας (*On Piety*). It also contains a long fragment from the *Cretans* of Euripides. The Πρὸς Μαρκέλλαν is an exhortation to his wife Marcella to practise virtue and self-restraint and to study philosophy. The letter to the Egyptian priest Anebo, dealing with religious questions, was answered by a member of the school of Iamblichus, who called himself Abammon, in the *De mysteriis.* It is frequently referred to by Eusebius, Cyril and Augustine. Eusebius preserved fragments of the Περὶ τῆς ἐκ λογίων φιλοσοφίας (*De philosophia ex oraculis haurienda*), in which he expressed his belief in the responses of the oracles of various gods as confirming his theosophical views. Porphyry is well known as a violent opponent of Christianity and defender of Paganism; of his Κατὰ Χριστιανῶν (*Adversus Christianos*) in 15 books, perhaps the most important of all his works, only fragments remain. Porphyry's view of the book of Dsniel, that it was the work of a writer in the time of Antiochus Epiphanes, is given by Jerome. There is no proof of the assertion of Socrates, the ecclesiastical historian, and Augustine, that Porphyry was once a Christian.

BIBLIOGRAPHY.—There is no complete edition of the works of Porphyry. Separate editions: *Vita Plotini* in the *Enneades* of Plotinus (edit. R. Volkmann, 1883); *Sententiae* (edit. B. Mommert, Leipzig, 1907); *Vita Pythagorae, De antro nympharum, De abstinentia, Ad. Marcellam* (edit. A. Nauck, Leipzig, 1885); *Isagoge et in Aristotelis categorias commentarium* in *Commentaria in Aristotelem graeca* (edit. A. Busse, 188;); *Boethii in Isagogen Commenta* (edit. S. Brandt, Vienna, 1906); fragments of the *Chronica* in *Fragmenta historicorum graecorum* (edit. C. W. Müller, 1849); *Quaestiones homericae* (edit. H. Schrader, 1880, 1890); *Letter to Anebo* in Iamblichus, *De mysteriis* (edit. W. Pharthey, 1857); *De philosophia ex oraculis Haurienda* (edit. E. Wolff, 1856); fragments of the *Adversus Christianos* (edit. A. Georgiades, Leipzig, 1891); English trans., Thomas Taylor, *De abstinentia, De antro nympharum* and *Sententiae* (1823), *De antro nympharum* (new ed. 1917); T. Davidson, *Sententiae,* in *Journal of Speculative Philosophy* (vol. iii., 1869); S. Hibberd, *De abstinentia* (1857), and A. Zimmern, *Ad. Marcellam* (1896).

Smith, *Dict. of Greek and Roman Biography* (1849), and for philosophy, T. Whittaker, *The Neo-Platonists* (2nd ed., 1918) and NEO-PLATONISM.

PORPHYRY, in petrology, a beautiful red volcanic rock (Gr. πορφύρεος, Lat. *purpureus,* purple), which was much used by the Romans for ornamental purposes when cut and polished. The famous red porphyry (*porfido rosso antico*) came from Egypt, but its beauty and decorative value were first recognized by the Romans in the time of the emperor Claudius. It was obtained on the W. coast of the Red Sea, where it forms a dike 80 or go ft. thick. For a long time the knowledge of its source was lost, but the original locality has been re-discovered at Jebel Dhokan, and the stone is again an article of commerce. In a dark red ground-mass it contains many small white or rose-red plagioclase felspars, black shining prisms of hornblende, and small plates of iron oxide. The red of the felspars and of the ground-mass is unusuaf in rocks of this group, and arises from the partial conversion of the plagioclase felspar into thulite and manganese-epidote. These minerals also occur in thin veins crossing the rock. Many specimens show effects of crushing and in extreme cases this has produced brecciation.

Many igneous rocks possess the scattered crystals of larger size in a fine-grained ground-mass which characterize the porphyries (*see* PETROLOGY), and most lavas and many of the rocks which occur as dikes and sills have porphyritic structure. The use of the term porphyry is now restricted to a series of rocks which are of intrusive origin and contain much porphyritic felspar (with or without quartz or nepheline). The porphyritic intrusive rocks with large crystals of augite, olivine, biotite and hornblende are for the most part grouped under the lamprophyres. Furthermore, it has become usual to subdivide the porphyries into two classes; in one of these the phenocrysts are mainly orthoclase, in the other mainly plagioclase felspar. The first series is known as the "porphyries," the second as the "porphyrites." There are porphyries which correspond chemically and mineralogically to granites, syenites and nepheline-syenites; while the porphyrites form a series parallel to the diorites, norites and gabbros. In each case the porphyritic type occurs generally as dikes and thin sheets which consolidated beneath the surface but probably at no great depth (hypabyssal rocks).

The principal subdivisions of the group are the granite-porphyries, the syenite-porphyries and the elaeolite-porphyries. In all of them porphyritic orthoclase or alkali felspar is the characteristic mineral. The granite-porphyries and quartz-porphyries consist mainly of orthoclase, quartz and ferro-magnesian mineral, usually biotite but sometimes hornblende, augite or enstatite. Granite-porphyries are exceedingly common in all regions where acid intrusive rocks occur. Many granite masses are surrounded by dikes of this kind, and in some cases the chilled margin of a granite consists of typical porphyry.

The syenite-porphyries, like the syenites, are less common than the granite-porphyries and granites. They are characterized by an abundance of orthoclase and a scarcity or absence of quartz. The phenocrysts are orthoclase (and oligoclase), biotite, hornblende or augite; the ground-mass is principally alkali felspar with sometimes a little quartz. In many specimens the felspars of the second generation form a mosaic of ill-shaped grains, in others they are little rectangular crystals which may have a fluxion arrangement (orthophyric type of ground-mass). Some of the rocks formerly known as orthoclase-porphyries belong to this group; others are ancient trachytic lavas (orthophyres). Closely related to the syenite-porphyries is the rhomb-porphyry of south Norway and West Africa. In these the large felspars have rhomb-shaped sections owing to their peculiar crystalline development. Olivine, augite and biotite occur in these rocks, but there is no quartz or soda-lime felspar. The porphyritic felspars contain both soda and potash and belong to anorthoclase. Rhomb-porphyries occur as dikes connected with the syenites (laurvikites of southern Norway), and many ice-borne boulders of these rocks have been found among the drift deposits of the east of England.

Elaeolite- and leucite- (syenite) porphyries form apophyses and dikes around nepheline- and leucite-syenite intrusions. The former contain porphyritic nepheline which is often weathered to soft, finely crystalline aggregates of white mica and other secondary products, as in the well-known liebenerite-porphyry of Tirol and gieseckite-porphyry of Greenland. The felspars of these rocks are albite, orthoclase and anorthoclase and they often contain soda-augite and amphiboles. Elaeolite-porphyries occur along with nepheline-syenites in such districts as the Serra de Monchique, south Norway, Kola, Montreal. Allied to them are the tinguaites (so called from the Serra de Tingua, Brazil), which are pale green rocks with abundant alkali felspar, nepheline, needles of green aegirine, and sometimes biotite and cancrinite. As a rule, however, these are not porphyritic. Grorudites are quartz-tinguaites free from nepheline, and solvsbergites are tinguaitic rocks in which neither quartz nor nepheline occur. The two last have been described from the Oslo district in Norway, but tinguaites are known with nepheline-syenites. in many parts of the world, *e.g.,* Norway, Brazil, Portugal, Canada, Sweden, Greenland.

The following analyses of porphyries of different types show the chemical composition of a few selected examples:—

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	K_2O	Na_2O	H_2O
I.	72·51	13·31	tr.	3·87	1·50	0·60	6·65	0·43	0·60
II.	67·18	16·65	0·55	2·15	1·54	2·35	2·91	4·03	0·75

IV., Rhomb-porphyry—Tönsberg, Norway. V., Elaeolite-porphyry—Beemerville, New Jersey. VI., Tinguaite—Kola. VII., Grorudite—Assynt, Scotland.

Porphyrites.—The porphyrites as above mentioned are intrusive or hypabyssal rocks of porphyritic texture, with phenocrysts of plagioclase felspar and hornblende, biotite or augite (sometimes also quartz) in a fine ground-mass. The name has not always been used in this sense, but formerly signified rather decomposed andesitic and basaltic lavas of Carboniferous age and older. Both the red and green porphyry of the ancients are more properly classified in this group than with the granite-porphyries, as their dominant felspar is plagioclase and they contain little or no primary quartz. Porphyrites occur as dikes which accompany masses of diorite, and are often called diorite-porphyrites; they differ from diorites in few respects except their porphyritic structure. The phenocrysts are plagioclase, often much zoned, with central kernels of bytownite or labradorite and margins of oligoclase or even orthoclase. In a special group there are corroded blebs of porphyritic quartz: these are called quartz-porphyrites, and are distinguished from the granite-porphyries by the scarcity or absence of orthoclase. The hornblende of the porphyrites is often green but sometimes brown, resembling that of the lamprophyres, a group from which the porphyrites are separated by their containing phenocrysts of felspar, which do not occur in normal lamprophyres. Augite, when present, is nearly always pale green; it is not so abundant as hornblende. Dark brown biotite is very common in large hexagonal plates. The ground-mass is usually a crystalline aggregate of granular felspar in which plagioclase dominates, though orthoclase is rarely absent. Diorite-porphyrites have almost as wide a distribution as granite-porphyries, and occur in all parts of the world where intrusions of granite and diorite have been injected; they are in fact among the commonest hypabyssal rocks.

To gabbros and norites certain types of porphyrite correspond which have the same mineral and chemical composition as the parent rocks but with a porphyritic instead of granitic structure. Norite-porphyrites have porphyritic plagioclase (labradorite usually) with hypersthene or bronzite, often altered to bastite. They accompany norite masses in Nahe (Prussia) and Tirol.

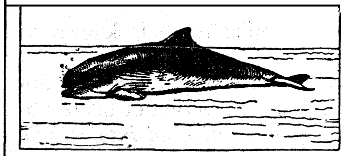
(J. S. F.)

PORPOISE, the name often applied to all the smaller cetaceans, but properly restricted to the genus *Phocaena.* The porpoise attains a length of $5\frac{1}{2}$ft. The head is rounded in front, lacking the characteristic beak of the dolphins, and the under-jaw projects slightly. The wide mouth is bounded by stiff, immobile lips. The low dorsal fin is triangular. In colour the porpoise is black or dark grey above and white below, with black flippers. The shape of the porpoise's teeth is characteristic. The porpoise prefers bays, estuaries and coasts to the open sea and inhabits the North Atlantic, entering the Baltic in summer; but it is rare in the Mediterranean. It feeds on salmon, mackerel, pilchards and herrings. In former days it was a common article of food. The "porpoise-hide" of commerce is now obtained largely from the beluga (*q.v.*). A second species, which may, however, be merely a variety, inhabits the Black sea; one or, more probably, two other species inhabit the La Plata region. The Pacific porpoise is now placed in a separate genus. The allied *Neomeris phocaenoides* from the Indian ocean and Japan has no dorsal fin. (*See* CETACEA.)



BY COURTESY OF THE N.Y. ZOOLOGICAL SOCIETY

THE COMMON PORPOISE (PHOCAENA PHOCAENA)

Porpoise oil, obtained from the soft fat of the head and jaw of the common porpoise has recently come into general use as a lubricant in the manufacture of watches, clocks and other delicate mechanisms made of hard steel. Its value lies chiefly in the fact that it is free from a tendency either to gum or thicken by oxidation or to corrode metal, and in its ability to withstand exposure to very low temperatures without freezing or thickening to any great extent.

PORPORA, NICCOLA [or NICCOLO] **ANTONIO** (1686–1767), Italian operatic composer and teacher of singing, was born in Naples on Aug. 19, 1686. His first opera, *Basilio,* was produced at Naples; his second, *Berenice,* at Rome. Both were successful, and he followed them up by innumerable compositions of like character; but his fame rests chiefly upon his unequalled power of teaching singing. At the Conservatorio di Sant' Onofrio and the Poveri di Gesu Cristo he trained Farinelli, Caffarelli, Mingotti, Salimbeni, and other celebrated vocalists. Unfortunately no written account of his method exists; all that remains is the tradition as handed down by his pupils. In 1725 Porpora visited Vienna, but the Emperor Charles VI. disliked his florid style, especially his constant use of the *trillo.* He then settled in Venice, teaching regularly in the schools of La Pietà and the Incurabili. In 1729 he was invited to London as a rival to Handel; but his visit was unfortunate. Little less disastrous was his second visit to England in 1734, when even the presence of his pupil, the great Farinelli, failed to save from ruin the dramatic company of Lincoln's Inn Fields theatre, set up in opposition to that directed by Handel. The sequence of dates and visits in Porpora's life are variously stated by different biographers. The electoral prince of Saxony and king of Poland had invited him to Dresden to become the singing master of the electoral princess, Maria Antonia, and in 1748 he is supposed to have been made Kapellmeister to the prince. Difficult relations, however, with Hasse and his wife resulted in his departure, of which the date is not known. From

Dresden he is said to have gone to Vienna, where he gave lessons to Joseph Haydn (*q.v.*), and then to have returned some time between 1755 and 1760 to Naples. From this time Porpora's career was a series of misfortunes. His last opera, *Camilla,* failed; and he became so poor that the expenses of his funeral were paid by subscription.

PORRENTRUY (1,400 ft.), a town in the northern or French speaking part of the canton of Berne, Switzerland, a station on the railways Basle-Delémont Delle and Altkirch-Mulhouse. It has famous schools and is an industrial centre with 2,348 inhabitants the great majority of whom are Roman Catholics. The castle overlooking the town was once the residence of the bishop of Basle. Population of commune (1930) 5,805.

PORSENA (or PORSENNA), **LARS,** king of Clusium in Etruria. He is said to have undertaken an expedition against Rome in order to restore the banished Tarquinius Superbus to the throne. He gained possession of the Janiculum, and was prevented from entering Rome only by the bravery of Horatius Cocles (*q.v.*). Porsena then laid siege to the city, but was so struck by the courage of Mucius Scaevola that he made peace on condition that the Romans restored the land they had taken from Veii and gave him 20 hostages. He subsequently returned both the land and the hostages (Livy, ii. 9–15; Dion. Halic., v. 21–34; Plutarch, *Poplicola,* p. 16–19). This story is probably an attempt to conceal a great disaster. According to other authorities, the Romans were obliged to surrender the city, to acknowledge Porsena's supremacy, to abandon their territory north of the Tiber, to give up their arms, and in future to use iron for agricultural purposes only. It is curious that, in spite of his military success, Porsena made no attempt to restore the Tarquinian dynasty. Hence it is suggested that the attack on Rome was merely an incident of the march of the Etruscans, driven southward by the invasion of upper Italy by the Celts, through Latium on their way to Campania. This would account for its transitory effects, and the speedy recovery of the Romans from the blow. With the departure of Porsena all traces of Etruscan sovereignty disappear *(see* Tacitus, *Hist.* iii. 72; Pliny, *Nat. Hist.* xxxiv. 39 [14]; Dion. Halic. v. 3j, 36, vii. 5). The tomb at Chiusi described by Pliny (*Nat. Hist.* xxxvi. 19) as that of Porsena cannot have been his burial-place *(see* CLUSIUM).

For a critical examination of the story, *see* Schwegler, *Römische Geschichte,* bk. xxi. 18; Sir G. Cornewall Lewis, *Credibility of Early Roman History,* ch. xii. 5; W. Ihne, *Hist. of Rome,* vol. *i.; E.* Pais, *Storia di Roma,* i. ch. iv. (1898). Macaulay's *Lays of Ancient Rome* gives a dramatic version of the story.

PORSON, RICHARD (1759–1808), English classical scholar, was born on Dec. 25, 1759, at East Ruston, in Norfolk, of humble parents. After attending the village school, he was entered on the foundation of Eton in 1774, and in 1778, through the generosity of Sir George Baker, the physician, entered Trinity college, Cambridge, of which he became a fellow four years later. The publication of his *Notae breves ad Toupii emendationes in Suidam* in 1790 established his fame as a scholar. During the same year, in the *Gentleman's Magazine,* he wrote the three letters on Hawkins's *Life* of *Johnson,* which have been reprinted in Kidd's *Tracts and Criticisms of Porson,* and in a volume of Porson's *Correspondence.* They are admirable specimens of his dry humour, and prove his intimate acquaintance with Shakespeare and the other English dramatists and poets. In the same periodical, in the course of 1788 and 1789, the *Letters to Archdeacon Travis, on the spurious verse i. John v. 7* (collected in 1790 into a volume), written in defence of Gibbon, had appeared. In 1792, his fellowship being no longer tenable by a layman, Porson moved to London, but in November of the same year was elected to the Greek professorship at Cambridge. Apart from his duties, the tragedians, Aristophanes, Athenaeus, and the lexicons of Suidas, Hesychius and Photius occupied most of his time.

In 1795, the year of his marriage to Mrs. Luman, appeared his anonymous edition of *Aeschylus* in folio, and in 1806 a small edition, also anonymous; these have formed the substratum for all subsequent editions. After his 1797 edition of the *Hecuba* of Euripides he published the *Orestes* in 1798 the *Phoenissae* in 1799 and the *Medea* in 1801, the last with his name on the title-page. Meanwhile he collated the Harleian ms. of the Odyssey for the Grenville *Homer* issued in 1801. When the London Institution was founded in 1806, he was appointed principal librarian. Porson died on Sept. 19, 1808.

In learning he was superior to Valckenaer, in accuracy to Bentley. His minute collations of mss. and his brilliant emendations marked a great advance in Greek scholarship, though in his day comparative philology scarcely existed.

See Barker, *Porsoniana* (London, 1852); Kidd, "Imperfect Outline of the Life of R.P.," prefixed to his collection of the *Tracts and Criticisms;* the *Life* by J. S. Watson (1861); *Dict. Nat. Biog.;* and J. E. Sandys, *History of Classical Scholarship,* ii. (1908). Porson's publications include: *Notae in Xenophontis anabasin* (1786); *Appendix to Toup* (1790); *Letters to Travis* (1790); *Aeschylus* (1795, 1806); *Euripides* (1797–1802); *Adversaria* (Monk and Blomfield, 1812); *Tracts and Criticism* (Kidd, 1815); *Aristophanica* (Dobree, 1820); *Notae in Pausaniam* (Gaisford, 1820); *Photii lexicon* (Dobree, 1822); *Notae in Suidam* (Gaisford, 1834); *Correspondence* (Luard, edited for the Cambridge Antiquarian Society, 1867). Dr. Turton's vindication appeared in 1827.

PORT: *see* PORT WINE; *see* also RULE OF THE ROAD AT SEA.

PORT ADELAIDE: *see* ADELAIDE.

PORTADOWN, market town, urban district, Co. Armagh, N. Ireland, on the river Bann and the G.N.R., 2j mi. W.S.W. of Belfast. Pop. (1937) 12.440. Area 1 2 sq.mi Linen and cotton are manufactured; there is considerable agricultural trade.

PORTAELS, JEAN FRANÇOIS (1818–1895), Belgian painter and teacher of art, was born at Vilvorde, Belgium, on April 30, 1818, and studied at the Brussels academy. In **1874** Portaels was appointed director of the academy of Brussels. His works include decorative paintings in the church of St. Jacques-sur-Caudenberg; biblical scenes and genre pictures, portraits, oriental scenes and pictures of fancy female figures, many of which are in the Brussels gallery. But it is as a teacher of art that Portaels is famous. He died at Brussels on Feb. 8, 1895.

See E. L. de Taeye, *Peintres belges contemporains.*

PORTAGE, a city of Wisconsin, U.S.A., 30 mi. N. of Madison, on the Wisconsin river; the county seat of Columbia county. It is at the western end of the ship canal connecting the Wisconsin and the Fox rivers; is on federal highways 16 and 51; and is served by the Chicago, Milwaukee, St. Paul and Pacific and the Soo Line railways. Pop. (1930) was 6,308; 1940 it was 7,016. It is a shipping point for dairy products, grain, tobacco, sandstone, granite, jasper and the products of its several manufacturing plants. As the Fox and the Wisconsin rivers are here only 2 mi. apart, this was the natural point for the portage on the route from Lake Michigan to the Mississippi. It was used by Radisson and Groseilliers in 1655 and by Marquette and Joliet in 1673. From about 1712 to 1743 the Fox Indians intermittently disputed the white man's right to passage. The first white settler (1793) was Lawrence Barth. In 1797 Jacques Vieau established a trading post here, which by 1820 was a thriving fur depot. A temporary military post was established by the United States during the Red Bird uprising (1827). Ft. Winnebago was begun in 1828. The canal was completed in 1856.

PORTAGE LA PRAIRIE, a port of entry and the chief city of Portage la Prairie county, Manitoba, Canada, 50 mi. W. of Winnipeg, on the Canadian Pacific and Canadian Northern railways at an altitude of 856 ft. above the sea. Pop. (1941) 7,187. The name had its origin in the fact that its situation on the Assiniboine is at the south end of a portage from Lake Manitoba used by the French fur traders.

PORTALEGRE, a Portuguese district and a city on the Lisbon-Madrid railway. City pop. (1930), 11,005. Portalegre is the Roman *Amaea* or *Ammaia,* and Roman and prehistoric remains have been discovered there. Pop., dist. (1940), 186,373.

PORTALIS, JEAN ÉTIENNE MARIE (1746–1807), French jurist, was born at Bausset in Provence on April 1, 1746. In 1778–81 he was one of the assessors or administrators of Provence. In November 1793, after the republic had been proclaimed, he came to Paris and was thrown into prison, being the brother-in-law of Joseph Jérôme Siméon, the leader of the Federalists in Provence. On being released he practised as a lawyer in Paris; and in 1795 he was elected by the capital to the *Conseil* *des Anciens,* becoming a leader of the moderate party opposed to the directory. As a leader of the moderates he was proscribed at the *coup d'état* of Fructidor, but he escaped to Switzerland, and did not return till Bonaparte became First Consul. Bonaparte made him a *conseiller d'état* in 1800, and then charged him, with F. D. Tronchet, Bigot de Préameneu, and Jacques de Maleville, to draw up the *Code Civil.* Of this commission he was the most industrious member, and many of the most important titles, notably those on marriage and heirship, are his work. In 1801 he was placed in charge of the department of *cultes* or public worship, and had the chief share in drawing up the provisions of the Concordat. He died at Paris on Aug. 25, 1807.

PORT ANGELES, a city of north-western Washington, U.S.A., on the Strait of Juan de Fuca, opposite Victoria, B.C., 60 mi. from the Pacific ocean at Cape Flattery and 90 mi. N.W. of Seattle; a port of entry and the county seat of Clallam county. It is on the Olympic Highway and is served by the Chicago, Milwaukee, St. Paul and Pacific and the Port Angeles Western railways, by auto-ferries and steamers to the cities on Puget sound, and by ocean steamship lines. Pop. (1940) 9,409. It is the gateway for the Olympic national park. The city fronts on Port Angeles Bay, a fine natural harbour, very deep, without a bar, rock or shoal. Mt. Angeles (7,000 ft.) is the immediate background, and beyond rise the peaks of the majestic Olympics, many of which are still unnamed and unexplored. Port Angeles has manganese mines, and manufactures lumber, shingles and paper. It was incorporated in 1890 and in 1921 adopted a commission form of government.

PORT ARTHUR, a city and harbour on Thunder bay, a northwestern arm of Lake Superior, Canada, and on the Canadian National and Canadian Pacific railways, and the Trans-Canada highway. The passenger and freight ships of the Great Lakes transportation systems meet the rail lines of western Canada there. The grain storage and shipment capacity is the largest on the continent. The city has large pulp and paper mills. There are gold mining plants in the tributary area to the northeast, and extensive and rich hematite iron ore deposits are tributary and under development to the west. Pop. (1941) 24.426. Drydock and shipbuilding are among the more important industries.

PORT ARTHUR (Ryojun), a harbour in S. Manchuria at southern extremity of the Liao-tung peninsula (38° 48' N. and 121° 20' E.)—the only part of the relatively short coast-line of Manchuria which is ice-free throughout the year. The town was given this name by Admiral Seymour when British forces were there in 1860. It occupies a particularly strong strategic position; commanding the entrance to the Gulf of Pechihli and the opposite peninsula of Shantung. Its main interest is historical. Until the Chino-Japanese War it was the chief Chinese naval arsenai, but in 1894 it fell to Japan which was, however, forced by the European Powers to retrocede it to China, along with the whole Liao-tung peninsula, almost immediately after the ratification of the Treaty of Shimonoseki. Russia was anxious to secure an ice-free Chinese port as a base for her Pacific fleet, and the capture of Kiaochow by the Germans in 1897 provided the necessary occasion for her to occupy with warships Port Arthur and Talienwan (Dairen). The British Government was "not opposed to the lease by Russia of an ice-free commercial port connected by rail with the Trans-Siberian Railway," but it was pointed out that "questions of an entirely different kind were opened if Russia obtained control of a military port in the neighbourhood of Peking." Russia, regarding Port Arthur as necessary for the protection of Talienwan, refused to change its status as a closed military port. In 1898 by agreement, Russia acquired from China the lease of the Liao-tung peninsula (including Port Arthur) for 25 years and the right to construct the branch railway from Harbin to Port Arthur and Talienwan. Subsequent events showed that Russia had been seeking a fortress rather than an ice-free port on the Pacific. Port Arthur was made an apparently impregnable stronghold and along with Talienwan accommodated 20.000 Russians by the end of 1899. During the Russo-Japanese War, it was the main strength of Russia and only fell to the Japanese after a terrific siege by land which cost Japan some 30–40,000 casualties. By the treaty of Portsmouth (1905) Port Arthur was transferred to Japan. As part of the famous Twenty-one demands in 1915 the Japanese lease of Kwantung and the railway as far as Changchun was extended to a period of 99 years. Port Arthur is at present the seat of Government of the Japanese leased territory of Kwantung, but its importance has diminished since it was the stronghold of Russian influence on the Pacific, and the chief town in South Manchuria, with a population of more than 42,000. The port, based on a fine natural harbour, entirely land-locked save on the south, is not now used as a naval base. A branch railway and excellent motor-road connect it with Dairen, the second port of China, and the real terminus of the South Manchuria Railway. The new town, dating from the Russian occupation, has been constructed on modern lines and is a popular summer resort because of its splendid beaches. Port Arthur has a population of 145,286, of whom 13,391 are Japanese. The town contains modern hotels and hospitals and advanced education facilities. *(See* Kwantung.)

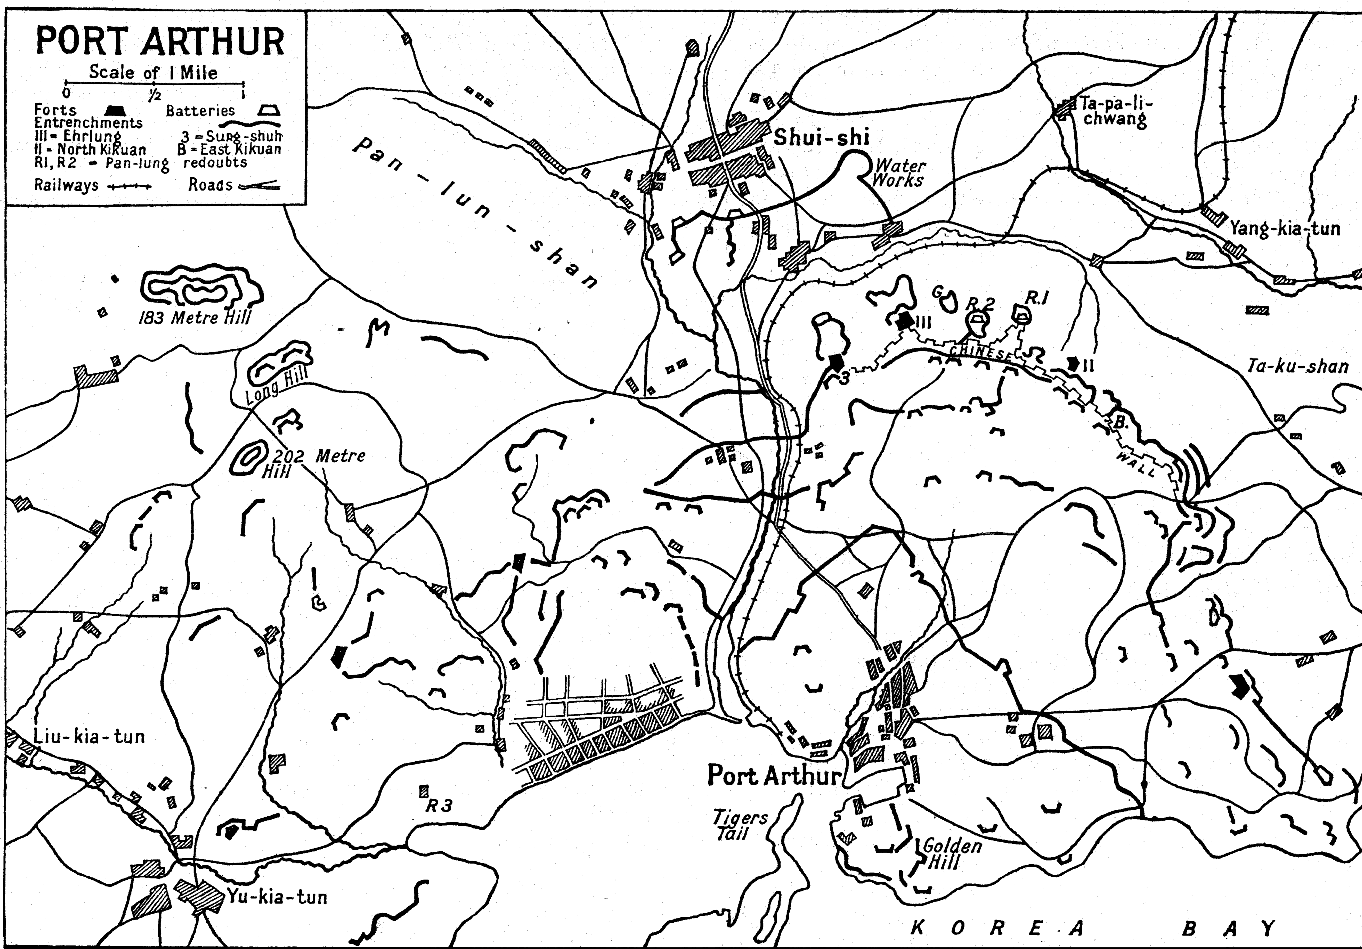
SIEGE OF PORT ARTHUR, 1904

While the fortunes of the siege of Port Arthur had undoubtedly a considerable influence on the outcome of the Russo-Japanese war (*q.v.*), its execution was separated both in space and design from the main operations of the field armies. The first clash of the armies took place on the Yalu on May 1, 1904, and five days later, Gen. Oku's 2nd Army, which had been waiting at Chinampo for the ice to melt, landed near Pitszewo. By storming Nanshan Hill, he gained command of the narrow isthmus which connected the Port Arthur peninsula with the mainland. This mission was a prelude not only to the siege, but to the 2nd Army's advance northward, its place being taken by the 3rd Army under Gen. Nogi.

Nogi landed on June 1, and his army (1st and 11th Divisions) gradually separated itself from Oku's and got into position for the advance on Port Arthur. Dalny, the commercial harbour, was seized without fighting, and a month was spent in preparing a base there. But so far from retiring within his fort-line, the Russian commander, Gen. Stossel took up a strong position outside. Dislodged from this on June 26, the Russians checked Nogi's further advance on July 3–4, by a fierce, though unsuccessful, counter-stroke. Having been reinforced by the 9th Division and two extra brigades of infantry, Nogi advanced again on the 26th. The Russians, having had a month wherein to intrench themselves, held out all along the line; but after two days and one night of fighting amongst rocks and on precipitous hill-sides, the Japanese broke through on the night of July 27–28. Stossel then withdrew in good order into Port Arthur, which, in the two months he had gained by his fighting manoeuvre, had been considerably strengthened. Nogi had already lost 8,000 men.

The defences of Port Arthur, as designed by the Russians in 1900, and owing to the meagre allotment of funds only partially carried out before the war, had some tincture, but no more, of modern continental ideas. The main line of defence followed the outer edge of the amphitheatre of hills surrounding the harbour. These hills had their greatest development on the north-east side, their outer crests being some 4,000yd. from the Old Town. Running south-west and south back to the coast, the line gradually drew in quite close to the south-west end of the harbour. The total length from sea to sea was some 12 miles. Its most obvious weakness was that 5,000yd. N.W. of the harbour and New Town, the now famous "203-Metre Hill" overlooked both. Here it had been intended to construct permanent works, but consideration of expenditure had caused this to be deferred.

The permanent works along the main line were supplemented before the siege began by a prodigious development of semi-permanent works and trenches. Every knoll had its redoubt or battery, and the trenches were arranged line behind line, to give supporting, cross and enfilade fire in every direction. On the north-west front, 203-Metre Hill, in advance of the main line, was occupied by strong, semi-permanent works, with trenches and redoubts on either flank. Wire entanglements were disposed in repeated lines in front of the defences, but they were not of a strong



type. The Russians, with the resources of the fleet at their disposal (just as at Sevastopol, in the Crimean War), used great numbers of machine guns and electric lights, and the available garrison at first was probably, including sailors, 47,000 men.

Such were the defences that the Japanese attacked, with a force at the outset (July 30) barely superior in numbers to the defenders, and an entirely inadequate siege train (18 6-in. howitzers, 60 4.7-in. guns and howitzers, and about 200 field and mountain guns). They were imperfectly informed of the strength of the garrison and the nature of the defences. Recollections of their easy triumph in 1894 and perhaps thoughts of Sevastopol, German theories of the "brusque attack," the fiery ardour of the army, and above all the need of rapidly crushing or expelling the squadron in harbour, combined to suggest a bombardment and general assault. The bombardment began on Aug. 19 and continued for three days, while the infantry was spreading along the front and gaining ground where it could. The real assault was made on the night of the 21st on the two Pan-Lung forts (semi-permanent) on the centre of the north-eastern front. Although the stormers captured the two forts they were unable to make any further progress under the fire of the permanent forts Erh-Lung and Chi-Kuan on either side of, and the Wan-tai fort behind, Pan-Lung. Every attempt to bring up support to the captured positions failed. On the night of the 23rd–24th, just as the assault was being renewed, Stössel delivered a fierce counter-attack against the lost positions, and the result of an all-night battle was that though the forts were not recaptured, the assault was repulsed with over 5,000 casualties, and the Japanese in Pan-Lung were isolated. This sortie raised the spirits of the Russians to the highest pitch. They seemed, indeed, to have broken the spell of defeat. On the Japanese side 15,000 men had been killed and wounded in three weeks, and their army had now to resign itself to a methodical siege. Small sorties, partial attacks[1] and duels between the Japanese guns and the generally more powerful ordnance of the fortress continued. The siege approaches were first directed against the Temple-Waterworks group, which was stormed on Sept. 19 and 20. Pan-Lung was connected with the Japanese lines by covered ways, approaches were begun towards several of the eastern forts, and on Sept. 20, 180-Metre Hill was stormed, though the crest was untenable under the fire from 203-Metre Hill. Further progress on the western side of the fortress was foiled after hard fighting, and the eastern forts remained the principal objective. Heavier howitzers had been sent for from Japan and on Oct. 1 the first batteries of 28-centimetre (11in.) howitzers came into action. They fired a shell weighing 48j lb. On the 12th, the Japanese took the trenches between the Waterworks Redoubt and the Erh-Lung, and from this time forward there was a desperate struggle at the sap-heads on the north front.[2] A lodgement on the counterscarp of Sung-Shu prepared the way for mining. On Nov. 17, seven mines were exploded.

On Nov. 26, another assault was made on the same lines as the earlier ones By this time the besiegers were sapping under the escarps of the northern forts, and it would have been better to delay. But the situation was serious in the extreme. In Manchuria Kuropatkin's army had reasserted itself. From Europe Rozhestvenski's squadron was just setting sail for the Far East. Marshal Oyama sent his principal staff officers to stimulate Nogi to fresh efforts, and some exhausted units of the besieging army were replaced by fresh troops from Japan. With 100,000 men and this urgent need of immediate victory, Nogi and the marshal's staff officers felt bound to make a third general assault. The siege works had, indeed, made considerable progress. The ditches of

[1]A feature of these constant night-fights was the effective use of the defenders' searchlight, both to show up the enemy and to blind him.

[2]Hand grenades and extemporized trench mortars were used on both sides with very great effect. The Japanese hand grenades consisted of about 1-lb. of high explosive in a tin case; the Russian cases were all sorts, including old Chinese shell The Japanese employed wire-netting screens to stop the Russian grenades. Various means were tried for the destruction of entanglements. Eventually it was found that the best plan was to sap through them.

Sung-Shu and Erh-Lung were partially filled. They held most of the ditch of Chi-Kuan Fort and were cutting down the escarp, and two parallels had been made only 30yd. from the Chinese Wall at Pan-Lung.

The general attack was made at 1 P.M. At Sung-Shu the stormers got into the fort, but suffered much from the artillery on the western side of the Lun-ho valley, and were beaten out of it again in 20 minutes; 2,000 men tried in vain to get up the Lun-ho valley to take Sung-Shu in rear. At Erh-Lung they could not get over the outer parapet. At "G" they took a portion of the Chinese Wall and lost it again, other trenches with a cross fire being behind. At Pan-Lung the machine guns on the Wall prevented them from leaving the parallel. At Chi-Kuan Fort the *terreplein* of the fort had been covered with entanglements defended by machine guns on the gorge parapets, and the Japanese could make no way. Briefly, there was a furious fight all along the line, and nothing gained. On Nov. 27, after losing 12,000 men, the assault was abandoned. On the north front the Japanese returned to mining.

But so urgent was the necessity of speedy victory that the fighting had to continue elsewhere. And at last, after every other point had been attempted, the weight of the attack was directed on 203-Metre Hill. A battery of 11-in. howitzers was established only one mile away. On Nov. 28 and 30, assaults were made and failed. On Dec. 1, there was a fresh bombardment by the big howitzers, which obliged the Russians to take shelter in rear of the ruined works. On Dec. 2, the Russians tried a counter-attack. During the next two days the artillery were busy. The engineers sapped up to the ruins of the western work, saw the shelters on the reverse slope and directed artillery fire by telephone. Thirty-six guns swept the grobnd with shrapnel. Finally, on Dec. 5, the Japanese attacked successfully. Their losses in the last 10 days at 203-Metre Hill had been probably over 10,000. Those of the Russians were about 5,000, chiefly from artillery fire.

This was the turning point of the siege. At once the 11-in. howitzers, assisted by telephone from 203-Metre Hill, opened upon the Russian ships; a few days later these were wholly hors de combat, and at the capitulation only a few destroyers were in a condition to escape. The siege was now pressed with vigour by the construction of batteries at and around 203-Metre Hill, by an infantry advance against the main western defences, and by renewed operations against the eastern forts. The escarp of Chi-Kuan was blown up, and at the cost of 800 men, General Sameyeda (11th Division), personally leading his stormers, captured the great fort on Dec. 19. The escarp of Ehr-Lung was also blown up, and the ruins of the fort were stormed by the 9th Division on Dec. 28th, though a mere handful of the defenders prolonged the fighting for eight hours and the assailants lost 1,000 men. Sung-Shu suffered a worse fate on the 31st, the greater part of the fort and its defenders being blown up, and on this day the whole defence of the eastern front collapsed. The Japanese 7th and 1st Divisions were now advancing on the western main line; the soul of the defence, the brave and capable Gen. Kondratenko, had been killed on Dec. 15, and though food and ammunition were by no means exhausted, Stössel surrendered on January 2, 1905, with 24,000 effective and slightly wounded and 15,000 wounded and sick men, the remnant of his original 47,000. The total losses of the 3rd Japanese Army during the siege were about 92,000 men (58,000 casualties and 34,000 sick).

PORT ARTHUR, a city of Jefferson county, Texas, U.S.A., in the south-eastern part of the state, on the west shore of Sabine Lake at the head of the Port Arthur canal, which leads to the Port Arthur docks (at the mouth of Taylors Bayou, 7 m. S.E.), and on the route of the intracoastal waterway from New Orleans to Corpus Christi. It is served by the Kansas City Southern and the Southern Pacific railways and by steamship lines.

The population was 22,251 in 1920, 76% native white, 6·4% foreign-born white, and 17·6% Negroes, and was, in 1940, 46,140 by the federal census.

Port Arthur is a great oil-refining cenrre. The commerce of the port in 1939 amounted to 19,510,962 tons, valued at $249,710,-169, of which about 90% was petroleum and petroleum products. Port Arthur is a salt-water sport fishing centre.

PORTATIVE ORGAN, a small mediaeval organ, not to be confounded with the positive (or portable) organ (*q.v.*). These miniature organs, used during the 14th and 15th centuries, were revivals of those used by the Romans, of which a specimen excavated at Pompeii in 1876 is preserved in the museum at Naples.

The case measures 14½ in. by 9⅓ in. and contains nine pipes, of which the longest measures but 9¾ inches.

PORT AUGUSTA, at the head of Spencer gulf, an arm of the sea which penetrates far towards the interior of South Australia. This position lends Port Augusta a potential importance which, however, is somewhat impaired by a shallow approach and a channel which requires dredging. It is the natural port for the wheat-growing areas to the east, and for the pastoral areas to the north and north-west. Since the construction of the east to west trans-continental line (Perth-Brisbane), Port Augusta has become a break-of-gauge station. Pop. 3,270 (1933).

PORT AU PRINCE (originally *L'Hôpital,* and for brief periods Port *Henri* and Port *Républicain*), the capital of the Republic of Haiti, West Indies, situated about 1,400 mi. S. of New York city in 18° 33' N. and 74° 47' W. at the apex of the Gulf of La Gonaive which strikes inland for about 100 mi. between the two great peninsulas of the west coast, with its upper recesses protected by the beautiful island of Gonaive (30 mi. long and 2 mi. broad). Pop. (1940 estimate) 125,000 (mostly Negroes and mulattoes). Port au Prince is the seat of the University of Haiti with its schools of law, medicine, pharmacy, dentistry and nursing. It also has a number of seminaries maintained by religious organisations. Communication with the interior is maintained by two railway lines, by highways and by telephone and telegraph connections. The excellent harbour serves as a port of call for both American and European vessels participating in the West Indian trade. The city was first laid out by M. de la Cuza in 1749. In 1751, and again in 1770, it was destroyed by earthquakes; and in subsequent years, the city has been ravaged frequently by fire. (See HAITI.)

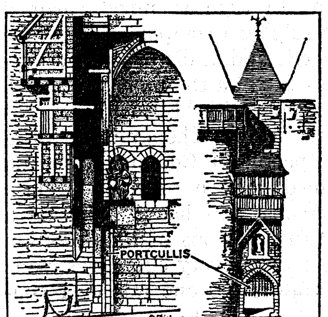
PORT AUTHORITY. For Great Britain the discussion of the constitution and powers of the different port authorities will be found in the articles on the various ports, *e.g.,* London, Liverpool, etc. The American Port Authority, in many respects peculiar, calls for special discussion. The American Association of Port Authorities issued, in April 1927, a port authorities directory for North America which indicated the adoption by an increasing number of American ports of some modification of the form of government established at European ports, notably at London and Liverpool. All facilities on the San Francisco water-front are owned by the State of California and operated by the board of State harbour commissioners. The State guarantees the bonds issued, the principal and interest of which are payable from harbour revenue. No funds are raised by taxation and the harbour has been self-supporting since its inception. Under the 1925 charter for the city of Los Angeles, the board of harbour commissioners has possession and control of the entire water-front. It may collect rates or charges for the use of facilities in connection with commerce and navigation, may acquire and operate such facilities and has power to regulate and control the construction, maintenance, operation or use of any such facility. An Act approved on March 14, 1911, authorizes the establishment of port districts in the various counties of the State of Washington, and the port of Seattle exists under this Act. It is a municipal corporation and has power to levy taxes and to issue bonds. It may acquire lands, etc. and exercise the right of eminent domain. Commissioners are elected. The port of Portland was established and incorporated by the laws of 1891. It has broad powers, among which are full control of the Willamette and Columbia rivers between Portland and the sea to the extent of the State's control, the right of eminent domain, the power to levy regular and special taxes on the property within the district and to bond the district to provide funds for carrying on its operations. The port of Houston, Texas, is operated by the navigation and canal commission. The board controls the commercial activities of the port and the maintenance and construction of the terminal facilities. A director of the port serves under the commissioners. The board of commissioners of the port of New Orleans was created by a Louisiana statute enacted in 1896. The board administers the public wharf system, has constructed and operates a public cotton warehouse, public grain elevator, public coal and bulk commodity handling plant and the great inner harbour navigation canal. The bond issues from Jan. 1, 1908, to Dec. 1, 1923, totalled $39,750,000, of which there had been redeemed as of Aug. 31, 1927, $980,000. The Virginia Assembly in 1926 created the State port authority of Virginia, superseding the Hampton Roads port commission. The board of harbour commissioners for the city of Wilmington, Del., an agency of the mayor and council of Wilmington, was created in 1917 by an Act of the General Assembly, which Act was amended in 1921 and 1925. In 1925 the commissioners were authorized to prepare a plan for the improvement of the water-front and to increase the harbour and shipping facilities of the city, and, after approval of the plan by the council, to proceed to acquire land, etc. The board was given authority to fix rates and charges for wharfage and other services rendered in the loading and unloading of vessels, as well as warehouse and storage charges. The Albany port district commission was created by the legislature of New York in 1925. It has broad powers to lease or construct and maintain and operate port facilities, to acquire real property, to contract with municipalities for the construction of port facilities, issue bonds, fix rates, charges and wharfage for the use of all port facilities and collect charges for facilities owned by the district. Provision for tax in the several municipalities in the port district is made.

The Port of New York is unique in that it is within the boundaries of two States, New York and New Jersey, each an independent sovereignty in its own land. As early as 1834 the two States found it necessary to enter into a treaty concerning the jurisdiction of each over the waters of the harbour. In 1917, in its decision in the New York harbour case, the interstate commerce commission said that "historically, geographically and commercially New York and the industrial district in the northern part of the State of New Jersey constitute a single community" and recommended that immediate steps be taken to reorganize and co-ordinate the terminal facilities at the port. In 1920, the New York-New Jersey port and harbour development commission, a bi-State commission appointed by the two States to study the problem, recommended the creation of a port authority and a port district. On April 30, 1921, the two States entered into a compact or treaty, creating the port of New York district and the port of New York authority. The consent of Congress to this treaty was given by joint resolution approved on Aug. 23, 1921. By the compact, the two States pledged, "each to the other, faithful co-operation in the future planning and development of the port of New York." The compact provided that the port authority should consist of six commissioners, three from each State, who should constitute a body, both corporate and politic, with full power and authority to purchase, construct, lease and operate any terminal or transportation facility within the port district; to own, hold, lease and operate real or personal property; to borrow money and secure the same by bonds or by mortgage upon any property held or to be held by it. No property held by any city, township or other municipality, or by either State, may be taken by the port authority without the consent of such owning body. The treaty provided for the adoption by the two States of a plan for the comprehensive development of the port. In 1922 the legislatures of both States adopted the comprehensive plan submitted and on July 1, 1922, the president of the United States approved the joint resolution of Congress granting its consent and authority to the port of New York authority to execute the comprehensive plan. Subsequent legislation adopted by the two States has authorized the construction of four bridges between the States. Two bridges across the Arthur Kill, opened to traffic in 1928, were financed by the sale of $14,000,000 port of New York authority $4\frac{1}{2}\%$ bonds. A total issue of $60,000,000 4% bonds has been authorized for the construction of the bridge over the Hudson river, between Ft. Washington, New York city, and Ft. Lee, N.J. It is expected that this bridge will be opened to traffic in 1932. Construction work on a bridge to span the Kill von Kull between Bayonne, N.J., and Port Richmond, Staten Island, N.Y., was begun in the summer of 1928. Four per cent. bonds to the amount of $12,000,000 have been issued in connection with this bridge. Redemption of the bonds and repayment of advances made by the States will be provided for out of tolls to be charged for the use of bridges. Construction of bridges forms only a small part of the port of New York authority's work and programme. It deals also with the problems of co-ordination of terminal facilities and of carfloating and lighterage arising out of the fact that most of the trunk-line railroads coming from the north and west have their terminals on the New Jersey shore of the Hudson river. It deals also with the problem of relieving the congestion of the valuable water-fronts of the Hudson, so as to leave them free for their appropriate use, that of shipping, rather than receipt and distribution of freight. The erection of union inland terminal freight stations is proposed as a means of lessening this congestion and reforming the handling of freight at the port. The port of New York authority acts also as spokesman and defender of the port's interests before the interstate commerce commission and other bodies. (J. H. Co.)

PORT BLAIR, the chief place in the Andaman islands convict settlement in the Indian ocean, situated on the south-east shore of the South Andaman island, in 11° 42' N., 93° E. It was first occupied by Lieut. Blair, R.N., in 1789, in order to suppress piracy and protect shipwrecked crews. Abandoned in 1796, it was not again occupied until 1856. It possesses one of the best harbours in Asia, while its position makes it an admirable naval rendezvous. (See ANDAMAN ISLANDS.)

PORT CHESTER, a village of Westchester county, New York, U.S.A., on Long Island sound, at the mouth of Byram river, 26 m. N.E. of the Grand Central station in New York city. It is on the Boston Post road, and is served by the New York, New Haven and Hartford railroad, interurban motorbus and truck lines. It is the largest village in New York state. Population (1940), 23,073 with 29% foreign-born white; 1930 by Federal census 22,662. It is a residential suburb, and has various manufacturing industries, with an output in 1937 valued at $12,021,204. The assessed valuation for 1941 was $44,583,575. During the Revolution the village was frequently occupied by American troops. Until 1837 Port Chester was known as Saw Pit. It was incorporated in 1868.



A PORTCULLIS: LEFT, A SECTIONAL VIEW SHOWING OPERATION; RIGHT. FRONT VIEW

PORTCULLIS, a strong-framed grating of wood, the lower points shod with iron, and sometimes entirely made of metal, counterbalanced, and hung so as to slide up and down in grooves, and intended to protect the gateways of castles, city gates, etc. The defenders having opened the gates and lowered the portcullis, could send arrows and darts through the gratings. The Romans used the portcullis in the defence of gateways. It was called *cataracta* from the Gr. *καταρράκτης*, a waterfall (*καταρρήγνυσθαι*, to fall down). Vegetius (De re *milit.* iv. 4) speaks of it as an old means of defence. Remains of a cataracta are clearly seen in the gateway of Pompeii.

PORTE, THE SUBLIME, in Turkey, the name once given to the government, derived from the high gate giving access to the building in Constantinople where the offices of the principal State departments were situated.

PORT ELIZABETH, a seaport 436 m. by sea E. of Cape Town, South Africa, in 33° 58′ S., 25° 37′ E. The white population increased from 26,303 in 1921 to 33,371 in 1926; in 1921 there were also 11,472 natives, 1,320 Asiatics and 13,203 coloured people. It is the third port of South Africa, and is situated on the shores of Algoa bay, to the east of Cape Recife.

Four distinct parts may be recognized: (1) the harbour and business quarter; (2) the "Hill," largely a residential part on the tableland overlooking the bay; (3) the "Valley," formed by the Baaken's river, and (4) the "South Hill," east of the river. Other suburbs have also grown up further from the town, such as Humewood, $1\frac{3}{4}$ m. along the shore.

The Harbour.—There is no enclosed basin, and shipping is rather exposed to the south-east winds. Schemes have been passed for the construction of a breakwater to provide an enclosed basin. There are three jetties provided with hydraulic cranes. The depths along side range from g to 24 feet. Larger vessels load and unload in the bay, by means of lighters, of which the port possesses 40, with a total capacity of 4,500 tons. Four refrigerating lighters were being constructed (1928) for the fruit export trade. The hinterland of Port Elizabeth for imports extends to Rhodesia. Its exports are mainly the products of the eastern part of the Cape Province, the most important being wool and mohair, and, until the World War, ostrich feathers. There is a growing export of fresh and tinned fruits.

History.—Algoa bay was discovered by Bartholomew Diaz in 1488. In 1754 the Dutch settlements at the Cape were extended eastward to this point. In 1799 Col. Vandeleur, after the British occupation of the Cape, built a small fort on the hill, west of the Baaken's river. By 1820, in addition to the troops, the civilian population had grown to 35. In April of that year arrived the first of the 1820 settlers. (See CAPE COLONY: History.) Under the supervision of Sir Rufane Donkin, a town was laid out at the foot of the hills. The real development of the port started when railways were constructed leading to the interior, Kimberley and the Witwatersrand. This work was begun in 1873, at the same time as the building of the existing jetties. Port Elizabeth is largely a British town.

PORTEOUS, JOHN (d. 1736), captain of the city guard of Edinburgh, whose name is associated with the riots of 1736, was the son of an Edinburgh tailor. Having served in the army, he was employed in 1715 to drill the city guard for the defence of Edinburgh in anticipation of a Jacobite rising, and was promoted later to the command of the force. In 1736 a smuggler named Wilson, who had won popularity by helping a companion to escape from the Tolbooth prison, was hanged; and, a disturbance occurring at the execution, the city guard fired on the mob. Porteous, who was said to have fired at the people with his own hand, was brought to trial and sentenced to death. The granting of a reprieve was hotly resented by the people of Edinburgh, and on the night of Sept. 7, 1736 an armed body of men in disguise broke into the prison, seized Porteous, and hanged him on a signpost in the street. It was said that persons of high position were concerned in the crime; but although every effort was made for the apprehension of the perpetrators, no one was ever convicted of participation in the murder.

See Sir Daniel Wilson, *Memorials of Edinburgh in the Olden Time* (2 vols., Edinburgh, 1848); *State Trials*, vol. xvii.; William Coxe, *Memoirs of the Life of Sir R. Walpole* (4 vols., London, 1816); Alexander Carlyle, *Autobiography* (Edinburgh, 1860), which gives the account of an eye-witness of the execution of Wilson; pamphlets (2 vols., in British Museum) containing *The Life and Death of Captain John Porteous*, and other papers relating to the subject,; W. E. H. Lecky, *History of England in the Eighteenth Century*, ii. 324, note (7 vols., London, 1892). *See* also Scott's notes to *The Heart of Midlothian.*

PORTER, DAVID (1780–1843), American naval officer, was born in Boston (Mass.), on Feb. 1, 1780. His father, David, and his uncle, Samuel, commanded American ships in the War of Independence. In 1796 he accompanied his father to the West Indies; on a second and on a third voyage he was impressed on British vessels, but he escaped. He became a midshipman in the U.S. Navy in April, 1798; served on the "Constellation" and was midshipman of the foretop when the "Constellation" defeated the "Insurgente"; was promoted lieutenant in October, 1799, and was in four successful actions with French ships in this year.

In 1803, during the war with Tripoli, he was first lieutenant of the "Philadelphia" when that vessel grounded; he was taken prisoner, and was not released until June, 1805. He was commissioned master commandant in April, 1806; from 1807 to 1810 he served about New Orleans, where he captured several French privateers, and in 1812 was promoted captain. He commanded the frigate "Essex" in her famous voyage (1812–14). In the Atlantic he captured seven brigs, one ship, on Aug. 13, 1812, the sloop "Alert," the first British war vessel taken in the War of 1812. Without orders from his superiors he then (February, 1813) rounded Cape Horn, and in the South Pacific captured many British whalers and took formal possession (November, 1813) of Nukahivah, the largest of the Marquesas islands. The United States, however, never asserting any claim to the island, it was in 1842, with the other Marquesas, annexed by France. During most of February and March, 1814, he was blockaded by British frigates in the harbour of Valparaiso, and on March 28 was defeated. Released on parole, he sailed for New York.

He was a member of the new board of naval commissioners from 1815 until 1823, when he commanded a squadron sent to the West Indies to suppress piracy. One of his officers, who landed at Fajardo (or Foxardo), Porto Rico, in pursuit of a pirate, was imprisoned by the Spanish authorities on the charge of piracy. Porter, without reporting the incident or awaiting instructions, forced the authorities to apologize. He was recalled (December, 1824), court-martialled, and suspended for six months. In August, 1826 he resigned his commission, and until 1829 was commander-in-chief of the Mexican navy, then fighting Spain. President Andrew Jackson appointed him consul general to Algiers in 1830, and in 1831 created for him the post of *chargk d'affaires* at Constantinople, where in 1841 he became minister. He died in Pera on March 3, 1843.

He wrote a *Journal of a Cruise made to the Pacific Ocean in the U.S. Frigate "Essex" in 1812–13–14* (1815; 2nd ed., 1822), and *Constantinople and its Environs* (1835), *a* valuable guide-book. *See* the *Memoir of Commodore David Porter* (Albany [N.Y.], 1875), by his son, Adniiral David D. Porter.

PORTER, DAVID DIXON (1813-IS~I), American naval officer, son of Capt. David Porter, was born in Chester (Pa.), on June 8, 1813. His first voyage, with his father in West Indian waters (1823–24), was terminated by the Fajardo affair (see PORTER, DAVID). In April, 1826, he entered the Mexican navy, of which his father was commander-in-chief, and which he left in 1828, after the capture by the Spanish of the "Guerrero," on which he was serving under his cousin, David H. Porter (1804–28), who was killed before the ship's surrender. He became a midshipman in the U.S. Navy in 1829, and was in the coast survey (1836–42). In 1839 he married the daughter of Capt. Daniel Tod Patterson (1786–1839), then commandant of the Washington Navy Yard. Porter became a lieutenant in Feb., 1841; served at the naval observatory from 1845 to 1846, when he was sent to the Dominican Republic to report on conditions there. During the Mexican War he served as lieutenant and then as commanding officer of the "Spitfire," a paddle vessel built for river use, and took part in the bombardment of Vera Cruz. In 1855 and in 1856 he made trips to the Mediterranean to bring to the U.S. camels for Army use in the south-west. In April, 1861, he was assigned to the "Powhatan," and was sent under secret orders from the President for the relief of Ft. Pickens, Pensacola. Porter was promoted commander on April 22, and on May 30 was sent to blockade the South-west pass of the Mississippi. Upon his return to New York in November, he urged an expedition against New Orleans (*q.v.*), and recommended the appointment of Commander D. G. Farragut (*q.v.*), his foster-brother, to the chief command.

In the expedition Porter himself commanded the mortar flotilla, which, when Farragut's fleet passed the forts on the early morning of April 24, 1862, covered the passage by a terrific bombardment that neutralized the fire of Ft. Jackson. At Vicksburg Porter's bombardment assisted Farragut to run past the forts (June 28). On July 9, Porter was ordered, with ten mortar boats, to the James river, where McClellan's army was concentrated. On Oct. 15 he took command of the gun-vessels and had a share in the capture of Arkansas Post (Jan. 11, 1863). In the operations for the capture of Vicksburg in 1863 unsuccessful attempts were made by Porter's vessels to penetrate through connecting streams and bayous to the Yazoo river and reach the right rear of the Confederate defences on the bluffs, but the fleet ran past the Vicksburg batteries, mastered the Confederate forts at Grand Gulf, and made it possible for Grant's army to undertake the bril-Rant campaign which led to the fall of the place (*see* AMERICAN CIVIL WAR and VICKSBURG). Porter received the thanks of Congress for "opening the Mississippi river" and was promoted rear admiral. He co-operated with Maj.-Gen. N. P. Banks in the Red river expeditions in March-May 1864, in which his gun boats, held above Alexandria by shallpw water and rapids, narrowly escaped isolation. On Oct. 12, 1864, he assumed command of the North Atlantic blockading squadron, then about to engage in a combined military and naval expedition against Ft. Fisher, N.C. Porter claimed that his guns silenced Ft. Fisher, but Maj.-Gen. B. F. Butler, in command of the land forces, refused to assault, asserting that the fort was practically intact. After Butler's removal, Porter, co-operating with Maj.-Gen. Alfred H. Terry, and commanding the largest fleet assembled at any one point during the war, took the fort on Jan. 15, 1865; for this he again received the thanks of Congress. From 1865 to 1869 he was superintendent of the U.S. Naval academy at Annapolis, which he greatly improved; his most notable change being the introduction of athletics. On July 25 he became vice admiral. From March 9 to June 25, 1869, while Adolph E. Borie (1809–80), of Pennsylvania, was secretary of the Navy in President Grant's cabinet, Porter was virtually in charge of the Navy department. In 1870 he succeeded Farragut in the grade of admiral. He died in Washington (D.C.), Feb. 13, 1891.

Porter wrote a *Life of Commodore David Porter* (1875), gossipy *Incidents and Anecdotes of the Civil War* (1885), a none too accurate *History of the Navy during the War of the Rebellion* (1887), two novels, *Allan Dare* and *Robert le Diable* (1885; dramatized, 1887) and *Harry Marline* (1886), and a short "Romance of Gettysburg," published in *The Criterion* in 1903. *See* J. R. Soley, *Admiral Porter* (1903).

Admiral Porter's three brothers were in the service of the United States: WILLIAM DAVID PORTER (1809–1864) commanded the "Essex" on the Tennessee and the Mississippi in the Civil War, and became commodore in July, 1862; THEODORIC HENRY PORTER (1817–1846) was the first officer of the American Army killed in the Mexican War; and HENRY OGDEN PORTER (1823–1872) resigned from the United States Navy in 1847, after seven years' service, fought under William Walker in Central America, returned to the American Navy, was executive officer of the "Hatteras" when she was sunk by the "Alabama," and received wounds in the action from the effects of which he died several years later.

PORTER, ENDYMION (1587–1649), English royalist, born at Aston-sub-Edge in Gloucestershire, was brought up in Spain—where he had relatives—as page in the household of Olivares. He afterwards entered successively the service of Edward Villiers and of Buckingham, and through the latter's recommendation became groom of the bedchamber to Charles I., who employed him on diplomatic business. During the Civil War Porter remained a faithful servant of the king.

At the end of 1645, when the cause of the king was finally lost, Porter abandoned England, and resided successively in France, Brussels, where he was reduced to great poverty, and the Netherlands. He returned to England in 1649, after the king's death, and was allowed to compound for what remained of his property. He died shortly afterwards, and was buried on Aug. 20, 1649, at St. Martin's-in-the-Fields. Porter had a great reputation in the world of art and letters. He wrote verses, was a generous patron of Davenant, who especially sings his praises, of Dekker, Warmstrey, May, Herrick and Robert Dover, and was included among the 84 "essentials" in Bolton's "Academy Royal." He was a judicious collector of pictures, and as the friend of Rubens, Van Dyck, Mytens and others painters, and as agent for Charles in his purchases abroad he had a considerable share in forming the king's magnificent collection. He was also instrumental in procuring the Arundel pictures from Spain. The authorship of **Εἰκὼν πιστή**, 1649, a vindication of the Εἰκὼν βασιλική, has been attributed with some reason to Porter.

Lloyd (1668), p. 657; Burton's *Hist. of Scotland* (1873), vi. 346–347; *Eng. Hist. Rev.* ii. 531, 692; Waters, *The Chesters of Chichele*, vol. i., 144–149; *Eikon Basilike*, by Ed. Almack, p. 94.

PORTER, FITZ-JOHN (1822–1901), American soldier, was born at Portsmouth (N.H.) on Aug. 31,1822. He was the son of a naval officer, and nephew of David Porter of the frigate "Essex." He graduated at the U.S. Military academy in 1845; in the Mexican War he won two brevets for gallantry. He served at West Point as instructor and adjutant (1849–55), and at the outbreak of the Civil War in 1861 he was employed on staff duties in the eastern States. He became colonel of a new regiment of regulars on May 14, and soon afterwards brig.-general of volunteers. Under McClellan he commanded a division of infantry in the Peninsular campaign, directed the Union siege operations against Yorktown, and was soon afterwards placed in command of the V. Army Corps. When the Seven Days' battle (*q.v.*) began Porter's corps had to sustain alone the full weight of the Confederate attack, and though defeated in the desperately fought battle of Gaines's Mill (June 27, 1862) the steadiness of his defense was so conspicuous that he was immediately promoted maj.-general of volunteers and brevet brig.-general. His corps, moreover, had the greatest share in the successful battles of Glendale and Malvern Hill. Soon afterwards, the V. Corps was sent to reinforce Pope in central Virginia. Its inaction on the first day of the disastrous second battle of Bull Run (*q.v.*) led to the general's subsequent disgrace; but it made a splendid fight on the second day to save the army from complete rout, and shared in the Antietam campaign.

On the same day on which McClellan was relieved from his command, Porter, his friend and supporter, was suspended and tried by court-martial on charges brought against him by Pope. On Jan. 21, 1863, he was sentenced to be cashiered "and for ever disqualified from holding any office of trust under the Government of the United States." In 1878 Porter's friends succeeded in procuring a revision of the case by a board of distinguished general officers. General Grant had now taken Porter's part, and wrote an article in vol. 135 of the *North American Review* entitled "An Undeserved Stigma." Against much opposition, a, relief bill finally passed Congress, and Porter was on Aug. 5, 1886, restored to the United States army as colonel and placed on the retired list, without compensation. After the Civil War he was engaged in business in New York, and held successively many important municipal offices. In 1869 he declined the offer made by the khedive of the chief command of the Egyptian Army. He died on May 21, 1901, at Morristown (N.J.).

See, besides General Grant's art., Cox, *The Second Battle of Bull Run as connected with the Porter Case* (Cincinnati, 1882); Lord, *A Summary of the Case of F. J. Porter* (1883), and papers in vol. ii. of the pub. of the Military Hist. Soc. of Mass.

PORTER, HENRY (*fl.* 1596–1599), English dramatist, author of *The Two Angry Women of Abingdon*, may probably be identified with the Henry Porter who matriculated at Brasenose

College, Oxford, on June 19, 1589. From 1596 to 1599 he was writing plays for Henslowe for the Admiral's Men, and his closest associate seems to have been Henry Chettle. None of the plays mentioned by Henslowe as being written by him are extant, unless, as has been suggested, *Love Prevented* is another name for *The Pleasant History of the Two Angry Women of Abingdon* of which Gayley says: "No play preceding or contemporary yields an easier conversational prose, not even the *Merry Wives.*"

Alexander Dyce edited the *Angry Women* for the Percy Society in 1841; and it is included in W. C. Haalitt's edition of Dodsley's *Old Plays* (1874). It was edited by Havelock Ellis in *Nero and other plays* (1888, "Mermaid Series,") and in *Representative English Comedies* (1903), with an introduction by the general editor, Professor C. M. Gayley.

PORTER, HORACE (1837–1921), American diplomatist and soldier, was born in Huntingdon, Pa., on April 15, 1837; son of David Rittenhouse Porter (1788–1867), governor of Pennsylvania in 1839–45. During the Civil War he served in the Army of the Potomac until after Antietam; took part in the battles of Chickamauga and Chattanooga; and in April, 1864, became aide-de-camp to Gen. Grant, in which position he served until March 1869. From Aug. 1867 to Jan. 1868, while Gen. Grant was secretary of war *ad interim,* Porter was an assistant secretary, and from March 1869 to Jan. 1873, when Grant was president, Porter was his executive secretary. He resigned from the army in Dec. 1873, when he became vice president of the Pullman Palace Car Company and held other business positions. From March 1897 to May 1905 he was United States ambassador to France. At his personal expense he conducted (1899–1905) a successful search for the body of John Paul Jones, who had died in Paris in 1792. For this he received (May 9, 1906) a unanimous vote of thanks of both Houses of Congress. In 1907 he was a member of the American delegation to the Hague Peace conference. He died in New York city on May 29, 1921. His publications include *West Point Life* (1866) and *Campaigning with Grant* (1897).

PORTER, JANE (1776–1850), British novelist, daughter of an army surgeon, was born at Durham in 1776. Her life and reputation are closely linked with those of her sister, ANNA MARIA PORTER (1780–1832), novelist, and her brother, SIR ROBERT KER PORTER (1775–1842), painter and traveller. After their father's death, in 1779, the mother removed from Durham, their birthplace, to Edinburgh, where the children's love of romance was stimulated by their association with Flora Macdonald and the young Walter Scott. Mrs. Porter moved to London, so that her son might study art, and the sisters subsequently resided at Thames Ditton and at Esher with their mother until her death in 1831. Anna Maria Porter published *Artless Tales* in 1793–95, the first of a long series of works of which the more noteworthy are *The Lake of Killarney* (1804), *The Hungarian Brothers* (1807), *Don Sebastian* (1809) and *Barony* (1830).

Jane Porter—whose intellectual power, though slower in development and in expression, was greater than her sister's—had in the meantime gained immediate popularity by her first work, *Thaddeus of Warsaw* (1803), which was translated into several languages and procured her election as canoness of the Teutonic order of St. Joachim. In 1810, four years before the appearance of *Waverley,* she attempted national romance in her *Scottish Chiefs.* The picturesque power of narration displayed by Miss Porter has saved the story from the oblivion which has overtaken the works of most of Scott's predecessors in historical fiction. Her later works included *The Pastor's Fireside* (1815), *Duke Christian of Lüneburg* (1824), *Coming Out* (1828) and *The Field of Forty Footsteps* (1828). In conjunction with her sister she published in 1826 the *Tales round a Winter Hearth.* She also wrote some plays, and frequent contributions to current periodical literature. On Sept. 21, 1832, Anna Maria died, and for the next ten years Jane became "a wanderer" amongst her relations and friends. She died at Bristol on May 24, 1850.

Robert Ker Porter painted altar-pieces and battle-scenes of imposing magnitude. He went to Russia as historical painter to the emperor in 1804, travelled in Finland and Sweden, where he received knighthood from Gustavus IV. in 1806, and accompanied Sir John Moore to Spain in 1808. In 1811 he returned to Russia and married a Russian princess. He was knighted by the Prince Regent in 1813. In 1817 he travelled to Persia by way of St. Petersburg (Leningrad) and the Caucasus, returning through Bagdad and western Asia Minor. He examined the ruins of Persepolis, making many valuable drawings and copying cuneiform inscriptions. In 1826 he became British consul in Venezuela. He died at St. Petersburg on May 4, 1842.

His works include: *Travelling Sketches in Russia and Sweden* (1808), *Letters from Portugal and Spain* (1809), *Narrative of the late Campaign in Russia* (1813), and *Travels* in *Georgia, Persia, Armenia, Ancient Babylonia, etc., during the years 1817–1820* (1821–22). After leaving Venezuela (1841) he again visited St. Petersburg, and died there suddenly on May 4, 1842. Jane Porter, who had joined him in Russia, then returned to England and took up her residence with her eldest brother at Bristol, where she died on May 24, 1850.

PORTER, NOAH (1811–1892), American educationalist and philosophical writer, of Puritan ancestry, was born in Farmington, Conn., on Dec. 14, 1811. He graduated at Yale college in 1831, for two years taught in the New Haven grammar school, was for two years a tutor at Yale, then becoming a Congregational minister. He was elected professor of moral philosophy and metaphysics at Yale in 1846, and from 1871 to 1886 he was president of the college. His best-known work is *The Human Intellect, with an Introduction upon Psychology and the Human Soul* (1868), abridged as *The Elements of Intellectual Science* (1871). He died in New Haven March 4, 1892.

See *Noah Porter, a Memorial,* edited by G. S. Merriam (1893).

PORTER, WILLIAM SYDNEY: *see* HENRY, O.

PORTES GIL, EMILIO (1891–), Mexican statesman and provisional president (Dec. 1, 1928, to Feb. 5, 1930), was born at Ciudad Victoria, Tamaulipas, on Oct. 30, 1891. He studied in the law school of the National university and was graduated in 1915 at the peak of revolutionary disorders. He took a prominent part in the revolutionary movement, serving in a judicial capacity in Sonora during Calles' administration as governor and in the legal section of the War Department while Gen. Obregon was Secretary of War. In 1919 he worked in favour of the candidacy of Obregon and was imprisoned for a time for his activities. Following the overthrow of Garranza in 1920, Portes Gil acted as provisional governor of Tamaulipas and subsequently was elected a deputy from that State for four terms. He took office as elected governor of Tamaulipas in Feb. 1925 and held this post until appointed Secretary of the Interior and head of the cabinet by President Calles in Aug. 1928. While governor, he worked on behalf of labour legislation and did much for the labouring and agrarian classes of his State. The number of schools in the State was increased from 280 to over 600 and special attention was given to agricultural and industrial instruction. He also abolished gambling and established partial prohibition by closing the groggeries in villages and on haciendas.

Portes Gil was elected provisional president of Mexico by a unanimous vote of the Mexican Congress (Sept. 25, 1928) to fill a temporary gap caused by the assassination of president-elect Obregon. His selection was supported by President Calles as well as the powerful Agrarian party. His brief administration was marked by a revolt in Vera Cruz and northern Mexico, and he retired in 1930 after the election of Pascual Rubio. In 1931 and 1932 he was minister to France and from 1932 to 1934 attorney-general of Mexico. In the latter year he was appointed secretary of foreign affairs in the cabinet of President Cardenas.

PORT GLASGOW, a burgh and seaport of Renfrewshire, Scotland, on the Firth of Clyde, 20¼ m. W.N.W. of Glasgow by L.M.S.R. Pop. (1938) 19,785 It is now continuous with Greenock. The industries include large shipbuilding and engineering works and sawmills. The area of the port (with wet and graving docks) is 16½ acres. The graving dock (1762) was the first dock of the kind in Scotland. In 1775 Port Glasgow was created a burgh of barony. Adjoining the town are the ruins of Newark Castle (16th century).

PORT HARCOURT, a port of Nigeria, British West Africa, on the Bonny river, 41 m. above its mouth. All ships which can cross Bonny Bar, where the depth of water is 23 to 25 ft. can ascend to the port and berth alongside the wharfs, ample facilities for loading and unloading cargo and bunkering coal being provided. Port Harcourt dates from 1914, being named after the then secretary of State for the Colonies. It owes its existence to the need of a port for the Udi coalfields. It serves a valuable oil-palm district and ranks second among the ports of Nigeria.

PORT HUDSON, a village in East Baton Rouge Parish, La., U.S.A., on the left bank of the Mississippi, about 135 m. above New Orleans. At the sharp turn of the Mississippi here the Confederates in 1862 built on the commanding bluffs powerful batteries covering a stretch of about 3 m., their strongest fortifications along the Mississippi between New Orleans and Vicksburg. On the night of March 14, 1863, Admiral Farragut, with seven vessels, attempted to run past the batteries, commanded by Brigadier-General William M. Gardner, but four of his vessels were disabled and forced to turn back, one, the "Mississippi" was destroyed, and only two, the "Hartford" and the "Albatross" got past. Gen. N. P. Banks's land attack, on May 27, was unsuccessful, the Union loss, nearly 2,000, being six times that of the Confederates. A second attack on June 14 entailed a further Union luss of about 1,800 men. But on July 9, two days after the news of the surrender of Vicksburg, after a siege of 45 days, Gen. Gardner surrendered the position to Gen. Banks with about 6,400 men, 50 guns, 5,000 small arms and ammunition, and two river steamers. The Union losses during the siege were probably more than 4,000; the Confederate losses about 800. The capture of Vicksburg and Port Hudson secured to the Union the control of the Mississippi.

PORT HURON, a city of south-eastern Michigan, U.S.A., 60 m. N.N.E. of Detroit, at the lower end of Lake Huron, on the St. Clair river at the mouth of the Black, and opposite Sarnia (Ontario), with which it is connected by a railway tunnel 6,025 ft. long and the Blue Water International bridge; a port of entry and the county seat of Saint Clair county. It is on federal highway 25, and is served by the Grand Trunk, the Pere Marquette, motor coach and truck lines and lake and river steamers. The population was 25,944 in 1920, 24% foreign-born white, and 32,759 in 1940 by the federal census. Port Huron is in a summer-resort region known as the Lake Huron beaches, stretching for 100 mi. along the lake to the north, and of the manufacturing district which borders the St. Clair for 30 mi. to the south. Its water-borne commerce is considerable.

Port Huron's factories had an output in 1940 valued at $61,643,850. A thick deposit of salt was discovered under the city in 1883, and gas and oil have also been found in the locality. Port Huron is the headquarters of the Women's Benefit association, which has assets of $42,518,238. In 1686 the French established Ft. St. Joseph within the present limits of Port Huron. It came into the possession of the British in 1761, and in 1814 was occupied by American troops and renamed in honour of General Charles Gratiot (1788–1855). The settlement which grew up around it was organized as a village in 1840, and in 1893 it was annexed to Port Huron. Another settlement (at first called La Rivière de Lude, and after 1828 Desmond) was made near the fort in 1790 by several French families. It was incorporated as the village of Port Huron in 1840 and chartered as a city in 1857.

PORTICI, a town of Campania, Italy, in the province of Naples, 5 mi. S.E. of Naples by rail, on the shores of the bay, and at the foot of Vesuvius. Pop. (1936) 26,049. The palace, erected in 1738, once contained the antiquities from Herculaneum, now removed to Naples (with the exception of some mosaic pavements), and in 1873 it became a government institute of agriculture. Just beyond Portici, on the southeast, is Resina (pop. in 1936, 30,707), on the site of the ancient Herculaneum, with several fine modern villas. The inhabitants are engaged in fishing, silk-growing and silk-weaving. The town was completely destroyed by the eruption of Vesuvius in 1631.

PORTICO, in architecture, a term loosely applied to many types of structure in which columns or colonnades are the most important part. Thus an entrance porch with columns is called a portico, and the colonnade at the end of a classic temple is also so named. In Rome an arcaded and colonnaded building surrounding an open space or temple, and built for a public covered promenade was termed a *porticus,* like the portico of Octavia (built by Augustus and restored by Septimius Severus and Caracalla, 203), of which there are extensive remains.

PORT JACKSON: see SYDNEY.

PORT JERVIS, a city of Orange county, New York, U.S.A., 70 m. N.W. of New York city, on the Delaware river at the mouth of the Neversink, where New York, New Jersey and Pennsylvania meet. It is on Federal highway 6, and is served by the Erie and the New York, Ontario and Western railways. Pop. (1920) 10,171 (90% native white); and in 1940, federal census, 9,749. Port Jervis is in a region of beautiful mountain scenery, waterfalls, lakes and trout streams. The Erie has extensive shops in Port Jervis, and the city has various other manufacturing industries.

Hydroelectric power is available from a development at Mongaup falls. Port Jervis was laid out in 1826, soon after work began on the Delaware and Hudson canal (now abandoned) and was named for the engineer who constructed the canal, John Bloomfield Jervis (1795–1885). It was incorporated as a village in 1853 and as a city in 1907.

PORT KEMBLA, a harbour and port on the east coast of New South Wales, Australia, in the Illawarra District, distant some 55 miles south of Sydney. It exports considerable quantities of coke in addition to coal from Dapto. A large electrolytic refining and smelting works treats ores (chiefly copper) from various parts of the Commonwealth (capacity: 47,000 tons refined ore per ann.), and has fertiliser and metallurgical works (copper wire, cables, etc.) associated with it. More recently Port Kembla has been chosen as the site for a steel industry. The Hoskins company (see LITHGOW)—which owns a coking-plant at Dapto—in conjunction with two English steel firms and a Melbourne shipping line, are erecting works with a view to large-scale production, while the New South Wales Government is improving the inland connections by constructing a line to Moss Vale (on the main Southern Line). Pt. Kembla is the third port of New South Wales; the shipping which used it in 1925–26 amounted to 660,000 tons. (See also WOLLONGONG.)

PORTLAND, EARL OF, an English title held by the family of Weston from 1633 to 1688, and by the family of Bentinck from 1689 to 1716, when it was merged in that of duke of Portland. Sir Richard Weston (1577–1635), according to Clarendon "a gentleman of very ancient extraction by father and mother," was the son and heir of Sir Jerome Weston (c. 1550–1603) of Skreens, in Roxwell, Essex, his grandfather being Richard Weston (d. 1572), justice of the common pleas. He was lord high treasurer from 1628 until his death on March 13, 1635. He received the earldom in 1633. The title became extinct in 1688. In 1689 it was revived by William III., who bestowed it upon William Bentinck (see below).

Sir Richard Weston must be distinguished from a contemporary and namesake, SIR RICHARD WESTON (*c.* 1579–1652), baron of the exchequer. Another SIR RICHARD WESTON (*c.* 1466–1542) was a courtier and a diplomatist under Henry VIII.; his son was SIR FRANCIS WESTON (*c.* 1511–1536), who was beheaded for his alleged adultery with Anne Boleyn. This Sir Richard had a brother, SIR WILLIAM WESTON (d. 1540), who distinguished himself at the defence of Rhodes in 1522, and was afterwards prior of the Knights of St. John in England. A third SIR RICHARD WESTON (1591–1652), was mainly responsible for introducing locks on the Wey and thus making this river navigable.

Another family of Weston produced Robert Weston (c. 1515–1573), lord chancellor of Ireland from 1566 until his death on May 20, 1573.

Much of the earl of Portland's correspondence is in the Public Record Office, London. For his political career see S. R. Gardiner, History of England (1883–84), and L. von Ranke, *Englische* Geschichte (Eng. trans., Oxford, 1875).

PORTLAND, WILLIAM BENTINCK, EARL OF (*c.* 1645–1709), English statesman, was born, according to the Dutch historian, Groen van Prinsterer, in 1645, although most of the other authorities give the date as 1649. The son of Henry Bentinck of Diepenheim, he was descended from an ancient and noble family of Gelderland. As page of honour and gentleman of the bedchamber to William, prince of Orange, he secured the friendship of William; which he justified by his prudence and ability. In 1677 he was sent to England to solicit for the prince of Orange, the hand of Mary, daughter of James duke of York, afterwards James II, and he was again in England in 1683 and in 1685. When, in 1688, William was preparing for his invasion Bentinck went to some of the German princes to secure their support, or at least their neutrality, and he was also a medium of communication between his master and his English friends. He superintended the arrangements for the expedition and sailed to England with the prince.

The revolution accomplished, Bentinck was made groom of the stole, first gentleman of the bedchamber, and a privy councillor; and in April 1689 he was created Baron Cirencester, Viscount Woodstock and earl of Portland. He fought at the battle of the Boyne (1690), the battle of Landen, and at the siege of Namur, but his main work was of a diplomatic nature. He helped to arrange the peace of Ryswick (1697); he negotiated with Louis XIV for a partition of the Spanish monarchy, and as William's representative, signed the two partition treaties. Jealous of the rising influence of Arnold van Keppel, earl of Albemarle, Portland resigned all his offices in the royal household in 1692, but he did not forfeit the esteem of the king, who continued to trust and employ him. He received 135,000 ac. of land in Ireland, and only the strong opposition of a united house of commons prevented him obtaining a large gift of crown lands in north Wales. For his share in drawing up the partition treaties he was impeached in 1701, but the case against him was not proceeded with. He was occasionally employed on public business under Anne until his death at his residence, Bulstrode in Buckinghamshire, on Nov. 23, 1709. Portland's eldest son Henry (1680–1724) succeeded as 2nd earl. He was created marquess of Titchfield and duke of Portland in 1716.

See G. Burnet, *History of My Own Time* (Oxford, 1833); Lord Macaulay, *History of England* (1854); L. von Ranke, *Englische Geschichte* (Eng. trans, Oxford, 1875); and especially Onno Klopp, *Der Fall des Hauses Stuart* (Vienna, 1875–88); M. E. Grew, *William Bentinck and William III* (1924). *See* also Dr. A. W. Ward's article in vol. iv of the *Dict. Nat. Biog.*

PORTLAND, WILLIAM HENRY CAVENDISH BENTINCK, 3RD DUKE OF (1738–1809), prime minister of England, son of William, 2nd duke (1709–1762), and grandson of the 1st duke. He was born on April 14, 1738, and was educated at Oxford. Under the marquess of Rockingham he was, from July 1765 to December 1766, lord chamberlain, and on the return of Rockingham to power in April 1782 he was made lord lieutenant of Ireland. After the short ministry of Shelburne, succeeding the death of Rockingham, the duke of Portland was selected by Fox and North as a "convenient cipher" to become the head of the coalition ministry, to the formation of which the king was with great reluctance compelled to give his assent. The duke held the premiership from April 5, 1783 until the defeat of the bill for "the just and efficient government of British India" caused his dismissal from office on Dec. 17 following. Under Pitt he was, from 1794 to 1801, secretary of state for the home department, after which he was, from 1801 to 1805, president of the council. In 1807 he was appointed a second time prime minister and first lord of the treasury. Ill health caused him to resign in October 1809, and he died on Oct. 30. He owed his political 'influence chiefly to his rank, his mild disposition, and his personal integrity.

PORTLAND, a city of eastern Indiana, U.S.A., 80 mi. N.E. of Indianapolis, near the headwaters of the Salamonie river; county seat of Jay county. It is on federal highway 27, and is served by the Nickel Plate, the Pennsylvania and electric railways. Pop. (1920) 5,958 (98% native white); 1940, 6,362.

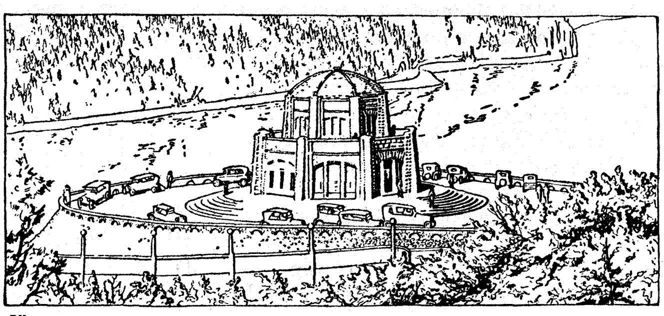
PORTLAND, the largest city of Maine, U.S.A., a port of entry and the county seat of Cumberland county; on Casco bay, 110 mi. N.E. of Boston. It is on the Atlantic highway, and is served by the Boston and Maine, the Grand Trunk, and the Maine Central railways, and by steamship lines operating to Boston and New York, the Pacific ports and the principal ports of the United Kingdom. Pop, in 1930 was 70,810 (83% native white); in 1940 it was 73,643. Its area of 21.6 sq.mi. includes a peninsula 3 mi. long and averaging less than a mile in width (the original town); another peninsula to the east, occupied by the former city of Deering (annexed in 1899); some encircling territory on the mainland; and islands aggregating 2,585 acres. The eastern promenade (161 ft. above sea level) overlooks beautiful Casco bay, its 365 islands and seven lights, the shores of Falmouth and Cape Elizabeth, to the open Atlantic beyond. From the western promenade (altitude 169 ft.) the view embraces a broad sweep of country, to the White mountains of New Hampshire. The public buildings are dignified and substantial. In Congress street (the main thoroughfare) is the Portland observatory (rising 227 ft. above tidewater) built in 1807 to sight incoming vessels. Many of the dwellings are in the simple and gracious architectural style of the 18th and early 19th century. Of special interest are the birthplace of Henry Wadsworth Longfellow and his early home in Congress street (now a museum) built by his grandfather Gen. Peleg Wadsworth in 1785–86. The Eastern cemetery (set aside in 1668) contains the graves of many citizens of note. The oldest church building in the city (1825) is that of the First Parish church (Unitarian), established in 1809. In Williston church (Congregational) the Young People's Society of Christian Endeavor was founded in 1881 by the Rev. Francis E. Clark. Portland is the seat of the Maine General hospital, a U.S. marine hospital, the Maine Institution for the Blind and has several special libraries and museums, besides the public library of 122,505 volumes.

The harbour has a water frontage of 8.5 miles. It is protected by a breakwater, and defended by Forts Preble, Levett, Williams and McKinley. The traffic in 1938 amounted to 799,000 short tons, of which almost 700,000 tons represented exports to foreign countries (largely lumber, scrap iron and canned vegetables) and about 100,000 tons imports (chiefly wood pulp, fuel oil, coal and china clay). The coastwise commerce (3,940,000 tons) consisted largely of textiles, coal, petroleum products, canned goods, paper and general merchandise. The output of the city's diversified manufacturing industries in 1937 was valued at $123,795,111. The fisheries are still important, but shipbuilding had declined but was revived in 1941. Bank clearings for 1940 aggregated $105,-480,724. The assessed valuation for 1940 was $77,164,450 for local purposes and $78,521,715 for state purposes. Since 1923 it has operated under a council-manager form of government.

The Indian name for the peninsula which constitutes the heart of Portland was Machegonne. It was first settled by George Cleaves and Richard Tucker in 1632. The early settlement, known by various names, was destroyed by the Indians in 1676, and again by the French and Indians in 1690, after which it remained desolate until 1715. In 1719 the town of Falmouth was organized, including Falmouth Neck (now Portland). On Oct. 18, 1775, it was bombarded and burned by a British fleet in punishment for showing its sympathy for the patriotic cause. Falmouth Neck was incorporated in 1786 as the town of Portland. It was the capital of the state from 1820 to 1832, and on April 30, 1832, adopted a city charter. About 200 ac. in the centre of the city was destroyed in 1866 by a fire resulting from a Fourth of July celebration. Portland was the birthplace of Henry Wadsworth Longfellow, Thomas Brackett Reed, Edward Preble, George Henry Preble, Mrs. Parton ("Fanny Fern"), Nathaniel Parker Willis, Seargent Smith Prentiss and Neal Dow, and was the home of William Pitt Fessenden, Theophilus Parsons and Simon Greenleaf.

PORTLAND, the largest city of Oregon, U.S.A., on the Willamette river, at its confluence with the Columbia, 110 mi. by water from the Pacific ocean, 118 mi. S.S.W. of Seattle, 700 mi. N. of San Francisco and 2,391 mi. from Chicago; a port of entry, the county seat of Multnomah county, and the financial, commercial and industrial centre of the vast Columbia River basin. It is at the intersection of the Pacific and the Columbia River highways; is a station on the Pacific coast airway; and is served by the Great Northern, the Northern Pacific, the Southern Pacific, the Union Pacific, and the Spokane, Portland and Seattle railways, electric interurban trolley and motor coaches, and over 50 steamship lines with sailings to all the principal ports of the world. Portland's population was 301,815 in 1930 and 305,394 in 1940. It ranked 27th in the country and had a metropolitan population of 406,406.

The city covers 63.5 sq.mi. on both sides of the Willamette river, rising to heights commanding magnificent views of the river valleys and of the snow-clad summits of Mt. Hood, 50 mi. E. by



BY COURTESY OF THE PORTLAND CHAMBER OF COMMERCE
VISTA HOUSE ON CROWN POINT. PORTLAND

S. (11,225 ft. high), Mt. Jefferson, Mt. Washington, The Three Sisters and other peaks of the Cascade range. The climate is mild and equable, with normal winter temperature 40·9°, normal summer temperature 65.3'—annual 53·1°, and an average annual precipitation of 41.6 in., of which 31.8 in. falls in the winter months. Violent storms and earthquakes are unknown. The annual rose festival in June is one of the famous events on the Pacific coast. The city park system embraces 2,292 ac., and includes 24 playgrounds, 3 public golf courses, 59 public tennis courts, 13 baseball diamonds, 7 swimming pools and a zoological garden. In one of the parks are the International Rose Test Gardens of the American Rose society. There is a public auditorium with a seating capacity for 6,600.

The municipal water supply comes from the Bull Run lake reserve, 3,000 ft. high in the Cascades, fed by melting snow from Mt. Hood. It is sufficient for a population of 2,000,000, is admirably suited for use in the colouring and manufacture of textiles, and is so pure that it does not need to be distilled for use in medical prescriptions or batteries.

The general death rate (12.9) is above average, but the infant mortality rate (35.7) is among the lowest in the country.

Since 1913 the city has operated under a commission form of government. The assessed valuation of property for 1940 was $263,376,090.

Portland is the seat of the University of Oregon Medical school, a branch of the extension division of the University of Oregon; the Northwestern College of Law, the North Pacific College of Dentistry, Pharmacy and Optometry, Albany College, Portland University, Hill Military Academy, several private junior colleges and preparatory schools; and Reed college, founded by Simeon G. Reed and his wife (pioneers of 1854) and opened in 1910.

There are 78 grade and 10 high schools.

The fine fresh-water harbour has a shore line of 29.5 mi. within the city limits, 6·5 mi. of docks, berthing space for 100 vessels and 65 ac. of cargo space. Over $50,000,000 has been invested by federal and municipal governments and private interests in channel improvement and port facilities. Rock jetties at the mouth of the Columbia protect the entrance and the river channel, which accommodates ships of 35 ft. draft at zero stage all the way to Portland. Port facilities are ample and modern. They include three municipal terminals, with cold-storage plants, a 2,053,800 bu. elevator, storage tanks for oil and molasses and efficient handling equipment; 7 lumber, 12 flour and grain, 10 oil, 10 general cargo docks, privately owned. The water-borne commerce amounted to 9,527,996 tons in 1939, valued at $308,932,477. Foreign commerce amounted to 110,336 tons of imports and 964,581 tons of exports.

Outbound cargoes consist largely of lumber, wheat, flour, canned and fresh fruits, paper and paper pulp, scrap iron, doors, furniture and ready-made houses, plywood, box shooks, battery separators, dried prunes and beans, onions and potatoes. Copra, coffee, burlap bags, sugar and bananas are leading articles among the imports.

In 1939 exports from the Oregon customs district, of which Portland is the headquarters, were valued at $30,422,795; imports at $8,269,144.

Portland is the leading wheat and lumber shipping port on the Pacific coast.

Nearly one-third the manufacturing of the state is concentrated at Portland. In 1939 the aggregate output of the 759 manufacturing establishments within the city was valued at $116,046,604. Lumber and lumber products in wide variety (shingles, sash. doors, windows, boxes, staves, shooks, furniture, ready-made houses, portable churches, barns and garages, and many smaller articles made of wood) are the leading manufactures. Others of importance are flour, cereals, bran and feeds; meat products, fruits and vegetables; machinery, logging and contractors' equipment, structural steel, automatic coal burners or stokers, oil burners, stoves, furnaces and other metal products; woollen textiles and clothing; paper and paper products; plywood, leather and rubber goods.

Debits to individual accounts in the local banking institutions amounted to $2,060,543,000 in 1940.

Portland was founded in 1845 by Francis W. Pettygrove from Maine and Amos L. Lovejoy from Massachusetts, who owned jointly a government land claim. They tossed a coin to decide whether the site should be named Portland or Boston, and Pettygrove won. By 1849 the new town was a thriving community. The city was chartered in 1851. In the year 1860, just before the Civil War, it had a population of 2,874, which increased to 8,293 in 1870 and (despite a destructive fire in 1873) to 17,577 in 1880. In 1883 railway communication with the east was established by the Northern Pacific, and in 1885 the federal government began to improve the mouth of the Columbia. By 1890 the population was 46,385, and in 1900, after annexations of territory, 90,426.

Since 1900 the area within the corporate limits has increased 50% and the population about fourfold. Since the war of 1914–18 the traffic of the port has more than doubled, and the foreign commerce has increased even more.

Building permits in the years 1935–40 represented values aggregating $45,435,045.

In 1905 an exposition and fair was held in Portland to celebrate the centennial of the expedition of Meriwether Lewis and William Clark to the region.

PORTLAND, ISLE OF, properly a peninsula on the coast of Dorsetshire, England; Chesil bank connects it with the mainland. Pop. of urban district (1938) 12,240. Area 4.5 sq.mi. It is 4 mi. long and nearly $1\frac{3}{4}$ mi. in extreme breadth, with an area of about $4\frac{1}{2}$ sq.mi. The shores are precipitous, and Portland is inaccessible from the sea except toward the south. The highest point is the Verne hill in the north. A raised beach is seen at Portland Bill. The substratum of the island is Kimmeridge clay, above uhich rest beds of sand and strata of Oolitic limestone, widely famed as a building stone. In the "dirt-bed" resting upon the Oolitic strata numerous specimens of petrified wood are found, some of great size. The G.W.R. and S.R. have a joint line south from Weymouth to Portland and Easton.

On the isle are the famous prison buildings, now a borstal institution. Portland castle, built by Henry VIII in 1520, is generally occupied by the commander of the engineers or of the regiment stationed on the island. On a rock on the eastern side are remains of a more ancient fortress, Bow and Arrow castle, ascribed to William Rufus. They are in the grounds of Pennsylvania castle, built by John Penn, grandson of William, governor of the Isle of Portland and founder of Pennsylvania.

A harbour of refuge was built by the admiralty, 1847–62. A breakwater stretching northward from the northeast corner of the island partially enclosed a large area of water naturally sheltered on the south and west. An inner arm ran nearly east from the island to a masonry head and fort, and an outer detached arm bent north to a circular fort, a narrow entrance for shipping being left between the two. Two new breakwaters were built after

1895 to close the gap between the end of the outer breakwater and the Bincleaves rocks near Weymouth. The defensive harbour thus completely enclosed has an area of 2,200 ac. to the one-fathom line, of which 1,500 ac. have a depth of not less than 30 ft. at low water.

PORTLAND CEMENT: see CEMENT.

PORT MAHON, the capital and principal seaport of Minorca, in the Spanish province of the Balearic islands. Pop. (1936) 18,000. Port Mahon is situated on the east coast, at the head of a deep inlet which extends inland for $3\frac{1}{2}$ m. It is an important harbour. (See MINORCA.) Mahon is the ancient *Portus Magonis,* which under the Romans was a municipium (Mun. *flavium* magontanurn), probably including the whole island under its authority. As the name suggests, it had previously been a Carthaginian settlement. The Moors, who occupied Minorca in the 8th century, were expelled by James I. of Aragon in 1232. Khair-ed-Din Barbarossa besieged and captured the city in 1535; and in 1558 it was sacked by a corsair called Piali. The British seized the island in 1708, and in 1718 declared Mahon a free port. In 1756 it fell into the hands of the French. Restored to the British in 1762, it was lost again in 1782. In 1802 it was finally ceded to Spain by the treaty of Amiens. Many of the houses date from the British occupation. The King's island is so called as the landing-place of Alphonso III. of Aragon in 1287; farther south-east on the shore is the village of Villa Carlos or George Town; and at the mouth of the port, on the same side, are the remains of Fort San Felipe, originally erected by Charles V. and twice the scene of the capitulation of British troops. Opposite San Felipe is the easily defended peninsula of La Mola (256 ft. high), which is occupied by extensive Spanish fortifications.

PORTO ALEGRE, a city and port of Brazil, capital of the state of Rio Grande do Sul, at the northern extremity of Lagoa dos Patos on the eastern shore of an estuary called Rio Guaiba, about 160 mi. from the port of Rio Grande at the entrance to the lake. The population of the *município* (275,678 in 1940) contains a large foreign element, chiefly German and Italian. The city has rail connection with all the main lines in the state. The Rio Guaiba, which is not a river, was once called "Viamão" because its outline is roughly that of the human hand, the rivers entering the estuary at its head corresponding to the fingers. The lower channels of these rivers (the Gravataí, Sinos, Caí, Jacuí and Taquari) are all navigable. Foreign trade is limited to light-draught steamers able to cross the bar at the entrance to the lake.

The city occupies a tongue of land projecting into the estuary, and extends along its shores. The climate is cool and bracing in winter but hot in summer. The mean annual temperature is slightly under 69" F., the average maximum being a little over 82° and the average minimum 59°. The annual rainfall is about $30\frac{1}{2}$ in. The city is laid out with broad streets. It is the chief commercial centre of the state, has shipbuilding yards and manufactures cotton fabrics, boots and shoes, iron safes and stoves, carriages, furniture, butter and cheese, macaroni, preserves, candles, soap and paper.

Pôrto Alegre was founded in 1742 by immigrants from the Azores and was first known as PBrto dos Cazaes. It was made a vila in 1803, and in 1807 the transfer of the capital from Rio Grande to PBrto Alegre was officially recognized. In 1822 it was raised to the rank of a city, and in 1841, as a reward for its loyalty in revolutionary wars of that province, it was distinguished by the title of leal e *valorosa* (loyal and valorous). The first German immigrants to settle near Pôrto Alegre arrived in 1825, and much of its prosperity and commercial standing is due to the German element.

PORTO FARINA, a town of Tunisia about 20 mi. E. of Bizerta, on the Ghar-el-Mela, a lagoon, also known as the Lake of Porto Farina, at the mouth of the Mejerda (the ancient Bagradas). Porto Farina was the naval arsenal of the piratical beys of Tunis and was bombarded by the English under Admiral Blake in 1655.

Ruins 10 mi. southwest, near the village of Bu Shater, are identified with the ancient Utica (*q.v.*).

PORTO MAURIZIO: *see* IMPERIA.

PORTO NOVO, a town of British India, on the Coromandel coast in the South Arcot district of Madras, 144 m. from Madras by rail. Pop. (1931), 13,762. It is famous for the battle in July 1781, in which Sir Eyre Coote with 8,000 men defeated Hyder Ali with 60,000 and saved the Madras presidency.

PORT OPERATION. The term "port operation" includes the receiving of ships in harbour, putting them in position to discharge or load their cargoes, the handling of the cargo and its despatch to or reception from inland destinations. The primary aim of all modern dock operation is to give ships quick despatch, *i.e.,* to keep down the time in port.

Before the cargo can be distributed it has to be landed, sorted to the various bills of lading, passed by the customs' officers, customs' and port charges paid, and the goods "released" by the shipowner to the merchant.

The shipper when despatching goods receives from the master of the ship a bill of lading, which is a negotiable document of title and which he sends to his consignee. While the goods are in the ship they are by law the property of the shipowner, and he has a prior lien on the goods for his freight. This lien is removed by the consignee taking the bill of lading to the shipowner and paying the freight, receiving in exchange a "release," which is the authority to the port authority or wharfinger to deliver the goods. But in order that the discharge of the ship shall not be delayed while the consignees are obtaining releases, the discharge of the goods is commenced at once into the transit sheds alongside. These transit sheds are, in the eye of the law, part of the ship. So long as the goods are in the transit shed the shipowner retains his lien for freight, and the port authority cannot allow the goods to leave the transit sheds until a release has been produced.

In the case of goods liable to customs' duty for which it is not desired to pay the duty at once, they are after being released passed under customs' guard into bonded warehouses. In the case of goods of high customs' value, such as wines and tobacco, the goods usually remain in bond until passed into consumption, the owner thus being relieved from the premature payment of heavy duty. Both transit sheds and bonded warehouses have, therefore, to be under double locks of the customs and wharfinger respectively, so that goods can only be handled in the presence of both parties.

To protect the customs, goods can by British law only be landed at duly authorized landing places called legal quays and sufferance wharves, the only difference between these terms is that the first is a permanent licence issued by the Treasury, and the second a restricted licence issued by the commissioners of customs. The services of the officers of the customs for watching goods in course of discharge in ordinary hours are paid for by the State, but all overtime is at the cost of the ship, and as customs' hours do not coincide with port hours, a ship working the ordinary hours has to pay at least one hour of customs' overtime, and more if she is herself working overtime.

"Rough cargoes" such as ores, timber, etc., which do not require shelter are landed at open quays, and the limitation of the shipowner's lien sometimes gives rise to difficult questions.

In the days before free trade, when nearly all goods were dutiable, it was the British custom to constitute a customs' area of the whole dock estate and to secure it within high walls and massive gates. These will still be found in the older ports, but in modern times it has become the practice to localize the control at sheds and wharves, and transit beyond these limits is free.

Custom of the Port.—A shipowner by his contract of carriage undertakes to deliver to the consignee the goods according to the bill of lading, which implies that he has to separate one man's goods from other people's goods and deliver each in one parcel. But this general rule of law is materially affected by the local "custom of the port" which varies everywhere and is a cause of much dispute and litigation. In some ports the custom ordains that the ship shall put the goods on the quay indiscriminately, and the work of sorting and removal is at the charge of the merchant; in some cases, goods are removed from the crane sling by one party, sometimes by the other, or again shared by the two parties. In some exceptional cases the cost of craning the goods from the hold is held to be on account of the merchant. For these reasons comparison of the working charges of different ports is always difficult.

The large cargoes now carried and the very mixed nature of the commodities necessitate in most cases landing on the quay for sorting before delivery. This requires much floor area, and has led to the introduction of two or more floor transit sheds to avoid excessive congestion of the cargo when landed. And for the subsequent delivery of these goods by rail or road, special facilities are needed. A single cargo of 8,000 tons of general cargo, if all had to be despatched by rail, would require 1,000 trucks to take it away. These trucks would occupy 3,000 yards of railway, which is some measure of the amount of siding accommodation which has to be provided for the efficient working of a discharging berth and also the great relief obtainable when a large part of the work is done by barge. The movement of these trucks has to be performed without interference with the work at adjacent wharves; hence the proportions which the three methods, barging, railway and road transport, bear to each other must largely affect the design of the shore equipment of a port.

The quick and economical movement of cargo is now largely obtained by the provision of mechanical appliances in substitution for manual labour, and the main staples when arriving or being despatched in whole cargoes, or in large quantities in mixed cargoes, are usually dealt with by special machinery, *e.g.,* for export, coal, and for import, grain, timber, meat and provisions, for all of which specially designed conveying machinery is installed at every port where the tonnage is sufficient to justify the expenditure. Mixed cargoes are discharged either by cranes on the shore or by the ship's gear. Such equipment is usually provided by the port authority.

The Provision of Port Machinery.— But as ships are often required to receive and deliver cargo in the open roadstead or at ports abroad not equipped with shore appliances, they must necessarily be fitted with booms and winches, and it is, therefore, often economical to make use of these appliances even when shore plant is available. In practice, however, competitive reasons compel port authorities to provide cranes, and in many cases more specialized working plant. Coal is shipped by means of (a) tips or hoists in which the wagon is lifted to a height above the ship's deck and the contents tipped into a shute to fall into the hold, (b) staithes, when the configuration of the ground permits, where the wagon is pushed to above deck level and the contents tipped into the hold, and (c) conveyors in which case the wagon at quay level is discharged on to a conveying band to the hatch. The last method is coming into increasing use. Grain is now mostly imported in bulk and is discharged by means of elevators which lift it in a continuous stream from the hold, convey it to the quay, and there deposit it on to conveying bands which carry it to silos where it is either stored or delivered by gravity into sacks for inland transport. These elevators are of either the bucket or the pneumatic type. When grain is imported in sacks the modern practice is to cut the bags in the ship and "start" the contents into bulk for discharge by this more economical method. Grain elevators may be either fixed on the quay or mounted on floating pontoons. The latter, though more costly, has the advantage of greater mobility. Grain discharging machinery has been passing through many stages of evolution during the last twenty years, and the pneumatic type seems to be gradually getting established. For inland transport in England and on the Continent (in contrast to all countries in America) the uneconomic method of carriage in sacks is still prevalent, but a small beginning has been made with bulk transport by rail.

Ores are now generally discharged by grab cranes which are self-filling and save the labour of loading into tubs. Iron is largely discharged by means of an electrified block on a crane which attracts the iron and when over the selected site releases by cutting off the current. Petroleum is usually discharged through pipe lines from the shore storage to the quays. This pipe is connected by means of a flexible hose to the ship's tank and pumped to the storage tanks. The same method is employed for vegetable oils and for molasses where the volume of trade is sufficient to justify the cost of the installation.

With free trade and the removal of customs restrictions, the tendency is increasing for the importing merchant to sell his goods "ex ship," and for goods to pass at once on discharge into consumption, but raw materials are still largely stored in dock warehouses or in adjacent warehouses of private owners for later consumption. Such deliveries are largely of a retail nature, and many of the chief ports have provided elaborate facilities for the storage, sampling, handling and accounting of warehoused goods. This branch of activity prevails in British and in some American ports more than on the Continent of Europe.

Rail Terminals and Docks.—At ports where barging is not the predominant method of handling cargo and at all modern ports to a greater or less degree, the railway facilities are an important feature as affecting the cost of distribution. There is great variety of method. At some railway-owned ports the docks are treated as a terminal goods station under main line control. At others, the railway working is self-contained under the docks superintendent. This affects the design of the railway system and the methods of working. In non-railway docks in some cases the railway company is given running powers to the quays, in others the port authority conducts its own railway operation. As in every properly conducted dock the first and principal aim is to give the ship despatch and with that object to avoid, by its rapid removal, the congestion of cargo at the ship's side, modern practice is to confide the control to the authority responsible for the despatch of the ship, providing an area away from the ship where the traffic is interchanged with the main line railway. In the United Kingdom this area is called the "exchange sidings"; in America the "belt line." One or more such points of interchange may be provided in accordance with the physical conditions of the main railways serving the port.

The post-war development of road transport has imported a new problem into the question of dock layout, and the need for providing facilities for economical loading to road vehicles in docks equipped only for loading to barge and rail requires many modifications of design.

Port Ownership.— The several descriptions of port ownership and operation may be classified under the following heads— (I) National ownership, (2) Trust ownership, (3) Municipal ownership, (4) Railway ownership, (5) Private ownership.

(1) Examples of National *Ownership* Are:— Rotterdam, and all the larger French ports. None are to be found in the United Kingdom except naval dockyards which do not come within the scope of this article.

(2) *Examples* of Trust *Ownership* Are:—In England, London and Liverpool; in Canada, Montreal and Vancouver; in United States, New York and New Orleans; in Australia, Sydney and Melbourne.

(3) *Examples* of *Municipal Ownership* Are:— In England, Bristol and Preston; on the Continent, Hamburg, which is the property of the Free City of Hamburg, and might perhaps be classed under national ownership; and Antwerp, the financing of which is divided between the State and the City.

(4) Railway Ownership.--Before the amalgamation of the railways of Great Britain in 1921 a number of docks were railway-owned, some having been acquired by railways when they had difficulty to maintain themselves as independent authorities, examples— Southampton, Hull; and others had been constructed by companies which, though nominally railway companies, were mainly ports (examples Cardiff and Newport), to serve the surrounding coal fields. Abroad the outstanding example is South Africa where all the ports are worked as part of the State owned railways. A few examples may be found in the United States, but the tendency in that country is to separate the port and railway ownership.

(5) Private *Ownership.*—In the United Kingdom few ports are to be found in this class, but the Manchester ship canal and the Gloucester Docks and Canal Company may be instanced.

The acceptance as a national liability of a larger or smaller proportion of the cost of construction, maintenance and working of a port prevails on the Continent much more largely than in the United Kingdom. For example, at Rotterdam and Antwerp the construction, dredging and maintenance of the harbour up to quay level are carried out by the State, as a national charge against the general revenues of the country, the super-structure above water level only being provided by the municipality and being the only portion of the charges to be recovered from the trade passing through the port. This is a potent cause of the lower charges prevailing on the Continent as compared with the United Kingdom. Under the policy which has generally prevailed in the United Kingdom of non-intervention by the State, economic forces have been allowed free play.

Public **Ownership.**—In the British dominions the policy of state or national ownership is almost universal, but the methods differ widely. In Australia the ports are financed by State loans and administered by nominated commissioners under the control of the Minister for Public Works; in South Africa, they are combined with the State owned railways under the general manager of the latter; in New Zealand and in India the ports finance themselves, but with the Government guarantee behind them, and are administered by a State appointed chief commissioner assisted by commissioners elected by the users of the port with, in some cases, representatives of the local inhabitants. In Canada ownership and administration are with the several States through the agency of nominated commissioners.

Port trusts are statutory bodies not working for a profit but they are obliged, in order to keep themselves solvent, to levy charges high enough to cover all their outgoings. The capital account has to bear all the cost of construction and equipping the port, and the revenue account has to bear the interest and sinking fund on such capital expenditure. Charges, therefore, have to be fixed so as to bring in sufficient revenue to pay this interest and sinking fund in addition to current working expenses. Surplus revenue is applied either to improving the facilities or reducing the charges of the port.

Municipal ports can, if the owners so desire as a matter of policy, be subsidized out of the general rates of the city, and in England these are the nearest analogy to the national ports of the Continent. As port works from their nature take a long time to construct, and as new trade offering naturally cannot wait while facilities are being provided, it is necessary if a port is to maintain its position to provide facilities in advance of the current demand. It is, therefore, in the power of a municipality, if it is prepared to accept a present burden upon its rates in the hope of being eventually recouped, to provide for the future to an extent which private enterprise cannot afford. In some cities of the United States the practice prevails of levying a specific rate on houses and property in aid of port improvements, and an early example in England is the case of Bristol, the largest municipally owned port, which from 1849 to 1897 levied a rate of £4,000 a year on houses for port purposes. Since the last date this levy has been merged in the general rate-in-aid to balance the revenue account which, however, for many years has been less than the annual contribution towards the sinking fund for the extinction of the capital.

Railway-owned docks also can, subject to certain provisions of the Railways Act of 1921 under which all the railways and their ports were amalgamated into four grouped systems, similarly meet any shortage of earnings of the port out of their general revenues, and this power similarly enables them to indulge in a more generous provision of facilities beyond the immediate needs of the trade in order to provide for future development.

Private Ownership. — In the case of the fifth class of ports, the property of private companies, the same end can only be obtained by the shareholders foregoing their dividends during a long fructifying period, which has actually been the experience of both the ports named above. In fact, in the case of the Manchester Ship Canal Company, now the outstanding example of a successful company port, the period of fruition was so long delayed that its capital and credit were exhausted and the Corporation of Manchester had to come to its aid by the provision of additional capital on which it had for a period to forego interest, and in consideration of which it was entitled to representation on the board of directors. But as the management is still with the company's directors, the classification of the undertaking here adopted remains correct.

The decadence of so many English ports under private ownership may be traced to this natural law. Ports constantly tend to become out of date owing to the increasing size of ships, and are faced with the alternative of seeing their present trade depart or of undertaking expenditure on which the return must be far distant, and which often proves to be beyond their unaided resources. London and Bristol, Southampton and Hull are examples of company owned undertakings which were becoming derelict when they obtained outside aid—the first absorbed by a powerful trust under the direct aegis of Government, the second by the local authority, and both have become self-supporting. The last two, though returning large profits to the railway companies which own them, have never directly given a commensurate return on their cost. Immingham and Fishguard, both railway owned from the beginning, have never been remunerative undertakings to their owners, or any great advantage to the trade of the country. The relation between the several classes of ports in the United Kingdom has been largely affected by the Railways Act of 1921 under which the great railway systems have become great port proprietors in competition with others dependent on their own resources. This implies a combination of the two systems of extraneous subsidy and self-containment, each of which has been applied successfully in some countries, but never before both in the same country, and it will be some years before the result can be determined.

Functions of Port Authority. — The functions of a port authority may be classified as conservancy and dock-ownership. The first head comprises all operations connected with making the port available for shipping, maintenance of navigation channels, surveying the same, buoying and lighting, removal of wrecks, signal service, pilotage service, supervision of foreshore to prevent interference with navigation channels.

The conservancy boundaries of a port are laid down in its Acts of Parliament, or in the case of ancient ports may be derived from Royal Charters, and if any portion of those waters form a highway to other ports, the lighting and charting of that portion is usually undertaken by the State, *e.g.,* Trinity House for English waters, and the Scottish Board of Lights for Scottish.

As dock owners the authority provides the equipment necessary for the accommodation of ships, their loading and discharging and the movement of their cargoes, including the provision of transit sheds, cranes and other cargo working machinery, power plants, railway lines and roads, etc.: "facilities," as working of lock gates (if any), lighting, berthing masters and everything necessary to enable a ship to get with safety to a position to discharge and load its cargo, and "services" which include everything connected with the handling of cargo, discharging or loading, receiving, sorting, despatching and storing. "Facilities" are necessarily provided by the dock owner. In regard to the rendering of "services," the practice varies within wide limits. In some ports these are rendered by the dock owners in whole, or in part. In others, the policy is to leave the services to private enterprise. The Port of Manchester is the only example in the United Kingdom of a statutory monopoly of all the services within the dock area, but all ports have power under their acts to provide services and to make "reasonable" charges therefor. The policy, however, differs materially in the various ports, some encouraging departmental working, and others favouring separate private enterprise. The principle of a complete monopoly of all services within the port limits is more prevalent in foreign ports.

The growing tendency to provide large scale equipment for handling staple commodities makes it seem possible that in the future, despite the objection that it would deprive the ship owners of the advantage of competition, economic reasons will force the more general undertaking of services by dock owners and the acceptance of the position by ship owners. In the case of Manchester the powers giving the authority the exclusive right are coupled with the proviso that their charges to their customers must not provide more than a ten per cent profit, and it is a generally accepted principle of port finance that the several departments, viz., conservancy, facilities and services should each be separately self-supporting, though many exceptions to this rule may be found.

In some cases the two functions of conservancy and dock ownership are combined in one authority; in others, they are under separate ownership and administration. There is considerable difference of opinion as to which is the better system, but it is perhaps more generally held that more satisfactory co-ordination can be secured, and therefore better efficiency and economy obtained when both functions are combined in the same authority. This is the case in most of the larger authorities of the United Kingdom, *e.g.*, London and Liverpool. Examples of ports where the conservancy authority is separate from the dock-owning authority are Southampton, Glasgow, Newport. There are cases also of which the following are examples—the East Coast rivers, the Tees, Tyne, Tay and Southampton—where the conservancy authority owns some docks, but other docks to a greater or less extent are provided either by the local railway company or by the local corporation. This entails a division of responsibility which it is sometimes complained leads to the neglect of the needs of trade.

Port Revenues.—The revenues of port authorities are principally obtained under the following heads: as conservancy authority, light dues, pilotage dues, and sometimes tonnage dues levied entirely on the shipping; as dock authority, dues on shipping calculated on the net register ton, import and export dues on the cargoes. Subsidiary, but sometimes very important, items of revenue are:—profits on the handling of cargo, warehousing, railway working round the docks, and rents of lands.

Most ports endeavour to obtain sufficient land to establish industries in the immediate neighbourhood of the docks, and owing to the high cost of inland transport, and the fact that with most commodities the finished article weighs less than the raw material required to produce it, the tendency is continually to move industries more and more from inland centres to the coast in the immediate neighbourhood of the great ports, and when possible to obtain the economic advantage of establishment within the dock area to avoid the cost of intermediate railway or road haulage.

A problem in port economics which has always been the subject of much difference of opinion is the proper distribution of the burden as between the ships and the goods they carry. The principle generally accepted is that the burden should be divided as equally as can be between the two, but this has many exceptions. Some ports adopt the policy of making the charges on shipping very light with a view that thereby freights will be kept low, greater cargoes obtained, and the revenue recouped from the tonnage of those cargoes. Other ports hold the view that the incidence of the port charges on the total expenses of a voyage is so small that it cannot affect the freight, and low charges on goods encourage manufacturers and merchants to use the port. This is the policy of all the railway-owned ports whose dues on goods are not only fixed on a low basis but who frequently render services for less than cost, recouping the cost from the profits on railway haulage.

An important factor affecting the quantum of port and harbour dues is the nature and the cost of the works necessary under the particular physical conditions of each harbour. In the United Kingdom, owing to the great variation of tides, it is in most cases necessary for the efficient working of ships to maintain a constant level in the docks by impounding the water within lock gates (a notable exception is Southampton, which has been favoured by nature with four tides in the 24 hours, reducing the difference between high and low water to a few feet). The Pacific and Indian oceans and the Mediterranean sea on the other hand, with their low rise and fall of tide, enable their ports to dispense with such expensive equipment, and the great ports of these oceans, Sydney, San Francisco, Singapore, Marseilles, etc., are examples where the features of the port as left by nature have been almost entirely retained. For this reason the capital cost, as measured by the accommodation afforded, is much lower and is reflected in the lower scale of dues which can be imposed.

The working expenses of a port are for the greater part of the nature of fixed charges, *e.g.*, interest and depreciation on the capital cost of the accommodation, working of the entrances which are the same whether they lead to few or to many berths, and whether the berths are occupied or not, and those expenses have to be distributed, as a rate per ton, over the shipping using the port. Hence economy of port charges can be obtained by concentrating the trade of a country into a few ports. But this may involve a longer and more expensive carriage to point of origin or destination, and there is constant play of these contending forces. England is a small island with a comparatively large number of ports. On the Continent of Europe, on the other hand, the area of distribution or collection runs into many thousands of square miles served in almost all cases by waterways concentrating in the mouths of a few great rivers. The number of ports is, therefore, fewer and the tonnage concentrated in each much greater than in Great Britain allowing of lower dues per ton to obtain the necessary revenue.

In England, again, the inland transport has mainly to be made by road or rail. On the Continent of Europe the goods are carried for the most part on waterways of a width and depth to take barges sometimes nearly as large as ocean-going ships.

Comparison is frequently made of the charges in English and Continental ports to the disadvantage of the former. The explanation can be found in the foregoing paragraphs, and may be summarized as—

(a) Substantial national expenditure not brought on to the port's accounts.

(b) Concentration of a greater tonnage over which to spread the fixed charges and

(c) The larger units and therefore the lower cost of transfer from ocean to land transport. (D. R.-J.)

IN THE UNITED STATES

The outline in the preceding article with respect to port operation in the United Kingdom is generally the operation found in the United States. The obligation of the steamship owner or the master, the method of cargo handling, customs regulation, provisions for customs custody and protection, are practically the same. The placing of all American port facilities under customs protection, however, depends upon the magnitude of the port's trade and the facilities with which the trade subject to customs supervision, operates. Ports commonly have all piers, or certain sections, supplied by supervisory customs agencies for the protection of customs and to facilitate the movement and clearing of merchandise. Likewise, bonded warehouses or bonded transit sheds have grown up, and the general system of providing customs facilities is similar to that of the United Kingdom.

Berthing Facilities.—A principal difference between English and American operation is in the type of facilities. In the quay system, generally adopted in European ports, the berthing structure runs parallel to the shore line and retards expansion because of the cost of land. However, this system probably provides the cheapest form of transfer from ship to shore, and is widely used. Newly created American ports have adopted, where possible in view of the cost of the necessary land and the saving in the cost of construction, the quay system. Generally, this development in America has been limited to ports built up a stream on rivers because of current conditions, lack of space and the difficulty of projecting piers at right angle to the shore line out into the stream.

The ports which avail themselves, for development purposes, of natural coast-line harbours such as Boston, New York and Newport have all adopted the pier system: the building of the structure out into the stream perpendicular to the shore line. The advantages of pier construction are: (1) increased berthing space, (2) building of facilities without interruption to the navigation of the stream itself, (3) less land per pier is required than that which would be used for a quay capable of berthing the same number of ships. A pier, suitable to accommodate four average ocean freight steamers, can be erected using only approximately 400 ft. of shore land whereas a similar structure built on the quay system would use approximately 2,500 ft. of shore front. The pier system has led to a somewhat different method of operation both respecting the loading and discharging of cargo as well as to the general port operation with respect to supporting warehouses and transferring facilities.

Mechanical Handling. — A great difference in the operation of ports in the United States and those of other countries is the absence of so-called mechanical appliances on American piers. The mechanical appliances required on the piers or quays to assist or to totally load and discharge cargoes is dependent upon the class of ships being handled. The steamships operating between American ports and other parts of the world are fully equipped to handle freight from and to the ship and the pier. No necessity has existed therefore for the installation of handling appliances on berthing structures such as are commonly seen in foreign ports.

Berthing Charges. — Another difference in European and American port operation is in business methods. Under the American system the steamship company assumes the entire charge for the berthing of the ship — paying for its berthing as well as its pier space which it uses to discharge or assemble its cargo. The shipper generally does not have imposed upon him any additional or auxiliary charges other than the freight rate which the ocean craft makes for the ocean movement or the flat rate which the inland railroad may charge for the movement to and from the port and to and from the particular pier at which a ship awaiting or discharging the cargo may be berthed.

With no progressive ocean freight or inland freight charge there is no inducement to the merchant, the shipper or consignee, to move his merchandise in any particular fashion which might reduce the cost of such movement, except where speed may be a factor. Moreover, because of the length of time which the merchant is given to move his material and because of certain local customs, the merchant prefers to have all of the merchandise discharged to the dock, sorted out and there held, availing himelf of the opportunity of selling direct from the dock or holding in case of a lower market. Thus the American system of handling merchandise at ports respecting international trade, involving the co-ordination of the inland system of transportation with the ocean system of transportation, is carried on in a relatively expensive manner. This being true, and the expenses being borne by not more than two parties — the owner of the steamship or the inland system of transportation — has caused the erroneous statement to be made that the cost of handling freight in American ports is lower per ton than in European ports.

Location and Development of Ports. — A tendency to develop greater inland ports has been noticed in recent years. Notable instances are the Canadian port of Montreal, and, in the United States, the artificially created port of Houston, Texas, also the agitation for the St. Lawrence waterway development. This latter is an effort to make ocean ports out of strictly lake ports and other interior points. Location of American ports near the coast-line generally has been possible because of favourable geographical advantages. Illustrating the advantages in this respect are the ports of New York, Norfolk, Newport News and Boston. Competition in sections of the United States for the creation of port facilities has caused some States to create ports artificially and to take other means than the general development of that of the older and more important ports on the Atlantic coast. This has sometimes led to the erection by public agencies of facilities operated at a loss in order to attract tonnage from the more important and older ports.

Until quite recently all port development in the United States has been of a private character while that of many other countries has been carried on by sovereign authority, either national, State or municipal and in many instances by a combination of the three, or through the activity of railroad companies. In 1928, however, there was a tendency to establish the development of ports by quasi-public bodies. The reason for this change of attitude is the increased importance placed on ports which the conduct of governmental operations under emergencies of war brought vividly before all public officers and public bodies. Moreover the development of ports situated in adjoining States has been of such great value to industrial progress, that the building of "outports" or smaller ports is being vigorously prosecuted. Thus due to the difficulty of development by private interests of a system of public control, the construction and operation of ports by the creation of "port authorities" is rapidly spreading.

The recently established American port authorities follow, in many respects, the fundamentals and basic organization of the port authorities of other countries. The water-front facilities have become so important to the place at which they exist that it has become a matter of police power of the sovereignty to see that public rights are protected. However, with the conflicts which exist in the legislation of some 48 States, there is no single method of port authority control in the United States. Some port authorities are organized without actual power to purchase, construct or operate port facilities but have police power. Others are formed with police power and with an indirect authority to purchase, construct, manage and operate port facilities on the basis of issuance of bonds, but without the credit of the State pledged to such bonds. Such port authorities have advantage of the low interest rates of sovereignty which creates it. In this respect alone, such authorities have an advantage in the matter of development not within the power of the private enterprise. The port authority is generally not subject to real estate taxes and other taxes which the private enterprise must bear. With this advantage, a development is more easily originated and carried to conclusion by a sovereign power operating through its agency of the port authority than might be expected for a development of the same facility by private capital.

Some of these adventures by quasi or public agencies representing a sovereign power have been attended by marked success, but the value of this phase has not been fully demonstrated to the degree of ownership, control, management and operations such as similar institutions in other countries have demonstrated. Federal regulation of ports rests with two departments of the Government. The War Department has exercised its power through the Corps of Engineers of the U.S. army. Since the World War, legislation has been passed which has placed in the hands of the War Department the duty of assisting in the matter of the development of ports and protection of ports to a greater degree than heretofore existed. Legislation creating the U.S. Shipping Board, likewise instituted a control jurisdiction over ports in certain respects by this body, comparable to that which the Interstate Commerce commission exercises over the interstate commerce of the country by railways. (P. L. G.)

PORTO-RICHE, GEORGES DE (1849–1930), French dramatist, born on May 20, 1849, at Bordeaux. When he was 20 his pieces in verse began to be produced at the Parisian theatres; he also wrote some books of verse which met with a favourable reception, but these early works were not reprinted. In 1898 he published *Théâtre d'amour*, which contained four of his best pieces, *La Chance de Françoise, L'Infidèle, Amoureuse, Le Passé.* The title given to this collection indicates the difference between the plays of Porto-Riche and the political or sociological pieces of many of his contemporaries. In Germaine, the passionate and exacting heroine of *Amoureuse,* Mme. Réjane found one of her best parts. In *Les Malefilâtres* (Odéon, 1904), also a drama of passion, the characters are drawn from the working classes. Later plays are *Le vieil homme* (1911) and *Le Marchand d'Estampes* 1918. He published in 1920, under the title *Anatomie sentimentale,* a collection of extracts from his works, which well illustrates his preoccupation with the *problème amoureux,* and his sense of the inevitableness of the continual duel between men and women. He was a member of the French Academy, and director of the Bibliothèque Mazarine. He died on Sept. 5, 1930.

See Etienne Rey, *G. de Porto-Riche* (1924); Henry Marx, *G. de Porto-Riche* (1924); and H. Charasson, *G. de Porto-Riche (1925).*

PORTO RICO or **PUERTO RICO** (second spelling, restored by the U.S. congress in 1932) is an island of the United States of America. It is the most easterly of the Greater Antilles, situated between 17° 50′ and 18° 30′ N., and 67° 30′ and 67° 15′ W. Its northern boundary is the Atlantic ocean, its southern the Caribbean sea, its western the Mona passage, its eastern the

Virgin Passage. It is situated about 70 m. E. of the island of Haiti, and about 40 m. W. of the island of St. Thomas, one of the Virgin islands and about 1,400 m. S.E. of New York city. It is nearly rectangular, with an average length from east to west of about 100 m. and a width of 35 to 40 miles. Its approximate area is 3,435 sq. miles.

Topography. — The island is the eastern extremity of a chain extending east and west over 1,000 m. and the northern extremity of a chain of smaller islands over 600 m. in length reaching to the northern coast of South America. These islands are the summits of submerged mountain ranges. The deep-sea soundings north of Puerto Rico disclose one of the most profound chasms on the globe, known as "Brownsons Deep." It measures more than 27,000 ft. The surface of Puerto Rico consists of plains from the mountains to the sea, while the interior and much the larger portion of the area consists of an irregular series of mountain ranges, the highest rising to an altitude of over 4 000 feet. These ranges extend from east to west across the island, but are broken in formation, with intervening valleys of surpassing fertility and beauty. The rivers are not navigable except for a short distance from the coast, but afford an abundance of water-power, and a supply for irrigation of the coastal plains and for the towns. The coastal plains are narrow on the southern slope. The principal mountain ranges are of the same geological period and of similar origin. They are of mixed volcanic and sedimentary formation, consisting chiefly of hornblende, gneiss and tuff, embedded in which at the higher altitudes are masses of blue limestone of the Cretaceous period. There is much underground drainage, the rivers often disappearing in chasms to reappear at a distance. Many of the mountains are honeycombed with caves, in some of which are found interesting Indian relics.

Gold mines were worked in the mountain regions and in the beds of the streams for some years in the first century of the Spanish conquest. According to official statistics, 2,700 lb. of gold were shipped to Spain from 1509 to 1536. This was probably the part belonging to the Crown of Spain, being one-fifth only of the amount secured. Some is still to be obtained by washing in the streams, but regular work has long been abandoned. Silver, lead and copper in small quantities were also discovered. Magnetic iron is found in many places in large quantities. It is of high grade and contains over 60% of metal. Transportation difficulties alone seem to prevent development. Manganese is sent to the States in considerable quantity. Marble deposits of the highest quality are found in large quantities. Granite is also found suitable for building. Limestone, gypsum, clays suitable for brick, tile and rough ceramics are abundant. Kaolin of superior quality suitable for the manufacture of porcelain is also found. No coal nor oil has so far been discovered. For the most part the mountain ranges are covered by erosion deposits forming a soil of deep, reddish clay loams and tenacious red clays. So cohesive and compact are these soils that they are maintained even in almost vertical positions. Cultivation is possible and profitable even to the tops of the mountains

Climate.—Puerto Rico is situated just within the torrid zone, but its climate is hardly tropical. The mean January temperature for the island as a whole is 73° F., and the mean July temperature is 79°, a range of only 6". The highest afternoon temperature is 86° and the lowest night temperature 68°. In the city of San Juan the highest temperature recorded is 94° and the lowest 62°. The mean annual temperature for Puerto Rico is 76·5°. The coastal plains have a somewhat higher average of about 78°. In the higher interior regions the mean temperature varies from 70° to 76°, according to the elevation above sea-level. The diurnal change in temperature from day to night is from 6" to 7°.

The average rainfall is 70 inches. For the north coastal region it is about 60 in., for the south about 30 in., and for the central mountain portion about 100 inches. This uneven distribution has been largely overcome by the irrigation systems, which collect in reservoirs the abundant rainfall of the northern side of the mountain ranges and tunnel through to the south plains which thus are regularly watered by irrigation. Winter rains are comparatively light, with a slight increase from February to May and thereafter the general average is maintained throughout the summer months. The rainfall is generally largest from September to November. The rains are sometimes heavy, but are usually of short duration. During the rare passage of a tropical hurricane the period of continuous rainfall may be extended. The average humidity during the day is about 70%, and during the night about 85%.

The trade winds, aided by the daily recurrence along the coasts of the cooi, invigorating sea breeze, constitute a most beneficent provision in the tropics. This is especially true in Puerto Rico. It is situated far out in the Atlantic ocean, nearly 1,000 mi. from the mainland. Thus it receives in full measure the trade winds which blow almost constantly from the northeast, veering sometimes to the east and southeast.

Puerto Rico is in the storm belt of the Caribbean region and is subject to occasional visits from the West Indies hurricane. It has suffered severe losses of life and property from these visitations. Fortunately these visits have been rare. Most of these storms occur from July to October.

Fauna and Flora. — Most of the domestic animals are now found in Puerto Rico. Bats, dolphins and manatees are the only indigenous mammals. As compared with many other countries of similar latitude the bird life of Puerto Rico is very poor. This is partly accounted for by its comparative isolation, and is sometimes explained by the destruction caused by tropical storms. Thus far 162 species and subspecies are recorded for Puerto Rico and the neighbouring islands. Birds of prey are rare. There is but one species of snake and specimens are rarely seen and are harmless. There are several types of the lizard group, feeding mostly on insects. They are harmless, and beneficial to plant life. There are five species of turtles, both of the small and large varieties. There are 291 species of fish.

The physical conformation of Puerto Rico, rising as it does from low coastal plains to mountains sometimes with altitudes of 4,400 ft. covered in most places with a generous and productive soil, is such as to furnish an astounding variety of plant life. The National Forest reserve at Luquillo, is a typical tropical forest with original growths of all kinds almost jungle-like in density and variety of tree and vine and shrub life. Compared with this the carefully cultivated orchards of the fruit growers afford a contrast most striking and interesting.

It is probable that before the coming of the Spaniards the entire island was densely wooded. Now little of the original forest growths remain. But there are coffee plantations, coconut groves, fruit farms and ornamental flowering trees and shrubs both indigenous and imported. There is a long list of what might be considered the common useful trees, among which are the bamboo, palm, cedar, ebony, calabash, whitewood, lancewood, boxwood and logwood. Among the fruit-bearing trees and shrubs are the avocado or alligator pear, orange, lemon, lime, grapefruit, almond, cocoa, coffee, coconut, nispero, pomegranate, gooseberry, raspberry, guava, banana, *plátano,* breadfruit, mango and papaya. Almost all the food plants are grown in Puerto Rico. Among the medicinal, useful and rare plants may be noted chicory, indigo, vanilla, castor, piumbago, ginger, sisal, mallow, pachouli, salvia, elder and aloe.

Government. — From 1493, the date of the discovery of Puerto Rico by Columbus, to 1898, when the first military governor was appointed by the president of the Gnited States, 142 governors ruled the island for Spain, the first being Ponce de León. Nearly all were army officers and most of them of inferior rank. By these officers Puerto Rico was governed practically on the same plan as other Spanish colonial possessions. The governor was supreme in military affairs, and practically so in civil The executive, legislative and judicial functions were for most of the time vested in the captain general. Whatever offices, boards or tribunals existed were used merely for the transactions of routine business. The captain general's authority was not limited except in a general way by the laws of the Indies and by royal decrees. This condition existed until 1870, when under a liberal government Puerto Rico mas made a province of Spain and given representation by deputies, elected by the people, in the Spanish Cortes. This lasted only four years when the provincial deputation was abolished and the island returned to its old status. In 1877 the deputation was re-established, and in 1897 Puerto Rico was given an autonomous government, but it never became operative because of the Spanish-American war and the consequent occupation of Puerto Rico by the American

THE CAPITOL IN SAN JUAN. ON THE NORTH COAST OF PUERTO RICO

army in 1898. The military government of Puerto Rico by the United States was of short duration, Oct. 18, 1898, to May 1, 1900. In April 1900 congress provided for a civil government in what was known as the "Foraker act," and on May 1, Charles H. Allen was inaugurated the first civil governor.

The first Organic act served a useful purpose, but the limitations on the exercise of self-government were unsatisfactory. As a result congress passed a new Organic act, which came into effect on March 2, 1917. Under its provisions the governor's term is made dependent on the pleasure of the president. Six executive departments were created: justice, finance, interior, education, agriculture and labour and health. Of these the heads of the departments of education and justice are appointed by the president, the others by the governor. The president also appoints the auditor and the members of the supreme court. The legislature consists of 19 senators and 39 representatives, all elected by the people. A resident commissioner to the United States, paid by the federal government, is elected by popular vote for a term of four years; he represents the island in the U.S. house of representatives, with a voice but without vote, and is recognized by all departments in Washington. There are four political organizations in the island—Union Republican, Socialist, Unification and Popular Democratic. At the 1940 election, the two first-named united on the same candidates, electing the resident commissioner. Groups of both of these parties voted with the Liberals. The Popular Democratic party won the largest number of seats in the legislature. The issues are mainly local, but there is great diversity of opinion as to what the future status of the island should be. All parties, however, seem practically united on the demand that the island be given the right to elect its own governor. Elections are held every four years. Suffrage is universal.

Production. — The products of Puerto Rico are principally agricultural. Sugar cane is grown and sugar is manufactured at the centrals or sugar factories. Tobacco is grown and there are cigar and cigarette factories. The principal products are sugar, tobacco, coffee and fruits.

Sugar. — It is said that in 1548 a rude sugar mill operated by oxen began the production of sugar in Puerto Rico. Eleven mills were in operation in 1581 producing 187 tons annually. With varying progress the amount produced reached 56,064 tons by 1850, and by 1899 it was 66,000 tons. By the time of the American occupancy, practically all the lands suitable for the production of cane had been brought under cultivation. While the cane lands had reached the limit so far as area was concerned, the product was small and the cost of production large. The causes were lack of fertilization, and proper cultivation, and antiquated mills and methods of operation. Then American capital was invested in sugar production, and progress since that time has been rapid. In the southern part of the island irrigation has brought some new land under profitable cultivation, otherwise the area has been almost stationary; but the production has been greatly increased. In 1901 only 68,900 tons of sugar were exported (value, $4,715,000). In 1915 the amount had increased to 427,955 tons (value, $45,000,000. The average production after 1930 was increased to over 900,000 tons. This amount is considerably below the island production capacity, which was restricted under the sugar laws of 1934 and 1937. The remarkable increase in productive capacity is the result of research and experiment, principally by insular government experts, who improved the sugar content and resisting varieties of the cane. The price of sugar has remained low. In 1938 the average price per pound was 2.94 cents; in 1939, 2.99; and in 1940, 2.79. Were it not for the increased production per acre and the conditional payments of the U.S. department of agriculture, losses would have resulted, for it is considered that the average cost of production in Puerto Rico is about 3.3 cents per pound.

Tobacco. — Tobacco has been produced for market since 1614. when by royal decree the colonists were permitted to plant and sell the crop. Small progress was made until 1870, when Cuban tobacco rose to great prominence and demand. For a time the Puerto Rican product was exported to Cuba and sold there as Cuban tobacco. This demand soon diminished and production decreased accordingly until in 1896, the tobacco exports were only one-third of the amount for 1846. Under the American administration, the United States tobacco industry entered Puerto Rico and undertook the production of tobacco and the manufacture of cigars, and the industry enjoyed a growing prosperity. The value of cigars exported increased from $306,000 (1901) to $7,196,365 (1926). The value of leaf tobacco exported increased from $1,232,058 (1907) to $20,587,484 (1927). Thereafter labour troubles and changes in American smoking habits reacted to cause a rapid decline in the Puerto Rican tobacco industry.

Coffee. — While sugar production is limited mostly to the low coastal plains and tobacco to the valleys, coffee is best produced in the higher altitudes, from 600 to 2,500 ft. In the higher valleys of the interior mountain ranges the coffee trees are principally grown. The trees are from six to 20 ft. high, with permanent leaves, a beautiful white blossom and a small flexible trunk only a few inches in diameter. Until the war of 1914–18 the industry enjoyed a growing prosperity. Its markets were mainly European, and these were never fully regained after the war. During the '20s, shipments decreased, but the product commanded a high price. The two destructive hurricanes of 1928 and 1932 still further depressed the industry.

Fruits. — About the only fruits grown in Puerto Rico of which account was made prior to the American occupancy were oranges, bananas and coconuts. The total value of fruit exports increased to $7,665,000 in 1940. The principal fruits now exported are grapefruit and pineapples. Grapefruit and pineapples are also canned extensively. Bananas and plantains are the largest fruit crop, alfhough but little exported. These are principal articles of food and are grown everywhere. Breadfruit is also extensively grown.

THE SCHOOL OF TROPICAL MEDICINE AT SAN JUAN

Other Products. — After the end of prohibition, the manufacture of rum grew rapidly, 1,137,235 gal. valued at $5,567,765 being exported in 1940. Upland rice is also produced. Beans are a profitable crop. Corn is grown quite extensively in the higher altitudes. As rice, corn and beans are the habitual foods of the people and are now principally imported, every effort is made to encourage their production. Exports of needlework products were valued at more than $15,000,000 in 1940. Molasses as a by-product of sugar was produced to the value in 1940 of about $1,500,000; much of this is also used in the manufacture of commercial alcohol.

Finance. — Up to the time of the Spanish-American war and the American occupancy, the crown appropriated an annual sum for Puerto Rico; this was the chief source of revenue. In the first year of the military government of the United States, the officers managed to collect $3,316,000. Increases in the amounts of revenue collected continued under the civil government until during the last three years it had reached the following amounts: (1937–38) $16,380,975; (1938–39) $15,424,505; (1939–40) $16,867,933. The total expenditures during these years were: (1937–38) $16,946,823; (1938–39) $16,355,715; (1939–40) $15,393,801. The fiscal years begin on July 1. The principal items of revenue collected each year during the years above stated were: excise taxes $10,000,000; income taxes $3,000,000; customs $1,200,000; insular property tax $400,000; U.S. revenue $1,500,000. The principal items of expenditure were about as follows: education $5,600,000; health $1,800,000; interior $800,000; police $1,200,000; treasury $1,100,000; justice $500,000; agriculture and commerce $370,000; labour $234,000; auditor $181,000; and executive $96,000.

The bonded indebtedness in 1940 was $27,200,000. Of this about $8,000,000 was for public improvements, such as the capitol building, an insane asylum, a penitentiary, hospitals and school buildings. About $7,000,000 was expended for permanent public roads and bridges and about $8,000,000 for irrigation and harbours. These last items are not a burden on the island as a whole, for the irrigation debt is paid by the tax levied on the lands receiving the benefits, and payment of the harbour improvement bonds is entirely met by harbour dues which more than pay in full the principal and interest of the debt. No default has ever been made in the payment of the principal or interest of the insular debt. Its bonds sell at a high premium. Interest rates are not more than 4½%. A sinking fund is provided for the payment of all outstanding bonds, principal and interest at maturity. The limit of insular indebtedness is placed by the Organic act at not more than 10% of the aggregate tax valuation of its property. The assessed valuation of real and personal property in 1941 was $311,800,349.

A comprehensive banking law was passed in 1923, under which proper government supervision, investigation and reports were made. The management of the banks is conservative and increasingly beneficial. The aggregate capital, surplus and undivided profits since the enactment of the law were, in 1924, $8,064,000; in 1925, $7,996,000; in 1926, $9,543,000; and in 1939, $5,700,000. The amount of loans was $28,200,000, June 30, 1939.

Commerce and Transportation.— Trade with the United States and foreign countries was valued in 1900, at $16,602,000; in 1938, at $175,391,961; in 1939, at $169,202,638; and in 1940, at $199,377,724. More than 90% of the island's commerce is with the United States, with which it has free trade. Shipments to the United States rose from $3,000,000 in 1900, to $90,902,156 in 1940. Puerto Rican purchases from the United States increased from $6,000,000 in 1900 to $100,517,184 in 1940. This unfavourable balance was due to extraordinary importations of defence materials. Total exports were in 1936, $99,298,046; in 1937, $114,953,827; in 1938, $82,077,178; in 1939, $86,486,570; and in 1940, $92,347,242. The total number of vessels which entered and cleared in 1940 was 2,424. As San Juan is about 1,400 mi. southwest of New York, which is the principal market for Puerto Rican products, ocean transportation is important. There are two principal steamship lines carrying both passengers and freight. Puerto Rico is becoming a distributing centre for the Caribbean. San Juan has passenger, air mail and air express service by Pan American clipper with Miami, the West Indies and the east and west coasts of South America. Three commercial cables extend from Puerto Rico, and there is government and commercial wireless service. A railroad following the coastal plains extends almost around the island. There are more than 1,300 mi. of public roads which reach all the cities and towns of the island and all parts of the interior. Hundreds of thousands of tons of freight are carried inland from the ports by motor truck, and everywhere there are motor vehicle and passenger service. Automobiles are in general use, the number of motors licensed exceeding 26,000. Many visitors from the States tour the island by automobile in the winter. The number of tourists visiting the island increased from 6,027 in 1936 to 15,842 in 1940.

Population.— The population of Puerto Rico in 1899, according to a census taken shortly after the island was ceded to the United States, was 953,243. In 1920 the population had grown to 1,299,809, and in 1940, to 1,869,255. This last figure represents an increase over 1930 of 21·1%, which is the largest decennial increase recorded since 1899. The population per square mile of land area was 549·8, as compared with 44·2 for continental United States, or with 545.9 for the highly industrialized state of Massa-

URBAN AND RURAL POPULATION OF PUERTO RICO, 1899–1940

chusetts. Of the 1940 population, 566.357, or 30·3%, lived in urban places, that is, in cities and towns of 2,500 or more. The colour line is much less sharply drawn in Puerto Rico than in continental United States. The census returns, which placed 76·6% of the 1940 population in the white classification, may therefore be considered somewhat of an overstatement, but the proportion definitely without admixture of coloured blood is a very substantial one. Practically all of the nonwhite population is Negro or mulatto. The population of the island and its principal cities is summarized in the following table:

Area	Population			Percent of increase	
	1940	1930	1920	1930–40	1920–30
The territory	1,869,255	1,543,913	1,299,809	21·1	18·8
Urban	566,357	427,221	292,841	32·6	45.9
Rural	1,302,898	1,116,692	1,006,968	16·7	10·9
Percent urban	30·3	27 7	22 5		
Principal cities and towns:					
San Juan	169,247	114,715	71,443	47.5	60·6
Ponce	65,182	53,430	41,912	22·0	27.5
Mayagüez	50,376	37,060	19,124	35·9	93·8
Caguas	24,377	[illegible]	[illegible]	[illegible]	[illegible]

Education.— There were probably no schools outside the cities of San Juan and San Germán as late as 1799. Some increase was made in private schools where instruction was paid for, but it was not until 1845 that any public primary schools were provided. In 1899, out of a reported total but 15% could read or write. The total number in all schools at that time was 22,265, or about 2% of the population. Of these 15,108 were boys.

The American military governors at once began reforming education, inaugurating a new system as nearly as possible like the free school system of the United States. In Jan. 1899, Gen. Henry called Dr. John Eaton to assume charge of education. Many changes were made: 16 English supervisors were appointed, who were also inspectors and teachers of English; they paid the teachers, accounted for the textbooks and supplies and secured suitable buildings for the schools. In 1899 an entire new code of school laws was promulgated. Dr. Eaton was succeeded by Mr. Clark, under whose direction the new code was put in successful operation. Mr. Clark was succeeded by Dr. Groff who served until the civil government was established, as commissioner of education. Thus an efficient free school system was established with schools in many localities. The first civil governor, Charles W. Allen, appointed Dr. Martin G. Brumbaugh as the first commissioner under the new law, who, with his successor Dr. Samuel McCune Lindsay, formulated and instituted the present system. In 1940 there were employed in the public schools 6,294 teachers, of whom 4,762 were women. The total enrolment was 286,098, 148,389 in the rural schools and 137,709 in the urban. The legal school year lasts ten months, and attendance is compulsory. There are 2,267 school buildings, with 5,201 schoolrooms. All new construction is of reinforced concrete, and ranges from one-room buildings in the remote country districts to consolidated rural school buildings with ten or 12 rooms, and to beautiful and extensive grade and high schools in cities and towns. Thirty-six new schools were completed in 1940. The expenditure for current expenses for the year was $6,396,398. The total cost per pupil enrolled was $25.85. There are 42 high and 87 secondary units. Courses in agriculture, health advancement, domestic economy, needlework, dressmaking and manual training are given.

The percentage of illiteracy has been reduced to 31·2%. There are adult-adolescent schools for illiterate, English and special students, evening high and eighth grade schools, and a school of the air. In 1940–41 there mere 559 school lunchrooms serving 34,743 students daily. There were 54 private accredited schools, with 11,328 students in 1940. All these accept the requirements and standards of the public schools and are inspected regularly by the supervisors.

University Training. — The University of Puerto Rico was established by the government in 1903. It was later entirely reorganized and is now being conducted as are the state universities of the United States. Its annual students number 4,993. The expenditure for 1940 was $1,678,706. A federal grant in 1935 made possible the construction of several buildings, among them an auditorium, air conditioned and seating 2,100. A feature is being developed of a Pan-American nature, by which students from the United States who desire special training for service in Central and South American countries, and those who from those countries desire special preparation for service in the United States and other English-speaking countries, may receive it there where work in the schools and colleges is conducted in both Spanish and English. A school of tropical medicine has been established under the joint auspices of Columbia university and the Puerto Rican university.

Customs and Habits. — The sugar factories and the larger tobacco and coffee plantations employ large numbers of men and women. There has been a great change in the manners and customs of the people since the American occupancy. The bankers, merchants and other business men have connections in the States and have largely developed American methods and customs. The lawyers, physicians and chief Government officials have for the most part received their professional training in the United States. The English language is taught in the schools and is used largely in business and trade. However, the language of the people is still Spanish and most of the periodicals are printed in Spanish.

The native rural citizen, born on the soil, clings to it tenaciously. After four centuries he still retains much of his Andalusian ancestry. He is rather small in stature and dark. He is unambitious but a good and obedient worker. He is rarely a land owner, but, for the most part, both a tenant and a farm-hand. He receives such pay as his landlord chooses; $1.40 a day is considered the standard wage. The coming of the free schools has awakened an ambition to learn.

Early History. — Puerto Rico was discovered by Columbus on his second voyage to the New World, Nov. 19, 1493. He landed on the western coast and took possession of the island in the name of Ferdinand and Isabella of Spain. This landing was the first and only time the feet of Columbus trod the soil of what is now United States territory. After replenishing his supply of water Columbus proceeded to Santo Domingo, first naming the island San Juan Bautista in honour of Prince Juan, heir to the Spanish throne. Occasional visits for supplies were made subsequent to the discovery, but no attempt was made to establish a colony until many years later. There was a marked difference between Columbus' first and second voyage. After months of trial he had at last been able by favour of the queen to equip his three small craft and collect a nondescript crew of 90 men to set sail on an unknown sea westward to an unknown destination. But when he returned, giving undoubted proofs of his discovery he at once became a hero. On his second voyage 17 ships and several smaller craft and over 1,500 men joined in the venture. Among the hidalgos and persons of rank who were anxious to share with Columbus the expected glories and riches of the voyage was Juan Ponce de León. After a stay in Santo Domingo of some 15 years, during which time he rendered valuable service to the colony, Ponce de León persuaded the governor to supply him with ships and men to make an exploration of the island which Columbus had named San Juan Bautista. With these he sailed in 1508 and landed first at the point he had visited with Columbus. Pursuing his voyage along the north coast toward the east he discovered the bay which afterward became the harbour of San Juan. Because of its excellence the explorer gave it the name of Puerto Rico or Rich Port. By a strange inversion the bay and capital city became San Juan and the island became Puerto Rico. Being favourably impressed, Ponce de León secured colonists and supplies in Santo Domingo and founded a settlement known as Caparra, near the harbour in an almost inaccessible location among the foot-hills. The situation was unfortunate and the colony moved to the island in the harbour on which is now located the city of San Juan. In 1510 Ponce de León became governor by order of King Ferdinand. Explorations were made with a view of finding gold but without much success, and the future did not seem promising for the colony. Trouble with the Indians threatened owing to the efforts made by the colonists to force them to work and dig for gold.

When discovered by Columbus Puerto Rico was peopled by a tribe of Indians known as Borinqueños. These Indians were a peaceful, agricultural people who had developed some progressive tendencies. The social organization was similar to that of the Indians on the northern continent; the unit was the clan and the chief was called the cacique. The cacique lived in a larger house than the others, which always contained the Zeni, or idol of the clan; his powers were supreme, and his wives were many. There would have been no trouble with these kindly disposed natives if the Spaniards had been disposed to treat them fairly. But the settlers were eager for gold and were determined to get it at any cost. The Indians were not used to hard work, having led an Arcadian existence which required little labour to maintain. When forced to dig in the hills or wash for gold in the streams all day under a tropical sun they succumbed or fled to the mountains to escape. The original number of the natives is difficult to ascertain; estimates vary from a few thousand to 600,000. By a system of allotment the whole population was gradually enslaved, and under this treatment the race was in a short time exterminated. In 1582 it was officially reported that none were left; all had died from ill-usage or disease or had successfully escaped to other islands.

Colonial Difficulties. — During these early years of colonization the island did not prosper. While considerable gold was secured the supply was soon practically exhausted. By the enforced labour of the Indians, and then by the labour of thousands of negroes brought from Africa, the gold digging continued until it became so unprofitable that it was abandoned. Its evil influence seemed to bring bad luck, and disaster followed disaster. The Caribs, a savage, warlike tribe inhabiting the southern islands of the West Indian group, made frequent incursions, carrying away what food and property were found and murdering the defenceless inhabitants. Hurricanes destroyed homes and crops. The people began to leave the island whenever opportunity offered. Then followed the attacks of the pirates and the French, Dutch and English freebooters which brought the record of calamities to a climax. San Germán, the most important town after San Juan, was completely destroyed by the French in 1554.

Conditions were so bad that petitions and delegations clamoured for protection. Spain was finally made to see that it would be necessary either to abandon or fortify her possessions. In 1533 the building of La Fortaleza was commenced. Its site was ill chosen and it was never completed as a fort but was converted into the Governor's palace and has since been so occupied. The high point at the entrance of the harbour was then covered by an excellently built and massive fortress which is still well preserved and is known as Morro Castle. San Cristóbal, a still larger and stronger fortress, was also constructed on the Atlantic side of the city. Several other points were fortified and the entire city was enclosed in a strong stone wall, two sides of which are still well preserved. These defensive works made the city of San Juan well nigh impregnable to attack from the sea. Sir Francis Drake attempted its capture in 1595, but the defence was so effective that the attack failed and his fleet retired. Later Lord George Cumberland entered the city by a land attack, but did not capture the fortifications and soon retired. In 1625, the Dutch also attacked and took the city, but did not capture Morro, and after partially burning the city they too retired. For many years, during which the European nations were striving for supremacy, the islands of the Caribbean region became the prizes for which the maritime powers contested; but Puerto Rico was never subjugated and remained a Spanish possession until 1898.

End of Spanish Rule. — The Spanish-American war began on April 21 and closed on Aug. 13, 1898. In May of that year Admiral Sampson, in search of Admiral Cervera's fleet, bombarded Morro for a short time without serious results and then retired. Gen. Nelson A. Miles, commander-in-chief of the U.S. forces, landed his troops on the southern coast of Puerto Rico on July 25. A short campaign followed, but the defensive Spanish forces were weak and retired before the advancing Americans. The people of Puerto Rico refused to join with the Spanish forces in defence of the island, and welcomed rather than resisted the coming of the Americans. When the news of the surrender was received, hostilities ceased and the American occupancy began.

American **Administration.**—On Oct. 18, 1898, the island was turned over to the American forces and Gen. John R. Brooke became military governor. In the work of policing the country, in the accompanying tasks of sanitation, construction of highways and other public works, accounting for the expenditure of public funds, and in establishing a system of public education, the military control which lasted until May 1, 1900, proved most effective in bridging over the period of transfer from the repressive control of Spain to the semipaternal system under the American civil government. But it was hardly adapted to teach a people utterly without political experience the essential elements of self-government. To meet this problem the U.S. congress passed the "Foraker act," under which civil government was instituted in May 1900. Under this act the American element exercised the controlling power; this, however, having proved distasteful to many Puerto Ricans, the Organic law was subsequently amended to give a wider native participation in the Government. The Olmsted act, approved by congress on July 15, 1909, placed the supervision of Puerto Rican affairs in the jurisdiction of an executive department to be designated by the president. He subsequently selected the war department. The people, however, demanded a larger measure of local control. The majority also asked for American citizenship and many other changes. As a result, congress passed a new Organic act (the Jones act), which came into effect on March 2, 1917. Under its terms Puerto Rico became a territory of the United States "organized but unincorporated," and citizenship of the United States was conferred collectively on Puerto Ricans, allowing the right to retain the old status if preferred. Only 288 persons so declared.

Means of transport, educational facilities and labour conditions have greatly improved since the American occupancy. Nearly all the beneficent legislation which has reflected the changing attitude of the people toward the labourer and social betterment has been extended to P'uerto Rico, which is now one of the most advanced of the states or territories which have adopted such laws. Chief among the laws bettering conditions of labour are the following: A law regulating working hours in public works; providing for the sale of public lands to labourers; determining the procedure of claims for wages; fixing the duties of employers in case of strikes; establishing workmen's settlements in the principal cities; providing a free dispensary with minor surgeons in shops and factories; regulating the weights to be carried by labourers; providing for the settlement of strikes and lock-outs; establishing a minimum wage for women and for labourers on public works; regulating the work of women and children and protecting them from dangerous occupations; creating a homestead commission; regulating the employment of minors and providing for the compulsory attendance of children in schools; regulating contracts for wages; providing workmen's accident, sickness and death compensation; creating a general employment agency, But these welfare measures failed to solve the problems of the increasingly overpopulated island with its agrarian economy: Recurring hurricanes, as in 1928 and 1932, joined with declining exports to aggravate the economic distress of the depression. The quota limitations on sugar and the application of the fair labour standards act to Puerto Rico caused a critical condition of unemployment principally among farm workers and needleworkers. The island shared in federal relief and rehabilitation expenditures. Rural resettlement and electrification, reforestation and rural and urban housing projects were completed. The plan to make the island the keystone of the U.S. Caribbean defences resulted in large military and naval troop concentrations.

PORT PHILLIP: see Melbourne.

PORT PIRIE, a seaport of South Australia situated near the northeastern extremity of Spencer Gulf. The harbour is poor, and Pirie won its place as the second port of the state because it is the nearest convenient maritime outlet for Broken Hill (*q.v.*), 205 miles inland (northeast). At Pirie the Broken Hill ores are smelted with coal from Newcastle (New South Wales), the smelters (which were burned down in 1920) being on a large scale.

The town is also the centre of an important wheat-growing area and wheat and minerals (zinc and silver concentrates and pig lead) constitute the bulk of the exports. (Pop., 1933: 11,680. Trade: £4,000,000 to £5,600,000 of which exports = £3,600,000 to £5,400,000. Total shipping, c. 750,000 registered tons. Trade figures are of 1927.)

PORTRAIT PAINTING. A portrait is a work of art representing an individual. It has been called a materialization of an individual soul. The pleasure we derive from the contemplation of a portrait is due to its value as a likeness as well as to its aesthetic qualities. A cast taken from life is not a portrait, nor is a photograph, nor any painting, drawing or sculpture which does not possess the harmony of line and colour which alone can give it aesthetic value.

A composer who wishes to give the impression of the song of birds does not imitate the notes of real birds, but invents notes which harmonize with his music. When heard alone they would have no meaning, but as part of the composition they convey to us the sensation of hearing birds sing. So the colours and lines of a picture gain significance only through their relation to each other. As in a poem not one word can be changed, so in a portrait not a touch can be added without unbalancing the whole. But whatsoever the aesthetic quality of a picture may be, it cannot be called a portrait unless it awakens in us the feeling that we are facing an individual with his physical and mental characteristics.

HISTORY

w

When the ancient Egyptians buried their dead they enclosed in the tombs statues representing the dead so that the Ka might find its earthly habitat in them. For this reason the statues of the ancient empire, and again of the Saïte epoch were of amazing realism: true portraits because they were at the same time superb examples of decorative sculpture. But as far as we kno , Egyptian painting remained a mere colouring of figures which had to conform to rigid formulae dictated by the priests.

The encaustic portraits found in Egyptian tombs of the Roman period are of small artistic value. As yet no fine examples of Greek or Roman painting have been unearthed. But from contemporary writers we learn so much about them that we have reason to believe that they were equal in quality to the sculpture. Inferior copies, such as the copy in mosaic of a painting representing Alexander the Great in the Battle of Issos, give us some idea of their style and colouring. The paintings of Pompeii and Herculaneum show that the Roman artists had an impressionistic method of indicating form and dividing colour.

As early as 1326 B.C. portraiture is mentioned by the Chinese. In accordance with the doctrine of filial piety, Confucius, in the 6th and 5th centuries B.C., taught that portraits of great men should furnish to the coming generation stimulating and ennobling examples. In temples some portraits of the best period have been preserved. Limited to line, the painters succeeded in producing the sensation of perfect modelling with mere contour. The primary condition of such a picture is to decorate a flat wall; the spaces covered are flat spaces. The artist invents a harmony of colour which intensifies and gives added charm to the harmony of line.

In Europe, for more than ten centuries, the Catholic Church placed restrictions on artists similar to those of the Egyptian priests. In A.D. 325 the Council of Nicaea proclaimed that the "composition of pictures should not be the invention of the artist but the rules and traditions of the church." In the 7th century St. Gregory the pope wrote, "Let the churches be filled with paintings that they who do not know their letters may be able to read on the walls what they cannot read in the manuscripts." It goes without saying that portraiture could not flourish under these conditions, since individualization was prohibited.

In Italy in the 13th century, Giotto was the first to introduce into his frescos of religious subjects groups of spectators for which his friends posed. Thus we have in a group of citizens on the fresco "Paradise" in the chapel of Bargello, in Florence, a portrait of Dante. Filippino Lippi (1457–1504) paints himself with Botticelli and Pollaiolo in the Brancacci chapel. Ghirlandajo (1449–1494) places himself and his family and the donors on the fresco in the Capella Tornabuoni.

Fresco painting developed in the Italian artists the ability to work very rapidly and therefore, very broadly, to ignore all possible detail. In Flanders the damp climate was so unfavourable for its use the artists perfected the more durable process of oil painting, which permitted them to work on panels with the same attention to detail which they had devoted to the miniatures of the manuscripts.

In spite of the rules of the church, the Gothic sculptors and illuminators had developed an astonishing degree of realism in their work, the realism which culminates in the painting of the Van Eycks.

In his portraits, which have never been surpassed, Jan Van Eyck (1385?–1441) shows us people of solid flesh and bone, on whose faces life has traced its story, and because they are real, we see their souls. He gives poetry to reality.

Rogier Van der Weyden and Hans Memling prepare the way for Italianism.

The Flemish love for detail was often carried to an excess by German artists. However, two men of genius, Holbein and Diirer, knew how to subordinate this detail and make of it a powerful aid in characterization. Just as an orchestra brings out a soloist, so the backgrounds and accessories in their portraits evoke sensations which make the impression of the figure all the stronger. As a thinker Durer ranks with Leonardo and Michelangelo; as an objective painter of portraits Holbein equals Rembrandt and Velasquez. His portrait drawings are the most striking examples of individualization. Never have lines expressed more powerful modelling, profound psychology, rhythm and harmony. When Germany was torn by religious strife he found at the court of Henry VIII. in England the right field for his work. Lucas Cranach (1472–1553) was an independent, positive artist. Antonello da Messina (*c.* 1414–*c.* 1493), who is said to have studied in Flanders and to have introduced the technique of oil painting into Italy, combined Flemish love of realism with his Italian sense of beauty.

The classic traditions had never quite died out in Italy, and were revived by the study of antique examples. The result was a magnificent school of portraiture which brought out the finest qualities of the sitter and artist. The Renaissance worshipped heautiful aristocratic types and the artists delighted in painting them at their best, accentuating their nobility of character by harmonious composition and colouring, ignoring all disturbing detail. If Waetzoldt has compared a portrait to a lyric poem, me are reminded by these Italian portraits of Shelley's definition of poetry:

> "Poetry is the record of the best and happiest moments of the highest and best minds. . . . Poetry thus makes immortal all that is best and most beautiful in the world. . . . Poetry redeems from decay the visitation of the divinity in man."

The artists were pioneers and delighted in solving new problems.

Many of the great painters of religious subjects excelled in portraiture. Leonardo da Vinci (1452–1519), in his search for greater truth, sacrificed the pure colouring and line of the primitives, enveloping his modelling, giving depth to his shadows. Raffaello Santi (1483–1520), Andrea del Sarto (1486–1531), Andrea del Castagno, Benozzo Gozzoli (1420–98), Pontormo (1494–1557) and Bronzino (1502–72) were masters in portrait painting. The Venetian, Giambattista Moroni (1510–78) was, however, the first artist to devote himself exclusively to portraiture.

In Venice conditions were favourable to the development of a brilliant school of portraiture with Bellini and Giorgione as leaders. There were fewer religious restrictions and the general atmosphere was one of wealth and splendour, of gaiety and moral and physical health. This reflects itself in the masterpieces of Titian Vecelli, whose rich colouring and profound insight into human nature places him among the greatest portrait painters. Sir Joshua Reynolds speaks of "the unaffected air of the portraits of Titian, where dignity, seeming to be natural and inherent, draws spontaneous reverence." Tintoretto, Sebastiano del Piombo, Paolo Veronese and Lorenzo Lotto have left us portraits of great strength and beauty. When the joy of blazing new trails was over and Italian painters settled down to inventing formulas for giving their sitters the aristocratic appearance they desired, the art degenerated into mannerism.

In Holland the reformation triumphed after a struggle of 80 years against the Spanish yoke. In 1579 the seven Dutch provinces had formed a republic which developed into the most civilized State of the times. Tolerance attracted to it those who were persecuted for their advanced ideas in other countries. Wise laws raised the standard of the people and a vast trade brought contacts with all countries of the world. General wealth and culture was the result. The Dutch burghers, who had accomplished so much, did not desire to ape aristocracy. Their success had given them self-respect and they wanted portraits which showed them as they were. This gave their great artists a most ideal opportunity. Their knowledge of composition had free rein in great group paintings ordered by societies and guilds to adorn their meeting halls and so perpetuate the memory of the men and women who had rendered services to their country. Little wonder that painting became the highest developed form of Dutch art. The painters reflected the love of independence in their work. They saw with their own eyes.

Rembrandt van Rijn (1607–69) and Frans Hals (1580–1666) are the great portrait painters. Each looked at life from an entirely different angle and treated what he saw with entirely different methods. Hals is known as the painter of laughter, but it is not only the laughter of merrymakers; it is also the smile of the man of the world too proud to show emotion—laughing so as not to weep. His amazing knowledge of anatomy permitted him to treat these fleeting expressions with an assurance and breadth of touch which fascinates.

Rembrandt was a profound student of human nature for whom every form, condition and action had its significance. Character and soulfulness interested him more than perfection of form. He saw with the eye of a lover, a lover of humanity, revealing beauty where it is least expected. What Holbein accomplished with line Rembrandt obtained with colour, with his golden light and luminous shadows. His etcher's point has left us portraits which are the classics of etching. (See DRYPOINT: Portrait of Arnold *Tholinx.*)

Among the numerous Dutch painters who devoted themselves to portraiture must be mentioned Bartolommeo Van der Helst and Jan Steen. As with all other schools, decadence began when the Dutch tried to reduce the methods of the masters to formulae.

Spanish artists always remained very free from academic tendencies. Their portraits are therefore unusually fine,

AN OIL PORTRAIT AND TWO WATER COLOURS BY SARGENT

"The Wyndham Sisters," painted in 1900 by John Singer Sargent (1856–1925), an important example of Sargent's portraiture, the type of work for which he was most widely known. He was equally a master of the technique of water colours, of which two examples are reproduced. Left "In a Levantine Port." Right "Santa Maria della Salute, Venice"

Dominico Theotocopuli, called El Greco, a Greek, born in Crete, settled in Spain after working in Titian's studio. His early influences were doubtless Byzantine. He owes perhaps to Tintoretto his impressionistic handling. Through Ribera (1588–1656) Caravaggio became the inspiration of most of the Spanish artists. Zurbaran (1598–?1669) excelled where most of the masters failed: in portraits of children.

It is difficult to trace the influences which might have affected Velasquez (1599–1660), so completely did he see with his own eyes. Even his technique was a new departure. He was the first to use oil as a sole medium in order to paint directly on his canvas without preparatory underpainting. This made possible the accurate values which give depth and air to his pictures. Although as a court painter to Philip IV. he was forced to repeat the same subjects many times, his sincerity and interest in the pictorial qualities of his sitters kept his vision keen. There was so much to fascinate him in light, colour and atmosphere besides the personality of his models, that his portraits are perhaps the most real ever painted. There is no evidence of preoccupation with technical problems. His palette was simple and his brush responded to his mind like the instrument of a great musician. His portraits make their appeal through truthfulness, refinement and reserve. Elie Faure compares him to Beethoven, because he possessed the supreme virtue—heroic simplicity.

Goya y Lucientes (1746–1828) kept alive the best Spanish tradition when in other countries artists had forgotten how to paint, and has had a great influence on modern art.

The wealth and wholesome vigour of Flanders which in the 17th century enjoyed the advantages of commerce with all parts of the world, found an interpreter in Petrus Paulus Rubens (1577–1640). The portraits of his family, especially of Helena Fourment, his second wife, are the best examples of his art and reflect his joy in life, his health and vitality. His pupil, Anthony Van Dyck, although brilliant when he painted his early portraits, as court painter to Charles I. of England, was so overwhelmed with work that he rarely painted more than the head himself, leaving the rest to assistants. The hands were painted from models and this, more than anything else, weakened the character of his portraits. He also used landscape backgrounds which shock our modern taste accustomed to the reflections and colour shadows of outdoor painting.

These insincere methods were unfortunately adopted by the English portrait painters of the 18th century. England had imported her portrait painters, Holbein, Rubens and Van Dyck, without developing any native talent except for some miniaturists such as Isaac Oliver and Samuel Cooper. (See MINIATURE PAINTING.)

Puritanism brought all art to a standstill. Under the reign of Charles II. other foreigners became the vogue—Sir Peter Lely (Dutch) and Sir Godfrey Kneller (German). William Hogarth (1697–1764) was the first native English painter of real merit. He rebelled against the prevailing insincerity in art and wrote of his "contempt of the portraits by native and foreign impostors who puffed and flattered themselves into fashion. By this inundation of folly and fuss I was much disgusted and determined to try if by any means I could stem the current and by opposing, end it." The few portraits he painted are of a high order, too true, perhaps, to make him popular.

It is a curious phenomenon that England in the 18th century should of a sudden develop a group of important portrait painters, such as Sir Joshua Reynolds, Thomas Gainsborough, George Romney, Allan Ramsay, John Opie, Hoppner, Sir Thomas Lawrence and Sir Henry Raeburn. Demand undoubtedly had a great deal to do with it. Their work reflects a refined, healthy, self-contented atmosphere that makes one feel as if one were moving in the best society. This, perhaps, explains the popularity of these pictures. Healthy complexions and beautiful clothes gave the artists an opportunity to make colourful pictures but there is little research into character. Shop methods prevailed. Like Van Dyck, Reynolds painted only the head. In this way he was able to paint about 150 portraits a year for several years.

Gainsborough's was the most artistic nature but he was more interested in a silk gown than in the sitter. Only an extravagant wife kept him from abandoning lucrative portraiture for landscape painting which he loved. (F. T. W.)

France.—Jean Fouquet (1415–1485), is the first of the great French portrait painters. Without departing from the technique of the miniature painters, with their gold background and attention to minute detail, he none the less treats the face and costume more broadly.

Jean and François Clouet (their dates are, approximately, Jean, 1485–1541?; François, 1510–72), attached to the court of Francis I. and his three successors, have bequeathed to us the physiognomy of these princes and their counsellors. Sharing in the Italianism which dominated manners at the period of the Renaissance and representing the old feudal order on which they rested their claims, these men are at once subtle and fierce; their sparkling glances, their flashing or gloomy eyes, their humble or haughty characters, their brilliant or sober costumes, all are studied with scrupulous detail, all speak to us of their hates, their fears, or their hopes. We look at their paintings like historical documents whose truth heightens their pictorial value.

Antoine Lenain (1598–1648), along with his brother Louis (1593–1648), are two portrait painters of high rank. The period which they represent is less violent; the power of royalty has triumphed over feudalism. But the realistic tradition of the Middle Ages still survives and resists the more decorative and more impersonal academic tendencies.

Philippe de Champaigne (1602–74), portrait painter of Louis XIII. and Richelieu, introduces a new element—the pomp of courts and the fashion of the official portraits. He portrays the majesty of royalty, flattering his models a bit in the way of nobility and dignity, and he paints the glowing colours of their royal vestments. Mignard (1610–95), and after him Tocqué (1696–1772), in his great portrait of Marie Leczinska, amplify and enrich the opulent style of the official portrait.

The sweeping lines of materials in rich folds become still more decorative in the eighteenth century. They give an air of awkwardness to the persons set off by them. Rigaud (1659–1743) less cold and simpler in his art, one of the fine talents of the end of the 17th century, is surpassed in brilliance by Nattier (1685–1766), whose famous "blue" has become celebrated; and especially by Largillikre (16j6–1746).

The latter returns to the naturalistic tradition with all the opulence of a palette worthy of Rubens at the service of a rather subtle understanding of the human soul. He defines the features clearly, he selects the characteristic detail to mark a momentary state of soul. He has left us a considerable number of magnificent portraits. His portraits of women have all the charm, all the grace and all the sumptuousness of that delightful century. The stiff school of Mignard is definitely vanquished by charm and light. It is not yet the famous "rayon rose" of Boucher. It is simply the harmonious balance of all, the joy of painting materials and beautiful flesh. Largillikre, like Oudry, is often influenced by Snyders and he knows how to enliven a portrait with a remarkable bit of still life, without going contrary to the spirit of the composition.

Charles Vanloo (1705–1765), in the portrait of Louis XV. at the Chase, introduces the element of landscape more extensively than ever before in portrait painting. Watteau (1684–1721), Chardin (1699–1779), Boucher (1703–1770), Fragonard (1732–1806), Greuze (1725–1805), are not actual portrait painters, but who would pass them without mention? Their varied palettes, the delicacy of their composition, their expressive design, compel us to note them and to class them among the greatest portrait painters. Perroneau and Latour, most famous of pastel painters, both broke deliberately with the tradition of official portrait painting. Latour is never constrained. All his portraits give the impression of having been fixed on the canvas at the moment when the subtlest smile of the subject is responding to a witty word. Madam Vigée-Lebrun (1755–1842), with her charm and grace, concludes the achievement of this brilliant century and fittingly introduces the next. (C. MAS.)

Already under Louis XV. the classic reaction had begun, due largely to the influence of the scholar Winckelmann. In 1764 the translation of his *History of Art Among the Ancients* appeared in which he exhorts the artists to take their models from antiquity. Piranesi's prints also served to draw attention to the art of ancient Rome. Philosophers and writers such as Diderot and Caylus attacked artists for their subservience to fashionable tastes. During the Revolution, just as in politics, theorists went to the limit of the absurd declaring that beauty could be obtained only through calculation by knowledge of the antique. Louis David (1748–1825) who became the apostle of this creed painted some truly fine portraits in which, however, reason takes the place of passion. Gérard, Girodet and Gros were not his equals. Prud'hon alone had an artist's vision, but due to the use of bitumen his paintings deteriorated.

The next generation which had grown up during the excitement of the Revolution and of the wars of the Empire rebelled against this art of reason. Géricault who died very young, and his friend, Eugène Delacroix (1798–1863), were inspired by the English landscape painters and introduced their brilliant colours and free methods. Delacroix fought classicicm with a "hate of systematic painting," but he, himself, distorted truth. For this reason his portraits are inferior to his compositions. A pupil of David, Jean Baptiste Dominique Ingres (1780–1867), enriched the field of portraiture with admirable pencil drawings. His painted portraits do not possess the same charm. His pupil Flandrin continued his decorative style. The revolt against Ingres and Delacroix was led by Courbet (1819–1877) who introduced the realism of the great Spaniards and Dutch into French art. In his "Funeral of Ornans" every figure is a portrait painted directly from the model. Rebelling against classicism and romanticism alike, he wanted to paint the life of his time in a method which his contemporaries could understand. That is the most important lesson taught by modern art, that beauty is all around us, if we only have eyes to see it.

From now on most of the best French portraits are painted by artists who did not take up portraits as a vocation. Daumier did a striking portrait of Berlioz. Jean Francois Millet's (1814–1875) portraits of his family and friends are as virile and as full of pathos, emotion and tenderness as his compositions. The landscape painter Corot (1796–1875) made a great contribution to modern painting with his exquisite portraits of woman. He sees women as pure nature, without sentimentality, and he is comparable to Jan van der Meer of Delft in the beauty of his colour and the strength of his construction. The portrait is the touchstone of an artist's ability.

Nothing bore richer fruits than the discovery of Japanese art and the influence of the Impressionists. Tired of the harsh, cold studio light, artists began posing their models in the open or in rooms flooded with sunlight. Muddy tones gave way to luminous shadows and reflections. With Edouard Manet (1823–83), Edgar Degas (1834–1917) and, above all, with Auguste Renoir (1841–1919) and Paul Cézanne (1839–1906), a new conception of painting developed. Art is at last free from the nightmare of classicism. The new ideas were applied especially to portrait painting by Anders Zorn in Sweden, Peter Severin Kröyer in Denmark, Sorolla y Bastida in Spain, and by others. It was especially the American-born James McNeill Whistler (1834–1903) who came under the influence of Japanese art. In his writings as well as his painting he focussed attention on the necessity of decorative qualities in a portrait. No one knew better than he the value of the silhouette against a background rendered interesting by discreet arrangement of flat spaces. His compatriot, John Singer Sargent (1856–1925), who, like him, spent most of his life abroad, became one of the most popular portrait painters.

It is significant that both these men made their homes abroad, while in America foreign artists, often inferior ones, were and still are popular. Yet America can boast of many able and talented portrait painters. Most of them had training abroad and their work can hold its own with that of their European contemporaries. It cannot be said, however, that a typically national style has developed. Even George Bellows (1882–1925) and Abbott Thayer (1849–1921) show European influences. The same applies to other American painters. Art has become cosmopolitan.

Fortunately the growing interest of Americans in modern art is creating a demand for colourful portraits, so artists should give their talent freer rein. Perhaps Grant Wood (1892–1942) sounded a new note in his "American Gothic" with its bold colour and uncompromising realism. The portraits of Luigi Lucioni (1900–) combine true decorative qualities with sincere characterization. He says of himself: "I try more and more to create reality with the simplest means and with all essential detail. But I feel that all this should be part of a design, which I believe every canvas must primarily possess." This should be the aim of every true portrait painter.

PROBLEMS AND TECHNIQUE

While the old masters excelled in portraits of men, man's modern attire makes it most difficult for an artist to obtain satisfactory results. The harsh collar, the drab colouring and the standardized cut all unite to ruin the effect of the finest head. Women, on the contrary, have much greater freedom than the women who posed for the old masters, with their rigid garments and their stiff attitudes prescribed by fashion and convention. However, the use of cosmetics is a great drawback. Rouge, lipstick and powder conceal, camouflage so to speak, the fine modelling on which a great portrait depends and they defeat their own purpose by rendering the surface of the skin opaque. The natural skin is semi-translucent and therefore more luminous than anything that can be applied to it. As long as cosmetics are generally used there is little hope that the finest type of portrait will be appreciated. Paint and powder are used to deceive, to produce an artificiality which does not give beauty to commonplace, and which makes common the most beautiful.

For a connoisseur, "the question of portrait painting is a matter of birth, associations and character. In other words, one cannot expect a man born and bred in a low environment and associating with people of his own status to understand the character of a noble sitter; nor can he have any insight into the essence of such a person's nature. Therefore, he cannot paint a portrait of such a one. The grand manner is a question of grand association. If it is mere imitation, it is worthless and shows how spurious it is."

Psychologically different types cannot be expected to understand each other. This must be considered when people offer their criticisms of a portrait. Portraits which are entirely satisfactory to the family of the sitter often displease outsiders. The sitter himself may be unsympathetic to them. For this reason the artist and client must be careful in accepting criticism without making due allowance for difference of temperament and the state of mind which has much to do with opinion. Mood, health, age, sex and eyesight are factors to be counted with. A man's portrait may delight girls and meet with adverse criticism from men. A shortsighted person can never see a portrait as it should be seen. A bilious critic can never be expected to find beauty in anything. From day to day we change our opinions. What we liked yesterday may not appeal to us tomorrow. An artist can class people psychologically by the remarks they make about a portrait; one will see a benevolent smile where another sees a sneer. One notices a frown where another finds thoughtfulness. Then according to the occupation of the beholder certain things attract undue attention. A physician will notice the anatomy, a tailor the clothing. Likeness, the *sine qua non* of the portrait, is after all very relative.

It is curious how blind most people are to the characteristics of those around them. The artist will often reveal traits which are unsuspected—good as well as bad. Any one who wishes a flattering likeness should endeavour to keep his relations with the artist very cordial. Abbott Thayer explains in a letter to Royal Cortissoz the reaction of the artist to his sitter: "The violin, whose strings ring whenever their note is sounded by an outside instrument, is pure symbol of the poet. In the poet cumulative images of every form of beauty begin in earliest infancy to occupy the brain, till, in his early maturity, these have become true touchstones, like the violin string. Let the painter once look upon a person who has, beneath no matter how many surface defects, one dominant greatness—purity at heart and fiery love of truth and beauty—and in his own heart the image of such a person-

16TH CENTURY PORTRAIT AND EXAMPLES OF MODERN WORK

1. "Mother and Daughter," by Frederick T. Weber (1883–), American
2. "Don Raimundo de Madrazo y Garreta," by Joaquin Sorolla y Bastida (1863–1923), Spanish
3. "Woman in Green Velvet," by Abbott H. Thayer (1849–1921), American
4. "Portrait of the Painter," by Paul Cézanne (1839–1906), French
5. "Lady Orpen," by Sir William Orpen (1878–1931), English. In the Tate Gallery, London
6. "Portrait de Jeune Fille," by Hilaire Germain Edgard Degas (1834–1917), French
7. "Portrait de Mme. Charpentier," by Pierre Auguste Renoir (1841–1919), French
8. "Phil May," by Sir J. J. Shannon (1862–1923), English. In the Tate Gallery, London
9. "Portrait of a Man in a Broad Brimmed Hat," by Hans Holbein (1497–1543), German
10. "Members of the Committee for the French exhibition of Fine Arts at Copenhagen," by P. S. Kroyer (1851–1909), Danish
11. A pencil Portrait, by Jean A. D. Ingres (1780–1867), French

ality wakes into brilliant ringing clearness and takes the helm, saying: 'Watch this being! Thou wilt surely see, now and then, the being she really is (it's now a she!) come forth and be fully in sight. Watch, then, and take in how she looks, for in those aroused moments she dominates the whole face and body, ruling all their details into her heavenly form.' " Breaking appointments, coming too late to sittings, bargaining over the price, making remarks about the portrait before the artist asks for criticism, can mar the spirit that should reign during the pose. Hatred and contempt can find their way into the portrait. We have examples of this in Goya's portraits of the Bourbons and in some of Sargent's portraits; and often when artists paint from models of a race they dislike.

The artist owes the greatest consideration to his sitter and should avoid fatiguing him. A comfortable position is necessary if the expression is to be natural and the sitting should be a delightful experience to both the artist and the sitter. Van Dyck realized this and would often invite his sitters to dine with him so that he could study their expression when they were at their ease. Most people will be self-conscious and stiff at first but after some time will fall into natural poses. It is therefore wise to make small preliminary colour sketches until a good pose is found. This method has the added advantage that it gives the client an opportunity to express his opinion before the real work begins. An artist can do many different portraits of the same person. They may be all good and yet the client will have his decided preference for one.

It is the duty of the artist to find out what his client wants. Far from being a hindrance this may lead him to new ideas, just as the restriction of rhyme can suggest new thoughts to a poet. The greater the artist the more willing he will be to put his faculties to a test. Of course, this does not mean that he should do anything against his better knowledge. Holbein painted Erasmus in many different poses but the profile in the Louvre alone gives us the impression of greatness. Often the profile is the only advantageous view of a head and yet there seems to be a prejudice against it. Some people think it is easier to do. It is said that some of the men who had their portraits done by Rembrandt in large groups refused to pay him because he did not show their full face. Needless to say, it requires just as much knowledge to build up the modelling of the side face as it does to paint any other view of the head. From a decorative standpoint a profile is certainly the most advantageous. It predominated in the early Italian portraits.

Lighting presents many difficulties and so much depends on it that it requires the greatest attention. We have seen how largely the effects of the old masters depended on lighting. Holbein, Clouet and other early painters posed their sitters in full light which cast as few shadows as possible. Leonardo let the light fall from above to accentuate modelling. Rembrandt evidently used a small window which concentrated the light on one part. Ribera and his followers are known for their harsh light effects. It is evident that by manipulating the light different characteristics can be brought out or suppressed. The old masters generally posed women facing the light; while with men they let shadows accentuate the features.

The pose of the body and hands can be a great aid in obtaining a likeness but if too much emphasis is laid on action the attention can be diverted from the head. For the ancient Greeks the body had as much significance as the head; now after ages of neglect, it is coming to its own again, and the modern artist should make the most of this opportunity. The choice of costume is of the greatest importance. As every woman knows, different dresses bring out different qualities in their face. Often when an artist is unable to obtain the desired expression he finds that changing the dress is all that is necessary. The lines of the costume react on the lines of the face just as in music a note has its overtones. This is why artists are always glad to use scarfs, furs or anything they can arrange themselves on their sitters.

One of the most difficult problems is that of the background, which is just as important as any other part of the portrait. It can be compared to the accompaniment in music, strengthening by relative values the illusion of colour and form in the figure.

Each portrait presents its own individual problem. The surest way to fail is to try to develop a formula. It is impossible to paint two subjects with the same methods. For this reason great artists often have stage-fright before beginning a portrait. The brush work which makes the work of Rembrandt, Hals and Velasquez so astonishing was certainly not planned in advance but dictated by the inspiration of the moment and the vividness of the impression made on the artist. This does not mean that the artist should make experiments on his clients. He should not accept a commission to paint a portrait before he has solved all technical problems on portraits of friends or of hired models. It is one thing to paint from a hired model, accustomed to sit for many hours and indifferent about the results, and another to deal with a client easily fatigued, pressed for time and entitled to have a word in the proceedings.

A portrait painter can rarely put his canvas aside, forget about it and take it up again after months, when his vision is fresh. For this reason he must depend on comments made by the client and his friends, trying to glean from them where the trouble lies. It is rarely where the layman thinks but with experience and a little psychology the artist can profit by learning how the portrait reacts on different people. However, remarks offered before he is ready for them can be very harmful. It is difficult for the layman to realize that a portrait cannot be a perfect likeness until it is entirely finished; nor that the artist must work up all parts of the picture simultaneously in order to make a harmonious whole. He cannot finish the head and then progress to the body and hands any more than an architect can finish one room in a building before the roof is on. Each colour, each line, in a picture affects all others. It is their relative value alone which gives the illusion of form.

Modern artists as a rule paint directly, trying to place the right tone in its right place immediately. Charles Hopkinson recommends the process probably used by many of the old masters. Over a monochrome under-painting he models carefully with red, black, white and blue, mixing the lights with red and white; the shadows with red and black. These simple tones permit him to devote his full attention to the form. When this under-painting has dried he glazes with the bright colours, the yellows, bright reds, greens, etc. Rich, luminous transparent tones are obtained in this manner and by contrasting transparent flesh tones with opaque touches in accessories a great variety of texture is obtained. Both processes have their advantages and their disadvantages. Glazes do not permit a very sincere study of colours in relation to other colours and they can endanger the durability of the painting. Many of Reynolds' canvases faded, cracked and pealed off during his life-time. The direct method is very durable if it is not retouched too soon, but many of Sargent's portraits covered with cracks are sad examples of what happens when paintings are worked upon before they are thoroughly dry. Titian and Rembrandt are said to have let their work dry for months, but few modern people would be able to let their sittings cover so long a period.

The frame should be chosen before the portrait is finished and the final work on the canvas should be done after it is framed. The frame can be toned and antiqued so that the whole is harmonious. An unsuitable frame can affect the likeness and cause great trouble to the artist. It is well for the artist to know beforehand where the portrait is to be hung. He can then arrange his colouring and lighting to harmonize with the surroundings. Some people decorate their rooms to bring out a picture. The illusion of form is more vivid if the portrait is hung with the light falling from the direction of the light in the picture. The client should live with the portrait for some time before requesting changes. Often he becomes reconciled to the artist's vision and does not wish changes made which generally impair the beauty of the whole for the sake of some detail.

The opinion seems to prevail that different subjects require different mediums. Oils are supposed to be best for men, pastels and crayons for women and children. But we must remember that Holbein's magnificent drawings of men are equal, if not superior, to any painting. Latour could render in pastel the strength of men as well as the delicacy of women and the portraits of women and children by the great English painters, or by Renoir, prove that with oil paints the most subtle qualities can be obtained. However, the lighter mediums permit the artist to abandon and take up his work at will, an important factor where capricious women and children are concerned. Oil painting requires longer sittings.

It is wise for an artist to change his medium now and then. Nothing freshens up his colour sense better than a water-colour or pastel and etchings stimulate his interest in line. Sculpture is the greatest tonic a painter can use. Most of the great masters devoted themselves to other subjects besides portraits. It is needless to mention the religious paintings of the old masters, the landscapes of Rembrandt, Rubens, Gainsborough, Whistler and Sargent. When tired of the sickly court Velasquez would take as models robust peasants. No artist can paint day after day the same type of picture without lessening the keen interest which is necessary for success. The joy which the artist takes in his work is communicated to the beholder.

It is difficult to form an opinion about contemporary portrait painting, as some of the best portraits are never exhibited. There are sincere, conscientious artists who with the right encouragement would be able to leave important work, but there are also many of the kind Hogarth attacked: those who impose on an ignorant public by painting from photographs; those who hide their ignorance and lack of talent behind all sorts of theories, claiming that likeness is not necessary; those who are more interested in paint and in clever brush work than in their sitter.

The sincere modernist in his effort to give to painting the emotional quality of music, finds in likeness as yet an obstacle, although his idols, the Orientals, Egyptians and primitives, made of it a powerful aid. He is governed by taboos and prejudices as bad as those of the academy, but rigid as are the rules and laws laid down by the modernist, they are "subject to change without notice." He is quick to admit an error in his arguments as in the case of cubism. Fortunately there is an increasing number of cultured people who know what a fine portrait is, and who have pride and standing enough to uish to be painted as they are. (F. T. W.)

PORT RICHMOND, a community of the borough of Richmond in New York city, on the north shore of Staten island and on the Kill van Kull channel. It is one of the leading business areas of Staten island. Among its places of historic interest are the Dutch Reformed church, which is the direct successor of the church established at the Voorlezer's house (still standing) at Richmondtown, Staten island, about 1695; and the Daniel Mesereau house, built about 1787. In this house Aaron Burr spent the last years of his life, dying there on Sept. 14, 1836.

PORT ROYAL, an island in Beaufort county, South Carolina, U.S.A., at the head of Port Royal sound, about 16 mi. from the Atlantic coast, and about 50 mi, southwest of Charleston. It is about 13 mi. long and 7 mi. wide, generally flat, and with much marshland in its southern part and along the northeastern shore. The principal town is Beaufort (pop. 1940, 3,185), a port of entry and the county seat of Beaufort county. It is served by the Charleston and Western Carolina railway, has inland water communication with Savannah, Ga., and its harbour is one of the best on the South Carolina coast. Its situation and climate make it a popular winter resort. In the vicinity, cotton, rice, potatoes and other vegetables are raised, and there are groves of yellow pine and cypress. About 5 mi. south of Beaufort is the town of Port Royal (pop. 1940, 342), the terminus of the C. and W. C. railway. The island was named by Jean Ribaut (1520–65) who in May 1562, entered the harbour with a shipload of Huguenot colonists from France. Ft. Charles (probably situated on Parris island) was built and 29 volunteers under Captain de la Pierria were left as the first garrison. Soon afterward they mutinied, killed Pierria, put to sea in an insufficiently equipped vessel, from which they were rescued by an English ship and carried to England. In 1683 a settlement of Scotch families led by Henry Erskine, third Lord Cardross, was established; but three years later most of the settlers were murdered by Spaniards from Florida and the remainder fled to Charleston. In 1710 after the lords proprietors had issued directions for "the building of a town to be called Beaufort Town" in honour of Henry Somerset, duke of Beaufort, the first permanent settlement on the island was established. In Jan. 1779, during the American Revolution, the British occupied the island but were dislodged in February by Col. Moultrie. In the Civil War, Confederate forts on Hilton Head and Bay Point were reduced by the bombardment of a northern naval expedition, after which Port Royal harbour became a Federal coaling, repair and supply station.

PORT ROYAL, a celebrated Cistercian abbey, occupied a low and marshy site in the thickly wooded valley of the Yvette, at what is now known as Les Hameaux near Marly, a few miles southwest of Paris. It was founded in 1204 by Mahaut de Garlande, wife of Mathieu de Montmorenci-Marli in 1204; the church was built in 1229. During the three succeeding centuries its discipline became relaxed; reform was only attempted when Angélique Arnauld (*q.v.*) was appointed coadjutor to the abbess in 1598. Angélique's reforming energy soon brought her into contact with Jean du Vergier (*q.v.*) abbot of Saint Cyran, and chief apostle in France of the Jansenist revival.

In 1626 ague drove the nuns to Paris; they settled at Port Royal de Paris, at the end of the Faubourg Saint Jacques. The deserted buildings of Port Royal des Champs were presently occupied by "hermits," laymen, mostly relatives of the abbess, who wished for a semimonastic existence, though without taking formal vows. In 1648, however, some of the nuns returned, and the hermits retreated a short distance from the abbey. Here they set up a "little school" for the sons of Jansenist parents; and here Racine received his education. But in 1653 Innocent X condemned Jansenism and in 1656 "the hermitage" and school were broken up, and the nuns forbidden to receive new members.

In 1660 Louis XIV condemned the order and, between 1664 and 1669, the archbishop of Paris laid under an interdict those nuns who refused to subscribe to the papal censure on Jansen. In 1669, however, came the so-called "Peace of Clement IX," when the Jansenists generally were admitted to grace, and the interdict was removed from Port Royal, though the authorities broke up the convent into two distinct communities. The conformist nuns were gathered together at Port Royal de Paris, under an independent abbess, their Jansenist sisters at the original building in the country. Thereupon followed ten years of peace, through the protection of the king's cousin, Mme. de Longueville. But in 1679 she died, and Louis at once ordered the nuns to send away their novices and boarders and to receive no others. Finally, in 1705, he got from Clement XI a new condemnation of the Jansenists, which the few remaining nuns, all of whom were over sixty, refused to sign: and on the 29th of October 1709 they were forcibly removed from Port Royal by the police, and distributed among various conformist convents. In the

VAN DYCK AND REMBRANDT

Top: Anthony Van Dyck (1599–1641), "Children of Charles I.," painted in England in 1635. The original hangs in Windsor Castle
Bottom: Rembrandt Van Riln (1606–69), "Sortie of the Banning Cock Company," also known as the "Night Watch," 1642. In the Rijks Museum, Amsterdam

next year the buildings were pulled down. The land on which the convent had stood was made over to Mme. de Maintenon's college of St. Cyr; in 1825 it was bought by some descendants of Jansenist families, who have done their best to restore the grounds to their original appearance, and have built a museum rich in Jansenist relics. Port Royal de Paris was secularized at the French Revolution, and is now a maternity hospital.

For a classified list of the chief books, ancient and modern, dealing with Port Royal, *see* the *Abrégé de l'histoire de Port Royal*, by Jean Racine, ed. E. Gazier (Paris, 1908). *See* also C. A. Sainte-Beuve, *Port Royal* (6 vols. and index, Paris, 1882); Charles Beard, *Port Royal* (2 vols., London, 1861); H. Reuchlin, *Geschichte von Port Royal* (2 vols., Hamburg, 1839–44), and the books recommended under the articles ARNAULD, JANSENISM and PASCAL.

PORTRUSH, an urban district and seaside resort of Co. Antrim, Northern Ireland; the terminus of a branch of the Northern Counties (L.M.S.) railway. Pop. (1937) 3,386. Area, .8 sq.mi. It is situated on the basaltic peninsula of Ramore head, with a deep bay on either side, and a harbour protected by the natural breakwater known as the Skerries. It is the tourist centre for the Giants' Causeway, with which it is connected by an electric railway. The extensive ruins of Dunluce castle, between Portrush and Bushmills, stand on a rock separated from the mainland by a chasm spanned by a bridge. Portrush has a salmon trade.

PORT SAID (sah'ed), a seaport of Egypt, at the entrance of the Suez Canal, in 31° 15′ 35″ N., 32° 19′ 20″ E., and 145 mi. by rail N E. of Cairo, pop. (1937) 124,749, lies on the western side of the canal on the [illegible] narrow and treeless strip of land which separates the Mediterranean from Lake Menzala, the land at this point being raised and its area increased by the draining of part of the lake and by the excavation of the inner harbour. The outer harbour is formed by two breakwaters which protect the entrance to the canal; altogether the harbour covers about 570 acres and accommodates ships drawing 28 ft. The port possesses a floating dock 295 ft. long, 85 ft. broad and 18 ft. deep, capable of lifting 3,500 tons, and a patent slip taking 300 tons and ships drawing 9 ft. 9 in. water. On the western breakwater is a colossal statue of Ferdinand de Lesseps by E. Fremiet, unveiled in 1899, and a lighthouse 174 ft. high. Among the few buildings of note in the town are the offices of the Suez Canal Company and the British barracks, the last having been built by Prince Henry of the Netherlands (d. 1879) as a dépôt for Dutch trade.

Port Said dates from 1859. Originally it depended entirely upon the traffic of the canal, being the chief coaling station of all ships passing through and becoming the largest coaling station in the world. In 1902, however, a new industry was added in the export of cotton from the eastern provinces of the Delta, the cotton being brought from Mataria by boat across Lake Menzala. In 1904 the opening of a standard gauge railway to Cairo placed Port Said in a position to compete with Alexandria for the external trade of Egypt generally, besides making it a tourist route to the capital from Europe.

PORTSMOUTH, EARLS OF. In 1743 John Wallop (1690–1762) of Farley Wallop in Hampshire was created earl of Portsmouth. He belonged to an old Hampshire family and had been a lord of the treasury from 1717 to 1720, when he was created Baron Wallop. The earldom has since been held by his descendants, one of whom, Newton Wallop (b. 1856), became the 6th earl in 1891; he was a member of parliament from 1880 to 1891 and was under-secretary of state for war from 1905 to 1908.

PORTSMOUTH, LOUISE DE KEROUALLE, DUCHESS OF (1649–1734), mistress of the English king Charles II., was placed early in life in the household of Henriette, duchess of Orleans, sister of Charles II. In 1670 she accompanied the duchess on a visit to Charles II. at Dover. The king placed her among the queen's ladies-in-waiting. Her intrigue with Charles was vigorously pushed by the French ambassador, Colbert de Croissy, aided by the secretary of state, Lord Arlington, and his wife. Louise, who concealed great cleverness and a strong will under an appearance of languor and a rather childish beauty (Evelyn the diarist speaks of her "baby face"), yielded only when she had already established a strong hold on the king's affections. Her son, ancestor of the dukes of Richmond, was born in 1672.

The support she received from the French envoy was given on the understanding that she should serve the interests of her native sovereign. The bargain was confirmed by gifts and honours from Louis XIV., and was loyally carried out by Louise. The hatred openly avowed for her in England was due as much to her own activity in the interest of France as to her notorious rapacity. The titles of Baroness Petersfield, countess of Fareham and duchess of Portsmouth were granted her for life in 1673. Her pensions and money allowances of various kinds were enormous. In 1677 alone she received £27,300. Soon after the king's death she retired to France, where, except for one short visit to England during the reign of James II., she remained. Her emoluments were lost in her later years, which were spent at Aubigny, but she was protected from her creditors by Louis XIV. She died in Paris on Nov. 14, 1734.

See H. Forneron, *Louise de Kéroualle* (Paris, 1886).

PORTSMOUTH, a city, county and parliamentary borough, and seaport of Hampshire, England, 74 mi. S.W. from London, on the S.R. Pop. (est. 1938) 258,400. Area 14.4 sq.mi. The city suffered heavy air raids during World War II. About 93% of the houses were damaged, though many were repairable, but the gild hall (1890), both the main shopping centres and many public buildings were gutted.

Portsmouth owes its origin to the retreat of the sea from Porchester. No town existed there until the 12th century, when its strategical advantage induced Richard I to build one. The borough is governed by a charter granted by Charles I in 1627, modified by the municipal acts of the 19th century. The market, dating from 1194, is held on Tuesday and Saturday.

The naval station and arsenal is an aggregate of four towns, Portsmouth, Portsea, Landport and Southsea, and occupies the southwestern part of Portsea island, which lies between Portsmouth harbour and Langstone harbour, two inlets of the English Channel. Portsmouth harbour opens into Spithead, one of the arms of the Channel separating the Isle of Wight from the mainland. The harbour widens inwards in bottle form, Portsmouth lying on the east shore of the neck, with Gosport opposite to it on the west side. Portsmouth proper may be distinguished as the garrison town; Portsea as the naval station with the dockyards; Landport is occupied chiefly by the houses of artisans; and Southsea is a residential quarter and a watering-place. There is a modern Roman Catholic cathedral. The church of St. Thomas of Canterbury, a cruciform building, dates from about 1180. It was restored in 1904, and in 1935 a scheme of enlargement was begun. In 1924 the foundation of a new diocese of Portsmouth and the Isle of Wight, taken from that of Winchester, was approved, and St. Thomas's was designated as the pro-cathedral. The see was created in 1927. The garrison chapel originally belonged to the hospital of St. Nicholas, a foundation of the 13th century. Passenger steamers from Portsmouth harbour serve Ryde in the Isle of Wight. A ferry and a floating bridge connect with Gosport. The parliamentary borough was divided into central, north, and south divisions in 1918, each returning one member. The county borough was created in 1888 and raised to the dignity of a city (1926) with a lord mayor in 1928.

Nelson's flagship, H.M.S. *Victory*, on which he met his death at Trafalgar in 1805, is in dry-dock in Portsmouth; she is the flagship of the admiral of the station. (*See* NELSON.)

The dockyard dates in its earliest form from 1496, though the town was already of importance as a naval station. Its later rise began with the building of one dry and two wet-docks in 1698. In 1848 a steam basin and four new docks were opened, the dockyard ground being extended to 115 ac. In 1865 extension works decided upon included a tidal basin and a deep dock and two locks, in themselves serving as large docks, which lead to three basins and four docks. Subsequent improvements included two new dry docks (1896); the construction of jetties at the entrance to the tidal basin and at the north wall; the establishment of a coal wharf with hydraulic appliances; numerous subsidiary works; and extensive dredging of the harbour to increase the berthing accommodation for the fleet. New locks and a dry dock were completed shortly before World War I. In 1925 the government decided to reduce the dockyards at Rosyth and Pembroke to a care-and-maintenance basis and to concentrate all admiralty home dock work at Portsmouth, Devonport, Chatham and Sheerness. Portsmouth royal dockyards cover an area of 500 ac. There is a gunnery establishment on Whale Island and barracks, including those of the Royal Marine Artillery at Eastney, beyond Southsea.

PORTSMOUTH, a city of New Hampshire, U.S.A., the only seaport of the state; on the Piscataqua river, near its entrance into the Atlantic ocean. It is on federal highways 1, 4 and 16 and is served by the Boston and Maine railroad and bus lines. It is connected with Maine by two bridges, the Memorial bridge (1923) and the $3,000,000 Interstate bridge (1940). Pop. (1930) 14,495 (17% foreign-born white); in 1940 by federal census 14,821. On Fernald's and Seavey's islands, opposite the city (but in the town of Kittery, Me.), is the Portsmouth navy yard (established 1800), one of the largest in the country, and the principal yard for building. fitting out and overhauling submarines. The treaty ending the Russo-Japanese War was negotiated there in 1905. During the Spanish-American War, Admiral Cervera and other Spanish officers and sailors were imprisoned on Seavey's island, where later a large naval prison was built. Portsmouth is the seat also of a naval hospital (1891).

At New Castle (2 mi. S.E.), guarding the entrance to Portsmouth harbour, is Ft. Constitution, on the site of Ft. William and Mary (1630); and across the river, on Kittery Point, is Ft. McClary, a colonial blockhouse. Portsmouth is rich in historic associations and in beautiful buildings of the 18th and early 19th centuries, many of which are open to the public. The two oldest houses in the city were built in 1664 and 1668. Among fine examples of colonial architecture are the Wentworth-Gardner house (1760), and the Tobias Lear house (1740) both recently renovated; the Moffatt-Ladd house (1753); the mansion built by Governor Benning Wentworth in 1750; the house occupied by John Paul Jones in 1779 (built in 1758), now the home of the Portsmouth Historical society; the William Pitt tavern (before 1767); and the Assembly house, a dance hall built in 1750 and described by Washington as one of the finest in the United States. The Athenaeum, a valuable library established by a society organized in 1817, occupies a building erected in 1803. Portsmouth was the birthplace of Governors Benning Wentworth, John Wentworth and John Langdon; Thomas Bailey Aldrich (whose home is now a museum), Gen. Fitz John Porter and Celia Thaxter. Daniel Webster practised law there from 1807 to 1816.

In 1623 David Thomson, with a small company from Plymouth, England, established a fishing and trading station at Little Harbor (now Odiorne's Point in the town of Rye); and in 1630 another band, sent over by the Laconia company, occupied Thomson's house and Great Island (New Castle), and built the "Great House" on what is now Marcy street, in Portsmouth. The settlement was known as Strawberry Banke until 1653, when it was incorporated by Massachusetts under the name of Portsmouth. It was the capital of New Hampshire from 1679 (when the province was separately constituted) until 1775, and was chartered as a city in 1849. One of the first military exploits of the Revolution took place at New Castle, when the Portsmouth committee of safety, on receiving from Boston (through Paul Revere) a copy of the order prohibiting the exportation of military supplies, organized militia companies and captured Ft. William and Mary (Dec. 14, 1774). During the Civil War the "Kearsarge" and several other war vessels were built at the Portsmouth navy yard, and in the 20th century it became a centre for the construction of submarines.

PORTSMOUTH, a city of southern Ohio, U.S.A., the county seat of Scioto county; on the Ohio river, at the mouth of the Scioto. It is on federal highways 23 and 52, and is served by the Baltimore and Ohio, the Chesapeake and Ohio, and the Norfolk and Western railways, and by river packets and barges. A highway bridge across the Ohio was opened in 1927. Pop. (1920) 33,011 (94% native white); 1940 by the federal census, 40,466. It has a picturesque site on a bend in the river, protected from high water by a concrete flood wall 62 ft. above normal water stage, The Shawnee state forests, a state reservation of 45,000 ac., is near the city; and along the Ohio for 8 mi. extend earthworks of the mound builders, including the Great Serpent mound at Locust Grove (25 mi. W.). Products are iron and steel, shoes (4,000,000 pairs annually), heels and lasts, shoelaces, stoves and ranges (20,000 annually), brick (60,000,000), coke and by-products, paper boxes, and work clothing, There are large sandstone quarries which have supplied material for the Canadian parliament buildings and many other important structures of America. The city's assessed valuation for 1940 was $49,500,000. Settlement in this vicinity began in 1796. In 1799 Thomas Parker, of Alexandria, Va., laid out a village (called Alexandria) below the mouth of the Scioto, but it suffered from floods, and about 1810 the inhabitants moved to Portsmouth, which had been laid out in 1803. Portsmouth was incorporated as a town in 1815, as a city in 1851. The Ohio and Erie canal from Cleveland to Portsmouth was opened in 1832.

PORTSMOUTH, a city of southeastern Virginia, U.S.A., on the Elizabeth river (an estuary of Hampton Roads) opposite Norfolk; the county seat of Norfolk county, but independent of it. It is on federal highway 17, and is served (either directly or through the industrial Belt line which encircles Portsmouth and Norfolk) by the Atlantic Coast Line, the Chesapeake and Ohio, the Norfolk Southern, the Norfolk and Western, the Pennsylvania, the Seaboard Air Line, the Southern and the Virginian railways, and by interurban trolleys, motorbus and truck lines, ferries and steamship lines. Pop. 54.387 in 1920 (43% Negroes) and 50,745 by the federal census of 1940. On the eastern water front is the Norfolk navy yard, the oldest, and one of the most important, in the country. It has an area of 433 ac., 176 buildings with 65 ac. of floor space and 39 berths. Civilians employed in 1941 numbered 20,227; annual pay roll is $44,550,000. On a promontory about a mile west is the U.S. naval hospital. Trinity church (1762) is the oldest building in the city. Portsmouth is a shipping point for large quantities of oysters, vegetables and farm produce. Its manufactures in 1937 were valued at $10,768,307. Commercially Portsmouth is an integral part of the great port of Hampton Roads. (See NORFOLK.) The city operates under a commission-manager form of government.

Portsmouth was established in 1752 by act of the Virginia assembly, incorporated as a town in 1852 and chartered as a city in 1858. The navy yard, established by the British shortly before the Revolution, was confiscated by Virginia during the war and in 1801 was sold to the United States. In April 1861, it was burned and abandoned by the Federals, and then for a year was the chief navy yard of the Confederates. They raised the frigate "Merrimac" and transformed her into the ironclad "Virginia" which on March 9, 1862, fought the famous battle with the "Monitor" in Hampton Roads (*q.v.*). Two months later (May 9) the Confederates abandoned the navy yard and evacuated Norfolk and Portsmouth.

PORT SUDAN, a town and harbour on the west coast of the Red Sea, in 19° 37' N , 37° 14' E., 700 mi by boat S. of Suez and 495 mi. by rail N.E. of Khartoum. Pop. (1926), 21,535. It is the principal port of the Anglo-Egyptian Sudan and the headquarters of the customs aciministration. The coral reefs fringing the coast are here broken by a straight channel with deep water giving access to the harbour, which consists of a series of natural channels and basins. Depth 10 to 14 fathoms; at the permanent quays, 28 ft. On the north side of the inlet are quays (completed 1909), fitted with electric cranes, etc. Here are the customhouse, coal sheds and goods station. The town proper lies on the south side of the inlet, connected with the quays by a railway bridge. Besides government offices the public buildings include hospitals, and a branch of the Gordon college of Khartoum.

The port dates from 1905. It owes its existence to the desire of the Sudan administration to find a harbour more suitable than Suakin (*q.v.*) for the commerce of the country. The railway (which has termini both at Port Sudan and Suakin) was opened in January 1906 and the customhouse in the May following. Port Sudan immediately attracted a large trade, and became a regular port of call of British, German and Italian steamers. The imports and exports in 1925 were valued at £7,000,000, and the largest vessel yet entered was one of 27,132 tons. The imports are largely cotton goods, provisions, timber and cement; the exports gum, raw cotton, ivory, sesame, durra, senna, coffee (from Abyssinia), goat skins, etc. Forty miles north of Port Sudan is Mohammed Gul. the port for the mines of Gebet.

PORT TALBOT, Glamorganshire, Wales, a municipal borough on the Avon, near its mouth in Swansea Bay, 11 mi. E.S.E. of Swansea and 170 mi. from London by G.W.R. Pop. (1938) 40,180. Area 38.8 sq.mi. A castle once stood at Port Talbot, but, despite its apparent strategic importance, the Normans allowed it to remain in the hands of Welsh chieftains who, from the 13th century on, styled themselves De Avan or D'Avene. A town grew up around the castle; one of its charters was granted in 1372 by Edward le Despenser. During the early industrial period. Cornish pioneers were attracted to the Avon valley by its possibilities as a coal-mining and manufacturing centre. The early tendency was to take the ores to the coal and thus Cwmavon, 1½ mi. N.E. of Aberavon, flourished in the middle of the 19th century, being noted for its copper-smelting works and other metallurgical activities. Copper was brought from Cornwall and discharged at Aberavon, the ships then going to Taibach to load a return cargo of coal from the Morfa collieries. With the increase in coal production for export. the need for better shipping facilities was felt. The river below Aberavon was deflected into an artificial channel, its former mouth blocked, and its lower course converted into a dock, which was again extended in 1898. Railway enterprises linked the town with the coal-mining valleys, especially with Cwm Rhondda, and in 1921 the G W R. took charge of the docks. With the development of the port, the town took over many of the activities of Cwmavon, coal being brought down to the port to work up imported ores. Consequently, a modern industrial centre sprang up between the old centres of Aberavon and Taibach, and in 1921 the town of Aberavon and the urban district of Margam were amalgamated as Port Talbot. The town suffered severely in the depression of the 1930s, 34.4% of the insured male population being unemployed in May 1934. The establishment of a trading estate resulted in some improvement.

PORTUGAL: a republic of western Europe, forming part of the Iberian peninsula, and bounded on the N. and E. by Spain, and on the S. and W. by the Atlantic ocean. Pop. (1940), 7,174,899; area 34,234 sq.m. In shape the country resembles a roughly drawn parallelogram, with its greatest length (362 m.) from N. to S., and its greatest breadth (140 m.) from E. to W. For physical details see also SPAIN. The frontiers are partly defined by the course of the four principal rivers, the Minho and Douro in the north, the Tagus and Guadiana in the south; elsewhere, and especially in the north, they are marked by mountain ranges; but in most parts their delimitation was originally based on political considerations. The Portuguese seaboard is nearly 500 m. long. From the extreme north to Cape Mondego and thence onward to Cape Carvoeiro the outline of the coast is a long and gradual curve; farther south is the prominent mass of rock and mountain terminating westward in Capes Roca and Espichel; south of this, again, there is another wide curve, broken by the headland of Sines, and extending to Cape St. Vincent, the south-eastern extremity of the country. The only deep indentations of the Portuguese littoral are the lagoon of Aveiro (*q.v.*) and the estuaries of the Minho, Douro, Mondego, Tagus, Sado and Guadiana, in which are the principal harbours. The only islands off the coast are the dangerous Farilhões and Berlings (Portuguese *Berlengas*) off Cape Carvoeiro. Pop. Azores and Madeira isls. 534,526. area 1.190 sq m.

Physical Features. — Few small countries contain so great a variety of scenery as Portugal. The bleak and desolate heights of the Serra da Estrella are almost alpine in character; at a lower level there are wide tracts of moorland, covered in many cases with sweet-scented cistus and other wild flowers. The lagoon of Aveiro, the estuary of the Sado and the broad inland lake formed by the Tagus above Lisbon (*q v*), recall the waterways of Holland. The sand-dunes of the western coast and the Pinhal de Leiria (*q.v.*) resemble the French Landes. The Algarve and parts of Alentejo might belong to North-West Africa rather than to Europe. The Paiz do Vinho, on the Douro, and the Tagus near Abrantes, with their terraced bush-vines grown up the steep banks of the rivers, are often compared with the Rhine and the Elbe. The harbours of Lisbon and Oporto are hardly inferior in beauty to those of Naples and Constantinople. Apart from this variety, and from the historic interest of such places as Braga, Bussaco, Cintra, Coimbra or Torres Vedras, the attractiveness of the country is due to its colouring, and not to grandeur of form. The following mountain ranges belong to the Transmontane system, which is the southern extension of the mountains of Galicia: Peneda (4,728 ft.); the Serra do Gerez (4,817 ft.); La Raya Seca, a continuation of Gerez, which culminates in Larouco (4,390 ft.); Cabreira (4,196 ft.); Marão (4,642 ft.); Villarelho (3,547 ft.); Padrella (3,763 ft.); Nogueira (4,331 ft.) and Bornes (3,944 ft.). The Beira system comprises two quite distinct mountain regions. North of the Mondego it includes Montemuro (4,534 ft.); Gralheira (3,681 ft.); the Serra do Caramulo (3,511 ft.) and the Serra da Lapa (3,215 ft.). South of these ranges, but nominally included in the same system, is the Serra da Estrella, the loftiest ridge in Portugal (6,532 ft.) continued by the Serra de Lousã (3,944 ft.). They form the last link in the chain of mountain ranges, known to Spanish geographers as the Carpetano-Vetonica, which extends across the centre of the Peninsula from east to west. The Transtagan mountains consist for the most part of isolated ranges or massifs. The Serra da Arrabida (1,637 ft.) rises between Cape Espichel and Setubal. São Mamede (3,363 ft.), extends along part of the frontier of northern Alentejo. Ossa (2,129 ft.), Caixeiro (1,483 ft.), Monfurado (1,378 ft.) and Mendro (1,332 ft.) form the high ground between the rivers Sado, Sorraia and Guadiana. In the extreme south the ranges include Monchique (2,963 ft.). There are numerous large expanses of level country, the most notable of these being the plains (*campos*) of the Tagus vailey, and of Aviz, Beja and Ourique, in Alentejo and the high plateaux (*cimas*) of Mogadouro in Trazos-Montes and Ourem between the Tagus and the upper Sorraia.

The three principal rivers which flow through Portugal to the sea — the Douro, Tagus and Guadiana — are described in separate articles. The whole country drains into the Atlantic, to which all the main rivers flow in a westerly direction except the Guadiana, which turns south by east in the lower part of its course. The Minho (Spanish *Miño*) is the most northerly river of Portugal, and is only inferior to the three great waterways already mentioned. Its length is 170 m. Small coasters can ascend the river as far as Salvatierra in Galicia (20 m.), but larger vessels are excluded by a sandy bar at the mouth. Between the Minho and Douro the chief rivers are the Lima (Spanish Limia or *Antela*), the Cavado, and the Ave. Between the Douro and Tagus the Vouga rises in the Serra da Lapa and reaches the sea through the lagoon of Aveiro; the Mondego flows north-east through a long ravine in the Serra da Estrella, and then bends back so as to flow west-south-west. Its estuary contains the important harbour of Figueira da Foz; its length is 125 m. of which 52 m. are navigable by small coasters. Portugal abounds in hot and medicinal springs, such as Caldas de Monchique, Caldas da Rainha and Vidago.

Climate. — The climate of Portugal is equable and temperate. Lisbon, Coimbra, Evora and Oporto have mean temperatures between 60° and 61·5° F, and the daily variation nowhere exceeds 23°. The rainfall has been as heavy as 16 ft. in a year, and sometimes, as in the winter of 1909–1910, great damage is wrought by floods. Heavy fogs are also common along the coast, rendering it dangerous to ships. The rainfall is heaviest in the north and on the Serra da Estrella; it is least in Algarve. In the deep valleys where the mountains keep off the cool winds. it is excessively hot in summer while on the summits of the mountains snow lies for many months. The meteorological station on the Serra da Estrella, with a mean annual temperature of 44·7° F, is the coldest spot in Portugal in which systematic observations are taken. Montalegre has a mean of 48·3° and Guarda of 50·3°. Even in Lisbon the yearly variation is not less than 50° but it is less at Estoril. In Alentejo the climate is very unfavourable; Algarve (where Lagos has a mean of 63°), is hotter than Alentejo but a profuse vegetation takes away much of the tropical effect Portugal is very rarely visited by thunderstorms; but shocks of earthquake are frequent, and kecall the great earthquake of Lisbon (*q.v.*) in 1755.

Fauna and Flora.—An account of the fauna of the Iberian peninsula as a whole is given under SPAIN. Wolves are found in the wilder parts of the Serra da Estrella, and wild boars are preserved in some districts. As far as the constituents of its flora are concerned Portugal is not very dissimilar from Spain, but their distribution is peculiar. The vegetation of Spain is distributed in clearly marked zones; but over the whole of Portugal, except the hottest parts of Algarve and Alentejo, the plants of northern Europe flourish side by side with cacti, palms, aloes and tree-ferns (see CINTRA). This is largely due to the fact that the moisture-laden winds from the Atlantic penetrate almost as far inland as the Portuguese frontier, but do not reach the interior of Spain. The soil is fertile, and the indigenous flora has been greatly enriched by the importation of such plants as the agave, the Mexican opuntia, the American maple, the Australian eucalyptus, the Scotch fir and the so-called Portuguese cypress (*Cupressus* lusitanica) from the Azores. There are many fine tracts of forest, among which may be mentioned the famous convent-wood of Bussaco (*q.v.*); cork trees are extensively cultivated, Barbary oaks (Quercus bellota, Port. *azinheira*) furnish edible acorns and excellent timber for charcoal, and carob-trees (*Ceratonia siliqua,* Port. alfarrobeira) also produce edible seed-pods somewhat resembling beans. Elms, limes and poplars are common north of the Tagus, ilex, araucaria, myrtle, magnolia and a great variety of conifers in all parts. The Serra da Estrella has a rich alpine flora, and the lagoon of Aveiro contains many aquatic plants.

Inhabitants.— The birth-rate is about 30 per 1,000, while the mortality is only about 20 per 1,000. Large bodies of emigrants, chiefly recruited from the sober, hardy and industrious peasantry of the northern provinces, annually leave Portugal to seek fortune in America. A few go to the Portuguese colonies, the great majority to Brazil. Many of these emigrants return with considerable savings and settle on the land. The mortality is highest among male children, and the normal excess of females is in the proportion of 109 to 100. Six-sevenths of the population of continental Portugal inhabit the provinces north of the Tagus. The density of population is greatest in Madeira (479.5 per sq.m. in 1900), Entre-Minho-e-Douro (419·5) and the Azores (277·9), nowhere else does it reach 200 per sq.m. In Alentejo the percentage sinks to 45·1, and for the whole country, including the islands, it amounts only to 152.8.

The Portuguese people is composed of many racial elements. Its earliest known ancestors were the Iberians (*q.v.*). The peasantry, especially in the north, are closely akin to the Galician and Asturian Spaniards in character, physique and dialect; and these three ethnical groups—Portuguese of the north, Galicians, Asturians—may perhaps be regarded as the purest representatives of the Spanish stock. The Romans gave to Portugal its language and the foundation of its civilization; there is, however, no evidence that they seriously modified the physical type or character of its people. In these respects the Suevic and Visigothic conquests left a more permanent impression, especially in the northern provinces. After 711 came the long period of Moorish (*i.e.,* Arab and Berber) predominance. The influence of the Moors was greatest south of the Tagus. In Alentejo, and still more in Algarve, Arab and Berber types are common; and the influence of these races can everywhere be discerned in the architecture, handicrafts and speech of the peasantry. An intermediate "Mozarabic" population arose, Portuguese in blood, Christian in religion, but Arab in language and manners. Many of the Mozarabs even adopted the characteristic Mohammedan rite of circumcision. Under the tolerant rule of Islam the Portuguese Jews rose to a height of wealth and culture unparalleled in Europe; they intermarried with the Christians both at this period and after their forced conversion by King Emanuel I. (1495–1521). After 1450 yet another ethnical element was introduced into the nation, through the importation of African slaves in vast numbers. Negroid types are common throughout central and southern Portugal.

National Characteristics.— The normal type evolved from this fusion of many races is dark-haired, sallow-skinned, brown-eyed and of low stature. The staple diet of the labouring classes and small farmers is fish, especially the dried codfish called bacalhdo, rice, beans, maize bread and meal, olive oil, fruit and vegetables. Meat is rarely eaten except on festivals. Drunkenness is extremely rare. There is no single national dress, but a great variety of picturesque costumes are worn. The sashes, broad-brimmed hats and copper-tipped quarter-staves of the men, and the brilliant cotton dresses and gold or silver filigree ornaments worn on holidays by the women are common throughout the country and may be seen at their best at bull-fights and at the *romarias* or pilgrimages, which combine religion with the attractions of a fair. The national sport of bull-fighting (*q.v.*) is conducted as humanely as possible, for the Portuguese are lovers of animals. Although the ancient ballads are not forgotten, new words are also fitted to the plaintive folk-tunes (fados) which every farm-hand knows and sings, accompanied sometimes by a rude clarinet or bagpipe, but more frequently by the so-called Portuguese guitar—an instrument which resembles a mandolin rather than the guitars of Italy and Spain. The native dances are obviously Moorish in origin, and depend for their main effects on the movement of the arms and body. Many curious superstitions survive in the country districts, including the beliefs in witches (*feitiçeiras, bruxas*) and werewolves (*lobis-*homens); in sirens (sereias) which haunt the dangerous coast and lure fishermen to destruction; in fairies (*fadas*) and in many kinds of enchantment.

Population.— The population of Portugal, which includes the Azores and Madeira, amounted, in 1940, to 7,709,425 compared with a population of 5,957,985 in 1911. The colonies, which cover a total area of 812,606 sq.mi., have a population of 8,913,076. Emigration has tended to keep the population fairly stationary. In 1919, emigrants mainly to the United States and Brazil numbered 31,138, while between 1912 and 1922 the total emigration was estimated at 700,000. In the first ten years of the 20th century the city population increased by 15% as compared with an increase of 10% for the entire population. The number of foreigners in Portugal remained stationary, with a slight increase of Germans and English. According to the 1930 census, the population of the chief towns was as follows: Lisbon, 594,390; Oporto, 232,280; Setubal, 46,398; Coimbra, 27,333; Braga, 26,962; Evora, 22,061; Faro, 18,019; Covilha, 15,640; Tavira, 12,562; Aveiro, 12,735; Elvas, 12,413; Portalegre, 11,005.

Colonies.—At the beginning of the 19th century Portugal possessed a larger colonial empire than any European power except Grest Britain and Spain. At the beginning of the 20th century its transmarine possessions had been greatly reduced in size by the loss of Brazil, but were still only surpassed in extent by those of three powers—Great Britain, France and Germany. Their total area was about 812,606 sq.m., of which 803,634 sq.m. are in Africa. They comprised, in Africa, the Cape Verde Islands, St. Thomas and Prince's islands, Portuguese Guinea, Angola and Portuguese East Africa or Mozambique; in India, Goa, Damão and Diu; in China, Macao; and in the Malay Archipelago part of Timor. All these are described in separate articles.

BIBLIOGRAPHY.—Numerous official reports, chiefly statistical, are published periodically in Lisbon; a few are written in French, the majority in Portuguese. Read in conjunction with the British consular and diplomatic reports, they afford a comprehensive survey of the movement of population, the progress of trade, etc. The following state papers deserve special notice: *Caminhos de ferro* (1877, etc.), *Commercio e navegação* (annual, issued by the Ministry of Marine), *Le Portugal vinicole* (1900), *Le Portugal . . . agricole* (1900), *Notas sobre Portugal* (2 vols., 1908). For geology, see the section of *Le Portugal . . . agricole* written by P. Choffat and entitled "Aperçu de la géologie de Portugal," also "The Work of the Portuguese Geological Survey," by Philip Lake, in *Science Progress* (1896) v. 439–453; both these summaries refer to the most important original papers. Two illustrated volumes by Oswald Crawford, *Portugal Old and New* (London, 1880) and *Round the Calendar in Portugal* (London, 1890) contain much valuable information on agriculture, viticulture and peasant life in the northern provinces. *Through Portugal,* by Major Martin Hume (London, 1907) and *Lisbon, Cintra, etc.,* by A. C. Inchbold (London, 1907), describe the towns, etc., most frequently visited by tourists, and are illustrated in colours. *Le Portugal* (Paris, 1899), by 18 writers, is a brief but encyclopaedic description of continental Portugal. *See* also *Portugal: its Land and People,* by W. H. Koebel (London, 1909), *Por-*

tuguese Architecture, by W. C. Watson (London, 1908); *A.* Marvaud, *Le Portugal et ses Colonies* (Paris, 1912); G. Diercks, *Das moderne Portugal* (Berlin, 1913); B. Carqueja, *O Povo Portuguez* (Porto, 1916); L. Poinsard, *Le Portugal Inconnu* (Paris, 1910). *In* 1915 Portugal was included in the "Countries and Peoples" Series.

(X.)

DEFENCE

Historical.—The Portuguese army bore its full share in the expulsion of the French army in the Peninsular war. In the later days of the monarchy the army was maintained partly by conscription and partly by voluntary enlistment under an Act of 1887. The army was reorganized by subsequent acts in 1899 and 1901 and it has since passed through various changes due to those in the political situation. Two Portuguese divisions served in France with the British Army in the World War.

Recruitment and Service.—Preliminary military training is given to youths of 18 to 20 years, after which age compulsory military service in the home army is enforced. This service is for 10 years with the active army and 10 years in reserve, followed by 5 years in the territorial army, ending at the age of 45. Certain exemptions are allowed. The first training consists of a 5 months recruit course followed by 12 months further training. There is a war school to train officers and also a central sergeants school through which non-commissioned officers can obtain commissions. Recruiting for the Colonial Forces, which form an integral part of the Portuguese army, is for 15 years of which 10 years are spent in the active army and 5 years in the territorial reserve. Members of the home army who join the colonial army spend 4 years therein. Reductions are made for volunteers and for certain others, from the 10 year period of active service.

Strength and Organization.—The budget effectives in the home army in 1927 numbered 52,747, including 4,320 officers, and 25,000 recruits undergoing their 5 months recruit course. The army is organized in 22 infantry regiments (which in peace-time act as training centres, etc.); 10 battalions of light infantry, each of which contains 4 rifle companies, a machine-gun company, headquarter wing and depot section; 2 cyclist battalions, each having 2 cyclist rifle companies and a machine-gun company; and 3 machine-gun battalions. The cavalry is organized in 2 brigades, each of 3 regiments (temporarily two), one motor machine-gun squadron, one cyclist battalion, and a horse artillery group. The artillery which has headquarters in Lisbon, the Azores and Madeira, is organized in 5 regiments of light artillery, 3 of heavy artillery, in addition to a battery of heavy trench mortars, and 2 regiments of coast artillery with 3 batteries of mobile coast artillery, a submarine coast defence group (for Lisbon defences) and 2 specialist companies. The engineers contain the usual branches and include telegraphists. The National Republican Guard, distributed over all Portuguese territory, numbers about 9,joo, organized in one cavalry regiment and 8 infantry battalions. The Colonial army numbers 12,500 and possesses an Air Service.

The war minister is the head of the army. In war the Government appoints a commander-in-chief to control operations and command the troops under the war ministry. There is a supreme council for national defence, of which either the President or the prime minister acts as chairman, a chief of the army staff, and inspectorates of the various arms.

In addition to the Central Schools mentioned above, there is a military college, military school and schools for all arms of the service, for motor drivers and for military administration. Certain ports in the Azores have been classed as fortresses, but Lisbon is the only one that is provided with any modern defences. The army air force is being reorganized in one offensive and defensive group, one bombing group, and one observation group, each of 2 squadrons; and a train and depot squadron. The air service includes a command headquarters and inspectorate, aeroplane and balloon departments, anti-aircraft defence, and flying schools. There are 59 instructional machines of various types; 14 bombing machines of which 12 are Breguet 14 A2 type; 14 scouts of which 10 are of Vickers-Valparaiso type; and 14 fighters, of "Squad VII." type.

See also League of Nations *Armaments Year-book* (Geneva 1928).

(G. G. A.)

Navy.—The fleet of Portugal consists (1928) of two old cruisers, the "Vasco da Gama" (1876, reconstructed 1902), the "Adamaston" (1896, refitted 1919–22); two sloops (ex-British fleet sweeping vessels); five destroyers; five torpedo boats; four submarines; and 18 miscellaneous craft. The personnel consists of 725 officers and 4,445 men. There is a minister of marine, who is a member of the Council for National Defence. (E. A.)

ECONOMIC CONDITIONS

Agriculture.—Portugal is primarily an agricultural country, 60% of the population being engaged in agricultural pursuits, though there are signs that the country, like so many Continental states, is becoming industrialized. The land is exceedingly fertile owing to its sunny and moist climate; yet more than a third of the land awaits exploitation. The principal handicap to agricultural development is the lack of adequate transport facilities. The roads have not been adequately repaired for 15 or 20 years, and their condition is estimated to have doubled the cost of transport.

The state railways have also fallen into a serious state of disrepair and consequently it has been found cheaper to import wheat direct from the Argentine than to send supplies to the north of Portugal from the Alentejo. Lack of fertilizers is another serious handicap. The most valuable crop is wheat, the harvest averaging 230,000 tons annually. The country, however, is compelled to import between 100,000 to 150,000 tons of wheat annually, despite the efforts of successive Governments to encourage wheat growing.

Wine is the principal product of Portugal, accounting for 50% of its exports; for the first six months of 1927 over one million pounds' worth of port wine was shipped to Great Britain. Table wines are produced all over the country, and are exported to Brazil and also to France.

Portugal is the third olive-producing country in the world, her olive-trees occupying an acreage of 750,000 and giving 12,760,000 gal. of oil. Other crops grown on a large scale are maize, rye, oats and barley. About 200,000 tons of potatoes are produced and there is a large export trade in fruit, mainly to England. Livestock is about equal in number to the population and an important industry is the production of corks which reaches about 70,000 tons annually.

Commerce and Manufactures.—Portuguese trade has been considerably hampered by the political uncertainty and by the fall and instability of the escudo, whose value at par is 4s. $5\frac{1}{4}$ d, but which in 1928 was worth about $2\frac{1}{2}$d. Great Britain is still Portugal's best customer, buying the greater portion of her port and madeira, her fruit, cork, sardines and mineral ore. After wine, the most important export is canned sardines and tunny fish, the principal customers being Great Britain and the United States.

Portugal is hampered by the necessity of having to buy abroad foodstuffs, particularly wheat and maize and fish (bought from Newfoundland and Norway). The value of the oil imported now exceeds that of coal which averaged before the World War about 1,000,000 to 1,500,000 tons, almost entirely bought from Great Britain. Cotton and woollen goods are also largely imported from Great Britain; agricultural machinery comes mainly from the United States and Germany; and Belgium supplies most of the railway material. The following are the latest Portuguese figures: for the year 1926, general imports, 2,685,385 contos[1]; general exports (including re-exports) 1,072,574 contos. In 1927, according to British figures, the British imports from Portugal amounted to £4,718,733; exports to £3,889,703; re-exports to £430,645.

Portugal's principal manufacturing industry is the production of textiles, employing 45,000 work-people, half of whom are in the cotton factories of Oporto and district, the remainder being engaged in the wool, silk and linen industries. Other industries are the making of tiles and the embroideries of Madeira, the annual export of which to the United States alone amounts to about £2,000,000.

On April 30 the 35-year monopoly of the tobacco industry came

[1]The *conto* of 1,000 *escudos* is equal (1929) to about £9.5s.

to an end; it was this burning question which was the main cause of the revolutionary movement in May 1926, which brought the dictatorship into power. The Government which came into office in May 1926 considered themselves compelled to establish free conditions for the industry, but were confronted with a difficult problem owing to the number of existing factories and large personnel. Under the new régime then established, the finance minister expected a revenue of at least two million sterling.

Finance. — Portuguese financial difficulties are due to causes which may be stated thus: (1) One-half the national expenditure is devoted to the military establishment. (2) The tendency of wealthy Portuguese to send their capital abroad. (3) The hoarding habits of the peasantry. (4) The large purchases of foodstuffs and raw materials from abroad. (5) Foreign liabilities like the debt to Great Britain, which was funded in 1927 on the basis of a present cash value of £5,500,000,—the debt actually amounting, with accumulated interest, to over £22,000,000. (6) The increase in the number of civil servants and in their emoluments.

During the first nine months of the financial year June 30, 1926, to March 31, 1927, the total expenditure amounted to 1,468,486 contos, revenue falling short of this amount by 494,924 contos, or five million sterling. The official estimate of the probable deficit for the full year ending on June 30, 1927, was 564,025 contos.

See British Department of Overseas Trade, *Annual Reports* on *Portugal* (London); *Annuario Estatistico de Portugal* (Lisbon).
(N. F. G.)

HISTORY

Throughout the centuries which witnessed the destruction of Carthaginian power by Rome, the establishment and decline of Latin civilization, the invasion by Alani, Suevi and other barbarian races, the resettlement under Visigothic rule and the overthrow of the Visigoths by Arab and Berber tribes from Africa, Portugal remained an undifferentiated part of Hispania, without sign of national consciousness. The Iberian Peninsula was one: and its common history is related under SPAIN. In 1095 Portugal was still an obscure border fief of the kingdom of Leon, bounded on the north by the Minho, on the south by the Mondego. Its name (*Portucalia,* Terra *portucalensis*) was derived from the little seaport of Portus Cale or Villa Nova de Gaia, now a suburb of Oporto, at the mouth of the Douro. Its inhabitants, surrounded by Moorish or Spanish enemies and distracted by civil war, derived the rudiments of civilization from Arabic or Leonese sources.

The history of the nation comprises eight periods. (1) Between 1095 and 1279 a Portuguese kingdom was established and extended until it reached its present continental limits. (2) Between 1279 and 1415 the monarchy was gradually consolidated in spite of resistance from the Church, the nobles and the rival kingdom of Castile. (3) In 1415 began a period of crusades and discoveries, culminating in the discovery of an ocean-route to India (1497–99). (4) From 1499 to 1580 Portugal acquired an empire stretching from Brazil eastward to the Moluccas, reached the eenith of its prosperity and entered upon a period of swift decline. (5) Spanish kings ruled over Portugal from 1581 to 1640. (6) The chief event of the years 1640 to 1755 was the restoration of the Portuguese monarchy. (7) Between 1755 and 1826 the reforms of Pombal and the Peninsular War prepared the country for a change trom absolutism to constitutional monarchy. (8) In 1826 the era of constitutional government began.

Establishment **of the Monarchy.**—Among the crusading knights in Spain was Count Henry of Burgundy, an ambitious warrior who, in 1095, married Theresa, natural daughter of Alphonso VI., king of Leon. The county of Portugal, which had already been won back from the Moors (1055–64), was included in Theresa's dowry. Count Henry ruled as a vassal of Alphonso VI., whose Galician marches were thus secured against any sudden Moorish raid. But in 1109 Alphonso VI. died, bequeathing all his tersitories to his legitimate daughter Urraca, and Count Henry at once invaded Leon, hoping to add to his own dominions at the expense of his suzerain. At his death in 1112 he left Theresa to govern Portugal north of the Mondego during the minority of her infant son Affonso Henriques (Alphonso I.): south of the Mondego the Moors were still supreme.

Theresa renewed the struggle against her half-sister and suzerain Urraca in 1116–17, and again in 1120; in 1121 she was besieged in Lanhoso and captured. But a peace was negotiated by the archbishops Diego Gelmirez of Santiago de Compostela and Burdino of Braga, rival churchmen whose wealth and military resources enabled them to dictate terms. It was arranged that Theresa should be liberated and should continue to hold the county of Portugal as a fief (honor) of Leon. During the next five years she lavished wealth and titles upon her lover Fernando Peres, count of Trava, thus estranging her son, the archbishop of Braga, and the nobles, most of whom were foreign crusaders. In 1128, after her power had been crushed in another unsuccessful conflict with Leon and Castile, she was deposed by her own rebellious subjects and exiled in company with Peres. She died in 1130.

Her son, Alphonso I., was occupied in almost incessant border fighting against his Christian or Moorish neighbours. Twelve years of campaigning on the Galician frontier were concluded in 1143 by the peace of Zamora, in which Alphonso was recognized as independent of any Spanish sovereign. In 1167, war was renewed. Alphonso succeeded in conquering part of Galicia, but in attempting to capture the frontier fortress of Badajoz he was wounded and forced to surrender to his son-in-law, Ferdinand II. of Leon (1169). He was released under promise to abandon all his conquests in Galicia.

He had already won many victories over the Moors. On July 25, 1139, he defeated their combined forces on the plains of Ourique, in Alentejo. On March 15, 1147, he stormed the fortress of Santarem, and about the same time a band of crusaders on their way to Palestine landed at Oporto and volunteered for the impending siege of Lisbon. Among them were many Englishmen, Germans and Flemings, who were afterwards induced to settle in Portugal. Aided by these powerful allies, Alphonso captured Lisbon on Oct. 24, 1147. Between 1179 and 1184 the Moors retrieved many of their losses in Alentejo, but were unable to retake Santarem and Lisbon. Alphonso died on Dec. 6, 1185. He had secured for Portugal the status though not the name of an independent kingdom, and had extended its frontier southwards from the Mondego to the Tagus.

Sancho I. continued the war against the Moors with varying fortune. In 1189 he won Silves, then the capital of Algarve; in 1192 he lost not only Algarve but the greater part of Alentejo, including Alcacer do Sal. A peace was then arranged, and for the next eight years Sancho was engaged in hostilities against Alphonso IX. of Leon. He granted fresh charters to many cities, legalizing the system of self-government which the Romans had bequeathed to the Visigoths and the Moors had retained or improved. Lisbon had already (1179) received a charter from Alphonso I. Towards the close of his reign he became embroiled in a dispute with Pope Innocent III. As Sancho was in weak health and had no means of resisting papal pressure, he made full submission (1210); and after bestowing large estates on his sons and daughters, he retired into the monastery of Alcobaca (*q.v.*), where he died in 1211.

The reign of Alphonso II. ("the Fat") is noteworthy for the first meeting of the Portuguese cortes, to which the upper hierarchy of the Church and the nobies (*fidalgos* and *ricos* homens) were summoned by royal writ. The king was no warrior, but in 1212 a Portuguese contingent aided the Castilians to defeat the Moors at Las Navas de Tolosa, and in 1217 the ministers, bishops and captains of the realm, reinforced by foreign crusaders, retook Alcacer do Sal (first captured in 1158). Alphonso II. repudiated the will of his father, refused to surrender the estates left to his brothers, who went into exile, and only gave up the property bequeathed to his sisters after a prolonged civil war in which Alphonso IX. of Leon took part against them. Even then he compelled the heiresses to take the veil. His attempts to strengthen the monarchy and fill the treasury at the expense of the Church resulted in his excommunication by Pope Honorius III., and Portugal remained under interdict until Alphonso II. died in 1223.

Sancho II. succeeded at the age of 13. In 1227 he assumed control of the kingdom. He continued the crusade against the Moors, who were driven from their last strongholds in Alentejo, but his career of conquest in Algarve was cut short by a revolution (1245). The pope issued a bull of deposition in favour of Alphonso, who reached Lisbon in 1246; and after a civil war lasting two years Sancho II retired to Toledo, where he died in Jan. 1248.

One of the first acts of the usurper was to abandon the semi-ecclesiastical titles of visitor (visitador) or defender (curador) of the realm, and to proclaim himself king (rei). Shortly afterwards the conquest of Algarve deprived the Moors of their last remaining stronghold. A war with Alphonso X. of Leon and Castile followed; it ended by Alphonso III. consenting to wed Doña Beatriz de Guzman, illegitimate daughter of Alphonso X., and to hold Algarve as a fief of Castile. The celebration of this marriage, while Matilda, countess of Boulogne and first wife of Alphonso III., was still alive, entailed the imposition of an interdict upon the kingdom. The clergy suffered more than the laity under the interdict, and in 1262 Pope Urban VI. legalized the disputed marriage and legitimized Dom Diniz, the king's eldest son. In 1263 Alphonso X. renounced his claim to suzerainty over Algarve, and thus the kingdom of Portugal simultaneously reached its present European limits and attained its complete independence. Lisbon was henceforth recognized as the capital. Alphonso III. continued to reign until his death in 1279, but the peace of his later years was broken by the rebellion (1277–79) of D. Diniz, the heir-apparent.

Consolidation of the Monarchy: 1279–1415.—The chief problems now confronting the monarchy were no longer military, but political. Hostilities between Portugal and the reunited kingdoms of Leon and Castile were terminated in 1297 by a treaty of alliance, in accordance with which Ferdinand IV. of Leon and Castile married Constance, daughter of Diniz, while Alphonso, son of Diniz, married Beatrice of Castile, daughter of Ferdinand. A further outbreak of civil war, between the king and the heir-apparent, was averted in 1293 by the queen-consort Isabella of Portugal, who had married Diniz in 1281, and was canonized for her many virtues in the 16th century. Diniz earned his title of the *rei lavrador* or "farmer king" by introducing improved methods of cultivation and founding agricultural schools. He encouraged maritime trade by negotiating a commercial treaty with England (1294) and forming a royal navy (1317) under the command of a Genoese admiral named Emmanuele di Pezagna (Manoel Pessanha). In 1290 he founded the University of Coimbra (*q.v.*). He was a poet and a patron of literature and music (see Literature, p. 290). He encouraged and nationalized the military orders.

Alphonso IV. adhered to the matrimonial policy initiated by Diniz. He arranged that his daughter Maria should wed Alphonso XI. of Castile (1328), but the marriage precipitated the war it was intended to avert, and peace was only restored (1330) after Queen Isabella had again intervened. Pedro, the crown prince, afterwards married Constance, daughter of the duke of Peñafiel (near Valladolid), and Alphonso IV. brought a strong Portuguese army to aid the Castilians against the Moors of Granada and their African allies. In the victory won by the Christians on the banks of the river Salado, near Tarifa, he earned his title of Alphonso the Brave (1340). In 1347 he married his daughter Leonora to Pedro IV. of Aragon. The later years of his reign were darkened by the tragedy of Inez de Castro (*q.v.*). He died in 1357, and the first act of his successor, Pedro the Severe, was to take vengeance on the murderers of Inez. Throughout his reign he strengthened the central Government at the expense of the aristocracy and the Church, by a stern enforcement of law and order. In 1361, at the cartes of Elvas, it was enacted that the privileges of the clergy should only be deemed valid in so far as they did not conflict with the royal prerogative. Pedro maintained friendly relations with England.

During the reign of Ferdinand (1367–83) and under the regency of Leonora the ruling dynasty ceased to represent the national will. Ferdinand, a weak but ambitious and unscrupulous king, claimed the thrones of Castile and Leon, left vacant by the death of Pedro I. of Castile (1369). In 1371 Pope Gregory XI. intervened, and it was decided that Ferdinand should renounce his claim and marry Leonora, the daughter of his successful rival. Ferdinand, however, preferred his Portuguese mistress, Leonora Telles de Meneses, whom he eventually married. To avenge this slight, Henry of Castile invaded Portugal and besieged Lisbon. Ferdinand appealed to John of Gaunt, who also claimed the throne of Castile, on behalf of his wife Constance, daughter of Pedro I. of Castile. An alliance between Portugal and England was concluded; and although Ferdinand made peace with Castile in 1374, he renewed his claim in 1380, after the death of Henry of Castile, and sent João Fernandes Andeiro, count of Ourem, to secure English aid. In 1381 Richard II. of England despatched a powerful force to Lisbon, and betrothed his cousin, Prince Edward, to Beatrice, only child of Ferdinand, who had been recognized as heiress to the throne by the cortes of Leiria (1376). In 1383, however, Ferdinand made peace with John I. of Castile at Salvaterra, deserting his English allies, who retaliated by ravaging part of his territory. By the treaty of Salvaterra it was agreed that Beatrice should marry John I. Six months later Ferdinand died, and in accordance with the terms of the treaty Leonora became regent until the eldest son of John I. and Beatrice should be of age.

Leonora had long carried on an intrigue with the count of Ourem, whose influence was resented by the leaders of the aristocracy, while her tyrannical rule also aroused bitter opposition. The malcontents chose D. John, grand-master of the knights of Aviz and illegitimate son of Pedro the Severe, as their leader, organized a revolt in Lisbon, and assassinated the count of Ourem within the royal palace (Dec. 6, 1383). Leonora fled to Santarem and summoned aid from Castile, while D. John was proclaimed defender of Portugal. In 1384 a Castilian army invested Lisbon, but encountered a heroic resistance, and after five months an outbreak of plague compelled them to raise the siege. John I. of Castile, discovering or alleging that Leonora had plotted to poison him, imprisoned her in a convent at Tordesillas, where she died in 1386. Before this, Nuno Alvares Pereira, constable of Portugal, had gained his popular title of "The Holy Constable" by twice defeating the invaders, at Atoleiro and Trancoso in the district of Guarda. On April 16, 1385, the cortes assembled at Coimbra declared the crown of Portugal elective, and at the instance of João das Regras, the chancellor, D. John was chosen king.

Ferdinand had been the last legitimate descendant of Count Henry of Burgundy. With John I. began the rule of a new dynasty, the House of Aviz. The most urgent matter which confronted the king—or the group of statesmen, led by João das Regras and the "Holy Constable" who inspired his policy—was the menace of Castilian aggression. But on Aug. 14, 1385, the Portuguese army, aided by 500 English archers, utterly defeated the Castilians at Aljubarrota. In October the "Holy Constable" won another victory at Valverde; early in 1386 5,000 English soldiers, under John of Gaunt, reinforced the Portuguese; and by the treaty of Windsor (May 9, 1386), the alliance between Portugal and England was confirmed and extended. Against such a combination the Castilians were powerless; a truce was arranged in 1387 and renewed at intervals until 1411, when peace was concluded. D. Diniz, eldest son of Inez de Castro, claimed the throne and invaded Portugal in 1398, but his supporters were easily crushed. At home John I. endeavoured to reform administration, to encourage agriculture and commerce, and to secure the loyalty of the nobles by grants of land and privileges so extensive that, towards the end of his reign, many nobles who exercised their full feudal rights had become almost independent princes. Abroad, he aimed at peace with Castile and close friendship with England. In 1387 he had married Philippa of Lancaster, daughter of John of Gaunt; Richard II. sent troops to aid in the expulsion of D. Diniz; Henry IV., Henry V. and Henry VI. of England successively ratified the treaty of Windsor; Henry IV. made his ally a knight of the Garter in 1400. The convent of Batalha (*q.v.*), founded to commemorate the victory of Aljubarrota, is architecturally a monument of the English influence prevalent at this time throughout Portugal.

The cortes of Coimbra, the battle of Aljubarrota and the treaty of Windsor mark the three final stages in the consolidation of the monarchy. A period of expansion oversea began in the same reign. with the capture of Ceuta in Morocco in 1415.

The Period **of** Discoveries: **1415–1499.**—As the south-westernmost of the free peoples of Europe, the Portuguese were the natural inheritors of that work of exploration which had been carried on during the middle ages, chiefly by the Arabs. They began where the Arabs left off, by penetrating far into the Atlantic. The long littoral of their country, with its fine harbours and rivers flowing westward to the ocean, had been the training-ground of a race of adventurous seamen. It was impossible, moreover, to expand or reach new markets except by sea. The long struggle to expel the Moors, with the influence of foreign Crusaders and the military orders, had given a religious sanction to the desire for martial fame.

It was the genius of Henry of Portugal (*q.v.*) that co-ordinated and utilized all these tendencies towards expansion. Prince Henry placed at the disposal of his captains the vast resources of the Order of Christ (the Portuguese branch of the Knights Templars, reformed and renamed in 1319), the best information and the most accurate instruments and maps. On land he again defeated the Moors, who attempted to re-take Ceuta in 1418; but in an expedition to Tangier, undertaken in 1436 by King Edward (1433–38), the Portuguese army was defeated, and could only escape destruction by surrendering as a hostage Prince Ferdinand, the king's youngest brother. Ferdinand, known as "the Constant," from the fortitude with which he endured captivity, died unransomed in 1443. By sea Prince Henry's captains continued their exploration of Africa and the Atlantic. In 1433 Cape Bojador was doubled; in 1434 the first consignment of slaves was brought to Lisbon; and slave-trading soon became one of the most profitable branches of Portuguese commerce. The Senegal was reached in 1445, Cape Verde was passed in the same year, and in 1446 Alvaro Fernandes pushed on almost as far as Sierra Leone. This was probably the farthest point reached before the Navigator died (1460). Meanwhile colonization progressed in the Azores and Madeira, where sugar and wine were produced; above all, the gold brought home from Guinea stimulated the commercial energy of the Portuguese. Under Alphonso V., surnamed the African (1443–ST), the Gulf of Guinea was explored as far as Cape St. Catherine, and three expeditions (1458, 1461, 1471) were sent to Morocco; in 1471 Arzila and Tangier were captured from the Moors. Under John II. (1481–95) the fortress of São Jorge da Mina, the modern Elmina (*q.v.*), was founded for the protection of the Guinea trade in 1481–82; Diogo Cam, or Cão, discovered the Congo in the year 1482 and reached Cape Cross in 1486; Bartholomeu Diaz doubled the Cape of Good Hope in 1488, thus proving that the Indian ocean was accessible by sea. After 1492 the discovery of the West Indies by Columbus rendered desirable a delimitation of the Spanish and Portuguese spheres of exploration. This was accomplished by the treaty of Tordesillas (June 7, 1494) which modified the delimitation authorized by Pope Alexander VI. in two bulls issued on May 4,1493. The treaty gave to Portugal all lands which might be discovered east of a straight line drawn from the Arctic Pole to the Antarctic, at a distance of 370 leagues west of Cape Verde. Spain received the lands discovered west of this line. On its provisions were based both the Portuguese claim to Brazil and the Spanish claim to the Moluccas (see MALAY ARCHIPELAGO: History).

After the death of Edward further attempts to curb the power of the nobles were made by his brother, D. Pedro, duke of Coimbra, who acted as regent during the minority of Alphonso V. (1438–47). The head of the aristocratic opposition was the duke of Braganza, who contrived to secure the sympathy of the king and the dismissal of the regent. The quarrel led to civil war, and in May 1449, D. Pedro was defeated and killed. Thenceforward the grants made by John I. were renewed, and extended on so lavish a scale that the Braganza estates alone comprised about a third of the whole kingdom. An unwise foreign policy simultaneously injured the royal prestige, for Alphonso married his own niece, Joanna, daughter of Henry IV. of Castile, and claimed that kingdom in her name. At the bahtle of Toro, in 1476, he was defeated by Ferdinand and Isabella, and in 1478 he was compelled to sign the treaty of Alcantara, by which Joanna was relegated to a convent. His successor, John II. (1481–95) reverted to the policy of matrimonial alliances with Castile and friendship with England. Finding, as he said, that the liberality of former kings had left the Crown "no estates except the high roads of Portugal," he determined to crush the feudal nobility and seize its territories. The leader of the nobles, Ferdinand, duke of Braganza, was beheaded for high treason in 1483; in 1484 the king stabbed to death his own brother-in-law, Ferdinand, duke of Vizeu; and 80 other members of the aristocracy were afterwards executed. Thus John "the Perfect," as he was called, assured the supremacy of the Crown. He was succeeded in 1495 by Emanuel (Manoel) I., who was named "the Great" or "the Fortunate," because in his reign the sea route to India was discovered and a Portuguese empire founded.

(K. G. J.; A. B.)

MODERN TIMES

The Portuguese Empire: 1499–1580. In 1500 King Emanuel assumed the title "Lord of the conquest, navigation and commerce of India, Ethiopia, Arabia and Persia," which was confirmed by Pope Alexander VI. in 1502. The expansion of national interests proceeded rapidly in almost every quarter of the known world. In the North Atlantic Gaspar and Miguel Corte-Real penetrated as far as Greenland (their "Labrador") in 1500–1; but these voyages were politically and commercially unimportant. Equally barren was the intermittent fighting in Morocco, which was regarded as a crusade against the Moors. In the South Atlantic, however, the African coast was further explored, new settlements were founded, and a remarkable development of Portuguese-African civilization took place in the kingdom of Congo. (See ANGOLA.)

Pedro Alvares Cabral, sailing to India, but steering far westward to avoid the winds and currents of the Guinea coast, reached Brazil (1500) and claimed it for his sovereign. Jodo da Nova discovered Ascension (1501) and St. Helena (1502); Tristdo da Cunha was the first to sight the archipelago still known by his name (1506). In East Africa the small Mohammedan states along the coast—Sofala, Mozambique, Kilwa, Brava, Mombasa, Malindi --either were destroyed or become subjects or allies of Portugal. Pedro de Covilham had reached Abyssinia (*q.v.*) as early as 1490; in 1520 a Portuguese embassy arrived at the court of "Prester John," and in 1541 a military force was sent to aid him in repelling a Mohammedan invasion. In the Indian ocean and Arabian sea, one of Cabral's ships discovered Madagascar (1501), which was partly explored by Tristdo da Cunha (1507); Mauritius was discovered in 1507, Socotra occupied in 1506, and in the same year D. Lourenço de Almeida visited Ceylon. In the Red sea Massawa was the most northerly point frequented by the Portuguese until 1541, when a fleet under Estevdo da Gama penetrated as far as Suez. Hormuz, in the Persian gulf, was seized by Alfonso de Albuquerque (1515), who also entered into diplomatic relations with Persia. On the Asiatic mainland the first trading-stations were established by Cabral at Cochin and Calicut (1501); more important, however, were the conquest of Goa (1510) and Malacca (1511) by Albuquerque, and the acquisition of Diu (1535) by Martim Afonso de Sousa, east of Malacca, Albuquerque sent Duarte Fernandes as envoy to Siam (1511), and despatched to the Moluccas two expeditions (1512, 1514), which founded the Portuguese dominion in the Malay archipelago (*q.v.*). Fernão Pires de Andrade visited Canton in 1517 and opened up trade with China, where in 1557 the Portuguese were permitted to occupy Macao. Japan, accidentally discovered by three Portuguese traders in 1542, soon attracted large numbers of merchants and missionaries (see JAPAN). In 1522 one of the ships of Ferdinand Magellan (*q.v.*)—a Portuguese sailor, though in the Spanish service—completed the first voyage round the world.

Afonso de Albuquerque (*q.v.*), who succeeded Almeida in 1509, modified the policy formulated by his predecessor. Command of the sea could not be maintained while the Portuguese fleets were based at Lisbon. In 1510 he seized Goa; other seaports and islands were conquered or colonized in rapid succession, and by 1540 Portugal had acquired a line of scattered maritime possessions extending along the coasts of Brazil, East and West Africa, Malabar, Ceylon, Persia, Indo-China and the Malay archi-

pelago. The most important settlements in the East were Goa, Malacca and Hormuz. West of the Cape the settlements in Africa and the Atlantic were governed, as a rule, by officials directly nominated by the king. East of the Cape the royal power was delegated to a viceroy or governor, whose legislative and executive authority was almost unlimited during his term of office. The viceroyalty was created in 1505, and from 1511 the Indian capital was Goa. Between 1505 and 1580 only four holders of the office—Almeida (1505–09), Albuquerque (1509–1s), D. Vasco da Gama (1524) and D. João de Castro (1545-45)—were men of marked ability and character.

In theory the most lucrative branches of commerce, such as the pepper trade, were monopolies vested in the Crown which the Crown farmed out to individual merchants, or granted trading-licences by way of pension. Two great powers, Egypt and Turkey, challenged the naval and commercial supremacy of the Portuguese, but an Egyptian armada was destroyed by Almeida in 1509, and though Ottoman fleets were on several occasions (as in 1517 and 1521) despatched from Suez or Basra, they failed to achieve any success, and the Portuguese were able to close the two principal trade routes between India and Europe. After the arrival of the Franciscan missionaries, in 1517, Goa gradually became the headquarters of an immense proselytizing organization, which by 1561 had extended to East Africa, China, Japan and the Malay archipelago, playing an important part in missionary enterprises in the Orient (see GOA, Ecclesiastical History).

The banishment, or forcible conversion of the Jews deprived Portugal of its middle class and of its rnost scientific traders and financiers. John II. gave asylum to 90,000 Jewish refugees from Castile, in return for a heavy poll-tax and on condition that they should leave the country within eight months, in ships furnished by himself. These ships were not provided in time, and the Jews who were thus unable to depart were enslaved, while their children were deported to the island of St. Thomas, and there left to survive as best they might. In 1496 Emanuel I. desired to wed Isabella, daughter of Ferdinand and Isabella, but found that he was first required to purify his kingdom of the Jews, who were accordingly commanded to leave Portugal before the end of Oct. 1497. But in order to avoid the economic dangers threatened by such an exodus, every Jew and Jewess between the ages of four and 24 was seized and forcibly baptized. "Christians" were not required to emigrate. In October 20,000 adults were treated in the same way. These "New Christians," or "Marranos" as they were called, were forbidden to leave the country between 1498 and 1507. In April 1506 nearly 2,000 residing in Lisbon were massacred during a riot, but throughout the rest of Emanuel's reign they were immune from violence, and were again permitted to emigrate—an opportunity of which the majority took advantage. Large numbers settled in Holland, where their commercial talent afterwards greatly assisted the Dutch in their rivalry with the Portuguese. In 1536 the Holy Office was established in Lisbon, where the first auto-da-fk was held in 1540, and in 1560 its operations were extended to India.

During the reign of Emanuel I. (1495–1521) the Church was never permitted to encroach upon the royal prerogative. He even sent ambassadors to Rome to protest against ecclesiastical corruption, as well as to checkmate the Venetian diplomatists who threatened Europe with Ottoman vengeance if the Portuguese commercial monopoly were not relaxed. But Emanuel I. was the last great king of the Aviz dynasty. He had pursued the traditional policy of intermarriage with the royal families of Castile and Aragon, hoping to weld together the Spanish and Portuguese dominions into a single world-wide empire ruled by the house of Aviz. But his ambition was not fulfilled, for Prince Miguel, his eldest son, died in infancy, and the inheritance passed to the Habsburgs. John III. (1521–57) was a ruler of fair ability, who became in his later years wholly subservient to his ecclesiastical advisers. He was succeeded by his grandson Sebastian (1557–78), aged three years. Until the king came of age (1568), his grandmother, Queen Catherine, daughter of Isabella the Catholic, and his great-uncle, Prince Henry, cardinal and inquisitor-general, governed as joint regents. Both were dominated by their Jesuit confessors, and a Jesuit, D. Luiz Gonçalves da Camara, became the tutor and, after 1568, the principal adviser of Sebastian.

The king was a strong-willed and weak-minded ascetic, who entrusted his empire to the Jesuits, refused to marry although the dynasty was threatened with extinction, and spent years in preparing for a crusade against the Moors. He collected a force of some 18,000 men, chiefly untrained lads, worn-out veterans, and foreign free-lances; but on Aug. 4, 1578, they were surrounded at Al Kasr al Kebir (*q.v.*) by the superior forces of Abd el Malek, the reigning sultan, and after a brave but ineffective resistance Sebastian was killed and his nondescript army almost annihilated (see SEBASTIAN).

Cardinal Henry, who now became king, died on Jan. 31, 1580, and the throne was left vacant. There were five principal claimants—Philip II. of Spain; Philibert, duke of Savoy; Antonio, prior of Crato; Catherine, duchess of Braganza; and Ranuccio, duke of Parma—whose relationship to Emanuel I. is shown in the table above.

The "Sixty Years' Captivity": 1581–1640.—The prior of Crato was the only rival who offered any serious resistance to Philip II. D. Antonio proclaimed himself king and occupied Lisbon. The advocates of union with Spain, however, were numerous, influential, and ably led by their spokesmen in the cortes, Christovão de Moura and Antonio Pinheiro, bishop of Leiria. In 1581 a Spanish army, led by the duke of Alva, entered Portugal and easily defeated the levies of D. Antonio at Alcbntara. The prior escaped to Paris and appealed to France and England for assistance. In 1582 a French fleet attempted to seize the Azores in his interest, but was defeated. In 1589 an English fleet was sent to aid the prior, but owing to a quarrel between its commanders, Sir Francis Drake and Sir John Norris, the expedition was abandoned. D. Antonio returned to Paris, where he died in 1594.

Meanwhile, the victory of Alcdntara left Philip II. supreme in Portugal, where he was soon afterwards crowned king. His constitutional position was defined at the cortes of Thomar (1581). Portugal was not to be regarded as a conquered or annexed province, but as a separate kingdom, joined to Spain solely by a personal union similar to the union between Castile and Aragon under Ferdinand and Isabella. At Thomar Philip II. promised to maintain the rights and liberties conceded by his predecessors on the Portuguese throne, to summon the cortes at frequent intervals, and to create a Portuguese privy council.

Insurrections in Lisbon (1634) and Evora (1637) bore witness to the general discontent, but until 1640 the Spanish ascendancy was never seriously endangered. In 1640 war with France and a revolution in Catalonia had taxed the military resources of Spain to the utmost. The royal authority in Portugal was delegated to Margaret of Savoy, duchess of Mantua, whose train of Spanish and Italian courtiers aroused the jealousy of the Portuguese nobles, while the harsh rule of her secretary of state, Miguel de

Vasconcellos de Brito, provoked the resentment of all classes. Even the Jesuits, whose influence in Portugal had steadily increased since 1555, were now prepared to act in the interests of Cardinal Richelieu, and therefore against Philip IV. A leader was found in John, 8th duke of Braganza, who as a grandson of the duchess Catherine was descended from Emanuel I. On Dec. 1, 1640, various strategic points were seized, the few partisans of Spain who attempted resistance were overpowered, and a provisional government was formed under D. Rodrigo da Cunha, archbishop of Lisbon.

The Restoration: 1640-1755. On Dec. 13, 1640, the duke of Braganza was crowned as John IV., and on Jan. 19, 1641, the cortes formally accepted him as king. Thus the "Sixty Years' Captivity" came to an end and the throne passed to the house of Braganza. In the subsequent struggle the Portuguese armies were at first successful. D. Matheus de Albuquerque defeated the Spaniards under the baron of Molingen at Montijo (May 26, 1644), and throughout the reign of John IV. (1640–56) they suffered no serious reverse.

John IV. was succeeded by his second son, Alphonso VI. (1656–83), then aged thirteen. During the king's minority the queen-mother, D. Luisa, acted as regent. She prosecuted the war with vigour, and on Jan. 14, 1659, a Portuguese army defeated the Spaniards at Elvas. In March 1659, however, the war between France and Spain was ended by the treaty of the Pyrenees; and D. Luis de Haro, acting as the Spanish plenipotentiary, obtained the inclusion in the treaty of a secret article by which France undertook to give no further aid to Portugal. In May 1663 the marriage was celebrated between Charles II. of England and Catherine of Braganza and Great Britain took the place of France as the active ally of Portugal. The dowry to be paid by Portugal was fixed at £500,000 and the cession to Great Britain of Bombay and Tangier.

On June 20, 1662, the feeble Alphonso VI. declared himself of age and seized the royal authority. The count of Castello Melhor directed the policy of the nation while Schomberg took charge of its defence. The army, reinforced by British troops under the earl of Inchiquin and by French and German volunteers or mercenaries, was led in the field by Portuguese generals, who successfully carried out the plans of Schomberg. On June 8, 1663, the count of Villa Flor defeated D. John of Austria, and retook Evora, which had been captured by the invaders; on July 7, 1664, Pedro de Magalhães defeated the duke of Osuna at Ciudad Rodrigo; on June 17, 1665, the marquess of Marialva destroyed a Spanish army at the battle of Montes Claros, and Christovão de Brito Pereira followed up this victory with another at Villa Viçosa. The Spaniards failed to gain any compensating advantage, and on Feb. 13, 1668, peace was concluded at Lisbon, Spain consenting to recognize the independence of the Portuguese kingdom.

Pedro II., who by a palace intrigue had deposed and imprisoned Alphonso VI., acted as regent for 15 years. In 1683, on the death of the latter at Cintra, he became king. His reign (1683–1706) is a period of supreme importance in the economic and constitutional history of Portugal. The goldfields of Minas Geraes in Brazil, discovered about 1693, brought a vast revenue in royalties to the Crown, which was thus enabled to govern without summoning the cortes to vote supply. In 1697 the cortes met for the last time before the era of constitutional government.

On March 7, 1704, a British fleet under Sir George Rooke reached Lisbon, convoying the archduke Charles and 10,000 British troops, who were joined by a Portuguese army under D. João de Sousa, marquess das Minas, and at once invaded Spain. (For the campaigns of 1704–13, see SPANISH SUCCESSION, WAR OF THE.) In 1705 Pedro II. was compelled by failing health to appoint a regent, and chose his sister, Catherine of Braganza, queen dowager of England. On the death of the king (Dec. 9. 1706) his minister, the duke of Cadaval, arranged a marriage between his successor John V. (1706–50) and the archduchess Marianna, sister of the archduke Charles, thus binding Portugal more closely to the Anglo-Austrian cause. The strain of the war was acutely felt in Portugal, especially in 1711, when the French admiral Duguay-Trouin sacked Rio de Janeiro and cut off the Brazilian treasure-ships. On Feb. 6, 1715, nearly two years after the Treaty of Utrecht, peace between Spain and Portugal was concluded at Madrid.

The Reform of the Monarchy. — John V. was a spendthrift and a bigot. He gave and lent enormous sums to successive popes, and at the bidding of Clement XI. he joined a "crusade" against the Turks in which his ships helped to win a naval action off Cape Matapan (1717). For these services he received the title of Fidelissimus, "Most Faithful"; "Majesty" had already been adopted by John IV. instead of the mediaeval "Highness."

Pombal.—John V. was succeeded by his son Joseph (175—77). Two days after his accession, Sebastião José de Carvalho e Mello, better known as the marquess of Pombal (*q.v.*), was appointed secretary of state for foreign affairs and war. In a few months he' gained an ascendancy over the king's mind which lasted until the end of the reign, and was strengthened by the courage and wisdom shown by Pombal at the time of the great national disaster of the Lisbon earthquake (see LISBON). He sought to undo the consequences of the Methuen Treaty by the creation of national industries, establishing a gunpowder factory and a sugar refinery in 1751, a silk industry in 1752, wool, paper and glass factories after 1759. Colonial development was fostered, and the commercial dependence of Portugal upon Great Britain was reduced by the formation of chartered companies, the first of which (1753) was given control of the Algarve sardine and tunny fisheries. Both his commercial policy and his desire to strengthen the Crown brought Pombal into conflict with the Church and the aristocracy. In 1751 he had made all sentences passed by the Inquisition subject to revision by the Crown. The liberation of all slaves in Pará and Maranhão except negroes (1755), and the creation of the Pará company, were prejudicial to the interests of the Jesuits, whose administrative authority over the Indians of Brazil was also curtailed. Various charges were brought against the society by Pombal, and in Sept. 1759, after five years of heated controversy (see JESUITS), he published a decree of expulsion against all its members in the Portuguese dominions; in June 1760 the papal nuncio was ordered to leave Lisbon, and diplomatic relations with the Vatican were only resumed after the condemnation of the Jesuits by Clement XIV., in July 17j3.

In 1760 Admiral Boscawen had violated Portuguese neutrality by burning four French ships off Lagos; Pombal protested and the British Government apologized, but not before the military weakness of Portugal had been demonstrated. Two years later, when the Family Compact involved Portugal in a war with Spain, Pombal called in Count William of Lippe-Biickeburg to reorganize the army, which was reinforced by a British contingent under Brigadier-General John Burgoyne, and was increased from 5,000 to 50,000 men. The Spaniards were at first successful, and captured Braganza and Almeida; but they were subsequently defeated at Villa Velha and Valencia de Alcantara, and the Portuguese fully held their own up to the signature of peace at Fontainebleau, in Feb. 1763. After the death of King Joseph (Feb. 20, 1777) and the accession of his daughter Maria I., Pombal's dismissal, brought about by the influence of the queen-mother Mariana Victoria, did not involve an immediate reversal of his policy. The controversy with Spain was amicably settled by the Treaty of San Ildefonso (1777) and further industrial and educational reforms were inaugurated. Queen Maria, who had previously shown signs of religious mania, became wholly insane after 1788, owing to the deaths of her consort, Pedro III. (May, 1786), of the crown prince, D. Joseph, and of her confessor, the inquisitor-general, D. Ignacio de S. Caetano. Her second son, D. John, assumed the conduct of affairs in 1792, although he did not take the title of regent until 1799.

The French Revolution. — To face the revolutionary movement in France a treaty of alliance was signed at Aranjuez in March 1793 between Spain and Portugal; 5,000 Portuguese troops were sent to assist in a Spanish invasion of France; a Portuguese squadron joined the British Mediterranean fleet. But in July 1795 Spain concluded a peace with the French republic from which Portugal, as the ally of Great Britain, was deliberately excluded. In 1797 Spain, at war with Great Britain, secretly negotiated with

France for the partition of Portugal. D. John appealed for help to Great Britain, which sent him 6,000 men, under Sir Charles Stuart, and a subsidy of £200,000. In 1799 negotiations with France were reopened, but D. John rejected the demands of Lucien Bonaparte, Napoleon's emissary, and on Feb. 10, 1801, declared war upon Spain. His territories were at once invaded by a Franco-Spanish army, and on June 6, 1801, he was forced to conclude the peace of Badajoz, by which he ceded the frontier fortress of Olivenza to Spain, and undertook to pay 20,000,000 francs to Napoleon and to exclude British ships from Portuguese ports.

The Peninsular War.—By his Berlin decree of Nov. 21, 1806, Napoleon required all Continental states to close their ports to British ships. As Portugal again refused to obey, another secret Franco-Spanish treaty was signed at Fontainebleau on Oct. 27, 1807, providing for the partition of Portugal. General Junot hastened westward across Spain, at the head of 30,000 French soldiers and a large body of Spanish auxiliaries. So rapid were his movements that there was no time to organize effective resistance. On Nov. 29 D. John, acting on the advice of Sir Sidney Smith, British naval commander in the Tagus, appointed a council of regency and sailed for Brazil, convoyed by Sir Sidney Smith's squadron. On Aug. 1, 1808, Sir Arthur Wellesley, with 9,000 British troops, landed at Figueira da Foz. He defeated a French division at Roliça on the 17th, and on the 21st won a victory over Junot at Vimeiro. Fearing an attack by Portuguese auxiliaries and the arrival of British reinforcements under Sir John Moore, Junot signed the Convention of Cintra by which, on Aug. 30, 1808, he agreed to evacuate Portugal (see WELLINGTON). In Feb. 1809 Major-General 'William Carr Beresford was given command of the Portuguese army. In March Soult crossed the Galician frontier and captured Oporto, while an auxiliary force under General Lapisse advanced from Salamanca. On April 22, however, Wellesley, who had been recalled after the Convention of Cintra, landed in Lisbon. On May 12 he forced the passage of the Douro, subsequently retaking Oporto and pursuing Soult into Spain.

After his defeat by Wellesley (at that time Viscount Wellington) at Bussaco on Sept. 27, 1810, the French general, Marshal Masséna turned the position of the allied army on the Serra de Bussaco, and caused Wellington to fall back upon the fortified lines which he had already constructed at Torres Vedras. On March 5, 1811, after a winter of terrible sufferings, Masséna's retreat began; he was harassed by the allied troops all the way to Sabugal, where the last rearguard action in Portugal took place on April 3 (see PENINSULAR WAR).

The Constitutional Movement.— By a decree dated Jan. 16, 1815, Brazil was raised to the rank of a separate kingdom. The importance of this change became apparent when Queen Maria I died (March 1816) and D. John succeeded to the united thrones as John VI. The king refused to leave Brazil, partly owing to the intrigues of Carlota Joaquina, who hoped to become queen of an independent Brazilian kingdom. In 1817 a military revolt (pronunciamento) in Lisbon was crushed by Beresford, and the leader, Gen. Gomes Freire de Andrade, was executed; but on Aug. 16, 1820, after Beresford had sailed to Brazil to secure the return of John VI., a second rising took place in Oporto It soon spread southward. A new council of regency was established in Lisbon, the British officers were expelled from the army; Beresford, on his return from Brazil, was not permitted to land; a constituent assembly was summoned and drew up a highly democratic constitution. Great Britain insisted on the return of John VI., who entrusted the government of Brazil to his elder son D. Pedro and landed in Portugal on July 3, 1821. In 1822, on the advice of D. Pedro, he swore to obey the constitution (the "constitution of 1822"). But his younger son, D. Miguel, and the queen, Carlota Joaquina, refused to take the oath; and in Dec. 1822 sentence of banishment was pronounced against them, though not enforced. D Miguel appealed to the army to "restore liberty to their king," and the army, incensed by the loss of Brazil (1822), gave him almost unanimous support. At this juncture John VI., vainly seeking for a compromise, abrogated the constitution of 1822, but appointed as his minister D. Pedro de Sousa Holstein, count (afterwards duke) of Palmella and leader of the "English" or constitutional party. These half-measures did not satisfy D. Miguel, whose soldiers seized the royal palace in Lisbon on April 30, 1824. Palmella was arrested, and John VI forced to take refuge on the British flagship in the Tagus But the united action of the foreign ministers restored the king and reinstated Palmella; the insurrection was crushed; D. Miguel submitted and went into exile (June 1824).

In Brazil also a revolution had taken place. The Brazilians demanded complete independence, and D. Pedro sided with them, The Portuguese garrison of Rio de Janeiro was overpowered; on Sept. 7, 1822, D. Pedro declared the country independent, and on Oct. 12 he was proclaimed constitutional emperor.

John VI. died on March 10, 1826, leaving his daughter, D. Isabel Maria, as regent for Pedro I. of Brazil, who now became Pedro IV. of Portugal. To conciliate the Portuguese, Pedro IV. drew up a charter (the "charter of 1826") which provided for moderate parliamentary government, To conciliate the Brazilians, he undertook (by decree dated May 2, 1826) to surrender the Portuguese Crown to his daughter D. Maria da Gloria (then aged seven); but this abdication was made contingent upon her marriage with her uncle D. Miguel, who was first required to swear fidelity to the charter.

Constitutional Government.— The charter was brought to Lisbon by Sir Charles Stuart in July 1826. The absolutists had hoped that D. Pedro would abdicate unconditionally in favour of D. Miguel, and the council of regency at first refused to publish the charter. They were forced to do so (July 12) by a pronunciamento issued by the count of Saldanha, commander of the army in Oporto, who threatened to march on Lisbon if the regency did not swear obedience to the charter by July 31 In October D. Miguel took the oath and was betrothed to his niece, D Maria da Gloria (Maria II.). Pedro IV. appointed him regent in July 1827 and in Feb. 1828 he landed in Lisbon, where he was received with cries of "Viva D. Miguel I., rei absoluto!" In March he dissolved the parliament which had met in accordance with the charter. In April the Tory ministry under Wellington withdrew Clinton's division, which had been sent by Canning and was the mainstay of the charter. In May D. Miguel summoned a *cortes* of the ancient type, which offered him the Crown; and on July 7, 1828, he took the oath as king.

The Miguelite Wars.—In March 1829 Palmella established a regency in the Azores on behalf of Maria II.; and D. Miguel's fleet was defeated in Praia bay on Aug. 12. In Brazil, D. Pedro abdicated (April 1831), and determined to return to Europe and Conduct in person a campaign for the restoration of Maria II. He was received with enthusiasm by Louis Philippe. In Great Britain Palmella raised a loan of £2,000,000 and purchased a small fleet, of which Captain Sartorius, a retired British naval officer, was appointed admiral. In Feb. 1832 the "Liberators," as they were styled, sailed from Belleisle to the Azores, with D. Pedro aboard the flagship. In July they reached Portugal and occupied Oporto, but the expected constitutionalist rising did not take place. The country was almost unanimous in its loyalty to D. Miguel, who had 80,000 troops against the 6,500 (including 500 French and 300 British) of D. Pedro. But the Miguelites had no navy, and no competent general. They besieged D. Pedro in Oporto from July 1832 to July 1833, when the duke of Terceira and Capt Charles Napier, who had succeeded Sartorius, effected a daring and successful diversion which resulted in the capture of Lisbon (July 24, 1833). Maria II. arrived from France in September, D. Miguel surrendered at Evora-Monte on May 24, 1834. On Sept. 24 D Pedro died.

Maria II was 15 years old at her accession. She was twice married—in Dec. 1834 to Augustus, duke of Leuchtenberg, who died four months afterwards; and in April 1836 to Ferdinand of Saxe-Coburg, who received the title of king-consort in Sept. 1837 By a successful *coup d'état* of Sept. 9–11, 1836, the constitution of 1822 was substituted for the charter of 1826, A pronunciamento by Costa Cabral led to the restoration of the charter on Feb. 10, 1842, and Cabral, who became count of Thomar in 1845, ruled until the "War of Maria da Fonte" (May 1846) drove him into exile. Oporto was held by a revolutionary junta, and Saldanha, who had become prime minister, persuaded the Quadruple Alliance to intervene. In June 1847 the Oporto *junta* surrendered, under promise of an amnesty, to a combined British and Spanish force, and the Convention of Granada (July 24, 1847) ended the war. Saldanha was rewarded with a dukedom, and retained office until June 1849. When Thomar was reinstated his dictatorial rule provoked another successful rising on April 7, 1851. Thomar again fled from the country; Saldanha again became prime minister, but at the head of a moderate coalition. He remained in power for five years (1851–56), and carried many useful reforms. Maria II. died on Nov. 13, 1853, and was succeeded by her eldest son D. Pedro, during whose ministry the king-consort D. Ferdinand acted as regent.

Under the brothers Pedro V. (1853–61) and Luiz[1] (1861–89) Portugal obtained a respite from civil strife. Pedro V. came of age and assumed the government on Nov. 16, 1855; in 1857 he married Princess Stephanie of Hohenzollern. The king died of cholera on Nov. 11, 1861, and two of his brothers, D. Ferdinand and D. John, died shortly afterwards. D. Luiz was absent at the time, and his father, D. Ferdinand, again became regent until his return, soon after which (1862) the new king married Maria Pia, daughter of Victor Emanuel II. of Italy. In 1869 slavery was abolished in every Portuguese colony.

King Luiz died on Oct. 19, 1889, and was succeeded by his son, D. Carlos (*q.v.*). Shortly after his accession a dispute arose with Great Britain (*see* AFRICA), when a Portuguese force under Maj. Serpa Pinto invaded the Shiré highlands in order to forestall their annexation by the British, and the British government demanded satisfaction. Public opinion rendered compliance difficult until a British squadron was despatched to the mouth of the Tagus, and the British minister presented an ultimatum (Jan. 11, 1890), requiring the withdrawal of all Portuguese forces from the Shiré. Barros Gomes was then able to yield under protest; but disturbances at once broke out in Lisbon and Oporto, and the ministry resigned. A republican rising was suppressed in Lisbon, and many suspected officers were degraded.

The extravagant management of the railways guaranteed by the State had entailed such heavy deficits that the payment of the coupon of the railway State loan, due on Jan. 2, 1892, had to be suspended. A serious financial crisis arose, and in May the Portuguese government committed a formal act of bankruptcy by issuing a decree reducing the amount then due to foreign bondholders by two-thirds. The budget showed a deficit. In these circumstances the Republican Party which had been formed in 1881 rapidly gained ground.

The Dictatorship, 1906–8.—An experiment in government by decree had been made in May–Oct. 1894; it was repeated in Sept. 1905, when the king consented to prorogue the *cortes* until Jan. 1906 in order to postpone discussion of the terms upon which the tobacco monopoly was to be allocated. A general election, in Feb. 1906, was followed by three changes of ministry, the last of which, on May 19, inaugurated the *régime* known in Portugal as the *dictadura* or dictatorship. João Franco, the new prime minister, was conspicuous among Portuguese politicians for his integrity, energy and courage; he intended to reform the national finances and administration—by constitutional means, if possible. When the *cortes* met, on Sept. 29, the opposition accused King Carlos of complicity in grave financial scandals. All parties believed that the ministry would fall, when, on May 2, 1907, João Franco reconstructed his cabinet, secured the dissolution of the *cortes* and announced that certain bills still under discussion would receive the force of law.

Assassination of King Carlos.—The ministerial press from time to time announced the discovery of sensational plots against the king and the dictator. It is, however, uncertain whether the assassination of King Carlos and the crown prince (*see* CARLOS I.), on Feb. 1, 1908, was part of a widely organized conspiracy, or whether it was the act of an isolated band of fanatics, unconnected with any political party. The republican press applauded the murder; the professional politicians benefited by it. On May 6, 1908, D. Manoel (*q.v.*) swore to uphold the constitution and was acclaimed king by the *cortes*. His uncle D. Afonso (b. 1865) took a similar oath as crown prince on March 22, 1910.

(K. G. J.)

The Revolution of 1910.—At the general election of Aug. 1910 the republican candidates in Lisbon and Oporto were returned by large majorities. On Oct. 3 the murder of a distinguished republican physician, Dr. Miguel Bombarda, precipitated the revolution which had been organized to take place in Lisbon ten days later. The republican soldiers in Lisbon, aided by armed civilians and by the warships in the Tagus, attacked the loyal garrison, and municipal guards, shelled the Necessidades Palace, and after severe street-fighting (Oct. 4–6) became masters of the capital. The king escaped to Ericeira, and thence, with the other members of the royal family, to Gibraltar. Soon afterwards they travelled to England, where the king was received by the duke of Orleans. A provisional government was formed under the presidency of Dr. Theophilo Braga.

The subsequent political history of Portugal is a record of short-lived ministries and of revolutionary outbreaks. The effects of the revolution fell most heavily on the poor of the country districts and emigration increased to an unprecedented extent.

The Constitution.—The Provisional Government of the republic consisted of Dr. Theophilo Braga (1843–1924), president, Dr. Antonio Almeida (1866–1929), home affairs, Dr. Afonso Costa (justice), Col. Corrêa Barreto (war), Dr. Amaro Azevedo Gomes (marine), Dr. Bernardino Machado (foreign affairs), Dr. Basilio Telles and, later, Dr. José Relvas (finance), Dr. Antonio Luiz Gomes and, later, Dr. Brito Camacho (public works). It lasted till Aug. 24, 1911. On March 18, 1911, the new electoral law came into force. It gave the vote to all Portuguese over 21. By the law of 1918 the number of deputies was reduced to 155, returned by 51 constituencies, of which Lisbon returned 14, Oporto six. The representation in the senate, consisting of 77 members, was made regional and professional.

The constitutional assembly was opened on June 19, 1911, and a decree was passed declaring the monarchy abolished and the house of Braganza for ever banished. On Aug. 20 the new constitution was voted. It provided for two chambers, that of the deputies, consisting of 163 members to be elected every three years, and the senate, consisting of 71 members. The president of the republic was to be elected by both chambers for four years and could not be re-elected.

The first president under the new constitution was Dr. Manuel de Arriaga. Dr. João Chagas (d. 1925) was premier and minister of home affairs in the first constitutional ministry.

Church and State.—The anti-clerical policy of the provisional government had entailed serious difficulties. The bishops signed a pastoral letter of protest, and on March 8, 1911, the bishop of Oporto was removed from his see. The religious orders had been expelled by the decree of Oct. 8, 1910, their property confiscated and the convents closed. By that of Oct. 22 the teaching of religion in the primary schools was forbidden. Marriage of priests became legal. On April 20, 1911, the decree of separation between Church and State was drawn up, and the Roman Catholic religion ceased to be that of the State, which recognized all creeds as of equal authority.

The law was extended in Nov. 1913 to the Portuguese colonies, where the discouragement of Portuguese missions later gave rise to serious fears of the denationalization of the colonies through the activity of foreign missionaries. (Administrative and financial autonomy was given to the colonies on Aug. 15, 1914.) When Paes subsequently became president, one of his first acts was to redress some of the grievances suffered under the law of separation, and, by a decree of Dec. 22, 1917, banishment imposed on the priests was annulled, and the cardinal patriarch returned to Lisbon. Relations with the Vatican, broken off on July 10, 1913, were resumed in 1918.

The Royalist Invasions.—The main event of Senhor Chagas's premiership was the first royalist invasion. Capt. Paiva Couceiro crossed the frontier on Oct. 3, 1911, at the head of about 1,000 men, not a quarter of whom were armed with rifles. He advanced

[1]During the 18th and 19th centuries the name, spelt Luis in the 16th century and since 1911, was spelt Luiz.

towards Braganza, and took the small town of Vinhaes, but evacuated it on Oct. 6 and, after maintaining himself for a fortnight in the hills, recrossed the frontier. A royalist rising in Oporto, timed to coincide with this invasion, was brought prematurely to a head by Carbonario agents on Sept. 29. King Manoel and the pretender, Dom Miguel, met at Dover on Feb. 6, 1912. On July 7 Couceiro again crossed the frontier, with a slightly larger force, but most of his arms and ammunition had been seized in Belgium and Galicia. The royalists' attacks on Valença and Chaves failed, and within a week they returned to Spain.

The arrests after the invasions of 1911 and 1912 were very numerous. Special tribunals were set up in Lisbon and Oporto in Jan. 1911, to try cases of political conspiracy, and in July 1912 Parliament voted still more stringent laws of defence.

Reforms were opposed by the Carbonarios and the radical republicans, and some of the worst outrages were committed under the weak Government which succeeded that of Chagas in Nov. 1911, with Dr. Augusto de Vasconcellos as premier, and under the third coalition ministry formed by Dr. Duarte Leite in July 1912. Dr. Afonso Costa, the radical leader, came into power in Jan. 1913, and the minister of justice introduced a bill modifying the penitenciaria *re'gime,* but the general amnesty was delayed till Feb. 1914. The situation was one of growing unrest. Dr. Afonso Costa, who gave much of his attention to finance, resigned on Feb. 9, 1914, and Dr. Bernardino Machado became premier. He was in office when Portugal definitely ranged herself on the side of the Allies during the World War.

The World War.—At a special joint sitting of both chambers on Aug. 7, 1914, Portugal proclaimed her loyalty to the British alliance, and on Nov. 23 formally committed herself to participation in military operations. She served the cause of the Allies by furnishing munitions, guns and a division of artillery, and acted in close co-operation with Great Britain. On Sept. 11 the first expedition of Portuguese troops left for Africa under the command of Cols. Alves Roçadas and Massano de Amorim, and fresh contingents followed at intervals, 40,000 troops in all being despatched for the defence of the colonies. As early as Aug. 24, 1914, however, a raid by German forces was made on the Portuguese post of Maziwa on the northern frontier of Mozambique. On Oct. 19 the Germans attacked Naulila (on the Angola frontier), where more serious fighting occurred two months later, and on Oct. 30 they stormed the fortress of Kwangar and put the garrison to the sword. On April 11, 1916, Portuguese troops occupied Kionga (south of the Rovuma river), which Germany had seized in 1894, and on May 27 they crossed the Rovuma river. They were still co-operating with the British in rounding up the Germans when the war ended. The British Government had deprecated any unnecessary intervention of Portugal in the war, but agreed to the requisitioning of German ships lying in Portuguese ports, and this was carried into effect in Feb. 1916.

Consequently, Germany retaliated by declaring war on Portugal on March 9 and the declaration of war between Portugal and Austria followed on March 16. German submarines were active off the coast of Portugal during the autumn, many ships being sunk in 1917. By a decree of Jan. 17, 1917, Gen. Fernando Tamagnini de Abreu (d. 1924) was given command of the Portuguese expeditionary force, and by July there were over 40,000 Portuguese troops on the Western Front, with 20,000 in Portugal ready to reinforce them. On April g, 1918, on the Lys river, the Portuguese contingent met a formidable attack by the Germans.

Political Movements During the War.—On Dec. 13, 1914, Dr. Machado was succeeded in the premiership by the democrat, Senhor Azevedo Coutinho, but a military movement following, President Arriaga appealed to Gen. Pimenta de Castro to constitute a Government representative of a wider body of opinion in the country; the latter formed a ministry on Jan. 28, 1915.

The general election was fixed for June 6, 1915. In April an amnesty emptied the prisons. The democrats were, however, able to count on the support of the marines, and on May 14 the sailors mutinied, shot the captains of the "Almirante Reis" and "Vasco da Gama" and bombarded Lisbon, about 100 persons being killed. Pimenta de Castro resigned on May 15 and was arrested next day and transported to the Azores. The revolutionary committee nominated Chagas as premier, but on May 16 he was shot at and wounded in the train on his way to Lisbon. Chagas was succeeded by Dr. José de Castro. In a message addressed to Parliament Arriaga resigned the presidency as from May 29, 1915 (he died on March 5, 1917), and, after an interim presidency under Dr. Theophilo Braga, was succeeded, on Aug. 6, 1915, by Dr. Bernardino Machado. The Government resigned in June, Castro again becoming premier, but in November Dr. Costa returned to office. On Dec. 5, 1917, a revolution, directed against the internal policy of Costa and the Democrats, broke out at Lisbon. After two days' fighting victory was won by the insurgents, whose artillery had opened fire upon the fleet. Dr. Costa was arrested and President Machado was banished. Vice-Admiral Machado dos Santos was released from prison, and with Maj. Sidonio Paes, the leader of the movement, and Capt. Feliciano Costa, formed a revolutionary committee. A provisional government was now constituted, Maj. Paes becoming president and Minister for War and Foreign Affairs. The radical sailors mutinied on Jan. 8, 1918, and bombarded Lisbon, but the movement was quelled and several hundreds were deported to Africa.

In March 1918 Paes reconstructed his ministry, and the elections, on an enlarged franchise, were held on April 28. Paes was elected president by 500,000 votes and was proclaimed president on May g, the Powers recognizing the new *re'gime.*

The first anniversary of the revolution was celebrated with national rejoicings on Dec. 5–8, 1918, but on Dec. 14 President Paes was shot at the Rocio station by José Julio da Costa and died a few minutes later. On Dec. 16 Admiral João de Canto e Castro was provisionally elected president, and in Jan. 1919 Senhor Tamagnini Barbosa formed a ministry, reviving the office of premier. The Peace Treaty was ratified on March 30, 1920. At the Spa Conference (*q.v.*), in July 1920, Portugal secured three-fourths of one per cent as her share of the total indemnity from Germany, and also received Kionga.

On June 1, Admiral Canto e Castro resigned and was succeeded by Dr. Antonio José de Almeida on Aug. 6. There followed a succession of short-lived ministries and on March 2, 1921, a new coalition ministry was formed, under the premiership of Dr. Bernardino Machado. A military *pronunciamento* on May 20 caused the resignation of Dr. Machado. He was succeeded by a Liberal ministry under Dr. Barros Queiroz, who dissolved Parliament and held a general election on July 10.

A solemn pledge had been taken to punish all who had supported the moderate republican, President Paes; in Oct. 1921, the barbarities culminated in the murder of the new premier, Dr. Antonio Granjo, the founder of the republic, Admiral Machado dos Santos, and other prominent persons. The appearance of foreign battleships in the Tagus brought the assassins to their senses for a time. Capt. Cunha Leal formed a short-lived ministry and was succeeded in Feb. 1922 by Sr. Antonio Maria da Silva. A number of ministries, lasting two or three weeks apiece, followed his resignation 21 months later, political instability being further increased by divisions in the Democrat Party.

In the general election of Jan. 1922, the Lisbon democratic candidate, Dr. Afonso Costa, was successful by a small majority. Successive revolutionary movements took place; these had become a regular political weapon and were attended by little loss of life. Those of April and July 1925 were of a more conservative character and showed an inclination on the part of the army to expel the politicians from power. In Aug. 1923 Sr. Teixeira Gomes, Portuguese Minister in London, was elected president of the republic in succession to Dr. Antonio Almeida (1866–1929), the first president to serve his full term of four years.

The elections of Nov. 8, 1925, gave a clear majority to the Democrats, who numbered 82 against 66 for all other parties, and it seemed at last that Portugal might achieve a comparatively stable government. The resignation of the president had long been expected, and when it took effect (Dec. 10) the election of his successor Dr. Machado, took place without incident. The new Democrat ministry formed on Dec. 16 consisted of experienced politicians, with Sr. Antonio da Silva once more as premier.

But on Feb. 2, 1926, a military revolt broke out in Lisbon. It was rapidly quelled and the leaders deported. On May 30 a more serious revolutionary attempt was made. Commander Mendes Cabeçadas, leader of the revolt of July 1925, was one of the leaders; the other, Gen. Gomes da Costa, had also been implicated in former risings. The outbreak of May 30 was a revolution led by the army and provoked by the corruption and inefficiency of successive governments. On June 1 the whole country was in the hands of the revolutionaries, the president was deposed and banished, and Cabeçadas then formed a provisional government with Gen. Gomes da Costa as minister of war. The May revolution was the 18th *pronunciamento* since the foundation of the republic and Sr. da Silva's cabinet was the 40th to be overthrown in the same brief period.

Differences were immediately manifest between the army leaders and Com. Cabeçadas, representing the politicians. Gen. Gomes da Costa marched on Lisbon and Com. Cabeçadas resigned the premiership. Gen. Gomes da Costa, now premier and acting president, disagreed with his cabinet, and within a few weeks was deposed and deported to the Azores, being succeeded at Lisbon by his foreign minister, Gen. Carmona. The new government ruled peaceably (without parliament) for some months, but on Feb. 3, 1927, a revolution, fostered by Communists broke out at Oporto and Lisbon, where the marines and part of the republican guard were overcome through the energetic action of the minister of war, Col. Passos. This was the bloodiest revolution Since Oct. 1910. On April 15, 1928, Gen. Carmona was proclaimed president, having been elected by 750,000 votes. A new constitution, adopted on March 19, 1933, provided for the .president's election for seven years by direct vote of the heads of families, a privy council of ten, a National Assembly of one chamber of go deputies, elected for four years. Despite this constitution, the government became in fact a dictatorship of the president and the prime minister. On Feb. 17, 1935, General Carmona was elected unanimously for a further term of 7 years. In 1936 the Spanish civil war, and Portugal's fear of a victory for the Spanish Left, emphasized the importance of Portugal in European politics.

(A. B.)

PORTUGUESE EAST AFRICA or **MOZAMBIQUE** (Official name: A Provincia de Moçambique). This Portuguese possession, bounded east by the Indian ocean, north by Tanganyika Territory, west by the Nyasaland Protectorate, Rhodesia and the Transvaal, south by Tongaland (Natal), has an area of 770,000 square kilometres. It is divided in two by the river Zambezi. The northern portion, between the ocean and Lake Nyasa and the Shiré river is a compact block of territory, squarish in shape, being about 400 m. long by 360 m. broad. South of the Zambezi the province consists of a strip of land along the coast varying from 50 to zoo m. in depth.

Physical Features.—The coast-line extends from 26° 52′ S. to 10° 40' S., and from south to north makes a double curve with a general trend outward, *i.e.,* to the east. It has a length of 1,430 miles. Some 40 m. N. of the Natal (Tongoland) frontier is the deep indentation of Delagoa bay (*q.v*). Far to the north is the wide Zambezi delta. From this point onward the coast is studded with small islands, mainly of coral formation, on one of which is Mozambique. To the north of Mozambique the coast is much indented, abounding in high, rocky headlands and rugged cliffs. South of Mozambique the coast-line is low, sandy, and lined with swamps. The eastern scarp of the continental plateau is much broken in the lower Zambezi region but elsewhere rises to heights of 6,000–7,875 ft. in the south, though behind Delagoa bay the greatest height is only 2,070 feet. In the north the forested hills of the scarp reach 6,500–8,600 feet.

Near the south-east shore of Nyasa there is a high range (5,000 to 6,000 ft.) with an abrupt descent to the lake—some 3,000 ft. in six miles. The plateau lands west of the escarpment are of moderate elevation—perhaps averaging 2,000 to 2,500 feet. The chief rivers are the Zambezi and Limpopo, both cutting back far into the plateau.

Geology.—The central plateau consists of gneisses, granites and schists of the usual East African type which in part or in whole are to be referred to the Archaean system. Rocks of the Karroo period occur in the Zambezi basin, where at Tete they contain workable seams of coal, and have yielded plant remains of Upper Carboniferous age. Sandstones and shales, possibly of Upper Karroo age, form a narrow belt at the edge of the foot-plateau. Upper Cretaceous rocks crop out from beneath the superficial deposits along the coast belt between Delagoa bay and Mozambique. The highest Cretaceous strata occur in Conducia, where they contain the huge ammonite *Pachydiscus conduciensis.* The Eocene formation is well represented in Gazaland by the nummulitic limestones which have been found to extend for a considerable distance inland. Basalts occur at several localities in the Zambezi basin. On the flanks of Mount Milanje there are two volcanic cones which would appear to be of comparatively recent date; but the most interesting igneous rocks are the rhyolitic lavas of the Lebombo range.

Fauna and Flora.—The lion, of both the yellow and the black-maned varieties, leopard, spotted hyena, jackal, serval, civet cat, genet, hunting dog (*Lycaon pictus*) and mongoose occur in the Mozambique district. The elephant and the black rhinoceros are common, and south of the Zambezi are a few specimens of white rhinoceros (*R. simus*). The rivers and marshes are the home of hippopotami, which have, ho ever, deserted the lower Zambezi. The wart-hog and the smaller red hog are common. A species of zebra is plentiful, and herds of buffalo (*Bos caffer*) are numerous in the plains and in open woods. Many antelopes are found, but the giraffe does not occur. The scaly anteater is fairly numerous, and rodents are common. There are several kinds of monkeys and lemuroids, but the anthropoids are absent. Crocodiles, lizards, chameleons, land and river tortoises are all very numerous, as are pythons (some 18ft. long), cobras, puff-adders and vipers. Centipedes and scorpions and insects are innumerable. Among insects mosquitos, locusts, the tsetse fly, the hippo-fly, cockroaches, phylloxera, termites, soldier ants and flying ants are common plagues. As has been indicated, the Zambezi forms a dividing line not crossed by certain animals, so that the fauna north of that river presents some marked contrasts to that of the south.

Flamingoes are common in the Mozambique district. Cranes, herons, storks, pelicans and ibises are numerous, including the beautiful crested crane and the saddle-billed stork (*Mycteria* senegalensis), the last-named comparatively rare. The eagle, vulture, kite, buzzard and crow are well represented, though the crested eagle is not found. The guinea fowl, partridge, bustard, quail, wild goose, teal, widgeon, mallard and other kinds of duck are all common. A small green parrot is found.

The coconut is common in the coast regions and often attains 100ft.; the date palm, mostly in marshy ground and near rivers, is seldom more than 20ft. in height; four other palms occur. A kind of cedar is found in the lower forests; ironwood and ebony are common, and other trees resemble satin and rosewood. The large *Khaya senegalensis* found in ravines and by river banks, affords durable and easily-worked timber; there are several varieties of vitex and of ficus, notably the sycamore, which bears edible fruit. Excellent hardwood is obtained from a species of grewia. Other characteristic trees are the mangrove (along the sea shore), sandal-wood, gum copal, baobab and bombax, and, in the lower plain, dracaenas (dragon trees), candelabra euphorbia, and many species of creepers and flowering shrubs, and several prickly shrubs. Acacias are numerous, including the gum-yielding variety, while landolphia rubber vines grow freely in the forests. Coffee, cotton, indigo and tobacco plants, castor oil, bananas, mangoes and pineapples are found. The bamboo is common. Phragmites *communis,* spear grass, with its waving, snowy plumes, grows 12 to 14ft. and is abundant along the river banks and along the edges of the marshes.

Climate and Health. — Malaria is endemic on the coast and along the banks of the Zambezi. On the uplands and the plateaus the climate is temperate and healthy. At Tete, on the lower Zambezi, the annual mean temperature is 77·9°, the hottest month being November, 83·3°, and the coldest July, 72·5°. At Quelimane, on the coast, the mean temperature is 85·1°, maximum 106·7° and minimum 49·1°. The cool season is from April to August. During the monsoons the districts bordering the Mozambique channel enjoy a fairly even mean temperature of 76·1°, maximum mean 88·7°, and minimum mean 65·3°. The rainy season lasts from December to March, and the dry season from May to the end of September. November is a month of light rains. Rainfall, average mean for many years, in millimetres, is: Lourenço Marques 776, Beira 1,534, Quelimane 1,433, Mozambique 797, Tete 538, Shiré 1,885.

A scientific mission has verified endemic foci of sleeping-sickness of the Rhodesian type in 18 places in the territory studied. Cases of fever were also noted, due generally to *Laverania malariae,* but also to *Plasmodius vivax;* and malaria, recurrent fever and filariasis. The tsetse fly, mostly *morsitans,* was found in several districts. It is spreading in that of Tete. Good results had been obtained by the use of atoxil in the initial stages, and of Triparsamida in advanced cases of the disease. The mission emphasizes the necessity of the study of the disease *"nagana"* in cattle.

There are good Government hospitals at Lourenqo Marques and other centres.

Population and Towns. — Portuguese East Africa is sparsely inhabited, the native population being, in 1934, 4,028,746 90% of the inhabitants belong to various Bantu tribes, from whose ranks most of the natives employed in the Transvaal gold mines are recruited. The most important in the northern half of the province are the Yaos (*q.v.*) and the Ma Kua (Makwa). The Makwa, notwithstanding the presence of Arabs, Banyans (Hindus) and Battias in all the coast districts, have preserved in a remarkable degree their purity of race, although their language has undergone considerable change (see BANTU LANGUAGES). The Makwa are divided into four families or groups — the Low Makwa, the Lomwe or Upper Makwa, the Maua and the Medo. Yao possess the country between the Msalu river and Nyasa. The dominant race between the Zambezi and the Mazoe are the Tavala, with other tribes mainly of Zulu origin. Between the Zambezi and the Pungwe are the Barue, Batoka, etc. In the district south of the Pungwe river, known as Gazaland, the ruling tribes are of Zulu origin, all other tribes of different stock being known as Thongas, resembling the Basutos, peaceful stock-raisers and cultivators. Among them are the BaTonga south of Inhambane, and the BaRonga mainly in the Lourenqo Marques district. The BaChopi in the Inhambane district are a Bantu tribe of different origin and language. The white inhabitants are chiefly Portuguese and British, and nearly half live in Lourenqo Marques.

The most important towns are Lourenqo Marques (the capital), Mozambique, Quelimane, Inhambane, Beira and Chinde. Sofala has now little but historical interest. These towns are separately noticed. Other European settlements are Chingune (see SOFALA), Angoche and Ibo, Porto Amelia on the coast, and Sena, Tete and Zumbo on the Zambezi, Macequece and Vila João Belo. Angoche, midway between Quelimane and Mozambique, dates from the 17th century. It has become the port of one of the most important commercial centres of the district of Mozambique, the coconut industry being rapidly developed there. It is connected with the Mossuril-Mozambique motor road. In 1925–6, 761 ships entered and left the port, representing a gross tonnage of 158,188. 6,793 tons of cargo were loaded. Ibo, founded at the beginning of the 17th century, on Ibo island, one of the Querimba archipelago, stands in 12° 20′ S., 40° 38′ E., off the northern arm of Montepuesi bay. It is 180 m. north of Mozambique. The harbour is sheltered but shallow.

The Zambezi towns, Sena, Tete and Zumbo, for long marked the limits of Portuguese penetration inland. Comparatively important places in the 17th and 18th centuries, with the decline of Portuguese power they fell into a ruinous condition. The opening up of Rhodesia and British Central Africa in the last quarter of the 19th century gave them renewed life.

Sena, some 150 m. by river from Chinde, is built at the foot of a hill on the southern side of the Zambezi, from which it is now distant 2 m. It has an 18th century fort, and is the head of a circumscription with a population of 78 Europeans and 40,140 natives.

Tete, founded about the same time as Sena, is also on the south bank of the Zambezi. It is about 140 m. by river above Sena. Since 1894 there has been a regular service of steamers between Tete and Chinde. A transit trade to British possessions north and south of Tete was later developed. It is the seat of government of a district of 65,000 sq.m. with a population of 350,472, including 400 Europeans. The district is rich in minerals.

Zumbo is picturesquely situated just below the Loangwe confluence and commands iarge stretches of navigable water on the Loangwe and middle Zambezi. Zumbo is 400 km. distant from Tete, and is in 1j° 37′ 36″ S., 30° 24′ 38″ E. The sub-district has a population of 33,106 natives.

Porto Amelia, 50 m. S. of Ibo, is the main seat of government of the Nyasa company, the charter of which expires in Oct. 1929, when the State will take over the administration of the company's territory. Porto Amelia stands on Pemba bay, one of the finest harbours in the world, which, a mile and a half wide at the entrance, has an extent of seven miles by five. It is the natural port, not only of its own hinterland, but of part of the highly developed Nyasaland protectorate and perhaps a part of northern Rhodesia also. It is healthy, well drained and free from malaria. It is connected with the State telegraphs at Mozambique.

Macequece, on the railway line from Beira to Rhodesia, 17 m. from the border, is the centre of the Manica goldfields. It is 2,500 ft. above the sea, and 194 m. N.W. of Beira by rail. It is picturesquely situated in a fertile and well-wooded district with a good water supply. The climate is healthy except in February and March. On the railway line from Lourenqo Marques to the Transvaal, Moamba, the junction for the Xinavane railway and seat of the Sabie circumscription, and Ressano Garcia, the last Portuguese station, are also trading settlements, cotton being grown near the former.

Vila João Belo (formerly Chai-Chai and later Vila Nova de Gaza), 23 m. up the Limpopo river, is a growing commercial settlement doing an increasing business with the interior in agricultural products. There is a bi-weekly steamer service to Lourenqo Marques.

Communications. — The province is served by many regular lines of steamships, furnishing communication between Lourenqo Marques, South African ports, Europe, India and America. In 1927, 1,737 ships (tonnage 4,682,893) entered the ports under the direct administration of the State, disembarking 53,435 passengers and 348,289 tons of cargo, and embarking 52,194 passengers and 822,175 tons of cargo.

There are many good motor roads, especially in the district of Lourenço Marques and Inhambane, of which the most important is perhaps that linking Lourenço Marques with Goba on the Swaziland border. New constructions are roads from Tete to Blantyre, and Tete to Salisbury. An important new road linking Mocubu with Nyasaland is under construction. The province belongs to the South African Postal Union, and is in telegraphic communication with Europe via South Africa and via Zanzibar. A cable connects Mozambique with Madagascar. Inland lines connect the ports with adjacent British possessions. There are 22,640 kilometres of telegraph and telephone lines in the province. There is a direct wireless service, with g stations, to the west coast, Europe, North and South America.

The railway to the Transvaal (j j m) belongs to the State, connecting with the Union of South Africa railways at Komatipoort, and is of prime importance. In the last three months of 1927, the total receipts of the Lourenqo Marques railway were £125,623. New railway shops are to be built at Lourenço Marques. New engine sheds are nearly complete. The Swaziland line (44 m.) to Goba on the Swaziland border, is to link up eventually with the Union system at Breyten, considerably reducing the distance from Lourenqo Marques to Germiston. The Gaza railway (51 m.) with a 2 ft. 6 in. gauge, runs from Vila João Belo (Chai-Chai) to Chicomo, near the river Inharrime. This railway handles about 9,000 tons of goods per year, mostly agricultural produce. The Beira railway (200 m.) in the Mozambique Company's territory, links up with Rhodesian railways at the frontier. The Trans-Zambezia railway (156 m.) from Dondo on the Beira Junction railway to Murraqa, on the south bank of the Zambezi, was opened in 1922. The Central African railway on the north bank of the Zambezi (61 m. long, of which 45 m. are in Portuguese territory) is connected at Port Herald with the Shiré Highlands railway. The Xinavane railway from Moamba to Xinavane (55 m.) is to be prolonged via Chissano to Vila João Belo (Chai-Chai), or via Chihuto to Chicomo (70 m.). The line from Inhambane to Inharrime is 55 miles; and that from Lourenqo Marques to Marracuene is a light railway (extension to Manhiça is authorized) with gauge 0·60 metres, 32 km. long. In 1927 it carried 20,736 passengers, and receipts were £5,150 libras. The Quelimane-Mocuba line is on the river Lujella; the Lumbo line (on the mainland off Mozambique), to Mkonta, is 94 kilometres. This is to be extended to the Nyasaland border, when it will be the shortest route from the sea to Lake Nyasa, Lines projected are: the prolongation of the Gaza railway. Chicomo via Jinagai to Inharrime, 51 m., and southwards to Xinavane; Quelimane—Shiré Highlands; Port Amelia—Lagos district; Nambula and Serra de Chinde sections of the Mozambique railway.

The Zambezi is navigable by light draught steamers throughout its course in Portuguese territory with one break at the Kebrassa Rapids—400 m. from its mouth. By means of the Shiré affluent of the Zambezi there is direct steamer and railway connection with British Central Africa.

Agriculture. — The province is, on the whole, very fertile, especially between Angoche and Quelimane, and in the Limpopo valley, where, as in the valley of the Zambezi, the soil is fertilized by inundations. The chief products are: sesame, indigo, coffee, ground-nuts, gum copal, rubber, sugar, cashew-nuts, coconuts, copra, mangrove-bark, maize, tobacco, cotton, etc. The irrigation and drainage scheme for the Limpopo valley, worked out by Col. Balfour, which will affect 20,000 hectares of good land, and cost £500,000, providing work for about 40,000 natives, has been officially approved. It has recently been decided to send five students from the province to agricultural schools in the Union of South Africa, with a subsidy of £100 per ann. each, on condition of their serving the State for at least two years on their return.

The following are notes on some chief products (see further under section on Mozambique and Nyasa Companies). Cotton production has diminished south of the Save river, owing to irregular rains. Total export in 1926 was 1,154 tons, valued at £81,765. Of this, the Mozambique company exported 652 tons, value £66,709. There are 11,000 hectares under cotton in the Quelimane district. In 1926 the total sugar production (including that of the Mozambique company), showed an increase of 16,000 tons on the previous year. Of this total, 50,966 tons, value £540,982, were exported. The chief centres are the lower Zambezi, and on the Buzi and Incomati rivers. 5,524 hectares are under sugar in the Quelimane district; production in 1924–25 being 10,100 tons. The chief producers are the Incomati sugar estates at Xinavane in the Lourenqo Marques district, and the Sena sugar estates and the Companhia Colonial do Buzi, in the Nyasa company's territory.

In 1926, exports of oil seeds, etc., equalled 52,030 tons (the largest item of export), value £810,862. (This is apart from the Mozambique and Nyasa companies, of which there are no returns.) There has been a considerable increase in export of oilseeds. Macurra is increasingly exported. With the exception of the last, production of oil seeds is almost entirely limited to the districts of Mozambique and Quelimane; ground-nuts, castor-oil seeds and sesame are limited to the district of Mozambique, and copra to that of Quelimane, which exported 18,065 tons, valued at £363,454 in 1926. Tobacco is being increasingly grown, principally for cigarettes. Growers ask for stoppage of importation. 500 tons were exported in 1924–25 in Quelimane district. 74% of the tobacco used in the province is local, the rest being imported from America and the Union of South Africa. Prospects are good. Export duties in 1926 were £103,499, an increase of about £13,000. The production of tea increased from 45 tons in 1924–25, to 55 in 1926–27, and 63 in 1927–28. Wheat has given good results experimentally, and is being increasingly cultivated, especially in the Zambezi valley. In the first three months of 1927, 1,627,661 kilos of bananas were exported from Mozambique, of a value of £21,660. A recent decree regulates concessions of five years for the exploitation of wild, fibrous and rubber plants. Rubber plantations exist in the Quelimane district, but owing to the price, fresh planting has practically ceased. There was no production in 1924–25.

The conditions for growing sisal are excellent, except in the district of Lourenqo Marques. Great plantations exist in the north, especially in the territories of the Nyasa company, Mozambique company, and in the Quelimrne district. Quality is not as good as in Tanganyika sisal. There are 8,344 hectares under sisal in the Quelimane district. Over 9,000 tons were exported last year, at an expected return of £10 per ton. There are five varieties of coffee native to the province. Tney have small grains, with little caffeine. Most of that exported is grown by natives, but there are a few plantations in the Mozambique district. Maize is grown, mostly by natives, in every part of the province. In 1926 the Mozambique company exported' maize to the value of £36,722. Coconut is exploited especially in the Quelimane district, where are some of the largest plantations in the world. Copra valued at £363,454 was exported in 1926. Kapok is cultivated in the Quelimane district.

Forestry, Stock-raising and Other Industries. — The most important timbers produced are: Mahogany (Khaya *Nyassica*); Ebony or Grandilha (*Dalbergia melanoxylon*); Mussacossa or Pod Mahogany (*Afzelia Quanzensis*), called Chanfuta in the south of the province, used for furniture, vehicles, etc.; M'Bila (Ptero carpus *erinaceus*) or Bloodwood; Pau-Ferro (Swartsea *Madagas-*

carensis), suitable for high class furniture; African Sandal Wood (Excoecaria Africana) for furniture and waggon work, etc.; Ziba (*Andrades* arborea) a valuable hardwood; Moanjwa (*Cordyla* Africana); M'Zimbiti (Androstachys Johnsoni), impervious to white ants, and used for railway sleepers and piles; Panga-Panga (*Lonchocarpus Mossambicensis*) suitable for furniture; Muanga or Chuanga (*Ormosia* Angolensis) used for bridge building, being impervious to white ants; Monhé or Gone (Adina microcephala) similar to teak; Messanda (Erythophloeunz *Guineensis*), a very hard red wood, suitable for railway sleepers.

The stock industry, especially the raising of bovine stock, has increased greatly, especially in the districts of Lourenqo Marques and Tete. At the end of 1925 there were 393,798 head in the province (excluding the Nyasa company), of which 300,000 were in the Lourenqo Marques district.

A modern, well-equipped cement factory, owned by the Mozambique Portland company, is working at Matola, near Lourenqo Marques, and is capable of producing 50,000 tons of cement a year. Its products are used in the province. Tobacco is manufactured, four factories being at work. Bricks and tiles are made at Incomati, on the Lourenqo Marques railway. Oils and soaps, in the Lourenqo Marques and Inhambane districts. Milling is carried on. Tannin is extracted in the Quelimane and Mozambique districts. A Portuguese company has undertaken the production of paper and paper-pulp.

Minerals and Mining. — Mining can be carried on only under concession from the Government. In future, exclusive concessions for prospecting for minerals are not to be renewed. The chief mining centre is Manicaland, but minerals have been extensively proved elsewhere. Active prospecting is being carried on in the Lourenqo Marques and other districts. The Zambezia Development company is prospecting systematically the whole of the Tete district. Extensive coal fields exist near Zumbo. The quality is excellent. Other deposits are known at Sena and Massurize, along the Shirk and Zambezi rivers, and in the Nyasa Co.'s territory. Coal has been reported in the Lourenqo Marques district, but not proved. The Zambezia Mining company is working coal at Mantize. Malachite is found in the interior, north west of Mozambique. The whole of the region north of Delagoa bay to the Zambezi, and inland to and beyond the Portuguese frontier, is auriferous, and ancient gold workings abound. Many writers have sought to identify this region with the land of Ophir. In Manica several gold mines are worked (quartz formation). In 1906–07 a rich formation similar to the American "placer" deposits was discovered in the Manica goldfields. Gold mines are also worked at Missale and Chifumbaze, north of Tete. The Missale mines are just south of the frontier of British Central Africa.

An important tin deposit is being worked at Neves Ferreira. Iron is found at Sena and Tete, and in the area of the Nyasa company. Asbestos occurs in the area of the Nyasa company. Copper is found at Sena and Tete, along the Shirk and Zambezi rivers. It is chiefly worked near Macequece. Diamondiferous ground is known at Govuro. Wulfram also occurs and graphite is found along the Shiré and Zambezi rivers. Mineral oils occur in the lands of the Nyasa company, and near Inhambane.

Administration and Finance. — The province is divided, for administrative purposes, into the five districts of Lourenqo Marques, Inhambane, Quelimane, Tete and Mozambique, each under a governor. The capital of the province is Lourenqo Marques (*q.v.*), the capitals of the other districts being the towns after which they are named. Apart from these territories directly administered by the State, two great chartered companies, the Mozambique and Nyasa (*q.v.*), have exercised sovereign rights in areas granted to them, with power to make local regulations, but remaining integral parts of the province. Beira (*q.v.*) is the seat of the administration of the Mozambique company and Porto Amelia that of the Nyasa company. Each administrative district is divided into circumscriptions, each being under an administrator; and in some of these there are smaller dependent administrative posts. The government of the colony is carried on by a legislative council, consisting of four official members, five memhrrs nominated hy the governor-general, arid elected representatives of the five districts. This council meets twice a year. The governor-general, who resides in Lourenqo Marques, serves for four years, but may be reappointed. The local government has administrative and financial autonomy, but the Lisbon Government must be consulted. There are six legal districts, Ibo, Mozambique, Quelimane, Beira, Inhambane and Lourenqo Marques. There is a provincial court of appeal.

The Mozambique company is a Lisbon company, incorporated by royal charter (1891), for a term of 50 years, renewable on expiry. Its capital is £1,500,000, much of which is foreign, and it holds sovereign rights over the territories of Manica and Sofala, an area of 153,666 sq.km. Its main activities are agricultural, but mining operations are very promising. Its capital Beira (*q.v.*) is the natural port of Rhodesia, and the carrying trade is constantly developing. The total trade of the territory was valued at £13,156,131 in 1925. In 1924 a profit of £152,079 was recorded. Gold, both reef and alluvial is produced, as also silver, tin and copper. Coal measures are known. The chief agricultural products are: cotton, of good staple, mainly on the Zambezi, and in Manica, Chimoio, Neves Ferreira and Buzi; sisal at Chupanga on the Zambezi; maize throughout the territory; oilseeds; rice, in increasing quantity, and citrus fruits. In 1926 there were 88,060 head of cattle in the territory.

The Nyasa company, which began work in 1894, had rights similar to those of the Mozambique company. It has had under its control territories, with area 73,292 square miles, in the north, the region between the Rovuma, the Lurio and Lake Nyasa. Porto Amelia, the capital, is about 150 miles north of Mozambique. Trade is mostly in the hands of Indians, and development has been slow and inconsiderable. Agricultural and mineral possibilities are probably considerable. Active prospecting is going on, and there are said to be indications of coal, oil, graphite, mica, iron, and alluvial gold. The territory of the company is being taken over by the provincial Government in 1929.

The difficult conditions of the last few years have disappeared, and the financial condition of the colony is encouraging. The escudo currency is now on a firm basis. Transfers to Portugal now cost only 3%. Revenue is mainly derived from customs, a hut tax (for which in 1925 a poll tax was substituted) and a tax on labourers who emigrate; the last source is not available in the territories of the chartered companies. The budget for 1927–28 shows total receipts 328,483,961 escudos, of which 318,978,090 escudos rank as ordinary. This is a great increase on the preceding year. The total expenditure is 311,397,476 escudos, leaving a surplus of normal receipts over necessary expenditure of over 1,700 contos, which is to be used for development. The colony has no external debt.

Economic Conditions and Commerce. — Economic development is considerable in the province, especially in the Mozambique company's territory. The Portuguese, however, have lacked capital to carry out large enterprises, while the constant ministerial changes at Lisbon and the financial embarrassment of Portugal have reacted unfavourably on Mozambique. Development has been most marked where British interests were concerned and British capital was forthcoming. The transit trade is large, Lourenço Marques serving the eastern Transvaal, and Beira being the chief port for Rhodesia, Ratanga and British Nyasaland. A railway from Beira to the Zambezi, completed in 1922, was built with British capital to meet the needs of the Nyasaland protectorate. This railway superseded the route by the Zambezi. The Beira-Zambezi railway also opened up rich tracts suitable for sugar, cotton and other crops. Moreover it brought a step nearer the exploitation on a large scale of the coalfields on the north side of the Zambezi near Tete. Another railway, from Inhambane to Delagoa bay (280 m. long), built in sections, is open to Inharrime. This line also serves fertile regions.

Imports were, in order of value: iron, steel and machinery and building material; flour, cereals in grain, cotton stuffs, timber, petrol; others were alcoholic drinks, automobiles and rice. The chief exports were, in order of importance, sugar, copra, maize, fresh fruit, coal, sisal, mangrove bark, nuts, beans and cotton

Apart from local trade, the transit trade to British dominion;

through Lourenqo Marques and Beira is most important. The chief exports to the Union of South Africa are copra, sugar, fresh fruit and ground-nuts; the chief imports from that source being coal, maize, fresh milk, eggs, beer and potatoes. In 1926, 33·07% of imports came from the British Empire, 14·46% from the Union of South Africa, 14·11% from Germany, and 13·86% from Portugal.

Missions and Education. — The province forms a diocese (in the ecclesiastical province of Goa) of the Roman Catholic Church which has been established in the colony from the beginning, ministering to Europeans and carrying on missions and educational work among natives in many places. There are several Protestant missions, cooperating loyally with the Government. Their educational work amongst natives is especially valuable. The most important of these are the Mission Suisse Romande, in the Lourenço Marques district; the Universities' Mission in the Nyasa company's territory; the Anglican diocese of Lebombo in the districts of Lourenqo Marques and Inhambane; the Methodist Episcopal mission in the Inhambane district; the Wesleyan Methodist church in the Lourenço Marques district; the Church of Scotland in the District of Quelimane; the American Free Methodist mission in the district of Inhambane.

Complete statistics as to education are wanting. The only secondary school (liceu) in the province is in Lourenqo Marques. An elementary commercial course has been instituted in connection with this school. Training schools for native teachers are maintained by the Missiqn Suisse Romande at Rikatla, near Lourenço Marques; another at Lourenço Marques, is conducted jointly by the Anglican, Swiss and Wesleyan Methodist missions; at Lourenço Marques the Anglican mission trains teachers and evangelists; and at Kambini, Inhambane district, the Methodist Episcopal Church has a training school. In Nov. 1925, the number of children attending primary schools in Lourenço Marques was 4,766, and those attending the secondary school 65. In Dec. 1924, the total number returned as attending primary schools in the province was given as 24,296. Agricultural and industrial schools have been opened in some of the circumscriptions.

HISTORY

By the 10th century A.D. the Arabs had occupied the seaboard of East Africa as far south as Sofala, and until the close of the 15th century their supremacy was unchallenged. But in 1498 Vasco da Gama entered the mouth of a river which he called Rio dos Bons Sinaes (River of Good Tokens), as there he first found himself in contact with the civilization of the East. This stream was the Quelimane river, taken by the Portuguese a little later to be the main mouth of the Zambezi. From this river da Gama continued his voyage, putting in at Mozambique and Mombasa on his way to India. Hostilities between the Arabs and. Portuguese broke out almost immediately. In 1502 da Gama paid a visit to Sofala to make enquiries concerning the trade in gold carried on at that place, and the reports as to its wealth which reached Portugal led to the dispatch in 1505 of a fleet of six ships under Pedro da Nhaya with instructions to establish Portuguese influence at Sofala. By 1510 the Portuguese, who had seized and fortified the port of Mozambique in 1507, were masters of all the former Arab sultanates on the East African coast.

Quest for the Land of Gold.—For 40 years Sofala was their only station south of the Zambezi. Thence they traded with the chief of the "Mocaranga" (*i.e.,* the Makalanga or Karanga) in whose territory were the mines whence the gold exported from Sofala was obtained. This potentate was known as the Monomotapa (*q.v.*). The efforts made by the Portuguese from Sofala to reach him were unsuccessful. It was probably the desire to penetrate to the "land of gold" by an easier route that led, in 1544, to the establishment of a station on the River of Good Tokens, a station from which grew the town of Quelimane. It was at this period also that Lourenqo Marques and a companion entered Delagoa bay and opened up trade with the natives. This was the most southerly point occupied by the Portuguese. In 1569 the East African dominions, hitherto dependent on the vice-royalty of India, were made a separate government with headquarters at Mozambique.

Francisco Barreto, a former viceroy of India, appointed governor of the newly formed province, was instpucted by King Sebastian to conquer the country of the gold mines. Unwisely the route via the Zambezi, and not that from Sofala, was chosen by Barreto. His expedition, including over 1,000 Europeans, started in Nov. 1569, and from Sena marched south. His force was so greatly weakened by deaths and disease that Barreto was obliged to return to Sena, whence he went to Mozambique to put down disorder among the Portuguese there. He returned to Sena in 1570, only to die a few days after his arrival. His successor, Vasco Fernandes Homem, made his way inland from Sofala to a region where he saw the ground being worked for gold. The comparative poorness of the mine filled him, it is stated, with disappointment, and he returned to Sofala.

Era of Decline. — The Portuguese for some time failed to make any effective use of their East African possessions Among the causes of non-success must be reckoned the "Sixty Years' Captivity" (1580–1640), when the Spanish and Portuguese crowns were united, and the neglect of Africa for the richer possessions in India and the Far East. A more permanent reason for the non-development of Mozambique province was the character of the government and the settlers. For a series of years the Jesuits and Dominicans were the most energetic sections of the white community. The first Jesuit missionaries began work in the neighbourhood of Inhambane in 1560; in the same year another Jesuit, Gonçalo da Silveira, made his way to the zimbabwe (chief kraal) of the monomotapa, by whose orders he and his converts were strangled (March 16, 1561). Mission work was soon afterwards begun by the Dominicans and for nearly two centuries the two orders between them had agents spread over the greater part of the country from Mozambique southward. Traces of their influence are still to be found among the tribes. In 1759 the Jesuits were expelled. Three attempts by the Dutch in the 17th century to capture the port of Mozambique were unsuccessful, but in the early years of the 18th century the Arabs wrested from the Portuguese their African possessions north of Cape Delgado. The merchants of Sofala and Mozambique had, since the middle of the 17th century, found a new source of wealth in the export of slaves to Brazil. This trade, due directly to the capture of the ports of Angola by the Dutch (1640–48), continued until nearly the middle of the 19th century, while slavery in the province was not abolished until 1878; and then abolition was largely nominal.

In 1752 the government of the East African possessions was again, and this time permanently, separated from that of Goa, and 20 years later Francisco José Maria de Lacerda e Almeida, a man of high attainments, made governor of the province at his own request, endeavoured to reform the administration. Lacerda is chiefly remembered for his journey to the heart of Central Africa, where he died in Oct. 1798. After his death a state of decay was again manifest throughout Portuguese East Africa. During the greater part of the 19th century the country south of the Zambezi was devastated by hordes of savages of Zulu origin (see GAZALAND).

Modern Developments. — The discoveries of David Livingstone in the period of 1850–65 led to the establishment of British settlements at the southern end of Lake Nyasa and in the Shiré highlands. These events aroused anxiety in Lisbon, which was increased when the British secured Matabele, Mashona and Manica lands—the lands of the earlier monomotapas. With sudden energy the Portuguese engaged in the "scramble for Africa," and they obtained much better terms than might have been anticipated, having regard to the extremely limited area over which they exercised jurisdiction. (The story of the partition is told in the article AFRICA.)

Under the republic the Portuguese made serious efforts to improve the administration. In 1914 a measure of autonomy, enlarged in 1920, was granted to the province. In general the treatment of the natives was satisfactory, but labour conditions left much to be desired. Compulsory unpaid labour in the province of Mozambique was not abolished until 1925. In 1927 reports were spread that Germany might acquire a mandate under the League of Nations to administer Mozambique or Angola. This led (Dec. 1927) to a reaffirmation of the ancient Anglo-Portuguese alliance which covers the Portuguese colonies. On Sept. 11, 1928, at Pretoria, after prolonged negotiations the Mozambique Convention was signed with the Union of South Africa respecting the trade of the Transvaal with the port of Lourenço Marques (Delagoa bay), the recruitment of natives in Portuguese territory for work in the Rand mines, and other matters. It replaced the Mozambique Convention which had been concluded with the Transvaal Government in 1909 and had lapsed in 1923.

PORTUGUESE GUINEA, a Portuguese possession in West Africa, extending along the Guinea coast from Cape Roxo in 12° 9′ N. to the Cogon estuary in 10° 50′ N. Inland it reaches to 13° 40′ W., being enclosed landward by French territory, the Casaniance district of Senegal to the north and French Guinea north and south. The country has an area of about 14,000 sq.m., and a population very variously estimated. It is probably about 350,000. The country consists largely of a low-lying deltaic region, together with an adjacent archipelago of small islands called the Bissagos. The principal rivers are, in the north the Cacheu (225 m. long); in the centre the Geba, and in the south the Rio Grande, which turning north-west in its lower course falls into the same estuary as the Geba. In the coast regions the temperature varies from a mean maximum of 85° F in May to a mean minimum of 77° F in January. From December to April is the dry season, with a strong *harmattan* blowing. June and July are marked by severe thunderstorms, and the rainy season lasts to the end of November. The rainfall is about 77 in. a year, practically all between June and November.

Flora and Fauna.—Large forest regions extend behind the mangrove-lined lagoons. Their characteristic trees are the oil and date palms, the baobab, the shea-butter tree, ebony, mahogany and calabash trees, and the acacia. Rubber vines are fairly abundant. Besides the forests, densest along the river valleys, there are extensive tracts of grassland and park-like country. Fruit trees include the papaw, with fruit the size of ostrich eggs, the guava, custard apple, mango, the banana, the orange and the citron. The tobacco, indigo and cotton plants grow wild, and the coffee plant is also found. Ground-nuts and kola nuts are cultivated, and rice and millet are the chief crops grown.

The elephant is found in the district between the Geba and Grande rivers, and hippopotamus are numerous. Other animals include the panther, wild boar, various antelopes, baboons, chimpanzees and large snakes. Crocodiles and sharks abound in the rivers. Birds include the pelican, heron, marabout, the trumpet bird and innumerable yellow parrots.

Inhabitants.—The people of the interior are mostly Fulani (*q.v.*), among whom are scattered a large number of Mandinga (*q.v.*). The coast regions and the islands are inhabited by negro tribes, which live side by side, mixing little with one another and preserving their own customs. Descendants of persons of various tribes who became Christian converts are called Gurmettes; they form the bulk of the population of the towns. Of the other inhabitants, going from south to north, the chief tribes are the Nalu, who dwell by the Kasini and are keen traders; the Biafare or Biaffade, who occupy the region between the sea and the Rio Grande: the Bulam (Mankaie), living in the island of Bolama, and much given to adorning their bodies by long cuts formed into patterns; the Balanta, an industrious, agricultural race (though formerly addicted to piracy), inhabiting the banks of the Geba; the Papel (Papies) of the island of Bissao, formerly cannibals, also an agricultural people, untamed and warlike; the Manjak and a branch of the Felup peoples, these last living near the Rio Cacheu in savage isolation and much given to waylaying and pillaging strangers. The Manjak (Manjacos) inhabit the country between the Mancoa and the Cacheu, and the neighbouring islands. Excellent seamen, good artisans and sharp traders, they maintain a sort of feudal system. The seaward islands of the Bissagos are inhabited by a tribe of fishers and pirates called Bidiogos.

The non-native inhabitants include a number of mulatto descendants of the Portuguese and people from the Cape Verdi whose dialect of Portuguese known as creole is widely understood by the natives. There are Portuguese officials and soldiers.

Towns and Trade.—Bissao (Sbo José di Bissao), near the mouth of the Geba estuary, is the chief port, with a safe and deep anchorage. Bolama (pop. 4,000), on the island of the same name, is the capital of the country. It also has a good harbour, small naval workshops and an aerodrome. Cacheu is a port on the river Cacheu near its mouth, and Farim 90 m. up-stream is a trading centre, other trading-centres are Bafata on the Geba and Xitoli, on the Rio Grande. The chief exports, practically all native produce, are ground nuts and palm kernels; with hides, rubber and bees-wax in smaller values. The imports include cotton piece goods (from England) kola-nuts (from Sierra Leone), trade spirits (from Hamburg) and wines (from Portugal). No discriminatory duties were imposed on foreign goods (except wines) and before the World War fully 70% of the exports went to Germany, which supplied some 40% of the imports. Later the French took a good share of the trade. The import of trade spirits was greatly restricted. The value of exports, £46,000 in 1890, had risen to £232,000 in 1914, and was £416,000 in 1924. The imports in the years named were valued at £69,000, £312,000 and £513,000 respectively. Revenue is derived from customs and a hut tax; in modern times, revenue first exceeded expenditure in 1910–11. For 1926–27, revenue was estimated at 19,966,000 escudos (about £170,000 sterling), and expenditure at 19,685,000 escudos.

History.—Bolama (Boulam, Bulama) island was discovered by the Portuguese in 1446; in the next year Nuno Tristâo, exploring the Rio Grande (and probably seeking slaves), was attacked by the Nalu and killed, together with many of his followers. In 1462 rights over this part of the Guinea coast were granted to the Cape Verdi islanders, who appear to have founded the "factories" at Cacheu. In the 17th and 18th centuries the supplying of slaves to Brazil and Spanish America was a very flourishing industry, Bissao becoming the chief port for this commerce. Dispossessed by Dutch, French, British and other rivals of all the rest of the Seignory of Guinea, Portuguese rule in this district was only effective on the coast—and even the islands had been left for long unoccupied. In the middle of the 19th century the extension of French authority in the hinterland, and claims by Great Britain to Bolama island and the adjacent mainland, seemed to threaten to reduce the Portuguese territory to very small proportions. However, the British claim was referred to the arbitration of the United States and President Grant's award (April 21,1870) was in favour of Portugal. By a convention with France in May 1886 the inland frontiers mere fixed mainly on arbitrary lines, the frontier being demarcated in 1902–05 by a Franco-Portuguese commission. Portugal had succeeded in retaining an area about twice the size of Wales. Meanwhile, in 1879, the country had ceased to be a dependency of the Cape Verdi islands and had been made a separate province under a governor. But most of the tribes were practically independent and in 1908 there was a rising of the Papel tribe on Bissao island, and of the other tribes on the mainland. Troops sent from Portugal succeeded in restoring order. Other risings and inter-tribal warfare followed, but not of so serious a character. The disestablishment of the Church in 1912 greatly hindered the work of the missionaries, one of the most civilizing influences in the province, but in 1925 the Portuguese Government reversed its policy, restored to the missions their churches and schools, and gave them subsidies—the avowed object being to exert a national, *i.e.*, Portuguese influence on the natives (this change applied to all the Portuguese colonies).

PORTUGUESE LANGUAGE.

PORTUGUESE LANGUAGE. Portuguese-Galician constitutes the second branch of the Latin of Spain. In it we must distinguish—(1) Portuguese (Portuguez, perhaps a contraction from the old *Portugalez*=Portugalensis), the language of the kingdom of Portugal and its colonies in Africa, Asia and America (Brazil); (2) Galician (Gallego), or the language of the old kingdom of Galicia (the modern provinces of Pontevedra, La Coruña, Orense and Lugo) and of a portion of the old kingdom of Leon (the territory of Vierzo in the province of Leon). Portuguese, like Castilian, is a literary language, which for ages has served as the vehicle of the literature of the Portuguese nation constituted in the beginning of the 12th century. Galician, on the other hand, which began a literary life early in the middle ages—for it was employed by Alfonso the Learned in his *Cantigas* in honour of the Virgin—decayed in proportion as the monarchy of Castile and Leon, to which Galicia had been annexed, gathered force and unity in its southward conquest.

Vowels.—Lat. *ĕ, ŏ* with the accent have not been diphthongized into ie, uo, ue: *pé* (pedem), *bom* (bonus). On the other hand, Portuguese has a large number of strong diphthongs produced by the attraction of an *i* in hiatus or the resolution of an explosive into *i*: *raiba* (rabia), *feira* (feria), *oito* (octo). A peculiar feature of the language occurs in the "nasal vowels," which are formed by the Latin accented vowels followed by *m, n,* or *nt, nd*: *bẽ* (bene), *grã* (grandem), *bõ* (bonum). These nasal vowels enter into combination with a final atonic vowel: *irmão* (germanus); also *amão* (amant), *sermão* (sermonen), where the *o* is a degenerated representative of the Latin final vowel. In Old Portuguese the nasal vowel or diphthong was not as now marked by the *til* (˜), but was expressed indifferently and without regard to the etymology by *m* or *n*: *bem* (bene), *tam* (tantum), *disserom* (dixerunt), *sermom* (sermonem). The Latin diphthong au is rendered in Portuguese by ou (*ouro,* aurum), also pronounced oi. With regard to the atonic vowels, there is a tendency to reduce a into a vowel resembling the Fr. e "muet," to pronounce *o* as *u*, and to drop *e* after a group of consonants (dent for dente).

Consonants.—Here the most remarkable feature, and that which most distinctly marks the wear and tear through which the language has passed, is the disappearance of the median consonants *l* and *n*: *corõa* (corona), *lua* (luna), *pôr* formerly *poer* (ponere), *conego* (canonicus), *vir* (venire), *paço* (palatium), *pego* (pelagus). Lat. *b* passes regularly into *v*: *cavallo* (caballus), but, on the other hand, Lat. initial *v* readily tends to become *b*: *bodo* (votum). Lat. initial *f* never becomes *h*: *fazer* (facere). Lat. *c* before *e* and *i* is represented either by the hard sibilant *s* or by the soft *z*. Lat. *g* between vowels is dropped before e and i: *ler* for leer (legere), *dedo* (digitum); the same is the case with *d*, of course, in similar circumstances: *remir* (redimere), *rir* (ridere). Lat. *j* has assumed the sound of the French *j*. The Latin combinations *cl, fl, pl* at the beginning of words are transformed in two ways in words of popular origin. Either the initial consonant is retained while the *l* is changed into r: *cravo* (clavum); or the group is changed into *ch* (=Fr. *ch*. Catal. *x*) through the intermediate sounds *kj, fj, pj*: *chamar* (clamare), *chão* (planus), *chamma* (flamma). Within the word the same group and other groups also in which the second consonant is an l produce *l* mouillée (written lh, just as n mouillée is written nh, as in Provençal): *ovelha* (ovic'la), *velho* (vec'lus); and sometimes ch: *facko* (fac'lum), *ancho* (amplum). Lat. ss or *sc* before e and *i* gives *x* (Fr. *ch*): *baixo* (bassus), *faxa* (fascia). The group *ct* is reduced to it: *leito* (lectum), sometimes to *ut*: *douto* (doctus).

Inflexion.—The Portuguese article, now reduced to the vocalic form o, a, os, as, was *lo* (exceptionally also el, which still survives in the expression *El-Rei*), *la, los, las* in the old language. Words ending in *l* in the singular lose the *l* in the plural (because it then becomes median, and so is dropped): *sol* (solem), but *soes* (soles); those having *ão* in the sing. form the plural either in *ães* or in *ões* according to the etymology: thus *cão* (canem) makes *cães*, but *ração* makes *rações*. Portuguese conjugation has more that is interesting. In the personal suffixes the forms of the 2nd pers. pl. in *ades, edes,* ides lost the *d* in the 15th century, and have now become *ais, eis,* is, through the intermediate forms aes, ees, eis. The form in des has persisted only in those verbs where it was protected by the consonants *n* or *r* preceding it: *pondes, tendes, vindes, amardes.* Portuguese is the only Romance language which possesses a personal or conjugated infinitive: *amar, amar-es, amar, amar-mos, amar-des, amar-em*; e.g., antes de *sair-mos,* "before we go out." Again, Portuguese alone has preserved the pluperfect in its original meaning, so that, for example, *amara* (amaveram) signifies not merely as elsewhere "I would love," but also "I had loved." Among the peculiarities of Portuguese conjugation are—(1) the assimilation of the 3rd pers. sing. to the 1st in strong perfects (*houve, pude,* quiz, fez), while Castilian has *hube* and *hubo*; (2) the imperfects *punha, tinha, vinha* (from *pôr, ter* and *vir*), which are accented on the radical in order to avoid the loss of the n (*ponía* would have made *poía*), and which substitute *u* and *i* for *o* and e in order to distinguish from the present subjunctive (*ponha, tenha,* venha).

Galician.—Almost all the phonetic features which distinguish Portuguese from Castilian are possessed by Gallego also. Portuguese and Galician even now are practically one language, and still more was this the case formerly. In conjugation the peculiarities of Gallego are more marked; some find their explanation within the dialect itself, others seem to be due to Castilian influence. The 2nd persons plural have still their old form ades, *edes,* ides, so that in this instance it would seem as if Gallego had been arrested in its progress while Portuguese had gone on progressing; but with these full forms the grammarians admit contracted forms as well: *ás* (Port. *ais*), *és* (Port. *eis*), *ís* (Port. is). The 1st pers. sing. of the perfect of conjugations in er and *ir* has come to be complicated by a nasal resonance similar to that which we find in the Portuguese *mim*; we have *vendin, partin,* instead of *vendi, parti,* and by analogy this form in in has extended itself also to the perfect of the conjugation in ar, and falin, *gardin,* for *falei, gardei* are found. The second persons of the same tense take the ending *che,* ches in the singular and chedes in the plural: *falache* or *falaches* (fabulasti). The 3rd pers. sing. of strong perfect is not in *e* as in Portuguese (*houve, pode*), but in *o* (*houbo, puido, soubo, coubo,* etc.); Castilian influence may be traceable here.

PORTUGUESE LITERATURE.

PORTUGUESE LITERATURE. The literature of the Portuguese is distinguished by the wealth and variety of its lyric poetry, its primacy in bucolic verse and prose, the number of its epics and historical books, and the relative slightness of its drama, biography and letters. Rich as its *romanceiro* is, its volume is far less than the Spanish, but the *cancioneiros* remain to prove that the early love songs of the whole Peninsula were writteh in Portuguese, while the primitive prose redaction of *Amadis,* the prototype of all romances of chivalry, was almost certainly made in Portugal, and a native of the same country produced in the *Diana* of Montemôr (Montemayor) the masterpiece of the pastoral novel. *The Lusiads* may be called at once the most successful epic cast in the classical mould, and the most national of poems, and the great historical monuments and books of travel of the 16th and 17th centuries are worthy of a nation of explorers who carried the banner of the Quinas to the ends of the earth. On the other hand, Portugal gave birth to no considerable dramatist from the time of Gil Vicente, in the 16th century, until that of Garrett in the 19th, and it has failed to develop a national drama.

The first literary activity of Portugal was derived from Provence, and Provençal taste ruled for more than a century; the poets of the 15th century imitated the Castilians, and the 16th saw the triumph of Italian or classical influence. Spain again imposed its literary standards and models in the 17th century, France in the 18th, while the Romantic movement reached Portugal by way of England and France; and those countries, and in less degree Germany, have done much to shape the literature of the 19th century. Nearly every Portuguese author of renown from 1450 until the 18th century, except Antonio Ferreira, wrote in Spanish, and some, like Jorge de Montemôr and Manoel de Mello, produced masterpieces in that language and are numbered as Spanish classics. Again, in no country was the victory of the Italian Renaissance and the classical revival so complete, so enduring.

Yet Portuguese literature has a distinct individuality which appears in the *romanceiro,* in the songs named *cantares de anzigo* of the *cancioneiros,* in the *Chronicles* of Fernão Lopes, in the *Historia tragico-maritima,* in the plays of Gil Vicente, in the bucolic verse and prose of the early 16th century, in the *Letters* of Marianna Alcoforado and, above all, in *The Lusiads.*

Early Period.—Though no literary documents belonging to the first century of Portuguese history have survived, there is evidence that an indigenous popular poetry both sacred and profane existed, and while Provencal influences moulded the manifestations of poetical talent for nearly zoo years, they did not originate them. A few compositions which have come down to us bear a date slightly anterior to the year 1200. One of the earliest singers was D. Gil Sanches, an illegitimate son of Sancho I., and we possess a *cantar de anzigo* in Galician-Portuguese, the first literary vehicle of the whole Peninsula, which appears to be the work of Sancho himself. The pre-Alphonsine period to which these men belong runs from 1200 to 1245 and produced little of moment, but in 1248 the accession of King Alphonso III., who had lived 13 years in France, inaugurated a time of active and rich production which is illustrated in the *Cancioneiro da Ājuda,* the oldest collection of Peninsular verse. The apogee of palace poetry dates from 1275 to 1280, when young Dinis, who had been educated by Aymeric of Cahors, proved himself the most fecund poet-king of his day, though the pleiad of *fidalgos* forming his court and the *jograes* who flocked there from all parts, were fewer in number, less productive, and lacked the originality, vigour and brilliance of the singers who versified round Alphonso III.

The principal names of the Dionysian period (1284–1325) which is illustrated in the *Cancioneiro da Vaticana* are the king himself and his bastards D. Alphonso Sanches and D. Pedro, count of Barcellos. Of the two last, the former sings of love well and sincerely, while the latter is represented by some satirical songs of *maldizer,* a form which, if it rarely contains much poetical feeling or literary value, throws light on the society of the time.

The verses of Dinis, essentially a love poet, are conventional in tone and form except when he uses the indigenous parallel-strophed or *cossante* form which gives their real originality to the Galician-Portuguese *cancioneiros.* Speaking generally, the *cancioneiros* form monotonous reading owing to their poverty of ideas and conventionality of metrical forms and expression, but here and there men of talent enaeavoured to lend their work variety by the use of difficult processes like the *lexaprem* and by introducing new forms like the *pastorela* and the *descort.* It is curious to note that no heroic songs are met with in the *cancioneiros;* they are all, with one exception, purely lyrical in form and tone. The *romanceiro,* comprising romances of adventures, war and chivalry, together with religious and sea songs, forms a rich collection of ballad poetry which continued in process of elaboration throughout the whole of the middle ages, but scarcely any of those existing bear a date anterior to the 15th century.

Epic poetry in Portugal developed much later than lyric, but the signal victory of the united Christian hosts over the Moors at the battle of the Salado in 1340 gave occasion to an epic by Alphonso Giraldes of which some fragments remain.

The first frankly literary prose documents appear in the 14th century, and consist of chronicles, lives of saints and genealogical treatises. The more important are the *Chronica breve* do *archivo nacional,* the *Chronicas de S. Cruz de Coimbra,* the *'Chronica da conquista do Algarve* and the *Livros das Linhagens,* portions of which have considerable literary interest. All the above may be found in the *Portugaliae monumenta historica. Romania* has printed some hagiographical texts, and the *Vida dos Santos Barlaão e Josafate* has been issued by the Lisbon Academy of Sciences.

Romances of chivalry belonging to the various cycles must have penetrated into Portugal at an early date, and the *Nobiliario* of the Conde D. Pedro contains the genealogy of Arthur and the adventures of Lear and Merlin. There exists a mid-14th-century *Historia do Santo Graal,* and an unprinted *Josep ab Aramatia,* and we have some evidence of the existence of a primitive Portuguese prose redaction of *Amadis de Gaula* anterior to the present Spanish text.

The 15th Century.—In the reign of John I. the court became an important literary centre, and the king himself composed a *Livro de Montaria.* His son, King Edward (Duarte), collected a precious library composed of the ancient classics, some translated by his order, as well as mediaeval poems and histories, and he wrote a moral treatise *Leal conselheiro,* and hints on horsemanship, or *Livro da ensinança de bem cavalgar toda sella.* His brother *D.* Pedro also wrote a moral treatise *Da virtuosa bemfeitoria,* and caused Vegetius's ***De re*** *militari* and Cicero's ***De*** *officiis* to be turned into Portuguese. This travelled prince brought hack from Venice a ms. of Marco Polo as the gift of the senate. The age is noted for its chronicles, beginning with the anonymous life of the Portuguese Cid, the Holy Constable Nuno Alvares Pereira, told in charming prose. Fernão Lopes (*q.v.*), the father of Portuguese history and author of chronicles of King Pedro, King Ferdinand and King John I., has been called by Southey the best chronicler of any age or nation. Gomes Eannes de Azurara completed Lopes's chronicle of King John by describing the capture of Ceuta, and wrote a chronicle of D. Pedro de Meneses, governor of the town down to 1437, and a chronicle of D. Duarte de Meneses, captain of Alcacer, but his capital work is the chronicle of the conquest of Guinea. *(See* Azurara.)

Though not a great chronicler or an artist like Lopes, Ruy de Pina is quite free from the rhetorical defects of Azurara, and his chronicles of King Edward and King Alphonso V. are characterized by unusual frankness. All these three writers combined the posts of keeper of the archives and royal chronicler, and were, in fact, the king's men, though Lopes at least seems rather the historian of a people than the oracle of a monarch. Garcia de Resende (*q.v.*) worked up Pina's chronicle of King John II. and added a wealth of anecdote and gossip. The taste for romances of chivalry continued throughout the 15th century, but of all that were produced the only one that has come down to us is the *Estorea do Zmperador Vespnsiano,* an introduction to the Graal Cycle, based on the apocryphal gospel of Nicodemus.

The Constable D. Pedro of Portugal (1429–66), son of the prince of that name already referred to, has left some verses marked by elevation of thought and deep feeling, the *Satyra de felice e infelice vida,* and the death of his sister inspired his *Tragedia de la insigne reyna Isabel* (1457); he is best remembered by his *Coplas del contempto del mundo* in the *Cancioneiro Geral.* D. Pedro, who wrote in Castilian, is one of the first representatives of those Spanish influences which set aside the Provençal manner and in its place adopted a taste for allegory and a reverence for classical antiquity, both imported from Italy. It was to the constable that the marquis de Santillana addressed his historic letter dealing with the origins of Peninsular verse. The court poetry of the reigns of King Alphonso V. and King John II. is contained in the *Cancioneiro Geral*, compiled by Garcia de Resende and printed in 1516. Some zoo authors are there represented by pieces in Portuguese and Castilian, and they include D. João Manuel, D. João de Meneses, Joio Rodrigues and de Sá e Meneses, Diogo Brandão, Duarte de Brito and Fernio da Silveira. The main subjects are love, satire and epigram. The epic achievements of the Portuguese in that century hardly find an echo, even in the verses of those who had taken part in them. Instead, an atmosphere of artificiality surrounds these productions, the influence is Spanish, and the verses that reveal genuine poetical feeling are very few, but some names appeared in the *Cancioneiro Geral* which were to be among the foremost in Portuguese literature; *e.g.,* Bernardim Ribeiro, Christovam Falcão, Gil Vicente and Sá de Miranda, who represent the transition between the Spanish school of the 15th and the Italian school of the 16th century, called *Os Quinhentistas.* Ribeiro and Falcão, the introducers of the bucolic style, put new life into the old forms, and by their eclogues in *redondilhas* gave models which subsequent writers worked by but could never equal.

Gil Vicente and the Eschola Velha.—The transition of the drama from the presentment of traditional types to the modern play can be traced in the works of Gil Vicente, the father of the Portuguese theatre. His first efforts belonged to the religious drama, and some of the more notable had edification for their object; *e.g.,* the trilogy of *Barcas,* but even in this class he soon introduces the comic element by way of relief, and in course of time he arrives at pure comedy, and develops the study of character. For a detailed description of his work, *see* VICENTE.

In the various towns where he stayed and produced his plays, writers for the stage sprang up, and these formed the Eschola Velha or school of Gil Vicente, the best known being Affonso Alvarez, author of religious pieces; Antonio Ribeiro, nicknamed "the Chiado," an unfrocked friar with a strong satirical vein who wrote farces in the Bazochian style; and his brother Jeronimo Ribeiro. In Santarem appeared Antonio Prestes, a magistrate, who evinced more knowledge of folk-lore than dramatic talent; while Camoens himself felt Vicente's influence. Another poet of the same school is Balthazar Dias, the blind poet, whose simple religious *autos* are still performed in the villages, and are continually reprinted, the best liked being the *Auto of St. Alexis,* and the *Auto of St. Catherine.* One of the last dramatists of the 16th century belonging to the old school was Simão Machado, who wrote the *Comedy of Diu* and the *Enchantments of Alfea,* two long plays almost entirely in Spanish.

Except Camoens, all these men, though disciples of Gil Vicente, are decidedly inferior to him in dramatic invention, fecundity and power of expression, and they were generally of humble social position. The favour of the court was withdrawn on the death of Gil Vicente and the old dramatists had to face the opposition of the classical school and the hostility of the Inquisition, which early declared war on the popular plays on account of their grossness. The way was thus clear for the Jesuits, who introduced Latin tragi-comedies or dramatized allegories written to commemorate saints or for scholastic festivals. The four Indexes of the 16th century give some idea of the rich repertory of the popular theatre, and of the efforts necessary to destroy it; moreover, the Spanish Index of 1559, by forbidding *autos* of Gil Vicente and other Portuguese authors, is interesting evidence of the extent to which they were appreciated in the neighbouring country.

The movement commonly called the Renaissance reached Portugal both indirectly through Spain and directly from Italy, with which last country it maintained close literary relations throughout the 15th century. King Alphonso V. had been the pupil of Matthew of Pisa and summoned Justus Balduinus to his court to write the national history in Latin, while later King John II. corresponded with Politian, and early in his reign the first printing press got to work. In the next century many famous humanists took up their abode in Portugal. Nicholas Cleynaerts taught the Infant Henry, afterwards cardinal and king, and lectured on the classics at Braga and Evora, Vasaeus directed a school of Latin at Braga, and George Buchanan accompanied other foreign professors to Coimbra when King John III. reformed the university. Many distinguished Portuguese teachers returned from abroad to assist the king at the same time, among them Ayres Barbosa from Salamanca, André de Gouvêa of the Parisian college of St. Barbe, whom Montaigne dubbed "the greatest principal of France," Achilles Estaço and Diogo de Teive.

At home Portugal produced André de Resende (*q.v.*), author of *De antiquitatibus Lusitaniae,* and Francisco de Hollanda, painter, architect, and author of *Quatro dialogos da pintura antiga.* Women took a share in the intellectual movement of the time, and the sisters Luisa and Angela Sigêa, Joanna Vaz and Paula Vicente, daughter of Gil Vicente, constituted an informal female academy under the presidency of the Infanta D. Maria, daughter of King Manuel. Luisa Sigêa was both an orientalist and a Latin poetess, while Publia Hortensia de Castro defended theses at Evora in her 18th year.

The Italian School or Os Quinhentistas.—The Italian school was founded by Sá de Miranda, a man of excellent character, who, on his return in 1526 from a six years' stay in Italy, initiated a reform of Portuguese literature which amounted to a revolution. He introduced and practised the form of the sonnet, canzon, ode and epistle in *ottava rima* and in tercets. At the same time he gave fresh life to the national octosyllabic metre *(medida velha)* by his *Cartas* or *Satiras* which with his *Eclogues,* some in Portuguese, others in Castilian, are his most successful compositions. His chief disciple, Antonio Ferreira (*q.v.*), a convinced classicist, went further, and dropping the use of Castilian, wrote sonnets much superior in form and style, though they lack the rustic atmosphere of those of his master, while his odes and epistles are too obviously reminiscent of Horace. D. Manoel de Portugal, Pero de Andrade Caminha, Diogo Bernardes, Frei Agostinho da Cruz and André Falcão de Resende continued the erudite school, which, after considerable opposition, definitively triumphed in the person of Luis de Camoens. The *Lima* of Bernardes contains some beautiful eclogues as well as *cartas* in the bucolic style, while the odes, sonnets and eclogues of Frei Agostinho are full of mystic charm. Immediately on its appearance *The Lusiads* took rank as the national poem *par excellence,* and its success moved many writers to follow in the same path; of these the most successful was Jeronymo Corte-Real (*q.v.*). All these poems, like the *Elegiada* of Luis Pereira Brandão on the disaster of Al Kasr, the *Primeiro cêrco de Diu* of the chronicler Francisco de Andrade, and even the *Affonso Africano* of Quevedo, for all its futile allegory, contain vigorous descriptive passages.

Sá de Miranda and his followers protested against the name *auto,* restored that of *comedy,* and substituted prose for verse. They generally chose the plays of Terence as models, yet their life is conventional and their types are not Portuguese but Roman-Italian. The revived classical comedy was artificial both in subject and style. Though it secured the favour of the humanists and the nobility, and banished the old popular plays from both court and university soon after Gil Vicente's death, its victory was short-lived. Jorge Ferreira de Vasconcellos, who produced in *Eufrosina* the first prose play, really belongs to the Spanish school, yet, though he wrote under the influence of the *Celestina,* which had *a* great vogue in Portugal, his types, language and general characteristics are deeply national. This and his other plays, *Ulisipo* and *Aulegraphia,* are novels in dialogue containing a treasury of popular lore and wise and witty sayings with a moral object. So decisive was the success of Jorge Ferreira's new invention, notwithstanding its anonymity, that it decided Sá de Miranda to atternpt the prose comedy. He modelled himself on the Roman theatre as reflected by the plays of Ariosto, and he avowedly wrote the *Estrangeiros* to combat the school of Gil Vicente; in it, as in *Os Vilhalpandos,* the action takes place in Italy. Antonio Ferreira, the chief dramatist of the classical school, attempted both comedy and tragedy, and his success in the latter is due to the fact that he was not content to seek inspiration from Seneca, as were most of the tragedians of the 16th century, but went straight to the fountain heads, Sophocles and Euripides. His *Bristo* is but a youthful essay, but his second piece, *O Cioso,* is almost a comedy of character, though both are Italian even in the names of the personages. Ferreira's real claim to distinction, however, rests on *Ines de Castro. (See* FERREIRA.)

Sixteenth-century History. — A pleiad of distinguished writers arose to narrate the discoveries and conquests in Asia, Africa and the ocean. Many of them saw the achievements they relate and were inspired by patriotism to record them, so that their writings gain in picturesqueness what they may lose in scientific value. In the four decades of his *Asia,* João de Barros, the Livy of his country, tells in simple vigorous language the "deeds achieved by the Portuguese." His first decade undoubtedly influenced Camoens, and together the two men fixed the Portuguese written tongue, the one by his prose, the other by his verse. The decades, which were continued by Diogo do Couto, a more critical writer and a clear and correct stylist, must be considered the noblest historical monument of the century. *(See* BARROS.) Couto is also responsible for some acute observations on the causes of Portuguese decadence in the East, entitled *Soldado practico.*

The word encyclopaedist fits Damiio de Goes, a diplomatist, traveller, humanist and bosom friend of Erasmus. One of the most critical spirits of the age, his chronicle of King Manoel, the Fortunate Monarch, which he introduced by one of Prince John, afterwards King John II., is worthy of the subject. Goes (*q.v.*) wrote a number of other historical and descriptive works in Portuguese and Latin, some of which were printed during his residence in the Low Countries. After 20 years of investigation at Goa, Fernão Lopes de Castanheda issued his *Historia do descobrinzento e conquista da India* (1 j52–54 and 1561), a book that ranks beside those of Barros and Couto. Antonio Galvio, who, after governing the Moluccas with rare success and integrity, had been offered the native throne of Ternate, went home in 1540, and died a pauper in a hospital. His brief *Tratado,* which appeared posthumously in 1563, is of unique historical value. Like the preceding writers, Gaspar Corrêa lived long years in India and embodied his intimate knowledge of its manners and customs in the picturesque prose of the *Lendas da India,* which embraces the events of the years 1497 to 1550. Among other historical works dealing with the East are the *Commentarios de Affonso d'Albuquerque,* an account of the life of the great captain and administrator, by his natural son, and the *Tratado das cousas da China e de Ormuz,* by Frei Gaspar da Cruz.

Coming back to strictly Portuguese hisiory, we have the uncritical *Chronica de D. João III.* by Francisco de Andrade, and the *Chronica de D. Sebastiho* by Frei Bernardo da Cruz, who was with the king at Al Kasr al Kebir, while Miguel Leitio de Andrade, who was taken prisoner in that battle, related his experiences and preserved many popular traditions and customs in his *Miscellanea.* The bishop Osorio, a scholar of European reputation, wrote chiefly in Latin, and his Chronicle of King Manoel, based on that of Goes, is in that tongue.

The books of travel of this century are unusually important, because their authors were often the first Europeans to visit or at least to study the countries they refer to. They include, to quote the more noteworthy, the *Descobrimento de Frolida,* the *Itinerario* of Antonio Tenreiro, the *Verdadeira informacão das terras do Preste Joant* by Francisco Alvares, and the *Ethiopia oriental* by Frei João dos Santos, both dealing with Abyssinia, the *Itinerario da terra santa* by Frei Pantaleão de Aveiro, and that much-translated classic, the *Historia da vida do padre Francisco Xavier* by Padre João de Lucena. Fernão Cardim, in his *Narrativa epistolar,* records a journey through Brazil, and Pedro Teixeira relates his experiences in Persia. But the work that holds the palm in its class is the *Peregrinação* which Fernão Mendes Pinto (*q.v.*), the famous adventurer, composed in his old age for his children's reading. The *Historia tragico-maritima,* a collection of 12 stories of notable wrecks which befell Portuguese ships between 1 j52 and 1604, contains that of the galleon "St. John" on the Natal coast, an event which inspired Corte-Real's epic poem as well as some poignant stanzas in *The Lusiads,* and the tales form a model of simple spontaneous popular writing.

Sixteenth-century Romances, etc.—The *Menina e moça* of Bernardim Ribeiro, a tender pastoral story inspired by *saudade,* probably moved Montemôr or Montemayor (*q.v.*) to write his *Diana.* To name the *Palmeirim de Inglaterra* of Moraes (*q.v.*) is to mention a famous book from which, we are told. Burke quoted in the House of Commons, while Cervantes declared that it ought to be guarded as carefully as the works of Homer. Its sequels, *D. Duardos* by Diogo Fernandes, and *D. Clarisel de Bretanha* by Soncalves Lobato, are inferior. The historian Barros tried his youthful pen in a romance of chivalry, the *Chronica do Imperador Clarimundo,* while in the Arthurian cycle the dramatist Ferreira de Vasconcellos wrote *Sagramor* or *Memorial das proesas da segunda Tavola Redonda.* A book of quite a different order is the *Contos de proveito e exemplo* by Fernandes Trancoso, containing a series of 29 tales derived from tradition or imitated from Boccaccio and others, which enjoyed favour for over a century.

Among the moralists of the time three at least deserve the title of masters of prose style, Heitor Pinto for his *Imagem da vida Christã,* Bishop Arraez for his *Dialogos,* and Frei Thomé de Jesus for his mystic and devotional treatise *Trabalhos de Jesus,* while the maxims of Joana da Gama, entitled *Ditos da Freira,* though lacking depth, form a curious psychological document. The ranks of scientists include the cosmographer Pedro Nunes (Nonius), a famous mathematician, and the botanist Garcia da Orta, whose *Coloquios dos simples e drogas* was the first book to be printed in the East (1563), while the form of Aristotelian scholastic philosophy known as *Philosophia coimbricensis* had a succession of learned exponents, who mainly used Latin, in which also Francisco Sanches wrote his notable treatise *Qvod nihil scitvr* (1581).

The 17th Century. — From a literary as from a political point of view the 17th century found Portugal in a lamentable state of decadence which dated from the preceding age. In 1536 the Inquisition began its work with the censorship of books and the Index, while between 1 j52 and 1 jjj the control of higher education passed into the hands of the Jesuits. Next the taint of Gongorism appeared, and the extent to which it affected the literature of Portugal may be seen in the five volumes of the *Fenix renascida,* where the very titles of the poems suffice to show the emphatic futilities which occupied the attention of some of the best talents. The prevailing European fashion of literary academies was not long in reaching Portugal, and 1647 saw the foundation of the *Academia dos Generosos,* which included in its ranks the men most illustrious by learning and social position, and in 1663, the *Academia dos Singulares* came into being. In bucolics there arose a worthy disciple of Ribeiro in Francisco Rodrigues Lobo (*q.v.*), author of *Corte na Aldeia* and the lengthy pastoral romance *Primavera,* the songs in which, with his eclogues, earned him the name of the Portuguese Theocritus. The foremost literary figure of the time was the encyclopaedic D. Francisco Manuel de Mello (*q.v.*), who, though himself a Spanish classic, strove hard and successfully to free himself from subservience to Spanish forms and style. Most of the remaining lyricists of the period were steeped in Gongorism or, writing in Spanish, have no place here. It suffices to mention Soror Violante do Céo, an exalted mystic called "the tenth muse"; Bernarda Ferreira de Lacerda, author of the *Soledades de Bussaco;* the *Laura do Anfrizo* of Manoel Tagarro, the *Sylvia de Lisardo* attributed to Frei Bernardo de Brito, and the poems of Frei Agostinho das Chagas, who, however, is better represented by his *Cartas espirituaes.* Satirical verse had two notable cultivators in D. Thomas de Noronha and Antonio Serrão de Castro, the first a natural and facile writer, the second the author of *Os Rntos da Inquisição,* a facetious poem composed during his incarceration in the dungeons of the Inquisition, while Diogo de Sousa Camacho satirised the slaves of Gongorism.

The gallery of epic poets is a large one, but most of their productions are little more than rhymed chronicles. These works include the *Ulyssea* of Gabriel Pereira de Castro; the *Ulysipo* of

Sousa de Macedo; the *Malaca* conquistada of Francisco de Sá de Meneses; Rodrigues Lobo's 20 cantos in honour of the Holy Constable; and the Viriato *tragico* of Garcia de Mascarenhas.

History, Oratory and **Drama.**—Frei Bernardo de Brito began his ponderous *Monarchia Lusitana* with the creation of man and ended it where he should have begun, with the coming of Count Henry to the Peninsula. His contribution is a mass of legends destitute of foundation or critical sense, but both here and in the Chronica de Cister he writes a good prose. Of the four continuers of Brito's work, three are no better than their master, but Frei Antonio Brandão, who dealt with the period from King Alphonso Henriques to King John II., proved himself a man of high intelligence and a learned, conscientious historian.

Frei Luis de Sousa, a typical monastic chronicler, although he had begun life as a soldier, worked up the materials collected by others, and after much labor limae produced the panegyrical Vida de D. Frei Bartholemeu dos Martyres, the *Historia* de S. *Domingos,* and the Annaes *d'el* rei D. *João* III. His style is excellent, but he lacks the critical sense. Manuel de Faria e Sousa (*q.v.*), a voluminous writer on Portuguese history and the commentator of Camoens, wrote in Spanish, and Mello's classic account of the Catalan War is also in that language, while in Portuguese Jacinto Freire de Andrade thought to picture and exalt the Cato-like viceroy of India by his grandiloquent Vida de D. *João* de Castro.

Other historical books of the period are the valuable Discursos of Severim de Faria, the Portugal *restaurado* of D. Luis de Meneses, conde de Ericeira, the ecclesiastical histories of Archbishop Rodrigo da Cunha, the Agiologio lusitano of Jorge Cardoso and the Chronica da *Companhia de* Jesus by Padre Balthazar Telles. The last also wrote an *Historia* da *Ethiopia,* and, though the travel literature of this century compares badly with that of the preceding, mention may be made of the Itinerario da *India por* terra ate' a *ilha* de *Chipre* of Frei Gaspar de S. Bernardino, and the *Relação* do *novo* caminho *através* da Arabia e Syria of Padre Manuel Godinho.

The Jesuit Antonio Vieira (*q.v.*), missionary, diplomat and voluminous writer, repeated the triumphs he had gained in Bahia and Lisbon in Rome, which proclaimed him the prince of Catholic orators. Vieira was a man of action, while the oratorian Manuel Bernardes lived as a recluse, hence his sermons and devotional works, especially *Luz* e Calor and the *Nova* Floresta, breathe a calm and sweetness alien to the other, while they are even richer treasures of pure Portuguese. Perhaps the most human documents of the century are the five epistles written by Mariana Alcoforado (*q.v.*), known to history as the Letters *of* a Portuguese *Nun.* Padre Ferreira de Almeida's translation of the Bible has considerable linguistic importance, and philological studies had an able exponent in Amaro de Roboredo.

The popular theatre lived on in the *Comedias* de *Cordel,* mostly anonymous and never printed; the popular autos that have survived are mainly religious, and show the abuse of metaphor and the conceits which derive from Gongora. All through this century Portuguese dramatists, who aspired to be heard, wrote, like Jacintho Cordeiro and Mattos Fragoso, in Castilian, though a brilliant exception appeared in the person of D. Francisco Manuel de Mello (*q.v.*), whose witty Auto do *fidalgo aprendiz* is eminently national in language, metre, subject and treatment. The court, after 1640, preferred Italian opera, French plays and *zarzuelas* to dramatic performances in the vernacular, with the result that both Portuguese authors and actors of repute disappeared.

The 18th Century.— In the first part of the 18th century bad taste tended to increase, but gradually signs appeared of a literary revolution, which preceded the political and developed into the Romantic movement. Men of liberal ideas went abroad to France and England, and to their exhortation and example are largely due the reforms which were by degrees inaugurated in every branch of letters. Their names were, among others, Alexandre de Gusmlo, the Cavalheiro de Oliveira, Ribeiro Sanches, Corrêa de Serra, Brotero and Nascimento. They had a forerunner in Luiz Antonio Verney, who poured sarcasm on the prevailing methods of education in his *Verdadeiro methodo de estudar.*

From time to time literary societies, variously called academies or arcadias, arose to co-operate in the work of reform. In 1720 King John V., an imitator of Louis XIV., established the academy of history. The 15 volumes of its Memorias, published from 1721 to 1756, show the excellent work done by its members, among whom were Caetano de Sousa, author of the colossal *Historia da Casa* Real portugueza; Barbosa Machado, compiler of the invaluable Bibliotheca Lusitana, and Soares da Silva, chronicler of the reign of King John I.

The Royal Academy of Sciences, founded in 1780 by the 2nd duke of Lafões, produced a Diccionario da lingua portugueza and the Memorias (1788–95), and included in its ranks nearly all the learned men of the last part of the 18th century. Among them were the ecclesiastical historian Frei Manoel do Cenaculo, bishop of Beja; the polygraph Ribeiro dos Santos; Caetano do Amaral, a patient investigator of the origins of Portugal; João Pedro Ribeiro, the founder of modern historical studies; and the critics D. Francisco Alexandre Lobo, bishop of Vizeu; Cardinal Saraiva and Frei Fortunato de S. Boaventura.

The **Arcadias.**—In 1756 Cruz e Silva (*q.v.*), with the aid of friends, established the Arcadia *Ulysiponense.* Garção, the most prominent Arcadian, composed the Cantata de Dido, a gem of ancient art, as well as some charming sonnets to friends and elegant odes and epistles. The bucolic verse of Quita, a hairdresser, has a tenderness and simplicity which challenge comparison with Bernardim Ribeiro, and the *Marilia* of Gonzaga contains a celebrated collection of bucolic-erotic verse. Their conventionality sets the lyrics of Cruz e Silva on a lower plane, but in the *Hyssope* he improves on the *Lutrin* of Boileau. In 1790 a New Arcadia came into being. Its two most distinguished members were the rival poets Bocage (*q.v.*) and Agostinho de Macedo (*q.v.*). The only other poet of the New Arcadia who ranks high is Curvo Semedo; but the Dissidents, a name bestowed on those who stood outside the Arcadias, included two distinguished men now to be cited, the second of whom became the herald of a poetical revolution. No Portuguese satirist possessed such a complete equipment for his office as Nicolao Tolentino, and though a dependent position depressed his muse, he painted the customs and follies of the time with almost photographic accuracy, and distributed his attacks or begged for favours in sparkling verse. The task of purifying and enriching the language and restoring the cult of the Quinhentistas was perseveringly carried out by Francisco Manoel do Nascimento (*q.v.*). Shortly before his death in Paris he became a convert to the Romantic movement, and he prepared the way for its triumph in the person of Almeida Garrett, who belonged to the Filintistas, or followers of Nascimento, in opposition to the *Elmanistas,* or disciples of Bocage.

Early in the 18th century an attempt at the restoration of the drama by authors sprung from the people was made at the theatres of the Bairro Alto and Mouraria, and the numerous pieces staged there belong to low comedy. The Operas *portuguezas* of Antonio José da Silva (*q.v.*), produced between 1733 and 1741, owe their name to the fact that arias, minuets and *modinhas* were interspersed with the prose dialogue, and if neither the plots, style nor language are remarkable, they have a real comic force and a certain originality. Like Silva's operas, the comedies of Nicolao Luiz contain a faithful picture of contemporary society; but except in *Os* Maridos Peraltas, his characters are lifeless and their conventional passions are expressed in inflated language. Notwithstanding their demerits, however, his comedies held the stage from 1760 until the end of the century.

Meanwhile the Arcadia also took up the task of raising the tone of the stage, but though the ancients and the classic writers of the 16th century were its ideals, it drew immediate inspiration from the contemporary French theatre. All its efforts failed, however, because its members lacked dramatic talents and, being out of touch with the people, could not create a national drama.

Garção (*q.v.*) led the way with the Theatro Novo, a bright little comedy in blank verse, and followed it up with another, Assemble^ou partida; but he did not persevere. Figueiredo felt he had a mission to restore the drama, and wrote 13 volumes of plays in prose and verse, but, though he chose national subjects, and could invent plots and draw characters, he could not make them live.

Finally, the bucolic poet Quita produced the tragedies *Segunda Castro*, *Hermione* and two others, but these imitations of the French were still-born.

The 19th Century and After.—The 19th century witnessed a general revival of letters, beginning with the Romantic movement, of which the chief exponents were Garrett (*q.v.*) and Herculano (*q.v.*), both of whom had to leave Portugal on account of their political liberalism, and it was inaugurated in the field of poetry. Garrett read the masterpieces of contemporary foreign literature during his exiles in England and France, and, imbued with the national spirit, he produced in 1825 the poem *Camões*. His poetry, like that of his fellow *émigré*, the austere Herculano, is eminently sincere and natural, but while his short lyrics are personal in subject and his longer poems historical, the verse of Herculano is generally religious or patriotic. The movement not only lost much of its virility and genuineness, but became ultra-romantic with A. F. de Castilho (*q.v.*), whose most conspicuous followers were João de Lemos and the poets of the collection entitled *O Trovador;* Soares de Passos, a singer for the sad; the melodious Thomas Ribeiro, who drew his inspiration from Zorrilla and voiced the opposition to a political union with Spain in the patriotic poem D. *Jayme*. Mendes Leal, a king in the heroic style, Gomes de Amorim and Bulhão Pato, belong more or less to the same school. On the other hand José Simões Dias successfully sought inspiration from popular sources in his *Peninsulares* (1870).

In 1865 the revolt of the younger men of letters against the primacy of Castilho took the form of a fierce war of pamphlets. The leaders in the movement were Anthero de Quental (*q.v.*) and Theophilo Braga, the first a student of German philosophy and poetry, the second a disciple of Comte and author of an epic of humanity, *Visão dos tempos,* whose immense work in the spheres of poetry, criticism and literary history cannot be judged at present. In the issue literature gained considerably, and especially poetry, which entered on a period of active and rich production. The *Campo de flores* of João de Deus (*q.v.*) contains some of the most splendid short poems ever written in Portuguese. Simplicity, spontaneity and harmony distinguished his earlier verses, which are also his best. Anthero de Quental, the chief of the Coimbrans, enshrined his metaphysical neo-Buddhistic ideas, overshadowed by extreme pessimism, and marked the stages of his mental evolution, in a sequence of finely-wrought sonnets. These place him in the sacred circle near to Heine and Leopardi, and though strongly individualistic, it is curious to note in them the influence of Germanism on the mind of a southerner. *Odes modernas,* written in youth, show him in revolutionary, free-thinking and combative mood, but the prose of his essays, *e.g., Considerations on the Philosophy of Portuguese Literary History,* has that peculiar refinement, clearness and conciseness which stamped the later work of this sensitive thinker. A subtle irony pervades the *Rimas* of João Penha, who links the Coimbrans with Guerra Junqueiro and the younger poets. Partly philosophical, partly naturalistic, Junqueiro began with the ironical composition, *A Morte de D. João;* in *Patria* he evoked in a series of dramatic scenes and lashed with satire the kings of the Braganza dynasty; and in *Os Simples* (1892) he interprets in sonorous stanzas the life of country-folk by the light of his powerful imagination and pantheistic tendencies. His last poems appeared in *Poesias Dispersas* (1921). The *Claridades de Sul* of Gomes Leal, a militant anti-Christian, at times recall Baudelaire, and flashes of genius run through *Anti-Christo,* which is alive with the instinct of revolt. The *Só* of Antonio Nobre is intensely Portuguese in subjects, atmosphere and rhythmic sweetness, and had a deep influence. Cesario Verde sought to interpret universal nature and human sorrow, and the Parnassian Gonqalves Crespo may be termed a deeper, richer Coppée. His *Miniaturas* and *Nocturnos* have been re-edited by his widow, D. Maria Amalia Vaz de Carvalho, a highly gifted critic and essayist whose personality and *cercle* call to mind the 18th-century poetess, the Marqueza de Alorna. The French symbolists found an enthusiastic adept in Eugenio de Castro, who adopted a more natural and national manner in later works, such as *Canções desta negra vida* (1922) and *Chamas de uma candeia velha* (1925), and after the death of Junqueiro stood at the head of Portuguese poets. Antonio Feijó and José de Sousa Monteiro have written verse remarkable by its form. The most admired of the younger poets of this period, Antonio Corrêa de Oliveira, draws inspiration from the soil and religion, as in the *Auto das Quatro Estações* (1911) and *Pão nosso, Vinho alegre, Azeite de candeia* (1922). *A Minha terra* (1916) contains some true poetry and technical skill.

The best known books of Augusto Gil are *Sombra de Juno* (1915) and *Alba Plena* (1916). Teixeira de Pascoaes, a sincere but nebulous pantheist, the inventor of what is called *saudosismo,* is distinguished by love of nature, but he pays too little attention to form, though his verse has a music of its own. Affonso Lopes Vieira, a writer of exquisite taste and sense of rhythm, translated the traditions of the race and the poetry of the sea in *Zlhas de Bruma* (1918) and produced *rifacimentos* of two works of world fame in his *Amadis* and *Diana,* marked by rare artistry and understanding of the originals. The last publication of the Republican politician João de Barros, prolific in verse and prose, is a poem *Sisifo,* in which he treats the classical legend in a novel way.

The Drama.—Garrett took in hand the reform of the stage, moved by a desire to exile the translations on which the playhouses had long subsisted. He chose his subjects from the national history, began with the *Auto de Gil Vicente,* and followed this up with other prose plays, among which the *Alfageme de Santarem* takes the palm; finally, he crowned his labours by *Frei Luiz de Sousa,* a tragedy of fatality and pathos, and one of the really notable pieces of the century. The historical bent thus given to the drama was continued by the versatile Mendes Leal, by Gomes da Amorim and by Pinheiro Chagas, who all, however, succumbed more or less to the atmosphere and machinery of ultra-Romanticism, while the plays of Antonio Ennes deal with questions of the day in a spirit of combative liberalism. In the social drama, Ernesto Biester, and in comedy Fernando Caldeira, also no mean lyric poet, are two of the principal names, and the latter's pieces, *A Mantilha da Reizda* and *A Madrugada,* have a delicacy and vivacity which justifies their success. The comedies of Gervasio Lobato are marked by an easy dialogue and a sparkling wit, and some of the most popular of them were written in collaboration with D. João de Camara, the leading dramatist of the day, one of whose pieces, *Os Velhos,* was translated and staged abroad. To Henrique Lopes de Mendonqa, scholar, critic and poet, we owe some strong historical plays, as well as several stirring tales of old Portugal. Dr. Marcellino Mesquita is the author of *Leonor Teles* and other historical dramas, as well as of a powerful piece, *Dôr suprema.* Julio Dantas wrote many plays remarkable for their pliant style and delicate reconstruction of the past, such as *A Severa* (1901), *Rosas de todo o anno* (1907) and *Mariana* (1915). Among other pieces may be mentioned *O herdeiro* and *Entre Giestas* of Carlos Selvagem, a talented prose writer, *D. JoZo a a mascara* (1924) and the lyrical play *Diniz e Isabel* (1919) of Antonio Patricio, *O Gebo e a Sombra* (1923), a tragedy of unrelieved gloom and considerable power by Raul Brandão, and *Egas Moniz* (1918) by Dr. Jaime Cortesão.

The **Novel.**—Herculano led the way in the historical romance by his *Lendas e narrativas* and *O Monasticon,* two somewhat laboured productions, whose progenitor was Walter Scott; they still find readers for their impeccable style. Their most' popular successors have been *A Moçidade de D. JoZo V.* and *A ultima corrida de touros reaes em Salvaterra* by Rebello da Silva, and *Um Anno na Corte* by the statesman, Andrade Corvo. The novel shares with poetry the predominant place in the modern literature of Portugal, and Camillo Castello Branco (*q.v.*), Gomes Coelho and Eça de Queiroz are names which would stand high in any country. The first, a wonderful impressionist though not perhaps a great novelist, describes to perfection the domestic and social life of Portugal in the early part of the 19th century. His remarkable works include *Amor de Perdição, Amor de Salvação,* and the series entitled *Novelas do Minho.* Gomes Coelho, better known as *Julio Diniz,* records his experiences of English society in Oporto in *A Familia ingleza.* Portuguese critics have accused him of imitating Dickens. His stories, particularly *As Pupillas do Snr. Reitor,* depict country life and scenery with loving sympathy, and hold the reader by the charm of the characters, but Diniz is a rather subjective monotonous writer and he is no psychologist. Eça de Queiroz (*q.v.*) founded the Naturalist school in Portugal by a powerful book written in 1871, but only published in 1875, under the title *The Crime of Father Amaro;* and two of his great romances, *Cousin Basil* and *Os Maias,* were written during his occupancy of consular posts in England. *The Relic* conveys the impressions of a journey in Palestine and in parts suggests his indebtedness to Flaubert, but its mysticism is entirely new and individual; while the versatility of his talent further appears in *The Correspondence of Fradique Meizdes,* where acute observation is combined with brilliant satire or rich humour. The later portion of *The City and the Mountains,* in the truth and beauty of its descriptive passages shows him as a more regional writer. Among other novelists are Oliveira Marreca, Pinheiro Chagas, Arnaldo Gama and Luis de Magalhães.

Constant political unrest has been prejudicial to letters in a small country without a numerous leisured class, and no distinguished literary figure arose during the years 1910–25, but even before 1910 a reaction had begun against revolutionary methods in politics and laxity or agnosticism in religion, which may lead to a healthier national life. This movement showed itself in the later works of Eça de Queiroz, and in the return to the church of the prose writer Ramalho Ortigão and of the poet Guerra Junqueiro. It is not only found in the writers of the Integralist school (a Portuguese counterpart to the *Action française*); most of the leading poets and prose writers are once more declared Catholics, and they have gone back to the people for inspiration, with happy results. Nationalism and regionalism have taken the place of naturalism and symbolism, which were copied from France and never commended themselves to Portuguese feeling as a whole. The inability of 60% of the country-dwellers to read, saved many of them from losing their ideals and character during the period when a Liberal, destructive and anti-religious atmosphere permeated newspapers and books.

The new manner is seen especially in the novel, though it did not touch,the austere Republican and conscienlious analyst of middle-class society Teixeira de Queiroz (d. 1919). Following in the steps of Oliveira Martins, Anthero de Figueiredo has sought to combine history and art in *D. Pedro* e *D. Ines* (1913), *Leonor Teles* (1916), and *D. Sebastião* (1924), where he revives the figure of the last crusading king, and paints a picture of the times with abundant imagination. His *Espanha* (1923), *Jornadas em Portugal* (1918) and *Senhora do Amparo* (1920) are regional works, in a glowing style, which in the second suffers from over-elaboration.

The lack of a sound classical education is too evident in modern Portuguese prose, and few dare to attempt the straightforward narrative, sparing of adjectives and uncommon words, which is the chief attraction of the classics. Raul Brandão is an exception; his *Pescadores* (1924) tells of fisher folk and the tragedy of the ocean with poignant realism, and contains magnificent descriptions of the coast scenery. The book is worthy of the author of *Os Pobres* (1921). The trilogy of Manoel Ribeiro, *A Catedral,* probably suggested by Huysmans, *O Deserto* and *A Resurreição,* constitute a remarkable performance in subject and atmosphere, without precedent in modern Portuguese, and its popularity is not less remarkable. No better proof could be adduced of the changed times than these "clerical" books by a man of far from clerical ideas. At the close of this period he initiated a new trilogy with *A Colina Sagrada* (1926) and *A Planicie Heroica* (1927). The naturalism of Eça de Queiroz found a fresh interpreter in Aquilino Ribeiro, a novelist highly considered throughout the Peninsula. He is possessed of a rich vocabulary, and no one can create characters or picture one side of country life so faithfully as he has done in *A Via Sinuosa* (1918). In 1925 he produced *Filhas de Babilonia,* an unpleasant book, and *Estrada de Santiago.* The voluminous João Grave added *Gente Pobre* (1912), *Parsifal* and *A vida e Paixão da Infanta* to his list of romances. A brilliant satire on contemporary political events is to be found in *Saude* e *Fraternidade* by Campos Monteiro.

History. — Years of persevering toil in archives and editions of old chronicles prepared Herculano for his *magnum opus,* the *Historia de Portugal.* The *Historia da Origem e Estabelecimento da Inquisição em Portugal* followed and confirmed the position of its author as the leading modern historian of the Peninsula, and he further initiated and edited the important series *Portugaliae Monumenta historica.* The Visconde de Santarem, and Judice Biker in geography and diplomatics, produced standard works; Luz Soriano compiled painstaking histories of the reign of Ring Joseph and of the Peninsular War; Silvestre Ribeiro printed a learned account of the scientific, literary and artistic establishments of Portugal, and Lieut.-Col. Christovam Ayres was the author of a history of the Portuguese army. Rebello da Silva and the voluminous and brilliant publicists, Latino Coelho and Pinheiro Chagas, wrote at second-hand and rank higher as stylists than as historians. Gama Barros (1833–1925) and Costa Lobo followed closely in the footsteps of Herculano, the first by a *Historia da Administração publica em Portugal nos Seculos XII. a XV.,* positively packed with learning, the second by a *Historia da Sociedade em Portugal no Seculo XV.* Though he had no time for original research, Oliveira Martins (*q.v.*) possessed psychological imagination, a rare capacity for general ideas, and the gift of picturesque narration; and in his philosophic *Historia de Portugal,* his sensational *Portugal contemporaneo, Os Filhos de D. João* and *Vida de Nun' Alvarez,* he painted an admirable series of portraits, and, following his master Michelet, made the past live again. Prof. Fortunato de Almeida's *Historia de Portugal* marks a great advance on its predecessors. The same scholar published in four stout volumes a *Historia da Igreja em Portugal* (1910, etc.), equally well documented. J. Lucio d'Azevedo, the authority on Pombal, produced an excellent biography of the 17th century missionary, preacher and diplomat, Antonio Vieira, S. J., and the first volume of his *Cartas* appeared in 1925. D'Azevedo's most notable book is the *Historia dos Christãos novos portugueses* (1922). The same editors published (1912–27) the Lisbon parochial Registers of the 16th century. The statesman João Franco, last minister of King Carlos, issued a number of autograph letters received by him from the King shortly before his tragic death. Affonso de Dornellas in genealogy and history and Antonio Ferrão in the latter have done considerable work.

The Conde de Sabugosa, Lord Chamberlain under the monarchy, published (1912–24) five volumes of historical studies marked by critical ability, imagination and a sense of humour. His most substantial work is *A Rainha D. Leonor* (1921). The Visconde de Santarem printed the correspondence and re-issued some of the geographical and historical works of his famous namesake, including the *Historia e Theoria das Corfes Geraes* (1924). The Integralist leader Antonio Sardinha (d. 1925) left several volumes of essays and poetry. Dr. M. Gonçalves Cerejeira made his name by a work on the Renaissance with versions of the letters of the humanist Cleynaerts. Braamcamp Freire (1849–1921), the historian, was joint editor with D. Carolina Michaelis de Vasconcellos (1851–1925) of the works of Bernardim Ribeiro and Christovam Falcão. This great Romance scholar issued the 4th of her illuminating *Notas Vicentinas* in 1922. (E. P.; A. B.)

BIBLIOGRAPHY.—The chief works of a bibliographical character are the *Bibliotheca Lusitana* of Barbosa Machado and Innocencio da Silva's *Diccionario Bibliographico Portuquez,* continued by Brito Aranha. A smaller work is the *Manual Bibliographico* (1878) by Pinto de Mattos. Dr. Fidelino de Figueiredo's *A Critica Litteraria como Sciencia,* in its 3rd ed. (1920) contains an elaborate bibliography; and in 1922 the Hispanic Society of America published a concise *Portuguese Bibliography.* The *Catalogo Razonado* (1890) of Garcia Peres, and Figanière's *Catalogo dos Manuscriptos portuguezes no Museu Britannico* (1853) contain invaluable information. The general histories are those of Theophilo Braga, in many separate volumes, with a summary in four (1909–18); *Geschichte der Portugiesischen Literatur* (1894) by Carolina Michaelis de Vasconcellos in Grober's *Grundriss;* and three volumes (1912–25) by Dr. Fidelino de Figueiredo, who deals more fully with the modern literature in his *Historia de la Literatura Portuguesa* (Barcelona, 1927). In 1922 the Clarendon Press published the first complete history of *Portuguese Literature* in English (by Mr. A. F. G. Bell). Mr. Edgar Prestage's earlier valuable criticism is dispersed over various publications. Dr. Mendes dos Remedios's compendious *Historia da Literatura Portuguesa* attained a fifth edition in 1921.

Portuguese texts are still deficient as a whole, although much valuable work has been done, in articles and editions, by C. Michaëlis de Vasconcellos, as in her edition of the *Cancioneiro da Ajuda* (2 vols., 1904); E. Prestage, J. Leite de Vasconcellos, J. J. Nunes (in *Chrestomathia Archazca,* 1905, and many early texts), Col. Esteves Pereira, and A. Braamcamp Freire. Some of the Latin texts of Portuguese humanists have been made accessible, and their poetry was published in *Corpus illustrium poetarum lusitanorum qui latine scripserunt* (1745–48). The *Parnasso Lusitano,* in 6 vols. (1826), and Costa e Silva's *Ensaio Biographico-critico* (10 vols. 1850–55) have been supplemented and superseded by Dr. Agostinho de Campo's *Antologia Portuguese.* Bouterwek's history, translated into English in 1823, is similarly out of date. No weekly or monthly literary journal exists, but the *Revista Lusitana, Lusitania* and the *Boletim* of the Academy of Sciences are published at irregular intervals.

PORTUGUESE MAN-OF-WAR (*Physalia*), a colonial jelly-fish, one of the most beautiful of the pelagic group Siphonophora, found in tropical seas; it is occasionally drifted as far as the British coasts by the Gulf Stream. Its sting is exceedingly powerful and may have serious results. See HYDROZOA.

PORTUNUS, in Roman cult, originally the god of gates and doors (Lat. *porta*), and as such connected with Janus. Gradually he was transformed into the protector of harbours (*portus*) and ensured a safe return to seafarers. (Cicero, *Nat. deor.* ii. 26; Virgil, Acn. v. 241.) With the introduction of the Greek gods, he became merged with Palaemon-Melicertes. He had a special priest (*flamen* portunalis) and temples on the Tiber near the Aemilian bridge and near Ostia, where a festival was celebrated in his honour on Aug. 17. (See G. Wissowa, *Rel. u. Kultus* der Romer, pp. 111–112.)

PORTUS, an ancient harbour of Latium, Italy, on the right bank of the Tiber, at its mouth. For its origin *see* OSTIA. Claudius constructed the first harbour here, 2½ m. north of Ostia, enclosing an area of 170 acres, with two long curving moles projecting into the sea, and an artificial island, bearing a lighthouse, in the centre of the space between them; the harbour thus opened directly to the sea on the north-west and communicated with the Tiber by a channel on the south-east. The object was to obtain protection from the prevalent south-west wind, to which the river mouth was exposed. Though Claudius, in the inscription which he caused to be erected in A.D. 46, boasted that he had freed the city of Rome from the danger of inundation, his work was only partially successful. The Via Portuensis (15 m.) ran over the hills as far as the modern Ponte Galera, and then straight across the plain. An older road, the Via Campana, ran along the right bank of the Tiber. In A.D. 103 Trajan constructed another harbour still well preserved farther inland—a hexagonal basin enclosing an area of 97 acres. It communicated with the harbour of Claudius and with the canal constructed by him (though it bears the name Fossa Trajana) now forming the navigable arm of the Tiber (reopened for traffic by Gregory XIII. and again by Paul V.). It was surrounded by extensive warehouses, remains of which may still be seen: the fineness of the brickwork of which they are built is remarkable. The perforated travertine blocks to which the ships were made fast may still be seen. Farther to the east is a circular building in brick with niches called the temple of Portumnus.

Portus eventually captured the main share of the harbour traffic of Rome, and though the importance of Ostia did not at once decrease we find Portus already an episcopal see in Constantine's time not very long after Ostia, and the only harbour in the time of the Gothic wars. Its abandonment dates from the partial silting up of the right arm of the Tiber in the middle ages, which restored to Ostia what little traffic was left. To the west of the harbour is the cathedral of S. Rufina (10th century, but modernized except for the campanile) and the episcopal palace, fortified in the middle ages, and containing a number of ancient inscriptions from the site. On the island (Isola Sacra) just opposite is the church of S. Ippolito, built on the site of a Roman building, with a picturesque 13th century campanile; 2 m. to the west is the modern village of Fiumicino at the mouth of the right arm of the Tiber, 21 m. west-south-west by rail from Rome. It is a portion of the commune of Rome. Three miles to the north is the pumping station by which the lowland (formerly called Stagno di Maccarese, now reclaimed and traversed by many drainage canals) is kept drained (Bonifica di Maccarese).

PORT WINE, a wine made from grapes grown in the valley of the Douro, fortified at the time of the vintage, and shipped from Oporto. By virtue of the Anglo-Portuguese treaties of 1914 and 1916, no other wine can legally be called port.

The quality of port depends in the first place upon the quality of the grapes from which the wine was made originally, the best wine being made only from the finer species of grapes and from the more suitable vineyards. The quality depends in the second place upon the quality and quantity of the brandy used at the vintage time to check fermentation; also upon the time and manner in which this addition is carried out. When the grapes are pressed, their sweet juice begins to ferment at once, *i.e.,* the grape sugar is being gradually converted by the natural process of fermentation into carbon dioxide and ethyl alcohol. In order to retain a certain proportion of this grape sugar, brandy is added at a given time and fermentation is immediately checked. At that stage port is a blend of fermented grape-juice (wine), distilled wine (*brandy*) and unfermented grape-juice; and its quality depends chiefly upon the length of time and manner of keeping it.

Vintage Port is a wine made in any one year, shipped from Oporto usually two years after it is made, and bottled almost immediately by the importer. Vintage port matures slowly but it retains more body and more colour, and it acquires with age a finer bouquet than any other type of port. Vintage port, to be at its best, must be a wine shipped by a reliable port shipper, and well bottled by an expert wine-merchant; it must have been kept long enough but not too long; it must be carefully decanted.

Tawny Port is a wine which has been kept in cask and has been in contact with a greater proportion of oxygen from the outside air than the early-bottled wine: it has aged more rapidly and possesses less colour and less body than the vintage port. Tawny port is not, usually, the wine of any one year's grapes but a blend of wines made in different years. Tawny port is kept by the port shipper in his "lodges," at Oporto or Villa Nova da Gaia, and is shipped when ready for consumption.

Ruby Port is a compromise between the early-bottled vintage port and the matured-in-wood tawny port. It may be the wine of one vintage kept in cask for some years and bottled whilst still deep in colour, or it may be a blend of ports of different years and styles, a blend which may be made by the port shipper, at Oporto, or by the importer at home to suit the taste of individual customers.

E. dos Santos, *O Vinho do Porto* (1916). (A. L. S.)

PORUS (4th century B.C.), an Indian prince, ruler of the country between the rivers Hydaspes and Acesines at the time of the invasion of Alexander the Great. In the battle on the banks of the Hydaspes he offered a desperate resistance, and Alexander, struck by his independent spirit, allowed him to retain his kingdom, which he increased by the addition of territory. From this time Porus was a loyal supporter of Alexander. He still held the position of a Macedonian satrap when assassinated some time between 321 and 315 B.C.

See Arrian v. 18, 19; Plutarch, *Alexander,* 60; Quintus Curtius viii. 14.

PORVOO (Swed. *Borgå*), a seaport in the province of Nyland, republic of Finland, situated at the entrance of the river Borgå into the Gulf of Finland, about 33 mi. E N.E. of Helsinki by rail. Pop. (1939) 7,100. It is the seat of a Lutheran bishopric which extends over the provinces of Viipuri and St. Michel with portions of Tavastehus and Nyland; it possesses a beautiful cathedral and a high school, and is the seat of a court of appeal. Once a city of great dignity, the rapid growth of Helsinki has eclipsed it. In 1809, when the estates of Finland were summoned to a special diet to decide the future of the country, Porvoo was the place of meeting, and it was in the cathedral that the Tsar Alexander I. pledged himself as grand duke of Finland to maintain the constitution of the grand duchy.

POSEIDON, in Greek mythology, god of the sea and of water generally, son of Cronus and Rhea, and brother of Zeus and Pluto (perhaps "lord of moisture"; *see* Carnoy in *Musée Belge,* xxviii. p. 175 or connected with πόσις drink, ποταμός a river). When the three brothers deposed their father, Cronus, the kingdom of the sea fell by lot to Poseidon. His home was in a golden palace in the depths of the sea near Aegae in Achaea. In his hand he bore a trident, wherewith he lashed the sea into fury, split the rocks, and caused horses and fountains to spring from them. But, while he caused storms and shipwrecks, he could also send favouring winds; hence he was known as *Sōtēr,* "the preserver." Another of his titles was *Gaieochos,* "holder (*i.e.,* encircler?) of earth." He was the god of navigation and his temples stood especially on headlands and isthmuses. Every occupation connected with the sea was under his protection, and seafaring people, especially the Ionians, regarded themselves as his descendants. As god of the sea he disputed with other deities for the possession of the land. Earthquakes were thought to be produced by Poseidon shaking the earth—hence his epithet of *enosichthon,* "earth-shaker"—and hence he was worshipped even in inland places which had suffered from earthquakes. Several striking seismic and other phenomena in historical times were attributed to him. Poseidon was also the god' of springs, which he produced by striking the rock with his trident, as he did on the acropolis of Athens when disputing with Athena for the sovereignty of Athens (Herodotus viii. 55; Apollodorus iii. 14). As such he was called *Nymphagetes,* the leader of the nymphs of springs and fountains, a god of fresh water, probably his original character, and in this connection was φυτάλμιος, a god of vegetation, frequently associated with Demeter. At Athens, he is closely associated with Erechtheus (*q.v.*), with whom many identify him. As he gave, so he could withhold, springs of water; thus the waterless neighbourhood of Argos was supposed to be the result of his anger: Black bulls were sacrificed to him and often thrown alive into rivers; in Ionia and Thessaly bull-fights took place in his honour; at a festival of his at Ephesus the cupbearers were called "bulls," and the god himself was surnamed "Bull Poseidon." The horse was especially associated with his worship. Several legends represent him as creating the first horse; horses were occasionally sacrificed to him; and he is called *Hippios* ("lord of steeds"). In the deme of Colonus he was worshipped with Athena, the reputed inventor of the bridle. Various explanations of the title ἵππιος have been given: (1) that the horse represented the corn-spirit; (2) the resemblance of the crested waves to horses; (3) the impression of horses' hoofs near the god's sacred springs, and the shaking of the earth by them when galloping (*see* Farnell, *Cults of the Greek States,* iv. 20). In the Trojan War he takes the side of the Greeks, because he had been cheated of his reward by Laomedon, king of Troy, for whom he had built the walls of the city. The blinding of his son Polyphemus by Odysseus brings upon the hero the wrath of Poseidon. He is famous for his numerous amours; his offspring were mostly wild and cruel, like the sea—the Laestrygones, Polyphemus, Antaeus, Procrustes, and the like. He was worshipped as a national god by the Ionians, who took his worship over with them from Peloponnesus to Asia Minor. His chief sanctuary was at Mycale, where the Panionia, the national festival of the Ionians, was held. Other seats of his worship were in Thessaly, Boeotia (*see* Farnell, p. 29 ff.) and Peloponnesus. At Taenarum in Laconia he had a famous cave-like temple with an asylum, and on the island of Tenos he was worshippec! as the *physician,* probably in reference to the health-giving properties of the sea air. By far the most famous of his festivals was that celebrated every alternate year on the isthmus of Corinth, at which the "Isthmian games" were held. The horse, the dolphin (the symbol of the calm sea) and the pine-tree, with wreaths of which the Isthmian victors were crowned, were sacred to him. His attributes are the trident and dolphin or tunny fish.

As represented in art, Poseidon resembles Zeus, but possesses less of his majestic calm. In modern Greece St. Nicholas has taken the place of Poseidon as patron of sailors. But the Zacynthians have a special sea god, half man, half fish, who dwells under the sea, rides on dolphins or in a car drawn by dolphins, and wields a trident. By the Romans Poseidon was identified with Neptune (*q.v.*).

See Preller-Robert, *Griechische Mythologie,* i. 566 ff. (1894); O. Gruppe, *Griechische Mythologie,* vol. ii. (1906); and especially L. R. Farnell, *Cults of the Greek States,* vol. iv. (1907).

POSEIDONIUS (130?–50 B.C.), nicknamed "the Athlete," Stoic philosopher, the most learned man of his time and perhaps of all the school. A native of Apameia in Syria and a pupil of Panaetius, he spent many years in travel and scientific researches in Spain (particularly at Gades), Africa, Italy, Gaul, Liguria, Sicily and on the eastern shores of the Adriatic. When he settled as a teacher at Rhodes his fame attracted numerous scholars; next to Panaetius he did most, by writings and personal intercourse, to spread Stoicism in the Roman world, and he became well known to many leading men, such as Marius, Rutilius Rufus, Pompey and Cicero. The last-named studied under him (78–77) B.C.), and speaks as his friend.

The titles and subjects of more than twenty of his works, now lost, are known. In common with other Stoics of the middle period, he displayed eclectic tendencies, following the older Stoics, Panaetius, Plato and Aristotle. Unquestionably more of a polymath than a philosopher, he appears uncritical and superficial. But at the time his spirit of inquiry provoked Strabo's criticism as something alien to the school (τὸ αἰτιολογικόν καὶ τὸ ἀριστοτέλιζον, ὅπερ ἐκκλίνουσιν οἱ ἡμέτεροι). In natural science, geography, natural history, mathematics and astronomy he took a genuine interest. He sought to determine the distance and magnitude of the sun, to calculate the diameter of the earth and the influence of the moon on the tides. His history of the period 146–88 B.C., in 52 books, must have been a valuable storehouse. Cicero made much use of his writings.

POSEN: *see* POZNAN.

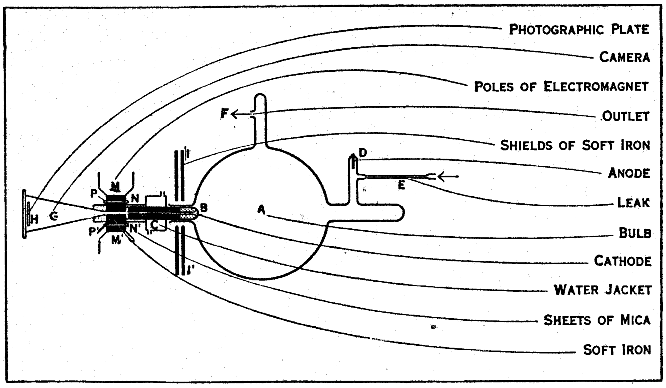
POSIDIPPUS (3rd cent. B.C.), Greek dramatist, of Cassandrea in Macedonia, the last and one of the most distinguished of the writers of the new comedy. He began to write for the stage in 289 B.C., and, according to Suïdas, wrote 40 plays, of which 17 titles and some fragments have been preserved. His comedies were frequently imitated by the Romans (Aulus Gellius ii. 23), and it is considered very probable that the *Menaechmi* (a comedy of errors) of Plautus is an adaptation from him. His statue in the Vatican is considered a masterpiece of ancient art.

Fragments in *A.* Meineke, *Poet. comic. graec. fragmenta* (1855).

POSITION ANALYSIS: see ANALYSIS SITUS.

POSITIVE (or PORTABLE) **ORGAN,** a mediaeval chamber organ which could be carried from place to place, and when played was placed on a table or stool and required a blower for the bellows, as well as a performer. It was larger and more cumbersome than the portative organ (*q.v.*).

POSITIVE RAYS. In 1886 Goldstein while experimenting with the discharge in gases at low pressures observed luminous streamers passing through perforations in the cathode and illuminating the gas behind it. The luminosity, he assumed, was due to rays of some sort which travelled in the opposite direction to the cathode rays (*q.v.*) and so passed through the aperture in the cathode. On account of the method by which they were obtained he called them "Canalstrahlen." Subsequently Wien showed that they could be deflected by means of a magnetic field. They were very fully investigated by Sir Joseph J. Thomson who called them "Positive Rays" on account of the fact that normally they are positively electrified. Recently they have been included in the general term "Mass Rays" which covers all swiftly moving particles of matter of atomic or molecular size whether charged electrically or not. The rays may be developed in many different ways, the most general being ionization of a gas at low pressure in a strong electric field. Ionization, which may be due to collision or radiation, means in its simplest case the detachment of one electron from a neutral atom. The two resulting fragments carry



FROM DR ASTON, "ISOTOPES (EDWARD ARNOLD & CO)

FIG. 1.—APPARATUS FOR THOMSON'S "PARABOLA" METHOD OF POSITIVE RAY ANALYSIS. SHOWING PARTS

charges of electricity of equal quantity but of opposite sign. The negatively charged portion is the electron, the atomic unit of negative electricity itself, and is the same whatever the atom ionized. It is extremely light and therefore in the strong electric field rapidly attains a high velocity and becomes a cathode ray. The remaining fragment is clearly dependent on the nature of the atom ionized. It is immensely more massive than the electron, for the mass of the lightest atom, that of hydrogen, is about 1,845 times that of the electron, and so will attain a much lower velocity under the action of the electric field. However, if the field is strong and the pressure so low that it does not collide with other atoms too frequently it will ultimately attain a high speed in a direction opposite to that of the detached electron, and become a "positive ray." The simplest form of positive ray is, therefore, an atom of matter carrying a positive charge and endowed, as a result of falling through a high potential, with sufficient energy to make its presence detectable. Positive rays can be formed from molecules as well as atoms, so that it will at once be seen that any measurement of their mass will give us direct information as to the masses of atoms of elements and molecules of compounds, and that this information will refer to the atoms and molecules individually, not, as in chemistry, to the mean of an immense aggregate. It is on this account that accurate analysis of positive rays is of such fundamental importance in research on the structure of atoms.

For visual effects the rays are best detected by a screen made of powdered millemite, which glows a faint green when bombarded by them. When permanent effects are required this screen is replaced by a photographic plate. The sensitivity of the plate to positive fays bears no particular relation to its sensitivity to light; so far the best results have been obtained from comparatively slow process plates of the type known as "Half Tone."

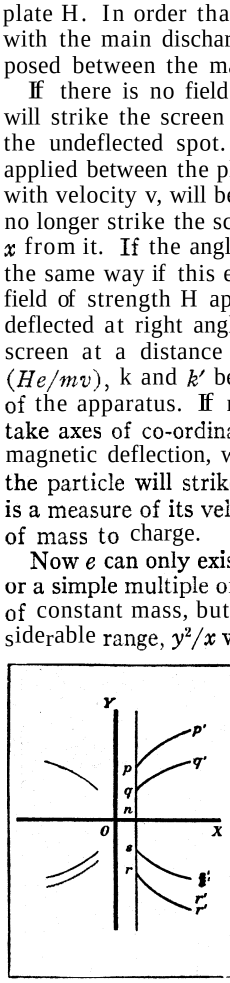
Thomson's "Parabola" Method **of** Analysis.—The method by which Sir J. J. Thomson investigated the properties of positive rays, and which still remains pre-eminent in respect to the variety of information it supplies, consists essentially in allowing the rays to pass through a very narrow tube and then analysing the fine beam so produced by electric and magnetic fields.

The construction of one of the types of apparatus used is indicated in fig. 1. The discharge by which the rays are generated takes place in the bulb A. The cathode B is placed in the neck of the bulb. Its face is of aluminium and so shaped as to present a hemispherical front provided with a funnel-shaped depression. This hole through which the rays pass is continued as an extremely fine-bore tube, mounted in a thick iron tube forming the continuation of the cathode as indicated. The finer the bore of this tube the more accurate are the results obtained, and tubes have been made as narrow as one-tenth of a millimetre, but as the intensity of the beam of rays falls off with the inverse fourth power of the diameter a practical limit is soon reached The cathode is cooled by the water-jacket C. The anode D may be placed in a side tube. The gas to be examined is led in through a fine leak E and pumped off at F. The pressure is usually adjusted so that the discharge potential is 30,000to 50,000 volts.

During the discharge all the conditions necessary for the production of positive rays are present in **A.** Under the influence of the high potentials they attain high speeds as they fly towards the cathode, and those falling axially pass right through the narrow tube emerging as a fine circular beam. This beam is subjected to analysis by causing it to pass between the pieces of soft iron P,P′ which are placed between the poles M.M′ of a powerful electromagnet. P and P' constitute the pole pieces of the magnet, but are electrically insulated from it by thin sheets of mica *N,N*, and so can be raised to any desired potential by means of the leads shown. The rays then enter the highly exhausted camera G. and finally impinge upon the fluorescent screen or photographic plate H. In order that the stray magnetic field may not interfere with the main discharge in A, shields of soft iron I,I′ are interposed between the magnet and the bulb.

If there is no field between the plates P.P′ the beam of rays will strike the screen at a point in line with the fine tube called the undeflected spot. If an electric field of strength X is now applied between the plates a particle of mass m, charge e, moving with velocity v, will be deflected in the plane of the paper and will no longer strike the screen at the undeflected spot, but at distance x from it. If the angle of deflection is small $x=k\,(Xe/mv^2)$. In the same way if this electric field is now removed and a magnetic field of strength H applied between P and P' the particle will be deflected at right angles to the plane of the paper and strike the screen at a distance y from the undeflected spot where $y=k'(He/mv)$, k and k' being constants depending solely on the form of the apparatus. If now, with the undeflected spot as origin we take axes of co-ordinates OX, OY along the lines of electric and magnetic deflection, when both fields are applied simultaneously, the particle will strike the screen at the point (x, y) where y/x is a measure of its velocity and y^2/x is a measure of e/m, its ratio of mass to charge.

Now e can only exist as the electronic charge $4{\cdot}77\times10^{-10}$ C.G.S. or a simple multiple of it. Thus if we have a beam of positive rays of constant mass, but moving with velocities varying over a considerable range, y^2/x will be constant and the locus of their impact with the screen will be a parabola pp' (fig. 2). When other rays having a larger mass m' but the same charge are introduced into the beam, they will appear as another parabola qq' having a smaller magnetic displacement. If any straight line p,q,n be drawn parallel to the magnetic axis OY cutting the two parabolas and the electric axis OX in p,q,n it will be seen at once that $m'/m=pn^2/qn^2$. That is to say, the masses of two or more particles can be compared directly by merely measuring lengths the ratio of which is entirely independent of the form of the apparatus and the experimental conditions



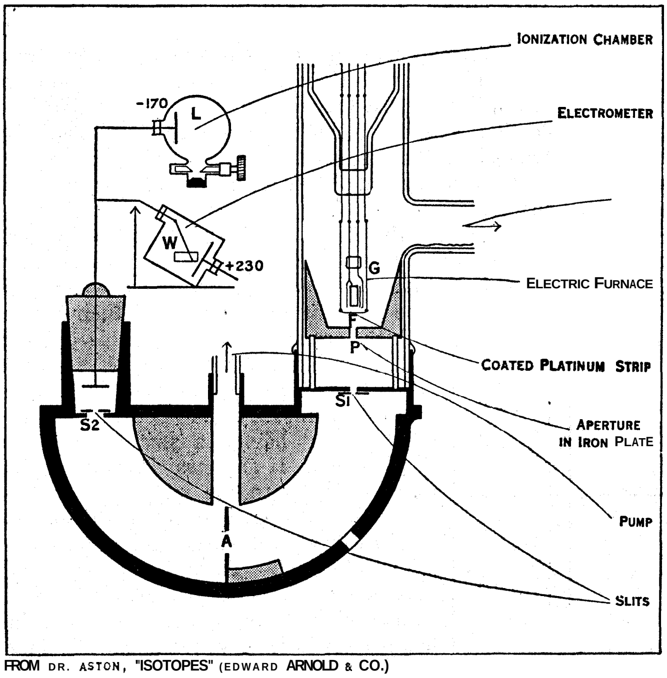
FROM DR. ASTON, "ISOTOPES (EDWARD ARNOLD & CO.)

FIG. 2—PARABOLAS OF POSITIVE RAYS
OY is the magnetic, OX the electric, axis

The principle of the method is, therefore, to obtain a photographic record upon which at least one parabola can be identified with particles of known mass; all the other parabolas can then be measured against this one and their masses deduced. In practice, since OX is an imaginary line and has no existence on the photograph, in order that the measurements may be made with greater convenience and accuracy, the magnetic field is reversed during the second half of the exposure, when—in the case we are conside ing--two new parabolas will appear rr', ss', due to m and m' respectively; the masses can now be compared by the equation $m'/m=pr^2/qs^2$ where p,q,r,s is any straight line cutting the curves approximately parallel to the magnetic axis. The measurement of these lengths is independent of zero determinations, and if the curves are sharp, can be carried out with considerable accuracy. It has been shown that the electrical displacement is in inverse proportion to the energy of the particle. This energy has a maximum limit determined by the potential of the discharge so that normal parabolas will end fairly sharply at points p,q, etc., equidistant from the magnetic axis This is clearly shown in the photographs reproduced in Plate, figs. 1 and 2.

Negatively Charged Rays.—As there is intense ionization in the fine tube the charged particles may easily collide with and capture electrons in passing through it. A singly charged particle capturing a single electron will, of course, proceed as a neutral ray, and being unaffected by the fields will strike the screen at the central spot. If, however, it makes a second collision and capture it will become a negatively charged ray. Rays of this kind will suffer deflection in both fields in the opposite direction to the normal ones, and will, therefore, give rise to parabolas of a similar nature but situated in the opposite quadrants, as indicated by the fine lines in fig. 2. Such negative parabolas are shown in the photographs. They are always less intense than the corresponding normal ones, and are usually associated with electronegative atoms.

Rays with Multiple Charges.—If during ionization more than one electron is split off, the resulting positive ray will have a double or multiple charge. Taking the case of a doubly charged particle it may give rise to two distinct effects, In the first place if it retains its double charge while passing through the analysing fields its behaviour will be quite indistinguishable from that of a normal ray of half its mass. Thus the effective mass of a doubly charged oxygen atom, written O^{++}, will be 8. Parabolas due to C^{++} and O^{++} may be seen in Plate, fig. 2. In the second place, the



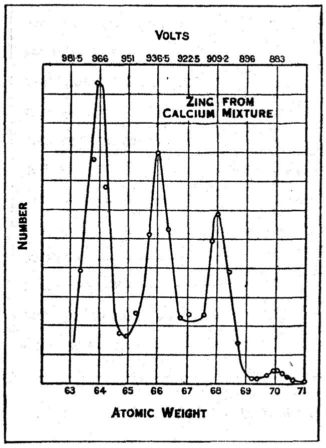
FROM DR. ASTON, "ISOTOPES" (EDWARD ARNOLD & CO.)

FIG. 3.— DIAGRAM OF APPARATUS FOR DEMPSTER'S METHOD OF ANALYSIS

particle may retain its double charge through the whole potential fall of the discharge but capture an electron in the fine tube. It will then constitute a ray of normal ratio of mass to charge but with double the normal energy, so that the normal parabola will show an extension towards the axis OY to a point half way between that axis and the line pq. The extension of the oxygen parabola due to this cause is clearly shown on the photograph.

Most elements are capable of losing two electrons, some, such as krypton, three or more, while mercury can lose no less than eight at a time. The results of the multiple charge on atoms of mercury is beautifully illustrated in Plate, fig. 3. The parabola a corresponding to normal single charge will be seen extended almost to the origin itself, while above a series of parabolas of diminishing intensity β,γ, etc., indicate the atoms which have retained two, three or more charges.

Dempster's Method of Analysis.—This method makes use of the principle first used by Classen and now generally adopted for beta-ray analysis, that a homogeneous beam of charged particles diverging from a narrow slit may be focussed by bending them through 180° in a uniform magnetic field. One form of Dempster's apparatus is shown in fig. 3. The element, the rays of which are to be analysed, is vaporized in a small electric furnace G and its vapour ionized by bombardment with electrons from a coated platinum strip F near the mouth of the furnace. The positive ions so produced pass into an accelerating field through the aperture in the iron plate P. The energy of the rays at this point is regarded as negligible so that all reach the slit S_1 with the same energy which can be controlled by varying the potential between P and S_1, usually 800–1,000 volts. The rays passing down in a narrow beam through S_1 are bent into a semicircle S_1,A,S_2 by the magnetic field, and so focussed upon a second slit S_2. Beyond this they are collected on an insulated plate and their charge measured. This is done by connecting the plate to an electrometer W and balancing the current brought up by the rays against a known and controlled leak produced in the ionization chamber L by means of a constant radioactive source.



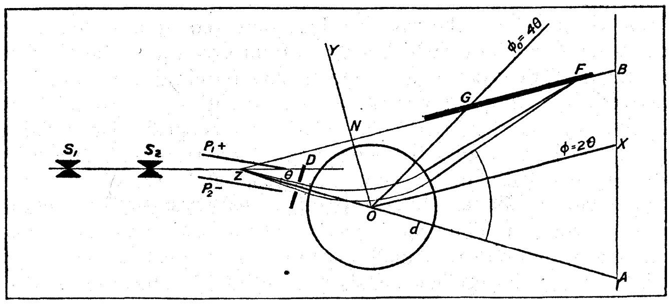
FROM DR. ASTON, "ISOTOPES" (EDWARD ARNOLD & CO.)

FIG. 4.—CURVE OBTAINED FROM ZINC, WITH A PEAK FOR EACH VALUE OF MASS IN BEAM OF RAYS

If V is the accelerating potential and r the radius of curvature it can easily be shown that $e/m = 2V/H^2r^2$. By keeping the magnetic field constant and plotting current against accelerating potential a curve is obtained having a peak for each value of mass present in the beam of rays. The ratios of the masses can be calculated from the voltages corresponding to the peaks. In this way Dempster was able to perform the first analyses of magnesium, calcium and zinc into their isotopes. *(See* ISOTOPES.) Fig. 4 shows a curve obtained from zinc.

The method is unfortunately limited in its application but it has the notable advantage that the relative abundance of the different isotopes can be directly deduced from the heights of their respective peaks.

Aston's Method of Analysis, the Mass-spectrograph.—This instrument was primarily designed to determine the constitution



FROM DR. ASTON, "ISOTOPES" (EDWARD ARNOLD & CO.)

FIG. 5.—DIAGRAM OF THE MASS SPECTROSCOPE USED IN ASTON'S METHOD OF ANALYSIS

of neon, a problem which required considerably greater accuracy than that given by the parabola method by which this element had been previously examined. In it electric and magnetic fields are employed to deflect the rays but they are so arranged that their deflections are at 180° instead of at 90° as used in the parabola method. The principle is indicated in fig. 5. The rays are collimated into an extremely thin ribbon by passing them through the two parallel narrow slits S_1,S_2. They are then deflected by

POSITIVE RAYS

1. Typical positive ray parabola. Particles of like mass and charge, but of different velocities, give parabolic curves
2. Parabolas of carbon, oxygen, mercury, etc.
3. Parabolas of mercury (Hg) atoms with multiple charges
4. Typical Mass Spectra obtained from the mass-spectograph. The dark lines represent images of slits corresponding to particular masses, while the numbers above the line indicate the masses they correspond to on the ordinary chemical scale

the electric field between the plates P_1,P_2. This spreads them out into an electric spectrum in which the deflection of any particular particle is e/mv^2. After emerging from the electric field the rays may be taken, to a first degree of approximation, as radiating from a virtual source Z half way through the field. A group of these rays is now selected by means of the diaphragm D, and allowed to pass between the poles of a powerful electromagnet. For simplicity the poles may be taken as circular, the field between them uniform and of such a sign as to bend the rays in the opposite direction to the foregoing electric field.

If θ and ϕ be the angles through which the selected beam of rays is bent by passing through fields of strength X and H then $\theta v^2 = lXe/m$ and $\phi v = LHe/m$ where l,L are the lengths of the paths of the rays in the fields. From these equations it can easily be shown that if the magnetic deflection is greater than double the electric deflection all rays of constant mass, or more precisely of constant m/e, will come to a real focus F, and that the locus of the foci so generated will lie along the line GF passing through Z and parallel to the line $\phi = 2\theta$. If a photographic plate is placed at GF a spectrum depending on mass alone will be obtained. On account of its analogy to optical apparatus the instrument has been called a mass-spectrograph and the spectrum it produces a mass-spectrum.

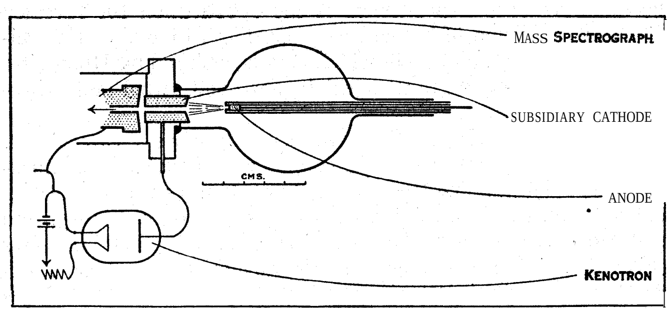
The use of slits instead of a fine circular tube, combined with the enhanced intensity obtained by means of the focussing principle, enables a very much higher resolving power to be used than was possible with the parabola method. Hence, although the photographs obtained do not afford so wide a range of general information upon the rays, the limit of accuracy in comparison of mass is notably increased. The first mass-spectrograph was set up in Cambridge in 1919 and used continually till 1925. In it θ the angle of electric deflection was one twelfth of a radian. It had a resolving power of about 1 in 130 and an accuracy of about 1 in 1,000. By its means over 50 elements were analysed and the "whole nnmber rule" established. (*See* ISOTOPES.) For details of its construction and technique the reader is referred to the works quoted at the end of this article.

Plate, fig. 4 shows a number of mass-spectra obtained by its means. Each dark line represents the image of the slits corresponding to a particular mass. The number above the line indicates the mass it corresponds to on the ordinary chemical scale O=16. The whole spectrum represents a range of mass of about 3 to 1, and the position of any line on the spectrum can be altered at will by changing the strength of the deflecting fields as shown by the positions of the chlorine group 35,36,37,38 in spectra II., III., IV. It will be noticed that the displacement to the right with increasing mass is roughly linear, a fortunate occurrence of great assistance in making the necessary calibrations. The measurements of mass are not absolute, but relative to certain reference lines which correspond to known masses. Such lines, due to hydrogen, carbon, oxygen and their compounds, are generally present as impurities or purposely added for the smooth working of the discharge tube. The two principal groups of these reference lines are the C_1 group, due to C(12),CH(13),CH_2(14),CH_3(15),CH_4 or O(16), and the C_2 group (24 to 30) containing the very strong line (28) due to CO and other bodies. The latter group and part of the former are well shown in spectrum I., where between them may be seen the lines due to the isotopes of neon 20 and 22. These two groups form with CO_2(44) a good scale of reference. The remarks already made about parabolas due to multiply charged rays apply to the lines obtained by this form of analysis. Lines due to particles carrying one, two, three, or more charges are called lines of the first, second, third or higher order, thus in spectrum II. the faint lines at 17·5 and 18·5 are chlorine lines of the second order. In spectrum V. taken with argon the third order line of its principal isotope (40) is clearly shown at $13\frac{1}{3}$ among the C_1 group of reference lines. Spectrum VIII. shows the six isotopes of krypton; on the left their second order lines can be seen close to the first order line of argon 40.

The remarkable property possessed by the atoms of mercury, of carrying multiple charges is well exhibited in mass-spectra. Mercury is a complex element and the characteristic closely packed group of lines due to its isotopes can be seen, progressively weaker in intensity up to the sixth order. Some of these groups appearing as unresolved blurrs may be recognized in the plate The lines of mercury have now been satisfactorily resolved and its constituent isotopes determined by a mass-spectrograph of higher power. (See ISOTOPES.)

Method of "Bracketing."—The method of determining masses by the position of lines with regard to known reference lines cannot be conveniently applied to the elements hydrogen and helium as these are too remote from the scale of reference. Their masses were first compared by the following principle which involves change in the deflecting fields. It is not practicable to determine the absolute values of the magnetic field but it can be kept constant without much difficulty. On the other hand, it is easy to apply electric fields whose ratios are known with certainty. From the equations already given it can be shown that for a given position on the spectrum $mv^2 \propto X$ and $mv \propto H$. Therefore if H is constant $m \propto X^{-1}$. If, therefore, after taking a spectrum we take another with the same magnetic field and, say, exactly double the electric field, the position due to a mass m on the first will be occupied by a line due to a mass $\frac{1}{2}m$ on the second. Hence if V is the original potential on the plates and v a suitable small voltage, and we take three spectra on the top of each other, one with a potential V, one with $2V+v$, and a third with $2V-v$, the magnetic field being identically the same for all, a line due to a mass m will appear bracketed on each side by lines due to $\frac{1}{2}m$. If the two to one relation between the masses is an exact one the bracket will be symmetrical as in the case of the hydrogen atom and molecule spectrum VII. c. If the bracket is not symmetrical the ratio of the masses is not 2 as in the case of the hydrogen molecule and helium atom spectrum VII. b and d. In this way it was first proved that the hydrogen atom had a mass considerably greater than a whole number on the oxygen scale, the value agreeing with 1·008, that deduced by chemical methods. This result, which has since been amply confirmed, is of great theoretical importance.

Anode Rays.—The usual source of positive rays, as has been stated, is the ordinary discharge in gases at low pressures. For examination by this process a substance must itself be volatile or capable of yielding a stable compound which can be introduced as a vapour into the discharge tube. The majority of elements are metals and do not behave in this manner. To obtain mass rays of these other methods must be used. As long ago as 1906 it was observed that halogen salts when heated and used as anode in a discharge tube behaved in a very remarkable manner giving off pencils of coloured rays. Thus the salts of lithium produced brilliant red streamers corresponding to the well-known red line



FROM DR ASTON, 'ISOTOPES' (EDWARD ARNOLD & CO)

FIG. 6.—APPARATUS FOR ACCELERATED ANODE RAYS, IN WHICH THE DISCHARGE TAKES PLACE BETWEEN ANODE AND SUBSIDIARY CATHODE

of the lithium spectrum. These were called "Anode Rays" and proved to be positively charged atoms of the metals employed. These rays are usually too slow to be suitable for direct analysis by the mass-spectrograph but they can be made so by the device illustrated in fig. 6, called the method of "accelerated anode rays." The discharge providing the rays takes place between the anode, containing halogen compounds, and a subsidiary cathode as shown. The slow rays passing through the latter are accelerated by introducing between it and the cathode of the mass-spectrograph a kenotron which will only allow a current of a value desired to pass. Now if the discharge tube becomes too hard the cathode rays from the subsidiary cathode will increase in energy heating the anode and softening the tube. If, on the other hand, the discharge becomes too soft the energy is absorbed in the kenotron, that in the cathode rays decreases and the anode cools down hardening the discharge. Also, whatever the state of the discharge tube, the energy of the rays reaching the mass-spectrograph is roughly constant, for this is governed by the watts in the high tension discharge and the current allowed to pass through the kenotron. By means of this device applied to the original mass-spectrograph the isotopic constitution of a large number of metallic elements was demonstrated. (See ISOTOPES.)

Mass-spectrographs of **High** Precision.—The accuracy and resolving power of the original mass-spectrograph have since been greatly exceeded. Costa, in 1925, described an instrument capable of an accuracy of 1 in 3,000 by which he compared the masses of the atoms of lithium and other light elements by the method of bracketing. The latest model now in use by the writer in the Cavendish laboratory has a resolving power of 1 in 600, more than sufficient to resolve the mass lines of the isotopes of any known element, and, when suitable systems of measurement are used, an accuracy of 1 in 10,000. This instrument has been used to measure the very small divergencies from the whole number rule. (See ISOTOPES.)

In conclusion, it may be stated that the discovery of positive rays gave a very valuable weapon into the hands of the physical investigator. The study of their analysis is less than 20 years old, yet already it has established facts of revolutionary importance and has provided a means of measuring the weights of atoms, free from ambiguity and of an accuracy equal to that of the finest chemical methods.

See J. J. Thomson, *Rays of Positive Electricity* (2nd ed.); F. W. Aston, *Isotopes* (2nd ed., 1924) and Bakerian Lecture, *Roy. Soc. Proc.* A. 115 (1927); W. Wien, *Kanalstrahlen* (1923). (F. W. A.)

POSITIVISM, a philosophical term, applied somewhat loosely to any system which confines itself to the data of experience and declines to recognize a priori or metaphysical speculations. In this sense the term may be applied to empirical philosophers in general. Thus Hume is a positivist in the sense that he specifically restricts philosophy to the sphere of observation, and regards the causal relation as being nothing more than what we have been accustomed to expect. Similarly Mill, Spencer and physical scientists generally view the universe from the positivist standpoint. In its commonest acceptation, however, the term is used of the philosophy of Auguste Comte, who applied the term to his system according to which knowledge is based exclusively on the methods and discoveries of the physical or "positive" sciences (*see* COMTE). The outcome of this positivism is the substitution for revealed religion of a religion of humanity—according to Huxley "Catholicism minus Christianity"—in which God is replaced by Humanity. This religion was to have its special priesthood, ritual and organization.

In England a number of prominent Positivists carried out Comte's ideal of a Church of Humanity with ritual and organization. The chief building (in Chapel Street, Lamb's Conduit Street, London)' is adorned with busts of the saints of humanity, and regular services are held. Positivist hymns are sung and addresses delivered. Among the leaders of this movement have been Frederic Harrison, Richard Congreve, E. S. Beesly and J. H. Bridges (d. 1906). Services are also held weekly in Essex Hall, London, and there are a few other centres in the provinces, including a prosperous church in Liverpool.

POSSE COMITATUS, a summons to every male in the county, between the ages of 15 and 20, to be ready and apparelled, at the command of the sheriff and the cry of the county, to maintain peace and pursue felons. In England. ecclesiastics, peers and the infirm were not compellable to attend. Owing to the establishment of county police, the sheriff does not now pursue felons, but by the Sheriffs Act, 1887, he is expressly authorized to call out the posse comitatus if he suffers resistance in the execution of a writ. Thus it is no answer by him, for non-execution of a writ, to say that he was resisted.

In the United States, where used in the states, it is the assemblage of males of 15 years and over called by the sheriff to aid him in maintaining peace.

POSSESSION, the supposed control of a human body and mind by an alien spirit, human or non-human; or the occupation by an alien spirit of some portion of a human body, causing sickness, pain, etc. The term obsession (Lat. for siege) is sometimes used as equivalent to possession; sometimes it denotes spirit control exercised from without, or it may mean no more than a maniacal monoideism. The spirit is held to have entered the person in order to foretell the future or to proclaim the will of a god; the god himself may be regarded as speaking through the mouth of his devotee. Hence the authority of a prophet. Among peoples in the lower stages of culture possession by spirits of the dead is common and is related to ancestor worship. This kind of possession is found in Africa, Polynesia and Asia. Many of the classical oracles were regarded as due to divine inspiration. The manifestations are often voluntarily induced and are provoked in many different ways; in classical times the eating of laurel leaves, the inhaling of fumes which ascended from a cleft in the rocks of Delphi, the drinking of intoxicating liquors, or of a more widely found means of inducing the phenomena—blood—were all in use. Hypnosis was produced by drugs, draughts of animal blood, or as in Siberia, America and many parts of Africa by drumming, contortions and orgiastic dancing.

Demoniacal possession is a widely spread explanation of such psychopathological conditions as epilepsy, somnambulism, hysteria, etc.; especially in the East Indian field lycanthropy (*q.v.*) and magical power (for evil) are commonly attributed to possession. Demoniacal possession is familiar to us from the New Testament narratives, in which those possessed are stated to live among the tombs, to be deaf and dumb, or blind, to be possessed by a multitude of evil spirits or to suffer from high fever as a result of possession; the demons are said to pass into the bodies of animals or to reside in waterless places. The facts recorded are explicable either as symptoms of mental disease or as results of suggestion.

In the lower stages of culture diseases are explained as due to the invasion of the body by spirits (*see* ANIMISM), but the effects are supposed to be physiological, not psychical. The wrath of an ancestor or other dead person or the malice of a spirit, such as the Malay *hantus,* or of any non-human spirit, may set up pathological conditions. Such cases may be distinguished from the inspirational form by their invariably involuntary character and are dealt with by a variety of means such as spells, purifications, sacrifices to the possessing spirit, etc. (*see* EXORCISM).

POSSESSION (IN LAW), a term derived from Roman law. It has been said to be either a right or a fact conferring a right, or both together. The latter is the view of Savigny, the leading authority upon the subject (Recht des *Besitzes*). The definition of W. A. Hunter may be accepted: "Possession is the occupation of anything with the intention of exercising the rights of ownership in respect of it" (*Roman* Law). Possession is inchoate or incomplete ownership; it is on its way to become ownership

In both Roman and English law the possessory tended to supersede the proprietary remedies from their greater convenience—that is to say, the plaintiff based his claim or the defendant his right upon possession rather than property. The English possessory action may have been directly suggested by the interdict. Bracton (103b) identifies the assise of novel disseisin, the most common form of possessory action, with the interdict unde *vi.* In England ejectment had practically superseded other real actions before the latter were (with the exception of dower, writ of dower and *quare impedit*) expressly abolished by the Real Property Limitation Act 1833, s. *36.* The action for the recovery of land, introduced by the Judicature Acts, is the modern representative of the action of ejectment.

Possession gives in English law, speaking generally, much the same rights as in Roman law. Thus it serves to found a title (see LIMITATION, STATUTES OF; PRESCRIPTION), and to throw the onus of proof upon the claimant. In an action for the recovery of land the defendant need only allege that he is in possession by himself or by his tenant, and (where such an allegation is necessary) that he had no notice to quit.

In English law the doctrine of possession becomes practically important in the following cases: (1) Possession serves as a convenient means of division of estates. (See LAWS OF REAL PROPERTY.) One of the divisions of estates is into estates in possession and estates in reversion or remainder. It also serves as a division of personal property (*q.v.*). A chose in action is said to be reduced into possession when the right of recovery by legal proceedings has become a right of enjoyment. (2) Possession gives a title against a wrongdoer. In the case of real property it is regarded as prima facie evidence of seisin.[1] In the case of personal property the mere possession of a finder is sufficient to enable him to maintain an action of trover against one who deprives him of the chattel.[2] (3) What is called "unity of possession" is one of the means whereby an easement is extinguished. (4) Possession is very important as an element in determining the title to goods under 13 Eliz. c. 5, the Bills of Sale Act 1878 and the Bankruptcy Acts 1883 to 1890. (5) Possession of goods or documents of title to goods is generally sufficient to enable agents and others to give a good title under the Factors' Acts. (See FACTOR.) (6) In criminal law the question of possession is important in founding the distinction between larceny and embezzlement. (See Stephen, Digest of the Criminal Law, note xi.) (7) Actions of possession of ships fall within the jurisdiction of the admiralty division. This jurisdiction in the case of British vessels depends upon the Admiralty Court Act 1861 (24 Vict. c. 10, s. 8), in the case of foreign vessels (in which the jurisdiction is rarely exercised) upon the general powers of the court as a maritime court.

Under the Statutes of Limitation the only question now is, not whether possession has been adverse or not, but whether twelve years have elapsed since the right accrued.

Scotland. — In Scotland possessory actions still exist eo *nomine.* Actions of molestation, of removing, and of maills (payments) and duties are examples. A possessory judgment is one which entitles a person who has been in possession under a written title for seven years to continue his possession (Watson, Law *Dict., s.v.* "Possessory Judgment").

United States. — In American law possession carries much the same important significance that it does in English law. Except in Louisiana where the civil law prevails, possession is commonly divided into actual and constructive possession. The former concerns actual occupancy or the exercise of dominion over a thing; the latter occurs where there is no actual possession but simply ownership and the possession is either vacant or consistent with the outstanding ownership, such as possession by a servant or bailee. The doctrine of possession has an outstanding importance in practically every branch of the law, especially in the numerous cases where ownership to realty or personalty is in issue. Especially significant are the doctrines of adverse possession, where long continued and uninterrupted possession of chattels or realty under a claim of right and hostile to the true owner ripens after the statutory period into indefeasible ownership.

In addition to the authorities cited may be mentioned W. A. Hunter, *Exposition of Roman* Law (4th ed. 1903); O. W. Holmes, *The Common Law* (1882); F. Pollock and R. S. Wright, *Possession in the Common Law* (1888); *W.* Markby, *Elements of Law* (1905); *T.* H. Holland, *Elements of Jurisprudence* (13th ed. 1924).

[1] "Seisin" and "possession" are used sometimes as synonyms, as generally by Bracton; at other times thev are distinguished: thus there can be possession of a term of years, but no seisin (Noy, *Maxims,* p. 2). It seems doubtful, however, how far in English law a tenant for years has true possession, for he is in law only a bailiff or servant of the landlord. But he certainly has possessory remedies.

[2] Compare the *Code Napoleon,* art. 2,279: "*En* fait de meubles la possession vaut titre."

POSSUM, a variant name for the opossum. See OPOSSUM.

POSTAL INSURANCE: see INSURANCE: POST OFFICE FACILITIES.

POSTAL ORDER, in the United Kingdom, is a post-office facility for making small remittances. The postal order is a voucher which can be bought at any post office and is payable at any other post office either to its bearer or to the nominee if a name is filled in. Orders are sold for sums from 6d. to 21/–, and odd pence can be filled in by affixing postage-stamps. The poundage charge ranges from 1d. to 2d. Larger sums can be made up by buying several orders. Thus £3 17s. 4d. can be remitted by buying three 20/– orders and one 17/– order and affixing 4d. in postage-stamps to one of the orders. If the order is crossed it is only paid through a banker as in the case of a cheque. About £45,000,000 a year is remitted by this means. See POST AND POSTAL SERVICES.

United States Postal Notes. — By an Act of Congress signed March 3, 1883, a form of postal order known as the postal note was authorized for use in transmitting through the mails any amount less than five dollars. This postal note for which a fee of three cents was charged became immediately popular but as it was payable to bearer many complaints of loss and theft were received. Notwithstanding the increasing number of such losses and depredations the use of the note was continued until January 1894, when it was abolished and, a lower fee having been prescribed for the regular money order of small amount, the latter took the place of the postal note without any serious confusion or complaint.

POST AND POSTAL SERVICES. The history of postal services goes back to the early days of the great empires of the east, when the permanent maintenance of control over a wide area was seen to depend on the organization and maintenance of rapid and frequent communication. The posts of the Persian empire under the successors of Cyrus are the first great example; the Macedonian successors of the Persian kings appear to have maintained, on a smaller scale, a similar service. In fact one of the earliest postal documents, now in the Berlin Postal Museum, is an interesting letter bill — the forerunner of many millions of successors — of the mail for the court of one of the Ptolemies. The Roman empire brought the official postal service to a very high degree of perfection; but with the collapse of the Western empire and the relapse into barbarism there was a long eclipse of this as of the rest of the machinery of the imperial government.

The provision of a regular system of private communication formed no part of the cares of ancient or mediaeval governments, and during the middle ages such private posts as existed were maintained by the universities or by the gilds of merchants. With the renaissance of civilization the need for private communication forced itself inevitably upon the notice of the governments of the day; and in its gradual growth and expansion the policy followed can be traced to three distinct motives, the relative importance of each of which has varied considerably from century to century. These are the desire to ensure an official control or censorship, mainly of international correspondence; the search for additional sources of revenue; and the wish to provide an efficient service.

The first motive is prominent in a proclamation of Queen Elizabeth dated 1591, which prohibits the carriage of letters to and from "the Countreys beyond the seas" except by messengers duly authorized by the master of the posts. This was directed at the private posts maintained by the foreign merchants in London and seems to have been effective at the moment in bringing them to an end. In 1609 James I. extended the prohibition to the inland as well as the foreign post; but in this case the motive may have been the protection of the postmaster general's revenue. The importance of state control emerged again during the protectorate; and in Cromwell's Post Office Act of 1657 stress is laid on the importance of a centralized post office as a means not only of promoting trade but of discovering and preventing "many dangerous and wicked designs which have been and are daily contrived against the peace and welfare of this Commonwealth, the intelligence whereof cannot well be communicated but by letter of escript." Postal censorship, long discontinued, was revived during the World War.

The growth in intelligence and prosperity which' marked the

17th century soon led to deep dissatisfaction with the limited and somewhat inefficient services which prevailed under Elizabeth and James I.; and the reign of Charles I. saw the first of the great postal reformers in the person of Thomas Witherings. Witherings began his career as "postmaster of England for foreign parts" and carried out sweeping reforms of the foreign post, including the very remarkable measure of organizing a service through France, with the consent of the French Government, by his own direct employees. In 1635 he was authorized to bring into operation a reorganization of the inland posts, which he proposed to make self supporting, instead of being a charge to the crown, by the simple method of making them efficient and cheap. Witherings' scheme consisted in the organization of posts travelling night and day on each of the great post roads, and covering a minimum distance of 120 miles a day, with branch posts working to and from the post towns on the way. A letter could thus be sent to Edinburgh and a reply received in six days—an enormous improvement on anything hitherto attempted. A regular tariff of rates was established, based on the "single letter," *i.e.,* one sheet of paper. This method of charging and the zone system of postage rates remained as the underlying principles of the postal service until the reforms of Rowland Hill.

Witherings' rates on the single letter were as follows:

	d.
Under 80 miles	2
80 to 140 miles	4
Over 140 miles	6
On the borders and in Scotland	8
In Ireland	9

For letters carried on the branch posts an additional 2d. was charged. Witherings, owing to some intrigue, was removed from office in 1637; but he continued to be connected with the postal service for some years, and he appears to have succeeded in combining efficient administration with a certain amount of personal profit.

After some years of improved postal services the possibility of developing the post office as a source of revenue was taken up by the Government, and in 1653 it was decided to let the posts out to farm. In view of the fact that the rates charged by the farmers were fixed, this measure, while convenient to the State, was free from the objections usually inherent in the farming of public services. The successful tenderer paid £10,000 a year, and the system was continued under the Restoration until 1667. The revenue of the post office, however, was not considered simply as a contribution to the general expenses of government. En 1663 it was settled on the duke of York and his male heirs, and somewhat later was charged with a number of pensions; *e.g.,* the duchess of Cleveland received £4,700 and the duke of Schomberg £4,000. In 1713 these pensions amounted to £22,120, or one third of the total net revenue. The system had a singularly long life, as the last of these pensions, that payable to the duke of Grafton as successor to the duchess of Cleveland, was continued until 1856, when it was commuted for £91,000.

London Penny Post, 1680.—The next great reform came from outside the post office. In 1653 Louis XIV. had authorized the establishment of a local post in Paris at a charge of one sou (which by a notable anticipation was paid by means of a postage stamp). Profiting no doubt by this example a London merchant, William Dockwra, brought into existence in 1680 the London penny post. A rate of 1d., to be prepaid, was charged on all packets up to 1 lb. in weight, the packets being insured up to £10. Some hundreds of receiving offices were opened, from which an hourly collection was made, the letters being brought into 6 central offices, where they were sorted and date-stamped, and sent out for delivery. There were 4 to 8 deliveries a day in the greater part of London and 10 or 12 in the business centres. The area covered by this service extended from Hackney to Lambeth and from Blackwall to Westminster; and there was also a daily delivery, for which an additional 1d. was charged, to places 10 or 15 miles from London. The staff employed in London by Dockwra considerably exceeded that employed by the post office in the whole kingdom. This truly remarkable enterprise gave London a postal service which in some respects has never been equalled before or since.

For some time Dockwra struggled with serious financial difficulties; but no sooner had the penny post begun to show a profit than the duke of York, on whom the Post Office revenues were settled, asserted his monopoly. Dockwra was condemned to pay damages and his undertaking was incorporated in the General Post Office; but the London penny post long survived its creator and was maintained until 1801.

The First Postmaster General.—The act of 1657, to which reference has already been made, was the first comprehensive attempt to regulate the postal service by statute. It established a government monopoly, provided for the post of postmaster general, regulated the treatment of letters brought by private ship and prescribed the rates of postage, both inland and foreign. The act was renewed with practically no alteration, immediately after the Restoration. The inland rates were somewhat lower than those charged by Witherings, the maximum rate being 6d. for a single letter to or from Ireland.

Another Post Office Act was passed in 1711, uniting the post offices of England and Scotland, which had been separated in 1695, regulating the postal service in New York, the West Indies and the other American colonies, prohibiting post office officials from taking part in politics and lastly increasing substantially the rates of postage in order to provide for the expenses of the war with France.

The development of the posts since the reforms of Witherings had now raised a difficult administrative problem, viz., that of the "cross-posts," or letters exchanged between one town and another without passing through London. As all accounting arrangements were centralised in the capital, there was here room for a serious leakage of revenue, and adequate control of the cross-posts was becoming essential. At this juncture another reformer appeared in the person of Ralph Allen, postmaster of Bath. Allen, who had been in the postal service since his boyhood, had acquired an extraordinarily detailed knowledge of the working of the mail services in all parts of the country, and was convinced that with proper management the cross-posts could be turned into a source of revenue. In 1719 he offered to farm them for £6,000 a year, or 50% more than the net receipts at that time, and in 1721 this offer was accepted for a term of seven years. Allen's farm was after a short time a great success and the contract was renewed, at a constantly increasing rent, until his death in 1769. The secret of his success was his intimate knowledge of the roads and the post towns, the introduction of a simple system of accounting, and constant scrutiny of postmasters' accounts and inspection of their proceedings. In the 48 years for which he successfully managed this department of the post office, Allen not only built up a system far in advance of that to which he succeeded, but showed clearly the financial possibilities of improved communication, since he not only increased fivefold the revenue of the post office from the cross-posts, but accumulated a considerable fortune, which is said to have amounted to £500,000, for himself. The net revenue of the post office increased from £96,000 in 1724 to £165,000 in 1769.

The later years of the 18th century were marked by a great development of the main roads and a consequent improvement in speed of communication. Regular stage-coach services began to be established; but for some time the post office persisted in despatching its mails by the postboys of the earlier period. The result was that the coaches, travelling at double the speed of the postboys, were largely used for the illegal transmission of private letters, and the post office revenue suffered correspondingly. The establishment of the mail coach service was due to John Palmer, a theatre proprietor of Bath, who devised a scheme for organizing coaches running on regular schedules on the main roads and thus giving to letters the same speedy transmission which was available for passengers and parcels. The coaches were all to leave London at the same time—8 P.M.—and to return together as far as possible. The security of the mails was to be provided for by armed guards.

First Mail Coach, 1784.—Palmer succeeded in bringing this project under the personal notice of Pitt, who saw its merits and ordered its adoption. The first mail coach was established between

London and Bath in 1784; and within two years coaches were running to Norwich, Nottingham, Liverpool, Manchester, Leeds, Milford, Holyhead, Exeter and many other places. By 1797 there were 42 mail coach routes in operation; and Palmer's prediction that they would cost no more than the postboys was borne out by the fact that after some years their cost was only one half that of the system they superseded. The time taken from London to Holyhead was 27 hours, to Edinburgh 43 hours, to Falmouth 29 hours and so on, The development of the post was, however, severely hampered by the necessity of obtaining revenue to finance the war with France, and the rates of postage were periodically increased until in 1812 they attained the highest point they had ever reached, and at which they remained until the reforms of Rowland Hill. The charge for a single letter for a distance of 15 miles was 4d.; the graduation of the scale of distances was very steep and reached a maximum of 17d. for a distance of 700 miles. Whatever may be thought of the policy of extracting revenue from a tax on communications, it cannot be denied that it was extremely efficient up to a point, as by 1815 the post office was yielding a net revenue of £1,500,000 a year or nearly three times its total expenditure.

It is surprising that rates so high could have been retained for 25 years after Waterloo, and when Rowland Hill published his pamphlet on postage in 1836 he had behind him a substantial volume of public discontent. His main argument for reform was that in spite of the growth of trade and population the postal revenue had remained stationary for a long period, while revenue from other sources had been steadily increasing. Hill argued from this that the postal administration was conducted on principles which were in effect an obstacle to the development of postal business. The principal features of the scheme put forward were the abolition of the method of charging postage on the basis of distance—Hill arguing with great cogency, on the basis of such statistics as were available, that the actual cost of carriage varied within such extremely small limits that differences due to distance could be ignored; the abolition of the old method of charging one sheet of paper as a single letter, two sheets as a double letter, and so on, and the substitution of rates based simply on weight; the prepayment of letters by postage stamps; and the adoption of a uniform minimum rate of 1d.

Rowland Hill's Success, 1840.—So drastic a change of policy was not to be carried without a struggle; and it was only after four years of agitation and parliamentary enquiry that penny postage was finally established in 1840. This was the most signal service Great Britain has rendered to the cause of postal progress, and from the point of view of developing social relations and business communications it was an unqualified success, and established a standard to which it became the ambition of the rest of the world to attain.

This success, however, had to be paid for in another direction. Cheap postage rates are not in themselves the gold mine that certain of their enthusiastic supporters appear to imagine; and it is significant to note that the post office revenue, which in 1839 was over £1,600,000, dropped to £500,000 in the following year. It was not until 35 years after the introduction of Rowland Hill's reform, and until there had been an increase of a thousand per cent in the number of letters delivered, that the revenue again reached the level at which it had stood in 1839.

THE BRITISH POST OFFICE IN MODERN TIMES

For some years after the introduction of penny postage the post office prudently abstained from introducing any more far-reaching reforms and devoted itself to developing its existing services. The effect of the new rate on the volume of correspondence was immediate and continuous; and its effect was of course emphasized by the economic development of the country during the following years. In 1840 the number of letters posted was 169,000,000, or more than double that posted in the previous year. In ten years it had quadrupled, and by 1870 had reached the total of nearly 800,000,000, or about ten times the figure of 1839. Although other and cheaper postage rates were introduced after 1870 the 1d. letter continued to reflect the growing prosperity of the country and also the spread of education, and in spite of the check to development imposed by the war and the subsequent industrial depression it stood in 1928 at the total of 3,000,000,000 a year.

A lower initial rate was of course impracticable; and the only concessions which could be made to the public were increases in the initial weight and concessions in the rates charged on the heavier packets. The initial weight remained unchanged at the ½ oz., adopted by Rowland Hill, for over 30 years; it, was raised in 1871 to 1 oz., at which it remained until the Jubilee Reform of 1897, when the weight carried for 1d. was raised to 4 oz., the highest limit it had reached since the days of Dockwra's reform of 1680. The concessions on the heavier letters were of much less importance; various adjustments were made in 1865, 1871, 1885 and finally in 1897, when the postage on all weights above the initial 1d. was fixed at ½d. per 2 oz., the letter post rate for heavier packets being thus reduced to the low rate of 4d. a lb.

The war, among its other retrogressive results, brought about the abolition of penny postage 78 years after its first establishment. In 1918 the Government reluctantly decided to raise the letter rate to 1½d., and in view of the continued advance in working costs it was again raised in 1920 to 2d. As soon as the peak period of prices was passed the rate was again reduced to 1½d., at which it still stood at the beginning of 1929. The re-establishment of penny postage is a step which receives the careful consideration of successive governments. The argument in its favour is that it would give a much needed stimulus to trade and would extend still further private correspondence; the counter argument is that 1d. postage under present conditions would be considerably cheaper by comparison with the general level of prices than 1d. postage before the war, and that the cost of the concession would be extremely heavy, as the postmaster general estimates that even after making full allowance for the probable growth of traffic, the loss to the post office revenue would be £5,500,000 a year. The post office surplus is a considerable item in the budget; and it is for the chancellor of the exchequer to decide whether any reduction of revenue which can be contemplated should take the form of a reduction in postage rates or of some other concession to the taxpayer.

Newspapers.—For a long period, and even for some time after the establishment of penny postage, the post carried only two kinds of correspondence—letters and newspapers. The newspaper post had a varied and anomalous history. In 1840 newspapers were by statute carried free of postage. This, however, was not equivalent to the free postage which has been given on a more or less extended scale in other countries, as from the time of Queen Anne all newspapers had contributed to the revenue by the stamp duty which was levied on every copy. This state of things continued until 1855 when the duty was made optional, the privilege of free postage being continued to such newspapers and even to such periodicals as chose to pay it. Unstamped papers were forwarded by book post (*see* below). In 1870 the position was altered by act of parliament, which established a rate of ½d. for each newspaper irrespective of weight, the privilege being confined to papers published at intervals of not more than 7 days and complying with certain specified conditions. The rate, like others, was raised after the war and has not yet been reduced. The principle of a flat rate irrespective of weight has been abandoned, and the initial rate of 1d. covers only a weight of *6 oz.*

It is noteworthy that the post has never played the same part in the distribution of newspapers in England as it has in most other countries, as private distributors by concentrating on this one class of business and profiting by specially low rates of conveyance, etc., can carry it on more economically than a Government department. Incidentally the postal budget has been spared the heavy losses entailed on the revenues of so many foreign post offices by the low and unremunerative charges at which newspapers are still conveyed. The United States post office in particular has for years been endeavouring to raise its very low rates, under which it is difficult for the postal revenue to avoid showing a serious working loss, to a level more commensurate with its costs, but hitherto with only partial success. Before the war some 200,000,000 newspapers annually were delivered in Great Britain through the post, a large part of these of course being for places to which distribution by other means was impossible; at the present time the number is about 165,000,000.

Book Post.—The first special rate of postage introduced after 1840 was the book post, instituted in 1848. This was intended to benefit education and literature and was fixed at 6d. a lb. Various reductions were made in the scale until in 1870 it was reduced to ½d. per 2 oz., at which after a temporary increase in the post-war period it still remains. This post, owing to successive enlargements in the definition of articles admissible at the low rate, now comprises practically all kinds of commercial documents wholly or partly printed. It is not remunerative but is naturally extremely popular. Before the war the annual number was about 1,100,000,000. The increase to 1d. seriously checked the use made of it, but by 1928 it had recovered its popularity and was used to the extent of about 1,750,000,000 packets a year.

Postcards.—The next reform was not of British growth. The Austrian post office introduced the inland postcard in 1869; it won immediate success, and was adopted in England in 1870, the rate being fixed at ½d. For many years only official postcards were allowed; but the admission of private cards paid at the postcard rate, first allowed in 1894, was the origin of that notable development, the picture postcard, the numbers of which, though checked by the raising of the rate to 1d. (at which it still remains) in 1918, still represent, particularly at holiday resorts, a formidable addition to the work of the post office. In 1871 the number of postcards passing through the post was 75,000,000; in 1928 it was approximately 470,000,000.

Sample Post.—Only one of the experiments in postage rates carried out under the Rowland Hill regime has failed to establish itself permanently in the modern inland service. This is the sample post, established in 1863, with the idea of allowing a special rate to bona fide trade patterns and samples. The rate charged at the outset was 3d. for 4 oz., rising to 1s. 6d. for 24 oz., the maximum weight permitted; but after successive reductions it was brought down in 1870 to the book post rate of ½d. per 2 oz. The rule that the sample post should be restricted to bona fide samples was found in practice to be extremely difficult to enforce; and constant difficulties were experienced in securing strict application of the regulations, which was necessary to prevent the post going beyond its recognized objects and being transformed into a post for small parcels of every kind. The sample post was therefore abolished in 1871, the letter post rates being adjusted at the same time so as to reduce the postage on light packets. The sample post was, however, again revived in 1887, but gave rise to the same difficulties as before; and it was again merged in the letter post under the reduced rates conceded in 1897. Finally it had a further temporary lease of life during the war, following on the increase in the letter post rates, and was abolished for the third time in 1918. Although the sample post still survives in the international post under the terms of the Postal Union Convention it is even there a constant source of difficulties; and its history is an example of the unsoundness of the practice of making postage rates rest not on such simple and indisputable principles as weight or, in certain cases, character of contents, but on the elusive and unsatisfactory basis of the motive with which the packets are sent.

The parcel post, established in 1883, is referred to in detail later.

Registration.—The system of granting compensation for the loss of a packet in the post was a feature of the original London penny post of 1680; but the present system of registration is a comparatively modern development. A parliamentary commission in 1838 recommended a uniform system of registration at a charge of ad., liability being accepted up to £5. The reform of postage rates, however, caused the postponement of the scheme and it was not until 1841 that a general registration system came into being, and then only in an attenuated form, a fee of 1s. being charged and no responsibility being accepted in the event of loss. The service was not attractive, and little traffic was obtained; but though the fee was reduced, it was not until 1878 that the principle of compensation was adopted. The amount was originally fixed at £2, but was gradually increased, by a combination of registration with insurance and the introduction of a graduated scale of fees, until in 1906 the present system was introduced under which the minimum fee (now 3d. as compared with the pre-war 2d.) covers compensation up to £5, and the maximum fee £400. The service is very popular, some 57,000,000 registered letters and parcels being sent annually; and the percentage of losses on this total is infinitesimal.

The statistics of the growth of post office business are of considerable interest as an indication of the expansion of trade, the spread of education, and of course of the extension of postal facilities. The following table gives for each decade since the establishment of penny postage the total number of packets of all kinds sent by post and the number per head of the population.

Date	No. of postal packets of all kinds	Increase per cent	No. per head of the population
1839	82,000,000	..	3·1
1840	169,000,000	106	6·4
1850	327,000,000	93·5	13·2
1860	646,000,000	94·5	22·2
1870	877,000,000	35·7	28
1880	1,662,000,000	89·5	47·5
1890	2,620,000,000	57·6	69.4
1900	3,723,000,000	42·1	89·7
1910	5,281,000,000	41·8	116·7
1920	5,716,000,000	8·2	127
1926	*6,204,000,000	8·5	138

*Excluding the Irish Free State.

THE BRITISH RAILWAY MAIL SERVICE

Letter Mails.—The first regular railway service to be established was that between Manchester and Liverpool in 1830, and it was not long before it was recognized that this new means of locomotion would bring with it a revolution in the old methods of the conveyance of the mails. The post office authorities were not slow to recognize the necessity of obtaining adequate powers to secure the running of an efficient mail service, and the first Conveyance of Mails Act was passed in 1838. Under this act, the provisions of which still govern in essentials the relations between the post office and the railway companies, the postmaster general was given powers to call on the railway companies to convey his mails and guards in all trains, whether ordinary or special, and to provide if required the use of a whole carriage for the purpose of sorting letters. The only financial provision in the act was that the railway companies should receive "reasonable remuneration" for their services, any negotiations which could not be settled amicably being referred to arbitration.

Even at this early stage it was seen that the value of the railways lay not only in their superior speed but in the facilities they afforded for doing in a swiftly moving railway carriage the work of sorting letters which would otherwise fall on a stationary office, and so of securing a very considerable advantage in time of delivery. The first travelling post office was established between Birmingham and Liverpool in 1838. It was 16′ in length, 7′ 6″ in width, and the Railway Company protested that the running of so large and broad a vehicle would, owing to its wind resistance, delay their trains. Later in the same year another travelling post office was established between London and Preston, leaving Euston station at 8.30 P.M., a time which after 90 years is still maintained. The speeds on the earlier railways were comparatively slow. The journey from London to Birmingham occupied 5½ hours, and from London to Manchester or Liverpool 9½. These times were, however, less than half those occupied by the stage coaches, and the extension of the railways gradually drove the whole of the mail coaches off the road. The process was not a very rapid one as the last coach was not withdrawn until 1847. In spite, however, of the great improvements which they offered in the mail service the railways entailed a much heavier cost on the post office than their predecessors, and for some years after their establishment there was a constant series of disputes and difficulties between the companies and the post office on the question of payment.

At the outset the mails when not carried in a travelling post office were despatched by train exactly in the same way as by stage coach, that is, in charge of a post office guard. The system worked satisfactorily enough for the small mails of the 'thirties; but the great growth in the number of letters, which followed the introduction of penny postage soon made this method of transmission inconvenient and unnecessarily costly, and in 1848 statutory powers were obtained, under which the railway companies were obliged to convey mails by train in charge of their own guards, which is still the normal method of transmission for the great bulk of the mails sent by railway. During the next 50 or 60 years the post office was occupied in making the best use possible of the extension of the railway systems, and of the increase in the speed and the frequency of their trains, the results appearing in a constant improvement in the rapidity of postal communications and in the number of despatches and deliveries. On the financial side the great increase in the volume of the mails was, as was only natural, reflected in a gradual reduction in the relative cost of conveyance. In 1850 the annual payment to the railway companies was approximately £230,000; in 1928 it was approximately £2,000,000; but great as this increase is it is very considerably less than the increase in the same period in the number of letters handled by the post office.

Far reaching as are the statutory powers of the postmaster general with regard to the railways, in practice they are never invoked, and the details of the postal service are settled by contracts negotiated with the various railway companies. Under existing legislation any difference in regard to remuneration which cannot be settled amicably can be referred to the Railway and Canal Commissioners, but this power has not been exercised for many years. The main requirement of the post office in the contract is the running of trains at times convenient to the mail service, which cannot be altered without the consent of the postmaster general. Although separate contracts must be made with the individual companies the railway services are naturally correlated for the country as a whole, and Great Britain is now covered by an intricate network of mail trains providing complete and direct communication between the different systems, and between all parts of the country, the speed of which is equal to, or in some cases, better than that of the best passenger trains. On the west coast line to Scotland, on which, as above mentioned, the first travelling post office was established 90 years ago, there is now a special train devoted entirely to the post office, running nightly in each direction between London and Edinburgh, Glasgow and Aberdeen. This is the trunk main line mail service of Great Britain and as many as 50 post office employees are engaged in each train. A similar special train runs in each direction between London and Penzance. In all other cases the mail trains convey passengers as well as mails.

A special feature of the English mail train service is what is known as the mail bag apparatus, an efficient mechanical contrivance by which mail bags can be despatched from and received in travelling post offices while the train is travelling at full speed. This enables an extremely good service to be afforded to all places along the main lines of railway, and in sparsely populated districts, such as in the north of Scotland and parts of Wales it enables the post office to deliver correspondence at least a day earlier than would be possible by any other means.

The Parcel Post.—An international parcel post was established at the Postal Union Congress in Paris in 1878. Great Britain at that time had no such service, but the question of establishing one was immediately put in hand, and after prolonged negotiations with the railway companies the Post Office Parcels Act of 1882 was passed, establishing an inland parcel service which came into operation in the following year. The maximum weight of parcels was fixed at 7 lb., with a scale of postage varying from 3d. to 1s., according to weight. No individual contracts were made with the separate railway companies, but the post office paid to the Railway Clearing House 55% of the postage received on all parcels conveyed by railway, the distribution of the sums thus received among the railway companies being undertaken by the clearing house. This arrangement enabled the post office to maintain the principle of a flat rate of postage for the whole country in contradistinction to the railway companies' parcel tariffs which were based on zones of distance.

It soon became evident, however, that for short distances it was possible to convey parcels by road at a considerably lower cost than the payment to the railway companies provided under the act, and very shortly after the establishment of the parcel post parcel coaches were established by the post office. These road services took on a new development with the coming of the internal combustion engine. The higher speed and greater capacity of the motor van made a large extension of the coach system practicable, and at the outbreak of the World War it had reached very considerable dimensions, parcels being carried by road during the night between large towns up to a distance of 120 miles. After the war, however, fresh negotiations were entered into with the railway companies, and by the Post Office Parcels Act of 1922 it was enacted that the percentage of the postage payable to the railway companies should be reduced from 55% to 40%, the post office on its part agreeing that the railway companies should be entitled to claim a revision of their remuneration if the number of parcels conveyed otherwise than by railway exceeded 10% of the total number transmitted by post.

Since the establishment of the service, the maximum weight has been raised from 7 to 11 lb., and the postage rates have been varied from time to time. The minimum rate is now 6d. for a parcel not exceeding 2 lb., and the maximum 1s. 3d. for a parcel of 11 lb. The number of parcels posted annually is approximately 140,000,000, and the payment to the Railway Companies over £2,000,000 per annum.

The total earnings of the railway companies for letters and parcels are thus over £4,000,000 a year, and the post office is by far their greatest single customer, contributing no less than 2% of their total revenue.

The latest development of co-operation between the post office and the railways is the extension of the cash-on-delivery service to cover consignments despatched by railway as well as by post. The sender of the goods forwards to the consignee as a cash-on-delivery letter a document which entitles him to take delivery of a consignment despatched by railway. The sender's charges are paid by the consignee on receipt of the cash-on-delivery letter, the money is forwarded at once to the sender by the post office, and the consignee presents his document and receives the goods from the company.

THE BRITISH MAIL PACKET SERVICE

The first regular Government mail packet service was established by Queen Elizabeth in 1598 between Holyhead and Dublin. At that period, however, foreign communications were of greater postal importance than those with Ireland, and when James I. reaffirmed the post office monopoly in the case of foreign letters and appointed a postmaster for foreign parts, it clearly became incumbent on the post office to provide a regular means of communication with foreign countries. Witherings, who subsequently reformed the inland post, began his career by establishing efficient and regular communication with France by means of hired boatmen engaged to carry the mail between Dover and Calais. For the next 50 years the service appears to have been somewhat unsatisfactory and development slow; but in 1686 a regular service was established by Government packet between Harwich and Holland, which was followed in 1688 by a service from Falmouth to Corunna, and in 1703 by a weekly service from Falmouth to Lisbon. The growth of the British oversea possessions in the 18th century led to further developments. After an unsuccessful attempt at the beginning of the century, regular packets were put on from Falmouth to the West Indies in 1745; packets also ran to North America; and by the end of the 18th century they served a great part of the world.

Efficient as the packet service was in many respects, its history, which is known in considerable detail, is a curious commentary on 18th century administration. The packets themselves were small, being only 70 tons on the shorter services and on the ocean routes 150—vessels of the latter tonnage being, according to a report of 1788, considered fit to go to any part of the world. The crews, at any rate in peace time, were small, and the pay very low. The commander of a Falmouth packet in 1797 received the sum of 30s. a week in peace time, and £2 in time of war; the boatswain drew 7s. 6d. a week and the able seaman 7s. There was naturally every temptation to increase their incomes by such means as presented themselves, the favourite one being smuggling and, in war time, the capture of enemy ships when opportunity offered. The first practice led naturally to a good deal of trouble with the customs, in which the postmasters general supported their captains; the latter was often inevitable and was the well earned reward of a hard fight against heavy odds; occasionally it was hardly distinguishable from piracy. The management of the service, however, is a sordid history of corruption and maladministration. The cost went up rapidly towards the end of the century. The agents at the ports abused their powers by supplying defective stores, or claiming payment for provisions never supplied; by drawing the wages of non-existent hands, or the pensions of sailors long dead; by selling passes and pocketing the proceeds, and the like. Finally in 1787 the scandal became so intolerable that a parliamentary enquiry was instituted, at which it was discovered that the post office itself was also implicated, the secretary to the post office being not only a large owner of the boats (which were in many cases hired, not owned, by the Government), but also drawing $2\frac{1}{2}$ per cent on the total expenditure on packet services—a privilege which brought him altogether some £50,000.

The next important event in the history of the packets was the introduction of the steamship. Steamship communication with Ireland was established in 1816, and in 1821 a mail packet of 205 tons burden was put on this service, being followed in the next year by a steamship on the Dover–Calais route. It soon became evident, however, that mails could be carried more advantageously by private companies than by the government, and in 1831 the principle of inviting tenders for the mail service from private companies was introduced. In 1837 the Admiralty decided that the post office packets ought to be considered as forming a naval reserve of both ships and men and succeeded in having the management transferred from the post office to themselves. It was an inopportune moment, however, as the system of state-owned packets was already moribund, and being gradually displaced by the employment of private ships under contract. The Admiralty, however, retained the control of packet services for over 20 years and it was not till 1860 that it was retransferred to the post office.

In the earlier part of this period the Government definitely adopted the policy of subsidising steamship companies in order to establish regular communication on routes where ordinary traffic would not have justified the requisite expenditure, and to ensure the provision of a better type of vessel than would otherwise have been forthcoming. The first contract was made with Samuel Cunard in 1839 for a subsidy of £60,000 a year and was speedily followed by others. The subsidy policy, however, proved in practice very costly, the expenditure having by 1853, when it became the subject of a parliamentary enquiry, reached the very considerable sum of £853,000. Since that time the principle of the subsidy has gradually disappeared; its object had been fulfilled by the establishment of such far-reaching mail services as those of the Peninsular and Oriental Company, the Royal Mail Steam Packet Company and Messrs. Cunard. For the last 60 years the size and speed of mail ships has steadily increased, and the cost of the carriage of the mails diminished. At the present time even the practice of concluding regular contracts for the overseas mail service is becoming less and less frequent. The only contracts in force in 1928 were those with the White Star and Cunard companies for the Atlantic service, and with the Peninsular and Oriental Company for the service to India, Australia and the Far East. For all other destinations mails are carried by vessels running to ordinary commercial schedules, which are now so regular as to afford as satisfactory a mail service as that for which large subsidies were necessary at an earlier stage. At the time of writing (1928) the whole expenditure on the overseas packet services is £746,000.

The use of non-contract ships for providing the mail service is, however, only a return to an earlier epoch in the history of the overseas mail service. The Government packets in the 17th and 18th centuries were far from covering the whole field; for example Africa and Asia were never touched by them, and for correspondence to and from a great part of the world the only means of transport was the private ship. The post office for a long period made only a feeble attempt to secure control of this means of communication. It is true that as early as 1660 it was provided that letters brought by private ships should be handed over to the post office, and in 1711 it was enacted that fees should be paid to the captains for all letters handed over; but during the whole of the 18th century letters were accepted for private conveyance without regard to the technical monopoly of the post office, and shipowners and the proprietors of coffee-houses openly kept bags for the acceptance of letters for abroad. The post office attempted in 1799 to incorporate the ship letter system into the ordinary postal service and to insist that all letters for private ships should pass through the post office, suitable gratuities being paid to the master for their conveyance. But the measures taken were not effective, and as late as 1827 certain coffee-houses were still collecting letters in defiance of the law.

The general improvement in the postal service, and in particular the effective measures taken to establish regular mail services by private ships whenever such a course was advantageous, gradually abolished the incentive to forward letters by other means than by the post office; but by an odd survival of old practice the law still expressly permits any person to send his letters by private ship without thereby infringing the monopoly of the postmaster general.

AIR MAILS

The history of air mails in Great Britain begins in 1911, when to celebrate the coronation of King George V. an air mail service was run between Hendon and Windsor. Twenty-one trips were performed and a considerable number of picture postcards, etc., carried; but the service was very irregular and did not hold out much promise of the development which came a few years later.

The enormous development of aviation during the war inevitably caused the question of air mails to come up again for serious consideration. After the armistice an experimental service which was run between Folkestone and Cologne for the benefit of the Army of Occupation clearly demonstrated the possibilities of this means of transport; and after some negotiation between the French and British post offices a regular service between London and Paris was established in Nov. 1919. The time-table was so arranged as to admit of a letter posted in London in the morning being delivered in the afternoon in Paris, and vice versa. The letters were considered as being more analogous to telegrams than to letters, and a fee of 2s.6d. per oz. was charged in addition to the postage. Little traffic, however, was attracted; and in a few months the fee was reduced to 2d. per oz., which of course sent up materially the volume of the air mail. The establishment of *a* service to Paris was followed in 1920 by the establishment of air mails to Brussels and to Amsterdam, and in 1922 by the setting up of an air parcel post between London and Paris.

The next few years were remarkable for a considerable extension of air services all over Europe, and also in Asia and America. The most extensive service now in operation is that run by the United States post office. Starting from modest beginnings it has developed until it now includes a Government-operated trans-continental service, running continuously night and day, between New York and San Francisco, and a considerable number of other services in various parts of the country which are run under contract with the post office. The installation for the trans-continental service, with its system of continuous beacons and landing grounds, is the most complete in the world, and the service is in other respects in a unique position, as climatic conditions are unusually favourable, and the districts linked up by air are wealthy and populous. From the point of view of traffic this is the most successful air service in the world.

In 1921 an Air Mail Service was established between Egypt and 'Iraq by means of regular service flights undertaken by machines of the Royal Air Force, but in 1927 ~~ transferred to Imperial Airways. The saving of time effected was very great, as the short transit of 850 miles across the Desert cut out the long sea journey from Egypt to Bombay and from Bombay to the Persian Gulf. In March 1929, however, this service was superseded by a through Air Mail between London and Karachi by way of Italy, Greece, Egypt and 'Iraq. This is the longest regular through Air Service in existence, and the time occupied from London to Karachi is 7½ days as compared with 14½ by ordinary mail from London to Bombay. The London-Karachi service will in the immediate future be extended by the creation of air services in and across India under the auspices of the Indian Government. Another recent development of considerable postal value is the French service to Brazil and the Argentine via Morocco and Dakar.

The experience of air mail services since 1919 has been sufficient to enable certain definite conclusions to be drawn. In the first place, for short distances, such as London–Paris or London–Amsterdam, the existing means of communication are so good that the amount of traffic attracted to an air mail is and must remain exceedingly small. When, however, the services cover greater distances and the high speed of the aeroplane can thus offer a definite and tangible advantage, the possibilities of attracting traffic are considerably greater; if and when the difficulties of night flying are successfully overcome, and it is possible for letters posted in the evening in London to be delivered next morning in Berlin, Vienna, Milan, Berne, or Copenhagen, the European air mail will offer advantages which it will be impossible to ignore. In the second place, the air mail will, so far as can be foreseen, remain definitely as a luxury service. The capacity of aeroplanes, and even of the largest airship at present in contemplation, is only adequate to convey a fraction of the mails available; and the cost of air transport is very substantially in excess of that of transit by railway and steamship.

The importance of air mails from the international standpoint was recognized at an early stage by the postal administrations of the world, and provision was made to include them in the general Postal Convention signed at Madrid in 1920. The relative provisions were amplified at the later congress of Stockholm in 1924; but their rapid development has resulted in the calling of a special International Air Mail Conference in 1927, at which a definite code of regulations to be applied between the signatories was devised as a preliminary step to an expansion of the provisions of the Postal Convention. Considerable progress was made in the direction of standardizing rates of air postage, and of unifying practice generally. It is worthy of remark that in accordance with postal tradition, complete liberty of transit is established for air mails; *i.e.*, every country which establishes an air mail gives to every other country the fullest facilities for despatching its own mails by it, on the payment of certain definite and uniform charges. The result is that the latest developments in aviation are placed at the disposal of the public of all countries, and new air lines, wherever established, are available without restriction for the development of international communication.

THE BRITISH POST OFFICE AS BANKER

Savings Bank.—The idea of establishing a savings bank for the benefit of those who were not in a position to use the ordinary banking system, and of administering it through the post office, appears to have originated with Whitbread in 1807; but the project came to nothing, and was dormant for half a century until it was successfully revived by Sykes of Huddersfield, whose efforts were supported by W. E. Gladstone, then chancellor of the exchequer, and by Sir Rowland Hill. The necessary legislation was passed in 1861 and the Post Office Savings Bank came into existence in the same year. The object was to encourage thrift among the poorer classes, and deposits were therefore limited to £30 in one year or £150 in all. Deposits were handed over to the National Debt Commissioners and interest was allowed on complete pounds at the rate of £2.10s.od. per cent. All accounting was centralized in London; but any depositor might pay in or withdraw money at any office in the country at which savings bank business was transacted. To make a withdrawal, notice had to be sent to headquarters and an authority to pay was issued to the office named by the depositor.

The main outlines of the system have not been changed; but a number of detailed improvements, in the interest of depositors, have been made from time to time. In particular, the limits of deposits have gradually been raised, and £500 may now be deposited in one year, while the maximum limit has been entirely abolished. In cases of urgency money may be withdrawn at once by telegram; while any sum up to £2 may be withdrawn on demand at any office, nearly half the total number of withdrawals being effected by the latter method. The saving of small sums is encouraged by the use of "home safes," by slips to which postage stamps may be affixed, etc. The establishment of the savings bank was an immediate success, and its growth in popularity has been a proof of the foresight of its founders. In the years 1863–1868 the average number of accounts was 663,000 and the total of deposits £7,000,000; the number of savings bank offices was 3,390. In 1927 the number of accounts was over 12,000,000—one to every fourth person of the whole population—and the amount standing to the credit of depositors £283,000,000. The number of savings bank offices exceeds 14,000.

Two years after the establishment of the post office savings bank the Government passed a further act establishing a life insurance and annuity system to be run by the post office. At that time certain private insurance companies were in a doubtful financial position, and it was anticipated that a Government scheme would have a wide appeal. Though remodelled 20 years after its establishment and linked up with the machinery of the savings bank, annuity and insurance business has never exceeded a very modest total, in spite of frequent attempts to popularize it by advertisements and other propaganda. The canvassing and the direct collection of premiums which are an essential part of the procedure of the private insurance company have never been considered suitable for adoption by the State; and the doubts as to the stability of the private companies which prompted the establishment of the Government scheme have long disappeared.

A much more successful development was instituted in 1880 when facilities were given to depositors in the savings bank to purchase Government stock, up to a limit of £300. A very simple method of purchase was devised, at a low rate of commission, and dividends were credited to the purchaser's savings bank account as they fell due. In 1914 stock of the nominal value of £26,000,000 stood to the credit of post office depositors; and the machinery thus ready to hand proved of the greatest value to the Government in their appeal to all classes of the population to finance the war. In 1915, when the 4½% war loan was issued, a special post office register, managed by the post office savings bank, was formed and in subsequent loans the same procedure was followed. The post office investor now has his choice of some twenty different Government securities, and dividends are no longer restricted to payments into a savings bank account, but can be paid in cash or through a bank at the investor's option. The number of investors on the post office registers is now about 2,500,000, the nominal value of the stocks held is £190,000,000, and the annual interest payments amount to over £7,700,000.

A further simple and popular method of investment offered by the post office is the National Savings Certificate (originally known as the War Savings Certificate). This was a further outcome of the war effort to attract the savings of all classes and has successfully maintained itself since the war. The nominal value of a certificate is £1, or certain multiples of £1; the purchase price, however, is considerably less, and though there is no separate payment of interest the certificate increases in value annually up to the maximum and is repayable at any time with accumulated interest. As the interest is free from income tax it is necessary to impose a certain restriction on the issue, and the number of certificates which may be purchased by any individual is limited to 500. The terms of issue have varied from time to time, and become gradually more favourable to the exchequer; at the present time (1928) the purchase price of the £1 certificate is 16s., and the maximum value, £1. 4s., is reached in 10 years. Owing mainly to the activities of the National Savings Committee and the local Savings Associations, the investments in Savings Certificates have been on a far larger scale than those in the post office issues of war loan. In the first ten years over £598,000,000 was invested, the nominal value thus represented being nearly £766,000,000, of which £372,000,000 still remains invested. The number of investors is about eight millions, or three times the number of stockholders in the savings bank.

Money Orders.—The original establishment of the money order service was due to the desire of the postmasters general at the end of the 18th century to devise some method of preventing the frequent theft of money letters in the post. There was some doubt whether such a service could be established by the post office under its existing powers, so by a curious compromise certain officers of the London post office were allowed to set up a service on their own account, the cost of advertising it being borne by the postmaster general, who also allowed the relative advices to pass free of postage under the post office frank. The maximum value of a single order was fixed at five guineas and the commission at 6d., subsequently raised to 8d., in the pound. As the letter containing the order was a "double" letter under the regulations and thus liable to double postage the money order service was by no means cheap and the amount of business was at first not considerable. After being carried on as a private venture, with varying degrees of profit and loss to its managers, for nearly 50 years, and after being definitely condemned by a parliamentary committee, the money order service was in 1838 taken over by the Government. The rates of commission were gradually reduced, and the maximum amount of an order increased to £10. In 1871 the commission was fixed as low as 1d. on orders of 10s.; but this was unremunerative and the service began to show a substantial loss. Since 1871 a number of further modifications have been made; the maximum for a single order was raised in 1904 to f40, at which it still stands; and the raies of commission, which were raised during the war to cover increasing costs, now vary from 4d. on an order not exceeding £3 to 1s. on an order of from £30 to £40. Notwithstanding the competition of the cheaper postal order (*see* below) the money order still appeals to a large number of remitters who value the security afforded by the special feature of the money order service—the advice note which is sent to the office of payment and against which the order is checked before payment. In the year 1926–27 the number of inland money orders was 12,000,000, and the total amount remitted £71,000,000. The telegraph money order service, under which remittances may be telegraphed to any telegraph office at which money order business is transacted, on payment of the telegraph charges and a special fee, came into operation in 1889. The service is utilized to a considerable extent, as in the years 1926–27 785,000 telegraph money orders were sent to a total value of £4,000,000.

The foreign money order service, though advocated by Rowland Hill in 1843, only came into being in 1856, when arrangements were made to send home money from the British army in the East by means of money orders issued by the army post office. The system was extended the same year to Malta and Gibraltar, and in 1859 to Canada. Two years later it was decided to include all the 'colonies and by degrees the service came to include every foreign country of importance. At the present time there is practically no part of the world, in which an inland money order service is in operation, to which money cannot be remitted, either directly or indirectly, through the post office. The telegraph money order in the international service dates only from 1898 and it is not yet universal.

The financial chaos which followed the war and the rapid fluctuations of currencies led to considerable difficulties in maintaining a money order service with foreign countries and in many cases it was necessary to suspend it temporarily. The gradua! stabilization of the last few years has, however, generally permitted of its resumption and the extent of the service is now practically the same as it was before the war. The most recent statistics show that the annual number of imperial and foreign money orders is 2,880,000, representing about £9,500,000.

Postal Orders.—The comparatively high cost of the money order, if it was to cover its expenses, led the post office to consider the possibility of introducing a new method of remittance, which would dispense with the most costly feature of the money order service, the advice, and thus be available at a lower rate of commission and give less trouble to the remitter. The objections to the creation of what might be considered a paper currency for small amounts were for some time thought to be insurmountable; but finally in 1881 the postal order (originally styled postal note) was issued. Orders are issued for certain fixed denominations up to a maximum of 21s.; they can be made payable to a particular person and at a particular office, and can be crossed for payment through a bank. Their period of validity is limited to three months from the last day of the month of issue.

The simplicity, convenience and cheapness of the postal order made it an immediate success. In the first two years the number grew from 4,500,000 to 33,000,000, of the value of £13,500,000; and at the present time the number sold annually has reached the total of 142,000,000, representing remittances of £45,500,000.

The great convenience of the postal order led soon to a proposal to extend its use throughout the empire; and in 1903 the whole of the colonies and dependencies were invited to adhere to a scheme for making the postal order available for remittances not only to and from Great Britain, but between one part of the empire and another. The proposal was generally adopted; and with the exception of Australia, which for financial reasons has felt unable to adhere to it, and the partial exception of Canada, which pays but does not issue the orders, practically the whole British empire, comprising some 60 separate postal administrations, uses the postal order for its small remittances. The number of orders issued in the empire outside Great Britain is about 6,500,000 a year, of a total value of £3,760,000.

THE BRITISH POST OFFICE AND SOCIAL SERVICES

One of the most striking developments of post office activities in the last generation has been its gradual assumption of functions which have no connection whatever with its primary purpose, but have been imposed upon it because its far reaching organization has presented the only means of carrying out with reasonable economy certain social services which the State has from time to time established. This development began many years ago in the utilization of the post office for the collection of revenue in the form of licence duties, the proceeds of which are now handed over to local taxation. Dog, gun and game licences, for example, excise licences, and motor vehicle licences are obtainable from the post office, some £3,500,000 a year being thus collected.

This, however, was a comparatively small item of business. A more serious innovation was made when the Old Age Pensions Act of 1908 came into operation. It was necessary to devise some means by which pensioners could obtain payment of their pensions with the minimum of trouble and inconvenience to themselves and of cost to the State, and the obvious course was to fall back on the post office. The pensioner is provided with a bound book of orders, similar to postal orders, which show the date of payment and the amount of the pension; this is presented at the post office by him, or by his agent in case of illness, and the paid orders are retained by the post office as vouchers. The original act has been gradually modified, and the Widows', Orphans' and Old Age Contributory Pensions Act of 1925, which came into full operation in Jan. 1928, substantially enlarged the scope of pensions business. Nearly 2,000,000 pensioners are now included in the scheme. In addition to old age pensions, war pensions to the number of over 1,100,000 and the amount of £54,500,000 annually are paid by the post office. The machinery is generally similar to that employed for the old age pension.

The use of stamps, which was a part of Rowland Hill's scheme for cheap postage, has been extended in many ways never dreamed of when they were first introduced. Certain small inland revenue duties may be paid by postage stamps; but in addition the post office has long assisted the inland revenue authorities by selling such inland revenue and fee stamps and forms as are in general use; more recently income tax and entertainment duty stamps have been added. The great development, however, came with the establishment of State insurance schemes under the legislation of the early 20th century. The payment of contributions by means of adhesive stamps affixed to the relevant forms was an integral part of the new schemes, and the post office was again called in to help as being the only agency which could do what was required. The amounts of the weekly or quarterly contributions, however, are very varied, and the denominations of stamps required for National Health and Pensions Insurance and for Unemployment Insurance considerably exceed those required for purely postal business. The functions of the post office are, of course, limited to the sale of the stamps, etc., required under the insurance schemes; but the addition to both complexity and volume of its business has been considerable; the annual value of insurance stamps sold is nearly £70,000,000.

Of the convenience and economy of the system of carrying out schemes of social reform through the instrumentality of the post office there can be no doubt; but whether the system is capable of indefinite extension without interfering with the proper discharge of the functions for which the post office was intended may perhaps be questioned. Each addition to the complexity of the business—which has of course to be done not only at the large and specialized post offices in towns, but in the small village post office—increases the difficulty of securing a satisfactory standard of efficiency; and if the scope of social legislation develops in the next few years at the same rate as during the last ten or fifteen, questions of considerable difficulty may obviously arise.

Miscellaneous Services.—In addition to the general postal service placed at the disposal of the public a certain number of special facilities may be obtained by those who wish to have a more rapid or convenient method of delivery. The most important is the express delivery, which was established in 1891. There are several varieties of express delivery, the most useful perhaps of which is that by which a letter or packet may, at any time at which messengers are on duty, be despatched by special messenger to its destination on payment of a small mileage fee. This is the only postal service which is not limited to inanimate objects; dogs may be taken by the messenger, and any other live animal if enclosed in a suitable receptacle; and a stranger may use the express service to have himself conducted to his destination. A iurther service provides for the delivery, immediately on arrival, of letters or parcels received by the ordinary mail, at the request of the sender; and the same facility is given at the request of an addressee who is expecting an important letter. The number of express services performed is about 2,000,000 annually.

When a quicker transmission is desired than that afforded by ordinary mail, letters may be taken to any station and forwarded, on payment of a small railway fee in addition to the postage, by the next train to the place of destination and either kept at the station to be called for or posted in the nearest letter box. This may be combined with the express service in various ways; *e.g.*, a post office express messenger can be summoned to meet the train and convey the letter at once to its destination.

When a regular early delivery of correspondence is desired any firm or person may rent a private box at the post office, from which he or his messenger may obtain his letters and parcels on application. If, again, his postings are on so considerable a scale that the application of postage stamps becomes inconvenient and expensive, he may on certain conditions arrange to pay the postage in cash; and large users of the post may also have their correspondence or parcels collected from their premises by the post office.

Another method of avoiding the use of postage stamps is the employment of postal franking machines, which are now licensed by the post office. These machines impress the correspondence with a red franking stamp which is accepted as the equivalent of a postage stamp. Each machine is provided with a meter, which is set from time to time at the post office, postage being prepaid in cash on the number of impressions which the meter is set to register.

THE BRITISH ARMY POST OFFICE

The history of the British army post office goes back to the Napoleonic wars; and post office records contain a vivid account of the experiences of a postal official who was despatched in 1792 to supervise the postal arrangements for the British troops then in Holland. A post office staff was also sent out in 1854 to conduct the postal business of the troops in Turkey and the Crimea; but an army post office on modern lines was first established in the Egyptian campaign in 1882, and was continued and developed in the South African War.

In the reorganization of the army after the South African War the War Office adopted the sound principle of having a definite military unit (technically known as the Royal Engineers, postal section, special reserve) recruited entirely from the staff of the post office and destined to apply to conditions in the field the expert knowledge they possessed of postal organization. This unit is kept in constant touch with active service conditions, so far as possible, by carrying on the postal service for the troops on manoeuvres; and thus a trained force of some 300 men was at once available at the outbreak of war and was despatched with the British Expeditionary Force. The great expansion of the army however called for continuous increases in the personnel, and by the end of the war the strength overseas numbered nearly four thousand. Each new expedition took out its postal complement and the Dardanelles, Egypt and Palestine, Salonica, East Africa, Italy and North Russia were in turn provided with a complete army postal service.

At the outset all mails were sent in bulk to the overseas base post office, and there sorted for the various units in the field. This system was however soon abandoned, and the home depot of the army postal service, originally intended mainly for the provision of recruits for the overseas establishments, gradually developed into a large central sorting office for all the Expeditionary Forces. A system was built up under which the home depot made up a separate mail for every unit, down to the smallest, in all the overseas armies wherever they were stationed. Full and detailed information was received either from the War Office or from the army post offices overseas as to the location of each unit; each bag of the many thousands made up was suitably labelled with a code denoting the field or other post office to which it was to be forwarded; and the result was a service of remarkable expedition and completeness.

The volume of the mail handled by the army post office was enormous, and when it was at its maximum some 12,000,000 letters and a million parcels a week were sent out. In the later stages a substantial number of parcels for prisoners of war in Allied hands was forwarded through the home depot from Germany; and the whole of this traffic rose at Christmas to a level which it taxed the whole resources of the service, both in personnel and in transport, to handle successfully. The effect on the morale of the troops at the front of being in such close and constant communication with their families at home must be left to military historians to estimate. For the work at home it gradually became impossible to provide sufficient men, and at a fairly early stage recourse was had to the services of women, of whom about 1,200 were employed in London alone. Their work proved to be successful beyond all expectations; they combined genuine enthusiasm with remarkable aptitude for postal work.

The staff problem, however, was not the only one which the army post office had to meet. For traffic on so large a scale there was no adequate accommodation on post office premises; and a temporary building covering five acres was put up in Regent's park to house the parcel work alone. Even this proved scarcely sufficient and a system of decentralization was set up by which certain large provincial post offices acted as subsidiary army sorting offices and thereby relieved the London offices of a substantial part of the work. The organization of the postal system was carried out by the militarized personnel of the civil post office; its successful execution depended entirely on the provision of adequate transport. In this respect unstinted assistance was given by both naval and military authorities. A daily service was provided across the Channel to France; for more distant theatres ships of every kind which could convey mails carried their full complement; and on land the organization of both railway and road transport almost reached the level of an efficient postal service in times of peace.

THE INTERNATIONAL POSTAL SERVICE

The importance of the international service is evident from the earliest days of post office history; but the working of the service is somewhat obscure. In the 16th century, a regular service seems to have been provided between London and Calais, which was the port on which foreign communications mainly centred. The outward letters seem to have been carried to their destination by English post office messengers, while inward letters were brought by foreign messengers as far as Calais. Many of these couriers appear to have paid but scant attention to their duties, for early in the 17th century the delay in the arrival of important foreign mails was put down to the fact that the messengers minded "their own peddling traffic more than the service of the State or the merchants," and were often found "lying in tippling houses."

Witherings, as mentioned above, reorganized the foreign service; and shortly after his time (1670) a regular postal treaty was concluded between England and France. This was renewed in 1698 after the conclusion of the Peace of Ryswick. The treaty provided that the mail from London for Paris and from Paris for London was to leave twice a week, and was to be conveyed throughout with the utmost possible speed. Between Dover and Calais the English Post Office provided the mail packets in both directions; the service beyond Calais was provided by France. Letters could only be prepaid to a limited number of destinations — Paris, Rouen or Lyons; any charges for further transmission were collected from the addressee. In view apparently of the longer distances provided for by the French post office a fixed annual payment of 36,000 livres, to cover everything except these additional charges, was made by England.

This treaty, soon interrupted by further hostilities, was again renewed in 1713. The new version is interesting as containing the germ of the international system of accounting for transit mails which lasted with but slight alteration until the latter part of the 19th century. On letters for Italy, which could be franked to Turin, France was to be paid at the rate of 21 sols per single letter; on letters for Spain franked to Bayonne the payment was 19 sols, on letters for Turkey franked to Marseilles, 17 sols. Double letters were charged approximately twice, and letters weighing one ounce four times the single rate. The accounting between the two offices was based on the sum of the amounts due on the separate letters, mail by mail. The principles adopted in the 17th century show little change in the 18th, and a treaty concluded with France in 1802 shows comparatively little variation from its predecessors of over a century before.

As time went on the postal treaties required for the establishment of a gradually expanding foreign service became more and more numerous. The effect on the public of their varying and complicated provisions can in these days of simplicity scarcely be imagined; but until well into the second half of the 19th century they presented a bewildering complexity, which made it impossible for any one but an expert to be certain that the rate of postage to a particular destination was correct and that the postal regulations had been complied with. The postage depended on the sums payable to the various post offices concerned in the transit of the letters, and these were often based on their own internal rates and units of weight. The result was an extraordinary variety of rates — often differing materially for the same destination according to the route employed — and a considerable variety in the weight covered by the initial postage rate. Moreover, prepayment was in some cases compulsory, in some cases optional; but compulsory prepayment only covered conveyance up to a certain point, all charges beyond that point being collected from the addressee. The unit of weight was in a large number of cases $ o~., any letter above that weight being charged "pro rata." The lowest postage in force was that to France, which was 4d. per $\frac{1}{4}$ oz. A letter from England to Belgrade via France, weighing one ounce, cost 5s.; a half ounce letter to California via Panama cost 4s. 8d., in addition to a further charge on delivery. Even to Spain the postage was 2s. 2d. per half ounce plus a charge on delivery.

Articles other than letters were not encouraged. There was practically no case in which a newspaper could be prepaid to its destination; books were usually liable to the prohibitive letter rate, as were periodicals other than registered newspapers. For printed papers other than books, newspapers and periodicals no special rates were in force.

From the point of view of post office management also, the complexity of the service was, with the industrial development of the 19th century and the constant growth of correspondence, reaching a point at which the rapid and accurate handling of the mails became wellnigh impossible. Before a mail could be despatched it had to be classified into perhaps a dozen distinct divisions. Each section had to be separately weighed and full details entered on an elaborate waybill in accordance with the particular method of accounting in force with the country concerned. On the arrival of a mail the details given by the country of origin had to be checked and a form of receipt on the lines of the original waybill completed and returned. Almost the only advance made over the procedure in force in the 17th century was that letters were weighed in bulk instead of singly. With this procedure there was naturally considerable delay both in making up the outward mails and in releasing the inward letters for delivery. The example of a simple and uniform tariff had been set by the establishment of penny postage; but the principle which underlay Hill's scheme for obtaining uniformity, viz., that the cost of conveyance of a letter represented only a small fraction of the total cost of its treatment, was far from being applicable to the conditions of the international post.

Formation of the Postal Union. — The first step in the direction of reform was taken by the United States, which in 1862 suggested a conference for the purpose of considering the improvement and simplification of international postal relations. This met in Paris in 1863 and adopted a code of 31 articles, intended to serve as the basis of international conventions. Further progress was delayed first by the American Civil War and then by the Franco-German War. In the meantime, however, another great postal reformer, Dr. von Stephan, of the North German Postal Confederation, had devoted himself to the question of developing and expanding the somewhat meagre results of the conference of 1863, and had prepared a project for a universal postal union, based in part on the conclusions of the conference and in part on the experience of Germany, which had some years before formed a postal union including Prussia, Austria and the whole of the other German States, nearly 20 in number. The Swiss Government, at the instance of Germany, summoned a conference to meet at Berne to consider the proposal to form a general postal union.

The Congress of Berne met in September 1874 and was attended by the representatives of 22 States, including the whole of Europe, the United States and Egypt. The result of the Congress was the signature of the first International Postal Convention, which has remained from 1875 to the present time, with comparatively little modification, the foundation of the international postal service.

The fundamental principle of the union is contained in a striking article which lays down that for the purposes of postal communication the whole of the signatory countries form one single territory. The practical application of this principle lies in the doctrine of liberty of transit; every member of the union binds itself to transmit the mails entrusted to it by every other member by the best means of communication which it employs for its own letters. Thus each country has in effect the full and unrestricted use of the railway and steamship services of the whole world, and any improvement made by any member of the union is placed at the disposal of any other which desires to utilize it.

The membership of the union was at first somewhat limited, and was mainly European, although from the first the United States, Asiatic Russia and Asiatic Turkey, were included. Extensions of membership, were, however rapid. Ten years after its foundation the union included 86 postal administrations; by 1900 there were 113, and the process has steadily continued. China (1914) was the last large country to adhere; Russia fell out for a time after the revolution, but subsequently adhered anew; and at the present time there is hardly any part of the world which still remains outside. As an indication of the range of the postal service, it is of interest to note that the countries which are members of the union are responsible at the time of writing (1928) for the delivery of some forty thousand million letters a year.

The Postal Union Organization.—The organization of the union is simple, but effective. Most questions are naturally settled directly between the countries immediately concerned; but for matters in which the whole union is concerned a central office or international bureau is maintained at Berne. The bureau collects and distributes information of common interest, publishes statistical returns, a monthly journal, lists of steamship and air services, etc., and acts if required as a clearing house for the settlement of accounts. The cost of the bureau is apportioned in a ratio corresponding to their importance between the various members of the union; the annual cost in the case of an office paying the maximum quota is some £350 a year; whilst a small state pays the modest subscription of about £15.

The Postal Convention and the subordinate agreements are reviewed periodically, usually at intervals of five or six years, by a congress to which every member is invited to send delegates. Each country submits in advance any proposals which it may have to offer on any article in the agreements, and these are debated first by a special committee and afterwards by the whole congress in plenary session, all questions being decided by a simple majority. The voting system gives every metropolitan country one vote irrespective of its size or importance. The British dominions and India are considered as metropolitan countries; but votes are only allotted to colonies and dependencies by special vote of the congress, the number being subject to revision on each occasion. In cases of dispute between postal administrations the union has adopted the principle of compulsory arbitration. Serious disputes are infrequent, but when they occur the arbitration machinery has invariably been effective.

The principles adopted by the first congress in 1874, which for the first time introduced order and uniformity into the international service, were simple and well conceived.

Four Chief Principles.—The first was the uniformity of postage rates and of units of weight. The congress of Berne adopted the rate of 25 centimes per 15 grammes for letters, but permitted a certain variation within a definite maximum and minimum, and the rate of 7 centimes, with a similar variation, per 50 grammes of printed papers. In 1878, however, standard uniform rates of 25 centimes for a letter, 10 centimes for a postcard, and 5 centimes per 50 grammes for printed papers, were adopted and were retained unaltered until 1920. The only variation allowed was the addition of a surtax in cases where heavy costs for sea transport were incurred. The conditions which followed the war swept away the uniformity which had prevailed for 40 years and brought about a reversion to the original principle of a maximum and a minimum rate. At the most recent congress (1924) the old rates were reaffirmed, and the limits of variation reduced—a process which will no doubt continue until the old stability and uniformity are re-established. The only change in the units of weight has been the raising of the letter unit from 15 to 20 grammes, or to an ounce for English speaking countries.

The second basic principle is the classification of postal correspondence into three groups—letters, postcards, and printed papers (including commercial papers and samples). Definite conditions of acceptance, as well as separate rates of postage, were adopted; the delicate distinctions between what can be sent at the cheap rate and what must be charged as a letter, which are often puzzling to the public, depend on international decisions which no individual country is in a position to vary.

The third principle was the adoption of definite payments to be made by the country which despatches mails by the trains or steamships of another country for the use of those services, with the exception that no payment is made to the country of destination, the flow of correspondence in each direction being assumed to be approximately equal. Here there has been no continuity of practice. Rates for sea services in particular were at the outset extremely high; in some cases as much as 25 francs a kilogramme (representing about 2½d. a letter) was charged. The gradual cheapening of the cost of sea transport has been reflected at successive Congresses in the reduction of the scale of sea rates, while a similar though smaller reduction has been made in land rates; at the present an equitable scale is in force which varies in accordance with fixed zones of distance, and represents the lowest point which transit rates have reached in the history of the foreign post.

The fourth principle was the universal adoption of a system of registration and compensation. International registration differs from internal registration in one important particular, which often puzzles and annoys the sender of a letter. The compensation payable is a fixed amount (50 francs or £2) and is allowed only in the event of the entire loss of the registered packet and not for damage or loss of contents. This principle the union has steadily maintained from its inception.

Later Changes.—The original convention applied only to letter mails; but from an early date supplementary agreements were adopted at successive congresses for various extensions of the postal service.

In 1878 an agreement for an international money order service was signed by a considerable number of countries; and at the same time an insurance service, which provided for payment of compensation for loss or damage of letters containing documents of value (paper money, etc.) was established. This was later extended to cover insured boxes containing valuables such as gold or jewellery. The amount insured varies with the fee paid, and the maximum varies in different countries. The highest value for which a letter or box can be insured as 10,000 francs or £400.

A further considerable advance was made in 1880, when 19 countries concluded a parcel post agreement. The original agreement was limited to parcels not exceeding three kilogrammes; it prescribed a simple procedure and fixed rates of payment both for terminal and for transit countries. The scope of the service has expanded considerably since 1880. Over 70 post offices now take part in the service; it has been extended to include parcels up to 10 kg. (22 lb.); and it now provides both for an insurance and a cash-on-delivery service. The agreements above mentioned are not adopted universally throughout the union; for example, neither Great Britain nor the United States have adhered to the parcel post and money order agreements; but where separate agreements have to be concluded, they generally follow with only slight variations the principles sanctioned by the union.

From time to time other agreements, of minor importance, have been concluded between various members of the union for the extension to international traffic of certain functions performed by the post office in the internal service. These are the agreements relating to *"recouvrements"* (collection of bills, payment of coupons, etc., through the post) *"abonnements"* (collection of subscriptions to newspapers and their delivery at specially low rates) and postal cheques. The latter provides for the transfer of money between postal cheque accounts in different countries, as a supplement to the ordinary money order service.

Imperial Penny Postage.—The reduction of postage rates which followed on the establishment of the Postal Union was considerable, and it was many years before the rate to distant places was brought down to the standard level. For instance, as late as 1890 the rate on a letter to Australia or New Zealand was 6d., to India 5d., and to South Africa 4d. By degrees, however, the idea of establishing preferential postage rates on political grounds began to develop; and a decision of the postal congress of Washington in 1897 that the Postal Union Convention permitted the establishment of rates below the standard postage, coinciding with the growth of imperial sentiment in the British empire, led to the summoning of a conference to consider the possibility of imperial penny postage. The result was that in 1899 the rate of 1d. per half ounce was established to Canada, India, South Africa and the Crown Colonies generally; it was extended to New Zealand in

1901 and to Australia in 1905. A few years later (1908) the United States were included in the scheme. Throughout the various changes in letter postage brought about by the war the principle of maintaining the initial imperial letter rate at the same point as the initial Inland rate has been uniformly observed. The adoption of preferential rates has not been limited to the British empire, and a number of "restricted unions" have been established. For example, the French internal rates are applicable to all the French Colonies: Germany has reduced rates to Austria, Czechoslovakia and Hungary: and the United States has low letter and newspaper rates to Canada.

The most interesting experiment in this direction is the formation of the Pan-American Postal Union, founded at Madrid in 1920 and developed at the congress of Mexico in 1926. To this the Latin American States, the United States and Spain are parties. The main provisions of the Pan-American Convention are that the maximum rates to be charged between one member and another are the inland rates of the country of origin, and that each member conveys the transit mails of any other member free of charge. The development of this union, and the effect of its policy both on postal traffic and on the finances of the countries concerned will furnish an interesting study in postal history.

BRITISH POSTAL STAFF

The enormous expansion of post office business since 1840 has naturally resulted in a corresponding increase in the number of the staff, and brought with it its full complement of the problems which arise in modern conditions in regard to the relations between the employer and the employee.

In the 17th and 18th centuries the number of employees was insignificant; in 1763, for example, the secretary's office—the G.H.Q. of the service, which to-day has a staff of nearly 900—employed 4 clerks. At the time of the introduction of penny postage the total staff numbered 10,000, a number which of course soon increased with the growth of business. In 15 years it had more than doubled; by 1870 it had reached nearly 30,000; and the later expansion of the field of post office activities by such new developments as the telegraph service, the parcel post and the telephone service caused an even more rapid development. By 1885 the staff numbered over 90,000; twenty years later it had risen to 190,000; and in 1914 the total was 227,000, the post office being by that time the largest employer of labour in the country. At the present time, in spite of the separation of the Irish Free State, the staff still numbers 229,000.

The principal questions which arise are of course those common to all employers of labour on a large scale—the methods of appointment, the fixing of pay and conditions of employment, and the relations with the staff organizations. The majority of the post office staff consist of "established" persons, *i.e.,* employees enjoying the usual civil service conditions of permanence of employment and pension on retirement. The clerical branches are mainly staffed by the classes common to all the departments of the civil service; but employees in the "manipulative" grades in the post office have a certain proportion of clerical posts reserved for competition among themselves. Manipulative grades are generally recruited in one of two ways. Postmen are recruited to the extent of at least 50% from ex-service men; with this exception the normal entry is through the class of boy messengers, who are given facilities for continuing their education, and at the age of 16 enter for a limited competition, their future career as sorter, telegraphist, postman, or engineering workman, depending on their success in the examination.

The post office staff includes over 50,000 women, employed in various grades—clerks, writing assistants, counter clerks, telegraphists, telephonists, sorting assistants, typists, etc. The method of recruitment varies according to the work on which they are employed.

The rates of pay and conditions of service have undergone a long succession of modifications, as the result of enquiries which have been instituted periodically, through the medium of departmental committees, committees of employers of labour, etc., and select committees of the House of Commons. At the present time the established machinery is to refer all claims which cannot be settled by negotiation to the industrial court, which has been entrusted by the Government with the duty of dealing with the claims of state employees, and whose awards the Government undertakes to carry out, subject to the overriding authority of Parliament. The result of successive revisions, which have in turn benefited practically every class of the post office service, has been to place the present day employee in regard to pay, hours of duty and general conditions, in a situation which is conspicuously superior to that which prevailed a generation ago.

British Postal Trade Unions — The difficulties which Trade Unionism in outside employments has had to meet have been reflected in the history of the post office staff. Throughout the latter part of the 19th century the attempts of the staff to organize themselves for the purpose of collective representation met with but little encouragement; and discontent went so far as to produce a sporadic strike of telegraphists in 1871 and a partial strike of postmen in 1890. It was not until 1899 that the duke of Norfolk consented to receive representations from the Postmen's Federation or from any similar body; and in 1906 Sydney Buxton (now Lord Buxton) agreed to recognize any duly constituted association of post office servants and to allow the associations to employ officials outside the postal service.

The result of this recognition was the formation of a large number of associations, as owing to the variety of the work undertaken by the post office the number of grades into which the service is organized is very numerous. Of late years there has been a marked tendency to amalgamation among the various unions; but even at the present time, after all the reductions thus brought about, there are no fewer than 42 separate associations officially recognized, with an aggregate membership of 154,000.

The principal associations and their membership were in 1928 as follows:

Title	Approximate membership
Union of Post Office Workers	90,000
Post Office Engineering Union . . .	21,100
National Federation of Sub-postmasters . .	11,100
Civil Service Clerical Association . . .	5,000
Controlling Officers' Association . . .	4,400
Guild of Postal Sorters	3,400
Association of Executive officers, etc. . .	2,400
Association of Post Office Women Clerks . .	1,400
Society of Post Office Engineering Inspectors	1,200
Association of Counter Clerks and Telegraphists	660

Of late years the relations of the administration of the post office and the staff have entered on a new phase by reason of the establishment of Whitley councils in 1920. Apart from the consideration of general questions common to the post office and the rest of the civil service, which is undertaken by the national Whitley council, the post office has its own departmental councils, which meet periodically at headquarters for the discussion of questions affecting the general conditions of service. The departmental council does its most effective work by the appointment of joint committees for the purpose of considering questions which are too complicated to be discussed adequately by a large council meeting, the recommendations, if agreed by both sides, being then submitted to the departmental council for confirmation.

All matters of purely local interest are handled by the local Whitley committees, of which one exists in each head post office, and also in each sub-department of the post office. These meet much more frequently than those held at headquarters, and generally speaking they have worked with marked smoothness. The staff takes considerable interest in the discussions; disagreements are comparatively infrequent; and the substitution of personal discussion for prolonged correspondence which has resulted from the Whitley scheme has been a distinct improvement in organization. By the Trade Union Act of 1927 the post office union have been forced to sever their connection with the Trades Union Congress.

UNITED STATES POSTAL SERVICE

Early Colonial Period.—As between the villages of the same colony, special messengers were employed to carry mail, but between colonies, letters were entrusted to merchants and travellers. A proposal to the English Government to establish a post office in America was made in 1638, but the first formal step toward such an establishment was made by the General Court of Massachusetts in 1639. Provision for postal service was made in other colonies considerably later. The first advance toward an organized intercolonial service was made by the granting of a patent to Thomas Neale on Feb. 17, 1692, to establish post offices in North America. An office was established at Philadelphia and rates fixed to most of the colonies. Receipts did not cover expenses.

In 1707 the Government purchased the rights. The service grew and improved with the development of the colonies. Benjamin Franklin became deputy postmaster in 1737 and postmaster general in 1753. Under his administration and with the improvements in service it showed a substantial surplus. A packet line was established direct from England to New York in 1755 and from Falmouth to Charleston in 1768. In the approaching crisis between the colonies and the mother country, Franklin was dismissed from office in 1; 74. The service continued until taken over by the second Continental Congress.

The Continental Post.—The establishment and maintenance of postal facilities was given early attention by the Continental Congress in 1775. The establishment of a post office and the appointment of a postmaster general with office at Philadelphia was provided for. Franklin was chosen the first postmaster general. Because of the special conditions existing the Continental post office was not able to operate at a profit. A provision in the Articles of Confederation gave to Congress the sole and exclusive right to establish and regulate post offices from one State to another throughout the United States and exact such postage on papers passing throughout the same as might be necessary to pay expenses of the office.

Under the Constitution.—A distinctly new era began with the adoption of the Constitution. The postal grant in that instrument gave to Congress much wider powers. Under the express and implied powers of this brief provision a vast and most important public service has been established and developed. Post offices were established as rapidly as possible, speedy transportation of mails provided and service extended unifying the distant parts of the country.

In 1789 there were only 75 post offices; in 1928 there were 49,944. In 1790 there were only 1,875 m. of post routes; in 1928 there were 1,776,396.

Policies.—The policy in colonial times was to make a profit out of the postal business. In 1791 the post office was annexed to the Treasury department. By 1796 it was felt that the post office should become a pioneer of civilization and the means to rapid and regular communication between remote posts and the Government.

In 1823 the post office became in fact and later in law, a separate department as distinguished from a subordinate branch of the Treasury. The present policy is that the department should render good service to the public consistent with due regard for cost, and in doing so it is not necessary for the service to be always self-sustaining. Deficits have not been unusual in the history of the service. In 1927 the operating deficit was $28,914,716.05, which, however, was only 4·06% of the total cost of the service.

Post Offices.—Post offices are established in every city, town and village in the country, for the receipt and delivery of mail matter and the performance of such special services as may be provided appropriate to their size and importance. These offices, with each a postmaster, are of four classes. Postmasters of the first three classes are appointed by the President with the advice and consent of the Senate and those of the fourth class by the postmaster general. There are 1,154 first class, 3,472 second class, 11,065 third class and 34,253 fourth class offices. There are employed in offices of the first and second classes 129,074, not including postmasters, rural carriers and motor service employees.

Transportation.—The earliest methods of transportation were by horseback riders, stage-coaches and steamboats. The advent of railroads in 1834 marked the beginning of a vast change in mail transportation. In 1838 Congress declared railroads which were or might be completed post roads. The great extent of this development is shown by the fact that in 1927 mails were carried over 226,965 m. of railroad. In 1927 there were 6,350,589,586 lb. of mail transported by all methods most of which was by railroads

The earliest use of the aeroplane for carrying mails was under occasional authorizations to postmasters to dispatch mails by planes in connection with fairs and other exhibitions. In 1918 Congress having made an appropriation, an air mail route was established between New York and Washington by way of Philadelphia. In 1919 the service was established between New York and Cleveland and in 1920 the transcontinental route, New York to San Francisco, was put into operation. This provided a schedule of 32 hours and 30 minutes west-bound and 29 hours east-bound. The first through day and night service was started July 1, 1924. The department established and maintained the Government-owned air mail service over the transcontinental route until its practicability was demonstrated and then released the line to contractors for its operation. There are (1928) 20 contract air mail routes with a total mileage of 10,932 m. each way. Direct contract air mail connection is made between 98 of the more important cities in the United States. During the fiscal year 1928 there were 1,861,800 lb. of mail carried by air mail; 5,585,224 m. of service were actually flown.

Experimental transportation of the mails by 6-inch pneumatic tubes underground was inaugurated in Philadelphia in 1893. The present system consists of 26.99 m. of double lines of 8-inch tubes in New York and Brooklyn and 1·6 m. of double tubes in Boston. The larger percentage of the letters passing through the postal points connected by the system are transmitted through the tubes.

Special Services.—With a vast organization touching every locality and equipment at its disposal for postal purposes, the postal establishment has taken on various activities that can be assimilated with the general service and best performed for the public by that means. Among the principal ones are the following: A uniform system of registration for mail matter was established in 1855 to insure the greater security of valuable letters. The system has been applied to the first, second and third classes of mail matter and extended to the foreign as well as domestic mails. Domestic third and fourth class matter may be sent collect-on-delivery on the payment of a special fee; that is, the price of the article and the charges thereon will be collected from the addressee. This service was inaugurated in 1913. The money order system was established in 1864. Under this system a patron may for a specific fee purchase a domestic money order in stipulated amounts not exceeding $100. This may be paid within a limited time at any money order post office. Under separate conventions with foreign countries an exchange of money orders is provided for. This was inaugurated first with Switzerland in 1869 and Great Britain in 1871. The Parcel Post Act (1912) created markets for merchandise throughout the entire country.

Prior to 1913 fourth-class matter constituted only about 5% of the total weight of the mails. Under the new system parcel post has grown to be 60·5% in weight of the mails.

For special fees a service of "special handling" is given fourth-class matter and special delivery is given all classes of mail.

The postal savings system was inaugurated in 1911 and provides for the deposit of savings at interest with the security of the United States Government for repayment on demand. Simple interest at the rate of 2% per annum is paid. At the end of the fiscal year 1928 postal savings deposits were received at 6,679 depositories and there was remaining to the credit of depositors the sum of $151,000,000.

Mail Distribution.—The distribution of the mails for ultimate delivery, including their preparation for dispatch en route, is handled in the post offices and in the railway mail service. The post offices distribute mails for local delivery locally deposited and those received from the railway mail service. Mails for dispatch by transportation means are distributed to railway post office and air lines according to prescribed schedules.

With the carriage of the mails on the railroads a system was developed in connection therewith of handling important mails en *route* by the employment of route agents. Their duties included the assortment of the mails for the several offices and the delivery and reception of mail bags. All classes of mail are handled in accordance with their importance to the public but letters and daily newspapers are given preferred attention.

At the close of the fiscal year 1928 there were in operation 4,661 railway post office trains covering 204,974 m. of railroads; there were 13,340 closed pouch trains and 14,092 regular and acting railway postal clerks working in these railway post offices.

Delivery.—The employment of letter carriers at such offices as the postmaster general should direct for the delivery of letters upon the payment by the addressee of a fee of two cents on each letter delivered, was authorized in 1794. The delivery of newspapers under like conditions on payment of a half-cent each was authorized in 1827. What was known as a "Penny Post" was in successful operation in several of the principal cities before 1859 but was unsatisfactory because of the competition of the "private expresses." This competition was ultimately disposed of under the prohibition of the Federal Statute. Free delivery in cities as distinguished from this service was inaugurated in 1863 under the Act of that year and the service in its present form was established at nine of the largest post offices. The service has had a great growth and is maintained at 2,899 cities and employs 51,293 carriers. Village delivery service was established at certain second and third class offices in 1912 and has had a substantial development. At the present time it is in operation in 705 villages. Rural free delivery, a service by carriers to the rural inhabitants, was inaugurated as an experimental service in 1896. At the end of the fiscal year 1928 there were 44,168 rural carriers, serving approximately 7,141,792 families or 24,282,092 individuals on 44,288 rural routes. Approximately 17% of all mail originating in the country is ultimately delivered to the patrons on these routes. Service is generally daily, except Sunday.

Mail Matter.—The Act of 1792, the first after the adoption of the Constitution, recognized letters, packets and newspapers as mail matter. Magazines and pamphlets were recognized in 1799 and unbound journals of the several States in 1825. Lithographed circulars, handbills or advertisements and every other kind or description of printed or other matter were recognized as mailable in 1845. In 1851 bound books were made mailable. In 1852 the limit of weight on books was 4 pounds. In 1861 maps, engravings, photographic prints, photographic paper, letter envelopes, cards, blanks, seeds and cuttings were made mailable and the weight limit was fixed at four pounds and the Act of 1863 excepted books circulated by order of Congress from the weight limit. Mail matter was classified in 1863 and again in 1872 into three classes. The postal card was authorized in the latter year. Mail matter was again reclassified in 1879 in four classes, namely, first class, written matter; second class, periodical publications; third class, miscellaneous printed matter; and fourth class, merchandise and matter consisting of that which is not included in the other classes not in form or nature liable to injure the contents of the mail bag or harm those engaged in the postal service, and not exceeding four pounds in weight for each package. By the Parcel Post Act of Aug. 24, 1912, the scope of fourth class matter was enlarged. Congress has vested in the Post Office department a monopoly in the conveyance of letters, but this monopoly does not extend to any other class of mail matter.

During the fiscal year 1927 the number of pieces of all mail originating by classes was as follows:

	Pieces
Domestic	
First class	16,283,564,220
Second class:	
Transient	36,556,627
All other second class:	
Exempt from zone rates	649,746,746
Newspapers, dailies	2,029,942,376
Newspapers, other than dailies	923,843,450
All other publications	1,113,201,806
Total, except transient	4,716,734,378
Total, all second class	4,753,291,005
Third class	4,061,604,835
Fourth class (parcel post)	742,589,397
Penalty matter	438,590,586
Franked matter	50,487,129
Free-for-the-blind	111,949
Totaldomestic	26,330,239,121
Foreign	
Outgoing (originating):	
Miscellaneous	299,783,200
Publishers' second class	56,533,408
Total foreign	356,316,608
Grand total, all mail matter	26,686,555,729

Revenues.—The use of postage stamps was inaugurated in 1847 and it is from this source that the revenues of the service are derived mainly. From all sources they amounted to $683,121,988.66 for the fiscal year 1927. The expenses of the service are paid from the revenues and if these are insufficient the remainder is paid from the U.S. Treasury. The audited expenditures for the fiscal year 1927 were $714,577,491.79.

International Postal Service—Postage rates on international mails are regulated by the Universal Postal Convention and for the Pan American countries by the Pan American Postal Convention, to each of which the United States subscribes. Parcel post exchanges are made under separate conventions negotiated with other countries, excepting Pan American, in which case the United States subscribes to the General Parcel Post Convention.

Dead Letter Office.—Letters or parcels which cannot be delivered, from defect of address or other cause, are sent to the Division of dead letters and dead parcel post. They are carefully examined on both front and back for the name and address of the sender; if these are found, they are returned to the sender. If the sender's address is lacking, they are kept for a period, after which dead letters are destroyed, while dead parcels are sold at auction.

Staff.—The Postal Department is administered by the postmaster general, who is a member of the President's cabinet. He is assisted by four assistant postmasters general, an executive assistant, a solicitor, a comptroller, a chief inspector, a purchasing agent, and a chief clerk, in the department at Washington, under whom deputy assistants and directors and superintendents of divisions supervise the work and the clerical forces. A special assistant to the attorney general, for the post office department, in charge of matters before the Interstate Commerce Commission involving railroad mail pay, is also a part of the staff. In the field service the postmasters are in charge of the post offices and their services, including the rural delivery service. The railway mail service is supervised by the general superintendent at Washington and 15 division superintendents and their assistants and 121 chief clerks. The inspection service is supervised by the chief inspector at Washington and 15 inspectors-in-charge of divisions-

POSTAL SERVICE OF THE BRITISH EMPIRE

In the early days of Colonial expansion the postal services established overseas were in theory and to a large extent in practice under the direct control of the Postmaster General of Great Britain. Reasons of practical convenience and the development of autonomy in the Dominions and Colonies, gradually led to the establishment of independent postal services. At the present time the British Empire comprises some 55 distinct postal administrations each responsible solely to its own Government.

Canada. — The Canadian Post Office, before the Declaration of Independence, was combined with that of the other North American Colonies, and after the separation it continued to be administered by the Post Office of Great Britain. In spite of the obvious difficulties of effective control, it was not until 1851 that it was abandoned and separate autonomous services were established in the different provinces, to be replaced by a centralized Post Office on the foundation of the Dominion in 1867. Canada in December 1928 restored the 2 cent rate on letters exchanged within the Empire which had been in abeyance since the War.

Canada has an extensive internal Money Order Service with a turnover of some $370,000,000 a year, and a considerable Savings Bank business; the Parcel Post is a relatively recent service, having been established only in 1914. A still later development is the Cash on Delivery service established in 1922.

Australia. — The history of the Australian Post Office goes back to 1810, when the first Post Office was opened in Sydney. Each State developed on its own lines, though joint action was, of course, essential in some matters of common interest. The State services were developed on the general lines of the English Postal service.

Regular sea communication with Great Britain was established in 1846, the overland route being utilized in 1850, while a regular sea service with the American Continent dates back to 1866. The high cost of transport in relation to general costs is evident from the statistics of expenditure, as no less than 28% of the total postal budget represents expenditure on the conveyance of mails. The volume of traffic is considerable; the total number of postal packets of all kinds delivered, in the last year for which statistics have been published was 1,139,000,000 or nearly 180 per head of the population. The newspaper rate is fixed at the low rate of 1d. per 10 oz.; and an unusual feature of the postal service is a specially low rate of postage for books printed in Australia, which are conveyed at one-half the rate applicable to other books; the same principle is applied also to magazines and periodicals. The aggregate length of the air routes is 3,487 miles and further considerable developments are in contemplation; the rates are moderate and the traffic is steadily increasing.

South Africa. — A regular postal service was established in South Africa immediately after the British occupation of the Cape in 1806. Regular communication was established between Cape Town and important centres by Hottentot postboys. The foot messengers were later replaced by horsed Post Orderlies; but it was not until a comparatively recent period that the development of railways made rapid local communication possible on an extensive scale.

The various States of South Africa maintained their separate Post Offices until the formation of the Union in 1910, when a centralized Postal Administration was established.

The inland letter rate is 1d. per oz., and the postcard rate ½d. For parcels of 1 lb. and over the rate is 6d. per lb.; but South Africa has introduced the interesting experiment of an agricultural parcel post, the rates on which vary from 3d. for 1½ lb. to 1s./– for 11 lb. The agricultural post includes fruit, grain, tea, poultry, meat, etc., but perishable or semi-perishable products such as butter, eggs and lard are excluded. Some 650,000 parcels annually are sent out by this service. A Cash on Delivery service has recently been introduced and though still small is increasing at a rapid rate.

The total volume of postal traffic for 1928 amounts to 309,000,000 articles of all kinds, or 40 per head of the population. The Post Office shows a small margin of profit.

South Africa, alone among the Dominions, is responsible for the whole of her sea communication with Great Britain in both directions; she also maintains the only Sea Post Office which still operates between Great Britain and any part of the Empire.

New Zealand. — The New Zealand Post Office is a comparatively modern growth, as it was not till 1854 that the first Postmaster General was appointed. In 1901 she advanced the idea of Universal Penny Postage, which was actually submitted to, though not adopted by, the Postal Union Congress of Rome in 1906. New Zealand, however, adopted Penny Postage not only within the Empire but also with every Foreign country which would accept it, even on a unilateral basis; and when she re-established the Imperial penny postage in 1923, the same measure was also extended to a number of foreign countries.

In 1905 she sanctioned the use of postal franking machines instead of postage stamps, and succeeded in 1920 in obtaining the general adoption of such machines by the Postal Union generally. In 1908 she established postal services by motor, and in 1909 introduced automatic stamp-selling machines.

The Postal business is heavy in relation to the number of the population. The number of articles of all kinds delivered in 1928 was over 244,000,000, or 181 per head.

India. — A postal service was first established in India by Clive in 1766; but it was mainly intended for official correspondence, and this principle was followed for many years during the gradual extension of British rule in India. It was not until 1837 that it was considered to be sufficiently developed to warrant the establishment of a monopoly in favour of the official post.

The Indian Post Office is governed by legislation based mainly on the English model. The area to be served is immense, and the cost of transport relatively heavy; moreover the policy of uniform rates irrespective of distance, adopted in England in 1840, was accepted in India as early as 1854, and the aim of the Government has been to fix the rates at as low a point as possible, the Post Office never having been expected to make any considerable profit. Moreover, although the population is very large, the letter-writing element is not very considerable. Although the number of letters delivered annually is about 1,300,000,000, this represents an average of only 4 letters per head per annum. Post Office work has, however, in recent years shown a steady and considerable increase, the volume having doubled in a period of about 20 years. At the present time the inland letter postage is 1 anna (1d.), the postcard rate $\frac{1}{2}$ anna, and the newspaper charge for a weight of 8 tolas (3$ oz.) is only $\frac{1}{4}$ anna. A considerable parcel post service is maintained at comparatively low rates, a parcel of 20 tolas (12 oz.) being conveyed for any distance for the low charge of 2 annas (2d.).

A Money Order Service with an annual turnover of nearly go crores of rupees (about £67,000,000) is maintained, and the value payable (Cash on Delivery) post, which has been established in India for over 50 years, is also highly developed, the annual value being over 27 crores of rupees (about £20,000,000).

POSTAL SERVICES IN OTHER COUNTRIES

France. — The establishment of a State post in France goes back to 1464, though its early history is very obscure. Improvements were made from time to time in organization, *e.g.,* by Richelieu in 1627 and Mazarin in 1643; but the system of farming, which was tried in England for a short time in the 17th century, persisted in France till the Revolution, when it was swept away and a Committee appointed to manage the postal service. Napoleon in 1804 replaced the Committee by a single Director General; and his organization has remained in general outline unchanged. Of recent years, however, the Post Office has rarely been entrusted to an independent Minister; it has usually been attached to another Ministry — Treasury, Public Works or Commerce and Industry; and its immediate chief is sometimes an under-secretary of State, sometimes a secretary-general drawn from the permanent Civil Service.

The financial conditions since the war have made the stabilization of postage rates a matter of. some difficulty; but they are now, generally speaking, fixed on the pre-war basis, having regard to the altered value of the franc. The inland letter rate begins at 50 c. (1d.) per 20 grammes; but the rate on heavy letters is relatively low; and on a letter weighing 1,500 grammes (about $3\frac{1}{2}$ lb.), the maximum weight, the charge is only 5 fr. 20, or about $10\frac{1}{2}$d. The domestic letter rates apply to the whole of the French Colonies.

The lowest postage rate is that applied to newspapers. Newspapers which have been "routed" by the publishers are accepted at the rate of $\frac{1}{2}$ centime ($\frac{1}{100}$ d.) for delivery in the department of publication and neighbouring departments or 1 centime ($\frac{1}{50}$ d.) for the whole of France and the Colonies.

At the present rates, however, the Postal service shows a considerable annual profit; in 1927 the balance of the "compte d'exploitation" amounted to nearly 300,000,000 francs.

The parcel post (colis postaux) though nominally a postal service, is operated by the Railway Companies. There is a particularly low rate (1 f. 25 for 5 kilos, or $2\frac{1}{2}$d. per 11 lb.) for the local service in Paris; and the rates for the whole of France are moderate.

One of the most recent undertakings of the French Post Office is the postal cheque system, which of late years has developed rapidly and is now a recognized feature of French finance. According to recent statistics there are about 370,000 depositors, and the annual sum paid in to postal cheque accounts is about 161,000,000,000 francs.

Germany. — Since the formation of the North German Postal Union, developed later into the Post Office of the German Empire, Germany has taken a prominent part in postal development. For the year 1927–28, the letter traffic amounted to 7,687,000,000 articles, in addition to which 309,000,000 parcels and over 2,000,000,000 newspapers and periodicals were handled in the post, the total number of postal packets thus reaching the total of 164 per head of the population. The Post Office conducts also a Money Order service with a turnover of 3,677,000,000 marks a year, an extensive Cash on Delivery service with a turnover only slightly less, and a Postal cheque service with 922,000 accounts.

The Reichspostfinanzgesetz (Imperial Post Office Finance Act) of 1924 changed the constitution of the Post Office and the service was separated from the general financial organisation and established on an independent basis analogous to that of a commercial company. The Post Office can now no longer look to the Treasury to recoup any losses.

The Administration is in the hands of a Minister, who is an Imperial official paid from Imperial funds and is responsible to Parliament for the general results of the service. The Minister is assisted by an Administrative Council of 41 members representative of the Reichstag, the Reichsrat, the Ministry of Finance, the staff of the Post Office, and of commercial interests.

The Minister is required to consult the Council, but the decisions of the latter are not necessarily binding. It cannot increase the estimates of expenditure presented to it by the Minister without his concurrence, and the latter may also refer to the Government for decision any resolution which he judges to be inexpedient.

The actual powers of the Post Office Administration are, however, very considerable. For example, it fixes the estimates of expenditure, decides on all questions of borrowing for post office purposes, of redemption of debt and of the investment of the Postal Cheque Office balances, settles the rates of pay of certain classes of Post Office employees, determines whether new classes of business are to be undertaken, and, what is most important from the public point of view, fixes rates of postage and telegraph and telephone charges.

The result of this organization is a close attention to the financial results of the undertaking. While questions of organisation and administrative economies are carefully studied, the question of rates is kept under constant observation; and when it was found that the maintenance of the old rate of 10 pf. (1d.) for the letter post could not be justified, the Administration in August 1927 raised the rate by 50% (to 15 pf.) and carried out corresponding alterations in other postal rates. The postal traffic for 1927–28, however, showed an appreciable increase over the previous year, and the contribution of the Post Office to the Exchequer was 70,000,000 marks (£3,500,000) for the year.

(F. H. W.)

POSTER. A poster is a printed, written or illustrated announcement publicly exhibited.. Its usual function is to call attention to goods or service; but, to fulfil that object completely, it has not merely to arouse attention; it must provoke interest and create a desire for purchase. However attractive pictorially or textually a modern poster may be, commerce, the chief patron of poster art, finally judges a design by its value as a link in the chain of salesmanship.

POSTER ADVERTISEMENTS

Four examples of poster design, illustrating the adaptation of art and colour printing to the uses of publicity

The poster is seldom given entire responsibility for influencing the public; rather is it regarded as a form of "reminder" advertising—an ally of the press advertisement, the creator of a favourable atmosphere. The average "commercial" poster is intended to influence two groups—the retailer, who, it is hoped will stock the advertiser's goods, and the public who will purchase them. Posters have a very wide range of duties to perform in addition to selling goods. They deliver every kind of message, to every type of "audience," in an infinite variety of styles. Actually, the poster or placard can trace its ancestry back almost to the dawn of civilization.

History.—Egyptian wall-paintings, mural decorations and inscriptions, produced over 3,000 years B.C., have been discovered by archaeologists, much of this work, together with that of the early-Babylonian, Assyrian, Greek and Roman craftsmen, displaying a precision of line and a decorative beauty which are the envy and despair of the modern poster-designer. Tablets of wood, papyrus and parchment were also used, in ancient Egypt, Greece or Rome, for the purpose of issuing announcements, while it is the lettering of the Trajan column which has inspired the finest types of poster lettering of to-day.

Later Developments.—In later days, the sign-board was adopted as a form of advertisement, the hanging sign being a picturesque feature of mediaeval architecture throughout Europe. Written handbills were an additional means of enabling the shopkeeper to bring his goods and service to the notice of the public, and vast possibilities were suddenly presented to him by the invention of printing, by Gutenberg, before 1450, and by its introduction into England by Caxton in 1476.

The first letterpress poster soon made its appearance in England; and shortly afterwards, in France, a royal proclamation was issued in poster form. During the 17th century, the general use of posters was forbidden, but in time their value to the community was recognized, official restrictions were removed, and the first pictorial posters made their appearance. These were illustrated by wood-cuts Pedlars and packmen, hucksters and showmen, strolling players and proprietors of booths, also used handbills and miniature posters, decorated by wood-cuts; and these simple, primitive illustrations have formed part of the artistic inspiration of the leading poster designers of to-day.

The wood-cut was, however, destined to be superseded by lithography (*q.v.*) as a medium for the designing and printing of posters. Invented in 1796, and developed for printing purposes by Senefelder, the new art of drawing and engraving on stone, metal plates and "transfer" papers, opened up possibilities almost as vast as those which followed the invention of the printing press.

The first lithographed posters are interesting as historical curiosities only, the earlier wood-cuts possessing infinitely more character. Lithography was seized upon as a means of producing a more elaborate, "highiy-finished" form of illustration, and it is to France that we have to turn for the earliest lithographed posters of quality.

The modem poster began with Jules Chéret, a Frenchman, born in Paris in 1836, self taught as a draughtsman. He served his apprenticeship as a lithographer in England, and when 30 years old became interested in announcements of theatrical managers and placards put out about that time urging recruiting for armies. In 1867 the world saw the first modern poster of Chéret's, an announcement of a play enacted by a young woman, then 22 years old, who was to make her name immortal—Sarah Bernhardt. The poster announced a fairy play, entitled: La Biche *au Bois.*

The first Chéret posters, with their filmy female figures seemingly floating in space and flaming colours, excited interest, held attention, and caused favourable comment. Orders for Chéret's posters came from music halls, dealers in cigarettes, drinks, toilet articles, newspapers, circuses, charity fêtes, and the streets were gladdened with merrily dancing figures. Chéret designed more than 1,000 posters, the best of which can be found in books devoted to the art.

The poster spread from France to Germany. Later it travelled across the Pyrenees to Spain, and from France to Switzerland, and over the Alps into Italy, from France to Belgium, and across the English channel to England, across the North sea to Holland, and from Germany it found its way to Austria-Hungary, the poster invasion finally reaching Russia and travelling across the Baltic sea to Norway and Sweden. From the British Isles and the Continent of Europe, the poster went to the United States, and later to Canada, thence to Australia.

In England the first to attract attention by his posters was Frederick Walker, who in 1871 made a poster for the dramatized version of The *Woman* in White. Members of the Royal academy were attracted to the newly discovered medium, and Sir John Millais exhibited "Bubbles," advertising a soap. This poster pleased England immensely. Then followed Aubrey Beardsley, with his weird posters, Walter Crane, R. Anning Bell, the "Beggarstaff Brothers" (James Pryde and William Nicholson), J. W. Simpson, Gordon Craig, Dudley Hardy, Maurice Greiffenhagen, J. Hassall, Will Owen and others.

In Germany Ludwig Hohlwein won not only a national, but an international reputation, and books of his posters are sold throughout Europe and America; his posters are so compelling that he is regarded as a master of his craft. Other German poster artists whose work reached the highest standards include Otto Fischer, Sattler, Speyer, T. T. Heine, Max Klinger, Dasio, Hofmann, Franz Stiick and L. Zumbrusch.

Leon Bakst, the Russian genius, and H. Cassiers, Belgian, have done much to bring renown to their native lands by their posters of distinction. Japan's greatest poster artist is Toyókuni.

The poster, as it is known to-day, did not exist in the United States previous to 1889, except for the theatrical and circus posters made by Matt Morgan. Posters began in the United States in the 'gos, when Louis Rhead and Will H. Bradley began to produce their decorative placards. These were used principally for the announcements of magazines and the books of publishers. Later business and commerce saw the great value of poster advertising, and enlisted the services of Maxfield Parrish, Ethel Reed, Will Carqueville, J. J. Gould, Howard Chandler Christy, J. C. Leyendecker, Frank Hazenpflug, James Montgomery Flagg, Charles Dana Gibson, and others.

On the poster panels of to-day, in the United States, may be seen the work of Harrison Fisher, Linn Ball, G. C. Beall, Norman Rockwell, Fred Stanley, William Oberhardt, Fred Mizen, Clarence F. Underwood, Karl Johnson, F. Nelson Abbott, Arthur von Frankenberg, John E. Sheridan, Harry Morse Mayers, Hadon Sundblum, John O. Brubaker, Charles E. Chambers, McClelland Barclay, Lucille P Marsh and other noted artists.

With the outbreak of the World War posters took on a new significance in all nations actively engaged in the struggle. In countries where there was not conscription, posters were most effectively used to stimulate recruiting. Before conscription in England (during the first stages of the war), more than 2,500,000 posters were posted in the British Isles alone to get men to enlist, the posters representing the work of about 100 artists. Taking a lesson from Great Britain, the Governments of the countries actively engaged in the war spoke to their nationals through the medium of the poster, appealing to the civilian population in behalf of subscriptions to the war loans, the conservation of food, aid for the organizations engaged in war work, such as hospitals, milk funds, destitute dependents, the Red Cross, the Y.M.C.A. and other activities that war entails.

Brangwyn and Spencer Pryse produced work for Britain and Belgium which was full of dignity and nobility. In France, Steinlen, Faivre, Willette, Poulbot and Fouqueray appealed to the patriotism of their countrymen. In Germany the belief in force and might was hammered into pictures by Engelhard, Louis Oppenheim, Puchinger, Otto Leonard and Wohlfeld. Austria's actions were justified or defended and her causes championed by Krafter, Arpellus, Buo and Kurthy.

Standards.—In the half century or more since the poster became a popular means of outdoor publicity, women have been predominant in many of the posters displayed. The irresistible charm of childhood illumines many posters. Birds and animals are also favourites with poster designers. But whatever is pictured on a poster, this courier of commerce must have these important features: it must be new and interesting, have attention-value, simplicity of design, brevity of text, good composition, pleasing colours, and "selling power"—the latter usually achieved through expression of a basic link of interest between the product and the public.

Great strides have been made in the development of the poster as an organized advertising medium. Modern business in America has discarded the old-fashioned and unkempt "billboard," and posters of various sizes are no longer made. Due to the Outdoor Advertising Association of America, there has come the standard structure in two sizes surrounded by a green moulding as a frame for the poster. These standard panels are found in over 16,000 cities and towns in the United States. Many of these structures are illuminated.

In Great Britain, hoardings, though not standardized, have greatly improved in character and design, under the influence of the British Poster Advertising Association. In Germany a poster hoarding is practically unknown, the design being shown on special advertising kiosks or pillars. France uses both kiosks and hoardings. *(See* PAINTING; ADVERTISING.)

POSTE RESTANTE, a facility, generally provided at post offices, for the receipt and care of postal packets addressed to be called for. There are usually strict regulations to prevent abuse or fraud. In the United Kingdom, it is stipulated that the words "to be called for" or "Poste Restante" should appear in the address, and it is notified that the facility is intended solely for the accommodation of strangers and travellers, and that even they may not use it for more than three months. Postal packets addressed to initials, or to fictitious names, or to a Christian name without a surname, are not taken in at the Poste Restante. Postal packets may not be re-directed from one Poste Restante to another in the same town or from a private address to a Poste Restante in the same town. Re-direction from a Poste Restante is not undertaken for more than 14 days, unless a longer period, not exceeding three months, is specified on the form of application. All persons applying at a Poste Restante are required to furnish sufficient particulars to prevent mistakes and to ensure delivery to the proper person Where a ship is in question the name of the vessel should always be mentioned.

The words "General Delivery" in the United States are synonymous with the words "Poste Restante." A general delivery window is maintained at every post office in the United States and is used for handling mail bearing as a part of its address the endorsement "Transient," "To be called for," "General Delivery," or other words indicating that it is intended for a transient person, such mail to be delivered upon application and identification.

At those post offices where delivery carrier service is maintained, residents who use the general delivery window are required to furnish in writing their names and addresses and the reasons for desiring to use the general delivery instead of the carrier service. Minors are required to furnish the names of their parents or their guardians whose written consent must accompany the application.

POSTGATE, JOHN PERCIVAL (1853–1926), English classical scholar and Fellow of the British Academy, was the son of Dr. John Postgate (1820–81), the initiator of the laws against the adulteration of food. He was educated at King Edward's school, Birmingham, and Trinity college, Cambridge, where he took his degree in 1876. He was elected to a fellowship at the college, where he was classical lecturer (1884–1909). He was professor of comparative philology at London (1880–1910) and Latin professor at Liverpool university (1909–20) He was accidentally killed in Cambridge by a steam lorry on July 14, 1926.

Postgate ranks very high among Latin scholars, but some of his due reputation was lost him by his vehement methods. Of these an example is to be found in his great *Corpus Poetarum Latinorum*. He expelled the writings of Ausonius from the *Corpus* on grounds which, though stated in mellifluous Latin, amount to little more than that he thought him a bad poet. Some have seen traces of the same vehemence in certain of the emendations in his Propertius (1894) and Tibullus (1905); he was, however, undoubtedly a very eminent critic and his article on TEXTUAL CRITICISM (written for the 11th edition of the *Encyclopædia Britannica,* and substantially retained in this) is a classic upon its subject.

His greatest successes were achieved in reforming the teaching of Latin. His *New Latin Primer* (1888, last ed. 1918) and his *Sermo Latinus* (1889, 1913) became widely used because of their simple methods. In particular he took a leading part in chasing out the old Victorian pronunciation of Latin—a mass of false quantities and mispronunciations which had no relation to the established facts of ancient pronunciation He was largely responsible, not only for the adoption of the reformed scheme by the Classical Association, but for the organization and propaganda which secured its general acceptance.

Before his death Postgate had the pleasure of knowing that the old pronunciation had been practically entirely wiped out of British scholastic and learned life and, as he said, that "even a lawyer had been known to pronounce *nisi prius* without making a false quantity."

Postgate's chief works, besides those mentioned above, were editions of Catullus (1894), Virgil (1912), Phaedrus (1920) and part of Lucan (1896, 1917); *How to Pronounce Latin* (1907); *Translation and Translations* (1922); *Prosodia Latina* (1923); *Guide to the Accentuation of Greek* (1925). The *Corpus* was published in parts in 1893, 1894, 1904 and 1905. *See* S. G. Owen, *J. P. Postgate* (British Academy, 1927).

POST-IMPRESSIONISM. The essential difference between impressionism and post-impressionism is perhaps best explained by the description of the former as an objective outlook which results in the rendering of the image received on the retina, and of the latter as the mental image expressed in accordance with a subjective outlook. In other words, whilst impressionism is based on strict fidelity to natural appearances, the need of post-impressionism consists, in the main, of absolute attachment to the personal vision, and, in reality, is the expression of the matter received through the glass of impressionism to be subsequently subjected to an individual thought process. The statement which emerges from the artist as a result of this process might well be termed expressionism, were it not that this name is more exclusively reserved for the excessively brutal German contribution to the movement under consideration. Post-impressionism (a term coined on the occasion of the first exhibition of the work of Cézanne, van Gogh and Gauguin in London, in 1911) provides an alternative which, if less apt, has the merit of being safe.

Post-impressionism was as much a revolt against the naturalism of the impressionists, as impressionism was a revolt against the tyrannical academic formula. It replaced analysis by synthesis. It despised representation and gave the artist unbridled licence to amplify and distort the forms of nature, acknowledging no law but the artist's sense of fitness in arranging and organizing the contents of his picture so as to express with the greatest possible directness and intensity the material and spiritual significance of his subject—the "treeness" of the tree, as Roger Fry has it, and the "wallness" of the wall. Delivered from all restraint and rules, the post-impressionists were able to proceed by leaps and bounds on their excursions into the realms of synthesis and abstraction, to the utter bewilderment of a public which, accustomed to judging art by the degree of its verisimilitude to nature, were left floundering hopelessly when attempting to fathom the meaning of these startling artistic manifestations.

A quarter of a century was enough to secure for the initiators and leaders of post-impressionism a position among the beacon-lights of European art. Cézanne, van Gogh and Gauguin are now referred to as "the glorious triumvirate" and "the old masters of

POST-IMPRESSIONISM AND CUBISM

1. "Nude' by Georges Braque (1881–), French painter, in his early days a follower of Picasso, and a prominent leader in Cubist research
2. "Les Baigneuses" by Paul Gauguin (1848–1903), French, one of the three leading painters in the post-impressionist movement. His revolt against impressionism took the form of a return to decorative pattern, and to the two-dimensional design characteristic of Far Eastern Art. The painting illustrated is an example of the work of Gauguin's later years, which were spent in the Marquesas Islands
3. "L'Homme à la Pipe" by Paul Cézanne (1839–1906), French painter, one of the so-called "Glorious Triumvirate" (Gauguin, Cézanne and Van Gogh) who were the initiators of post-impressionism. Cézanne's endeavour in portraiture and still life as well as in landscape painting was to make more clearly perceptible than it is in nature the sense of the third dimension, of volume and weight. In the collection of Mr. and Mrs. S. Courtauld
4. "The Yellow Chair" by Vincent Van Gogh (1853–90), a Dutch painter who derived his technique from the Impressionists but went on to more abstract and subjective methods of expression
5. "Arlequin au Violon" by Pablo Picasso (1881–), Spanish painter, famous as one of the leading exponents of Cubism. His work is characterized by abstraction of form and an aesthetic expression entirely separated from the physical appearance of objects
6. "La Jeune Fille à la poupée" by Paul Cézanne

post-impressionism." Their once despised, numerous, and by no means invariably successful paintings are in most of the galleries of modern art, and thousands of pounds are willingly paid for canvases for which the artists, during their lifetime would willingly have accepted a few hundred francs.

Cézanne.—Cézanne, who at the beginning of his career threw in his lot with the Impressionists, upon whose technique he formed his own, was among the first to realize the limitations imposed by the Impressionists' scientifically truthful rendering of colour and atmosphere. His dissatisfaction with what he considered the superficiality of impressionist productions led him to express, more basically and with greater structural firmness, the essential character of the countryside which forever offered him new vistas, new wonders for his interpretation. His endeavour, in portraiture and still life, as well as in landscape painting, was to accentuate volume and weight—to make the third dimension more clearly and immediately perceptible to the beholder's eye than it is in actual nature, where we are left to guess by experience and by memory of touch. To him is due the dictum that all forms in nature can be reduced to the cube, the cylinder and the pyramid.

Van Gogh.—Like Cézanne, van Gogh derived his technique from the impressionists; and like Cézanne, he was anything but a facile worker, his heavy hand being but an inadequate instrument for conveying his passionate aesthetic reaction to the thing seen. Of him it may truly be said that he did not paint, but rather battled with colour and essential line with a frenzy that took no count of finished execution. His pictures are executed in furiously energetic cross-hatchings of pure Prussian blue, emerald green, orange and yellow, with a daring justified only by the brilliant harmonies evolved from a palette on which he found no room for neutral tints. His brushwork can only be likened to vigorous hatchet-strokes, corresponding to the elemental force of his emotions. There was something uncanny in his power to perceive and to express the essential nature of any object or scene or person by which his aesthetic impulse was stirred. Inanimate things became somehow invested with a soul and with a life of their own—a sunflower, a wicker-chair, a cypress tree, or whatever it happened to be. He was a visionary who found a deep meaning in the humblest objects which his art invested with his own tortured spirit, and which he made eloquent of his own emotions. Van Gogh was the precursor of expressionism.

Gauguin.—The third member of the great triumvirate, Paul Gauguin, was a close friend of van Gogh, but of a less impulsive and more reflective turn of mind. Where van Gogh would shout and even shriek, Gauguin was content to talk, and his words carried more weight, for they were more considered. If Cézanne devoted his life to the search for volume, and van Gogh for material and spiritual significance, Gauguin's revolt against impressionism took the form of a return to decorative pattern, to two-dimensional design as practised by the artists of the Far East. He based his effects on abstract form and colour, not on representational truth or on over-accentuation of some particular truth. Ignoring the colour of nature, and relying, for the expression of his ideas upon his memory more than upon models, he produced first in Brittany, then in Tahiti, those splendours of harmonious decoration against which no arguments founded on convention can ever prevail. It was his belief that, before the spirit of a place could be interpreted, it needed study in all its parts during what he called a "period of incubation." Some proof of the peace Gauguin found in his retreat can be seen in the restful nature of his paintings.

Matisse.—Of the second generation of post-impressionists, Henri Matisse went farther even than Gauguin in reconciling Western art with the Chinese. He aims "at convincing us of the reality of his forms by the continuity and flow of his rhythmic line, by the logic of his space relations, and, above all by an entirely new use of colour." His is an art of extreme synthetic simplification, reducing objects almost to symbols, and disdaining any approach to make-believe of reality. It depends entirely on arabesque and is not concerned with the third dimension.

Cubism.—Cézanne had used colour in block form because, by that means. he could best express his feeling for the weight of whatever he depicted, and its relation to other things presented with it, but he kept to the accepted ideas of representation, which were discarded by his cubist followers, Picasso, Braque, Dérain and Leger, who evolved a new language from Cézanne's suggestion of space. It was a form of art that had nothing whatever to do with realism, and demanded concentration on aesthetic matters to the absolute exclusion of outside practical appearances and accepted canons of judgment. Cubism bears out Ruskin's theory that an artist may deny other truths to the end that one truth may be more apparent.

Like impressionism, the name "cubism" was first used in a derogatory sense; it was Henri Matisse who, in 1908, applied it to a painting in which the subject had received treatment of a markedly cubical character. About as far from the impressionist objective approach as anything could possibly be, cubism is really a stride—albeit a long stride, beyond the subjective outlook of the post-impressionists, in that it takes no heed of visual appearance, and renders what are thought to be essential realities in pure abstract form. Picasso, the most prominent follower of the cubist gospel, and, indeed, the creator of certain of its elements, is the exponent of scientific cubism in its purest sense. Another form of cubism, less pure, is that which is best described as physical, since its fundamentals are culled from visualized realities.

For example, in those of Picasso's works which are based on physical appearances, the objects are presented in a way at least sufficiently realistic to enable their perception by the ordinary beholder, although he may be at a loss to account for the shapes which they assume. Their recognition, incidentally, at once displaces the work from the category of cubism in its strict sense, for that entails matters of line and colour wholly unrelated to objects and figures, since the cult does not intend realism to enter into the question.

Braque stands, to some extent, as the codifier of Picasso's inventions, acting as an editor of his snipe-like movements. Thus, the products of Picasso are sobered down and reduced to a state of uncompromising logic before being handed on as standardized material.

The art of Fernand Leger is concentrated upon the mechanical age into which we are advancing. Working in the gay colours of contemporary life, he extracts excellent design from the solid strength of the mechanized world by which he finds himself enveloped.

Albert Gleizes is a devotee of two-dimensional treatment, and his attitude to a flat surface is that it has no need of the addition of a sculptural third, for the presence of such constitutes a denial of its very nature. This painter, too, does not regard painting as a form of representation, but of presentation of the spirit of the artist, and not of physical matter. Metzinger, Herbin and Lhote are others of the cubist persuasion, which has demanded, in its time, every conceivable form of liberty. Orphism, purism, synchronism, simultaneism, integralism, dadaism and numeralism, all have had their day, and now the parent bids fair to follow them into oblivion. But although cubism may prove to have been a blind alley, it has been, and still is, an invaluable discipline for artists in general and had its definite use in saving art from the rut of academic pedantry.

Futurism.—Italian futurism, initiated, heralded and extolled by the eloquent poet Marinetti, and practised by Boccioni, Severini, Carrà, Russolo, Balla, and other disciples of the founder, was really an offshoot of cubism, although the connection was not admitted in the futurist manifestos. It differs from cubism in so far as cubism is concerned with static conditions, whilst futurism is essentially dynamic. This dynamism aims at cinematographic effects, oblivious of the impossibility of creating on a flat surface the illusion of the sequence of movement. Thus, by depicting a horse with 20 legs in various positions to indicate the movement of the gallop, the futurist endeavours to express the action of the gallop, but does not get beyond the representation of a static horse with 20 legs. Any attempt to change an art of space into an art of time must needs prove abortive. The dynamic intention of the futurists also finds expression in "force-lines," that is to say in lines, radiating, swirling, wedge-shaped, to indicate either the direction of movement, or the manner in which objects would disintegrate in obedience to the force indicated by their form.

Another tenet of futurism denies the validity of the resemblance of a portrait to the sitter. To the futurist, a painting of one object covered by another in such a manner that both are visible, is a method of indicating his total disbelief in opacity, whilst a dozen people can be, at the same time, and in turn, ten, three, five in number, as well as simultaneously mobile and immobile. Paintings of a box, firmly shut but at the same time disclosing its contents, also are admissible. Pictures must be looked, not at, but through, and the spectator must feel himself to be in the midst of them.

In England, Marinetti's fiery eloquence enlisted for a time a small following, which included C. R. W. Nevinson, who adapted with great skill the futurist formula for a series of remarkable war paintings.

Vorticism.—The chief English contribution to post-impressionism was, however, the work of the short-lived group of "Vorticists" who, led by Wyndham Lewis, adopted a modified method of cubism, and included among their number William Roberts, Edward Wadsworth, and F. Etchells. In England, as in most countries, these innovators were regarded as incompetent cranks and charlatans, until their employment in connection with the Canadian war memorials and the Imperial War Museum brought them official recognition and public fame.

Expressionism. — In Germany the post-impressionist movement took root and spread with surprising rapidity. Its most abstract form is to be found in the art of the Russian-born W. Kandinsky, who has explained his outlook in a book entitled The Art of *Spiritual* Harmony. Pechstein, Marc, Nolde, Kokoschka and Corinth are the most prominent figures among the German expressionists, among whom must also be counted Marc Chagall, notwithstanding his Russian birth.

Certainly it would seem that the German activities which correspond to those of the post-impressionist painters in other European countries should be accorded some distinguishing title of their own. The term "expressionism," therefore, serves the purpose as well as any other, unless one were found which denotes a combination of truth, bestiality, creation and destruction — all expressed in a manner in which a snarling brutality obscures many finer feelings. At the same time it must be admitted that the artist to whom the expressionists owe so much, the Swiss, Ferdinand Hodler, cannot very well be held responsible for the excesses committed by his imitators or contemporaries.

Man and his relation to the world which contains him have been subjected by Hodler to every thought-process of which his clear brain is capable, and the resulting statements are models of simplicity, precision and originality. Hodler does not attempt to put the unreasoning at ease by being intimate with them, but compels them, rather by an almost holy power, to use their own imagination. Another artist, who with Hodler, Cézanne and van Gogh, left his mark upon the evolution of German expressionism, was the Norwegian, Edward Munch, whose achievement in painting leads from the subjective naturalism of the late 19th century to the post-impressionist tendencies of the present day.

In America the new art-gospel of post-impressionism or expressionism was popularized mainly by the activity of Jules Pascin (1885–1930), a Bulgarian by birth, who had been working from, 1905 onwards for *Simplicissimus* and living in France until 1914, when the World War made him seek for a new home in the United States. He is equally distinguished as an illustrator and as a painter, and his work, though always maintaining a very personal note, shows in turn the influence of Daumier, Cézanne, Degas, Renoir and Picasso. He resorted extensively to distortion for the definite purpose of forceful emphasis, and is in this respect related to the German expressionists.

Effect on Other Arts. — Post-impressionism, in its attempts at synthesis, drew on the past to as great an extent as any other movement, but, ignoring the representational tricks discovered by succeeding generations, adopted only the basic, elementary facts of the unsophisticated and consequently more sincere primitive races. Exploration has brought to light comparatively modern work, in the form of sculpture, pottery, and mat designs, by peoples who, throughout the ages, have known no art teaching or influences save those, possibly, of a conquering but equally primitive tribe. From the Congo, Bakota, Benin and other districts of lesser-known Africa, masks and figures have found their way to Europe, there to reveal to eager searchers for a means of expressing much without complication, wonders of form and rhythm which were bound to receive the investigation of serious artists. In the same way that Gauguin found stimulation in the vibrant colours of the Polynesian mat-makers, so Jacob Epstein, and to a lesser degree, Ossip Tadkine, have been helped to fuller expression by deep study of negro sculpture.

In almost everything — buildings, furniture, dress, design in the home or theatre, and especially, perhaps, in that powerful modern factor, advertising — the effect of post-impressionism and its more successful descendants is very marked, whilst the benefits accruing to sculpture and the minor arts — woodcuts, engravings, posters, wallpapers and others — have already altered the trend of public thought, and freed it to such extent as slow and inartistic officialdom will allow, from the morass of insincerity and vulgarity which had all but swallowed it up. (See IMPRESSIONISM, PAINTING.)

POST-MORTEM: see AUTOPSY.

POSTULATE, in philosophy, is now generally used in the wide sense of any fundamental assumption that is indemonstrable and yet necessary if the requirements of knowledge or of practical life are to be satisfied. In this sense Kant, for example, spoke of the postulates of the practical reason; and nowadays the so-called Laws of Thought are commonly described as postulates. The usage in mathematics is, or used to be, rather different. In philosophy, too, people sometimes employed the term "axiom" rather than postulate for the Laws of Thought and similar theoretical principles, the term "axiom" being defined as "a self-evident truth." But there is no virtue in claiming self-evidence for what is recognised to be indemonstrable. See AXIOM, THOUGHT, LAWS OF, KANT.

POSTUMIA, VIA, an ancient highroad of northern Italy, constructed in 148 B.C. by the consul Spurius Postumius Albinus. It ran from the coast at Genoa through the mountains to Dertona, Placentia (the termination of the Via Aemilia Lepidi) and Cremona, just east of the point where it crossed the Po. From Cremona the road ran eastward to Bedriacum, where one branch ran left to Verona and thence to the Brenner, the other right to Mantua, Altinum and Aquileia. The military occupation of Liguria depended upon this road, and several of the more important towns owed their origin largely to it. Cremona was its central point, the distances being reckoned from it both eastwards and westwards.

POSTUMIA-GROTTE (formerly Adelsberg, Slovene *Postojina*), a town in the province of Trieste, Italy (from which it is 51 mi. E. by rail). Pop. (1936) 3,804 (town), 6,j96 (commune). It is the frontier town of Italy on the railway to Ljubljana, Graz and Vienna. A mile from the town is the entrance to the stalactite cavern of Postumia, largest in Europe. The cavern is divided into several branches. The river Piuca enters the cavern 60 ft. below its mouth. In the Sala da ballo (ballroom) grotto a great ball is annually held on Whit-Monday, when the chamber is brilliantly illuminated. A mile from the entrance, the so-called Elysian fields are reached, from which a view of over 200 yd. in length can be obtained. The finest of all, however, is the Grotta del Paradiso. These caves are now joined by a tunnel to the Grotta Vera, and with the abyss of the Piuca, which can be traversed in a boat. The stalactite formations assume fantastic shapes. The length of the passages known is nearly 14 miles. These subterranean wonders were known as far back as 1213 (the earliest names found in it date from 1250) and were probably visited by Dante, who certainly knew the lake of Circonio (Cerkniza) in which the Javornik is reflected. But the cavern remained undiscovered in modern times until 1818. The Magdalene grotto is celebrated for the extraordinary subterranean amphibian, *Proteus anguinus,* first discovered there. It is about a foot in length, lives on snails and worms and is provided with both lungs and gills.

POTASHES, the crude potassium carbonate obtained by lixiviating wood ashes and evaporating the solution to dryness, an operation at one time carried out in iron pots—hence the name from "pot" and "ashes." The term potash or caustic potash is frequently used for potassium hydroxide, whilst such a phrase as sulphate of potash is now appropriately replaced by potassium sulphate. (See POTASSIUM.)

POTASSIUM [symbol K (from *kalium*), atomic number 19, atomic weight 39·105], a metallic chemical element, belonging to the group termed the metals of the alkalis. Although never found free in nature, in combination the metal is abundantly and widely distributed. In the oceans alone there are estimated to be $1{,}141\times10^{12}$ tons of sulphate, K_2SO_4, but this inexhaustible store is not much drawn upon; and the "salt gardens" on the coast of France lost their industrial importance as potash-producers when the deposits at Stassfurt in Germany came to be worked. These deposits, in addition to common salt, include the following minerals: sylvine, KCl; carnallite, $KCl\cdot MgCl_2\cdot 6H_2O$ (transparent, deliquescent crystals, often red with diffused oxide of iron); kainite, $K_2SO_4\cdot MgSO_4\cdot MgCl_2\cdot 6H_2O$ (hard crystalline masses, permanent in the air); kieserite $MgSO_4\cdot H_2O$ (only very slowly dissolved by water); besides polyhalite,

$$MgSO_4\cdot K_2SO_4\cdot 2CaSO_4\cdot 2H_2O,$$

and anhydrite, $CaSO_4$; salt, $NaCl$, and some minor components. These potassium minerals are not confined to Stassfurt; larger quantities of sylvine and kainite are met with in the salt mines of Kalusz in the eastern Carpathian Mountains. Important deposits are being worked in Thuringia and Baden, and others occur at Wittelsheim (Alsace) and at Suria (Catalonia, Spain). There are also undeveloped resources in Chile, Peru and Brazil. The Stassfurt minerals owe their industrial importance to their solubility in water and consequent ready amenability to chemical operations. In point of absolute mass they are insignificant compared with the abundance and variety of potassiferous silicates, which occur everywhere in the earth's crust; orthoclase (potash felspar) and potash mica may be quoted as prominent examples. Such potassiferous silicates are found in almost all rocks, both as normal and as accessory components; and their disintegration furnishes the soluble potassium salts which are found in all fertile soils. These salts are sucked up by the roots of plants, and by taking part in the process of nutrition are partly converted into oxalate, tartrate, and other organic salts, which, when the plants are burned, are converted into the carbonate, K_2CO_3. The "vinasse" of beet-sugar factories, *i.e.,* the material left in the retorts after the distillation of the fermented molasses. also consists largely of potassium salts (chiefly the carbonate) and the potash is either utilized directly as a manure or in the manufacture of soft soaps, or it is refined by fractional crystallization. It is a remarkable fact that, although in a given soil the soda-content may predominate largely over the potash salts, the plants growing in the soil take up the latter: in the ashes of most land plants the potash (calculated as K_2O) forms upwards of 90% of the total alkali. The proposition holds, in its general sense, for sea plants likewise. In ocean water the ratio of soda (Na_2O) to potash (K_2O) is 100:3·23 (Dittmar); in kelp it is, on the average, 100:5·26 (Richardson). Ashes particularly rich in potash are those of burning nettles, wormwood (*Artemisia* absinthium), tansy (*Tanacetum vulgare*), fumitory (*Fumaria officinalis*) and tobacco. According to Liebig, potassium is the essential alkali of the animal body; and it may be noted that sheep excrete most of the potassium which they take from the land as sweat, one-third of the weight of raw merino consisting of potassium compounds.

Sir Humphry Davy's Experiment.—To Sir Humphry Davy belongs the merit of isolating this element from potash, which itself had previously been considered an element. On placing a piece of potash on a platinum plate, connected to the negative of a powerful electric battery, and bringing a platinum wire, connected to the positive of the battery, to the surface of the potassium a vivid action was observed: gas was evolved at the upper surface of the fused globule of potash, whilst at the lower surface, adjacent to the platinum plate, minute metallic globules were formed, some of which immediately inflamed, whilst others merely tarnished. In 1808 Gay-Lussac and Thénard obtained the metal by passing melted potash down a clay tube containing iron turnings or wire heated to whiteness, and Caradau effected the same decomposition with charcoal at a white heat. Electrolytic methods are now generally employed for the manufacture of potassium. The Castner process used for sodium (*q.v.*) is somewhat unsatisfactory for potassium, but has been rendered more suitable by various modifications. Fused potassium hydroxide is electrolysed by means of a sheet-iron anode and an iron-wire cathode, the latter being surrounded by a cylinder of magnesite in order to prevent metallic potassium diffusing into the hydroxide in which it tends to dissolve. The temperature is kept as low as possible and air is excluded. The molten hydroxide may be replaced by a readily fusible mixture of potassium chloride and fluoride. The metal, however, is not in great demand, for it is generally found that sodium (*q.v.*), which is cheaper, and, weight for weight, more reactive, will fulfil any purpose for which potassium may be desired.

Pure Potassium.—Pure potassium is a silvery white metal tinged with blue; but on exposure to air it at once forms a film of oxide, and on prolonged exposure deliquesces into a solution of hydrate and carbonate. Perfectly dry oxygen, however, has no action upon it. (See DRYNESS, CHEMICAL.) At temperatures below 0° C it is hard and brittle; at the ordinary temperature it is so soft that it can be kneaded between the fingers and cut with a blunt knife. Its specific gravity is 0·865; hence it is the lightest metal known except lithium. It fuses at 62·5° C and boils at about 760°, emitting an intensely green vapour. It may be obtained crystallized in quadratic octahedra of a greenish-blue colour, by melting in a sealed tube containing an inert gas, and inverting the tube when the metal has partially solidified. When heated in air it fuses and then takes fire, burning into a mixture of oxides. Most remarkable, and characteristic for the group it represents, is its action on water. A pellet of potassium when thrown on water at once bursts out into a violet flame and the burning metal fizzes about on the surface, its extremely high temperature precluding absolute contact with the liquid, except at the very end, when the last remnant, through loss of temperature, is wetted by the water and bursts with explosive violence. The reaction may be written $2K+2H_2O=2KOH+H_2$, and the flame is due to the combustion of the hydrogen, the violet colour being occasioned by the potassium vapour. The metal also reacts with alcohol to form potassium ethoxide, while hydrogen escapes, this time without inflammation:

$$K+C_2H_5\cdot OH=C_2H_5\cdot OK+H.$$

When the oxide-free metal is heated gently in dry ammonia it is gradually transformed into a blue liquid, which on cooling freezes into a yellowish-brown or flesh-coloured solid, potassamide, KNH_2. When heated to redness the amide is decomposed into ammonia and potassium nitride, NK_3, which is an almost black solid. Both it and the amide decompose water readily with formation of ammonia and caustic potash. The metal dissolves in liquid ammonia to give a blue solution. Potassium at temperatures from 200° to 400° C occludes hydrogen gas, the highest degree of saturation corresponding approximately to the formula K_2H, but it seems probable that KH is the only compound formed. In a vacuum or in sufficiently dilute hydrogen the compound from 200° upwards loses hydrogen, until the tension of the free gas has arrived at the maximum value characteristic of that temperature. The hydride is used for the manufacture of potassium formate which results from the action of moist carbon dioxide: $KH+CO_2=H\cdot CO_2K$.

COMPOUNDS

Oxides and Hydroxide.— Potassium forms two well-defined oxides, K_2O and K_2O_4, whilst several others, of less certain existence, have been described. The monoxide, K_2O, may be obtained by strongly heating the product or burning the metal in slightly moist air; by heating the hydroxide with the metal:

$$2KOH+2K=2K_2O+H_2;$$

or by passing pure and almost dry air over the molten metal. It forms a grey brittle mass, having a conchoidal fracture; it is very deliquescent, combining very energetically with water to form caustic potash.

Potassium hydroxide or caustic potash, KOH, formerly considered to be an oxide, may be obtained by dissolving the metal or monoxide in water, but is manufactured by double decomposition from potassium carbonate and slaked lime:

$$K_2CO_3+Ca(OH)_2=2KOH+CaCO_3,$$

or by electrolytic methods similar to those used for sodium hydroxide. (See ALKALI MANUFACTURE.) In the former case, a solution of one part of the carbonate in 12 parts of water is heated to boiling in a cast-iron vessel by means of steam-pipes and the milk of lime added in instalments until a sample of the filtered mixture no longer effervesces with an excess of acid. The mixture is then allowed to settle in the iron vessel, access of air being prevented as much as practicable, and the clear liquor is syphoned off. The liquors after concentration in iron vessels are evaporated in a silver dish, and the residual oily liquid is then poured out into a polished iron tray, or into an iron mould to produce the customary form of "sticks," and allowed to cool. The solid must be at once bottled, because it attracts the moisture and carbonic acid of the air with great avidity and deliquesces. Nickel basins are better adapted than iron basins for the preliminary concentration of potash lye. The latter begin to oxidize before the lye has come up to the traditional strength of specific gravity 1·333 when cold, while nickel is not attacked so long as the percentage of real KOH is short of 60. For the fusion of the dry hydrate nickel vessels cannot be used; in fact, even silver is perceptibly attacked as soon as all the excess of water is away; absolutely pure KOH can be produced only in gold vessels. Glass and (to a less extent) porcelain are attacked by caustic potash lye, slowly in the cold, more readily on boiling.

Solid Caustic Potash.—Solid caustic potash forms an opaque, white, stone-like mass of dense granular fracture; specific gravity 2.1. It fuses considerably below and is perceptibly volatile at a red heat. At a white heat the vapour breaks down into potassium, hydrogen and oxygen. It is extremely soluble in even cold water, and in any proportion of water on boiling. On crystallizing a solution, the hydrate $KOH\cdot 2H_2O$ is deposited; $2KOH\cdot 9H_2O$ and $2KOH\cdot 5H_2O$ have also been obtained. The solution is intensely "alkaline" to test-papers. It readily dissolves the epidermis of the skin and many other kinds of animal tissue—hence the former application of the "sticks" in surgery. A dilute potash readily emulsionizes fats, and on boiling saponifies them with formation of a soap and glycerin. All commercial caustic potash is contaminated with excess of water (over and above that in the KOH) and with potassium carbonate and chloride; sulphate, as a rule, is absent. A preparation sufficing for most purposes is obtained by digesting the commercial article in absolute alcohol, decanting and evaporating the solution to dryness and fusing in silver vessels.

The peroxide, K_2O_4, discovered by Gay-Lussac and Thénard, is obtained by heating the metal in an excess of slightly moist air or oxygen, or better by melting the metal in a flask filled with nitrogen and gradually displacing this gas by oxygen; the first formed grey film on the metal changes to a deep blue, and then the gas is rapidly absorbed, the film becoming white and afterwards yellow. It is a dark yellow powder, which fuses at a high temperature, the liquid on cooling depositing shining tabular crystals; at a white heat it loses oxygen and yields the monoxide. Exposed to moist air it loses oxygen, possibly giving the dioxide, K_2O_2; water reacts with it, evolving much heat and giving caustic potash, hydrogen peroxide and oxygen; whilst carbon monoxide gives potassium carbonate and oxygen at temperatures below 100°. A violent reaction ensues with phosphorus and sulphur, and many metals are oxidized by it, some with incandescence.

Halogen Compounds.— Potassium fluoride, KF, is a very deliquescent salt, crystallizing in cubes and having a sharp saline taste; it is formed by neutralizing potassium carbonate or hydroxide with hydrofluoric acid and concentrating in platinum vessels. It forms the acid fluoride KHF_2 when dissolved in aqueous hydrofluoric acid, a salt which at a red heat gives the normal fluoride and hydrofluoric acid. Other salts of composition $KF\cdot 2HF$ and $KF\cdot 3HF$, have been described by Moissan.

Potassium chloride, KCl, also known as muriate of potash, closely resembles ordinary salt. It is produced in immense quantities at Stassfurt from the so-called "Abraumsalze" (waste salts). When hydrogen chloride is passed into a solution of potassium chloride the salt is completely precipitated as a fine powder. If the original solution contained the chlorides of magnesium or calcium or sulphate of potassium, all impurities remain in the mother-liquor (the sulphur as $KHSO_4$), and can be removed by washing the precipitate with strong hydrochloric acid. The salt crystallizes in cubes of specific gravity 1·995; it melts at about 800° and volatilizes at a bright red heat. It is extensively employed for the preparation of other potassium salts, but the largest quantity (especially of the impure product) is used in the production of artificial manures.

Potassium bromide, KBr, may be obtained by dissolving bromine in potash, whereupon bromide and bromate are first formed, evaporating and igniting the product in order to decompose the bromate:

$$6KOH+3Br_2=5KBr+KBrO_3+3H_2O;\ 2KBrO_3=2KBr+3O_2$$

(cf. CHLORATES); but it is manufactured by acting with bromine water on iron filings and decomposing the iron bromide thus formed with potassium carbonate. In appearance it closely resembles the chloride, forming colourless cubes which readily dissolve in water and melt at 722°. It combines with bromine to form an unstable tribromide, KBr_3.

Potassium *Iodide*.—Potassium iodide, KI, is obtained by dissolving iodine in potash, the deoxidation of the iodate being facilitated by the addition of charcoal before ignition, proceeding as with the bromide. The commercial salt usually has an alkaline reaction; it may be purified by dissolving in the minimum amount of water, and neutralizing with dilute sulphuric acid; alcohol is now added to precipitate the potassium sulphate, the solution filtered and crystallized. It forms colourless cubes which are readily soluble in water, melt at 685° and yield a vapour of normal density. It is sparingly soluble in absolute alcohol. Both the iodide and bromide are used in photography. Iodine dissolves in an aqueous solution of the salt to form a dark brown liquid, which on evaporation over sulphuric acid gives black acicular crystals of the tri-iodide, KI_3. The salt is very deliquescent; it melts at 45°, and at 100° decomposes into iodine and potassium iodide. For the oxyhalogen salts see CHLORATE, CHLORINE, BROMINE and IODINE.

Carbonate of Potash, popularly known as "potashes," was originally obtained in countries where wood was cheap by lixiviating wood ashes in wooden tubs, evaporating the solution to dryness in iron pots and calcining the residue; in more recent practice the calcination is carried out in reverberatory furnaces. This product, known as "crude potashes," contains, in addition to carbonate, varying amounts of sulphate and chloride and also insoluble matter. Crude potash is used for the manufacture of glass, and, after being causticized, for the making of soft soap. For many other purposes it must be refined, which is done by treating the crude product with the minimum of cold water required to dissolve the carbonate, removing the undissolved part (which consists chiefly of sulphate), and evaporating the clear liquor to dryness in an iron pan. The purified carbonate (which still contains most of the chloride of the raw material and other impurities) is known as "pearl ashes." Most of the carbonate which occurs in commerce is made from the chloride of the Stassfurt beds by an adaptation of the "Leblanc process" for conversion of common salt into soda ash. *(See* ALKALI MANUFACTURE.)

Chemically pure carbonate of potash is best prepared by igniting pure bicarbonate in iron or (better) in silver or platinum vessels, or else by calcining pure cream of tartar. The latter operation furnishes an intimate mixture of the carbonate with charcoal, from which the carbonate is extracted by lixiviation with water and filtration. The filtrate is evaporated to dryness (in iron or platinum vessels) and the residue fully dehydrated by gentle ignition. The salt is thus obtained as a white porous mass, fusible at a red heat (838° C) into a colourless liquid, which solidifies into a white opaque mass. The dry salt is very hygroscopic; it deliquesces into an oily solution ("oleum tartari") in ordinary air. The most saturated solution contains 205 parts of the salt to 100 of water and boils at 135°. On crystallizing a solution monoclinic crystals of $2K_2CO_3{\cdot}3H_2O$ are deposited, which at 100° lose water and give a white powder of $K_2CO_3{\cdot}H_2O$; this is completely dehydrated at 130°. The carbonate, being insoluble in strong alcohol (and many other liquid organic compounds), is much used for dehydration of the corresponding aqueous preparations. The pure carbonate is constantly used in the laboratory as a basic substance generally, for the disintegration of silicates, and as a precipitant. The industrial preparation serves for the making of flint glass, of potash soap (soft soap) and of caustic potash.

Potassium bicarbonate, $KHCO_3$, is obtained when carbonic acid is passed through a cold solution of the ordinary carbonate as long as it is absorbed. Any silicate present is also converted into bicarbonate with elimination of silica, which must be filtered off. The filtrate is evaporated at a temperature not exceeding 65°; after sufficient concentration it deposits on cooling anhydrous crystals of the salt, while the potassium chloride, which may be present as an impurity, remains mostly in the mother-liquor; the rest is easily removed by repeated recrystallization. The bicarbonate forms large monoclinic prisms, permanent in the air. When the dry salt is heated to 190° it decomposes into normal carbonate, carbon dioxide and water.

Sulphur Compounds.—Potassium sulphide, K_2S, was obtained by Berzelius in pale red crystals by passing hydrogen over potassium sulphate, and by Berthier as a flesh-coloured mass by heating the sulphate with carbon. When it is prepared by treating potash with sulphuretted hydrogen and adding a second equivalent of alkali, a solution is obtained which on evaporation in a vacuum deposits crystals of $K_2S{\cdot}5H_2O$. The solution is strongly caustic. It turns yellow on exposure to air, absorbing oxygen and carbon dioxide and forming thiosulphate and potassium carbonate and liberating sulphuretted hydrogen, which decomposes into water and sulphur, the latter combining with the monosulphide to form higher salts. The solution also decomposes on boiling. The hydrosulphide, KHS, was obtained by Gay-Lussac on heating the metal in sulphuretted hydrogen, and by Berzelius on acting with sulphuretted hydrogen on potassium carbonate at a dull red heat. It forms a yellowish-white deliquescent mass, which melts on heating, and at a sufficiently high temperature it yields a dark red liquid. It is readily soluble in water, and on evaporation in a vacuum over caustic lime it deposits colourless, rhombohedra1 crystals of $2KHS{\cdot}H_2O$. The solution is more easily prepared by saturating potash solution with sulphuretted hydrogen. The solution has a bitter taste, and on exposure to the air turns yellow, but on long exposure it recovers its original colourless appearance owing to the formation of thiosulphate. *Liver of sulphur* or *hepar sulphuris,* a medicine known to the alchemists, is a mixture of various polysulphides with the sulphate and thiosulphate, in variable proportions, obtained by gently heating the carbonate with sulphur in covered vessels. It forms a liver-coloured mass. In the pharmacopoeia it is designated *potassa sulphurata.*

Potassium sulphite, K_2SO_3, is prepared by saturating a potash solution with sulphur dioxide, adding a second equivalent of potash, and crystallizing in a vacuum, when the salt separates as small deliquescent, hexagonal crystals. The salt $K_2SO_3{\cdot}H_2O$ may be obtained by crystallizing the metabisulphite, $K_2S_2O_5$ (from sulphur dioxide and a hot saturated solution of the carbonate, or from sulphur dioxide and a mixture of milk of lime and potassium sulphate) with an equivalent amount of potash. The salt $K_2SO_3{\cdot}2H_2O$ is obtained as oblique rhombic octahedra by crystallizing the solution over sulphuric acid.

Potassium sulphate, K_2SO_4, a salt known early in the 14th century, was styled in the 17th century *arcanum* or *sal duplicatum,* being regarded as a combination of an acid salt with an alkaline salt. It was obtained as a by-product in many chemical reactions, and subsequently used to be extracted from kainite, one of the Stassfurt minerals, but the process is now given up because the salt can be produced cheaply enough from the chloride by decomposing it with sulphuric acid and calcining the residue. To purify the crude product it is dissolved in hot water and the solution filtered and allowed to cool, when the bulk of the dissolved salt crystallizes out with characteristic promptitude. The very beautiful (anhydrous) crystals have the habit of a double six-sided pyramid, but really belong to the rhombic system. They are transparent, very hard and absolutely permanent in the air. They have a bitter, salty taste. The salt is soluble in water, but insoluble in caustic potash of sp.gr. 1·35, and in absolute alcohol. It fuses at 1,078°. The crude salt is used occasionally in the manufacture of glass. The acid sulphate or bisulphate, $KHSO_4$, is readily produced by fusing thirteen parts of the powdered normal salt with eight parts of sulphuric acid. It forms rhombic pyramids, which melt at 197°. It dissolves in three parts of water of 0° C. The solution behaves as if its two congeners, K_2SO_4 and H_2SO_4, were present side by side uncombined. An excess of alcohol, in fact, precipitates normal sulphate (with little bisulphate) and free acid remains in solution. Similar is the behaviour of the fused dry salt at a dull red heat; it acts on silicates, titanates, etc., as if it were sulphuric acid raised beyond its natural boiling point. Hence its frequent application in analysis as a disintegrating agent. The sulphate is also used in alum manufacture; fertilizer and medicine. For the salts of other sulphur acids, *see* SULPHUR.

Potassamide, NH_2K, discovered in 1811, is obtained as an olive green or brown mass by gently heating the metal in ammonia gas, or as a white, waxy, crystalline mass when the metal is heated in a silver boat. It decomposes in moist air, or with water, giving caustic potash and ammonia, in the latter case with considerable evolution of heat. For the nitrite, *see* NITROGEN; for the nitrate, *see* SALTPETRE; and for the cyanide, *see* PRUSSIC ACID; for other salts *see* the articles wherein the corresponding acid receives treatment.

Analysis, **etc.**—All volatile potassium compounds impart a violet coloration to the Bunsen flame, which is masked, however, if sodium be present. The emission spectrum shows two lines, $K\alpha$, a double line towards the infra-red, and $K\beta$ in the violet. The chief insoluble salts are the perchlorate, hydrogen tartrate and chloroplatinate (platinichloride); and the difference in solubility between the potassium and ammonium salts of "eikonogen" enables a separation to be effected, most other salts of these two radicals being similarly soluble. The atomic weight was determined by Stas, Richards and Stahler.

MEDICINE

Pharmacology.—Numerous salts and preparations of potassium are used in medicine; viz., *Potassii Carbonis* (salt of tartar), dose 5 to 20 gr., from which are made *(a) Potassii Bicarbonas,* dose 5 to 30 gr.; (b) *Potmsa Caustica,* a powerful caustic not used internally. From caustic potash are made: (1) *Potassii Permanganas,* dose 1 to 3 gr, used in preparing *Liquor Potassii Permanganatis,* a 1% solution, dose 2 to 4 dr., (2) *Potassii Iodidum,* dose 5 to 20 *gr.,* from which are made the *Linamentum Potassii Iodidi cum Sapone,* strength 1 in 10, and the *Unguentum Potassii Iodidi,* strength 1 in 10. (3) *Potassii Bromidum,* dose 5 to 30 gr. (4) *Liquor Potassae,* strength 27 gr. of caustic potash to the oz. *Potassii Citras,* dose 10 to 40 gr. *Potassii Acetas,* dose 10 to 60 gr. *Potassii Chloras,* dose 5 to 15 gr., from which is made a lozenge, *Trochiscus Potassii Chloratis,* each containing 3 gr. *Potassii Tartras Acidus* (cream of tartar), dose 20 to 60 gr, which has a subpreparation *Potassii Tartras,* dose 30 to 60 gr. *Potassii Nitras* (saltpetre), dose 5 to 20 gr. *Potassii Sulphas,* dose 10 to 40 gr. *Potassii Bichromas,* dose $\frac{1}{10}$ to $\frac{1}{5}$ gr.

Toxicology.—Poisoning by caustic potash may take place or poisoning by pearl ash containing caustic potash. A caustic taste in the mouth is quickly followed by burning abdominal pain, vomiting and diarrhoea, with a feeble pulse and a cold clammy skin. The treatment is washing out the stomach or giving emetics followed by vinegar or lemon juice and later oil and white of egg.

Therapeutics. — Externally: Caustic potash is a most powerful irritant and caustic; it is used with lime in making Vienna paste, which is occasionally used to destroy morbid growths. *Liquor potassae* is also used in certain skin diseases. The permanganate of potash is an irritant if used pure. Its principal action is as an antiseptic and disinfectant. If wet it oxidizes the products of decomposition. It is used in the dressing of foul ulcers. The 1% solution is an antidote for snake-bite.

Internally: Dilute solutions of potash, like other alkalis, are used to neutralize the poisonous effects of strong acids. In the stomach potassium salts neutralize the gastric acid, and hence small doses are useful in hyperchlorhydria. Potassium salts are strongly diuretic, acting directly on the renal epithelium. They are quickly excreted in the urine, rendering it alkaline and thus more able to hold uric acid in solution. They also hinder the formation of uric acid calculi. The acetate and the citrate are valuable mild diuretics in Bright's disease and in feverish conditions, and by increasing the amount of urine diminish the pathological fluids in pleuritic effusion, ascites, etc. In tubal nephritis they aid the excretion of fatty casts. The tartrate and acid tartrate are also diuretic in their action and, as well as the sulphate, are valuable hydragogue saline purgatives. Potassium nitrate is chiefly used to make nitre paper, which on burning emits fumes useful in the treatment of the asthmatic paroxysm. Lozenges of potassium chlorate are used in stomatitis, tonsilitis and pharyngitis; it can also be used in a gargle, 10 gr. to 1 fl.oz. of water. Its therapeutic action is said to be due to nascent oxygen given off; so it is local in its action. In large doses it is a dangerous poison, converting the oxyhaemoglobin of the blood into methaemoglobin. Internally the permanganate is a valuable antidote in opium poisoning. The action of potassium bromide and potassium iodide has been treated under bromine and iodine (*qq.v.*). All potassium salts if taken in large doses are cardiac depressants; they also depress the nervous system, especially the brain and spinal cord. Like all alkalis if given in quantities they increase metabolism.

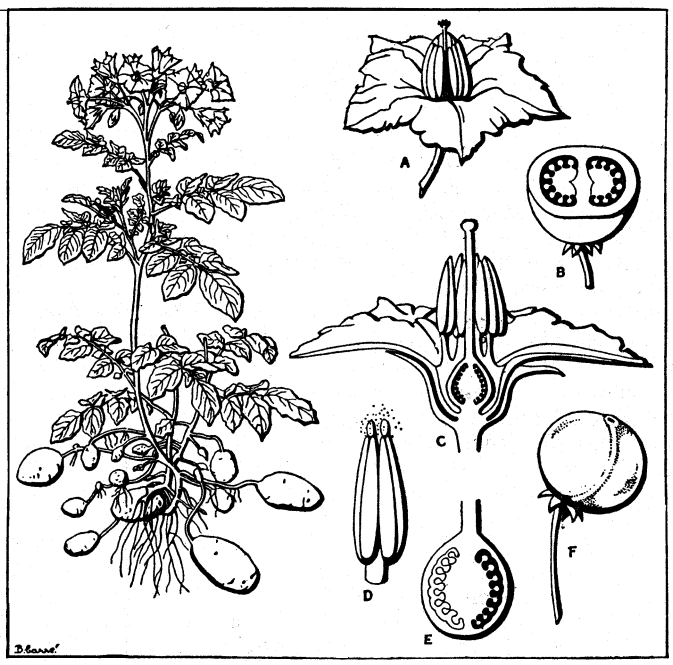
POTATO. The potato belongs botanically to the section *Tuberarium* of the genus *Solanum*, the members of which are. with few exceptions, tuber bearing. This section comprises not only the cultivated forms but many wild species, the number of which probably exceeds 100.

Formerly the species *Solanum tuberosum* was understood to comprise all cultivated varieties of the potato, but these were later assigned to 14 species. *S. tuberosum* is the most important of the group since it includes the Chilean cultivated forms as well as the commercial varieties of North America and Europe. Most of the common cultivated varieties of the Andes region belong to the species, *S. andigenum*. The 12 remaining species are grown in small local areas in the Andean countries and more or less resemble wild species in their general appearance.

Origin. — The origin of the potato is lost in antiquity, but it is known that when the Spaniards invaded South America in 1524 they found a large number of varieties and species under cultivation, the tubers of which were used as a common article of food by the natives. Where these varieties and species originated is more or less conjecture, but they seem to be native to the American continents since their relatives are still found growing wild in the elevated regions extending from the southwestern part of the United States to the southern part of South America, particularly in the higher altitudes of Bolivia and Peru and the coastal regions and nearby islands of Chile. All the species seem to require a cool climate; they are found growing in regions near the equator at high altitudes and none is known to occur under tropical conditions. If the origin of the potato is uncertain, information concerning its introduction into other countries is also shrouded in mystery. The exact history of such introductions has been lost, and the few historical stories that remain prove to have little solid foundation. Sir Walter Raleigh, for instance, is said to have brought back the potato from Virginia in 1585, yet on investigation it appears that the true potato did not reach Virginia until more than 100 years after this date. Nor could Raleigh have obtained the potato from Peru, for his ships apparently never visited that country.

Sir John Hawkins is also credited with having introduced the potato in 1565. Investigation shows that the potatoes brought back by Hawkins were the "sweet potato," *Ipomoea batatas* and not the ordinary potato, *S. tuberosum*. Claims are also made for Drake in this connection. Certainly his ships passed through the Straits of Magellan in 1578 and turned northwards looting the coast towns of Chile and Peru after which he returned to England across the Pacific and Indian oceans thereby completing his second renowned trip around the world. There is, however, no record that potatoes were brought on his ship "Pelican," and indeed it was not until 1586 that he is alleged to have introduced the potato. The Germans are exponents of the Drake story, for there stands in Offenburg, Baden a monument inscribed: "Sir Francis Drake introducer of the Potato into Europe in the year of our Lord 1580."

It is probable that the Spaniards gave the potato to Europe.



FROM BAILLON, "HISTOIRE DES PLANTES" (BONNAIRE)

POTATO (SOLANUM TUBEROSUM). SHOWING WHOLE PLANT WITH UNDERGROUND STEMS AND TUBERS (POTATOES)

A. Single flower. B. Fruit cut across to show placenta and ripening ovules. C. Longitudinal section through flower. D. Two ripe stamens opening and shedding pollen. E. Longitudinal section through ovary. F. Fruit

In the *Cronica de Peru* of Pedro Creça (Seville, 1553) the potato is mentioned under the name "battata" or "papa." Hieronymus Cardan, a monk, is supposed to have been the first to introduce it from Peru into Spain, from which country it passed into Italy, from there early in the 17th century to Austria, then to Germany, from Germany to Switzerland and finally to France.

The earliest representation of the plant is to be found in Gerard's *Herbal*, published in 1507. The plant is mentioned under the name *Papus orbiculatus* in the 1st edition of the *Catalogus* of the same author published in 1596 and again in the 2nd edition which was dedicated to Sir Walter Raleigh (1599). It is, however, in the *Herbal* that we find the first description of the potato accompanied by a woodcut sufficiently correct as to leave no doubt whatever as to the identity of the plant. In this work (p. 781) it is called "Battata virginiana sive Virginianorum et Pappus, Potatoes of Virginia."

In 1629, Parkinson, the friend and associate of Johnson, published his *Paradisus*, in which (p. 517) he gives an indifferent figure of the potato under the name of "Papas seu Battatas Virginianorum."

Little is known of the introduction of the potato into North America. It is generally believed that the English colonists of Virginia and Carolina obtained the potato from Spaniards or from other travellers. The most authentic report shows that potatoes were first grown in the United States at Londonderry, N.H., in 1719 from stock brought from Ireland. It was for this reason, no doubt, that the potato has been called the "Irish" potato. The name is still used, especially in the southern states, where it serves to distinguish the potato from the sweet potato.

Plant Characteristics. — The potato plant is a herbaceous annual, propagated by true seeds or by the tubers. The aerial stems may be erect or procumbent and have several axillary branches. Stems are round or angular, pubescent or glabrous, green or more or less purple. The first leaf on the stem is usually simple, and the later ones pinnate with three or four pairs of large, entire, petiolated leaflets and smaller ones between. The leaves are arranged on the stem in a spiral. Fibrous roots arise in groups of three just above the nodes on the underground part of the stem. They may extend to a depth of 3 or 4 ft. and nearly as far horizontally. As most of the roots are comparatively near the surface the potato does not seem adapted to culture without irrigation or frequent rainfall.

The cymose inflorescences occur in the axil of about every sixth node. The flowers of an inflorescence open progressively over a period of several days. They produce no nectar and are seldom visited by insects. The rotate corolla is five-lobed and white, yellow, purple, blue or striped, according to the variety. The five stamens are borne on the corolla tube and converge around the pistil. The large erect anthers dehisce by a terminal pore. There are two carpels forming the two-loculed ovary with a single style. The fruit, or seed ball, is a green round berry about $\frac{1}{2}$-$\frac{3}{4}$ in. in diameter and generally contains numerous seeds. The seeds are very small, kidney-shaped and smooth and are embedded in the pulp of the fruit.

The leaves on the underground part of the vertical stem are small and scalelike; in their axils lateral stems called stolons arise. These are of variable length, more or less fleshy and of typical stem structure. The tubers are swellings arising at the end of these stolons. The tuber is a shortened, thickened, underground stem, with scalelike leaves or leaf scars subtending the eyes. The eye in its entity is a leaf scar with its subtended axil which contains a lateral branch and the latter's axillary buds and undeveloped internodes. Because of short internodes, the nodes are brought close together and the buds lie in nearly the same plane. Since there are several buds on each of these shortened branches, it is possible to get several shoots from an eye. The central bud in an eye is the terminal bud of the branch and develops first upon renewal of growth. There is also a correlation between the development of different eyes on the tuber. Sprouts usually develop first from eyes at the apical or distal end of the tuber; this development is known as "apical dominance." When the vascular connection between the different eyes is severed by cutting the tuber into pieces or by notching around the eyes, apical dominance disappears and all eyes develop at about the same rate. Apical dominance within the tuber and within the individual eyes disappears when the first sprouts are destroyed or are checked in their growth.

The epidermis of the tuber sloughs off in the early stages of development and is replaced with a periderm six to ten cells thick. The periderm consists of small flat cells which become suberized during the ripening of the tuber or upon exposure to dry air. Thus a tough skin is formed which protects the tuber against

TABLE I.—Potato Area and *Output, 1937*

bruising. It is fairly impermeable to gases. Lenticels take the place of stomata. Below the periderm is a rather dense layer of cortex which is variable in width and consists of small parenchyma cells densely filled with starch grains. The vascular bundles approach the surface of the tuber at the eyes. The pith enclosed by the vascular ring constitutes the greater portion of the tuber It may be divided into the more dense portion, the outer medulla. and the less dense portion, the inner medulla. The medullary regions consist of large parenchyma cells less densely filled with starch and other contents than is the cortex.

World Production. — Most of the accounts of the introduction of the potato into Europe and North America are without doubt legendary, but the spectacular increase of the potato as a food crop is not legendary. It is one of the miracles of agriculture and is grown in almost every important agricultural country in the world. Though it succeeds best in the cooler regions, it has made rapid development as a food crop in many other places and exceeds, in point of total production, that of any other table plant grown.

It will be noted in Table I that the countries which may be classed as cool produced the highest average yields. The average for the United States as a whole is comparatively low, although it had increased to approximately 4 tons per acre in 1942. The yields in Maine and Idaho, with cool summer climates, and in California, where the potato crop is grown for the most part in late winter and early spring, compare favourably with the highest yielding countries of Europe. A plentiful supply of irrigation water in California and Idaho also accounts to some extent for the large yields produced there. The international trade in potatoes is quite important, as indicated by Table II.

Europe as a whole exports more potatoes than it imports, as do also Canada and the United States. On the other hand, Central America, South America, Africa and Asia are deficit zones.

The demand in England and Wales is not satisfied by the home crop, and supplies are sent from both Scotland and Ireland, where production is always in excess of home needs. In most seasons the British Isles as a whole are almost self-supporting in potatoes. Imports of early kinds, however, are brought in from the Canary Isles, Spain, France and the Channel Islands in the early months when people have tired of eating "old" tubers. Commercial production of the main crop is centred in Lincolnshire, Yorkshire, Lancashire and Durham in England; Forfar, Fife and Perth in Scotland and in Counties Down and Antrim in Northern Ireland.

Potatoes are grown throughout France, though in some of the departments the soils are not well suited to culture and acreages are small. In other departments, Vienne, Rhin, Saône-et-Loire, Loire, Haute-Loire, Loire Inférieure, Maine-et-Loire and Morbihan, considerable areas are planted for commercial production. In certain specially favourable places such as St. Malo, Brittany and also in the Rhône valley, quick-growing varieties are planted to give an early supply to the markets not only of France but in normal times to England also.

Potato production in Germany is of two kinds. The crop of the west is grown mainly for table purposes, that of the east mainly for industrial purposes — though naturally much variation occurs at times. In eastern Germany there exist vast tracts of light sandy soil of little use for grass or cereal production, but by continuous and judicious manuring with fertilizers they have been rendered fertile for potatoes which are grown in large quantities and largely used for making farina or alcohol.

The late or main crop of potatoes in the United States is grown mostly in the states bordering Canada, where climate and soil are most favourable. The states leading in production are Maine, Idaho, Minnesota, New York, Michigan, Wisconsin, Pennsylvania, North Dakota, Colorado and California. Every state produces potatoes at some season, but the surplus commercial crop is grown mostly in the above named states. Colorado, California, Florida, Alabama, Louisiana, North Carolina, South Carolina. Virginia, Maryland and New Jersey ship to distant markets when the potatoes from the north are scarce. The southern states grow the crop in the winter and spring, when the temperatures are comparatively cool,

Varieties — Many hundreds of varieties of potatoes are grown in the different countries of the world. In England and America they are divided into first earlies, second earlies, mid-season or early main crop and main crop or late varieties. In England the heaviest croppers among the first earlies are Epicure, Duke of York, Sharpe's Express and Immune Ashleaf. The principal second early and main crop varieties are Ally, King George, Great Scott, King Edward, Arran Chief, Majestic and Kerr's Pink.

For many years the varieties grown commercially in the United States were mainly those which were originated by pioneer potato breeders in the 19th century. Some of these were products of hybridization, some were discovered as mutations or "sports," others originated as chance seedlings. A number of these continue to be standard varieties in certain sections of the country. Among them are the early varieties, Irish Cobbler, Triumph and Early Ohio, and the late varieties, Green Mountain, Rural New Yorker No. 2, Russet Rural, White Rose, Burbank and Russet Burbank. The National Potato Breeding program, organized cooperatively by the U. S. department of agriculture and state experiment stations, distributed to growers 16 new varieties. Among these are 4 first earlies: Earlaine, Mesaba, Warba and Red Warba; 3 second earlies: Chippewa, Pawnee and Kasota and 8 late varieties: Katahdin, Houma, Golden, Pontiac, Sebago, Sequoia, Erie and Mohawk.

Dr. William Stuart of the department of agriculture classified the American varieties into 12 groups, largely on the basis of tuber characters, season of maturity and blossom colour. Each group was named for the leading variety in it and contains all of the commercially important varieties of the respective type which it represents. The 12 groups are: Cobbler, Triumph, Early Michigan, Rose, Early Ohio, Hebron, Burbank, Green Mountain, Rural, Pearl, Peachblow and Up to Date.

Potato Soils. — The potato can be grown on almost any soil, but deep, rich sandy loams or well drained alluvial silts are most suitable. The Lancashire and a part of the Lincolnshire and Irish crop are produced in black peat. These soils produce good yields, but the tubers are dull and dark in appearance and sell at lower prices than bright skinned tubers produced in the red sandstone silts and limestone soils. One of the most ideal soils for potatoes in the United States is the Caribou loam in Aroostook county, Maine. This is a chocolate brown coloured soil abundantly supplied with small decomposing fragments of shale rock with which it is underlaid.

It has been found highly profitable to grow potatoes on the muck or peat soils that are so extensive in a number of states. The potatoes grown on such soils usually have good shape, but like those grown on the Irish peat they have a dark appearance. This difficulty is overcome by the practice of many growers of brushing or washing the tubers before they are packed for market. When this is done the potatoes often bring a premium.

Rotations. — The importance of an abundant supply of organic matter in the soil cannot be over-emphasized. A large amount of humus keeps the land in a friable condition and provides a continuous supply of available plant food. There is no general and well-defined system of crop rotation adhered to in any of the large potato growing centres. The desirability of rotating crops is well understood, but the temptation to grow a money crop as often as possible is very great so that the benefits from the practice of rotation are often sacrificed to the prospect of immediate gain. In England the position of the potato crop in the rotation varies very much in different localities, but potatoes do particularly well after old grass or a short fallow. In the United States the potato is usually grown in a rotation series of two or more crops; the one preceding is preferably a legume. Type and length of rotation depend on the kind of agriculture practised. In the Aroostook section of Maine, where the potato is the major crop, a three-year rotation of potatoes, oats and clover is standard, the clover being usually plowed under as green manure.

Sweet clover commonly precedes potatoes in the rotation in the central states and alfalfa in the western states. In most New England and middle Atlantic states timothy sod containing clover residue is plowed before potato planting. Frequently the sod residue is too scanty to be of much benefit to the potato crop.

Along the eastern seaboard potatoes are commonly grown year after year on the same soil. If little or no stable manure is available, the growers depend on rye as a winter green manure crop to maintain the soil humus supply. In the south, velvet beans, soybeans and cowpeas are used for the same purpose. Rotation is necessary in many sections where the soil reaction is nearly or quite alkaline to avoid infection of the tubers with the common scab disease. In these sections growers avoid the use of lime, and an effort is made to use commercial fertilizers that increase soil acidity. It is usually advisable to decrease the acidity of potato soils only when and to the extent necessary to promote the growth of legumes in the rotation.

Fertilization and Preparation of Land.—Stable manure is always beneficial to the potato crop, and within reason the greater the dressing the larger the crop. In practice in England not more than 20 tons per acre should be applied. Often the amount has to be cut to 10 or 12 tons; and where this is done, the deficiency should be made good by using some other material. Seaweed, for instance, is an excellent substitute and is much used by the potato growers of Scotland, Ireland, Cornwall and the Maritime Provinces of Canada. Irish growers have to use artificial fertilizers as a supplement. Most experimenters are agreed that a fertilizer containing nitrogen, phosphates and potash is desirable, but the exact proportion in which they should be mixed depends in large measure on specific soil requirements.

The following mixture per acre may be generally depended upon to produce good crops:

2 cwt. sulphate of ammonia
6 cwt super phosphate,
2 cwt. sulphate or muriate of potash

In the trials conducted at the Rothamsted experimental station in England, the nitrogen fertilizers proved over a period of years the most consistent in their action, giving every year with rare exceptions an increase of about 20 cut. of potatoes per cwt. of sulphate of ammonia used, whatever the season and whether or not farmyard manure was used. At Rothamsted there was little variation from season to season in the maximum yield of potatoes obtainable by good manuring. Their maximum was 11-13 tons per acre and usually 4 cwt. of sulphate of ammonia and 4 cwt. of sulphate of potash per acre were necessary to secure this. Economy of either ammonia or potash reduced the yield. The action on other soil would no doubt be somewhat different.

In the eastern and southern sections of the United States, chemical fertilizers make up nearly 3 of the total cost of production. In Maine and along parts of the Atlantic seaboard 1-1½ tons to the acre of a complete fertilizer is commonly applied. Westward and on heavier soils a smaller quantity of fertilizer containing less nitrogen and potash is used. In the first mentioned regions 5-8-7 or 4-8-7 analyses are recommended while on the newer and heavier soil types 4-12-4 and 5-10-5 are often used. Double-strength fertilizer in correspondingly decreased acre applications is also used. When stable manure is applied liberally, as in the dairy regions, commercial nitrogen may not be needed.

Modern planters are equipped to distribute commercial fertilizer in bands on each side of the seed piece and well mixed with the soil to avoid possible burning of the sprouts. Stable manure when used may be spread on the land by hand or with a manure spreader, either before or after the land is plowed. Some growers prefer to plow the manure under while others favour its application to the plowed land. Regardless of how or when it is applied, the best results are obtained when it is thoroughly incorporated with the soil and well decomposed before planting time.

Where potatoes follow the cereal crop, which frequently happens in England, preparation of the land should begin with an autumn cleaning followed by deep winter plowing and spring cultivation to give moderately fine tilth. In April, the ridging plow is used to throw the soil into ridges between which lie the furrows (distance between the furrows being about 27 in.) into which the potato-sets will go; before these are planted it is customary to scatter the barnyard manure and artificial fertilizers in the furrows so that they lie close to the sets.

In the United States it is generally desirable to plow the land for the potato crop in the fall, except where soil is liable to wash badly during the winter. Fall-plowed land should be disked and harrowed as early as possible in the spring and then kept friable until the crop is planted. Spring-plowed land should be disked as plowed and kept mellow. The deeper it is prepared and the more finely it is pulverized, the more suitable it is for producing large yields. It is much easier to do this before than after planting. The old adage that "a stitch in time saves nine" is quite applicable to the proper preparation of the land.

Seed.—The importance of using good seed cannot be overemphasized. but the term "good seed" needs careful definition. A potato tuber of any size when planted is capable of giving a crop. but in practice in Great Britain and parts of the U.S. it is found most economical to select seed tubers weighing approximately 2-3 oz. These can be planted whole. If large tubers are used they may be cut into seed pieces or sets. The latter is the common practice in the larger growing areas of the United States.

Good seed cannot be judged by appearance alone. It should be true to name and free from diseases, and the variety should be well adapted to the region in which it is to be grown. It is impossible even for experts to recognize varieties by examination of the tubers alone, so a record of the purity of the crop from which the seed stock was selected is the most reliable guide. Unfortunately tubers infected with virus diseases such as mosaics, leaf roll, crinkle or curly dwarf cannot be distinguished from healthy potatoes. The disease readings of the crop from which the seed was harvested is the only sure guide. If the parent crop was all of one variety, free from mosaics, leaf roll, crinkle, spindle tuber and curly dwarf, the seed selected from it has a good history and a good potential yielding capacity; if the parent crop was mixed or had much virus infection, the seed from it will be distinctly inferior, regardless of the appearance of the seed tubers.

The virus diseases are not peculiar to any country or region, but in some places and in some seasons they spread more rapidly than in others. They are spread mostly by insect vectors such as aphids or plant lice; conditions that favour insect infestations also favour the spread of these diseases. Potato crops grown in the colder districts are known usually to be freer of viruses than those of the warmer regions, and in consequence the former districts are the better areas in which to grow potatoes for seed. Consequently, growers in the southern districts of the United States buy nearly all of their seed from producers in the north and the Maritime Provinces of Canada. This is necessary because southern-grown potatoes are often seriously devitalized by heat and virus diseases.

To combat these diseases and raise the standards of potato cultivation, many countries—including the United States, Canada. the Netherlands, England, Scotland, Northern Ireland and the Irish Free State—have established systems of seed-potato-certification under which fields of potatoes are examined by inspectors and certificates given for those crops that reach certain specified standards of purity to type and freedom from diseases. The increase in the production of such seed in the United States was tremendous. In 1919 about 475,000 bu. of potatoes were certified, and in 1941 more than 17,000,000 bu. met the certification standards.

Storage is an important factor in the maintenance of good seed. At harvest time potatoes are in a dormant condition and cannot be made to sprout at once. This rest period lasts from about 6 weeks to 3 months depending on the variety and the conditions under which the tubers are stored. Tests have shown that dormancy can be maintained in some varieties for 6 to 8 months at temperatures ranging from 36° to 40° F. When kept at high temperatures the tubers sprout after a few weeks and soon become shrunken and lose vitality; each successive generation of sprouts is weaker than the preceding one. In fact, seed vigour in stored tubers can be measured to a degree by noting the character of the sprouts; if slender and originating from many eyes the seed may be adjudged weak. Long storage sprouts should not be allowed to develop. In preparing the seed for planting it is common practice to disinfect uncut seed potatoes against such tuber-borne diseases as common scab, rhizoctonia (black scurf) and blackleg. This is done at any time up to the planting date, preferably when the tubers are in a clean, dormant condition Various disinfectants and methods are used. Corrosive sublimate (mercuric chloride) and formaldehyde have been used most. Treatment of uncut rather than cut tubers is advised.

In the mercuric chloride (corrosive sublimate) treatment the standard solution is made by dissolving 1 part of mercuric chloride in 1,000 parts of water, or, 4 oz. in 30 gal. of water. Potato tubers are immersed for 30 min. to 2 hr. in this solution. Mercuric chloride goes into solution very slowly in cold water and it should therefore be dissolved in a small volume of hot nater. The solution should be prepared and used in wooden, enamel or concrete containers. The solution decreases in strength with use. To correct this, ½ oz. of the chemical should be added for every 4 bu. of potatoes treated for 2 hr. If a shorter treatment is used, the amount of chemical added should be reduced proportionately. Enough water should be added each time to bring the solution up to its original volume. Make up a fresh solution after 4 treatments. Wetting the tubers for 20-24 hr. before treatment makes the disinfection more effective.

Cold formaldehyde is not effective in controlling rhizoctonia but may be used for the control of scab. The solution is prepared by adding 1 pt. of formalin (40% commercial formaldehyde solution) to 30 gal. of water. The tubers are immersed in this solution for 2 hr.

Hot formaldehyde is not so effective as mercuric chloride but is widely used in some places. Previous to being treated it is desirable to keep the potatoes wet for 24 hr. The solution is made up by dissolving 2 pt. of formalin in 30 gal. of water heated to a temperature of 124° to 126° F. and held within these limits by steam or by means of a fire maintained beneath the tank. The tubers are then dipped for 4 min. A false bottom to the tank is necessary to keep the tubers at the bottom from becoming overheated. The solution should not be warmer than 126° F. because above this temperature injury to the sprouting of the potatoes results. Nor should it be cooler than 124° as it would then not control the disease if the tubers are dipped for only the 4-min. period. To allow for condensation water when live steam is used for heating, 0.9 pt. of formalin should be added after every 50 bu. of tubers are treated. The solution does not lose its strength on standing if it is well covered and may safely be kept thus for a few days or weeks. Covering the tubers with a canvas or burlap for an hour after treatment adds to the efficiency of this method.

It is considered by a number of experts in the United States that such seed treatments are very inefficient in the control of disease and in most cases not worthwhile. If the seed tubers are clean there is no need for treatment. If they are badly infected they should be sold for table stock. If diseased tubers must be used some of the organisms will be killed by the mercuric treatments, but very few by formaldehyde and if the treated tubers are planted in soil infested with disease organisms, the resulting crop of tubers will be diseased.

Green sprouting seed potatoes before planting in order to hasten the development of marketable tubers is a common practice in Great Britain and on the continent but is employed to a very limited extent by U.S. growers. This is essentially a germination test which results in more perfect stands of plants, less disease, increased earliness and possibly higher yields.

The questions of size of the seed piece and of planting whole rather than cut seed are still not fully answered. The superiority of whole over cut or of cut seed over whole has been demonstrated for both, and the conclusion can be drawn that no general rule can be given, but that much depends on the variety and the environmental conditions in which the crop is grown. Seed pieces should be cut large enough to ensure at least one vigorous healthy sprout. They should be blocky and as uniform in size and shape as possible especially where they are planted with a self-feeder planter. Pieces weighing less than an ounce are subject to drying out when planted in hot dry soil and may result in weak plants or missing hills. Experiments have shown that the eyes from the basal and the seed end of the tuber of most varieties are of equal value for seed.

As a rule potatoes are planted as soon after cutting as possible. This is a satisfactory method in the large producing areas of the United States if the soil at planting time is not too wet or too dry and the weather too cold. In regions where seed piece rot is a problem, whole tubers or suberized seed should be used. Suberization or corking over is best accomplished by storing the cut tubers in an atmosphere of relatively high humidity and a temperature range of from 60° to 70° F. Under these conditions a protective layer of cork cells will develop over the cut surface forming an effective barrier against disease organisms in the soil. The use of such materials as hydrated lime, gypsum and sulphur to cause rapid drying is no longer recommended.

Planting and Cultivation. — Potatoes are planted in the United States every month of the year although the bulk of the crop is planted from March 15 to June 30. The date depends on the regional climate, latitude or altitude, but it is desirable to plant at such date as will allow the period of blossoming and tuber-setting to come in relatively cool weather. In some regions subject to late blight infection, the early planted crop is most likely to escape while at the same time it may be more subject to injury by leafhoppers and flea beetles.

In England the soil is thrown into ridges with a ridging plow. The seed pieces are planted by hand in the furrows between these ridges. The distance between the furrows is about 27 in. and between the plants in the row, 10 in.–I ft. The seed pieces are covered by splitting the ridges with the ridging plow so that the soil falls into the furrows on either side. There are potato planting machines which open the furrows, place the fertilizers and sets in position and cover them as they proceed across the field. Hand planting is practised on many of the small acreages in the United States, but probably more than ¾ of the commercial acreages are planted with machines. Many of these machines plant one row at a time, but two row planters are quite common and some plant 4 rows in one operation. These planters are of two types, an automatic picker type requiring only one man to operate or an assisted feed type requiring an additional man to regulate the flow of the seed. Modern planters are equipped to distribute fertilizer in bands on each side of the seed piece and mix it with the soil to avoid possible burning of the potato sprouts. These machines can be adjusted to various distances between rows and to drop the sets at various distances apart in the row. Four inches is the depth of planting recommended, with shallower depth for heavy soils and deeper for sandy soils. The average amount of seed used is approximately 15 bu. to the acre, the range being from 8 to 30.

Cultivation for weed control is very important, as the potato plant is very sensitive to weed competition. On the other hand the plant may be seriously checked in growth and yields reduced when harsh, deep, late season cultivation results in cutting off the extensive, lateral, fibrous root system and disturbing the developing tubers between the rows. Thorough seed bed preparation and early season cultivation rather than late are therefore recommended. If late cultivation is practised it should be very shallow and just deep enough to cut off the weeds. Moisture conservation is not, as was formerly thought, a prime factor in cultivation. Shallow cultivation of heavy soils to break the crust that forms after heavy rains is desirable to provide soil aeration and permit absorption of later rains. Ridging of rows especially on heavy soils has several advantages. It affords an effective means of weed control, run-off of excess surface water, protection of the tubers from sunburn and to a degree from late blight spores and allows easier digging of the crop. Tractor or horse drawn cultivators for early cultivation and hillers or hoe ridgers are used for ridging the rows.

POTATO DISEASES AND INSECTS

Potato diseases are very numerous. They can be classed as virus, fungus, bacterial and physiological.

Virus Diseases. — The virus diseases are not due, as far as is known, to any living organism or to nutritional disturbances. They were formerly believed to be the result of degeneration brought about by continuous vegetative propagation of a variety. Thby were spoken of as "degeneration" diseases. The fallacy of this belief has been clearly demonstrated. The most troublesome virus diseases are mild mosaic, latent mosaic, rugose mosaic, leaf roll, spindle tuber and yellow dwarf.

Mild Mosaic.—The usual symptom of mild mosaic is the mottling of the leaves. The leaflets, instead of being uniformly green, show different shades of green or a slight yellowness; the leaves may also show some crinkling. In many cases the name "mild" is a misnomer, since the disease can be very severe. In such cases the plants may be dwarfed and the yield markedly reduced. Under hot, dry conditions the mosaic symptoms may not be so marked or may disappear altogether, but the yield of diseased plants is nevertheless diminished.

Latent Mosaic.—This disease is true to name in varieties like the Green Mountain and Irish Cobbler, in which it is present in 100% of the plants. No disease symptoms develop in these varieties and it is not known if the yields are reduced since no tubers can be found free from the virus and as a consequence no comparative yield tests between diseased and healthy plants can be made. In other varieties and seedlings it can hardly be considered latent since various reactions are discernible. Some varieties show mottling, others a top necrosis and in some of them the yields are severely reduced even if no symptoms are observed.

Rugose Mosaic.—This disease is considered by some to be more serious than mild mosaic and is entirely distinct from it. The mottled areas are smaller and more numerous and typically are distributed closer to the main veins. The mottling is readily masked under high-temperature conditions but the crinkling of the leaves makes identification rather certain. The veins on the underside of the lower leaves often show necrotic areas as black, pencil-like lines. Affected plants are usually stunted and die much earlier than the healthy ones. Rugose mosaic is spread readily by aphids. If infection takes place early in the season, current-season symptoms are likely to develop before the plant dies. If infection occurs late, symptoms may not appear the same season but tubers from such plants will carry the disease. Current season symptoms are characterized by a burning and discolouration of the leaf veins and leaf blades, brittleness, leaf dropping and premature death.

Leaf Roll.—This virus disease is very common in Britain, Canada, the United States and in potato growing countries generally. It is characterized by the upward rolling of the leaflets so that the midrib remains at the middle of the trough thus formed. The lower leaves usually show the symptoms first. Other symptoms are dwarfing, rigidity, leathery texture, chlorosis and reddish or purplish discolouration of the affected leaves. Net necrosis appearing in newly infected tubers is a symptom of leaf roll of certain varieties. It is a network of small brown strands of discoloured tissue extending throughout the interior of the potato tuber, the discolouration usually beginning at the stem end. As in the case of the mosaics described above, the leaf roll virus can be transmitted by aphids and possibly by other insects. Infection can also be produced by grafting together of healthy and diseased tubers or other portions of the plant. Hot dry weather often causes a curling of the leaves which can easily be mistaken for the virus leaf roll.

Spindle Tuber.—This disease is so named because of the spindle-shaped tubers produced by infected plants. Such plants are often slender, upright and smaller than healthy ones and the foliage is sometimes darker green. In Triumph, infected tubers are lighter red than the healthy tubers and have a tendency to be blocky and cylindrical in shape. Experiments have shown that this disease can be transmitted by various insects, including grasshoppers, flea beetles, tarnished plant bugs and Colorado potato beetles. To some extent the disease may be spread by contact with cut seed pieces, by the seed-cutting knife and by picker-planters.

Yellow Dwarf.—The foliage of plants with yellow dwarf takes on a yellowish-green colour, whereas the upper surface of the leaves becomes slightly rugose. Dying from the tip downward is characteristic. High temperatures and low humidity tend to hasten the death of infected plants. Brown spots in the pith of the stem are common. In warm soil, seed pieces from infected tubers often fail to germinate; others produce shoots that die before they reach the surface. Infected plants often produce small, misshapen tubers which in cross-section show small necrotic areas scattered throughout the flesh.

Experiments conducted in New York state showed that this disease is transmitted by the clover leafhopper. This insect retains the virus during the winter and infects healthy potato plants in the spring.

Fungus Diseases.—*Late* Blight. This is the most serious of the many diseases to which the potato is heir. It is found in all the potato growing countries and as a whole causes more damage to the potato than all the other diseases combined. It is caused by a parasitic fungus *Phytophthora infestans*, which seems to have been noticed in Europe about 1840 and by 1845 had become widespread. It was the cause of the Irish famine in 1846. uhen the potato crop was almost completely destroyed. It is always present in Britain but is much more severe some seasons than others.

In the United States it is most destructive in the New England and north central states. At times it is responsible for considerable loss in nearly all the eastern seaboard states even as far south as Florida and along the Pacific coast. It is seldom of any importance in the other southern and central states. Wet seasons are particularly favourable to the disease and much of the crop may be lost unless preventive measures are taken; in dry summers it may do little damage. The disease generally shows itself as purplish brown or blackish patches on the leaves, often appearing first on the leaves near the top or margin. In damp weather the undersides of the patches may show delicate white threads, the hyphae of the fungus. Under such conditions also the dark coloured patches spread rapidly, and the whole foliage may be transformed into a moist black mass. Leaves badly attacked give off an offensive odour, detectable at a considerable distance.

The minute white threads which make up the body of the fungus branch and produce large numbers of pear-shaped structures, the spores of the fungus. These spores are detached and are carried by the movement of the air to other plants, where they germinate. The resulting threads pass through the stomata1 pores of the leaf and each starts a new infected area. Under suitable conditions a new crop of spores may be produced a few hours after infection so the fungus can spread rapidly. Under favourable warm and moist weather conditions all the plants in the field may be killed in a few days. The organism also attacks the tubers, which become infected either in the soil through spores washed from the diseased tops or in harvesting through contact with blighted foliage. When late blight tuber rot first develops in the soil, it is usually brown and spreads irregularly from the surface through the flesh. The affected part may become soft partly because of an abundance of moisture but mainly because other organisms, particularly bacteria, invade the diseased areas. Under storage conditions the disease is typically a dry rot forming irregular sunken patches, which under favourable conditions may involve the whole tuber. Secondary organisms may invade the tubers in storage and cause soft rots. The disease lives over in the tubers.

Early Blight.—Early blight, also known as leaf spot and caused by Alternaria *solani*, under some conditions occurs earlier in the season than late blight but under other conditions it may occur later. The fungus attacks the potato leaves causing the development of brown spots which, as they enlarge, develop concentric rings or markings. When the spots are numerous the leaves are killed and the yield of potatoes is consequently reduced. Small. shallow, more or less circular decayed lesions are sometimes iormed on the tubers. These lesions rarely cause serious harm but they do afford entrance for soft rot organisms that complete the decay of the tubers.

Potato Scab.—This disease, often known as common scab of potato, is caused by *Actinomyces* scabies. It is particularly troublesome in sandy and gravelly soils, especially neutral or alkaline soils. It is known to exist in every potato growing section of the United States. It attacks the tubers and, when very severe, renders them unfit for market. The scab lesions are small and brownish at first but later enlarge into hard, circular, or irregular corky areas on the surface of the tubers. They may separate or run together, sometimes covering the whole potato. They vary in type from shallow to deep.

Fusaria.—A number of species of Fusarium are known to attack the potato, causing wilt and other injury to the plants and tubers. Among these are F. *oxysporum,* F. *eumartii,* F. avenaceum, F. *coeruleum* and F. trichotheciodies. Plants attacked with F. *oxysporum* may wilt rather suddenly and die in a comparatively short time, or they may show the effects slowly and succumb gradually. The first symptoms are a yellowing and drooping of the lower leaves. There may be also some curling and rolling of the leaflets and tip burning. On hot days the yellowing is preceded by a wilting of the leaves and even of the stalks. The stems of affected plants are invariably discoloured in the interior. The woody tissues of the interior of the stem are yellow to brown, often extending from the base well into the top. The tubers of wilt infected plants often show a browning of the water vessels near the stem end. F. *eumartii* produces at first a burning and bronzing or slight yellowing of the upper leaflets. In late stages the plants wilt and die. Stems of the affected plants show a brownish flecking when cut longitudinally. Tubers of such plants show a browning of the stem end and vascular discolouration. The wilt organisms are carried over from one crop to the next in the tubers or in the soil. F. avenaceum has been reported from Wisconsin as behaving very much like F. oxysporurn. Dry rots caused by F. coeruleum and F. trichotheciodies are generally referred to as storage dry rots. F. coeruleum, apparently the most common, can penetrate through an unbroken skin, but it usually enters through wounds and produces large sunken pockets or a wrinkled decay. Numerous bluish or whitish protuberances are formed on the surface of the decayed parts. The powdery dry rot caused by F. trichotheciodies is limited to situations having warm dry summers. Affected tubers shrink considerably and often develop in the interior large hollow pockets partly filled with a brick-coloured powdery mass of fungus growth.

Rhizoctonia Canker (Black Scurf).—The fungus that causes rhizoctonia or black scurf on the tubers, Corticium *solani,* ordinarily shows as small brown-black bodies closely adhering to the skin. These sclerotia, as they are called, may be as small as a pinhead or half as large as a pea. They are composed of mycelial threads and represent the resting stage of the fungus. Lesions or dead areas may develop on the underground stems and on the stolons and may so interfere with the proper functioning of the plant that the leaves roll, small tubers form in the axils of the leaves or the nodes of the stems become considerably enlarged and knobby because the starch cannot be properly transported downward. Many small potatoes and a few large knotty ones may be developed underground. This result often gives rise to the term "little potato disease."

Wart.—This disease is due to a fungus, *Synchytrium endobioticum.* It was discovered in 1896 in upper Hungary and was thought to be a new form of scab. The earliest definite record of it in England was in 1898 and in North America in 1912. It has caused serious damage in Europe, especially in certain districts of England and Ireland, but has been confined in the United States to a few small areas in limited districts of Pennsylvania, Maryland and West Virginia. The disease generally shows itself as warty outgrowths on the tubers and stolons and occasionally the stems and even the leaves. In severe cases the tuber may become a warty mass. The warty tissue of the tuber shows thick-walled sporangia which, reaching the soil, liberate free-swimming cells, zoospores. These penetrate some part of the young potato plant, usually one eye of the tuber and develop there, causing the abnormal warty tissue. In the affected tissue thinner-walled sporangia, the summer sporangia, are produced. These discharge to the exterior and liberate fresh zoospores which cause new infections, and so the process is repeated. The zoospores may unite in pairs and then after infection produce the thick-walled resting sporangia which, when they escape into the soil, are the source of infection for new crops. The fungus may live for many years even when the soil is kept in sod. The disease is easily spread by infected soil and tubers; the winter sporangia pass through the alimentary canal of animals unharmed.

Bacterial Diseases.—Blackleg.—Blackleg is caused by *Erwinia phytophthora.* It causes heavy losses in some potato growing sections under conditions favourable for its development. It may cause seed piece decay or destroy the sprout before it appears above ground. It causes also serious rotting of tubers in storage. The first symptoms are the rolling of the upper leaves of one or more shoots, compactness of the foliage and the gradual yellowing of the leaves. The plant dies as the base of the stem is rotted away by bacteria. The plant tissue in this region usually turns black, giving rise to the name blackleg. In seasons of abnormal rainfall the disease develops rapidly and involves a greater part of the stem than in dry seasons. When the disease progresses slowly aerial tubers may be formed on the stems, as in rhizoctonia canker. Tubers not severely affected if harvested and planted will very likely carry the disease over to the resulting crop. Unless conditions for the development of blackleg are favourable, however, the disease will not develop even if infected tubers are planted. It has been demonstrated in Minnesota and Maine that the seed-corn maggot is active in spreading the disease. If the fly has access to seed potatoes, eggs may be deposited. The maggots hatched from these eggs may be contaminated with the bacteria and may infect the seed pieces.

Brown Rot (Bacterial Wilt).—Brown rot is a bacterial disease resulting from infection with Phytomonas solanacearum. It is often called southern bacterial wilt. Climatic conditions limit this disease to the warmer potato growing sections of the United States. It is found in the south Atlantic and gulf coast states from Maryland to Texas and sometimes in Ohio, Illinois, West Virginia and Kentucky. The first symptom of brown rot is a slight wilting of the terminal leaves during the hottest part of the day. The plants may recover at first during the night but each successive wilting becomes more severe until finally the plants die. The vascular bundles in the stems, roots and stolons turn brown when they become stopped up with bacteria, causing the wilting and death by cutting off the plant's water supply. The brown colour is finally evident on the stem one or more inches above the soil line. When the vascular bundles are cut or broken, bacteria ooze from them as a white slimy mass. The bacteria sometimes ooze from the eyes of affected tubers, and becomemixed with dirt which upon drying sticks to the surface. Tubers left in the ground continue to decay. Other rot organisms may invade the injured tissue and assist in making it a slimy mass with a very offensive odour. Plants with their tops killed by brown rot may bear healthy as well as diseased tubers. Other plants showing no signs of disease in their tops may sometimes produce diseased tubers.

Ring Rot (Bacterial **Ring** Rot) results from infection with *Phytomonas* sepedonica. It has been known in Europe for a relatively long time but has not been prominent in the United States until recently. It is an infectious bacterial wilt and ring rot disease. It differs from brown rot in that it is not so limited by climatic conditions and has been known to occur in nearly all the potato growing states. The symptoms of this disease generally do not become evident until late in the season. Some varieties become infected without showing symptoms in the leaves. When affected tubers are present there are usually found all gradations, from sound to completely decayed tubers. Decay begins in the region near the vascular ring of the tuber; hence the name ring rot. The decayed tissue is yellowish white and of a crumbly nature and may ooze from the infected parts under pressure. Infected tubers are often invaded by other soft rot organisms causing more rapid decay. The bacteria live over winter on slightly affected tubers. In many of these tubers the disease cannot be detected, but they may contain enough bacteria to contaminate the cutting knife, the receptacle that the seed is carried in or the planter; and the disease is spread to healthy seed by contact with such infested equipment.

Physiological Diseases.—These diseases are due to unfavourable environmental conditions and are not known to be caused by any virus, fungus or bacteria. A number of physiological diseases are due to a deficiency in the soil of the elements necessary for growth. Those most often deficient are nitrogen, phosphorus, potassium and magnesium. Other abnormalities in potatoes may be due to a number of causes.

Heat and drought necrosis occurs in tubers that are allowed to lie in the hot soil after the vines begin to die. The water vessels of the affected tubers take on a golden yellow to brown discolouration. Freezing necrosis is caused by limited ice formation within the tuber. Upon thawing several kinds of internal discolouration may appear. In the ring type discolouration is limited to the vascular ring and adjacent tissue; in the net type there is more or less blackening of the vascular tissue and the fine strands that extend from the vascular tissue into the interior pith and outer tissues; in the blotchy type discolouration is characterized by irregular patches ranging from an opaque gray or blue to sooty black and may occur anywhere in the tuber.

Sunburn or greening results from exposure to light. In case of long exposure the outer tissues turn deep green and those underlying a greenish yellow or deep yellow. Greened tissue is unpalatable for most people and may be poisonous for a few.

Sunscald is caused by the development of extremely high temperatures in the tuber when exposed to sunlight. Often the tissues are killed to a considerable depth. Tubers may become watery and turn brown throughout or at least to a considerable depth, or they may have a blistered appearance externally and a metallic colour. Such areas may dry out and appear chalky and granular or hard and leathery. Most frequently, however, they are attacked by bacteria and fungi that cause a rapid decay.

Blackheart is a result of the asphyxiation of the tissue of the potato tuber. It occurs either when the temperature is too high or when the ventilation is so poor that the supply of oxygen is inadequate. The external symptoms of blackheart are moist areas on the surface which may be purplish at first but turn brown or black within a short time. The internal symptoms are a dark-grayish to purplish or inky black discolouration. Tissues cut soon after injury are of normal colour; shortly after access to air, however, they turn pink, then gray or purple and finally jet black. Generally the discolouration is restricted to the interior but may radiate to the exterior. With slight drying, affected tissues are firm and leathery; with prolonged drying, cavities result.

Insect Pests.—The common insect enemies of the potato are the Colorado potato beetle, flea beetle, leafhopper, aphid, psyllid, seed-corn maggot and wireworm.

The Colorado Potato Beetle, *Leptinotarsa* decemlineata, was unknown to the potato growers of North America prior to 1855. About that time the potato growing industry had spread west, and when it reached the section where these beetles were native they left the mild solanums on which they customarily fed and began to infest the plants. They soon spread in all directions until they were found in nearly all the potato growing regions of the United States and Canada. The adult potato beetle is about three-eighths of an inch long and yellow in colour with five black stripes running lengthwise on each wing cover and a series of black spots on the thorax. The eggs, 500–1,000 of which may be laid by one female, are yellow and are usually deposited in clusters on the under side of the potato leaflets. They hatch out in about a week. The full grown larva is a stout fleshy grub with a black head and black spots over the body. It consumes a large amount of foliage; and if many larvae are allowed to remain on the plant, they soon strip it of all its leaves. They mature in about three weeks, after which they enter the ground to pupate. Two or three generations may be produced in a season. The last generation winters underground, emerging as mature beetles early in the spring.

Flea Beetle.—The potato flea beetle, *Epitrix cucumeris,* is a small black jumping beetle, slightly over one-sixteenth of an inch in length and about one twenty-fourth of an inch in width. The antennae and legs are yellowish but the body parts including the head, wing covers and thorax are jet black. These beetles eat small holes in the leaves and when they are present in large numbers cause serious injury and reduced yields. The eggs are laid under rubbish on the ground, and the larvae attack the underground parts of the plant. In some sections, particularly in the south, the tubers at times are so seriously injured that they are inferior in market quality, if not unsalable. One or two broods are produced each season depending on the locality.

Leafhopper.—The potato leafhopper, Empoasca fabae, is a sucking insect. It causes a very destructive disease-like condition called hopperburn. This condition begins with a yellowing of the leaf around the margin and tip followed by a curling upward and rolling inward. The leaf changes from yellow to brown and becomes dry and brittle. When the hopperburn is very severe, the plant may die prematurely. The adult leafhopper is a pale green insect about one-eighth of an inch in length with wings that fold over the back. The nymphs are wingless and usually feed on the underside of the leaves from which they suck the juices. Leafhoppers pass the winter in the adult stage hidden beneath weeds or other rubbish and appear in the spring, when they deposit their eggs. In some sections of the United States this insect is very destructive, causing as much as 50% reduction in yield.

Aphids.—Several species of aphids or plant lice attack potatoes. Among these are Macrosiphum solanifolii and *Myzus persicae*. The first of these is often called the pink and green louse; the second is known as the green peach or spinach aphid. Both live on the juice which they suck from the host plant, thus depriving it of its vigour and reducing the yields. They are the common vectors that spread most of the virus diseases and these diseases are more of a problem to the growers than the aphids themselves.

Potato *psyllid*.—This pest causes a diseased condition commonly called psyllid yellows. It has also been referred to as "blight" or "purple top." The adult psyllid is very active in hot weather and has been called the jumping plant louse. The average female lays about 700 eggs. The adults appear incapable of producing psyllid yellows. As many as 1,000 have been observed on a plant with no deleterious effects. The nymphs are very destructive; as few as from three to five on a plant have been known to cause yellows. They feed for about 16 days. Psyllid injury has been reported from all states west of the Missouri river, but it is most severe in the plateau section. It has been stated that in Colorado psyllid yellows spreads more rapidly and uniformly and causes greater losses than any other disease or pest.

The first symptom of the disease consists of an upward rolling or cupping of the basal portion of the leaflets at the top of the plant. This rolling is usually accompanied by a marginal yellowing. In some varieties such as the Triumph and Irish Cobbler the upper parts may assume a distinct reddish or purplish colour. The symptoms spread from the top downward, often involving the entire plant. In some cases the nodes of the plants enlarge and the axillary buds are stimulated into growth, producing either an aerial tuber or a stocky shoot capped with a rosette of leaves. The plants often set a large number of tubers, as many as 50 being sometimes found. These tubers seldom attain marketable size and often sprout in the ground before digging time. Results of planting such tubers have not been consistent. Some lots have produced normal crops, others have resulted in weak spindly plants and still others have remained dormant. Attempts at transmitting the malady except by the feeding of the nymphs have resulted in failure.

Prevention and Control of Diseases and Insects.—Since many diseases of the potato are tuber-borne, the most important preventive measure is to secure seed stock that is as free as possible from viruses or disease producing organisms. Virus diseases in susceptible varieties are especially difficult to control. They are spread for the most part by insect vectors, and theoretically it ought to be possible to control them by eradicating the insects; but this method has not proved very satisfactory. Tubers from infected plants carry the virus but generally do not show disease symptoms; consequently they cannot be separated from healthy tubers in the storage house. On the other hand inspection of potato fields early in the growing season makes it possible to detect the diseased plants by the definite symptoms they show. If these plants are rogued out promptly and destroyed before heavy infestations of insect vectors are present, further spread of the viruses is prevented and the crop is greatly improved for seed purposes. Since the heaviest infestations usually take place late in the growing season, early harvesting is often recommended to avoid consequent heavy spread of viruses.

The knowledge of potato diseases and especially of the virus diseases grew rapidly until the production of certified seed potatoes became a specialized industry. Standards for seed certification differ slightly in various countries and among the various states of the U.S.A., but they are all sufficiently high to ensure a minimum of virus diseases and, as a result, increased yields.

In the control of late blight, prevention is perhaps as important as protection. Partly rotted tubers taken out of storage and piled or scattered on the ground may sprout early in the spring; the blight fungus carried over in these decayed tubers develops on the new sprouts and is quickly carried by the wind to the growing crops in the field. These early infections often result in heavy epiphytotics. All waste potatoes should be prevented from growing by feeding them to livestock or by burning them. Seed tubers infected with blight should be discarded; if planted they may cause a recurrence of the disease. Under wet weather conditions, however, the fungus quickly comes in from outside sources so the vines have to be protected with copper sprays or dusts. The spray or dust must be applied before the blight makes its appearance and must adhere to the plant to prevent the fungus from penetrating into the tissues. In practice Bordeaux mixture (copper sulphate combined with lime) or Burgundy mixture (copper sulphate combined with washing soda) are used as sprays. There is some experimental evidence to show that both are equally effective. Bordeaux mixture is the standard spray in most potato growing sections. The formula commonly used is 8-8-100 (8 lb. of copper sulphate, 8 lb. of hydrated lime, 100 gal. of water).

For small areas the spray can be applied by means of a knapsack machine which must be provided with a nozzle that throws a fine misty spray. The Irish growers use these knapsacks. For the first spraying 120 gal. per acre or $\frac{3}{4}$ gal. per sq.rd. is sufficient. though for subsequent spraying 160 gal. per acre or 1 gal. per sq.rd. will be needed to cover the larger amount of foliage. In England, Scotland, Germany, Canada and the United States it is customary to use horse or tractor drawn machines, each capable of spraying many rows of potatoes at one time. Power sprayers fitted with 3 nozzles per row and delivering about 120 gal. per acre at 300-400 lb. pressure are used in many commercial fields. Copper dusts, although perhaps not so effective as the Bordeaux spray, give good control if proper materials are applied correctly.

It is fortunate that early blight and hopperburn can also be controlled by copper sprays or dusts; and if arsenical poisons are added, Colorado potato beetles and flea beetles can also be held in check. Copper lime arsenate dust (20 lb. monohydrated copper sulphate plus 70 lb. fresh hydrated lime plus 10 lb. calcium arsenate) is a standard mixture for dusting potatoes. It is usually applied at the rate of 25-35 lb. per acre. Machines are used for applying the dust. It should be blown on the leaves as a very fine powder when they are somewhat moist with dew or fine rain. Arsenical compounds are highly poisonous to men and animals and must be carefully handled. A respirator should be worn by the operator while mixing such chemicals and applying them as dusts. Hands, face and clothing should be washed thoroughly after spraying and dusting operations.

For the control of the tuber-borne diseases such as common scab, rhizoctonia and blackleg see the section Seed, above.

As fusarial wilts are carried over from one crop to another in seed potatoes and in the soil, seed selection and crop rotation are the means by which these diseases can be avoided.

Potato wart is controlled most satisfactorily by the use of immune varieties, a number of which are available.

Losses due to brown rot can be greatly reduced by the use of resistant varieties such as Katahdin and Sebago. It can be controlled to some extent in sandy types of soil by an application of 800 lb. of sulphur to the acre applied in the summer, followed by 3000 lb. of limestone per acre in the fall. The treatment is not recommended on muck, peat, loam or clay types of soil.

Colorado potato beetles, leafhoppers and flea beetles, as mentioned above, can be controlled by copper sprays or dusts combined with arsenical poisons. Aphids are more difficult to control. One of the best ways to eliminate heavy infestations of these insects is by eradicating the weeds, especially the mustards upon which they multiply and from which they migrate to the potato plants. Good results are often obtained by spraying at the early stages of infestation with a mixture of $1\frac{1}{2}$ pt. of nicotine sulphate in 100 gal. of Bordeaux mixture. Another spray for aphids on potatoes can be prepared by adding 3 lb. of either derris or cube root powder and 2 qt. of soybean oil to 100 gal. of Bordeaux mixture. If Bordeaux mixture is not needed for the control of diseases and other insects, a nicotine soap solution consisting of $1\frac{1}{2}$ pt. of nicotine sulphate, 4-5 lb. of soap and 100 gal. of water may be used. Dust mixtures containing .75% of rotenone are also effective against aphids. The principal objection to spraying or dusting for aphid control is the high cost of the chemical compounds. Psyllids can be controlled to a certain degree by spraying with liquid lime-sulphur. One gallon of lime sulphur is mixed with 40 gal. of water. The sprayer used in applying this mixture should be capable of maintaining a pressure of 300 lb. and there should be three nozzles per row, the two lower ones turned upward at an angle to cover the under surface of the leaves. The success of this treatment depends upon its thoroughness and timeliness.

Control of heat and drought necrosis involves keeping the soil moist and cool and shaded, and if the soil is light and the weather hot, digging as soon as the vines begin to die.

To prevent freezing injuries, tubers should not be exposed to temperatures below 32° F. Greening of the tubers may be prevented by protecting the tubers from light.

Sunscald can be avoided by protecting the tubers from long exposure to the sun. If tubers are not exposed to temperatures of more than 95° F. and are given good ventilation they will not develop black heart.

POTATO BREEDING

The potatoes that were brought to Europe from Peru and Chile in the latter half of the 16th century had very irregularly shaped tubers, disfigured by outgrowths and extremely deep eyes. These features were characteristic of the early Peruvian varieties, and in England and on the continent these very rough deep-eyed varieties were the rule until the earlier part of the 19th century. In the hands of plant breeders the shape, colour and quality were much improved. Most of the improvements were made after 1845, when potato diseases focused attention on the crop. In that year potato blight reached Europe and became so destructive in Ireland as to cause a famine and much loss of life. This gave an impetus to the search for varieties resistant to disease. Perhaps the first and most important introduction in Great Britain was the variety Victoria, raised and introduced by William Paterson of Dundee. Victoria was a great and successful cropper and proved the parent of many other great potatoes later produced, including Champion, Up-to-Date, Great Scott and Ninetyfold. Simultaneously and for the same reasons there was great activity in the production of new varieties in the United States. Reverend C. E. Goodrich of Utica, New York, conceived the idea that the disastrous epidemics of late blight during the years 1843–47 were the result of a reduction in the vigour of the plants caused by long-continued propagation by vegetative means, and that this vigour could be restored by growing plants from true seed. While he did not succeed in the control of late blight by this means, he may be considered to have laid the foundation of potato breeding in the United States by furnishing material to be used by other breeders. The ancestry of 170 varieties can be traced back to Goodrich's Garnet Chili, a seedling of the imported Rough Purple Chili. They include several well known varieties of commerce such as Beauty of Hebron, Burbank, Early Ohio, Early Rose, Green Mountain, Prolific and Triumph. The Magnum

Bonum, a very popular potato of England and north European countries, was bred from Early Rose by J. Clark of Christchurch. Clark also grew Abundance, Epicure and Ninetyfold, varieties still of some importance.

The second wave of potato blight came in 1870 and caused much destruction of the existing varieties. Breeders concentrated on securing more resistant forms. Nicol of Arbroath then introduced the Champion, a high yielding resistant variety, which soon became largely grown throughout Scotland and Ireland and in time in most potato districts of the world.

Great credit should be given to Archibald Findlay of Scotland. however, for his success in developing many varieties, including Up-to-Date and British Queen. The Up-to-Date, especially, made both Scotland and Ireland famous for potatoes, and this variety was exported to all parts of the world. From 1907 to 1928 Donald McKelvie was active as a potato breeder; his Arran Chief, Arran Banner, Arran Comrade and Arran Consul became popular in many places. German breeders raised Richter's Imperator, the President and Paulsen's Juli, all of such merit as to justify wide cultivation. The work of C. G. Pringle of Charlotte, Vt., is worthy of mention in that it is said to represent the first systematic effort to obtain seed by controlled hybridization. His varietal contributions were the Alpha, Adirondack, Rubicund, Ruby and Snowflake.

Early in the 20th century another era in potato breeding began in Europe. The recognition and alarming spread of potato wart forced to the front the question of "immune varieties." Immunity from wart, like any other genetic character, is the end result of the interaction of genetic factors and environment. Several genetic factors are involved in the inheritance of this character. Some of them are dominant, causing immunity independent of all other immunity factors; others work together in a complementary manner and still others are cumulative in effect. With a number of dominant factors available, it was not a difficult task to produce many new varieties with immunity from wart combined with other characters of economic importance.

When potato breeding was actively taken over by the United States department of agriculture in 1910 under the direction of Dr. William Stuart, the only disease resistance sought was that against the late blight fungus. It was not until some years later that it became evident that the virus diseases were a greater menace to potato production than late blight because the viruses are transmitted from one crop to the next through tuber infection and they cannot be controlled by fungicidal application to the foliage or by seed treatment. It was soon realized that the widespread occurrence of potato virus diseases such as the various types of mosaic, leaf roll, spindle tuber, curly dwarf, yellow dwarf and streak could be controlled only by the breeding mode of attack. The first step in this direction was toward the development of varieties resistant to one of the commonest of these diseases, mild mosaic. Seedlings that showed some resistance to virus infection were selected by Dr. Charles F. Clark, who became associated with Dr. Stuart in this work. Dr. Clark crossed the resistant seedlings with one another and with other seedlings and varieties. As a result a number of new varieties with a high degree of resistance to mild mosaic, with desirable tuber characters, good habit of vine growth and relatively high yield were distributed to growers. Katahdin. Chippewa and Houma were the first of these. Katahdin has exceptionally wide adaptation. It has been grown successfully in nearly every potato growing section of the United States and in Canada, Uruguay, Argentina, south Africa and Australia.

While this work was being carried on by the department of agriculture a few of the state experiment stations, especially Minnesota and Cornell university, had undertaken potato breeding work. It was soon realized that problems and objectives in this field of endeavour cut across state lines and involved large regions of the entire country. It was therefore decided in 1928 to organize the work as a national project with all interested state experiment stations and the United States department of agriculture co-operating. Material was sent also to any foreign country requesting it. The expansion in the organization greatly increased the number of problems attacked. The so-called "economic" characters such as yield, time of maturity, depth of eye, shape of tuber and culinary quality were given primary consideration but intensive work was done also on resistance to various diseases and insect pests. Resistance was obtained to the virus diseases such as mild mosaic, latent mosaic, veinbanding, leaf roll and yellow dwarf. Immunity from late blight was found in many hybrid seedlings of the wild species, *Solanum demissum,* crossed with cultivated varieties of *S. tuberosum.* Resistance to this disease was found too in some of the cultivated varieties themselves and in a number of progenies obtained from Germany. The latter may be related to *S. demissum.* Seedling varieties, both late and early, highly resistant to common scab under a wide range of environmental conditions were produced. Varieties tolerant to Fusarium wilt also were produced. Many of the new productions were resistant, if not immune, to potato wart. Resistance to brown rot and ring rot are inherent in a number of varieties and progenies. Wide differences were found between varieties and seedlings in their reaction to injury by the insect pests, leafhoppers, flea beetles and psyllids.

Composition of the Potato.— The composition of the potato is to some extent inherent in the variety but is modified greatly by the conditions under which the plants are grown. Some of the factors that are known to result in variability even between tubers of the same variety are: the physical and chemical make-up of the soil, the kind and amount of fertilizer applied, climatic conditions, cultural methods such as depth of planting, state of maturity at harvest time and in irrigated districts the time and rate of application of water. Storage conditions, especially temperature, contribute to the variability.

Eecause of the wide variability all statistics on composition are subject to error. The average potato tuber contains 75%-80% water, 11%-20% starch (occasionally 23%-25%), 1.5%-2% of proteins and 2%-3% of fibre and mineral salts or ash. Its value, both as a food and in the manufacture of by-products, is due to its starch content. The normal potato contains only a small quantity of sugar (about 0.3%). If the tuber is analyzed in parts it is found that the dry matter usually decreases toward the centre. In one type analyzed the percentage of dry matter in the cortex, outer medulla and inner medulla respectively was 22.20, 19.41 and 14.92.

The desirable characteristic of a potato in England and America is a capacity to develop mealiness when boiled, and this depends largely on the percentage of starch in the tuber. In France, however, potatoes are rarely boiled but usually cooked in fat, hence there is a demand for a potato with a firm flesh becoming not mealy but "soapy" on boiling; such a potato is usually low in starch and high in nitrogen content. Since the culinary qualities of a potato are closely associated with its starch content the factors that cause variation in the latter will also cause variability in the former. As a result, the cooking quality of a variety may range from poor to excellent according to the conditions under which it was grown and harvested. Some varieties are more variable than others when grown under similar conditions.

POTATO-LIFTER: *see* HARVESTING MACHINERY.

POTATO RACE, a contest, in which the winner is the first who collects in a basket or other receptacle a number of potatoes, usually eight, placed two yards apart along a straight line, and then crosses a line five or ten yards farther on.

POTATO SPIRIT. The use of the potato instead of grain as the source of supply of alcohol for commercial use has, during the past century, developed into an important industry, particularly in Germany where it is now a prominent feature in the organization of the agriculture of the country. In great measure it is carried on by the mutual co-operation of the farmers who supply to joint-owned distilleries the potatoes to be converted into alcohol, receiving later the spent wash and residues which are rich in nitrogenous matter and of considerable value as a cattle food. Extensive breeding of cattle is thus facilitated, resulting in a heavy production of manure useful in the cultivation of the potatoes. In 1913 there were in Germany eight million acres of land devoted to potato cultivation. Three million tons of the crop were used for the manufacture of sixty-seven million gallons of alcohol, this representing about 80% of the total alcoholic production of the country. In 1928 the industry had not recovered from the effects of the war, and in order to ensure that the supply of crops necessary for human and animal food should not be diverted to the production of alcohol, the price which might be paid for potatoes to be used for the latter purpose was restricted by the government.

The underlying principle in the production of alcohol from potatoes is the saccharification by means of malted barley or acids of the starch, of which there is usually about 20%. A little over 1 ton of potatoes produces spirit approximately equivalent to 19 gal. of alcohol.

The details of the process show considerable variation. In one method extensively adopted the potatoes, after being cooked by steam heating and reduced to a homogeneous pulp in a mill, are mixed with malt and water. After the mass has been maintained at a temperature of about 60° C. for 3–4 hr. yeast is added and fermentation takes place. Distillation is accomplished by a process of steam heating, the mass being agitated meanwhile.

In another method the potatoes after being reduced to a pulp in a rasping machine are partially drained of their natural water. Boiling water and malt are added, the mass being allowed to stand for 3–4 hr. The clear liquid and subsequent washings are fermented with yeast and the spirit distilled off in the usual manner. This method has considerable advantages over that first described, the distillation from the liquid being cleaner and the residual paste being excellent as a cattle food.

The spirit thus obtained by direct distillation is liable to act in a deleterious manner upon the animal economy. It has a strong odour and taste of fusel oil, amyl alcohol and isobutyl alcohol in particular being present in considerable proportion. This may be almost completely rectified by distillation in a patent still.

(F. G. H. T.)

POTATO WAR, the name given by the Prussians to the War of the Bavarian Succession in 1778–79 (Kartoffelkrieg). The Prussians and a Saxon contingent, commanded by Frederick the Great and his brother Prince Henry, were opposed to two Austrian armies under Loudon and Lacy. The operations consisted almost entirely of manoeuvres which had for their object the obtaining or the denial to the enemy of food supplies. The war thus acquired the name of Kartoffelkrieg. Its duration was from July 3, 1778, to the assembly of the congress of Teschen on March 10, 1779, and its total cost £4,350,000 and 20,000 men to all parties. The war may be studied from a military point as an extreme example of what Clausewitz calls "war with a restricted aim."

POTAWATOMI, a tribe of North American Indians of Algonkin stock. When first known, about 1670, they lived around Green Bay, Wis. They subsequently moved south and eventually settled in lower Michigan. They were allied with the French in their wars against the Iroquois and took part in the conspiracy of Pontiac (*q.v.*). In the American Revolutionary War they fought for England, as they also did in the War of 1812. In 1846 most of them were removed to a reservation in Kansas. Others are in Wisconsin and Oklahoma.

The name Potawatomi is properly *Potewatmik,* fire-makers, in allusion to the tribe's secession from the Ojibway and their establishment of a separate council fire.

POTCHEFSTROOM, a town in Transvaal, Union of South Africa, at 26° 30' S., 27° 40' E., altitude 4,436 ft., 88 mi. by rail S.W. of Johannesburg. Pop. (1936) 19,099, of whom 10,774 were Europeans, 7,234 natives (Bantu), 280 Asiatic and 811 coloured. The town is built on the banks of the Mooi river, 15 mi. above its junction with the Vaal. Gold occurs in the neighbourhood.

Potchefstroom was founded in Nov. 1838 by Hendrik Potgieter, and is the oldest town in, and first capital of, the Transvaal. In 1862 it was the scene of civil war between rival Boer factions. In 1880–81 the garrison camped outside the town was besieged by Boers under Commandant P. A. Cronje. The British troops, 250 in number, were confined to a fort 25 yds. square and lost more than a third of their strength in killed and wounded before they surrendered on March 21, the action having begun on Dec. 18, 1880. Charges of treachery were brought against Cronje for failing to notify the besieged that an armistice had been agreed to by the Boer leaders. Of this armistice Colonel R. W. C. Winsloe, who was in command of the British, became aware before the surrender took place. On the suggestion of Commandant General Joubert the capitulation was considered as cancelled, and a detachment of British troops reoccupied the town until the conclusion of peace. In the Anglo-Boer War of 1899–1902 Potchefstroom was occupied by the British without opposition.

Potchefstroom was developed as an educational centre. It has several high schools, a training college, a university college, the latest constituent of the University of South Africa and an agricultural school. The latter is situated on the government experimental farm.

POTEEN, called also potheen, potsheen and potyeen, the term usually applied in Ireland to any potable spirit illicitly distilled in a pot still—poit'in, pota or pot. Illicit distillation mas extensively practised in the 19th century, particularly in the inaccessible districts of the island, but it has in great measure been suppressed. The character of the substances used in preparing the wash, which is fermented preparatory to distillation (see WHISKY; RUM, etc.), varies greatly. While malt and barley chiefly are used, the spirit is often obtained by the fermentation of molasses or other saccharine matter. The method of fermentation, the type of still employed, the rate of distillation and the proportion of distillate to wash, depending as they do upon the circumstances and wish of the distiller, are also lacking in uniformity. This absence of standardization in materials and methods results in great variation in the composition of the resultant spirits. Generally they may be stated to fall into two classes, approximating to whisky when malt and barley are used, and to rum when the wash is of a more saccharine nature. The proportion of secondary ingredients almost invariably is high, however, even when compared with pot still spirits made by reputable firms. Allen, in a series of analyses presented to the Select Committee on British and Foreign Spirits, recorded 128.8 grains of amyl alcohol in poteen as compared with an average of 56 grains in eight samples of Irish whisky.

(F. G. H. T.)

POTEMKIN, GRIGORY ALEKSANDROVICH, PRINCE (1739–1791), Russian statesman, mas born at Chizheva near Smolensk. He was educated at the Moscow university and in 1755 entered the "Reiter" of the Horse Guards. His participation in the coup *d'état* of July 8, 1762, attracted the attention of the new empress, Catherine II, who made him a Kamnzerjunker and gave him a small estate. He distinguished himself in the Turkish War of 1769, and in 1771 he became Catherine's prime favourite. Catherine bestowed on him the highest honours, among others the post of commander-in-chief and governor-general of "New Russia" (Ukraine). In 1775 he was superseded in the empress's graces by Zavadovsky; but the relations between Catherine and her former lover continued to be most friendly, and his influence with her was never seriously disturbed by any of her subsequent favourites.

Potemkin's correspondence with the empress was uninterrupted. He was deeply interested in the question of the southern boundaries of Russia and consequently in the fate of the Turkish Empire. In 1776 he sketched the plan for the conquest of the Crimea which was subsequently realized; and he was busy with the so-called "Greek project," which aimed at restoring the Byzantine empire under one of Catherine's grandsons. In many of the Balkan states he had well-informed agents. After he became field marshal, in 1784, he introduced many reforms into the army, and built a fleet in the Black sea, which, though constructed of very bad materials, did excellent service in Catherine's second Turkish War (1787–92). His colonizing system was exposed to very severe criticism, yet it is impossible not to admire the results of his stupendous activity. The arsenal of Kherson, begun in

1778, the harbour of Sevastopol and the new fleet of fifteen liners and twenty-five smaller vessels, were monuments of his genius. But there was exaggeration in all he attempted. He spared neither men, money nor himself in attempting to carry out his gigantic scheme for the colonization of the south Russian steppes; but he never calculated the cost, and more than three-quarters of the design had to be abandoned when but half finished.

Catherine's famous expedition to the south in 1787 was a triumph for Potemkin, for he concealed all the weak points of his administration. On this occasion he received the title of prince of Tauris. The same year the second Turkish War began, and the founder of New Russia acted as commander-in-chief.

But the army was ill-equipped and unprepared; and Potemkin, in an hysterical fit of depression, would have resigned but for the steady encouragement of the empress. Only after Suvarov had valiantly defended Kinburn did he take heart again, and besiege and capture Ochakov and Bender. In 1790 he conducted the military operations on the Dniester and held his court at Jassy with more than Asiatic pomp. In 1791 he returned to St. Petersburg where, along with his friend Bezborodko (*q.v.*), he made vain efforts to overthrow the new favourite, Zubov. The empress grew impatient and compelled him (1791) to return to Jassy to conduct the peace negotiations as chief Russian plenipotentiary. On Oct. 5, while on his way to Nikolayev, he died in the open steppe, 40 mi. from Jassy.

Potemkin was indubitably the most extraordinary of all the Catherinian favourites. He was an able administrator, licentious, extravagant, but loyal. generous and magnanimous. Nearly all the anecdotes related of him by Helbig, in the biography contributed by him to the journal *Minerva* (1797–1800), and freely utilized by later biographers, are absolutely worthless.

See V. A. Bilbasov, *Grschichte Katharinas II.* (Berlin, 1891–1893); C. de Larivière, *Catherine la Grande d'après sa correspondance* (Paris, 1895); Anonymous, *La Cour de Catherine II. Ses collaborateurs* (St. Petersburg, 1899); A. V. Lopukhin, *Sketch of the Congress of Jassy, 1791* (Rus.; St. Petersburg, 1893); *The Papers of Prince Potemkin, 1744–1793* (Rus.; St. Petersburg, 1893–1895). (R. N. B.)

POTENTILLA, a large genus of plants of the rose family (Rosaceae, *q.v.*), comprising more than 200 species, mostly herbs, widespread in north temperate and Arctic regions, many of which are cultivated as border and rock-garden plants. Various species bear brilliantly coloured flowers and graceful foliage.

A soil of a good loamy staple, enriched with rotten dung is the most suitable. Potentillas may be increased, though not very freely, by parting them into as many pieces as there are crowns, the side growths being those which can usually be thus separated. This may be done in autumn or spring, and the plants will generally bloom the following season. The species and some of the varieties reproduce true from seed, and are readily increased by that means. Nine wild species occur in the British Isles and more than 50 in North America, many of which are called cinquefoil or five-finger.

POTENTIOMETER, an instrument, due to J. C Poggendorff, for the measurement of electromotive force and also of the difference of electric potential between two points. The term potentiometer is usually applied to an instrument for the measurement of steady or continuous potential difference between two points in terms of the potential difference of the terminals of a standard voltaic cell of some kind, such as a Clark or Weston cell but alternating current potentiometers are in use. (*See* INSTRUMENTS, ELECTRICAL.)

POTENZA (anc. *Potentia*), a town and episcopal see of Lucania, Italy, capital of the province of Potenza, 103 mi. by rail E. by S. of Naples. Pop. (1936), 18,872 (town); 25,103 (commune). Situated 2,700 ft. above sea level on an isolated hill above the Basento (anc. *Casuentus*), it is much exposed to winds and has a far more northerly climate than its position (40° 40' N.) implies, and is one of the coldest towns in Italy.

The ancient Potentia lay some 470 ft lower, by the river, at the intersection of the road leading west to the Via Popillia and northeast to the Via Appia, with the Via Herculia.

Potentia must be distinguished from Potentia in Picenum, on the Adriatic coast. In 1694 there was a severe earthquake; and the more terrible earthquake which on Dec. 16 and 17, 1857 passed through southern Italy, and in Basilicata (Lucania) alone killed 32,475 persons, laid the greater part of Potenza in ruins. It was also damaged by the earthquake of 1910. In 1860 it was the first town to rise against the Neapolitan government.

POTGIETER, EVERHARDES JOHANNES (1808–1875), Dutch prose writer and poet, was born at Zwolle, in Overyssel, on June 17, 1808. He started life in a merchant's office at Antwerp. In 1831 he made a journey to Sweden and then settled in Amsterdam. With Heije, the popular poet of Holland in those days, and Bakhuizen van den Brink, the historian, Potgieter founded *De Muzen* ("The Muses," 1834–1836), a literary review, which was, however, soon superseded by *De Gids* ("The Guide"), a monthly, which became the leading magazine of Holland In it he wrote, mostly under the initials of "W. D ——g," a great number of articles and poems. The first collected edition of his poems (1832–1868) appeared in 2 vols. (Haarlem, 1868–1875), preceded by some of his contributions to *De Gids*, in 2 vols. also (Haarlem. 1864), and followed by 3 vols. of his *Studien en Schetsen* ("Studies and Sketches." Haarlem, 1879). Potgieter's favourite master among the Dutch classics was Hooft, whose peculiarities in style and language he admired and imitated. In Holland Potgieter's influence has been very marked and beneficial; but his own style, that of ultra-purist, was at times somewhat forced, stilted and not always easily understood.

The best edition of Potgieter's works is that by his friend and executor J. C. Zimmermann (19 vols., 1885–90).

POTHIER, DOM JOSEPH (1835–1923), French musical scholar, was born at Bouzemont, near Saint Dié, Dec. 7, 1835. He became a Benedictine in 1859 and after holding various positions of authority in two French abbeys, was named abbot of a third, St. Wandrille, in 1898. In 1901, when members of religious orders were compelled by law to leave France, the monastery was temporarily located in Belgium. Shortly after he entered the Benedictine order at Solesmes, Dom Pothier was encouraged by Dom Guéranger, who had started a movement to revive the ancient plainsong, to study early church music. In 1880 Dom Pothier published *Les Mélodies grégoriennes*, which became the standard work on Gregorian chants. During the next 25 years he wrote 7 other treatises on various phases of ancient religious music and was responsible for beginning a collection of musical manuscripts at Solesmes.

Pope Pius X made him chairman (1904) of a commission which re-edited and published the musical parts of the Roman Catholic Mass. He died at Conques, Belgium, Dec. 8, 1923.

POTHIER, ROBERT JOSEPH (1699–1772), French jurist, was born at Orléans on Jan. 9, 1699. He studied law for the purpose of qualifying for the magistracy, and was appointed in 1720 judge of the presidial court of Orléans. This post he held for 52 years. He paid particular attention to the text of the Pandects, his *Pandectae Justinianae in novum ordinem digestae* (Paris and Chartres, 1748–1752) being a classic in the study of Roman law. In 1749 he was made professor of law in the university of Orléans. He wrote many learned monographs on French law, and much of his work was incorporated almost textually in the French Code Civil. He died March 2, 1772.

Of his numerous treatises the following may be especially mentioned: *Traité des obligations* (1761); *Du Contrat de vente* (1762); *Du Contrat de bail* (1764); *Du Contrat de société* (1765); *Des Contrats de prêt de consomption* (1766); *Du Contrat de depôt et de mandat* (1766); *Du Contrat de nantissement* (1767), etc. His works have several times been published in collected form (edited by Giffrein, 1820–24; by Dupin, 1823–25, and by Bugnet, 2nd ed. 11 vols. 1861–62). See Dupin, *Dissertation sur la vie et les ouvrages de Pothier* (Paris, 1825), and Frémont, *Vie de R. J. Pothier* (Orléans, 1850).

POTHOOK, a metal hook, frequently S-shaped, for suspending a pot over a fire. While one extremity is hooked to the handle of the pot, the other is caught upon an iron crane moving on a pivot over the fire. Modern cooking-ranges have obviated the necessity for this arrangement, but it is still to be seen in great numbers of country cottages and farmhouse kitchens all over England, and in small artisans' houses in the west midlands and the north. In the elementary teaching of writing, the "pothook" is a script of similar shape.

POTI, a seaport of Russia, in the Georgian S.S.R., in 42° 10′ N., 41° 38′ E., on the Rion river, on the Black sea coast, in a marshy and malarial district. Population 14,671.

During west and southwest gales the harbour is very difficult to approach.

There are berths for eight or ten large steamers and an elevator for loading manganese, the chief export from the Kvirili valley. The town is linked by rail with Baku, and there is a line northward along the coast.

The town has a saw-milling industry. The ancient Phasis, a commercial colony of the Greek city of Miletus, stood on this site. In 1578 Sultan Murad III, of Turkey, built a fortress here, destroyed during a war with Persia. In 1640 the Imeretians attacked the town. (*See* GEORGIA.) Poti was a great slave market. It was captured by the Russians in 1812 and in 1829 recaptured and annexed.

POTIOREK, OSKAR (1853–1933), Austro-Hungarian general of artillery, was born at Blieburg, Carinthia, in 1853. His career was chiefly spent on the general staff, where he held the post of chief of the section of operations, and later that of deputy to the chief of the general staff, Count Beck. After Beck's retirement he was in command of the III Corps, in 1911 army inspector and governor (*Landeschef*) in Bosnia and Hercegovina. As such, he was officially responsible for countenancing the fateful visit of the heir to the throne to Serajevo, out of which World War I ensued. In the offensive taken by Austria against Serbia in the winter of 1914, which eventually broke down after great initial success, his judgment was also found wanting. He was then relieved of his command.

POTLATCH, an Indian term, denotes the lavish feasts especially characteristic of the Tlingit, Kwakiutl, and other tribes of the northwest coast of America. The potlatch is given by one chief or clan to another, and is marked by great profusion of food and gifts, often accompanied by destruction of some of the property of the hosts, as in the breaking of highly prized copper plaques, an act which adds greatly to their fame. The keynote of such excesses is the exaggerated respect which these Indians show for wealth in use—an attitude shared by many other savage peoples and not without its cultural value. It is a matter of honour to accept any invitation to a potlatch, and to give a grander feast in return. Refusal involves loss of prestige and rank. Rivalry in feast-giving may become so intense that a man will beggar himself and relatives in the effort to win renown. But the potlatch is not a mere wasteful orgy; it maintains differences of chieftainship and rank, binds together kinship groups, and offers a medium for repayment of debts, thus serving as an institution of real importance in social and economic life.

See F. Boas, *Ethnology of the Kwakiutl,* Part I, 35th Ann. Rept. Bureau Amer. Ethnology (1914); Swanton, *Social Conditions, etc., of Tlingit Indians,* 26th Ann. Rept. *ibid.* (1905); Marcel Mauss, "Essai sur le Don," *L'Année sociologique,* n.s. I (1924).

POT-METAL. The glass employed in "stained-glass" windows is coloured in the making by tinting the glass in the melting-pot with various metallic oxides. This self-coloured glass, which may or may not be afterwards painted or decorated, is called pot-metal.

(*See* STAINED GLASS.)

POTOCKÍ, STANISLAW FELIX (1752–1805), Polish politician, son of Franciszek Salezy Potockí, palatine of Kiev, was born in 1752. Through family influence, he became grand standard-bearer of the crown at the age of twenty-two. In 1782 he was made palatine of Russia, in 1784 a lieutenant-general, and in 1789 purchased the rank of a general of artillery. Liberal, enlightened, a generous master and a professed patriot, he had awakened great hopes; but he identified the public welfare with the welfare of the individual magnates, and when elected to the Four Years' diet, schemed to divide Poland into an oligarchy of autonomous grandees exercising the supreme power in rotation (in fact a perpetual interregnum). The election of Malachowski (*q.v.*) and Kazimierz Sapieha as marshals of the diet still further alienated him from the Liberals; and he retired to Vienna whence he continued to carry on an active propaganda against the new ideas. He protested against the constitution of May 3, 1791, and after attempting fruitlessly to induce the emperor Leopold to intervene, proceeded with his friends in March 1792, to St. Petersburg, and subsequently with the connivance of the empress Catherine formed the confederation of Targowica (May 14, 1792), of which he was the marshal, or rather the dictator, directing its operations from his castle at Tulczyn. When the May constitution was overthrown, Potockí (March 1793) went on a diplomatic mission to St. Petersburg; but, finding himself duped, he settled down at Tulczyn. He wrote *On the Polish Succession* (Pol.) (Amsterdam, 1789); *Protest against the Succession to the Throne* (Pol.) (*ibid.* 1790); and other political works.

POTOMAC, a river in the east central part of the United States, having its source in the Allegheny mountains and flowing southeast into Chesapeake bay. It is formed by the union of its north and south branches, about 15 mi. S.E. of Cumberland, Md. The main stream has a length of about 450 mi. and is navigable for large vessels for 113 mi. above its mouth. From the junction of its two branches until it reaches Harper's Ferry the Potomac river separates Maryland from West Virginia. At Harper's Ferry it receives the waters of the Shenandoah river and cuts through the Blue Ridge mountains in a gorge noted for its beauty. From this point to its mouth it forms the boundary between Virginia and Maryland. The stream crosses the Blue Ridge mountains at an elevation of about 245 ft., and at Georgetown (Washington, D.C.), 62 mi. distant, it meets tidewater. Of this descent about 90 ft. occurs about 15 mi. above Washington at the Great Falls, a series of rapids about a mile long and including a cataract about 35 ft. high.

Three and a half miles above Washington are the Little Falls, which mark the head of navigation.

At Washington there are two channels, with respective depths at mean low water of 18 and 21 ft.

Large sums have been spent since 1870 on improving these channels.

A few miles below the city the river broadens into a deep tidal estuary from 2½ to 7 mi. wide; and channels 24 ft. deep and 200 ft. wide through all the shoals were secured by the project of 1899.

The Anacostia river, or "East Branch," which flows into the Potomac just south of Washington, is navigable for large vessels for about 2 mi. and for small scows and lighters as far as Bladensburg, Md., 8¾ mi. above its mouth. Improvements (begun in 1902) have produced a channel 21 ft. deep at mean low water and 380 ft. wide.

The Chesapeake and Ohio canal, from Georgetown to Cumberland, Md., follows the Potomac closely on the Maryland side.

POTOROO or **RAT KANGAROO,** any member of the diprotodont marsupial sub-family *Potoroinae* (*see* MARSUPIALIA). None of them exceeds a rabbit in size. They inhabit Australia and Tasmania, are nocturnal, and feed on leaves, roots, and bulbs, which latter they dig up with their forepaws. About ten species are known. The members of the type genus (*Potorous*) run, rather than leap, and do not use the hind feet for kicking. In the genus *Bettongia* the tail is prehensile.

POTOSÍ, a department of Bolivia occupying the southwestern angle of that republic, bounded N. by Oruro, Cochabamba and Chuquisaca, E. by the two last departments and Tarija, S. by Argentina and W. by Chile and Oruro. Pop. (1940 estimate), 649,000 the larger part Indians; area 41,297 sq.mi. The eastern part of the department is traversed north to south by the eastern branch of the Andes, locally known as the Cordillera de los Frailes and the Cordillera de Chichas. Spurs and broken ranges project eastward from these, between which are the headstreams of the Pilcomayo and Grande, the first flowing southeast to the Plata, and the second northeast to the Madeira and Amazon. The Pilcomayo itself rises in the department of Oruro, but several of its larger tributaries belong to Potosí—the San Juan, Cotagaita and Tumusla in the south, and Cachimayo in the north. The western part of the department belongs to the great Bolivian *altiplanicie,* or southern extension of the Titicaca basin. It is a barren, saline waste, almost uninhabitable. In the north, bordering on the transverse ridge of which the Cerro de Tahua (17,457 ft.) forms a part, is the depression known as the Salar de Uyuni, 12,080 ft. above sea level. Near the southern frontier is another transverse ridge, in part formed by the Sierra de Lipez and in part by apparently detached groups of high peaks; it is a waterless desert like the Puna de Atacama.

Potosi is essentially a mining department, though agriculture and grazing occupy some attention in the eastern valleys. The plateau there is rich in minerals, especially silver and copper. The Huanchaca-Pulacayo group of mines, situated on the slopes of the eastern Cordillera, about 13.600 ft. above sea level, overlooking the Salar de Uyuni, has the largest output of silver in Bolivia. Between 1873 and 1901 it yielded 4,520 tons of silver, of an estimated value of £23,200,000. Farther south are the Portugalete mines, once very productive, and near the Argentine border are the Lipez mines. East of the Cordilleras are the famous "silver mountain" of Potosi, once the richest silver mine in the world; the snow-capped peak of Chorolque (18,452 ft.), which is claimed to have the highest mine in the world, 18.000 ft. above sea level; Porco, a few miles southnest of Potosí; Guadalupe, Colquechaca and Aullagas. Besides silver most of these mines yield tin, copper, zinc, bismuth, tungsten, antimony and wolfram and are now being worked chiefly for their tin, of which Bolivia produced more than 42,000 tons in 1940. The production of minerals in these famous'centres has recently been eclipsed by the enormously rich deposits of tin at Uncia and Llallagua in the same department. The department is traversed by the Antofagasta & Bolivia railway and by a line from Uyuni to the Argentine frontier at La Quiaca. A branch line of the former also runs to Sucre via Potosi.

Besides Potosi, the capital of the department (pop. about 45,000), the principal towns are Huanchaca, Pulacayo, Uyuni (g mi. from Huanchaca, 12,100 ft. above sea level, a small town but an important railway junction and commercial centre on the waterless plain, the shipping point and supply station for an extensive mining region) and Tupiza (pop. about 8,000), a prettily situated town near the Argentine frontier, on a small branch of the San Juan river, 9,800 ft. above sea level.

POTOSÍ, a city of Bolivia, capital of the department of Potosi, 47 mi. S.W. of Sucre, or 106 mi. by the post-road. Pop. (1942, est.), 45,000. Potosi stands on a barren terrace on the northern slope of the Cerro Gordo de Potosi. 13,612 ft. above sea level, and is one of the highest towns in the world. The famous *cerro* from which its name is taken rises above the town to a height of 15,381 ft., a barren, white-capped cone, honeycombed with mining shafts.

The foundation of the city dates from 1547, two years after the first discovery of silver on the *cerro* by an Indian herder. Charles V conferred upon it the title of "villa imperial." From 1545 to 1800 the crown tax of one-fifth upon the mineral product amounted to £32,600,000, showing an acknowledged output of £163,000,000. The total output to 1864 has been estimated at more than £400,000,000, but the annual output at the beginning of the 20th century barely exceeded 400,000 oz. The town is regularly laid out with streets crossing each other at right angles. The age-begrimed buildings, many of which are unoccupied and in ruins, are commonly of adobe. A large plaza forms the conventional centre, around which are grouped various religious edifices. the government house, town hall, national college, the old "royal mint" dating from 1572, and the treasury. The city has a massive, plain cathedral, which in part dates from early colonial times, and in part from the closing years of Spanish rule. The water supply is derived from reservoirs constructed during the years of the city's greatest prosperity. Potosi, long accessible from the outside world only by rough mountain roads, now has rail connections with Rio Mulatos on the Antofagasta-Bolivia line and with Sucre. In 1611 the population of Potosi was reported to be 160,000, which probably included the whole mining district. A part of the diminution since then is explained by the fact that the great majority of the mines on the *cerro* were abandoned In recent years valuable deposits of tin have been found and many of the mines have re-opened.

POTOTAN, a municipality (with administrative centre and 64 *barrios* or districts) of the province of Iloilo, island of Panay, Philippine Islands, on the Jaluar river, and located along the railway, about 17 mi. N.E. of Iloilo, the provincial capital. Pop. (1939) 33,020; 15,871 were males and 7 were whites. The chief agricultural products are sugar, maize (corn), palay (rice), tobacco and abaci (Manila hemp). Cattle, carabao and horses are bred for local use and for export. Panay-Bisayan is the vernacular. Of the inhabitants aged 6 to 19 inclusive, 41.7% in 1939 attended school, while 51.8% 10 years old and over was literate.

POTSDAM, a town in Germany, the administrative capital of the Prussian province of Brandenburg and formerly one of the residences of the German emperor, on the river Havel, 16 mi. S.W. of Berlin, on the main line of railway to Magdeburg. Pop. (1939) 136,167. It is connected with the capital by two local lines and by a steamboat service through the chain of lakes formed by the river. Potsdam, originally Poztupimi, a Slavonic fishing-village, is first mentioned in 993. A town in the 14th century, it was unimportant until the great elector built a palace there between 1660 and 1682; and even at the close of his reign it only contained 3,000 inhabitants. The elector Frederick William I greatly enlarged Potsdam, and his stiff military tastes are reflected in the monotonous uniformity of the streets. Frederick the Great continued his father's work, and was the real creator of the splendour of the town.

The palace, a large quadrangular building of the 17th century, is chiefly interesting for the numerous relics it contains of Frederick the Great. It also contains reminiscences of Voltaire, who resided here for several years. The principal churches are the Nikolaikirche; the Church of the Holy Ghost, built in 1728; and the Friedenskirche, or Church of Peace, erected in 1845–50, to which is attached a mausoleum. Among other conspicuous buildings are the military establishments; the town hall; and the Brandenburg gate. Potsdam has manufactures of chemicals, furniture, chocolate, soap, tobacco and surgical and musical instruments. Market-gardening affords occupation to many of the inhabitants, and the cultivation of winter violets is a specialty. The Havel is well stocked with fish. To the south of the town lies the observatory.

POTSDAM, a village of St. Lawrence county, New York, U.S.A., on the Raquette river, Federal highway 11 and the New York Central railroad, 30 mi. E. of Ogdensburg. Pop. in 1930, 4,136; 1940, 4,821. It is the seat of the Clarkson College of Technology (1896), a state normal school (1869) with which is incorporated the former Crane Normal Institute of Music, and is the centre of a large dairy industry and of several electric power developments. Settlement here began in 1803 and the village was incorporated in 1831. It gives its name to deposits of a reddish sandstone studied here first by Emmons in 1838–42.

POTT, PEWCIVALL (1714–1788), English surgeon, was born in London on Jan. 6, 1714. He became assistant surgeon at St. Bartholomew's in 1744 and was full surgeon from 1749 till 1787. He died in London on Dec. 22, 1788. The first surgeon of his day in England, excelling even his pupil, John Hunter, he introduced various important innovations in procedure, doing much to abolish the extensive use of escharotics and the actual cautery that was prevalent when he began his career. A particular form of fracture of the ankle which he sustained through a fall from his horse in 1756 is still described as Pott's fracture. and his book, *Some Few Remarks upon Fractures and Dislocations,* published in 1768 and translated into French and Italian, had a far-reaching influence in Great Britain and France. "Pott's disease" is a spinal affection of which he gave an excellent clinical description in his *Remarks on that Kind of Palsy of the Lower Limbs which is frequently Found to Accompany a Curvature of the Spine* (1779).

There are several editions of his collected works; that published by Sir James Earle in 1790 contains a sketch of his life.

POTTER, ALONZO (1800–1865), American bishop of the Protestant Episcopal Church, was born at Beekman (now La Grange), N.Y., on July 6, 1800. He graduated in 1818 at Union college, where he became tutor and then professor of mathematics after a brief period spent in studying theology at Philadelphia. He was rector of St. Paul's, Boston, from 1826 to 1831, when he returned to Union as professor of philosophy and political economy, becoming vice president of the college in 1838. He was consecrated bishop of Pennsylvania on Sept. 23, 1845, and died on board ship in San Francisco harbour on July 4, 1865. By his publication with G. B. Emerson of The *School* and the Schoolmaster (1842) and by lectures Potter did much to extend and better public school education. He was particularly interested in work for young men and in temperance reform. As a legislator in the church he was wise and progressive. He established the Philadelphia Divinity school (1861), and laboured for the "Hospital of the Protestant Episcopal Church in Philadelphia."

See M. A. De Wolfe Howe, *Memoirs of the Life and Services of the Rt. Rev. Alonzo Potter, D.D.* (1870).

His brother, HORATIO POTTER (1802–1887), was born in Beekman, N.Y.. Feb. 9, 1802. He graduated at Union college in 1826 and was successively rector in Maine, professor of mathematics and natural philosophy at Washington (now Triniiy) college at Hartford, Conn., rector in Albany and after 1854 provincial bishop of New York. Failing health put an end to his active service in 1883, when his nephew, H. C. Potter (*q.v.*), became his assistant. He died in New York city Jan. 2, 1887.

POTTER, HENRY CODMAN (1834–1908), American Protestant Episcopal bishop, the son of Bishop Alonzo Potter, was born in Schenectady, N.Y., on May 25, 1834. In October 1883 he was consecrated assistant to his uncle, Horatio Potter, bishop of New York, whom he succeeded in 1887. He died in Cooperstown, N.Y., on July 21, 1908. During his administration the corner-stone of the cathedral of St. John the Divine was laid (Dec. 27, 1892). As rector of Grace church he worked to make it an "institutional church" with clubs for working men and girls, day nurseries and kindergartens. He won fame on the centennial of Washington's inauguration by his address on the dangers and corruptions of the spoils system.

See Harriette A. Keyser, *Bishop Potter, the People's Friend* (1910), and the official biography by George Hodges (1915).

POTTER, PAUL (1625–1654), Dutch animal painter, was born at Enkhuizen, Holland. He was instructed in art by his father, Peter Potter, a landscape and figure painter of some merit, and by Nicolas Moeyaert, of Amsterdam. Other masters and influences are mentioned by various writers, but more than any other of his contemporaries he learnt through direct study from nature. In 1646 he went to Delft, where he became a member of the gild of St. Luke. At the age of twenty he settled at the Hague, and there married in 1650. He was patronized by Maurice, prince of Orange, for whom he painted the life-size picture of the "Young Bull," now one of the most celebrated works in the gallery of the Hague. In 1653 he was induced by Burgomaster Tulp of Amsterdam to remove to that city. He died Jan. 15, 1654.

His paintings are generally small; early in life, however, he attempted, but with ill success, to work on a monumental scale, as in the "Bear Hunt" at the Rijks Museum and the "Boar Hunt" of the Carstanjen collection, Berlin. Even the famous "Equestrian Portrait of Tulp" formerly in the Six collection, Amsterdam, is awkward and stiff and hard in handling. His animals are accurately designed, and the landscape backgrounds are introduced with spirit and appropriateness. His colour is clear and transparent, his execution firm and finished without being laboured. His view of nature is purely objective and unemotional; he painted with the greatest directness and simplicity the things he saw before him, and his paintings of horses and cattle are so individualized that they become faithful portraits of the animals. The best among his small portraits of horses are in the Louvre and in the Schwerin Gallery; and certain of his studies are the most brilliant of all.

The earliest dated picture of importance is "Abraham Entering Into Canaan" (1642), at the Germanic Museum in Nuremberg, in which he makes the Scriptural subject an excuse for painting the patriarch's herds, just as in his "Orpheus" of 1650 (Rijks Museum, Amsterdam) he makes similar use of the Greek myth. Among his finest works on a small scale are a cattle piece (1653) in the Duc d'Arenberg's collection, and a similar, though earlier, picture in the Munich Pinakothek. Hofstede de Groot enumerates 177 works by Potter. He worked with feverish application, as though he were aware of the short span of life that was granted him. He executed a series of some twenty etchings, mainly of animals, which are simple and direct in method and handling.

Potter's works have been engraved by Bartolozzi, Danckerts, Visscher, Le Bas and others. There are two of his paintings at the National Gallery, three in Buckingham Palace and a few in the duke of Westminster's collection. On the continent of Europe the most numerous and representative examples are to be found at the Rijks Museum in Amsterdam, the Hermitage in Leningrad and the Dresden Gallery. (P. G. K.)

L.* F. Lecarpentier (Rouen, 1818); Hofstede de Groot, *Catalogue of Dutch Painters* (1912).

POTTERIES, THE, a name applied to a district of north Staffordshire, the principal seat of the china and earthenware industry in England. It lies in the upper part of the Trent basin. For a distance of 9 m. from south-east to north-west, and about 3 m. from north-east to south-west, the district resembles one great town, but the chief centres are, Burslem, Hanley, Longton, Stoke-on-Trent, Fenton and Tunstall. These towns were amalgamated in 1910 as one municipal borough under the name of Stoke-on-Trent, which was raised to the dignity of a city in 1925. Newcastle-under-Lyme, though not sharing in the staple industry, may also be reckoned in the district. In 1769 Josiah Wedgwood founded pottery works at Etruria, now in the parliamentary division of Hanley. The Wedgwoods and the Mintons are the two most famous family names connected with the china industry of the district. Coal and coarse clay are the only local natural products used in the industry, the finer clay and other ingredients being brought from Cornwall and elsewhere. Ironstone is raised, and many new industries have been established in the district.

POTTERY AND PORCELAIN. The word "pottery" (Fr. *poterie*) in its widest sense includes all objects fashioned from clay and then hardened by fire; the word "porcelain" should only be applied to certain well marked varieties of pottery. Pottery is dependent on two important natural properties of that great and wide-spread group of rocky or earthy substances known as clays, viz., the property of plasticity and the property of being converted when fired into one of the most indestructible of ordinary things.

"Ceramics" or "Keramics" (Gr. κεραμος, earthenware) is a general term for the study of the art of pottery. It is adopted for this purpose both in French (ceramique) and in German (Keramik).

INTRODUCTION

The primitive races took such clay as they found on the surface of the ground, or by some river-bed, and, spreading it our on a stone slab, picking out the rocky fragments, then beating it with the hands, with stones or boards, or even treading it with their feet, proceeded to fashion it into such shapes as need or fancy dictated. Fired in an open fire, such pottery may be buff. drab, brown or red—and those from imperfect firing become smoked, gray or black. For ages tools and methods remained of the simplest—the fingers for shaping or building up vessels, a piece of mat or basket-work for giving initial support to a larger vase—until some original genius of the tribe found that by starting to build up his pot on the flattened side of a boulder he could turn his support so as to bring every part in succession under his hand, and thus the potter's wheel was invented.

At first this simple hand-made pottery was hardened by drying in the sun, but the increasing use of fire soon brought out the fact that a baked clay vessel became as hard as stone. Different districts produced different colours of clay, and thus colour decoration arose. On this substructure all the pottery of the last 4,000 years has been built, for behind all Egyptian, Greek or

DECORATED POTTERY OF ANCIENT GREECE AND ITALY

1. Attic ***oenochoe*** or jug, with a moulded design representing a sacrifice. 4th cent. B.C.
2. Roman (Arretine) ***krater*** or mixing bowl, bearing a design of the Seasons. 1st cent. B.C.
3. Attic black-figure ***amphora*** or two-handled jar, signed by the potter Exekias, showing Achilles slaying Penthesileia. 6th cent. B.C.
4. Attic red-figure ***krater*** attributed to the painter Myson, showing Heracles and Apollo struggling for the Delphic Tripod. 5th cent. B.C.

Chinese pottery we find the same primitive foundations.

In subsequent articles on this subject we find that the Egyptians evolved schemes of glowing colour—brilliant glazes fired on objects, shaped in sand held together with a little clay, or actually carved from rocks or stone; the Greeks produced their marbles of plastic form, and then turned the plastic clay into imitations of metal forms; the Romans spread some knowledge of the craft over all the empire, but with its fall pottery was forgotten along with its greater achievement. Egypt and the Near East continued the splendours of their glorious past, and glazed and painted pottery was still made by traditional methods. Many interesting kinds of decorated pottery were made at Old Cairo, Alexandria, Damascus, in Syria, Anatolia and elsewhere (on which the later Moslem potters founded their glorious works).

Meantime, in the farther East, the Chinese—the greatest race of potters the world has ever seen—were quietly gathering strength, until from their glazed, hard-fired pottery there emerged the marvellous, white translucent porcelain, one of the wonders of the mediaeval world.

With the dawn of the 15th century, the state of affairs was practically this; In European countries proper, we find rudely fashioned and decorated wares in which we can trace the slow development of a native craft from the superposition of Roman methods on the primitive work of the peoples. The vessels were mostly intended for use and not for show; were clumsily fashioned of any local clay, and if glazed at all then only with coarse lead-glazes, coloured yellow or green; in no case above the level of workmanship of the travelling brick- or tile-maker. The finest expression of this native style is to be found in the Gothic tile pavements of France, Germany and England.

As early as the 12th century the superior artistic pottery of the Moslem nations had already attracted the notice of Europeans as an article of luxury for the wealthy; and we may well believe the traditional accounts that Saracen potters were brought into Italy, France and Burgundy to introduce the practice of their art, while Italian potters certainly penetrated into the workshops of eastern Spain and elsewhere and gathered new ideas.

During the 15th and 16th centuries, Chinese porcelain also began to find its way into Europe, and by the whiteness of its substance and its marvellous translucence excited the attention of the Italian majolists and alchemists. The first European imitation of this famous oriental porcelain of which we have indubitable record was made at Florence (1575–85) by alchemists or potters working under the patronage, and, it is said, with the active collaboration of Francesco de' Medici. This Florentine porcelain was the first of those distinctively European wares, made in avowed imitation of the Chinese, which form a connecting link between pottery and glass, for they may be considered either as pottery rendered translucent or as glass rendered opaque by shaping and firing a mixture containing a large percentage of glass with a very little clay.

During the 18th century not only was there a very large trade in imported Chinese and Japanese porcelain, but there was a great development of porcelain manufacture in Europe.

The 19th century witnessed a great and steady growth in the output of porcelain and pottery of all kinds in Europe and the United States. Mechanical methods were largely called in to supplement or replace what had hitherto remained almost pure handicraft. The English methods of preparing and mixing the materials of the body and glaze, and the English device of replacing painted decoration by machine printing, to a large extent carried the day, with a great gain to the mechanical aspects of the work and in many cases with an entire extinction of its artistic spirit.

The 20th century opened with a wider outlook among the potters of Europe and America. In every country men were striving once again to bring back to their world-old craft something of artistic taste and skill.

TECHNIQUE

All pottery, whether of ancient or modern times, is made by the simplest method. The clay, dug from the earth's surface, is prepared by beating and kneading with the hands, feet or simple mallets of stone or wood. Care is taken that all stones and hard particles are picked out. In ancient pottery, the clay, well tempered with water, was almost invariably used without any additional material. From this pure clay, vessels were shaped by scooping aut or cutting a solid lump or ball, by building up piece by piece or by squeezing cakes of clay on to some natural object or prepared mould or form. The potter's wheel, though very ancient, was a comparatively late invention, arrived at independently by many races of men. In its simplest form it was a heavy disk pivoted in a central point to be set going by the hand, as the workman squatted on the ground. About the Christian era, and in Egypt apparently, a much larger disk, which the potter could rotate with his foot, was introduced; this gave the potter an opportunity to use both hands in the manipulation of the clay. In the 17th century the wheel was spun by means of a cord working over a pulley, and in the 19th century the steam driven wheel was introduced.

The rotating process completed, the piece is removed from the wheel and set aside to dry. When it is about leather-hard, it may be recentred carefully on the wheel (the old practicej, or placed in a horizontal lathe (16th century) and turned down to the exact shape and polished to an even, smooth surface. Many Greek vases have obviously been "thrown" in separate sections. So too with the Chinese; many of their forms have been made in two or three portions, subsequently joined together and finished on the outside as one piece. (See TERRA-COTTA.)

Firing.—The type of kiln used by the potters of ancient Egypt or Greece have not entirely vanished from present day use; it is only in the civilized countries of the modern world that they have been replaced by improved and perfected devices. The potters of certain sections of the Near East and of Japan remain content with the crudest and most primitive types of kilns. With the organization of the pottery as a factory industry in the 18th century, improved kilns were introduced, and the type of kiln now used in civilized countries is a verticle furnace from 10 to 22 ft. in diameter and of similar height, capable, therefore, of containing at one firing a quantity of pottery that would have formed the output of a mediaeval potter for a year. Gas-fired kilns and ovens are now being used or experimented with in every country, and their perfection, which cannot be far distant, will improve the most vital of the potters' processes both in certainty and economy.

Glazes.—We can only consider as glazes those definite superficial layers of molten material which have been fired on the clay substance. Glazes are as varied as the various kinds of pottery, and it must never be forgotten that each kind of pottery is at its best with its appropriate glaze. The most important types of glaze are (1) alkaline glazes, *e.g.,* Egyptian, Syrian, Persian, etc., the oldest and most uncertain; (2) lead glazes, the most widespread in its use and the best for all ordinary purposes; (3) felspathic glazes, the glazes of hard-fired porcelains, generally unsuited to any other material; (4) salt-glaze, produced by vapours of common salt, the special glaze of stone-wares.

Colours.—The primitive potters of ancient and modern times have all striven to decorate their wares with colour. The simplest, and therefore the earliest, colour decoration was carried out in natural earths and clays. The clays are so varied in composition that they fire to every shade of colour from white to grey, cream, buff, red, brown or even to a bronze which is almost black. One clay daubed or painted upon another formed the primitive palette of the potter, especially before the invention of glaze. When glaze was used these natural clays were changed in tint, and native earths, other than clays, containing iron, manganese and cobalt, were gradually discovered and used. It is also surprising to note that some of the very earliest glazes were coloured glasses containing copper or iron (the green, turquoise and yellow glazes of the ancient Egyptians and Assyrians). Marvellous work was wrought in these few materials, but the era of the finest pottery-colour dawns with the Persian, Syrian and Egyptian work that preceded the Crusades. By this time the art of glazing pottery with a clear soda-lime glaze had been thoroughly learnt. Vases, tiles, etc., shaped in good plastic clay, were covered with a white, highly siliceous coating fit to receive glazes of this type, and giving the best possible ground for the painted colours then known. The colours already spoken of were either clay colours or what are known as "under glaze" colours, because they were painted on the pottery before the glaze was fired.

The earliest glazes of the Egyptians appear not to have been white, but were coloured throughout their substance, and this use of coloured glazes as apart from painted colour was developed along with the painted decoration by the later Egyptian, Syrian and Persian potters. Green, yellow and brown glazes were almost the only artistic productions of the mediaeval European potters' kilns, and their use everywhere preceded the introduction of painted pottery.

With the exceedingly refractory felspathic glazes of Chinese porcelain very few underglaze colours could be used; and the prevalence of blue and white among the early specimens of Chinese porcelains is due to the fact that cobalt was almost the only substance known to the potters of the Ming dynasty which would endure the high temperature needed to melt their glazes. Consequently the Chinese were driven to invent the method of painting in coloured fusible glasses on the already fired glaze. They adopted for this purpose the coloured enamels used on metal; hence the common term "enamel decoration," which is so generally applied to painting in those colours which are attached to the already fired glaze by refiring at a lower temperature. With the introduction of this many-coloured Chinese porcelain into Europe the same practice was eagerly followed by our European potters, and a new palette of colours and fresh styles of decoration soon arose amongst us.

It must be pointed out that the colour possibilities in any method of pottery decoration are largely dependent on the temperature at which the colour needs to be fired. The clay colours are naturally more limited in range than the under-glaze colours, and these in their turn than the on-glaze colours.

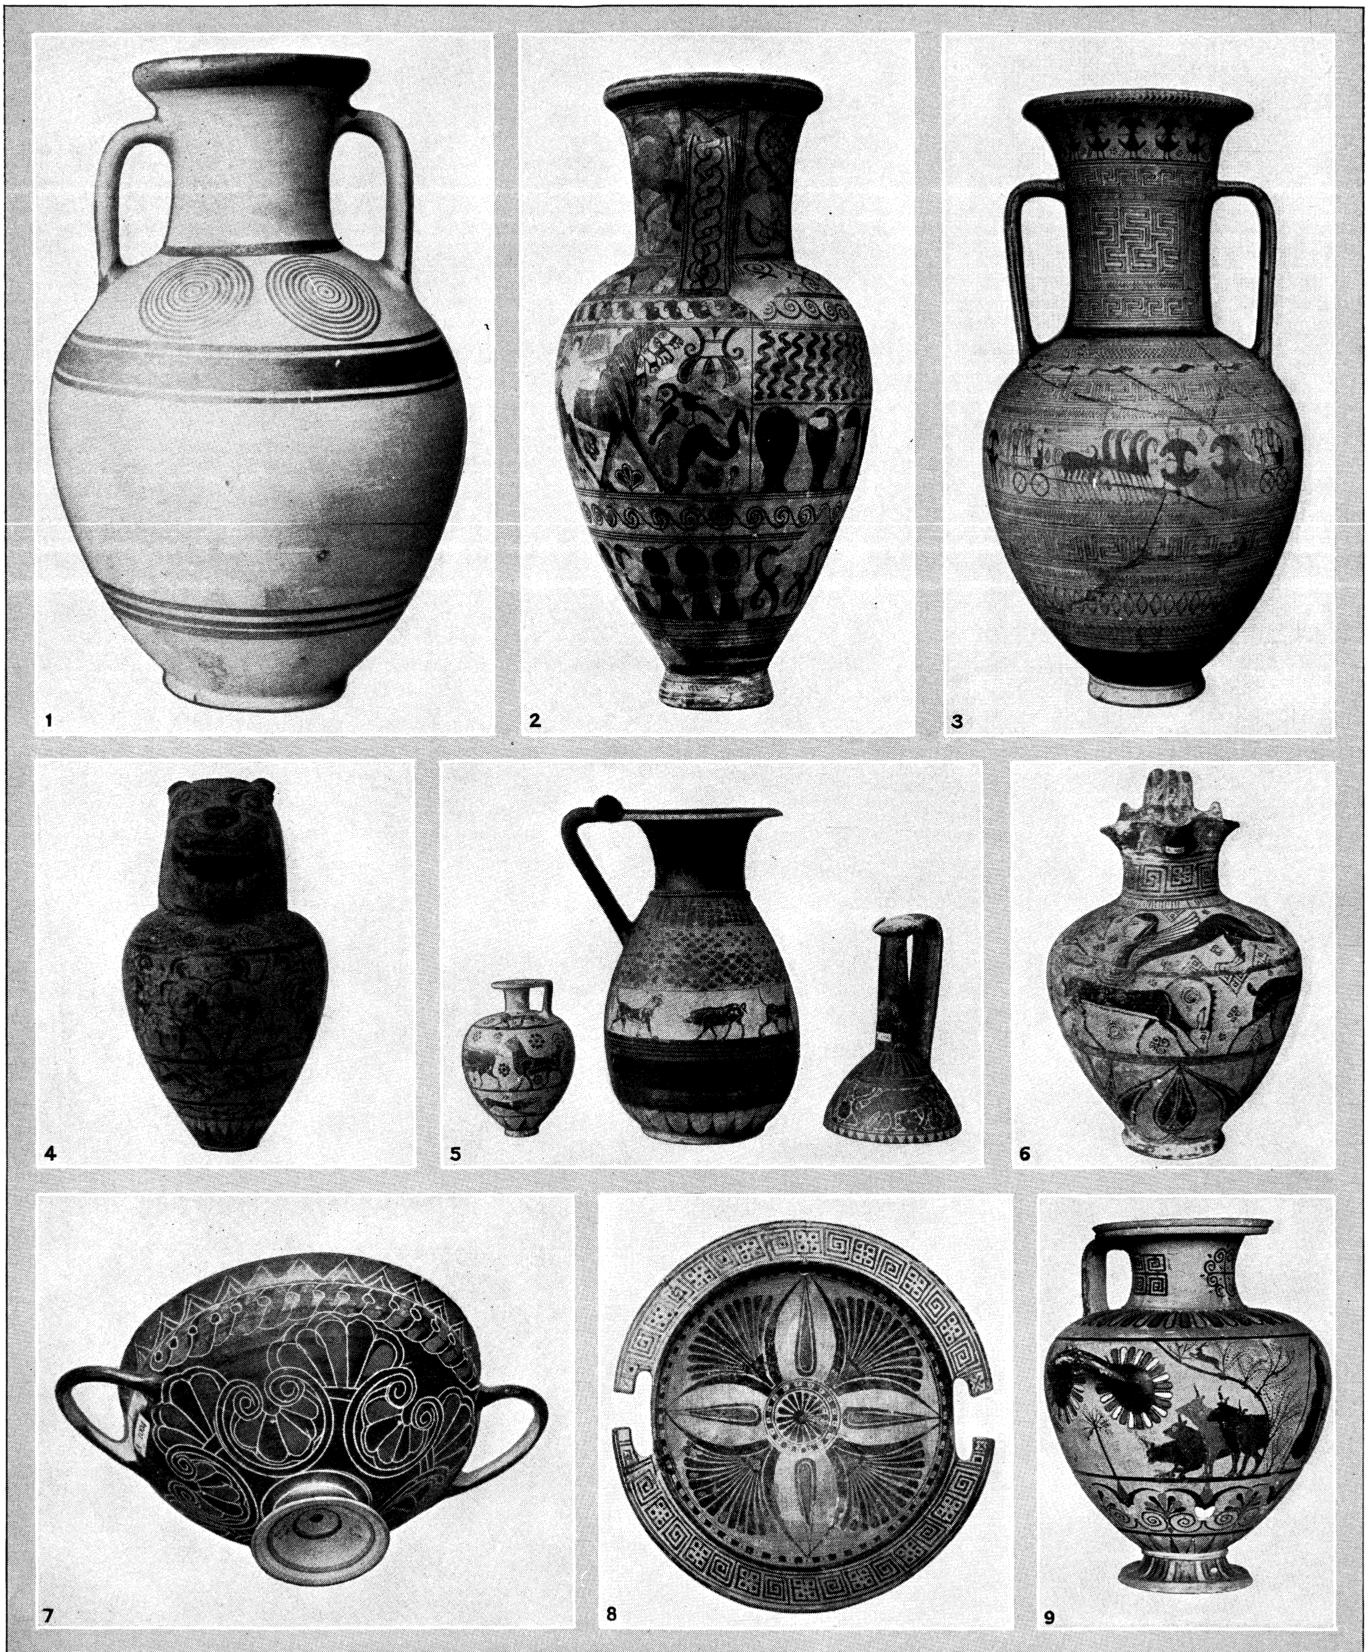
Metals.—The noble metals, such as gold, platinum and silver, have been largely used since the early years of the 18th century as adjuncts to pottery decoration, especially on the fine white earthenwares and porcelains of the last two centuries. At first the gold was applied with a kind of japanner's size and was not fired to the glaze, but for the last 150 years or so the metals have generally been fired to the surface of the glaze like enamel colours, by mixing the metal with a small proportion of flux or fusible ground glass. There can scarcely be a doubt that the ancient lustres of Persia, Syria and Spain were believed to be a form of gilding, though their decorative effect was much more beautiful than gilding has ever been. The early Chinese and Japanese gilding appears, like the European, to have been "sized" or water-gilt, not fired; and it seems probable that the use of "fired" gold was taught to the Oriental by the European in the 18th century. To-day "liquid" gold is exported to China and Japan from Europe for the use of the potter. (For Egyptian pottery, *see* EGYPT: ***Archaeology and Art,*** section ***Ceramics;*** for ***Primitive Far Eastern*** and ***Near Eastern Pottery, see*** those sections. ***See*** also BABYLONIA AND ASSYRIA: ARCHAEOLOGY, and POTTERY, PRIMITIVE.) (X.)

GREEK POTTERY

The pottery of ancient Greece, prehistoric and historical, is distinguished from all other fictile wares of the same ages by its free development of naturalistic painted decoration. The ceramic painter's art was so far separated from the potter's in the classical period, that each could put his signature to his own portion of the work, and there can be little doubt that the best Minoan pottery was equally the joint product of the two craftsmen. This uniformity in Prehellenic and Hellenic ceramics can hardly be fortuitous. Though Late Minoan (Mycenaean) vase-painting contains no visible element of design that was adopted by the Geometric artists, the technique of potter and painter passed intact across the apparent gap in culture that separates the Aegean ages of Bronze and Iron, and the subsequent revival of naturalistic ornament in the Archaic Greek period shows that something more than mere mechanical skill had been inherited.

Prehistoric Origins.—The technique in which the masterpieces of classical vase-painting were executed was first perfected in Minoan Crete, but its invention was not Cretan. Painted pottery was made in prehistoric Mesopotamia and Egypt long before its appearance in Aegean lands. Pre-Sumerian ware bears decoration fired on pale clay in a dark medium of ferruginous earth fused with an alkaline flux, and one variety of Egyptian predynastic pottery has dull white pigment similarly fired on a dark ferruginous wash. Both processes were applied in Early Minoan pottery; the latter was brilliantly exploited in the polychrome Middle Minoan style (Kamares ware), but the former finally prevailed, because of its greater freedom, in the Late Minoan age. ***(See*** ARCHAEOLOGY; ***Crete.)*** At the close of the M.M. period, when Cretan arts were transplanted to the Greek mainland, the colonial (Mycenaean) fabric of Minoan pottery displaced the inferior and largely hand-made native wares, Helladic, Cycladic and Thessalian, which formerly marked the various cultural regions. ***(See*** ARCHAEOLOGY; ***Greece.)*** By the end of the Mycenaean age the pottery of the whole Aegean area was uniform, except on its northern and eastern borders, where Danubian and Anatolian influences were preponderant. This latest Mycenaean ware preserves the forms and fabric of the best Minoan models, but its ornament is atrophied. Shells, octopods and seaweed have degenerated into rows of wavy lines, lily and papyrus flowers appear as groups of parallel curves or chevrons, and the rich designs of linked and running spirals give way to bands of single coils. But the clay is finely worked, the pots accurately turned, the firing hard and even, the glaze dense and lustrous. Two Mycenaean fabrics can certainly be distinguished. The more numerous class has a warm yellow clay surface and its black glaze fires red. The smaller group is made of exceedingly smooth pale greenish clay, and painted with brown-fired glaze, which tends to flake away from the close texture of the surface. The latter belongs to the Argolid, and was made from the same white clay that produced the later Protocorinthian and Corinthian wares.

The Geometric **Style.**—The next historical phase in Greece was the transition from bronze to iron, about 1000 B.C., a cultural change that involved the violent downfall of the Mycenaean polity. Arts were generally submerged, but the pottery can be identified. It is called Submycenaean or Protogeometric, as its elements appear to attach themselves to the old Minoan or the new Hellenic system. The technique is still Minoan and is often brilliant, but many of the pot-shapes are modified and the decorative patterns assume a new character. The surviving Mycenaean motives are resolved into their simplest linear elements, and these tend to combine again in rigid geometric schemes. Another tendency was to abandon painted patterns and cover the whole pot with black glaze. In this potent fallow the new principles of Hellenic art were laid, and the so-called Geometric style sprang rapid and luxuriant. In its mature phase a Geometric vase is covered with narrow horizontal bands of minute and crowded ornament, rows of repeated figures, triangles, lozenges, circles, continuous or panelled bands of zig-zags, chequers and, chiefly characteristic, the maeander. This last motive, always drawn in double outline filled with hatching, is probably the key to the origin of the style. It appears at the same period in Italy, in the pottery and bronze work of the Villanova culture, and since there is no evidence of intercourse between the two countries at this date, must have been introduced into both from a common northern source. Its first occurrence in Greece is in isolated bands or panels reserved on necks or bodies of black-glazed pots, a rudimentary form of decoration which was as universal as the former Mycenaean style. Subsequent developments were local, and many styles have been identified in mainland Greece, the Aegean islands and the coast of Asia Minor. The most elaborate is that of Athens, called Dipylon ware after the cemetery at the city-gate, where the largest vases have been found. These are huge sepulchral jars which sometimes bear among the geometric patterns broader bands or longer panels filled with pictures of funerals, a corpse surrounded by mourners, and processions of chariots, human and animal figures being drawn



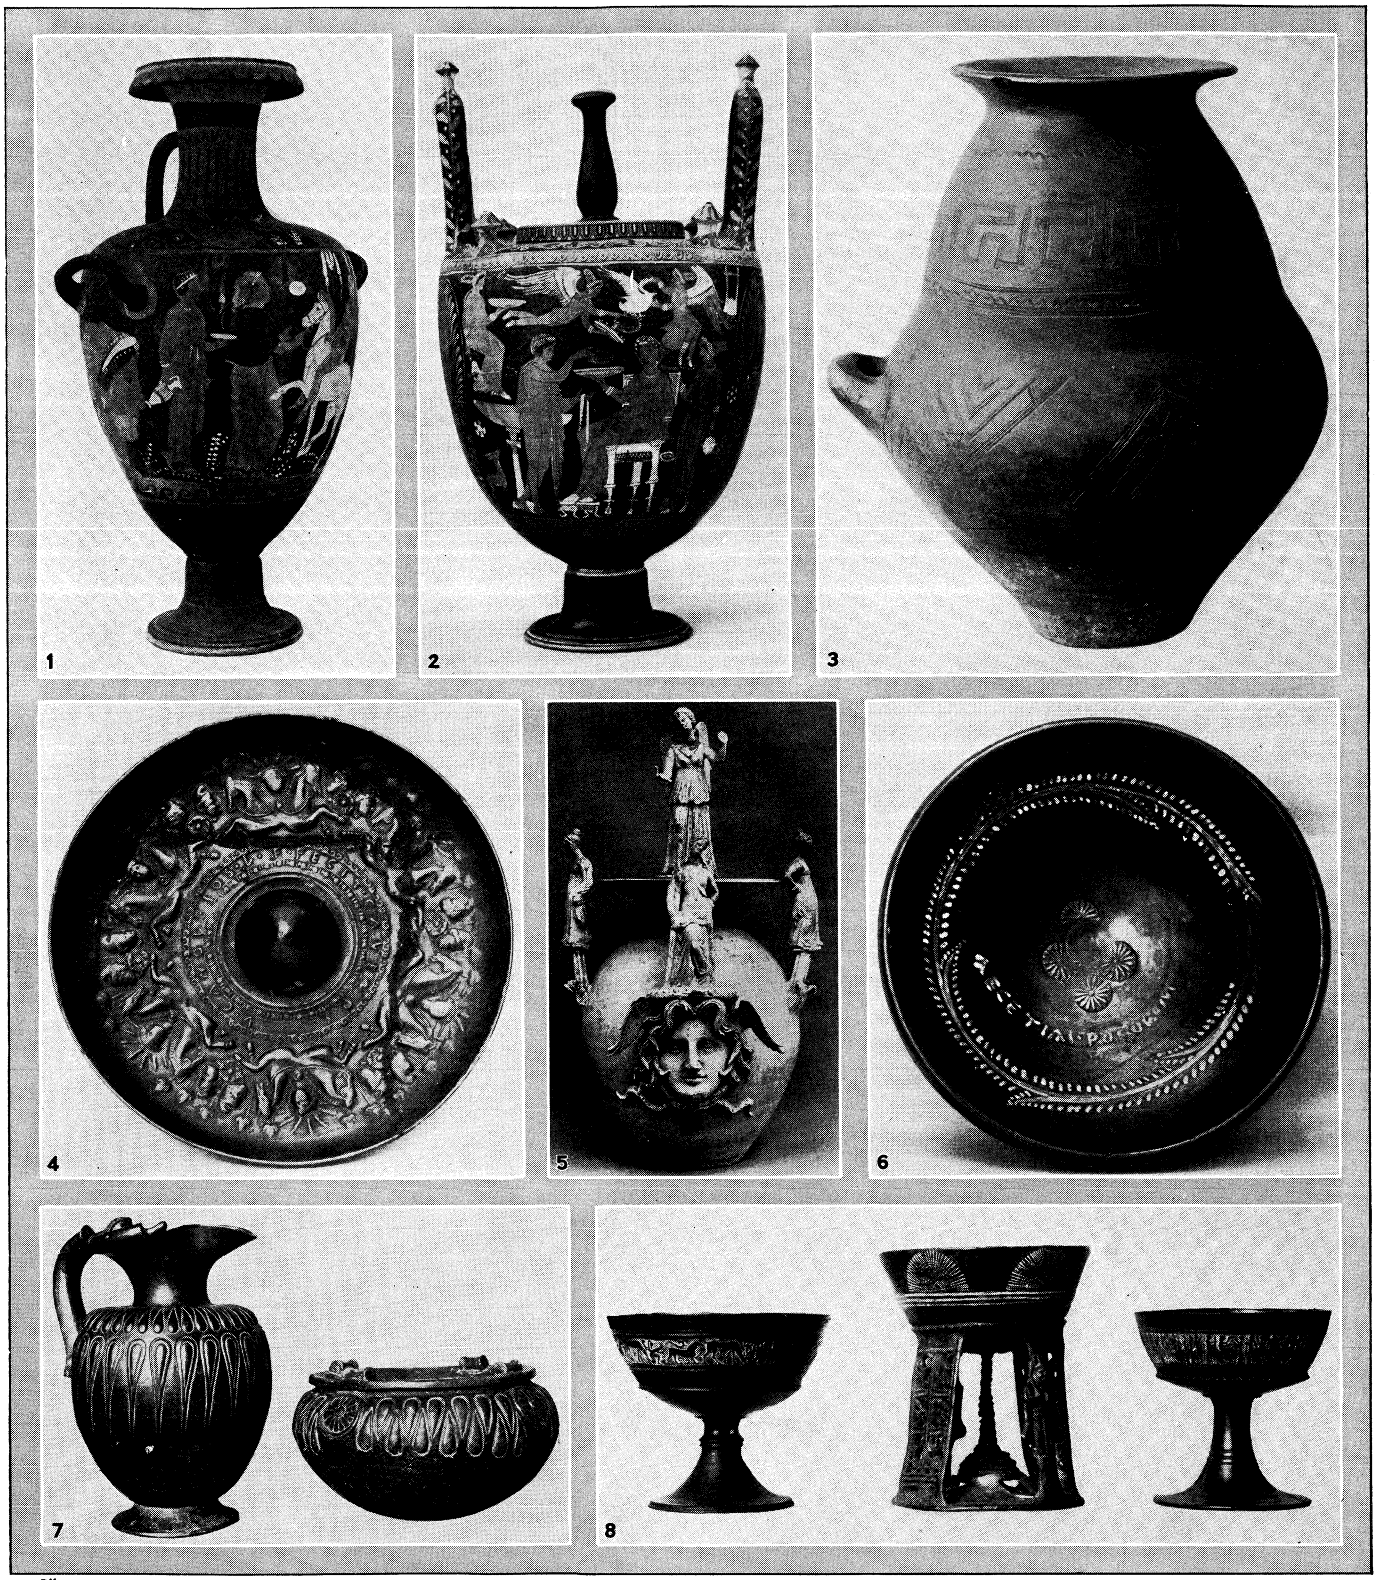
ANCIENT GREEK POTTERY

1. Sub-Mycenaean Amphora (storing vessel). Height 17"
2. Proto-Attic Amphora, combat of Heracies and Nessos. Height 3'7"
3. Dipylon Geometric Amphora. Height 30"
4. The Macmilian Lekythos (oil bottle). Proto-Corinthian. Height 2¾"
5. Proto-Corinthian and Corinthian Group. Height, central figure, 10½"
6. Rhodian Oenochöe (wine jug). Height 13"
7. Rhodian skyphos (drinking cup). Diameter 5"
8. Rhodian pinax (plate)
9. Caeretan Hydria (water jar). Height 18". In the Louvre

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

ANCIENT GREEK POTTERY

1. Chalcidian black-figure krater (vase for mixing wine and water). Height 18″
2. Attic black-figure hydria (water jar). Height 18″
3. Attic kylix (drinking cup), miniature style. Height 5½″
4. Eye **kylix.** Height 5″
5. Attic red-figure **kotylē** (drinking cup), signed by Hieron. Height 8¼″
6. Attic red-figure **lekythos** (oil bottle). Height 10″
7. Attic lekythos. Height 8″
8. Megarian bowl. Height 3½″
9. Vase of red Samian ware. Height 6¼″



ANCIENT ITALIAN POTTERY

1. Campanian hydria (water jar)
2. Apulian vase
3. Villanova cinerary urn. Height 15"
4. Calene (Campanian) bowl, with potter's signature. Diameter 7"
5. Canosa (Apulian) vase
6. Gnathia (Apulian) bowl with Latin inscription. Diameter 5½"
7. Etruscan bucchero jug and bowl. Height, jug, 16"; bowl 8"
8. Etruscan bucchero cups. Height, central figure, 7½"

ANCIENT ROMAN POTTERY

1. Arretine mould and stamp. Height 4¾″
2. Bowl of *terra sigillata*. Gaulish fabric. Diam. 9″
3. Bowl of *terra sigillata*. Gaulish fabric. Diam 5½″
4. Jar with *barbotine* and moulded ornament. Height 7½″
5. Arretine saucer with potter's stamp. Diam. 4½″
6. British castor ware. Height 6″
7. Black Rhenish ware. Height 5″
8. Lead-glazed ware. Height, central figure, 7″

schematically in black silhouette. These subjects are the first expression of Hellenic delight in representation, which quickly dominated decorative art and ultimately destroyed it. The live subject, human and animal, was also utilized in the Geometric style as a decorative unit, in bands of soldiers carrying shields and spears, of grazing horses, deer and goats, running dogs and birds. The birds belong, like the maeander, to primary sources of the style, but the grazing and running quadrupeds are a later feature, and are probably the first signs of oriental influence.

Oriental Influences.—The political changes that destroyed the Mycenaean power had also interrupted Aegean relations with Asia and Egypt, but when contact was restored, about the 10th century, the new Greek world became doubly linked with the ancient foreign civilizations, by its colonies on the coast of Asia Minor as well as by its own and Phoenician commerce. The effects of oriental contact are visible in all Greek arts after the 9th century. The actual commodities that served Greek vase-painters for models have not been identified, and if, as is possible, they were textiles, cannot have survived. They seem to have been brightly coloured, for touches of red and white paint enliven the black figures in all the orientalizing styles. But accurate drawing and incised contours suggest metal prototypes, and some bronze and silver bowls and cups engraved in the same manner have been found in Greece and Italy. (See BRONZE.) Oriental motives in the late Geometric style, besides the bands of animals, are cable-pattern (guilloche), palmettes in bands or panels, and base-rays. The latter are derived from the petals of a flower-calix; originally Egyptian, they are a common feature of Asiatic pottery, and particularly of late Hittite vases. These novelties broke up the conventional Geometric art, and the succeeding local wares bear very little resemblance to one another.

Protocorinthian, etc.—The principal early orientalizing styles are Protocorinthian, Protoattic, Island (Melian), and Ionian (Rhodian). They belong broadly to the 7th century. The true Protocorinthian fabric was located in the Argolid, where a very precise and simple geometric style had been established. Precision is the distinguishing feature of Protocorinthian ware, and is accentuated by the miniature forms of nearly all existing vases. They are made of the smooth pale yellow clay which distinguishes the local Mycenaean fabric, and which invites fine craftsmanship by its plasticity. Conical cups (skyphoi) and pointed oval scent-bottles (lekythoi) are typical forms. Their earliest subgeometric ornament of simple linear patterns was soon displaced by bands of animals, particularly running dogs, palmettes and lotus, cables and rays, all of which were in turn subordinated to a main frieze containing human or monstrous figures, sphinxes, chimaeras, centaurs and the like. The background in the figure-friezes is filled with detached ornaments, in this style typically the dot-rosette, a device which belongs properly to metal reliefs, where it is simply executed with a round-nosed punch. The influence of metal-work is also visible in the sharpness of this style and in its use of engraving to define outlines and inner markings of the silhouettes. The colour is enriched with patches of dull red and white, as if inlaid on the black-glaze figures, for details such as manes, throats and bellies of animals, armour, clothes and hair of men. Masterpieces of the Protocorinthian style are the Chigi vase in the Villa Gierlia at Rome, a large jug with an amazingly elaborate battle-piece and hunting-scenes in three friezes, and two small scent-bottles, with fancifully modelled tops and hardly less elaborate hunts and battles on their bodies, in Berlin and London (the Macmillan lekythos). A purely decorative Protocorinthian scheme consists of scales or tongues closely incised on a black-glazed surface and painted alternately white and red, together with thin bands and dot-rosettes in the same bright colours. Large and small vases are entirely or partially covered with these ornaments. This fabric was largely exported, particularly to Italy, where it was more or less successfully imitated by Greek and Etruscan potters. Another Protocorinthian group consists of little vases moulded in natural forms, squatting men, busts and heads, animals, birds and shells. They were largely copied from Egyptian faience figures, and in their turn influenced the Egyptian vase-shapes. Large quantities of these Egyptian blue-glazed wares were exported from the Greek settlement of Naucratis, and some were evidently made there, or in some Greek colony in Asia, for the style of many pieces is more Greek than Egyptian, and one found in Rhodes bears a Greek inscription. The same shapes, particularly heads in helmets, were made in ordinary Greek pottery in Rhodes, and other plastically decorated fabrics from the same island are made of black ware like the Etruscan bucchero nero. Large storage-jars, with plastic patterns worked in relief or impressed in friezes with engraved cylinders, are also represented on Ionian sites. Protoattic pottery exhibits the same developments as Protocorinthian, but in a very different style. Vases and their painted decoration are large and vigorous, their fabric rather coarse, in red clay. Various stages of development are called by names of places where typical examples have been found, Phaleron and Vourva. They illustrate the intrusion and refinement of the Oriental repertory, from the animal-frieze with its close array of filling-ornaments to the isolation of human subjects in a clear field. The Island style is as bold as the Attic; it affects heavy spiral ornaments, gay colours, and ambitious narrative-subjects. Crete was a main channel of the new influence, but its pottery is not yet adequately represented. A typical Island form is a large high-necked bowl with a tall conical foot. Some examples, usually attributed to Melos, are painted over a white slip.

Ionian.—In this technical peculiarity they resemble the fabrics of Ionia, where the white slip was universal. This is a pipe-clay wash laid on the rough body of the vase to make a ground for painting. It is rare in Geometric fabrics, and seems to have come in with Oriental decoration; it was probably an ancient Anatolian invention, for it occurs in Hittite, Syrian, and Cypriote wares, and its immediate source may have been Lydia. The many fabrics of early Ionian style are generally represented by Rhodian vases. These are mostly jugs with rays or lotus-wreaths on foot and shoulder, and animal-friezes on the body, done on the white ground in large black-glaze figures with dull red patches. Among the filling-ornaments are looped semicircles (roundels) attached to the borders of the frieze. Human subjects are rare, the most prominent animal-figures are sphinxes, and the characteristic motive is a band of grazing goats. Large plates are a frequent shape, painted with lotus designs, or with concentric panel-friezes containing heads of goats and birds. A very similar fabric, mostly found in the Ionian city of Naucratis in Egypt, has been called Milesian, but may have been made locally. Clazomenae is chiefly represented by large painted sarcophagi. The red and white ornament on black, which was used in Protocorinthian ware, appears also on Rhodian vases, though not quite in the same forms. Red and white bands stand alone, or separate the floral and animal friezes, and the same colours are used for drawing lotus wreaths, or for filling tongues or lotus and palmette-petals, or even animals outlined by incision on the black ground. A fabric resembling the Ionian, but apparently belonging to mainland Greece, is the so-called Cyrenaic, which, since the discovery of a complete stylistic series in Spartan temple-deposits, has been known rather as Laconian. The excavation of Cyrene should decide the question of its origin. It is a white-slipped ware with bold decorative painting, large black and white chequers and step-patterns and solid rays in its subgeometric form, pomegranates and lotus-buds formally disposed between animal-friezes in its orientalizing phase Its early shapes are somewhat fantastic; a typical drinking-cup (*lakaina*) has a low convex body, from which two long loop-handles spring, and a tall concave lip or neck. A mature work is the famous *kylix* in the Bibliothèque Nationale of Paris. with a picture of Ring Arcesilas of Cyrene supervising in oriental state the lading of a ship. It is this scene that caused the fabric first to be attributed to Cyrene.

The Black-figure Style.—Towards the end of the 7th century the local fabrics, which had diverged so widely in their orientalizing phases, tended to come together again, perhaps under Athenian influence, in the Black-figure style. The expansive interest in human form and human Iife enlarged the fields in which these subjects were accommodated; animal and floral friezes were reduced in width and relegated to the less conspicuous positions on the pots. In the mature style of the 6th century ornamental animals hardly occur at all, and floral patterns are only used for borders or bands and panels in which narrative-pictures are displayed. But the new pictorial style retained the technique of the old ornament. The figures are drawn in black silhouette on the clay ground, and inner details are indicated by incision and by colour. The same dull red and white pigments were laid on the black glaze or on the clay in place of it. Both were decoratively applied without consideration of reality to produce a colour-pattern, but white was specially used for faces and limbs of women. White slip disappears as a mark of locality, but occurs on special occasions in several fabrics. The normal surface has the same colour as the body of the clay, light yellow in Corinthian, light red in Attic and most other wares. The natural colour of Attic clay was enriched with red ochre (*miltos*) and this substance had such industrial importance that its supply was strictly controlled by the Athenian Government. Corinthian ware in its latest development tried to imitate the Attic colour with a red wash. The history of Greek pottery in the 6th century is the continuous progress of the Athenian fabric towards its ultimate monopoly. At the beginning of the century there were numerous other black-figure wares, Protocorinthian and Corinthian, Laconian (or Cyrenaic), Boeotian, Chalcidian, and Ionian, but hardly any of these survived beyond its elementary stages. The passing of Protocorinthian into Corinthian was accompanied by such a fundamental change of content that the process is obscured, and it is sometimes supposed that the Corinthian potteries displaced those of some neighbouring city, perhaps Sicyon, which had produced the Protocorinthian ware. But though the output was increased and the style changed, the fabric remained constant, and most of the old forms continue to appear with the new decoration. The change took place at the end of the 7th century, and was evidently due to new Oriental models, 'perhaps textiles instead of metal work. Globular and baggy oval bottles (aryballoi and *alabastra*) came into fashion, with large figures, often monstrous or grotesque, painted in a loose style which is the antithesis of Protocorinthian precision. Backgrounds that had been sparsely studded with neat dot-rosettes are now filled up with irregular patches. This is the common ware that was distributed east and west by Corinthian trade. Besides it is a pictorial style which omits the filling-ornament. There is a splendid series of large Corinthian bowls (*krateres*) bearing scenes from life and legend, with single subsidiary bands of animals or horsemen. In their free use of colour, their technique of outline-drawing, and their deep designs of overlapping figures, these vase-pictures 'probably give a better idea of monumental painting than any other surviving documents. Chalcidian pottery stands very close to metal work in its angular vase-shapes and sharp figures. The evidence by which the various fabrics are assigned to their localities lies in the forms of the letters in which the names of gods and heroes are inscribed beside their figures. Ionian black-figure designs are lively in colour and in action; the Clazomenian fabric, like the Laconian, retains its subgeometric subsidiary bands. Ionian wares were largely imitated in Etruria, and some of them may have been made there by immigrant craftsmen. Such are the Caeretan *Hydriai*, a brilliantly decorated series of water-jars found at Cervetri (Caere). Their free floral patterns connect them with the Fikellura vases (so-called after a Rhodian site), an odd old-fashioned group that keeps the white slip technique and is shy of narrative-pictures. One of the last Ionian inventions, the *eye-kylix* (a cup mainly decorated with two large pairs of eyes), mas adopted by Attic potters. A related Attic series (*Kleinmeister* kylikes) has miniature figures, often single, in an upper band, and below these, or sometimes alone, a line of minute writing, a drinking posy, a love-name or an artist's signature.

Signatures.—The practice of signing vases began in the 7th century; a Protocorinthian lekythos and a (perhaps Argive) krater with the names of their potters, Pyrrhos and Aristonothos, are the earliest examples. Timonidas, Chares and Milonidas are the only known Corinthian painters; there are four or five Boeotians, and the rest are Attic. Names are always accompanied by the words *made* (ἐποίησε) or *painted* (ἔγραψε), sometimes by both. The former is taken to be the potter's signature, but the term is not explicit, and may apply to the owner of the factory, to the manipulator of the clay, or to the maker and decorator. But double signatures indicate that the functions of potter and painter were generally separate: "Ergotimos made me, Klitias painted me" on the François vase; and one man occasionally claims both honours: "Exekias painted and made me." More than 100 Attic masters are known by name. Many were manifestly foreign, and some were slaves from the unpromising regions of Thrace and Scythia. One of the great black-figure potters bears an Egyptian name, Amasis; his work reveals Ionian affinities and shows that the Athenian monopoly was partly achieved by attracting foreign craftsmen to the city. Mature Attic pottery incorporates the best qualities of the fabrics which it superseded, technical excellence accomplished draughtsmanship and a large repertory of pot-shapes and decorative schemes.

Vase Shapes.—In archaeological usage the numerous shapes are denoted by ancient names which do not always rest on ancient authority, but they are accepted as a convenient means of classification. Important forms are two-handled storage-jars (*amphora*, *pelike*, stamnos), mixing-bowls (krater, in variety), water-pots (*hydria*, *kalpis*), jugs (oinochoe, *olpe*, *prochoos*), drinking-cups (*kylix*, *kantharos*, kotyle, *phiale*, skyphos), and oil-bottles (*alabastron*, *aryballos*, askos, lekythos). All were copied from metal models. Greek pottery was never a free art; its forms and decoration were inspired, controlled, and finally destroyed by progress in the arts of painting and metallurgy. After the middle of the 6th century, when technical perfection had been achieved, Attic decorators set themselves to perfect their draughtsmanship and power of expression, and the interest of painted pottery after that time is largely as a document in the history of drawing. The finest early black-figure work is the François vase in Florence, a monumental krater signed by Klitias and Ergotimos. It is covered with bands of lively narrative, the Calydonian boar-hunt, the funeral games of Patroclos, the marriage of Peleus and Thetis, the death of Troilos, and the battle of Pygmies and cranes. Among many later masterpieces is an amphora in the Vatican made and painted by Exekias, with a single panel-picture on each side. One picture shows Achilles and Aias playing draughts. The group is a stock subject reproduced by several painters, an excerpt, doubtless, from a monumental picture of the siege of Troy. The intentness of the poses and the elaboration of incised detail represent the last possible achievement of this style.

The Red-figure Style—The innovation was made before the end of the 6th century, about 520 B.C. Some masters, notably Andocides and Pamphaios, produced vases in both styles, and even combined the two on one vase. In the new process the background was blacked and the figures reserved on the red clay; inner markings, details of limbs and features were drawn in thin lines of black glaze, hair and clothing were occasionally done with a diluted brown or yellow wash of the same medium. The glaze has not been successfully reproduced by modern experiment, but analysis shows that it was composed of ferruginous earth with an alkaline flux. It was applied to the pot after the clay was dried, and before firing. The design was lightly sketched with a point, then drawn in outline and detail, apparently with a pen. The background was blacked in, and certain contours of the figures accentuated with relief lines of thick glaze. Touches of colour, red and gold, were very rarely added, and pot and glaze were fired together in a single operation. The new drawing had unlimited freedom and made rapid progress in truth and expression, but its decorative qualities were slight. The formality of archaic art and the restraint of early classical drawing preserved the decorative value of the figures to some extent, but after the middle of the 5th century, when the problems of representation had been solved, this character was lost, and facile drawing admitted weak design.

Attic Masters; Love-names.—Epiktetos, Euphronios, Euthymides, Brygos, Hieron, Douris, are a few names of the great archaic-masters; Sotades, Polygnotos, Meidias, of the free style. Some of these signed as potters, some as painters, and there are anonymous painters, no less capable and far more numerous,

EUROPEAN POTTERIES

1. Bowl with lion supports, *sgraffito* ware. Italian, late 15th century. In the Louvre
2. Side view of bowl shown in fig. 1
3. Dish with rampant lion, Hispano-Moresque ware; diameter 10″
4. Tray, Rouen faience; length 14⅞″, width 9¾″
5. Dish, Frankfort faience; diameter 13½″
6. Tureen, Strasbourg faience; height 19″
7. Jug, Raeren (near Aachen, Germany) stoneware
8. Dish, Palissy ware, second half 16th century; length 11″, width 7⅝″. From the Salting Collection

whose style can be recognized in their work. Recent research has gone far towards identifying all the hands in Attic red-figure drawing. Where the artist is not known by name, he is called after the potter for whom he worked (the Brygos painter, Meidias painter), after one of his vases or the collection in which it is preserved (the Villa Giulia painter, the painter of the Bowdoin Box) or a notable subject (the Pan painter), or after other persons named on his vases (the Panaitios painter). These, the so-called love-names, refer to popular idols of their day. When known to history they are youths of noble family, and the form of inscription *Panaitios* is handsome (Παναίτιος καλός) indicates that their fame rested on their good looks. The duration of this popularity was therefore not very long, and the use of historical names, Glaukon, Leagros, Miltiades, is valuable evidence for the dates of the vases. The character of red-figure subjects changes with the style. Archaic artists favoured heroic deeds and genial life, exploits of Herakles and Theseus, battles with Amazons and Centaurs, athletic contests and drinking-bouts. The early free style suited contemplative subjects, boys leaving home for the wars, religious and musical ceremonies. In the late free or florid style the scene is largely filled with idle women clad in voluptuous robes and trifling with winged love-gods.

Late Attic and Italian **Fabrics.**—In the early 4th century an attempt was made to revive this dull field again with colours, white generally for flesh of one or two figures in a group, blue, green, red and gold for drapery and jewels. Gold was often laid on details modelled in relief. These vases have been largely found in North Africa and South Russia, and take their name from the Crimean town of Kertch. They represent the last phase of pictorial painted pottery in Greece. The art survived, however, and even flourished for at least another hundred years in South Italy, where it was first established at the end of the 5th century. Another Attic fabric, the white-slipped ware which was regularly used for funeral *lekythoi* and occasionally for kylikes and other shapes in black-figure and outline-drawing, also came to a natural end in the 4th century, but was not involved in the same artistic decadence, since its decoration had proceeded on the broader lines of painting. These little vases, oil-bottles made for offerings to the dead, generally bear pictures of the tomb with boys and maidens bringing gifts. Clothes and mourning-sashes are painted in bright colours, and free brush-work dominates the designs. But painted patterns did not entirely disappear with pictorial subjects.

Hellenistic Relief-wares. — There was always a large class of black-glazed vases which had no other painting, but were sometimes fluted or impressed with slight ornaments in close imitation of metal. These were further adorned in the 4th and 3rd centuries with wreaths and necklaces drawn or engraved, or modelled and painted white or gilt, and occasionally with moulded figures like bronze plaques in relief. This style seems to have been universal in Hellenistic Greece, and was also produced extensively in Apulia and Campania (Gnathia and Capua wares). Another Hellenistic fabric, usually black-glazed, has purely plastic decoration, being exactly copied or even cast from contemporary bronze and silver vessels ornamented with reliefs. One group of bowls is called, for no good reason, Megarian or Homeric; it may be the Samian ware mentioned by Pliny, and is certainly the prototype of the Roman pottery wrongly called by that name. Bowls have decorative foliate patterns, or bear mythological and heroic scenes, often accompanied by written descriptions or verses quoted from the plays or poems which they illustrate. Another type, called Calene *phiale*, and mostly made in Italy, is a shallow bowl with a central medallion or interior border-frieze in relief. Two examples in the British Museum, with a frieze of chariots, are replicas of a silver bowl in the same collection. (See SILVERSMITHS' AND GOLDSMITHS'-WORK.) Some Hellenistic wares preserved the old tradition of black painted ornament on a light clay ground or slip. Their designs are mostly wreaths and garlands, and their fabrics seem to be located in the East, particularly at Alexandria in Egypt (Hadra vases). Alexandria and Tarsus were the first centres of manufacture of Greek pottery glazed in modern fashion. Blue and green faience was the speciality of Egyptian potteries. It had been imitated by the archaic Greeks and appears with Greek designs again in the Hellenistic age. But the new glaze is quite different, and was probably an Asiatic invention. It is a thick vitreous substance made with a metallic flux, in colours ranging from brown through yellow and green to blue, and was usually laid over lamps and similar small vessels moulded in relief or entirely modelled in natural forms. But at this point Greek plastic pottery finally merges with Italian. The art of the Mediterranean world in the 2nd century B.C. was Hellenistic, industry was cosmopolitan, and it is not always possible to know in which country the fabrics were located.

ANCIENT ITALIAN POTTERY

North and south Italy were separate cultural provinces in prehistoric times. The south, with Sicily, produced some elaborately painted pottery, which may be related to the Neolithic wares of mainland Greece, and some incised with rectilinear patterns like those on the earliest fabrics of Troy and Crete. But there is no evidence of contact between the Aegean and Italian areas before the Late Mycenaean age (c. 1300 B.c.), and the mutual resemblances in the pottery are equally referable to the universal similarity of primitive abstract decoration. In any case this south Italian art lived and died in isolation. Contemporary pottery of the north and central regions was of much coarser type, seldom decorated at all and never painted. But the Bronze age (*Terremare*) fabrics, though inferior in quality, had a plastic character that influenced the southern shapes and developed through the Villanova style into classical Etruscan ware. It was probably not fortuitous that the Hellenistic relief styles were largely established in Italy, and that the pottery of the Roman empire bore plastic decoration.

Prehistoric Origins. — The decorative elements in Terremare pottery are knobs and ribs on the bodies and fantastic modelling of handles, which often end in horns and crescents. The same elements, which had Danubian affinities, persisted in early Iron age (*Villanova*) fabrics, and the Geometric style in which the other Villanova ornament was designed also reflects the influence of central European art. The similarity of this Villanova Geometric to the contemporary Dipylon Geometric style of Greece has sometimes been referred to Greek influence in Italy, but there is no other trace of contact at this time (c. 900 B.C.), and it is probable that the same style penetrated both peninsulas from the north. In each case the new designs found an effective medium ready for their expression. Greek Geometric pottery was painted in the old Minoan technique, the Italian patterns were engraved or stamped or modelled in soft clay. The characteristic maeander, which the Greeks painted in a hatched band, appears in Italy in a band of parallel incisions. The Italian style, like the technique, is far more primitive than the Hellenic. Villanova pottery is not wheel-made; its clay is coarse, red or brown in body with a darker surface which at its best is polished black. This type of pottery is known in Italian archaeology as impasto. The surface colouring was probably done by fumigation. The fabric is thick and clumsy and the shapes are composed of the simple globular and conical forms that belong to elementary metalwork. A typical cinerary urn has a tall biconical body with a single horizontal handle on its wide middle. Its mouth is often covered with a shallow one-handled bowl. The natural development of such pottery was towards closer imitation of metal in refinement of fabric and accuracy of form, but the process was disturbed by the intrusion of foreign influences from Greece and Asia. This contact, which began in the 8th century, coincided with the first settlements of Greeks in Italy and with the rise of Etruscan civilization.

Etruscan **Bucchero.**—The native Etruscan pottery is called in Italian bucchero nero, or simply bucchero. The clay is fine and coloured black throughout its substance, probably by chemical reduction in the kiln or by previous staining. The fabric is generally heavy, since most of the vases were made in moulds and the wheel was rarely used. There are, however, some very fine, thin pieces. Besides the simple developments from Villanova forms, among which the arched band-handle is conspicuous, are copies of Greek and oriental models, *oinochoai, kantharoi, kylikes,* enriched with various kinds of moulded ornament, engraved, impressed or modelled. The three processes were often applied to one pot. Linear designs were drawn freehand with a graver or a wheel; they consist of animal and human subjects, floral ornaments, palmette and lotus and simple geometric figures, zig-zags, hatched triangles, linked arcs and spiral coils. Common patterns are fan-shaped groups of dots or dashes impressed with toothed wheels. Small decorative units like rosettes and stars were applied with separate stamps, and continuous patterns such as cables (*guilloche*) were done with engraved wheels. Elaborate friezes in relief were similarly executed with cylinders like Babylonian seal-stones engraved with real and monstrous animals and scenes of hunts, races, banquets and funerals. They were applied to all kinds of vases, but are particularly common on the body of the characteristic Etruscan *kylix* or *calix,* a cylindrical cup on a heavy stem which was a Phoenician form, and perhaps originally Hittite. Some ivory examples carved with similar reliefs were among the foreign articles in the Barberini tomb at Praeneste. Many of these cups are supported by three or four modelled struts, in addition to or instead of the central stem, set between the edges of base and body. They are in the form of human figures or flat strips decorated in relief or openwork. Plastic ornament was also applied to these and other vessels in large reliefs, usually of single animal figures on the bodies, rows of masks on rims, and heads standing free on handles. Bodies were also ribbed and fluted and moulded with gadroons, tongues and petals.

Greek Influences.—Though the foreign influence in this modification of Etruscan pottery may have been Asiatic and derived through Phoenician channels, Greek models introduced the innovation of painted patterns in ferruginous glaze. Greek artistic influence was doubly strong in Italy because the workmen were imported together with their works, either as colonists in the Greek settlements of the south or as adventurers in Etruscan cities. There was, for instance, a considerable manufacture of Protocorinthian ware at Cumae (Naples), founded from Chalcis about 750 B.C., and the local Greek fabric can only be distinguished from imported originals by a slight difference in the clay. But some other pieces found at Cumae reveal their provincial origin in coarser forms and decoration, and still more debased versions found on Etruscan sites are evidently the work of Italian potters. The Greeks rediscovered Italy at the end of their Geometric period and the first Etruscan ware painted in the Greek method bears simple rectilinear patterns, not often closely copied from Greek designs, in dull black glaze on light clay. At the same time, and perhaps earlier, there was painted decoration in Etruscan and Latin pottery done in dull white on the dark *impasto* and *bucckero* surfaces. A fabric of red *bucchero* connected with Falerii frequently bears white linear patterns. Greek and oriental subjects, bands of animals and lotus, were also painted in the same medium, and black *bucchero* was perhaps more often finished with polychrome ornament than the present condition of the vases indicates, for these colours were badly fixed and are very fugitive. Protocorinthian and Corinthian pottery were more skilfully copied and to such an extent that the Italian versions of these styles are now as plentiful as Greek originals, particularly jugs with subgeometric patterns, *lekythoi* and *alabastra* with polychrome imbricated decoration and those with bands of running dogs. In the black-figure period (6th century) Greek influence was so intense that it is not possible to decide whether some groups, Caeretan *hydriai* and Pontic *amphorae* were made in Italy, Ionia or Greece. But ordinary Italian products are easily detected by their inferior style and fabric. As Greek art progressed, Etruscan fell behind, and there can be no confusion between the two fabrics in the red-figure style, though most of the existing Attic vases have been found in Etruria. For this reason they were thought on first discovery to be Etruscan, and the false name still lingers in popular usage. It has also been supposed that Attic vases were made chiefly for the Etruscan market, but the fact is that their better preservation in Italy is due to the Etruscan practice of burying them as funeral furniture in chamber tombs.

South Italian Red-figure.—Between the later Attic originals and their Etruscan imitations stand the great series of red-figure vases made in the Greek cities of south Italy, which are derivative rather than imitative, and contain many Italian elements. They had a vigorous life for a hundred years after the disappearance of the true Greek industry. Painted pottery had been made by the natives of south Italy since the 8th or 7th century, at first without any traces of Hellenic influence, in fantastic shapes, large *askoi* and strongly curved and carinated cups with horned handles, elaborately ornamented with geometric patterns (Peucetian ware), and in the 5th century with Greek floral motives in place of the rectilinear designs (Messapian). Some of their peculiar shapes were ultimately incorporated in the red-figure fabrics, but the new style at first was wholly Greek, and its earliest examples are not easily distinguished from Attic vases; they may, indeed, be the work of Athenian artists living in Italy. But in the 4th century definite local styles were formed, differing from Attic in certain vase-shapes, colours of clay and paint, types of subjects and styles of drawing. The recognized south Italian fabrics are Lucanian, Campanian and Apulian, with a special group attributed to Paestum. They differ from one another in some technical and stylistic details, but all are marked by dull brownish clays, extravagant shapes and florid ornament. The simplest style is Lucanian, which probably represents an early phase of the industry. Mature Campanian and Apulian are gaily and profusely ornamented, but the effort is generally limited to one face of the pot, the reverse side being filled with dull conventional figures. Some large vases bear mythological scenes, but ordinary pieces have commonplace subjects of youths and maidens lounging in exaggerated elegance and a close atmosphere of ribbons, flowers, pet animals and domestic furniture. The filling of the backgrounds approaches that of the Greek orientalizing styles. Border patterns, palmettes, waves and foliate wreaths are bold and large. Subsidiary colours, white, yellow, red, were freely applied in dots, lines and washes. Men's costume often reflects Italian fashions, particularly on Campanian vases, a very short tunic with broad belt, and feathered helmets and triangular breastplates for soldiers, presumably the Samnite armour. Dress, pose and gesture of the figures have a histrionic extravagance which seems actually to have been taken from the stage. An important class of subjects consists of theatrical scenes, particularly from the tragedies of Euripides. Burlesques of tragic and heroic legends are also depicted. These were the local *phlyakes,* the kind of farce that the Tarentines were attending in the theatre when they saw the Roman fleet entering their harbour, in 302 B.C. The stage and scenery are often illustrated in these pictures. Only three artists are known in the Italian schools, and two of them, Assteas and Python, belong to the Paestum group. Both painted theatrical scenes. A *krater* by Pythoa shows Alcmena on the funeral pyre, Antenor and Amphitryon setting light to it, and in the upper background, by a characteristic and perhaps theatrical convention of perspective, half-figures of rain-nymphs pouring water out of pitchers on the fire at the behest of Zeus. The most imposing Apulian vases are great sepulchral *amphorae, hydriai* and *krateres.* They bear pictures of elaborate funeral monuments, done in white paint, gabled tombstones or shrines with reliefs or statues of the dead, to whom mourners (in red-figure) bring gifts. Another florid south Italian class of pottery has free plastic ornament; large globular *askoi,* a native shape, have gorgon-masks and fronts of horses on their bodies, large statuettes of women, cupids and winged goddesses standing on rims and handles, all brightly painted in blue and red.

Hellenistic Relief-wares.—These Graeco-Italian fabrics were succeeded, in the 3rd century, by Hellenistic pottery imitating metal, black glazed ware painted with white, yellow and red necklaces and garlands or moulded in relief. The first class takes the name from Gnathia (Egnazia) in Apulia, where much of it has been found. There was certainly an Italian fabric in this style, for several pieces bear Latin legends, mostly dedications to deities such as *Aecetiai pocolom* (*Aequitiae poculum,* the cup of Justice) painted with the foliate decoration. Some of the contemporary relief wares were also made in Italy. Moulded signa-

tures on several bowls fix their place of origin at Cales in Campania and their maker's nationality as Roman: L. *Canoleios* L. *F. fecit Calenos.* A similar fabric assigned to Bolsena in Etruria is unglazed, and may have been gilt or silvered.

Roman Pottery.—It was also in Etruria, at Arezzo (Arretium), that the first Italian fabric was established of the fine red pottery, variously called Arretine or Samian or *terra sigillata,* which became the standard ware throughout the Roman world for several centuries. *Terra sigillata* is the modern archaeological name for the whole class. Samian is a misnomer; it may perhaps be applied to some Greek fabrics, but means nothing definite. Pliny says that the reputation formerly held by Samian table pottery had passed in his day to Arretium and other places in Italy, Spain and Asia Minor. There is no trace of a Spanish fabric in the existing material, but examples of Asiatic origin have been found at Laodicea, Pergamon, Myrina and elsewhere. It is a purely Hellenistic type of pottery, whether made in Italy or Greece.

Arretine.—Arretine is the name of the Italian fabric, which was not made solely at Arezzo. Provincial Roman varieties, mostly Gaulish, are nanied from their places of manufacture, La Graufesenque, Lezoux, etc. All this pottery is made of bright red clay and, when ornamented, moulded with reliefs (*sigilla*). Some early (2nd century B.C.) products of Arezzo are black glazed, but they hardly enter into the series. The vases are generally small, for table use, and very rarely have handles; they are mostly bowls, cups and saucers of shallow cylindrical and globular forms. Their lustre was produced with a thin alkaline glaze, which gives an extraordinary depth and richness to the colour of the clay. The earliest decoration was copied from the embossed silverware which was originally a speciality of Alexandria and Antioch. *(See* SILVERSMITHS' AND GOLDSMITHS' WORK.) The bodies are completely covered with floral and foliate designs, masks and decorative furniture, human and animal figures, allegorical and mythological scenes, processions, sacrifices, battles, hunts, dances, feasts and similar episodes of social life The vases, or their decorated bodies, were cast complete in clay moulds, which were prepared mechanically by means of separate stamps, for the component elements of the design. The final artistic effect was therefore dependent on the potters' manipulative skill. The potters' signatures were stamped into the moulds, sometimes appearing in relief on small tablets among the ornamental figures, sometimes in sunk spaces, rectangular, round or fancifully shaped as footprints, wreaths or stars on rims or bases, inside or outside the vessels. Plain wares are ordinarily stamped inside the base. The names of Arretine potters begin about 100 B.C. They represent owners of factories, whose names are sometimes given in the formal Roman manner, sometimes greatly abbreviated and in monogram, and the actual potters, slaves, who often have foreign names. The master potter Marcus Perennius signed M. *Perenni,* M. *Peren, M. Pere, M. Per,* and *M. Pe.* Seventeen slave names occur on his vases, sometimes in conjunction with the master's, sometimes alone. Bargates and Tigranes are the best known; the latter signed *Tigran, Tigra and Tigr.* Aulus Titius signed *A. Titi. Figvl(ina) Arret(ina).* The factory of Rasinius was directed by Lucius of that family in the Augustan period and by Gaius Rasinius Pisanus in the Flavian, by which time the Arretine potteries were turning out replicas of Gaulish work. The large numbers of names and the many varieties of vase shapes and types of ornament that were produced during the long life of this pottery, have been very accurately recorded, and the pottery has become a valuable archaeological index for determining the dates of other Roman objects, buildings and sites, with which it is found in excavation.

Gaulish Terra **Sigillata.**—The Italian fabric came to an end about A.D. 100, being displaced in Italy and the provinces by *terra sigillata* made in France Italy still produced its own coarse pottery for ordinary domestic use, unglazed and undecorated vessels, which formed the bulk of ancient pottery at all periods. The new Gaulish ware was precisely the same as Arretine in fabric, and at least as good in technical quality; its colour is even superior, a darker and brighter red, and its paste is usually harder than the Arretine. But the decoration is inferior, the ornament is in very low relief, and designs and figures are generally small and mean. It is found all over the Roman world, but most abundantly in central France. Finds of moulds and kilns have fixed the localities of the two principal fabrics at La Graufesenque (Aveyron) and Lezoux (Puy-de-Dôme), in the ancient Rutenian and Arvernian territories. The Gaulish fabrics began before the middle of the 1st century A.D. and ended about the middle of the 3rd, but ornamented vases were probably not cast from moulds after the middle of the and century. The names are often Gaulish, and even Roman names are spelt in Gaulish fashion, *Tornos* for *Turnus.* It is a strange fact that native elements do not appear in the designs. The forms were at first identical with Arretine or derivative, and there was the same distinction of shapes for ornamented and plain wares. The commonest type of ornamented vase was a carinated bowl with a band of design on each plane *(Form* 29). It was succeeded in popularity about A.D. 150 by a bowl cylindrical in form, which in its turn gave place to a type of hemispherical shape (*Form* 37). The commonest plain red vessels are very wide and shallow cylindrical and conicai bowls or flat saucers. The earliest ornament consists of purely decorative motives, wreaths and scrolls. with a few animals incorporated in the foliate designs. These bands are continuous, but the figure-subjects, which began about A.D. 75, are broken up in panels, medallions and arcades, and a free style of figure composition was not reached until the 2nd century. It is characteristic of Lezoux bowls. The figures are minute and were generally taken from well-known Hellenistic sculptural types. There are a few mythological groups. **A** purely Roman subject, the gladiatorial duel, is very frequent. In the free style hunters chasing animals are popular subjects.

Barbotine and Lead-glaze.—A technical innovation of the 2nd century was relief applied in *barbotine,* slip clay laid on by piping. It seems to have been a German invention, since it appears first on native Rhenish pottery of the 1st century. Its early use in *terra sigillata* was for small foliate patterns on the rims of flat bowls and dishes, but in the 3rd century it began to replace moulded work on bowls of the standard Roman shape. Another Teutonic element in the Roman fabrics of this date is a globular jar with narrow neck *(olla),* which could not be cast entire. Its ornament was therefore made in separate plaques or medallions and affixed to the pot; scrolls in *barbotine* form a setting for these reliefs, which are largely topical in subject, portraits of emperors, gladiatorial contests and theatrical scenes, often accompanied by explanatory inscriptions. These were made in Provence and also at Lezoux, where they were the last products of the Roman industry. The Gaulish output was not large in Roman times and its forms were trifling, small vases and lamps and toys ornamented with reliefs or modelled in the shapes of animals and common objects. But in the Eastern empire the process was generally used for Byzantine pottery. It was adopted by the conquering nations after the fall of Rome, and became the medium of ceramic decoration in mediaeval Europe. • (E. J. F.)

EUROPEAN POTTERY
TO END OF 18TH CENTURY

Byzantine.—The Eastern Empire with its capital at Constantinople was the channel through which, after the downfall of Roman civilisation in the West, the art and culture of the East was communicated to Europe, and the artistic ancestry of later European pottery is to be sought, in part, in this quarter. Evidence is scanty, however, as to the nature of Byzantine pottery, owing to the cessation of the pre-Christian custom of burying earthenware and other vessels in the tombs of the dead. What little we know is derived from finds of potsherds in excavations at Constantinople and a few sites in Greece, Cyprus, the Crimea and elsewhere. These are of two main types, both of red-bodied earthenware with a surface coating of transparent lead glaze. The decoration in one type is in relief, produced with impressions of a wooden stamp; in the other it is of the kind known as *sgraffito*, engraved with a pointed tool through a coating of white slip. The fragments are mostly those of bowls and deep dishes; the ornamental motives include human figures, animals and birds of symbolic import, simple leaf designs, interlacements, monograms and the Greek cross. The glaze is generally yellow; a bright copper-green is also found.

Hispano-Moresque Ware.—The chronology of the Byzantine wares discussed above is difficult to establish, but it is probable that they date from the two or three centuries immediately preceding the Turkish conquest of Constantinople in 1456. Pottery of artistic quality was known long before this date in Spain, fragments with painted decoration akin to that of the contemporary wares of Mesopotamia and Egypt having been found on the site of Medina az-Zahra, the palace of the Caliphs near Cordova, destroyed in the 11th century. References are found in writers of the 12th century and later to the "golden pottery" of Calatayud (in Aragon) and of the Kingdom of Granada; this phrase undoubtedly means the tin-enamelled earthenwares painted in metallic lustre colours, derived from silver and copper, which are the most famous of the Hispano-Moresque wares, although no surviving specimens are known which can be referred to a date earlier than the 14th century. To this period belong the celebrated vase in the Alhambra, with its decoration of confronted gazelles, arabesques and inscriptions, in golden lustre with touches of blue, and the similar vases scattered in various museums. A bowl of similar style, at Berlin, which is marked with the name of Malaga, suggests that that city rather than Granada was the place of origin of this Andalusian class of lustred pottery. In later times the manufacture passed to the kingdom of VALENCIA, whence in the 15th century such wares were shipped to places so far distant as Leeuwarden, London, the Crimea and Cairo. The chief Valencian pottery centre in the 14th century was Paterna, where quantities of enamelled ware have been found with human figures, animals and foliage designs of pronouncedly Gothic character painted in manganese-purple and green. In the neighbouring town of Manises, on the domain of the Buyl family, lustred pottery was made which the writings of Eximenes show to have been already famous for its beauty in 1383. In the earlier Manises wares we find designs of strongly Oriental character, comprising the Islamic "tree of life," palm-motives and Arabic inscriptions (generally the word *alafia,* "blessing," repeated in formalized characters). Early in the 15th century we find bold heraldic animals in blue against lustred spirals, and from about 1450, especially in wares made with heraldic designs for export to Italy, beautiful diapers of vine-leaves and small flowers In the 16th century renaissance foliage makes its appearance, and in the decadent 17th century wares a crowded ornament of birds and leaves in a fiery copper lustre. Fine blue-and-white wares were made at Teruel (Aragon). At Seville and Toledo especially were produced polychrome-enamelled tiles, at first cut so as to form geometrical and other designs in enamel pigments, which are kept within the outlines, first by painting these in manganese mixed with a greasy medium (de cuerda seca), and afterwards (from about 1510) by moulding the outlines in slight relief (de cuenca). Earthenware dishes with bold animal designs executed by the cuerda seca technique were made at Toledo. Mention must be made also of the great amphora-shaped wine-jars, well-heads and fonts with stamped or incised ornament, sometimes covered with a green enamel, which were made at Triana (Seville) and elsewhere in southern Spain in the 14th and 15th centuries.

Italian **Maiolica.**—The Italian wares of the early Renaissance period represent the highest achievement of the potter's art in Europe. They are mostly of the type known as maiolica, that is, earthenware coated with an opaque tin glaze or enamel as a recipient for painted decoration. The name was first used in Italy in the 15th century of the lustred Valencian wares imported in Majorcan trading ships and mistakenly supposed to have been made in Majorca; it was afterwards extended to Italian imitations of them and finally to unlustred earthenware with a tin enamel. Such wares have been found at Orvieto, Faenza, Siena and elsewhere. dating from the 14th and 15th centuries, with designs of animals, birds, foliage and heraldry of Gothic style in manganese-purple and green, recalling those of the Spanish wares of Paterna. By the end of the 15th century the palette was extended to five principal colours or more, but the designs retained their purely decorative character. After 1500 a change to pictorialism came about, with a further range of colouring, dishes and vases being at last treated merely as recipients for subject-paintings (*istoriati*); later in the century the arabesaues of Raphael and his school based on ancient Roman wall-paintings began to influence maiolica design, and in the 17th century decoration of this type found a rival in monochrome blue painting in emulation of Chinese porcelain and the Dutch wares of the time, heralding the downfall of the art of maiolica in competition with English earthenware in the 18th century. A great part of the output of the maiolica-potters, in the form of large dishes, wall-panels and vases, was intended from the outset for decoration only; dishes with appropriate designs were a favourite form of gift as love-tokens or to celebrate betrothals and weddings. The "useful" wares include plates, jugs and large pitchers, and especially drug-pots for the equipment of feudal or monastic pharmacies, either with a handle and short spout or of the waisted cylindrical shape known as *albarello.* Pavement-tiles were also an important part of the output of certain workshops. From about 1500 onwards the influence of contemporary graphic art becomes increasingly apparent in the decoration of maiolica. Woodcuts in devotional and other books and the engravings on copper of German as well as Italian masters provided the painters with motifs.

DERUTA MAIOLICA DISH

Early in the 15th century, under the lordship of the Manfredi, Faenza became an important centre of the craft; the city soon rose to such predominance that its name was adopted in French and other languages for enamelled earthenware in general. Floor-tiles, dated 1487, of great beauty, powerful design and colouring, in the church of San Petronio, Bologna, are shown by inscriptions on them to have been made at Faenza in the workshop of the Betini family. The leading Faventine workshop from about 1500 was the Casa Pirota; the dishes and drug-vases there made display a great wealth and variety of ornament based on early Renaissance motives—cupids, masks, dolphins, cornucopias and the like, generally in reserve on a blue ground. One class of wares is painted in dark blue and white on an enamel stained lavender-blue. A great master of the craft, identified by the signature on the back of a dish painted with Christ amongst the Doctors as Ieronimo da Forli, is believed to have lived at Faenza; he adapted compositions of Dürer and others in paintings displaying all the resources of the art in unexcelled beauty of harmonious colour ("The Resurrection," Victoria and Albert Museum, London; "Martyrdom of St. Sebastian," Florence; "Death of the Virgin," British Museum).

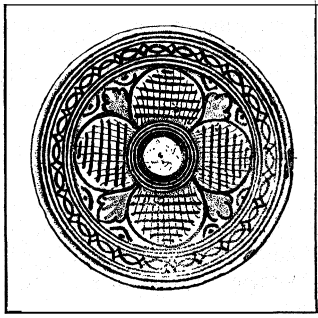
existed in its neighbourhood at Montelupo and Caffaggiolo. To the former perhaps belong the noble 15th century wares, especially two-handled nearly globular drug-pots, painted in a thick blackish blue and purple with animals, birds and human figures amongst foliage which from its type has won for these wares the appellation "oak-leaf jars"; in the 17th century this place produced dishes with crude figures of musketeers. A pottery attached to a castle of the Medici, Caffaggiolo, was the source of some of the most sumptuous maiolica ever made, great dishes, bowls and pitchers with the arms of the Medici and of the two popes of that family, triumphs in the manner of Mantegna, and subjects after Florentine artists. Hardly less splendid are the wares of Siena, particularly of one Maestro Benedetto; they excel in vigorous ornamental designs of early Renaissance character, in a palette dominated by a rich orange-yellow. Conspicuous among them are the drug-vases with an oval panel on one side formed by a ribboned wreath of fruit and foliage and traversed by a wide band bearing the name of the intended contents. The typical Sienese painting is seen also in the heraldic and grotesque designs of the pavement-tiles of the Petrucci Palace, Siena, now scattered in various museums. The Sienese wares were imitated at Deruta, near Perugia, which was, however, better known for its lustred wares (the earliest with a date, a relief of St. Sebastian in the Victoria and Albert Museum, is of 1501); these are painted in blue outline and shading, filled in with a pale lemon—or straw-yellow lustre. They take the form especially of two-handled vases and goblets and heavy wide-rimmed dishes, often painted with a lady's bust accompanied by a moralising adage or with figures influenced by Perugino.



BY COURTESY OF THE VICTORIA AND ALBERT MUSEUM
ANTWERP MAIOLICA DISH

A large share of the production of maiolica in the 16th century belongs to the duchy of Urbino. Castel Durante (now called Urbania) made wares predominantly decorated with fancifully-conceived arrangements of weapons, musical instruments and the like combined in trophies with grotesque masks, dolphins and cornucopias. One Zoua (*i.e.,* Giovanni) Maria employed such themes as borders to enclose figure-subjects of exquisite delicacy. Castel Durante was also the birth-place of Nicola Pellipario, the greatest of maiolica-painters, who migrated to Urbino and there adopted the name Fontana; he brought narrative (*istoriato*) painting to an unsurpassed pitch of perfection in several services of plates with mythological and other subjects, particularly one with the arms and devices of Isabella d'Este and another now in the Museo Civico, Venice. He freely adapted motives from engravings, including the woodcuts of an edition of Ovid's *Metamorphoses* published at Venice in 1497. Nicola's style was followed, in progressive deterioration, by his grandson, Orazio Fontana, and others of his family, and by Francesco Xanto and Alfonso Patanazzi, all of whom owned or painted at potteries at Urbino itself. In these, about 1550, a new and pleasing style of ornament was adopted, of airy and fanciful arabesques in the manner of Raphael scattered over a creamy white ground; about the same time also Urbino began to produce imposing snake-handled urns, fountains, wine-cisterns, salt-cellars and inkstands (the latter often in the form of a group of figures) in shapes largely borrowed from bronze or silver. Pictorial wares similar to those of Urbino were made about 1560 in the workshop of the Lanfranchi family at Pesaro. The maiolica of *Gubbio,* made by Maestro Giorgio Andreoli and his successors, is famous for its lustre painting, in golden yellow and especially in a rich ruby colour; at first this artist followed the style of the Deruta lustred wares, but about 1518 he began to produce designs of his own, including grotesques and trophies like those of Castel Durante, figures of *putti* within symmetrical border-ornament, and pictorial subjects based on engravings, chiefly after Raphael. Resides making pottery for his own decoration, he added lustre enrichments to already-painted wares sent from Urbino, Castel Durante and Faenza for the purpose.

There were several maiolica factories at Venice. In some of these pictorial wares were made like those of Urbino, but generally of indifferent quality. One Maestro Lodovico produced about 1530–50 a distinctive class of wares strongly influenced by the Near Eastern pottery and Chinese porcelain then beginning to be imported by Venetian traders; they are painted solely or chiefly in blue on an enamel stained to a pale greyish-blue. The 17th century Venetian maiolica displays a fondness for architectural subjects and occasionally ornament in high relief imitating contemporary *repoussé* silver.

The potteries of the Ligurian coast between Genoa and Savona came into prominence in the 17th century with their blue-and-white maiolica sometimes directly copied from Chinese porcelain; at the same time close imitations of Turkish earthenware were being made at Candiana near Padua. From about 1670 onwards the potteries of Castelli, in the Abruzzi, and its neighbourhood produced wares with polychrome painting in subdued colouring of figure-subjects and landscapes.

Italy is remarkable not only for its maiolica but also for a distinctive kind of lead-glazed earthenware with decoration incised through a coating of white slip (*sgraffito*). The glaze is generally of a deep buff tone, giving a dark brown colour to the red body where revealed by the engraving of the decoration, which is often heightened by touches of green and purple laid on with a brush before the application of the glaze. The technique, derived through the Byzantine dominions from the Islamic East, attained artistic importance in Italy towards the end of the 15th century. Recent investigations have shown that although it was practised at several other places north of the Apennines, the wares in which it is displayed at its best were made under the patronage of the Bentivoglio family at Bologna. Sgraffito ware was made at Bologna until the 17th century.

French Faience.—Pottery found in excavations at various places in Provence, and at Agen, and tiles from the church of Brioude, prove that tin-enamelled earthenware, with painting in manganese-purple and green, was made in Southern France as early as the late 14th century. Maiolica of a more developed type was made in the 16th century at Lyons by Italian potters from Florence and Faenza; to them are attributed certain wares with pictorial subjects in the Urbino style and French inscriptions, and tiles from the church of Brou. About 1540–60 Masseot Abaquesne was making maiolica and tiles painted with purely French renaissance designs at Rouen. Some rare examples with heraldic decoration are believed to be the work of Antoine Sigalon of Nfmes.

In 1578 a pottery for this kind of earthenware (called in French faience) was set up at Nevers by three brothers named Conrade, from Albissola near Genoa, and continued in the hands of their descendants. In the 17th century, under Chinese influences, polychrome gave way to blue-and-white painting, with manganese for the outlines, though classical themes continued for a time in favour. Soon after, subjects adapted from late Ming Chinese porcelain became the fashion.

A privilege for making faience at Rouen was accorded in 1644 to Nicolas Poirel, who was succeeded by Edme Poterat and his son, and in the reign of Louis XIV. the city became a thriving centre of the faience industry, noteworthy for the large dimensions of many of its wares—dishes, wall-cisterns, and life-size busts on pedestals. A distinctive style of decoration was introduced characterised by wide borders and radial arrangements of palmettes, scrolls and festoons somewhat resembling lace; in the motives of this graceful *lambrequin* decoration Chinese elements are blended with those of the classical baroque. The painting is carried out in blue, either alone or combined with red or ochre-yellow. About 1730, in the pottery of Guillibaud and others, a change came about in favour of a more varied polychrome palette; motives borrowed from the Far East assert themselves, together with the asymmetrical scrollwork. shells and cornucopias of the rococo, and towards the end of the century the enamel-painted flowers of contemporary porcelain were imitated. The faience industry at Rouen as elsewhere was killed by competition with imported English wares.

At Moustiers in Provence faience began to be made shortly before 1700 by members of the Clérissy family. Among their early productions are dishes of exceptionally large diameter with hunting-subjects after engravings by Tempesta and wares, especially oblong trays, with airy baroque designs in the manner of Bérain; these were at first in blue, afterwards polychrome. In 1738 Joseph Olerys, a Moustiers potter who had spent some years at Alcora in Spain, introduced a new floral style in colours with sprays resembling potato-blossoms, and grotesque figures borrowed from the engravings of Callot. About 1677 one of the Clérissys of Moustiers moved to Marseilles and there made faience, similar to that of his native town, in the suburb of St. Jean-du-Désert. Several factories were at work at Marseilles during the 18th century; chief among them were those of Veuve Perrin, Joseph Robert and Honré Savy.

In Lorraine flourishing faience-factories were carried on at Strasbourg and Niderviller, both conspicuous for the fine quality of their overglaze enamel painting. The Strasbourg pottery, in the hands of the Hannong family, came to an end in 1774 after some half century of existence. Its earliest wares were blue-and-white in the manner of Rouen. Its later table wares in good rococo shapes based on silversmith's work show quasi-naturalistic flower-painting skilfully rendered in fresh colours dominated by a strong crimson, which exercised a great influence on the work of other French faience factories. That founded by Baron Beyerlé in 1754 at Niderviller and transferred in 1774 to the Comte de Custine made similar enamel-painted faience, including admirable figures, mostly of children or peasants, from models by the sculptors Cyfflé and Lemire.

Faience of artistic quality was made at many other French towns in the 18th century. Sceaux near Paris produced both porcelain and enamel-painted faience hardly inferior to porcelain. Aprey is known for gaily-coloured wares of a more homely kind. In Paris, at Lille and Rennes the formal style of Rouen was followed. St. Omer and St. Amand-les-Eaux in French Flanders, and Montpellier in Languedoc also had faience-factories.

Faience of Northern Europe, Spain and Portugal. — Early in the 16th century an Italian potter from Castel Durante, Guido di Savino, was settled at Antwerp, and from this time may be dated the beginning of maiolica-production in the Netherlands. The Antwerp wares, which included pavement-tiles, show the influence of the Faenza potteries in simple floral and linear motives, but soon took on the distinctive characteristics of Netherlandish renaissance design. About 1560–70 maiolica-potters from Antwerp carried their art as Protestant refugees to Holland and England. Rotterdam and Haarlem became centres of production of earthenware and wall-tiles with animal, flower and fruit motives in strong colouring, and large tilework pictures with figure-subjects. Towards 1650 Delft came to the fore and for more than a century continued with its numerous potteries, known by their signs (the Peacock, the Star, etc.), as a thriving centre of industry exporting its wares all over the civilized world. Aelbrecht de Keizer is the earliest Delft potter whose productions are known, if the initials AK on certain blue-and-white pieces are rightly identified as his; the designs on these are borrowed from the contemporary Chinese porcelain then being imported in quantities by the Dutch East India Company. About 1600 we find plates and panels charmingly painted in blue with Dutch or Italian landscapes, by Frederick van Fritjtom. Samuel van Eenhoorn developed the Chinese fashion in a broad highly decorative manner of his own. To Adrianus Koek are owing the imposing blue-and-white hyacinth-vases made to the order of Queen Mary for the adornment of Hampton Court Palace; their ornament is borrowed from the French baroque designer, Daniel Marot. Other potters adopted Biblical subjects or scenes from Dutch life of the time (often in series continued through a set of plates or dishes) for the decoration of their wares. About 1700 close imitations of Chinese porcelain of the reign of K'ang Hsi, both blue-and-white and five-colour, were made, especially by Lambertus van Eenhoorn and Louwijs Fictoor, whose monograms are indistinguishable; notable amongst them are chimney-piece sets of large covered jars and vases, often reeded (so-called *cachemire* ornament). The wares produced became ever more varied, including statuettes and even model violins. Before 1700 muffle pigments and gilding were introduced by Rochus Hoppesteyn, in vases with classical figure-subjects, and by Adriaen Pijnacker, in imitations of Japanese polychrome porcelain dominated by a vivid red. Coloured enamel grounds were also occasionally used, notably a fine black in imitation of lacquer. As the 18th century advanced the wares became more commercial in character; the Delft potteries declined, only ten surviving till 1794. Somewhat rustic wares in the Delft style continued to be made till recent times at Makkum and elsewhere in Friesland.

BRISTOL DELFT DISH, TULIP DESIGN

In Spain the adoption of the renaissance and Italian influences resulted during the 16th century in the production of enamelled earthenware entirely different in character from Hispano-Moresque ware. The settlement of an Italian tile-painter, Nicoloso Pisano, in Seville about 1503 brought about a widespread employment of maiolica tile-pictures for wall-decoration. At the same time Talavera and the neighbouring Puente del Arzobispo became the leading centre of pottery production. They produced, alongside wares in which Netherlandish renaissance ornament can be recognised, others of a strongly native character painted with animated hunting and battle scenes or with large busts or animals amongst loose foliated scrolls, in blue alone or in a limited range of colours dominated by a strong copper-green. From Talavera, potters went out to Mexico and there founded a vigorous industry. The foundation of a faience factory by the Count of Aranda in 1727 at Alcora led to the decline of Talavera. The faience mostly painted in blue and purple made in the 17th century at Lisbon, in which freely-handled Chinese themes are blended with renaissance motives has decorative value.

It is recorded that about 1567 Jasper Andries and Jacob Sanson fled from Antwerp to England to escape religious persecution and set up potteries at Norwich, whence in 1570 they moved to London. Their productions have not been identified, but it is likely that they resembled the maiolica at that time made in the Netherlands, and it is possible that certain jugs with mottled blue, purple and orange colouring over a tin enamel, generally found with silver mounts, were made by them. The earliest piece of maiolica of certain English origin is dated 1601; we may note here that at a later stage such wares were known as "delft," after the chief Dutch centre of production from about 1650 onwards. After 1625 dated pieces made at Lambeth and elsewhere near London become plentiful, chiefly dishes and small mugs with decoration painted either in blue in crude imitation of contemporary Chinese porcelain or with coloured designs of fruit and flowers or arabesques in imitation of Dutch and Italian wares. Wine-bottles painted with the name of the intended contents were also made in quantity. Towards 16jo figure-subjects, mostly scriptural (especially the Fall) become plentiful. Imitations of the "Persian" blue ware of Nevers were also made. From London the maiolica industry was carried to Brislington, near Bristol, where in 1682 we find working one Edward Ward, who in 1683 established a pottery at Temple Back, Bristol. He was succeeded at Brislington in 1697 by Thomas Frank. Other leading Bristol potters of the 18th century were Richard Frank, and Joseph Flower. John Bowen and Michael Edkins were painters employed by several of the potters. The earliest recorded date on Brislington-Bristol ware is 1652. The early designs include tulip and other flower designs in the Dutch manner, Chinese subjects and portraits of sovereigns or celebrities of the day. After 1700 Chinese motives take the lead, but adapted in a free and original manner. Landscapes of a local character with figures, in blue, were also in favour. The third great centre of delft production in England was Liverpool, which in the 18th cenmry exported

LATER STEPS IN PORCELAIN MANUFACTURE

1. Car stacked with ware ready to enter a continuous or tunnel kiln. This type of kiln is used in large factories

2. Ball mills which grind the glazes

3. After the first firing, the ware is dipped in the glazing mixture. It is then returned to a kiln, where heat melts the glaze and forms a hard, transparent coating

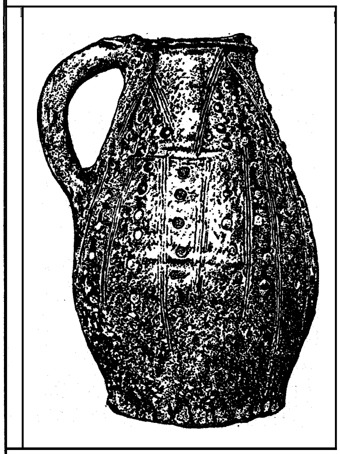
4. Decorating chinaware with raised gold, applied by brush

5. Printing designs by transfer on china. After decoration, the ware is fired again before undergoing final inspection such wares in quantity to America. Shaw, Pennington and Barnes were the leading potters. Their wares show less individuality than those of Bristol. Notable among them are the punch-bowls made for skippers with polychrome paintings of their vessels; a speciality of Liverpool were the delft tiles with transfer prints in black or red executed by Sadler and Green. Delft was also made at Wincanton, Dublin and Glasgow.

Tin-enamelled earthenware was made by German potters from 1620 onwards. They learnt the art of maiolica in Venice, amongst them Augustin Hirsvogel of Nuremberg; he is believed to have been the maker of the owl shaped jugs made apparently for presentation purposes. The earliest known date on German maiolica is 1526. These early wares were painted in blue, with imitations of venetian designs, or with figure-subjects derived from contemporary German engravings. Maiolica-painting was applied to the decoration of tilework stoves in the Tyrol, in Austria and especially at Winterthur in Switzerland, where from 1590 to 1740, approximately, a flourishing maiolica industry was carried on by the Pfau family and others. About 1618 the majolica technique was introduced by Lorenz Speckner in the potteries of Kreussen, in Bavaria (of special note are his drug-pots boldly painted with spirals in blue), and about the same time blue-and-white wares, especially narrow-necked pear-shaped jugs, showing Chinese influences, were made at Hamburg. The settlement of two Dutch potters at Hanau in 1661, and the establishment of a factory at Frankfort-on-the-Main in 1666 mark the beginning of a second phase, under Dutch influences, in which the Chinese fashions of the day determined the styles of decoration. Frankfort is notable for large dishes and jars with bold adaptations of late Ming motives in a remarkably clean vivid blue. Faience-factories at Nuremberg, Bayreuth, Ansbach, Dresden, Berlin, Potsdam and elsewhere are witnesses to the spread of these wares in cheap imitation of blue-and-white and five-colour porcelain. Potsdam was the first place to attempt to simulate Chinese "powdered blue" on faience. Tankards with baroque panelled designs or somewhat crude polychrome renderings of Chinese landscapes were made extensively at Erfurt and minor factories in Thuringia. In the 17th century glass-enamellers such as Johann Schaper and Abraham Helmhack of Nuremberg took to decorating in their own homes (as "*Hausmaler*") faience obtained "in the white" from the factories. Their paintings of landscape or scriptural and other figure-subjects in black monochrome (*schwarzlot*) or bright polychrome are often of extraordinary fineness of execution. From their work arose the adoption of overglaze enamel-painting in the potteries themselves. This prepared the way for the third phase, the spread of French influences from Strasbourg and Marseilles, seen in coloured naturalistic floral decoration and French rococo forms for the wares. Disseminators of this technique were Johann Eberhardt, Ludwig Ehrenreich and Johann Tännich; the latter, trained under Hannong at Strasbourg, worked afterwards in several factories, notably at Kiel and Mosbach. From Germany the manufacture of faience spread to Scandinavia; flourishing factories at Copenhagen, Sleswick, Rörstrand near Stockholm and Herreboe in Norway produced chiefly blue-and-white wares showing Dutch and Chinese influences; large tea-trays, sometimes used as table-tops, and punch-bowls in the form of a bishop's mitre are conspicuous amongst their output. At the Marieberg factory, Stockholm, founded in 1758, the enamel-painted faience of Strasbourg was successfully imitated. Hollitsch in Hungary also produced enamel-painted faience of good quality closely resembling that of Strasbourg.

Mediaeval Pottery of North-west Europe.—The mediaeval pottery of western Europe is unpretentious and often crude in technique, but shows at the same time great virility and dignity of form. Glaze had passed entirely out of use in the Dark Ages. On later wares, when present, it is a soft galena glaze, sometimes stained brown with iron or green with copper. Decoration is effected by scratching with a point, or by impression with cut stamps or the application of reliefs such as overlapping scales or strips of clay pressed on with the potter's thumb, or rough floral and heraldic ornaments shaped in moulds; painting with red, brown and white clay pigments is the exception, but clays of various colour are often combined in relief decorations. Vessels such as aquamaniles, in rude human or animal form, and jugs modelled into human features, are not unusual. These characteristics are common to France, Germany and England.

In France the revival of glaze began in the 13th century, when Savignies, in the neighbourhood of Beauvais, began to become an important centre of production, of which in the 15th and 16th centuries the bluish-glazed wares with applied heraldic and floral ornament enjoyed some esteem; from the 14th century La-Chapelle-des-Pots near Saintes, was another important centre. Fine earthenware with inscriptions in Gothic characters and floral designs, made after the Italian manner by the *sgraffito* technique and including Italian shapes such as the *albarello* jar, appear towards 1500, and shortly after polychrome lead-glazed wares began to be made. Ornamental earthenware finials for gables were produced, especially in Normandy, from late mediaeval times onward.



BY COURTESY OF THE YORKSHIRE MUSEUM
MEDIAEVAL ENGLISH JUG

Remains of mediaeval potter's kilns have been found in England at Nottingham, Lincoln and Cheam, and community of characteristics amongst vessels dug up at Oxford indicate local production; the same is true of York, and simple pottery must have been made at many other places. The earliest remaining wares, certain tall slender jugs of light buff earthenware, with a double swell in their profile, are attributed to the 13th century. In the 14th century forms tend to become more squat, glaze and applied or incised decorations appear. Greater refinement of shape is seen in green-glazed jugs of the 15th century, and under the Tudors elaborate moulded heraldic reliefs are found. In Germany the hard-fired semi-vitrified ware known as stoneware was first made, from the 14th century onwards. The earliest specimens are slender jugs, strongly wheel-marked, in a creamy-white body, made at Siegburg near Bonn. Drinking-vessels of great elaboration, often double-walled, the outer wall being pierced with Gothic tracery, were made of a hard brown ware in the 15th century at Dreihausen, Hesse. Floor-tiles form a great part of the output of mediaeval kilns, and were made wherever great churches were being built. Those of France and England have glazed bichromatic inlaid decoration, the German tiles, mostly unglazed, showing stamped or moulded designs. Tile-work was used in Germany for architectural details also, and especially for stoves.

French and German Lead-glazed Earthenware.—With the arrival of the renaissance in France pottery rose in that country to a higher level of general esteem, and two highly specialized experimental developments took place. One of these passed without lasting influence on ceramic history, that of the famous so-called Henri II. ware; the place of its production was for long a mystery but it is now known to have been made at St. Porchaire in Poitou, approximately from 1525 to 1560. It is of a fine whitish clay, with a cream-coloured glaze, and decorated with designs built up from impressions of metal stamps like those of a book-binder and inlaid in the manner of *niello* with darker clays; in the later examples touches of blue, green and purple pigment are added. The early forms are imitations of metalwork; later, salt-cellars, standing cups and ewers were built up like architecture in miniature with applied reliefs and statuettes and inlays imitating tile pavements. Devices of François I. and Henri II. and the crescents of Diane de Poitiers appear on many of the pieces.

Of greater significance was the work of Bernard Palissy (*q.v.*). After years of experiment he made coloured lead glazes, blue, green, purple and brown, of an excellence never attained before. His earlier wares were decorated with casts from the smaller fauna and flora of the district of Saintes. Later he adopted reliefs of figure subjects or formal designs. He was succeeded by two sons and by several potters who early in the 17th century made wares in his manner, including statuettes after bronze originals, at Avon and Fontainebleau, and at Manerbe (Calvados). Earthenware with a rich dark brown lead glaze, in forms copied from metalwork, was made towards 1600 at Avignon.

Contemporaneously with Palissy various potters in south Germany were making polychrome earthenware of a similar type, but combining a white tin enamel with coloured lead glazes. This technique was employed specially in the production of stove-tiles, which from about 1550 onwards were commonly decorated with figure-subjects of biblical or allegorical reference, reflecting the all-pervading religious pre-occupations of the time, rendered in relief under a renaissance arched recess. Potters known as Hafner, who worked in this manner, were settled at Nuremberg (Paul Preuning and others) and also at Salzburg and elsewhere in Austria. Besides stoves they made jugs with applied reliefs (sometimes including figures in the round in a recessed niche) and bright-coloured glazes. An analogous ware, made from about 1550 at Neisse in Silesia, is characterised by designs rendered by means of deeply-incised outlines separating the coloured glazes and enamels. In the 17th century the wares of the Hafner in Central Europe fell to the level of peasant pottery, which, however, has often great aesthetic value.

German and Flemish Stoneware.— Artistic stoneware began to be made at Cologne about 1540. It is characterised by the ferruginous brown stain of its salt glaze. Its commonest form is that of a round-bellied jug with a bearded man's mask applied on the front of the narrow neck, a form which under the name *Bartmann* or "greybeard" became common in most stoneware potteries. Small applied medallions resembling the Roman coins frequently dug up in the city and its neighbourhood, and coiled branches with small oak leaves and acorns, are also frequent motives of decoration. About 1566 one of the Cologne workshops was removed to Frechen, where the manufacture especially of greybeards for Rhenish wine, exported in quantity to England and elsewhere, lasted into the 18th century. At Siegburg the mediaeval white stoneware took on a renaissance dress about 1550; the place was famous for its tall slightly-tapering tankards (Schnellen) with heraldic and figure reliefs in three adjacent vertical panels, the finest being the work of the Kniitgen family. Raeren, near Aix-la-Chapelle, was also a centre of the industry; its wares are deep brown-glazed, and (at a later stage) grey ware with cobalt-blue colouring in places. The characteristic productions are jugs, often of large dimensions, with elaborate mouldings and reliefs which generally take the form of a frieze, either continuous or broken into arcading, round the belly and sometimes also the neck. Jan Emens and Baldem Mennicken were the most gifted of the Raeren potters. Soon after 1600 the potteries of Siegburg (sacked by the Swedes in 1632) and Raeren declined, and many of the potters migrated to the Westerwald district near Coblentz, where at Grenzhausen and Hohr the industry lasted till it was superseded by earthenware of the English type late in the 18th century. The Westerwald stoneware is grey in body, and its relief decorations, in which figure subjects tended to give place to formal floral motives, are picked out with colouring in cobalt blue and occasionally also in manganese purple. Stoneware, mostly inferior imitations of the Rhenish, was made in the 17th and 18th centuries at Bouffoualx and elsewhere in the south Netherlands. Kreussen in Bavaria produced in the 17th century a chocolate-brown stoneware with reliefs (of the Apostles, Electors of the Empire, etc.) painted in the vivid colours of the contemporary enamelled glass. Altenburg in Saxony and Bunzlau in Silesia also made relief-decorated stoneware.

BY COURTESY OF THE DIRECTOR OF THE VICTORIA AND ALBERT MUSEUM
JUG, OF COLOGNE STONEWARE

English Stoneware and Lead-glazed Earthenware.— The importation of German stoneware in the 17th century led to various attempts to imitate it in England. The most conspicuous was that of John Dwight, an Oxford scientist, who set up a pottery at Fulham about 1670 in which he made not only bottles and mugs in stoneware of various colours but also statuettes, modelled by an unknown artist (perhaps the sculptor, Grinling Gibbons), in white or dark brown clay with a thin coating of salt-glaze; these famous works, including busts of Prince Rupert and others and figures of classical deities, are amongst the most remarkable achievements in the history of plastic art. Stoneware of good quality, with a lustrous brown glaze, decorated with stamped, incised and moulded designs, often dated, was made at Nottingham from about 1695 onwards by John Morley and others of that family. Similar ware was made later at Chesterfield and Swinton. Another experimenter in stoneware was Francis Place, who worked about 168; at York. Dwight had competitors also in the brothers Elers, two Dutch silversmiths who made teapots in a fine red-bodied ware, imitating Chinese boccaro ware, at Bradwell Wood near Newcastle-under-Lyme; their work was of great importance in its revolutionary effect on the output of the North Staffordshire potteries.

Mediaeval traditions in the production of coarse red earthenware with decoration in white "slip" (that is, clay diluted to a creamy consistency) were followed throughout the 17th and 18th centuries in many small potteries throughout England. Wrotham in Kent produced "tygs" (drinking-vessels with several handles) and posset-pots with neatly applied pads of clay stamped with initials or floral devices, animals and birds. At Bethersden near Ashford the inlay technique of the mediaeval tiles was adopted for pottery. By working with a comb the different coloured clays in a semi-liquid state on the surface of the wares, marbled and feather patterns of real distinction were often produced. No attempt at lightness and refinement of shape was made in the district until the advent of the brothers Elers, which stimulated the local potters to improve their technique. Soon after 1700, in response to the demand newly created by the introduction of tea-drinking, John Astbury was making tea-services, with small stamped reliefs in white on a red ground, and similar wares in a harder fired drab stoneware, from which about 1720, by the introduction of ground flints into the body, the Staffordshire white salt-glaze ware was evolved. A further advance came with the introduction of the process of casting the wares in plaster moulds with relief designs. About 1750 "marbled" wares were made by mixing clays of different colours, also "tortoiseshell" ware with mottled glazes, and tea-services in the form of cauliflowers and pineapples coloured after nature; such wares were produced especially by Thomas Whieldon, who in 1753 took into partnership a young potter destined later to revolutionise the industry. This was Josiah Wedgwood (*q.v.*). His new productions were "black basaltes" ware, an improvement on the black unglazed stoneware of the district, and jasper ware, a fine stoneware stained with blue, green, lilac and other colours and generally decorated with applied cameo reliefs in white. For shapes and decoration he drew upon the recently-published repertories of Greek vases, conforming entirely to the neo-classical taste of the period. He engaged John Flaxman and other sculptors to provide him with designs. An important part of his output were small medallions with portraits or other reliefs, made for mounting in furniture or as jewellery. For decorating his Queen's ware he introduced transfer printing, sending it at first to Liverpool to be printed by Sadler and Green. Wedgwood had many competitors who produced imitations of most of his wares; in Staffordshire, Adams, Neale, Turner and Palmer were the most important. Cream-coloured ware of good quality was made from about 1770 onwards at Leeds and elsewhere in Yorkshire; pierced decoration is its most characteristic feature. Earthenware figures emulating those of the porcelain factories were made at Burslem from about 1765 onwards by Ralph Wood, his son Ralph, and his grandson Enoch, and by many other Staffordshire potters. The earliest, painted in coloured glazes in the manner of Palissy ware, are mostly from models by a French artist, John Voyez, who generally copied the figures of Cyfflé of Niderviller; they have considerable artistic merit Lead-glazed earthenware of good quality was also made in the late 18th century at Liverpool, Bristol, Swansea, Newcastle-on-Tyne and Sunderland, A variety made in many places is the so-called silver lustre ware, coated with platinum, in imitation of silver plate. After 1800 the English earthenwares were rapidly degraded. (B. RA.)

EUROPEAN PORCELAIN TO END OF 18TH CENTURY

From the time of its first appearance in Europe, at the latest in the 15th century, Chinese porcelain was regarded by potters as in the highest degree worthy of imitation. Admiration for its whiteness led to the use of a white enamel or slip-covering on the earthenwares of Italy and other countries, whilst its translucency and vitrified texture misled the potters into supposing that a substance of the nature of common glass entered into its composition. Attempts to imitate it in this way were made in small manufactories at several places—as at the glass-making centre of Venice and elsewhere in Italy, more particularly at Florence, where a factory was started under the patronage of Francesco de' Medici, not later than 1581. Medici porcelain was decorated, as a rule in a soft blue only, with motives drawn from Italian maiolica in combination with Chinese elements imitated from wares of the type made for export to Persia. The manufacture is supposed to have been continued at Pisa; later and not dissimilar porcelain is to be attributed to Candiana near Padua. No settled manufacture was, however, in existence before the latter part of the 17th century. Edme Poterat of Rouen and his son Louis were granted a privilege in 1673, whilst another factory founded in 1677 at St. Cloud near Paris had by the end of the century grown to considerable size. These artificial porcelains, fired at a low temperature and made translucent with the aid of a previously fired glassy mixture or frit, were of the type now known as soft-paste (*pâte tendre*). They remained the characteristic porcelains of France for nearly a hundred years, and somewhat similar compositions were widely used in England, Italy and Spain during the 18th century.

Meanwhile in Germany the insight of Tschirnhausen and Bottger (see below) had perceived that porcelain of Chinese type could be made only with potters' materials, and by experiments with the fusing of clays were discovered, first, a hard red stoneware, and in 1709 true, that is, hard-paste, porcelain, which is essentially a high-fired mixture of the fusible and non-fusible silicates of alumina, called by the Chinese *petuntse* and kaolin, and in English china-stone and china-clay. From the manufacture founded at Meissen upon Bottger's discovery sprang others making hard-paste at Vienna and other places in Germany, at Venice, St. Petersburg and elsewhere Hard-paste began to be made at Sèvres in 1769 but did not entirely displace the *pâte tendre* until the beginning of the 19th century In England hard-paste was independently rediscovered before 1768, but it was used in a single manufacture only and was superseded towards the end of the 18th century by a universally-adopted hybrid composition in which china-clay was partially replaced by the ashes of calcined bones, an ingredient which had for some time previously been used in a characteristic type of English soft-paste.

STAFFORDSHIRE SLIP WARE: DECORATION MADE WITH WHITE CLAY DILUTED TO CREAMY CONSISTENCY

France.—The rare porcelain attributed to the Poterats of Kouen resembles in decoration the blue-painted faience of the same city, and similar painting in *Louis Quatorze* style is characteristic also of much of the St. Cloud porcelain. Jugs, cups and saucers, pomade-pots and other small objects, as well as flower-pots of considerable size, were the chief productions of St. Cloud: they were as a rule tastefully and substantially potted with a fine feeling for the qualities of a rather yellowish but pleasant-toned material. Plum-sprays amongst other motives in relief were sometimes copied from blanc de *Chine*, for which this French porcelain has often been mistaken. Fluting and scale-pattern were also favourite decorations Painting in turquoise-blue, red, yellow and green was inspired by Japanese Kakiemon porcelain. Boldly modelled figures inclining to the grotesque were done. St. Cloud (which was founded by Pierre Chicaneau in 1677) came to an end in 1768. Very similar porcelain, as a rule indistinguishable from the St Cloud, was made in Paris at a factory in the Rue de la Ville-l'Evêque and at Lille.

Porcelain of distinctive character was made at Chantilly, where a factory was founded in 1725 by Louis-Henri of Bourbon, duc de Condé Here for the first twenty years or so the material was singular in being covered with a glaze made opaque with oxide of tin At its best Chantilly is of a beautiful creamy white colour. "Kakiemon" patterns were freely copied in designs of great charm. The Meissen styles of flower-painting (q *v.*) and the formal "Indian" and naturalistic "German" flowers were adapted in the French taste, as were some of the figure-models of the same factory. In the later Chantilly, coloured grounds were imitated from Sitvres and the tin-glaze was given up; slight decoration in underglaze blue was favoured for cheaper wares. The factory ceased to make soft-paste about the end of the century.

The factory at Mennecy-Villeroy, near Paris, was a continuation of one in the Rue de Charonne in Paris, founded in 1735 by François Barbin, who removed his establishment to Mennecy in 1748 to place it under the patronage of Louis François de Neufville, duc de Villeroy. The earliest of Barbin's productions were in Rouen-St. Cloud style, but later a great variety of small objects was made and enamelled in colours of a singular freshness, amongst which a purplish rose-pink is prominent. At its best, Mennecy porcelain is of unsurpassed quality, mellow in tone and texture and of a warm white colour. Some charming figures were made. The factory was removed in 1773 to Bourg-la-Reine and ceased to make porcelain about 1790.

The beauty of material characteristic of the French soft-pastes was achieved in the highest degree in the productions of the royal factory at Vincennes, which was removed to Sbvres, between Paris and Versailles, in 1756. This factory was established in 1738, under the patronage of Orry de Fulvy, by two workmen named Dubois, who, however, failed to produce porcelain. A workman named Gravant eventually succeeded, in 1745, and a company was formed with a subvention from Louis XV., who finally in 1759 took over the factory, which enjoyed certain exclusive privileges (such as the use of gilding) amounting to a monopoly. The Royal proprietorship ended, with the Revolution, in 1793, but the establishment has continued under State control to the present day. The Vincennes productions at first consisted chiefly of porcelain flowers in imitation of those of Meissen, intended for mounting in ormolu. Meissen styles of painting were copied in this early period, though the forms, largely in rococo style, were designed by the court-goldsmith Duplessis. Jean-Jacques Bachelier supervised the painting and gilding, whilst the chemist Hellot was in charge of the technical side. Painting in panels reserved on a coloured or diapered ground enriched with gilding, soon became the characteristic Sèvres decoration, and the succession of the ground colours is the chief feature in the chronology of the great period of 40 years from 1749 onwards. The dark gros bleu, probably imitating Chinese powdered-blue, was introduced in 1749 and abandoned in favour of the brighter bleu de roi about 1756. Turquoise-blue (*bleu céleste*), yellow (*jaune jonquille*) and green grounds made their appearance in 1752, 1753 and 1756, The rose *Pompadour* (miscalled in England rose *du* Bamy), invented by Chrouet, appeared in 1757 and went out of fashion in seven years. The favourite painting in monochrome (*en camaieu*) was at first generally in crimson, later in blue. Particulars of many of the painters and the marks used by them may be found in several books of reference. Late in the period, about 1780, an enameller named Cotteau invented the so-called jewelled decoration in which drops of coloured enamel were fused over gilding. Glazed and coloured figures were made in the early years of the factory in rivalry with Meissen, but about 1751 Bachelier introduced *biscuit* or unglazed porcelain as a medium for novel work for which the painter Boucher made designs to be executed by Blondeau and others. The sculptors Falconet and la Rue in the earlier period, and Pajou and Boizot in the later, created many models for execution in Skvres biscuit. The influence of Boucher is apparent throughout in the painting and modelling, whilst the so-called *Louis* Seize neo-classical style began to replace the rococo soon after the transfer to Skvres in 1756. For technical skill and perfection, and for delicacy and taste (if not for more vital qualities) Skvres porcelain is unsurpassed. Soft-paste at all times has the merit of absorbing enamel-colours into its easily-fusible glaze, and this is nowhere more evident than on Siivres china.

Though soft-paste was the medium of the finest Skvres productions, hard-paste was made occasionally (from kaolin found after long search at St. Yrieix near Limoges) as early as 1769 and finally superseded the other altogether in 1804, when the newly appointed director Brongniart gave up the manufacture of the more costly material with a view to repairing the financial distress of the factory, caused by the Revolution. Hard-paste became the medium of a style marked by a severe and even pompous classicism, shared also by a number of other factories which had sprung up in the latter part of the 18th century in Paris and the neighbourhood, largely under the patronage of members of the Royal family. Rue Thiroux, La Courtille, Rue de Bondy ("Manufacture d'Angoulême") and Rue Popincourt (Nast's factory) were the chief. Other French factories making hard-paste and equally concerned to imitate Siivres, were at Lille, Étiolles, La Seynie, Boissette, Limoges and Valenciennes.

Hard-paste of distinctive character was made at the faience factories of Strasbourg and Niderviller and of Joseph Robert at Marseilles. The first-named was closed at the instance of Vincennes in 1753 and Paul Hannong, its proprietor, crossed the frontier to found the Frankenthal factory.

Some soft-paste of fine quality was made also at Sceaux, Orleans, Arras and St. Amand-les-Eaux, whilst at Tournai (which was part of France in the 18th century) soft-paste was used for wares inspired as much by Meissen as by Sèvres.

Germany. — The discovery of hard-paste by Johann Friedrich Bottger was the result of experiments into the vitrification by heat of clays and rocks, conducted by him in association with Ehrenfried Walther Tschirnhausen, with whom he had been concerned in the establishment of a faience factory at Dresden. Like almost all scientists of the time, Bottger believed in the possibility of transmuting base metals into gold, and he was kept, virtually a prisoner, in the service of Augustus the Strong, King of Saxony, who hoped to benefit by the exclusive property of his alchemist's secrets. The first important product of Bottger's labours was a hard red stoneware, comparable with the so-called buccaro of Yi-hsing in China. First produced in 1708, it was quickly developed into a medium capable, by cutting and polishing, of expressing much of the baroque taste of the time. Silvering and gilding and a black glaze, invented by Bottger, were sometimes added to it. Imitations were made at Plaue-an-der-Havel, and at Bayreuth. The first glazed white porcelain was produced by Bottger alone in 1709; its regular manufacture did not begin until four years later. The earliest specimens inclined to a smoky tone, and the decoration (for which Irminger, a goldsmith, was responsible) of applied acanthus leaves, masks and rich mouldings, was similar to that of the red ware.

In 1710 the manufacture was removed to the Albrechtsberg at Meissen, but the making of the white porcelain was not fully mastered until 1715. Though without adequate financial support, Bottger succeeded in the four years before his death in 1719 in perfecting his material and in inventing a wide range of enamel colours, including a rare pale-violet lustre-colour almost peculiar to the factory and much used in the subsequent period.

In 1720 the painter Johann Gregor Heroldt was appointed director, and in the next 20 years introduced many new decorations — chinoisen'es in gold and colours, landscape- and figure-subjects, as well as adaptations of Japanese and Chinese flowers (*indianische Blumen*) and other designs. Purple and red monochromes were used in a novel style. About 1740 Heroldt introduced the naturalistic deutsche Blumen. Though underglaze blue was never thoroughly mastered, many new colours were compounded for use as grounds, often richly gilt in *baroque* style with panelled decoration. Almost every ground colour used elsewhere later on was employed at Meissen under Heroldt.

The appointment as modeller of Johann Joachim Kaendler in 1731 marked the beginning of a period of great development in the plastic decoration. The king had constantly pressed for colossal figures in porcelain which Kaendler's predecessor, Gottlob Kirchner, had failed to produce to his satisfaction. Kaendler succeeded with these so far as the natural unfitness of the medium would allow; and then proceeded to create a succession of new forms for table-ware — plates, tureens, sweetmeat-stands, candelabra, etc.—with modelled ornament, as well as a range of highly individual small figures. It was the court custom to group wax or sugar models on the dinner-tables, and Kaendler, helped by Friedrich Elias Meyer, Johann Friedrich Eberlein and Peter Reinicke, created many porcelain figures for use in the same way. Some subjects were novel in being drawn from contemporary life, embodying a satirical or witty commentary. Kaendler was the first to understand the potentialities of glaze and colour in the make-up of the porcelain figure, which in his hands was never merely monumental sculpture reduced in scale. French rococo was not without influence on Kaendler's style after about 1740, but he remained essentially a baroque sculptor, and continued to work for the factory until his death in 1775.

Meissen remained the premier porcelain factory in Europe until the Seven Years' War, which broke out in 1756, when Frederick the Great virtually sacked the place. Technically excellent work was done under the direction of Count Marcolini (1774–1813), but the former position was never regained. Skvres fashions were copied, and an artist actually from Sèvres, Michel-Victor Acier, made many characteristic models in the sentimental style, whilst an academic sculptor, Christoph Jiichtzer, made biscuit figures in the classical manner.

Following the fashion set in Saxony, many other German princes sought to establish or patronise china-factories, and by 1760 no fewer than eight had come into existence in this way. Broadly, Meissen styles prevailed until about 1760, when Sbvres fashions and the neo-classical began to predominate. The dependence upon Meissen and Skvres, however, was very much less than a superficial view would indicate.

In 1718 a runaway Meissen workman, Christoph Konrad Hunger, enabled Claude du Paquier to start a factory at Vienna, which was in 1744 sold to the state. Much of du Paquier's china was decorated by independent enamellers (Hausmaler) ; the factory's own styles were remarkable for the frequent use of a black (Schwarzlot) and other monochromes in rich baroque designs. Mayerhofer became director in 1751. Vienna figures of the period about 1760 have a very distinct and airy charm. In 1784 a prosperous period began under the directorship of Konrad von Sorgenthal. A modeller Anton Grassi (who had previously made some lively enamelled figures) began to use biscuit with success, whilst in the last decade of the century was made the porcelain with elaborate miniature pictures in the style of oil paintings, with rich gilding and coloured grounds which was formerly considered the best, and still is the most famous, Vienna work.

At Berlin, a wool manufacturer Wilhelm Kaspar Wegely made porcelain of fine quality, including figures, from 1752 to 1757. A few years later, a financier named Gotzkowsky started a factory which in 1763 was taken over by Frederick the Great. Berlin table-wares tend to favour simple colouring with a special fondness for pink diaper (*Mosäik*) borders. Some good figures were made by Friedrich Elias Meyer (brought from Meissen in the Seven Years' War), his brother, Christoph, and others.

With the help of one Lowenfinck from Meissen, porcelain was

made at a faience-factory at Hochst as early as 1746, under the patronage of the Elector of Mainz, but not in any quantity until 1760. Very lively figures in Meissen rococo styles preceded those made by Johann Peter Melchior (appointed 1767), upon which the factory's fame chiefly rests. Melchior's very personal style shares the same inspiration as the contemporary Sèvres models: he showed an equal mastery in the treatment of the nude, in figures of children, and in portrait busts and plaques. All have the smooth, not glossy surface and soft colouring that are characteristic of Hochst.

The factory at Furstenberg in Brunswick was established in 1753 by Duke Charles I. with the help of Johann Benckgraff of Hochst. A feature of the early porcelain was the use of elaborate moulded patterns designed to disguise the imperfections of the material. In the last twenty years of the 18th century biscuit was used for a series of portrait medallions in white on blue.

The Bavarian state factory, founded in 1747 at Neudeck, and transferred in 1761 to Nymphenburg, is chiefly famous for its figures, for which Franz Anton Bustelli (*fl.* 1754–63) made models which are perhaps the finest plastic expression of rococo. The same qualities, however, distinguish the delicately painted table-wares and vases of the factory. Bustelli was followed by Auliczek, who in turn gave place in 1797 to the Höchst and Frankenthal modeller J. P. Melchior.

The Frankenthal factory was founded by Paul Hannong of Strasbourg in 1755 under the patronage of the Elector Palatine. The early figures modelled by J. W. Lanz, their subjects chiefly drawn from contemporary life, are amongst the best produced in Germany, whilst the classical models of Konrad Link (made 1762–66) share the largeness of style of the best later work of Kaendler. Other able modellers were J. G. Luck, and Karl Gottlieb Luck, and in 1779 J. P. Melchior came to Frankenthal from Hochst.

Though the porcelain of Ludwigsburg is seldom free from imperfections and generally grey in tone, it was the medium of some excellent figures, for which amongst others the sculptor J. C. W. Beyer (1764–67) made some models combining rococo character with the classical style. The factory was founded in 1756 and taken over in 1758 by Charles Eugene, Duke of Wurttemberg.

Amongst the minor German factories founded in 1756 by the Prince-Bishop of Fulda has a deserved reputation for high quality both in the modelling of figures and the painting of table-wares. Another factory, started in 1758 at Ansbach and transferred four years later to Bruckberg, closely followed Meissen models. Others of some importance were at Ottweiler in Nassau-Saarbrucken (founded 1763), Cassel in Hesse (founded 1766), Pfalz-Zweibrücken (founded 1767), Baden-Baden and Kelsterbach. In the forest region of Thuringia, many private factories sprang up soon after 1760 making cheap useful wares, as well as imitations (often definitely fraudulent) of the better Meissen china. Very good porcelain, however, was made at Kloster-Veilsdorf, Gotha, Ilmenau and Vqlkstedt. The rather crude figures of Limbach sometimes have an attractive simplicity. Porcelain was also made at Gera. Gross-Breitenbach and Rauenstein.

In the earlier days of Meissen and Vienna no serious attempt was made to prevent undecorated porcelain from reaching the hands of independent enamellers, though eventually the Meissen factory adopted the plan of cancelling its mark (by a cut in the paste) on all defective pieces sold in the white. Amongst many excellent *Hausmaler* may be mentioned J. Aufenwerth of Augsburg and J. F. Metsch of Bayreuth; Preussler, Ignaz Bottengruber and his pupils H. G. von Bressler and C. F. von Wolfsburg, all of Breslau, who specialized in monochrome painting, chiefly in red and in black, in which last also Jacob Helchis decorated Vienna porcelain in a distinctive manner. The wandering arcanist C. K. Hunger of Meissen, Vienna and Venice, practised a style of painting in thick gold, and about the middle of the century, F. Mayer of Pressnitz worked in several styles, and Canon Busch of Hildesheim made original engravings on porcelain with a diamond-point and coloured them with black.

Switzerland. — In Switzerland, porcelain was made at a factory at Schoren near Zurich, founded in 1763. Though smoky in tone and painted in subdued colours, Zürich china has a very distinct charm and delicacy. Another Swiss factory at Nyon made hard porcelain in French style in the late 18th century.

Belgium and Holland. — Hard-paste factories of no great importance were in existence in the 18th century at Weesp (afterwards transferred to Oude Loosdrecht and Oude Amstel) and The Hague, where, however, Tournai and other porcelain was sometimes decorated and marked. Paris styles were followed at Etterbeek near Brussels.

Denmark and Sweden. — At Copenhagen as at Marieberg (Stockholm) soft-paste was made at first. At the former from about 1760 Louis Fournier from Vincennes made wares in French style until hard-paste began to be made about 1772: in this last a series of Norwegian peasant-figures is noteworthy. At Marieberg, Pierre Berthevin from Mennecy made soft-paste from 1766 to 1769, and a hybrid porcelain was used for the next twenty years.

Russia. — Hard porcelain in German style was made in Russia as early as 1745, but was scarcely an established manufacture until the time of Catherine II. (1762–96). Amongst the little that is distinctive in the Imperial porcelain from the St. Petersburg factory a series of figures of Russian folk-types may be mentioned. Other factories included one conducted by an Englishman, Gardner, at Verbilki and Tver near Moscow.

Italy. — Venice shares with Meissen and Vienna the distinction of a porcelain factory established in the first quarter of the 18th century, in the period of the baroque style. Two brothers, Francesco and Giuseppe Vezzi, founded their factory in 1720 with the aid of the Meissen and Vienna workman Hunger. It ceased to exist soon after the death of the first-named in 1740. The Vezzi porcelain resembles Meissen in its technique of painting, in which iron-red plays a prominent part, but a certain Italian fantasy and irresponsibility distinguishes it. Another Venetian factory seems to have been in operation from 1758 to 1763 under one Hewilcke of Dresden, but little is known of it, and that founded by Geminiano Cozzi in 1765 made most of the porcelain for which Venice is celebrated. Meissen was again much imitated, but the fantastic Italian rococo and a freshness of colour mark much of the Cozzi china, which was a kind of soft-paste. The existing Doccia factory was founded about 1735 by the Marchese Carlo Ginori, with the help of a chemist from Vienna, Karl Wendelin Anreiter. Its earliest work included some distinctive baroque decoration, and later on in the 18th century some highly dramatic groups were made. Factories at Nove, Vinovo near Turin, and Treviso produced more or less original work, whilst at Capo-di-Monte near Naples, a celebrated factory was in operation from 1743 until 1759, when its patron Charles, king of Naples, succeeded to the Spanish throne and the establishment was transferred to Buen Retiro. Typical Capo-di-Monte china is a glassy soft-paste, extravagantly decorated with reliefs, often of figure-subjects; it was much imitated at the Naples factory which was in a sense its successor (1771–1821), and at Doccia and elsewhere in the 19th century.

Spain and Portugal. — The Madrid or Buen Retiro porcelain (1759–1808) was of various quality but included some of the most beautifully modelled and coloured figures ever made in Europe. For these the modeller Giuseppe Gricci was probably responsible. Amongst many styles of painting on vases and table-wares there is much that is of a minute but significant delicacy. The manufacture was revived at La Moncloa from 1817 to 1849. Porcelain was also made at the count of Aranda's faience-factory at Alcora from 1774, and at Vista Alegre in Portugal from 1790.

England. — No certain English porcelain is known of earlier date than the so-called "goat and bee" jugs, made of a soft paste resembling milk-white glass and incised with the name of the Chelsea factory, the date 1745 and a triangle. This "triangle-period" of the Chelsea factory is believed to have ended about 1750, when Nicholas Sprimont apparently displaced Charles Gouyn as manager. Chelsea china of the next eight years is the finest ever made in England. Of a smooth soft-paste capable of giving the most delicate quality to enamel-painting, Chelsea is more often original than any other English porcelain, though its styles were largely inspired by Meissen. The figures in particular are unsurpassed for beauty of modelling. The mark of an anchor, at first in relief, later painted in red, belongs to this period, 1750–58, which ended with the death of the proprietor, Sir Everard Fawkener. In the subsequent period, when Sprimont was proprietor as well as manager, the rococo style (at the time outmoded at Sttvres) survived for ten years in extravagant forms of great interest. Coloured grounds, including a dark "mazarine" blue and a rich broken crimson were inspired by Siivres, as were figure-subjects, *chinoiseries,* and other styles of painting. Profuse gilding of fine quality, richly brocaded costumes and *bocages* or backgrounds of flowers and foliage were characteristic of the boldly modelled figures, some of which were at one time erroneously attributed to the sculptor Roubiliac. The beautiful Chelsea toys — scent-bottles, seals, bonbonnittres and the like — were made from about 1750 onwards and even continued to be done at the factory after its sale in 1770 to William Duesbury, the proprietor of the Derby factory. This had been in existence since 1750 and had made figures and other porcelain in Chelsea styles, but of comparatively little merit. The productions of the period 1770–1784 (when the Chelsea works were closed) are often known as Chelsea-Derby china. The pseudo-classical vases and the figures (including some in biscuit) in the fashionable sentimental Sèvres styles are of less importance than the table-wares which are the chief title to fame of the Derby factory. Later porcelain in the same excellent tradition was painted by artists whose names are known, such as Zachariah Boreman and William Billingsley. Derby declined after the succession to the management of Robert Bloor in 1811, and came to an end in 1848.

The Bow factory was perhaps in existence in 1744, but its productions before 1750 have not been certainly identified. From 1749 (when a distinctive bone-ash paste was adopted) to about 1760 its productions were largely inspired by, and often close copies of Meissen, but rank next to Chelsea for delicacy of modelling, and have the attraction of a beautiful ivory-toned material and clean strong colouring. Later Bow, which was marked with an anchor and a dagger, shows a distinct falling off in these respects. Lowestoft was an offshoot of Bow and largely imitated the productions of other factories, as well as Chinese models, in soft-paste. At Longton Hall in Staffordshire from about 1750 to 1760 William Littler made excellent figures and other wares of a soft porcelain in which are apparent some of the attractive qualities of the more rustic Staffordshire earthenware. A rich blue enamel used as a ground, and a fondness for dishes and vessels in the form of folded leaves were characteristic of Longton Hall. At Lowdin's factory at Bristol, transferred to Worcester in 1752, soapstone (steatite) was used in the paste, and Chinese, Japanese and Meissen motives were employed with an attractive simplicity. Amongst the best Worcester china, made between 1755 and 1765, may be singled out the beautiful armorial mugs. Transfer-printing was adopted very largely as a mode of decoration at Worcester. About 1768, painters from Chelsea were engaged, and a showy style with rich gilding and coloured grounds, including a distinctive "scale-blue," became the fashion of the day. The painting of highly-coloured "exotic birds" was inspired by Chelsea. The later "Flight" and "Flight and Barr" periods of Worcester (which succeeded the so-called Dr. Wall period, 1751–83) show a marked decline in taste. Some Liverpool factories and that at Caughley (the "Salopian" factory), making porcelain from about 1760 to 1772 respectively, may be regarded as offshoots of Worcester. At Plymouth, William Cookworthy had discovered the secret of hard-paste before 1768 (when he took out a patent), and made figures and useful ware employing Chinese, rococo and classical motives. His factory was transferred to Bristol in 1770, and sold in 1773 to Richard Champion, who made much handsome table-ware as well as figures in the classical style. The Plymouth and Bristol china often fails in effect on account of its comparatively hard glaze, into which the colours have not fused. Champion sold his patent in 1782 to a Staffordshire syndicate who continued to make hard-paste in "cottage style" at the New Hall factory until about 1810. Meanwhile a hybrid porcelain made of hard-paste materials in combination with bone-ash had been introduced before the end of the century by Spode and others. The history of this china, like that of a beautiful but unpractical soft-paste made by William Billingsley, at first at Pinxton (1796) and afterwards at Nantgarw and Swansea (1814–17), belongs to the 19th century.

NINETEENTH CENTURY EUROPEAN POTTERY AND PORCELAIN

The period of the Napoleonic Wars marks a definite break with the older traditions of craftsmanship: European civilization emerged impoverished and found the Industrial Revolution complete. In the more pretentious wares, the Empire style was a pompous and frigid continuation of the neo-classical, and the "revived rococo" of 1820–50 was one of the first of the series of revivals that make up the greater part of the "styles" of the century. Some of the older factories, such as Meissen and Vienna, were even content to reproduce their former inventions, whilst the Great Exhibition of 1851 saw a general attempt to outdo in "exquisiteness" the most costly Sèvres productions of the 18th century. At Sttvres itself work of a high order of technical accomplishment was done under the management of Brongniart, who remained director until his death in 1847. In England the porcelain made by the Spodes and their successors Copeland's, of Stoke-on-Trent, by Minton's of the same place, and at Coalport and Swinton (Rockingham factory) was often very creditable technically but artistically of little account.

Amongst the cheaper types of pottery, the cream-coloured earthenware of Staffordshire commanded at the beginning of the century a world-market which it retained for a long time despite Continental rivals perforce driven to make the so-called *faïence anglaise.* In France the English method of transfer-printed decoration was also adopted, notably at Creil and Montereau, and the development of the deposits of kaolin in the neighbourhood of Limoges led to a rapid growth of the pottery industry in that part of the country. In Italy, some distinguished and fanciful painting was done on cream-ware by the firm of Giustiniani of Naples.

After the Great Exhibition, manufacturers began to be aware of "Art," and pottery inspired by Renaissance models — by maiolica, "Palissy ware" and Limoges enamels — made its appearance. The Paris Exhibition of 1867 introduced a fashion for Japanese naturalism and asymmetry, and some European porcelain was even made (as at Worcester) in imitation of the degraded "export Satsuma" of the period. The collecting of Turkish and Syrian pottery (called at the time "Rhodian" and "Persian") brought a vogue for designs in the same style, from which issued the work of William de Morgan who at a later stage began to make ruby-lustred wares inspired by Italian maiolica; he was also in a sense the representative in pottery of the Morris movement towards handicraft as against industrial machine-work. In France Théodore Deck made similar essays towards the rich colour of the "Damascus" wares; and indeed the most noteworthy pottery of the last forty years of the century was the work of individual artists striving to emulate the great achievements of past times. In particular, Chinese single-coloured and flambe' glazes inspired the high-fired stonewares and porcelain of Chaplet, Lachenal, Delaherche and Dalpayrat in France, and of Mr. Bernard Moore in England. Mr. William Burton developed some distinctive single-coloured glazes and lustre-pigments for Pilkingtons of Manchester, and similar lustred effects were

MODERN AUSTRIAN AND FRENCH POTTERY

Upper Group: Left to right, Back row: Group by Kitty Rix; Animal (original) by Kitty Rix; Figure by Erna Kopriva; Jar by Josef Hoffmann. Front row: Animal group (original) by Mathilde Flögl; Figure group by Vally Wieselthier: Jar by Josef Hoffmann. All pieces are burnt and afterwards glazed in various colours. Lower Group: Left to right, Carriès (*Grès*, about 1890); Augusta Delaherche (*Grès*, 1901); Chaplet (Porcelain grand *feu*, about 1900)

also obtained by Zéolnay of Pecs (Fiinfkirchen) in Hungary, and by the Massiers of Golfe Juan in France. The so-called Arts and Crafts movement in England, by drawing attention to the virtues of peasant art, brought a sentimental fashion for simpler lead-glazed decorative wares; at Florence the Montelupo style was revived, whilst more or less exact copies of Hispano-Moresque and later Italian maiolica were made by Cantagalli and also by various other potters.

At the older porcelain factories in the latter part of the century some innovations of importance included the crystalline glazes and subdued green, grey, mauve and blue underglaze colours introduced at the Royal Copenhagen factory, and used for delicately painted vases and figures of Danish peasants and animals, modelled by some able sculptors. Similar work was and is being done by Bing and Grondahl of the same city, by Heubach of Lichte in Thuringia, and by the Meissen and Rorstrand (Stockholm) factories. A mode of impasto decoration, known as *pâte sur pâte,* in which successive layers of white or coloured slip were applied to a dark ground, was skilfully practised at Sbvres by several artists, notably by Taxile Doat, and was brought to England by M. L. Solon, who worked for Minton's of Stoke-on-Trent. This was perhaps the foremost English factory, where Léon Arnoux was director, and the well-known sculptor, A. Carrier-Belleuse (afterwards at Sèvres) a principal modeller. At Wedgwood's another French artist, Emile Lessore (who had also been at Minton's), developed a delicate and individual manner of painting on cream-coloured earthenware.

Salt-glazed stoneware was revived in national styles by Villeroy and Boch of Mettlach, and by Doulton's of Lambeth, one of whose modellers, R. W. Martin, with his brothers Edwin and Walter, employed the material for grotesque figures and vases which have the merit of attractive colour in their sombre browns and greens, and show, moreover, a true feeling for pottery technique. Equally attractive work in stoneware was done by the French sculptor, Jean Carribs, and by E. Bigot of Paris. In Germany, Max Lauger of Karlsruhe developed an interesting style of decoration modelled in slip under coloured glazes. At the national factories of Berlin and Sbvres, highly accomplished work was done in many styles, with the support of up-to-date scientific knowledge, and the Paris Exhibition of 1900 marked the culmination of what may be called the eclectic period of European ceramic art. (W. B. Ho.)

MODERN CONTINENTAL

At the end of the 19th century the movement in the domain of the applied arts, with which the names of Ruskin, William Morris, Walter Crane and their fellow-artists are connected, wrought a great change. At first this tendency scrupulously supported the preservation of the methods of handicraft, and strongly opposed manufactured articles. But the same principles with which it originated, and which were indeed identical with those out of which the applied arts had developed in all previous periods, gained ground in the meantime, and the possibility of having artistic articles for practical use came once more within the purview of increasingly larger groups. Gradually also there came into being a desire to bring them within the reach of the many by changing the expensive handmade articles for manufactured goods, but such production was to be led by artists. But in proportion as these ideas became more general, a reaction set in against their excessive rationalistic elements. Consequently, after the beginning of the 20th century taste inclined towards the ornamental, the lively, the richly coloured, though the basic principle that the shape and appearance of the object should be determined by the requirements of material, technique and purpose was not neglected.

Artists, sensitive to shape and colour, could be satisfied with the ceramic production, for working the soft clay on a potter's wheel allows scope for the most individual expression. So far as the continent of Europe was concerned, there were two centres whence the above described development sprang: France and Denmark, or, more strictly speaking Copenhagen. An important development in Holland has exerted little influence outside its own boundaries, and similarly in Germany, while both have undoubtedlv orofited from French and Danish artists.

MODERN CERAMIC TECHNIQUES

By ceramics is meant all production of which the final result is baked clay in different grades of hardness and purity.

Porcelain. — The composition of European hard porcelain has remained about the same since the 18th century. The ingredients consist of the plastic material, kaolin, and the non-plastic quartz and felspar, which, in the process of working, is used as a diluting element, and in firing, as a cement. The kaolin is principally found in Germany, but always mixed with another soil. It has to be purified by washing. The quartz and felspar must be cleaned. The fragments of iron, in particular, have to be removed, as they are dangerous to the product. By mixing these ingredients the plastic material is obtained. This is made homogeneous by a mechanical method, and it frequently lies unmoved for some months in a special cellar in order to be moulded once again. Then the shaping can begin. It is not usual to shape this fine material by hand, but moulds are used which have been made of plaster after the models fashioned out by artists. The plastic material is pressed into these moulds or poured out in them as a pulp. In the latter case the plaster absorbs so much liquid that a sheath is formed alongside the inside of the mould, out of which the superfluous pulp can be poured. Shaping is followed by drying. After that there is the controlling and the removing of the casting seam and other unevenness. If the object consists of more than one part these are joined together. They are then put in the kiln in sagars or clay boxes so that the heat is more evenly distributed over the piece, and heated to about 950 degrees. The porcelain has then become hard and water-tight but dull. This is therefore followed by glazing. The objects are dipped into a liquid consisting of the same ingredients as the material, but in which felspar and quartz predominate. The objects which have been glazed in this way must then be fired in a heat of 1,370°–1,458°, again in sagars. This heating lasts from 20 to 30 hours, and is followed by a gradual cooling which takes three days. A full kiln never produces everything perfect, the many dangers in the firing—for example all objects shrink about one-sixth of their volume—result in articles being spoiled by exploding, warping, etc.

The porcelain is then ready to be painted with dyes, with which a very lightly fusible glass-powder has been mixed. In order to make these melt together with the glazing and become durable the painted objects are heated in an enamelling-furnace to a heat of 700°–800°. This heat must be reached quickly and the cooling takes place equally rapidly in order to keep the colours bright. The old porcelain bakers painted on the so-called biscuit-ware, *i.e.,* after the first baking and before the glazing, but they could only make use of very few colours at this stage — really only cobalt blue, as most other colours could not endure the heat of the second firing. Modern ceramic technique, however, has considerably extended this process of painting before the glazing. Since Copenhagen's success with it, it has been more generally used and imitated. In these cases the paint is put on the material in a different way, viz., as a liquid with a brush or squirt and then engraved in order to increase the plastic impression of depth. After that the objects are glazed. In a high temperature the colours under the glazing mix with the material, except in the case of cobalt blue, which mixes with the glaze. This process has the technical advantage of making the colours durable, but on the other hand it has a disadvantage in the artistic sense, in that the covering colour reduces the lustre of the porcelain itself by breaking the rays of light which cause the minute crystals in the porcelain to glitter. This is not the case with painting after glazing. Another way of ornamenting, which, however, has the same artistic disadvantage, is to coat with coloured glaze, which is applied in one colour. By adding metals the glazing can be made what is known as "streaming"; or, by choosing a glazing compound, the coefficient of expansion of which is smaller than that of the material, irregular fissures or artificial crackles can be obtained with the cooling.

Grès.—Grès has many qualities in common with porcelain, but it is grey or ash-coloured and not translucent. The material needs less working in order to purify it. As this clay is already fairly hard after being dried in the open air the first firing can be omitted and the ornamenting begun at once. After being painted the objects can be put in the furnace without sagars and may be baked at a temperature of 1,190°. Throwing salt in the furnace causes an evaporation which brings a glaze on the objects. The colour is then ash-like, or, with a higher temperature, red-brown. The modern ceramist, however, prefers a superior kind of grks, which is more carefully washed, has the colour of ivory, and to which kaolin can be added (French grès kaoliné). The painting takes place as with the ordinary grès before the glazing, after which it is baked and is coated with lead glazing. The grbs can also be coated with an engobe-like pulp glaze.

Earthenware. — In England, at the end of the 18th century, this imitation and rival of porcelain was invented. In the course of the 19th century it obtained a prominent place in ceramic production, especially for domestic use. It consists of a plastic clay, freed as much as possible from iron and white-burning, but with which some quartz and felspar are mixed. Sometimes some kaolin also is added. The washing must be done very carefully. The exact shape is obtained by the moulding of the liquefied clay. Both during the first and second firing the objects are placed in sagars. Between the two firings the painting and the glazing take place. The ornamenting can also be done by coating the whole object with a pulp glaze.

Maiolica.—This is the name of a kind of porous pottery which after the drying and firing is coated with a tin glazing, either by immersion or squirting. On this non-transparent coating decoration is painted with dyes consisting of metallic oxides—a work that requires great skill, as retouching is impossible. During the process of baking the colours mix with the glaze. The effect is sometimes improved by coating the colours with a second glaze, this time a transparent lead glaze. So-called lustres can also be obtained by means of metallic reductions.

Pottery. — Pottery is the earliest ceramic production of mankind. For this a slightly calcareous potter's clay is used, which when baked becomes a red or yellow shard that still has to be glazed to render it water-tight. Decoration can be done in different ways—for instance by putting on ornaments of clay in a different colour (bnrbotine ddcor), or by painting them. The whole object can also be coated with another kind of clay and the décor in the original reproduced by scratching away the outer coating. It can also be engraved (*graffite* ddcor). In all these cases a transparent lead glaze is applied. By a combination of the different techniques all kinds of variety are possible and usual.

Historical Survey. — Interest in this fine old handicraft was revived in the period beginning with the Great Exhibition in London in 1851. Museums of industrial art were opened, and applied-art schools followed the lead, by the imitation of old models. Imitation led to a revival and improvement of old techniques and this was fostered by chemical science which in these years grew more and more important. People grew tired of imitation, however, and inspiration was sought elsewhere. It was found in the closer acquaintance with Japanese ceramic art at the Paris exhibition in 1867 and more especially in that of 1878. This inspiration took effect in two directions. First, it showed the possibility of another attitude towards nature and the reproduction of nature, and so pointed out a new way to porcelain; a new way to which Denmark was to lead a few years later. Secondly, it demonstrated the splendid ceramic qualities of the old Japanese grbs. From this originated the new ceramic art of the French. This is the starting point of the history of modern ceramics.

FRANCE

The revival of French ceramic art was initiated by Ernest Chaplet, who was born at Sèvres in 1835 and whose work became world famous 20 years before Jean Carriès, the sculptor, became a ceramist, under the influence of the exhibition of 1878. Chaplet entered the Skvres factory in 1848, and at the exhibition of 1855 he produced work of his own. Afterwards he worked at Laurin's at Bourg la Reine, where he reapplied the old barbotine technique. For it he used very white earth mixed with colour-oxides, which he painted on ordinary potter's earth. The success he had with this at the exhibition of 1878 did not last. In 1875 he became manager of the ceramic factory of Haviland in Paris, which factory he took over in 1885, and in 1887 he went to Choisy-le-Roi, where he lived and worked until his death in 1909. His great merit is the application of "flammés"—colour glazes without real figure ornamentation that cover his grbs and sometimes his porcelain, copper-red, white, violet and blue in all varieties and combinations. First Japanese grbs, and later the monochromatic Chinese porcelains inspired him, but his own work retains an independent quality. His trade mark is the rosary (*chapelet*). By the time that Chaplet reached the high-water mark of his fame Carries had already achieved success. Jean Carriès was born in 1855. As a sculptor, with strong leanings to the decorative, he sought for picturesque effects. Deeply influenced by the charm of the Japanese work exhibited in 1878, he decided to devote himself to ceramic art, and to use grbs as his material. Far from Paris, in St. Amand-en-Puisaye and Montriveau, in the neighbourhood of Nevers, where he found his material, he began to experiment in a furnace of his own, and in the exhibition of 1889 he showed the results which won universal admiration. The Japanese influence is strong, especially in his vases and bowls that are ornamented with streaming glazes. But his work has a character of its own, and he avoids what he considers the too great brightness of the Japanese glazes, and so obtains a better harmony between the colours of the glazes and the clay.

Besides numerous vases and bowls, simple and with no ornamentation other than the glaze, Carriès created a great number of plastic works such as masks, heads, figures of animals, etc., which please not only by their construction, their exquisite colour and beautiful surface, but also by their subtle characterization. His last work was a monumental hall which the Princess de Scey-Montbeliard had made in her hotel in the Avenue St. Martin. But he did not live to see it completed. He was ill when the work began, and on July 1, 1894, he died. His friend, the architect G. Hoentschel, who made china after the same method as Carries, gave a large collection of the latter's work to Paris (Musée du Petit Palais). Another disciple was Paul Jeanneny (1861–1920), who took over Carries' atelier in St. Amand. Neither he nor Hoentschel has done any plastic work. Jeanneny's work is even more closely connected with Japanese ceramics than is the work of the others.

In the meantime Chaplet had started a school, and the most prominent of the artists, who with their master formed the group of "L'Art du Feu," was Auguste Delaherche, who, when Chaplet went to live at Choisy-le-Roi, took over his furnace at Vaugirard in 1887. At first he worked with streaming glazes, and sometimes combined these with designs in relief. But gradually he simplified his methods. In the museum at Sbvres there is an early dish of his with a motif of oak leaves; but his later work is remarkable only for the dull glow of his warm-coloured émails, strong and deep, dark and velvety.' Other disciples of Chaplet are: Adrien Dalpayrat, born at Limoges, who collaborated first with Voisin-Delacroix and later with Mlle. Lesbros. His work can be recognized by the deeply coloured blue, blood-red or yellow opaque glazing, reminiscent of oil painting. Technically his workshop was very highly developed; sometimes he made vases several yards high in blue and red spotted grbs.

Edmond Lachenal was much more under Japanese influence. For ornamentation, especially in his dull green glazed pots, he used naturalistic branches and flowers or blossoms, brought out in relief, and tinged with white or rose red. By giving his works an acid bath he succeeded in making the surface peculiarly velvety

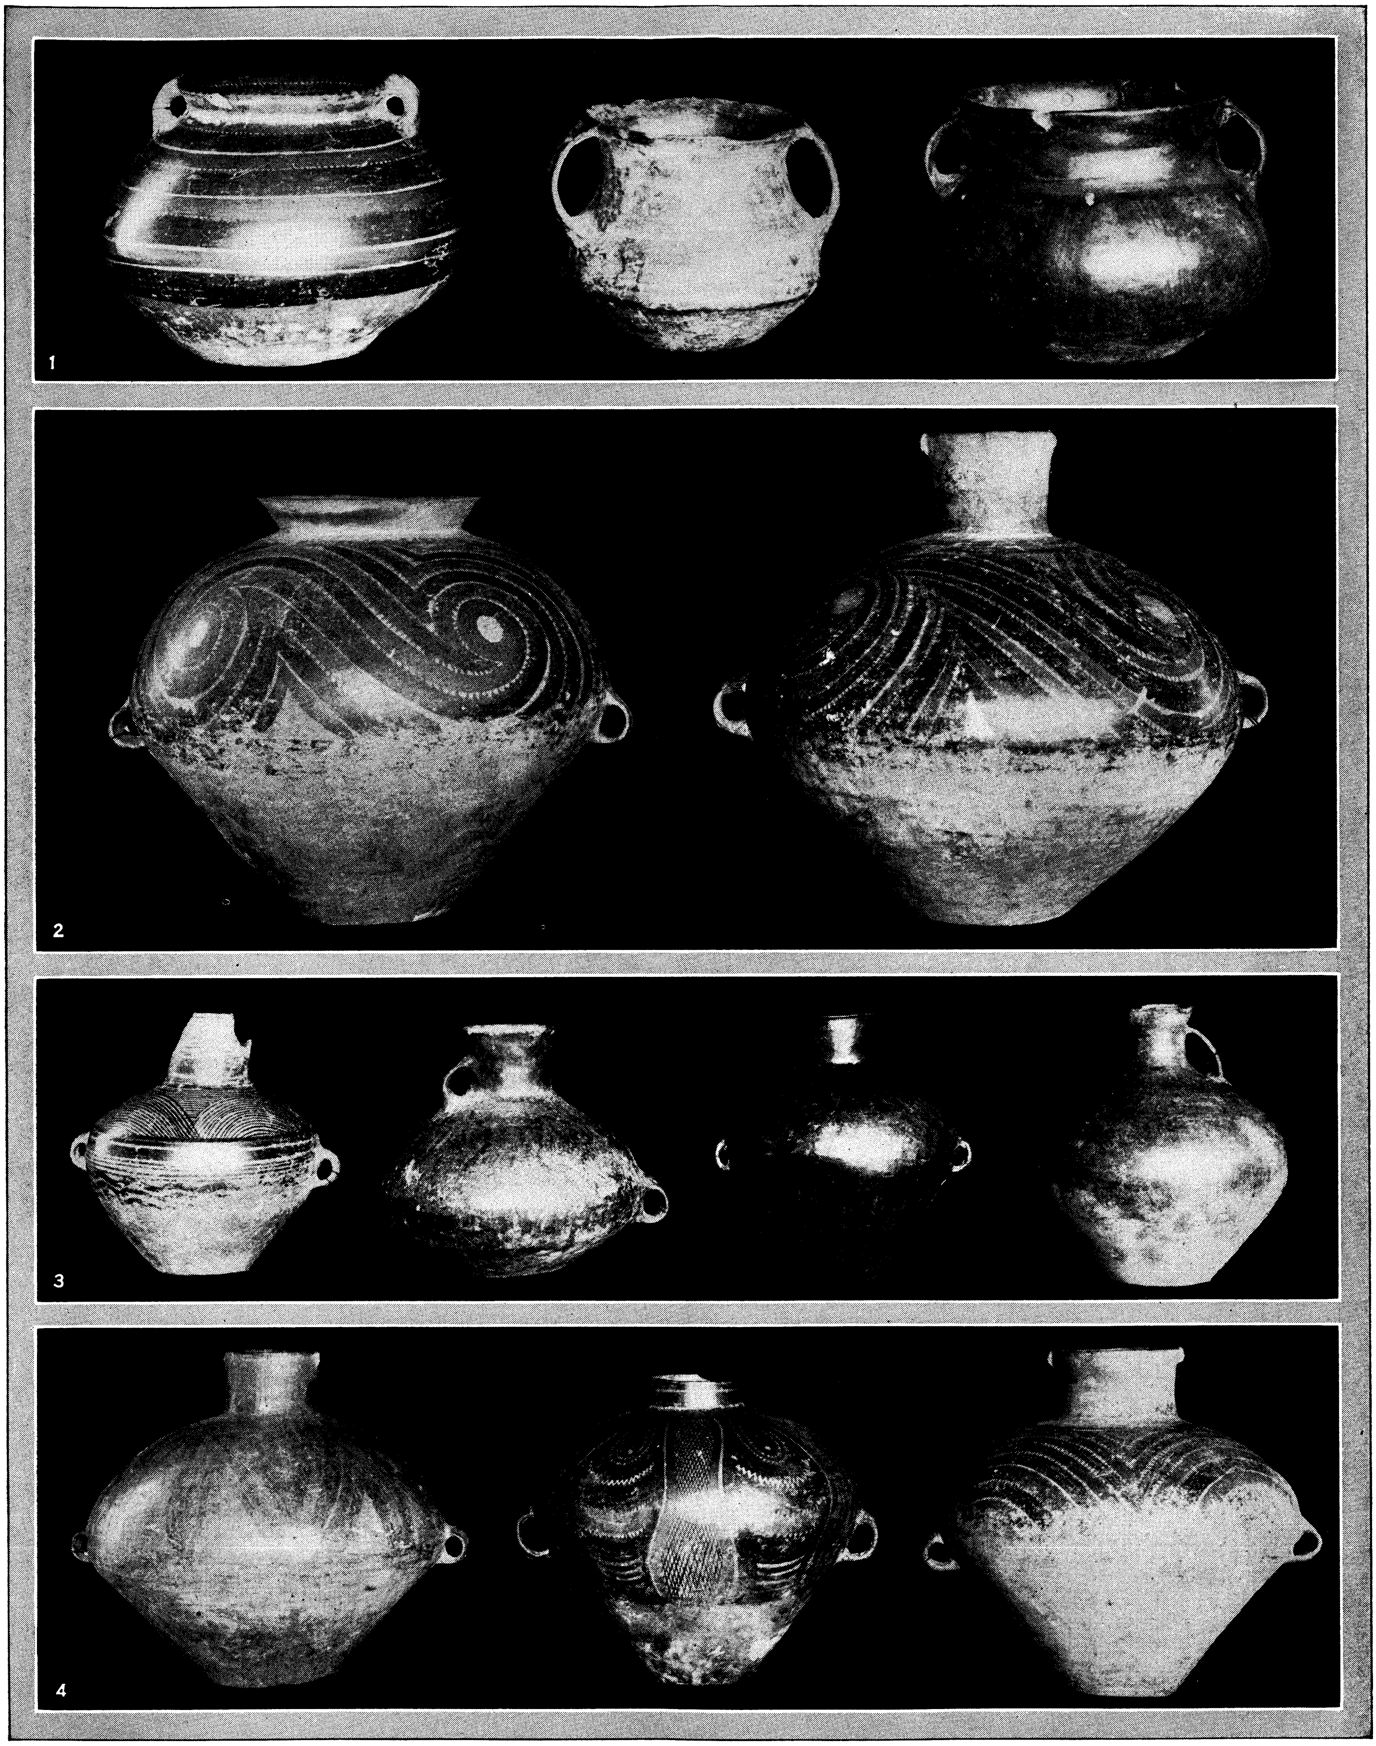
CHINESE EARLY POTTERY SCULPTURE

Top: Pottery horse of the T'ang dynasty (A.D. 618–907) decorated with rare blue glaze and touches of red paint on the saddle. It represents the Bactrian horse, a type introduced into China by the Mongols

Bottom: Pottery dog with puppy, pre-T'ang, an excellent example of vigorous primitive modelling, showing remnants of red and white paint on dark grey biscuit (unglazed surface)



EARLY POTTERY FROM THE PROVINCE OF KANSU, NORTH CHINA

Illustrations of 12 pottery vessels of a very early period (probably 3000 B.C.) discovered in the province of Kansu, North China, by J. G. Andersson, while excavating old sites. The pottery is generally red with black ornaments, clearly of the same family of design as the aeneolithic pottery found on many sites in the Near East

—*émail velouté*. Albert Dammouse considered the material more, and his work at the Sèvres factory has a character entirely its own. For the decorating of his rather simple forms he used plant motifs, and often those of mosses and seaweeds. In so-called *pâte-décor,* the glaze and the pâte material are applied side by bide or one over the other, as in enamel painting. Dammouse avoided bright colours and tried to get dark, deep harmonic tinges. In connection with this the Englishman Taxile Doat might also be mentioned. He worked at the Sèvres factory and produced *pâte-décor* Especially remarkable are his grès articles on the surface of which have been affixed small porcelain insets with heads of animals. Alexandre Bigot, who has carried out designs for Henri van der Velden, and J. C. and M. Cazin (father and son), attained fame with their richly coloured running-glazes. They are inferior, however, to some of the younger artists, who in closer association with Chaplet and Delaherche, raised, with the help of the latter, French grks to a height not reached by the older artists. First among these are Emile Lenoble and Emile Decoeur. Lenoble, Chaplet's son-in-law, not only took over Chaplet's furnaces, but also inherited his preference for grès. But his work is quite different. Except in some of his Japanese-like products with a half coating of brown-black glaze, he specialized in engobes, in which he knew how to produce simple but very strong straight-lined ornaments by erasing. The colours of his engobes are of a blackish brown, grey, deep blue, green, orange-red, and white, and always of a quiet tone that harmonizes with the simplicity of the grey clay material. Decoeur is finer and more complicated with his dim, delicate glazes, occasionally bright, but generally dull, in which colour is more important than with Lenoble. Other ornament is lacking in his work or is reduced to a minimum, such as a few simple lines, a small cufic motif in relief, or a margin of leaves reminiscent of Chinese celadons. His bowls and pots are covered with a soft brown-yellow, a delicate green or blue glaze, usually rather thick and applied in a somewhat streaming manner. For softness of surface, his work equals the very best old Chinese and Japanese wares. Raoul Lachenal, the son of Edmond Lachenal, follows after Decoeur, and sometimes his work is equally good. Henri Simmen does the same, but he often imitates Japanese examples too servilely. Jean Mayodon decorates his work with figures like those on antique and Persian examples; *e.g.,* slender, leaping deer. René Buthaud has another technique—his decoration' is of large flat human figures and a strong relief produced by deep incisions.

Of the artists who work in earthenware André Methey must be particularly mentioned. He is the greatest lover of colour and the greatest decorator, an artist who seeks inspiration not in Chinese or Japanese work, but in the rich ceramic production of ancient Persia whose metallic lustres he tries to equal. He is at his best when he builds up his décors from rhythmical repetition of very simple motifs taken from nature. Etienne Avenard follows his example. Félix Massoul uses in his work much heavier colours, his décor is more geometric and not so delicate as Methey's. Finally, the very simple but always fine forms and décors of Jean Besnard are not without merit.

While French ceramic artists were following new paths and bringing French work into world-wide prominence the development of the porcelain factory at Skvres—the former glory of France—was negligible save in one respect, that of technique. At the Great Exhibition of 1851, Sèvres created a very bad impression. In 1852 Regnault was made director. An improvement resulted, but only in so far as the art director Dieterlé (till 1856) and after him Nicolle tried to make very clever imitations of the 18th century examples, instead of the dull repetition of the old traditions. Under L. Robert who was in charge from 1872 the old post of "directeur des travaux d'art" was reinstituted, and Carrier-Belleuse was appointed to it; new men were engaged, amongst others the young Rodin from 1880-82. But, in spite of these efforts and the experiments of the able and resourceful T. Deck a new ceramic art was not born. After Deck's death in 1891 the factory was reorganized, and in 1896, in anticipation of the Paris Exhibition of 1900, an extensive working scheme was drawn up as the basis for more modern and artistic development.

By a decree of Oct. 1, 1926, greater independence was granted to this factory.

Outside the Sèvres factory the only names worthy of note are those of Taxile Doat who has already been mentioned, and Camille Naudot, who about 1900 did some fine work in porcelain tendre. Haviland, in Limoges, worked at painting-before-glazing and also tried to produce artistic earthenware, but without producing anything special. A group of artists in Glatigny, near Versailles, who called themselves after this place, produced porcelains with streaming glazes reminiscent of grès. Their example was followed by Pillivuyt in Paris. The first to attempt to make artistic stoneware of this kind in France was G. de Feure. In general, however, few good things have been produced. There were several tea and dinner sets at the exhibition of 1925, designed by decorative artists, but they seldom had a cachet of their own. Good work was done by Robert Bonfils, Maurice Dufresne, Suzanne Lalique and, probably the best of all, Marcel Goupy.

GERMANY

In connection with the revival of the German ceramic industry in the 20th century two names may be mentioned here, Th. Schmuz-Baudisz and Max Lauger. Both were attracted to the ceramic industry by knowledge of the so-called peasant pottery. and both learned the industry in its simplest forms from potters in Bavaria or the Black Forest. In this way it was impressed on them that the first thing a ceramist should know is that the shape and decoration of any object must depend very largely on the nature and composition of the material and on the technique of firing.

Max Läuger, who worked at Karlsruhe, decorated his vases and jugs, which were simple in shape and of a deep and even colour, with motifs from nature applied in clay of a different colour. His work resembles the *barbotine décor*. Working for a factory in Kandern he also designed, with the technical expert C. Mayer, architectonically applied earthenware, a great number oi tiles, tile-tableaux, and mural coverings. Later, he worked in maiolica for the Majolica Manufaktur at Rarlsruhe, and produced articles decorated in strong colours. These have greatly influenced younger artists, such as Ludwig Koenig and Georg Schrimpf, who, however, are inclined to an affected naïveté. Th. Schmuz-Baudisz was a painter at Munich, who after 1896 devoted himself to ceramics. He began to shape his objects himself and decorated them with motifs of flora and fauna which he cut out in the engobes that covered his pots. His decorations are much more strongly stylized than those of Lauger. In 1902 he became director of the Staatliche Porzellan Manufaktur at Berlin. The work of Elisabeth Schmidt-Pecht must also be mentioned; it is simple in decoration and form. In the meantime the porcelain factories took some interest in modern work. The Berlin factory, although strongly dependent on the taste of the court, had already, under Dr. Seger, about 1884, made experiments with copper-oxide glazes, and had even obtained good results in red and blue on the so-called flammés and running-glazes. The plastic articles, however, remained of little importance in spite of some successful products by Franz Metzner. But when Schmuz-Baudisz, who had started making domestic porcelain with simple decorations at the factory of Swaine and Company in Hiittensteinach, moved to the factory at Berlin, the example of Copenhagen was soon followed and painting-before-glazing was applied. Of the artists, Adolf Flad and Max Dürschke must be mentioned. Schmuz-Baudisz, who set himself the task of designing landscapes in colour on large porcelain tiles, attempted a difficult technique which was not always justifiable from an artistic point of view. For many years the plastic work at Berlin could not free itself from the influence of the court. Since that time, however, Hermann Hubatsch has made clever statuettes, and in animal pieces Anton Pachegger (1917) and Edmund Otto have done sensitive work. But a great deal has not been accomplished, and in this respect Berlin is just as unimportant as Meissen for the same period, in that, although technically very clever, it produced nothing really important until 1918.

In 1918 Max Adolf Pfeiffer was made director; he brought new life into the factory and made a great improvement especially in plastic work, to which some of the younger artists, for instance E. P. Borner, Max Esser and Paul Scheurich have contributed. More important than Meissen and Berlin in modern ceramics has been Nymphenburg in Bavaria. In 1888 Albert Bauml became director, and he soon attached some young artists to his establishment who, so far as plastic work is concerned, have obtained astonishing results. Jozef Wackerle was especially prominent here. He made beautiful types of peasant pottery, and also humorous groups from 18th century life. He fully mastered the possibilities of porcelain, and made some clever models in maiolica. For some years Wackerle worked at Berlin. Theodor Karner has done animal pieces which are in the first rank; of his disciples W. Neuhäuser must be mentioned.

Among other important factories may be mentioned the Schwarzburger Werkstatten fur Porzellankunst at Unterweissbach, later combined with those at Volkstedt, of which M. A. Pfeiffer was director. He knew how to escape the influence of Copenhagen and sought to produce original work. Jozef Wackerle first worked here and also Ernst Barlach, who with his figures of Russian peasants introduced an entirely new style. Moritz Pfeiffer's table decoration "Hunting scene" also deserves mention. Besides these, good plastic models have been made by Hugo Meisch and by Arthur Storch, while Hans Poelzig has succeeded in making porcelain subservient to modern interior decoration.

Andreas at Leipzig has attempted to make expressionist porcelain pieces, but so far the fine qualities of porcelain have not been adapted to this method of expression. Maiolica offers a better field, and is better adapted to painting. The somewhat affectedly naïve products of L. Koenig and G. Schrimpf have already been mentioned. They work at the Majolica Manufaktur at Karlsruhe, where other younger artists are also engaged. Another and smaller workshop is that of the women ceramists J. Biehler and M. Goossen at Nymphenburg. They have made good reliefs and also free pieces. Two other Munich workers deserve mention, Georg Kemper, who produces miniature pieces, sensitive in form and colour, of *putti* and such like; while Königsbauer attempts a close resemblance to mediaeval forms with his double-surfaced sided jugs of which the outer one is open-worked. Something like this is also found in the maiolica work of Otto Müller who was inspired by Chinese examples, and in the pottery of Kurt Feuerriegel who is more inspired by 16th century models, though both of them, especially the former, produce work with a character of their own. The same can be said of Auguste Papendieck who works independently in the neighbourhoed of Bremen, and who, in her monochrome, slightly glazed vases, aims at great simplicity and pure technique.

Finally some important progressive features can be seen in the cievelopment of stoneware. The domestic pottery of the firm of Villeroy and Boch, who have factories in various places, is frequently meritorious work. In particular their Dresden factory has obtained good results. J. Kühne and Jean Beck design forms and decors. The Wachtersbacher Steingutfabrik at Schlierbach has had as art directors Chr. Neureuther and, after his death, Ed. Schweitzer. Good plastics have been made by Ernst Riegel.

AUSTRIA

During the 19th century there was no artistic ceramic work to speak of in Austria. The revival dates from the first years of the 20th century. Following an exhibition of simple and brightly coloured ceramics at the Viennese Secession in 1902, Bertold Löffler began his attempts to create something new with ordinary red clay, and was joined soon after by Michael Powolny, the most important person in Austrian ceramics. They established a workshop, the Wiener Keramik, where Powolny's pieces of ordinary clay, fired and brightly glazed, were produced. In 1907 there followed the collaboration with the Wiener Werkstatte, where Josef Hoffmann sought and found new possibilities for the entire industrial art. On the ceramic side he was helped by Kolo Moser (d. 1918). The Werkbund exhibition of 1912 showed not only the *putti* and other figures wreathed and surrounded by flowers, but also the ceramics in black and white under-glaze which has become a special Viennese type and has been imitated endlessly. In the same year the Wiener Keramik collaborated with the Gmundener Keramische Werkstätte, where, under the directorship of Franz and Emile Schleisz, peasant pottery developed into an artistic product. An important side of this industry was practised by Powolny, who made work for interior decoration and tiles for stoves at Gmunden. One of the most prolific designers is Otto Prutscher. Meanwhile, Powolny has a number of disciples at the Wiener Kunstgewerbeschule, who work at the Wiener Werkstatte or in small studios of their own. The Wiener Porzellan Manufaktur has come under the influence of the revival in earthenware Multi-coloured decors by Franz Zulow cover its products. In general, however, lively and dainty as the whole of Austrian ceramic production may be, it is always in danger of becoming affected.

HOLLAND

In the 19th century the famous ceramic traditions of the early maiolica and Delft ware, with its cream pâte, had completely disappeared. That which had taste imported from elsewhere flourished. In the last quarter of the century there was a revival. J. Thooft in 1876 bought the last remaining Delft factory, De Porceleyne Fles, and, together with Ad. Lecomte, he applied himself to the revival of Dutch artistic pottery. Unfortunately at first this usually consisted of an imitation of old Delft ware,—blue and, later on, coloured; but shortly after, in 1884 at The Hague, the German ceramist W. Von Gudenberg together with the decorative artist Th. Colenbrander, began to make more original work in the Rozenburg factory. Colenbrander's designs were novel and distinguished, his décors sometimes under Japanese influence, but usually completely his own, were in rich colours and usually had phantasies of plant motifs. There are amongst these bright and slightly too brilliantly glazed pieces of faience hints of futuristic compositions, but they are purer from a decorative point of view. Production of this kind at the Rozenburg factory lasted only until 1889 when Colenbrander left it. It was not revived until 1916, when the vogue was for rather heavy, darkly painted faience. A peculiar product was a kind of very thin pseudo-porcelain, in pale colours, shaped and painted in Jugend style. Japanese influence can be recognized in the ornament. The material, as thin as paper, has not been generally used. Meanwhile the De Porceleyne Fles found two clever artists in L. Senf and E. L. F. Bodart who made various experiments, including dark brown earthenware with running glazes and graffite ornaments, and glass-covered faience with painting inspired by Persian colour and décor. Gold and silver lustre ware has also been successful.

A third tendency became apparent, the influence of the English movement in industrial art inspired by Morris and Crane. On the one hand this was seen in the workshops when first at Amstelhoek and later at Distel an attempt was made to produce beautiful domestic ware with simple materials and old ceramic techniques. On the other hand an independent potter, W. C. Brouwer, turned original shapes on a potter's wheel, which, coated with selfmade glazes, were simple but elegant objects. Very little plastic work was done, but the sculptor J. Mendes Da Costa made very delicate and typical small groups of Jewish women and animals in lead-glazed grbs.

An important figure in the 20th century was C. J. Lanooy, who, as an independent ceramist, imitated the grès flambés of the French, and produced very original and most beautifully coloured pieces. His glazes in which metallic oxides play an important part, are frequently very fortunate discoveries. B. Nienhuys, for a long time a teacher at Hagen, Westphalia, and later at the industrial school at Amsterdam, has a fine feeling for harmonious colouring, and his pots and vases certainly have good and original shapes. Th. Nieuwenhuys and C. Lion Cachet, who as decorative artists occupied themselves with many forms of art, designed faience for the Distel which is deserving of attention. About 1912 Colenbrander, for a short time, made faience covered with dull glazes on which his peculiar decors, principally in blue and brown, were painted. Again, about 1925, in his old age, he designed underglaze décors on the faience of the Arnhem factory Ram. At the same time the factory of Eskaf produced beautiful domestic ware with white streaming glazes, sometimes decorated in black in a

plastic manner, and also miniature plastics, both by H. Krop. At the factory of Z. Holland at Gouda, domestic ware of good shape and colour was made by C. De Lorm. Brouwer still continues his work and also frequently designs ware for interior decoration. Besides those of Senf and Bodart and their disciples the De Porceleyne Fles produces very good tiles, usually in monochrome, but also in fine colours. Generally speaking, Dutch faience—no porcelain or grès is produced—has a distinct character of its own.

(H. E. VAN GE.)

SCANDINAVIA

Interest in ceramics in Scandinavia was renewed with unusual vigour about the end of the 19th century. This movement, particularly in Denmark, may be attributed to Philip Schou, for some time the manager of the Royal Porcelain works. The white underglaze porcelain, introduced at the end of the 19th century by Arnold Krog, by virtue of its plastic qualities and the depth and perspective it can give to a picture, demands decorations taken from nature and everyday life. The decorations and the more severe ornamental lines which in other ceramic art attain such beauty of perfection, are out of place here; but a sentiment from the air, from the water, from bird, animal or plant life, is reproduced by this underglaze porcelain as by nothing else. This school, which is thus of a national character, is bound up with a great development in sculpture, especially of animals portrayed as they are in life, and of figures, which also reproduce Danish atmospheres, whether taken from life or literature, as for example, Hans Andersen's fairy tales. Another type, the fluted porcelain, which in English-speaking countries is called "the blue Danish pattern," is akin to the underglaze porcelain. The pattern originally came irom China, but in course of time has become entirely Danish and has undergone an interesting development. All the models, even the plainest, are the work of the best and most artistic designers and thus the whole set is stamped with a refinement which makes it probably the most popular dinner-service in the world at the present moment.

It is interesting to note that the first great novelty which appeared after underglaze porcelain had made its mark was its direct antithesis—the overglaze. It is interesting also to see how three different artists solved the problem of creating modern overglaze porcelain and its sculpture. Henning, imaginative, artistically great, with a cosmopolitan stimulus, conjures up romance by blending the cultures of East and West in beautiful, rather voluptuous figures; whereas Carl Martin Hansen takes his themes from the almost forgotten national dresses of men, women and children in the various parts of his native country; and A. Malinowski seeks the ideal of his art in white porcelain, only very discreetly and very slightly decorated with a little sepia and gold.

Biscuit, a peculiar material, was at one time, particularly towards the close of the 18th century, admired over the whole world, And then the taste for it died away, probably because the ceramic importance of the material was not sufficiently appreciated. Compare old Sèvres with modern Sèvres, old Wedgwood with modern Wedgwood, and the difference will be seen—and this difference is not due solely to age, for all porcelain changes slightly with age; it is presumably due to the failure to recognize the importance of the question of material. Even when biscuit was introduced in the reproduction of the works of Thorvaldsen, this recognition was lacking, and it was only after more than 20 years of research and experiment that the Royal Porcelain works in Denmark discovered a faintly cream-coloured biscuit—amber against the light—which artists, particularly Malinowski, have endeavoured to mould to their work.

Only three principal colours can be used on underglaze porcelain, blue, green and a reddish tone, and painters have therefore had recourse to overglaze technique where every colour is available, especially gold. However, after numerous experiments with white and grey porcelain, and with stoneware, etc., our artists have found in greyish crackled porcelain a background for painting that inspires them to break new ground. In this porcelain the artist works with vigour, and his decorations possess at the same time a sweetness, a charm, a freshness and a freedom made possible by the employment of this new material, and it is an interesting fact that to attain their effects the artists are not content with crackled porcelain; they wart the crackled large or small, square or round, according to the motifs they have created; and the potter knows how to satisfy these demands. A closer collaboration between technique and art scarcely exists.

Of late years unusual interest has been taken in celadon, that remarkable old Chinese porcelain which was discovered through iron having become mixed in the glaze, the effect being that the glaze became green when the porcelain was baked in a certain way. The material is not easy to work with; it requires its own artistic treatment, its own particular shapes, a very special glazing and a special glaze. The material gives opportunity for line effects, architectural effects and reliefs. Often it assumes a jade-like character and is in the closest harmony with the old Chinese culture.

Almost simultaneously with the renaissance of overglaze technique, work was started upon stoneware, a ceramic material that is between porcelain and faience. Porcelain is a siliceous, translucent material; stoneware is a siliceous, opaque material; faience is a porous material. It is interesting to see the strange and unexpected effects which appear gradually as one studies the material more and more. There are the coloured glazes, the fine surface aptly termed *peau* de *vierge* in France; Jais Nielsen's strong, turquoise-blue glazes, which make one think of the ceramic wonders of Persia and Samarcand, and Kyhn's splendid animals.

From the beginning of the 20th century the Copenhagen Faience works has endeavoured to create a modern style of faience of high artistic merit. It must be remembered that present-day faience is generally different from faiences which delighted the world in mediaeval times. The fine collections of Italian and French and Moorish faience all have tin glazes. These tin glazes are less used in modern faience; for technical reasons potters have turned to a lead glaze or a hydric borate glaze, and attention has principally been devoted to finding an artistic expression for a product of this kind. Here, too, the work is under the glaze where, in contrast to porcelain, one can employ the whole of the colour scale. The designs produced under the leadership of Joachim are gay and lively, rich and glowing, and characteristically Danish. The ground colour resembles that of English faience; but it will not be denied that the artistic treatment of faience in this modem material is much more difficult than tin faience and porcelain, because the glaze is a clearer and lighter glass than the glaze upon porcelain and tin faience, and it has required great trouble to obtain the proper harmony between body, colour and glaze. Joachim has attained great heights with this remarkable faience. The simplicity of decoration and colour, and the definite glaze shades are a constant source of pleasure.

There is in Denmark another very important pottery, Bing and Gröndahl's Porcelain works, which were established in 1853. The same desire which seized Philip Schou to ennoble the material on the basis of Danish artistic culture also animated Harald Bing, who was manager at that time. He engaged the artist, Peitro Krohn, whose finest work is, perhaps, the beautiful heron set, in which he has created something extremely decorative by means of a combination of underglaze and gold. In 1900, at the exhibition in Paris, it entered upon entirely new paths. Later on Bing and Gröndahl attached such artists to their establishment as Kai Nielsen, whose Venus seems to be a symbol of complete harmony between art and material. In 1925, at the exhibition at Paris, Jean Gauguin exhibited a number of works in stoneware with chamotte, in which he proved himself a very gifted artist. By various chemical means, he created peculiar and beautiful works which, in stoneware, may to some extent correspond to biscuit in porcelain. Jean Gauguin's latest works, in faience with tin glaze, demonstrate the fresh and bold imagination of the artist in a sculptural sense.

A beautiful and peculiar art which has arisen in Denmark is the manufacture of earthenware, particularly at Kähler's works at Nastved, where two generations have succeeded in showing novel and interesting results in refined glazed earthenware. The material itself is ordinary clay from the fields near the factory. The work lies in the baking, the painting and the glaze, in which much is done with lustres—the red copper lustres ranking higher, in some ways, than both Clément Massier's from Golfe de Juan and the Hungarian lustres from Fiinfkirchen. The factory has extended the colour range of these lustre glazes and has some grey lustres which, in the hands of the painter Tirslund, have attained the finest effects.

On the island of Bornholm there is a small factory Hjort's pottery. It is, perhaps, not very well known outside of Denmark, but Hjort's stoneware is of excellent quality, even though the output is limited. He turns out small vases and figures with coloured glazes, with a charm characteristic of his own touch. His glazes excel by their great thickness. And finally, we must not neglect to name the artist, Hansen-Jacobsen, who has dreamed of creating ceramic wonders and so often realized his dreams.

Sweden has worked on different lines. Whereas Denmark has, perhaps, devoted herself principally to the free ceramic art, Sweden has had a background for her ceramic development that might well be envied by other countries. Sweden has always possessed a great folk-art which has produced distinguished work, especially in her textile wares, her wood-carving and her iron. and this art has influenced the great factories, such as Gustafsberg, Rorstrand and Gafle, in their production of characteristic dinner-sets which are in the closest possible harmony with Swedish home-life. There is no doubt that this art is very desirable and peculiar to Sweden, and that the highest ceramic ideal lies in raising the artistic level of such dinner-sets, where the scope of the artist is so much more limited than in free art.

Norway, in the two factories, Porsgrund and Egernsund, the one porcelain and the other faience, has repeatedly been on the verge of creating something national and unique, but has unfortunately abandoned it uncompleted.

The factory, "Arabia," in Finland, has attempted to achieve the same end, but stern necessity has doubtless confined its production within the boundaries set by the economic life of the country. (F. Da.)

ENGLAND

English cream-coloured earthenware still retains much of the market it gained by its excellent quality in the latter part of the 18th century, and modern taste has reverted to slight graceful patterns not at all unlike those on Wedgwood's early "Queen's ware." Some noteworthy private decorators have contributed to this. Alfred and Louise Powell have painted some interesting designs on Wedgwood pottery, and latterly on wares of their own making. Dora Billington's fancifully decorated table-wares should also be mentioned here, amongst the work of a small group of people whose efforts, though slight in themselves, are significant as determining the styles eventually adopted by the manufacturers. Standing apart from all other "useful wares" are the charming and original things designed by John and Truda Adams and made by Carter, Stabler and Adams of Poole: a novel and pleasant half-glossy surface and distinctive clean colour are amongst their good qualities.

The decorative styles first inspired, late in the 19th century, by the Chinese *flambé* and other glazes have been continued by (amongst others) W. Moorcroft of Stoke-on-Trent, Doulton's of Burslem, IV. Howson Taylor (Ruskin Pottery, Smethwick), Bernard Moore and Pilkington's of Manchester. The last-named have continued their work in lustre-painting, and in 1928 introduced some very pleasant grey glazes, with effective slight designs in black by Gwladys Rodgers. The later work of the Martin brothers in salt-glazed stoneware showed a praiseworthy advance in simplicity. Doulton's Lambeth stoneware with coloured glazes has been used for statuary by Gilbert Bayes in a manner practised also with success by Mr. and Mrs. Harold Stabler. Perhaps the best and certainly the most promising work in glazed pottery-sculpture has been done by John Skeaping. Interesting figures on a smaller scale, inspired by 18th century china, have been made by Charles Vyse and Gwendolen Parnell.

Amongst the studio-potters, W. Staite Murray's genius has produced much work superficially resembling the early Chinese but highly personal in its low-toned glazes and austerely beautiful forms and decorations. Of equal importance is the fine work in stoneware of Bernard Leach, also inspired by Far Eastern models. The art of Reginald Wells is less simple and direct, stressing colour rather than form, but capable of charming effects. Amongst the other artist-potters, Frances Richards has produced some interesting glazes on stoneware and three other women, Nora Braden, K. Pleydell-Bouverie and Sylvia Fox-Strangways, deserve mention for original work. Mr. Leach and his pupil, Michael Cardew, have revived with success the interesting English slip-ware technique, but high-fired stoneware is likely to be the most fruitful medium in this branch of the potter's art. (W. B. Ho.)

Other Countries.—There has been no important development in ceramics in countries other than those dealt with above. Neither Spain nor Italy has produced more than imitations of the oid Spanish-Mauresque and Italian styles; Czechoslovakia and Switzerland are endeavouring to produce a distinctive native pottery, but with no very remarkable results.

NEAR AND FAR EAST

CHINA

The supreme excellence of Chinese pottery in mediaeval and later times gives an unusual zest to the enquiry into the first phases of Chinese ceramic history; and we welcome the new light recently shed on them by Prof. J. G. Andersson's discoveries in Honan and Kansu which reveal the existence of two distinct kinds of pottery in pre-dynastic times. The Andersson finds have been provisionally divided into six periods; and the earliest and, oddly enough, the most artistic of his pottery can hardly be later in time than 3000 B.C. It consists both of funerary wares and pottery for general use, made by hand (helped perhaps by a slow wheel) of

finely levigated, thin and strongly baked buff and red clays, shaped in pleasing, and often quite imposing, forms and decorated with elegant painted designs in red, black, purple and white clays which have been submitted to the fire of the kiln. This painted ware, which is superior in technique to any of the pre-Han pottery of dynastic times so far known, has interesting, if superficial, resemblances to the painted pottery found at Anau, Susa and other western Asiatic sites of late neolithic date.

Alongside this painted ware Andersson found another type of pottery, a coarser, grey earthenware made without the wheel and often impressed on the exterior with markings which suggest that

PORCELAIN OF THE SUNG PERIOD

1. Vase, Ju type, Sung period (A.D. 960–1279) or Yüan period (1280–1368). Height 7½″
2. Ewer, Ju type, Sung or Yüan period. Diameter 5¾″
3. Bulb-bowl, Lung-ch'üan celadon, Sung period, Diameter 11¼″

JAPANESE POTTERY

1. Square dish designed by Ogata Kenzan, one of the most famous potters of Japan, and painted by his brother, Ogata Korin (*c.* 1657–1716). Given to the Imperial Household Museum by the Dowager Empress Shoken
2. Water jar used in the tea ceremony (*q.v.*), by Nomura Ninsei, one of Japan's greatest ceramists. He worked chiefly at Awata in Kyoto and produced beautiful examples of jewelled faience. 17th century
3. Octagonal bowl by Sakrida Kakiemon, noted for his enamelled porcelain. Height, 13.6 cm. 17th century
4. Teapot used in *Sen-cha,* or steeped tea, by Aokj Mokubei, a celebrated Kiyomizu artist. 17th century
5. Incense case of Iga ware, used in the tea ceremony (*Chan-no-yu*). The incense often consists of small chips of wood or ground-up wood burnt in the charcoal fire which heats the water for making the tea

the wet clay had been wrapped in matting or some coarse textile. This mat-marked pottery evidently had a long life, for it was still made in Chou and Han times.

The next important discovery belongs to the Yin dynasty (1765–1122 B.C.). On the site of the Yin tombs near An-yang in Honan were found pieces of a white pottery, and of carved ivory and bone. The pottery, doubtless made of kaolinic earth, has been carved like the ivory and bone with the conventional designs and angular fret patterns which are usually associated with pre-Han bronzes. Complete vessels of this kind of carved white ware must have had a striking appearance, if indeed the fragments ever formed part of pottery vessels and were not, as has been suggested, moulds for the use of the bronze maker.

HAN WELL-JAR From the George Eumorfopoulos Collection

For the rest all the pre-Han pottery which we know is funeral ware of a rough and not very interesting type, and generally following the fornis of the more precious bronze vessels for which it was doubtless a substitute. It is frequently '.mat-marked," and much of it is roughly coloured with unfired pigments.

The Han Dynasty (206 B.C.–A.D. 220).—The Han pottery, though our knowledge of it is still confined to the funeral wares recovered from tombs, shows a considerable advance in ceramic technique. Many of the Han vessels, such as the wine vases, are of elegant form, and they are ornamented with artistic designs in a variety of ways, by painting with unfired pigments, by stamping. by the appiication of reliefs which have been separately formed in moulds, and by incising.

Glaze is now used, apparently for the first time, a transparent lead glaze of yellowish tone which is coloured green with copper oxide and variegated by the use of liquid clays or slips of different colours. The underlying body of the glazed ware is usually red and this showing through the transparent glaze gives a brown or reddish brown surface, when the glaze has not been coloured green by the use of copper.

Probably this lead glaze was introduced from western Asia, where it was in use in late Roman times; for the Chinese were in touch with the Roman empire in the Han dynasty.

Many of the pottery objects recovered from Han tombs are of deep archaeological interest, for they include, besides the household and ritual vessels, models of the buildings, implements, livestock and even human beings, which had belonged to the household of the deceased. Further it is noteworthy that the potters who supplied this funeral furniture evinced much artistic skill in the way in which they conventionalized their models. Thus the granary tower and the well-head are transformed into picturesque objects and even the model of the kitchen stove is not devoid of ornamental qualities.

PROTO-PORCELAIN VASE (3RD OR 4TH CENTURY)

Han to T'ang (A.D. 220–618).—To the interval between Han and T'ang belongs a considerable group of figures and other beings. Animals are in many ways the most attractive of all the Chinese grave goods. Some of them are little later in date than the Ran dynasty; but they evidently range over a long period, for whole sets of figurines of this class in the Toronto museum are known to have been found in tombs of the Liang dynasty (A.D. 502–557).

There are, besides, wine jars, vases, incense burners and toilet boxes of the 3rd and 4th centuries which are finely painted in unfired pigments with a style and execution not unworthy of the paintings on silk. The Han lead glaze continued in use, and it is by no means easy to differentiate the glazed pottery of the Han and of the immediately succeeding periods. There are, however, certain flask-shaped bottles with green and brown lead glaze over well moulded reliefs which, though certainly post-Han, are probably earlier than the T'ang dynasty. Some of them are remarkable for their Western types of ornament, such as dancing and piping figures, which would be at home in a Herculaneum frieze, surrounded by vine scrolls. Similar designs are seen on late Hellenistic pottery; and this doubtless was the source from which the Chinese potters drew their inspiration.

There is yet another kind of glazed ware which belongs to this interval, and which is apparently of purely Chinese origin. It is a kaolinic stoneware of hard grey body with a high-fired glaze of greenish brown tint. Specimens of this ware analyzed by H. W. Nichols of Chicago were pronounced to be a kind of proto-porcelain. In other words they are believed to contain the elements of porcelain, though in an unperfected state. Dr. M. Nakao holds that the glaze of this ware is a wood-ash glaze evolved from the accidental gloss which often forms on pottery fired to a high temperature in a wood-fed furnace, as in the case of the Early Korean pottery (see p. 369). It is practically certain that this kaolinic pottery with its glaze of feldspar and wood ashes forms a stage in the evolution of true porcelain which we know the Chinese to have discovered by the T'ang dynasty. Indeed it is highly probable that porcelain was evolved from this material at some period in the interval between Han and T'ang. It may be added that the colour of the glaze was probably due to iron impurities in the clay, and that this glaze is the beginning of the celadon green glazes which owe their colour to iron.

The T'ang Dynasty (618–907).—In the great T'ang dynasty the Chinese empire reached its widest expansion, and China was without doubt the greatest and most civilized power in the world. It mas an age of splendour for all the arts, and the potter's art was in no way behind the rest. Oddly enough. Chinese ceramic literature has little to tell us of the T'ang potters. But Chinese ceramic literature is a comparatively modern growth and the secrets of T'ang pottery, only recently laid bare, were known in Europe almost as early as in China.

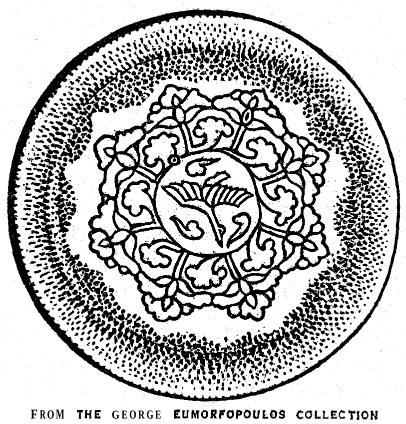
It was in fact largely due to the excavations msde by European railway engineers that the contents of many T'ang tombs came to light, and what we know of T'ang pottery, as in the case of the earlier wares, is practically limited to the sepulchral wares. Naturally these do not show the T'ang potters in the most favourable light, but they enable us to see the great progress which had been made in ceramic technique and to realize the artistic capabilities of T'ang craftsmen. They make it clear too that Western influences were active in China in this enlightened age, for we frequently find the traces of late Hellenistic, Sassanian and Persian art in the forms and designs of the pottery of this period.

FROM THE GEORGE EUMORFOPOULOS COLLECTION

FLASK OF BUFF STONEWARE WITH BROWN GLAZE, T'ANG PERIOD OR EARLIER

Of the T'ang funeral pottery the figures of human beings, birds and animals are modelled in a lively and spirited fashion, especially those of horses and camels, dancing girls and musicians. They are usually of a white or pinkish white clay. soft where lightly fired but some occasionally are baked to considerable hardness. Some of them are unglazed and tricked out with red, black and blue pigments. Others are covered aith a thin transparent lead glaze of faint yellowish tint, while on the more elabsrate this glaze is coloured nith washes, streaks or mottling of green, amber yellow or blue. The flesh parts of the glazed figures are commonly left without glaze, and in this case they are painted with the pigments mentioned above. Besides the figures, vases, ewers, bowls, cups and dishes of various kinds are found in the tombs; and among them are amphora-shaped jars of strikingly Hellenistic form and ewers of Sassanian type with a bird's head below the lip, a form common again in Persian pottery of a slightly later date.

The glazes used on the figures appear also on these vessels. sometimes in monochrome, more often in mottled colours, but they rarely cover the whole exterior of the vessel, stopping as a rule in a wavy line short of the base. The base of the T'ang vase is usually flat and shaved at the edge.

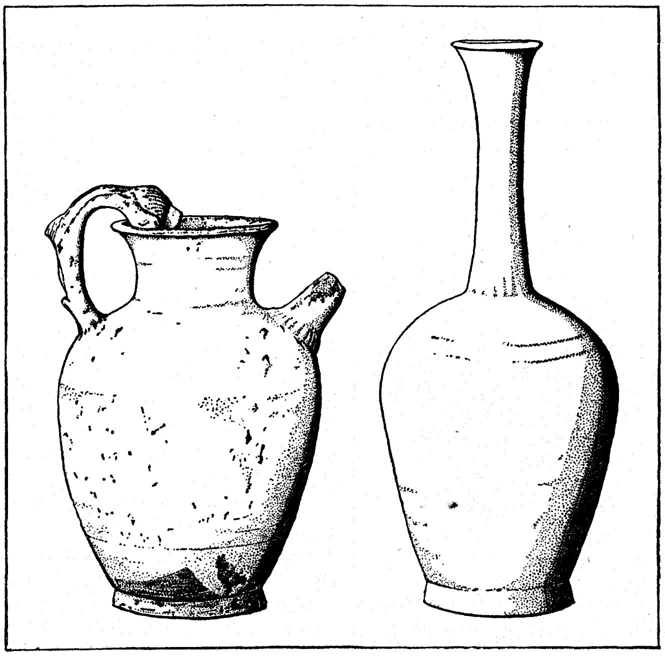


FROM THE GEORGE EUMORFOPOULOS COLLECTION
DISH OF THE T'ANG DYNASTY

The decoration of T'ang pottery is chiefly effected by moulding in relief, by applying reliefs which have been stamped out separately, by carving the surface or by incising it with a pointed instrument.

Painting with a brush was also used not only for the application of pigments on unglazed wares, but in rare instances for decorating in black under a green glaze.

The T'ang pottery so far discussed shows a considerable advance on its predecessors in the use of coloured lead glazes; but it is also apparent that great strides were now made with the harder, feldspathic glazes which were fired at a much higher temperature. The important excavations on the 9th century site of Samarra on the Tigris (*see* F. Sarre, *Die Keramik von Samarra,*



FROM THE GEORGE EUMORFOPOULOS COLLECTION
LEFT. PORCELAIN EWER WITH WHITE GLAZE. T'ANG PERIOD: RIGHT. WHITE PORCELAIN BOTTLE WITH UNGLAZED BASE. T'ANG PERIOD

1925, and also below under Persian pottery) revealed quite a number of fragments of porcellanous stoneware and even true porcelain of Chinese make. From them we gather that these advanced ceramic products were not only made, but had actually become articles of overseas trade in the T'ang dynasty. They include a semi-porcelain with closely crackled, yellowish white glaze or with green and mottled glazes, or again with the sea-green glaze which we distinguish by the name of celadon; besides pure porcelain with white or ivory glaze. Other high-fired T'ang glazes are a chocolate brown, verging on black, a watery green and a brown splashed with frothy grey.

But the progress of the T'ang potter is not to be measured by improved technique alone. The beauty of the vase-forms which he threw on the wheel places him in the front rank of potters, and his incised and moulded ornaments prove him to have been a true ceramic artist.

In the half century which intervened between the T'ang and Sung dynasties ceramic history records the manufacture of two interesting wares, both of which are still a puzzle to the student. One is the celebrated Ch'ai ware which was reputed to have been "thin as paper, resonant as a musical stone and blue as the sky seen between the clouds after rain." This was an imperial ware made for a few years only in the neighbourhood of K'ai-fêng Fu in Honan; and apparently no complete specimen of it remained above ground even in the 16th century. The traditional description of it suggests a kind of porcelain, and modern opinion holds that it probably belonged to the *ying ch'ing* class of ware which will be described presently. But this is only a theory and, it must be added, a theory which is by no means universally accepted.

The other is the *pi sê* (secret colour) ware made at Yueh Chou, the modern Shao-hsing Fu in Chekiang, for the princely house of Chien. It is generally agreed that this was a porcelain or semi-porcelain with grey green glaze of the celadon type.

The Sung Dynasty (960–1279).—The Sung dynasty was another Augustan age of Chinese art, and ceramic writers in after years described the Sung porcelains in reverential terms as the classic wares of China. Collectors treasured them with loving care, so that not a few have survived above the ground and we are not dependent entirely on excavated funeral goods for our estimate of the Sung potter's skill. Something too is recorded of the history of the more noted Sung factories, and slender as is the information given it has enabled the modern student to attempt a reasoned, though not yet assured, classification of the principal types, namely the Ju, Kuan, Ko, Ting, Lung-ch'uan, Chun, Chien and Tz'ŭ Chou, with a few subsidiary wares in addition.

The Imperial Ju ware was made at Ju Chou, near K'ai-fêng Fu in Honan, for a brief period at the beginning of the 12th century; but we gather that it belongs to a type of ware which was made at several potteries, *e.g.,* in the districts of T'ang Têng and Yao on the north of the Yellow river—besides at Ju Chou itself. The Ju Chou ware, however, excelled the rest and doubtless the imperial works were manned by picked Ju Chou potters. The Chinese descriptions of the Imperial Ju ware, which was already extremely scarce in the 16th century, leave us in some doubt as to its exact nature, but the most plausible theory is that it was of the *ying ch'ing* type. The term *ying* ch'ing, which means misty blue or green (the colour word *ch'ing* connoting both blue and green), is applied by the Chinese to-day to a soft-looking, bubbly porcelain glaze, white in colour but with a faint tinge of blue or greenish blue which sometimes develops a definite blue tint.

This tinge of colour has been traced to the presence of a minute quantity of iron in the ware. The *ying* ch'ing porcelain is a relatively low-fired ware and the body has a somewhat granular texture. It varies much in quality, from a coarse material with impure, pearly grey glaze to an exquisite eggshrll porcelain thin and translucent and of a deliciously soft and melting quality. The best specimens are skilfully potted and of elegant shape, and the decoration, if any, is carved in low relief, incised with a fine point or pressed out in moulds. It is surmised that some of the finer *ying ch'ing* porcelain may have been made at the Imperial Ju Chou factory, while the rest comes from the numerous private factories working with more or less skill on the same lines. It must however be understood that the identification of this ware with the famous Ju porcelain is not yet proved.

Another type which is still problematical is the Kuan. The name itself leaves room for various interpretations, and the description of it in Chinese works, like most Chinese descriptions, is full of ambiguities. Kuan means imperial, and Kuan ware may be nothing more than imperial ware of whatever kind. But Chinese writers evidently intended the Kuan wares of the Sung dynasty to be distinctive types. They describe first of all a Kuan ware

made in the neighbourhood of the capital, K'ai-fêng Fu, for a short time before 1127, when the Sung court was driven south of the Yangtze by the Kin Tartars. The ideniification of this northern Kuan is extremely uncertain, though there are reasons for thinking that it had the opalescent, blue-grey type of glaze which was developed to its full on the Chün Chou ware (see p. 364). The southern Kuan, made after 1127 in the precincts of the imperial palace at Hang-chou, whither the Sung court had been transferred, so closely resembled the Ko ware, that many Chinese writers do not attempt to discriminate between the Ko and Kuan.

FROM THE GEORGE EUMORFOPOULOS COLLECTION

TZ'U CHOU VASE, YUAN DYNASTY

A band of lotus scroll with one of foliage below, ornaments this buff grey vase which has a black finish

The Ko ware is described in some detail in Chinese books. It got its name from the elder of two potter brothers Chang who lived in the Lung-ch'üan district in Chekiang in the Southern Sung period, being in fact the ware of the "elder brother" (*ko*). It is evident, however, that the term Ko ware was not confined to any individual's work, but passed into general use as a generic term for a group of wares made over a long period at various places. Like the Hang Chou Kuan, the Sung Ko ware was made of a dark-coloured clay (we are told by one writer that this clay was actually brought from Hang Chou to the Lung-ch'uan district), and for this reason it has a dark brown edge on the unglazed foot-rim and a brown mouth-rim where the glaze is thin enough to allow the body material to show through it. The glaze itself was crackled, sometimes in a wide network of cracks, sometimes in a close pattern of small crackle which was likened to fish roe. The crackle was further emphasized by staining it with red or black. The colours of the Ko glaze are described as *fên* ch'ing, *hui sê*, mi *sê* which may be rendered grey green, ash colour and millet colour or yellowish, and less intelligibly as tan *pai* which was probably something of the *ying ch'ing* colour.

Well accredited specimens in Western collections have a blackish body material which gives the traditional "brown mouth and iron foot," a thick opaque glaze, lustrous and fat, with crackle stained red or black, and of bluish grey, greenish grey or buff grey colours, which tally well with the Chinese descriptions. We read of Ko mare made in the Yuan and even the early Ming periods; and in later times the term Ko glaze was current for all the grey and buff crackled glazes which figure so largely in the Chinese potter's output.

The crackle affected by the Chinese potter from the Sung dynasty onwards was deliberately sought by definite processes and was eventually got under perfect control, so that large or small crackle could be produced at will. It is unlikely that the earlier processes were very reliable, such as the plunging of the ware while still warm into cold water; but the Chinese eventually discovered that the mixing of a certain kind of stone (apparently pegmatite) with the glaze disturbed the relationship of body and glaze sufficiently to ensure crackle, and they learnt to prepare a crackle glaze which was applied in single, double or treble doses according to the size of the crackle desired.

Lung-ch'üan Celadon.—The Lung-ch'uan district in Chekiang, the home of the original Ko ware, had long been noted for a beautiful ware which is familiar to us under the name of celadon.

It is a porcelain or semi-porcelain of greyish white body with a thick translucent glaze varying from greyish and bluish green to sea-green and grass-green.

The most precious of the Lung-ch'iian celadons has a delicate bluish grey or greenish grey glaze over a finely potted porcelain body which is almost white. Such was the ware reputed to have been made by the younger Chang at the village of Liu-t'ien in the Southern Sung period; and collectors distinguish it by the Japanese name kinuta, after a famous vase in shape of a mallet (*kinuta*), which is preserved in a Japanese temple. Nothing could be more subtly beautiful than this soft, misty bluish grey porcelain.

It is not known how far back the industry of Lung-ch'iian dates; but the fragments of celadon found on the 9th century site of Samarra, in Mesopotamia, may well have been made there On the other hsnd we are told that the kilns were transferred to the neighbouring Ch'u-chou at the beginning of the Ming period and that they flourished there till the end of that dynasty. The output must have been large, and it formed from the earliest time an important item of Chinese export trade. Fragments of celadon are found in the ruins of ancient cities all over the Near East, and we know from actual records that celadon was imported into Egypt and carried thence along the Mediterranean coasts as far as Morocco. Fragments too have been found on the coastal sites of East Africa as far south as Zanzibar. India and the East Indies had their share of the trade, and a few pieces of celadon found their way even to western Europe in the middle ages. This justly celebrated ware, the export celadon, was a stoutly built greyish porcelain with a beautiful sea-green glaze of considerable thickness but transparent enough to allow the carved, moulded or incised designs to show through clearly.

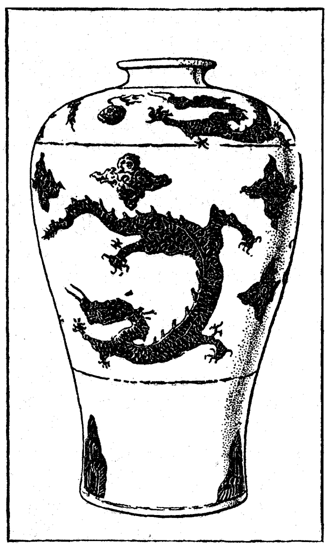
HSÜAN TÊ PORCELAIN STEM-CUP

One of the three crimson red fishes painted on the outside, is shown

Besides the carved and incised designs which are of great beauty, reliefs moulded or applied were effectively used. Sometimes these reliefs—floral medallions, fishes and even figure subjects—were left uncovered by the glaze, and in this case they invariably took on a red or reddish brown colour as a result of exposure to the fire in the kiln.

This browning, caused by the presence of iron in the clay, is in all parts of the ware which were unprotected by the glaze, such as the base-rims and the large unglazed ring which is often seen on the bottoms of dishes. It was thought at one time that the presence of this ring was a sign of Ming origin, but it is very doubtful if this rule holds good; and the distinction between Ming, Yuan and Sung celadons, no easy matter, must depend on an appreciation of style and finish. Much help in this delicate task of connoisseurship can be obtained from a study of the other Sung wares, especially the Ting porcelain (see below) with its carved and engraved floral designs which closely resemble those used on the celadons. In the hands of the Sung artists these designs had a freshness and spontaneity which is dulled by repetition on the Ming wares. A special type of celadon is variegated by patches of reddish brown derived from iron. This is known as "spotted celadon," the *tobi seiji* of the Japanese.



BY COURTESY OF THE BRITISH MUSEUM

PORCELAIN VASE WITH DRAGONS

Other Celadons.—Though the industry in Chekiang is said to have died out in the 17th century, it was not to be expected that such a beautiful glaze as the sea-green celadon would be allowed to disappear. It was in fact made with slight variations in many other pottery centres. At Ching-tê Chên it was used over the white porcelain body for which that place is noted, and the Ching-tê Chên celadons have the ordinary white glaze, and sometimes a reign-mark in blue, on their bases. A celadon glaze was used on the Kwangtung stoneware; and there are many specimens with glaze of celadon type but so different in body from the typical Chekiang ware that we must perforce look to some other centre ior their origin. If we consult the Chinese books we get little help in this quest. It is true that they speak of a certain T'ung ware, made near K'ai-fêng Fu in Honan, as if it were of the celadon class. Rut the identification of the T'ung is quite conjectmal. In the absence of definite indications, we have adopted the term "northern celadon" for one large and important group. It comprises bowls, small dishes, vases, incense burners, etc. with a dry buff grey stoneware body and an olive green celadon glaze. The decoration is carved, incised or moulded, often with much skill and taste; and it closely resembles that of the *ying ch'ing,* or Ju type of porcelain, a fact which suggests a Honan origin for the ware.

This northern origin, however, is not accepted by all authorities. Dr. Nakao, for instance, holds that it is only a variety of the Chekiang celadons, in spite of the very obvious difference between it and the usual Lung-ch'üan types, and he is probably right in supposing that the art of celadon manufacture was introduced into southern Korea from Chekiang, the most accessible Chinese ceramic centre. And it must be admitted that the resemblance between the so-called northern celadon and the Korean (see p. 369) is remarkably close.

A stoneware of celadon type but with a pale and watery glaze was made at Sawankhalok in Siam as early as the 14th century; and in more recent times good celadon wares, scarcely distinguishable from the Lung-ch'iian, have been made in several parts of Japan. And it may be added that the imported celadon wares were freely imitated in Persia and Egypt; but these imitations, made with the soft Near-Eastern pottery, are easily recognizable for what they are.

Ting Ware.—Another of the classic Sung types is the ivory white porcelain made at Ting Chou in southern Chihli. It is a singularly pure and beautiful ware with a flour-white body, slightly translucent, and a glaze of cream or ivory tint, which, however, tends to run in tears or drops on the outside of the bowls and dishes. A peculiarity of the ware, which it shares with the *ying ch'ing,* or Ju type, is that the mouth-rims of bowls and dishes are often unglazed while the base is covered with glaze, thus reversing the usual conditions. The rough rims of such vessels are generally concealed by a band of silver or copper. The Ting ware was exquisitely decorated with carved or incised designs, largely floral, and in some cases, especially in the later periods, the more mechanical method of pressing out the designs in moulds was used with good effect.

Besides the fine ivory white Ting ware there are several varieties. One is known as t'u (earthy) Ting because it has a more opaque and earthy-looking body. This kind has a soft, cream white glaze which is usually covered uith faint crackle. Chinese writers also speak of Ting wares with black, red and brown or purple glazes. The two first are probably glazes of the Honan *temmoku* type (see p. 365); but the purple Ting has so far eluded recognition. There is also mention of a painted Ting ware, which must have resembled the painted stoneware of Tz'ŭ Chou (see p. 365).

The beauty of the white Ting porcelain encouraged, while its simplicity abetted, numerous imitations, some of which are admitted by Chinese writers to be practically indistinguishable from the original. There was, for instance, the Southern Ting, made by Ting Chou potters who moved south with the Sung court in 1127 and who seem to have settled in the neighbourhood of Ching-tê Chên. Then there were the famous imitations made by P'êng Chün-pao at Ho Chou in Shansi; and the Ssŭ Chou and Su Chou wares of Anhwei which were bought for Ting ware in the Sung dynasty "by persons who liked a bargain." There are the white wares of Hsiian Chou, and those made at the "white earth village" near Hsiao Hsien in northern Kiangsu. There were the cream white wares made at Tz'ŭ Chou which were regarded as equal to Ting; and we know of a singularly pleasing stoneware with grey or light buff body covered with a wash of white slip and a beautiful waxen white glaze closely crackled and recalling the finer *t'u* Ting wares. Much of this ware has been excavated on the site of the submerged town of Kuluhsien (destroyed by flood in 1108); and many of the specimens have been made additionally attractive by pinkish grey stains acquired during burial.

The Ting Chou factories themselves, though their fame died down after the Sung period, continued in operation, and Ting ware is mentioned in court records as late as the middle of the 16th century. About this time too a celebrated potter at Ching-tê Chên, Chou Tan-ch'iian, made himself a name by his wonderful imitations of Sung Ting vessels; and we gather that he had many followers who kept up the traditions of his work at Ching-tê Chên long after his death.

Chun Ware.—Yet another celebrated ware was the Chun, which was made at Chun Chou in the K'ai-fêng Fu district of Honan. It was in fact, like the white Ting and the green celadon, one of key wares of the Sung dynasty. According to Dr. Nakao it is the type of ware which would naturally result from the firing of a kaolinic body and feldspathic glaze coloured by copper in the oxidizing flame of the typical round kiln of northern China.

The finer Chün wares have a grey porcellanous body and a thick opalescent glaze full of bubbles and minute pin-holes (caused by the bursting of bubbles), and displaying a wonderful variety of colours which are due in part to the protean changes of copper oxide in an oxidizing flame, in part to a trace of iron which is present in the body material, and in part to the play of light in a highly opalescent glaze. Copper under the conditions prevailing in the Chun Chou kilns was capable of producing a range of colour from blue to blood red, and the Chün glazes display endless combinations of these colours suffusing a basically grey glaze. Thus we have in the extremes an even lavender grey and an almost uniform purplish red, and between these a variety of splashed, streaked and mottled effects of blue, grey, purple and crushed strawberry red. Again the interior of shallow dishes is often frosted over with an opaque, greenish grey; and the Chün glaze is apt to break into irregular V-shaped lines known as earthworm marks, which the Chinese connoisseurs regard as a sign of genuine Sung make. The Chun ware is strong and heavy, and the finer specimens consist mainly of flow-er-pots and shallow bowls which could serve as stands for the flower-pots or alternatively as bulb-bowls. This class of Chun ware has a wash of brown glaze on the base and a ring of "spur" marks formed by the pointed stilts on which the vessel rested in the kiln. It is moreover usually incised with a series number which ranges from one to ten and apparently indicates the size. No. 1 being the largest. An "outsize" is indicated by addition of the character *ta* which means *large.*

It is known that the Chün factories continued active through the Sung and Yuan dynasties and as late as the 16th century. In fact we are not informed when their activity ended. Consequently there is much difficulty in distinguishing the Sung and later Chun wares: and the tendency is to call the finer specimens Sung and the coarser Yüan, too little regard being paid to the fact that much of the ware must be as late as Ming. All that can be said for certain is that the heyday of the Chün factories was in the Sung and that their reputation faded after the Yuan dynasty.

There is a peculiarly beautiful group of wares which belong to the Chün class, and, if fineness is a criterion, also to the Sung period. They have the grey porcellanous body of the numbered Chun wares, and an opalescent glaze which is, however, thinner and smoother than the usual Chün glaze. Its colour is lavender grey, but it is richly suffused, or splashed, with a lovely plum purple and this purple sometimes dominates the whole surface. The glaze flows more or less evenly down to the edge of the base-rims and it usually reappears on a small patch on the base. Sometimes the purple splashes on this ware are symmetrically disposed and even deliberately designed to suggest the forms of fishes, birds, animals or fruits, showing clearly that these patches, though doubtless at first accidental, were later brought under control. To what factory does this group belong? Is it inerely a variety of the Chün Chou ware or is it something else? One of

CHINESE POTTERY AND PORCELAIN, MING DYNASTY (1368–1644)

Upper left: Black rectangular vase bearing Wan Li mark (1573–1619) decorated with enamels. *Upper right:* three-colour vase and bowl with aubergine ground; 16th–17th century. *Centre:* Large deep peach-bloom glazed vase decorated with enamels and bearing Hsüan Tê mark (1426–35). *Lower left:* Three-coiour jar and cover with turquoise ground; 15th century. *Lower right:* Five-colour jar and cover; 16th century the descriptions given of the Northern Kuan ware suggests that it may belong to that obscure category; and some collectors distinguish it as Chün ware of Kuan type.

It is evident that many kilns were at work on the Chün type of ware, and probably in other districts besides Chun Chou, but we have little or no information on this point. We do, however, know that the Chun wares had many imitators. Good copies were made at Ching-tê Chên, probably as early as the Ming dynasty, certainly in the Yung Chêng period of the Ch'ing dynasty (1723–35); but there is little difficulty in distinguishing these later copies which have a white porcelain body and sometimes even a reign-mark. Other imitations made elsewhere can also be detected by variations of the body material and peculiarities of the glaze. Such are the Fatshan Chun ware made at the famous stoneware factories at Shekwan near Fatshan, in Kwangtung (*q.v.*), in Ming and later times; and the Yi-hsing Chüns which were made at Yi-hsing near the Great Lake in Kiangsu, the home of the red stoneware tea-pots. The Yi-hsing imitations have a buff or red stoneware body and a thick opalescent glaze of lavender turquoise colour with or without obviously artificial splashes of purple and crimson. While easily distinguished from the real Chün wares, they are often mistaken for another type which remains to be considered. This is the "soft Chun" (also called *ma chün* by Chinese traders), an attractive ware with light buff body and a beautiful, opaque turquoise or lavender blue glaze closely crackled and suffused here and there with purple or crimson splashes. Where it was made and when are by no means certain; but the shapes of the ware suggest in some cases the Sung and in others the Ming period, and the glaze is of the northern type. A degenerate descendant of this soft Chun is still made at Yu Chou which is the modern name of Chun Chou, and probably this was the original home of the ware.

Chien Wares.—Another large and widely distributed group of stoneware is commonly called, for want of a better general term, by the Japanese name *temmoku.* This name was first given to the black tea bowls for which Chien-an and afterwards Chien-yang, in Fukien, were noted in the Sung dynasty and even earlier. They are made of a blackish stoneware with a thick treacly glaze of purplish black shot with brown lines like hare's fur or mottled with brown like the breast feathers of a partridge. Their glaze stops in a thick irregular welt short of the base outside and forms in a deep pool on the bottom inside. The "hare's-fur or partridge" cups were commonly preferred for use in the tea-testing competitions, as their thick structure made the cup cool to handle and their dark glaze showed up the least trace of the green tea dust. In Japan they have always been fashionable in the tea ceremonies. The Chien glaze owes its colour to iron, which under varying conditions produces a reddish brown as well as a black colour. Indeed the brown and black seem to be always struggling for the mastery in the Chien glaze. Sometimes the brown completely dominates the black: sometimes it only emerges in streaks and spots, and sometimes again these spots are crystalline and have a silvery sheen.

The black ferruginous glaze is by no means confined to the Fukien factories. It was, and still is, made in many parts of China, chiefly in the north; and one of the northern wares which has this black and brown glaze over a whitish stoneware body is known to collectors as Honan *temmoku.* The northern black glazes are often of a peculiarly rich and luscious quality, and sometimes they are boldly flecked with lustrous brown and even painted with sketchy designs of flowers and birds in the same brown. On rare specimens the glaze is strewn more or less regularly with silvery crystals, the "oil spots" so greatly prized by the Japanese; while on others it comes out a uniform reddish brown, the *kaki temmoku* of the Japanese. Another ware which is commonly grouped with the *temmoku* is that believed to have been found on the site of the old Sung potteries at Yung-ho Chên near Ch'i-an Fu, in Kiangsi. In this case the body is a buff stoneware and the glaze is a rather thin blackish brown which flows evenly to the base and is often mottled with golden brown in tortoise-shell fashion or streaked and dappled with frothy grey. A further feature is painted ornament—prunus blossoms and sprays, birds, butterflies, inscribed medallions and symmetrical designs—in dull golden brown in the black or dappled glaze.

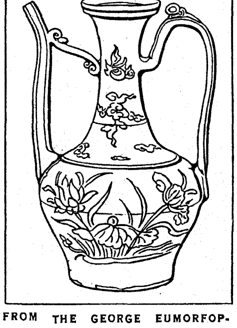
Tz'u Chou.—The last important group of Sung wares takes its name from the great pottery centre Tz'ŭ Chou, once in Honan and now in the south-west corner of Chihli. The Tz'ŭ Chou ware is a grey or buff-grey stoneware, which is usually coated with white slip and covered with creamy glaze. The plain cream white Tz'ii Chou stoneware has been mentioned among the Ting types, but the ware is more usually decorated with painted or incised designs.

The painted designs, floral or otherwise, are laid on with a bold brush in black or brown slip, sometimes supplemented by an ochreous red under the cream glaze. Painting in enamels—green, yellow and red—over the glaze was also used, occasionally in the Sung period and frequently in later times. The incised, or *graj'iato,* Tz'ii Chou ware has many varieties. Simple incised designs are comparatively scarce, the more usual practice being to coat the vessel nith white or brown slip which was then scraped away so as to leave the design slightly relieved in white or brown against a buff-grey body. A coating of transparent cream glaze over this produced cream white design on a mouse grey ground, if the slip was white. Where brown was used the slip usually contained the glazing material and the design appeared in brown or black glaze against an unglazed ground. Both of these *graj'iato* types have great decorative value. The black and brown painted Tz'ii Chou is the commonest type and its merits vary with the quality of the drawing.

The Tz'ŭ Chou potteries have a history which can be traced from the 6th century to the present clay, and there will always be room for debate as to the age of particular specimens. Further, most of the Tz'fi Chou types were made at other potteries scattered over northern China, and doubtless much that we call Tz'ii Chou really belongs to other potteries which worked on similar lines. This will explain variations in the body material of wares of the Tz'fi Chou type, and why a red body, quite unlike the original buff grey, is found on some of the most beautiful members of the group, such as the vases with black painted and *graffiato* designs under transparent green glaze or with black painted designs under a lovely peacock blue.

The potters who made these choice objects must have been among the foremost of their craft, but, though they used the Tz'fi Chou methods, their wares differ fundamentally from what we know as Tz'fi Chou.

Chinese ceramic records name several other Sung potteries in various parts of China, but they are hardly more than names to us and we know little or nothing of their productions. Practically all the Sung wares which we know, however, are comprised in the types already described. The forms, except where they were moulded after those of old bronzes, are simple and elegant, such as come naturally from the hands of a gifted "thrower" on the potter's wheel. The character of the classic Sung wares may be summed up in two words, simplicity and refinement.



FROM THE GEORGE EUMORFOPOULOS COLLECTION
MING EWER (1368–1644); INCISED DECORATION AND TURQUOISE GLAZE

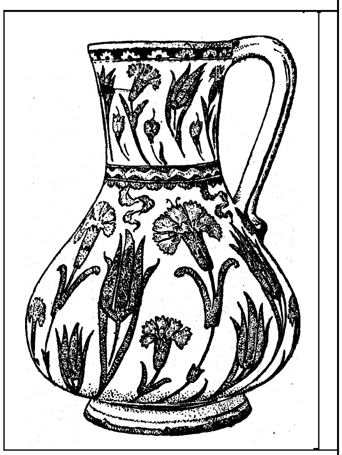
For the purpose of this brief sketch the Yuan dynasty (1280–1368) may be regarded as a continuation of the Sung. The Mongol conquerors had nothing to bring into the stock in trade of the Chinese potter except a taste for certain Western forms and designs acquired in the other extreme of their transcontinental empire. Further we are told that they were hard task-masters and that the ceramic industry, in common with many others, especially the more artistic crafts, lost ground under their unsympathetic rule.

The Ming Dynasty **(1368–1644).**—In 1368 the Yüan was replaced by the native dynasty of the Ming. which ruled China till 1644; and, when the country had recovered from the interdynastic struggles, the ceramic art took a new lease of life, though under somewhat changed conditions. The Sung monochrome wares, the celadons, Chun wares, etc., went out of favour and the old factories sank into obscurity, while the fame and importance of the great porcelain town of Ching-tê Chên, near the Po-yang lake in Kiangsi, overshadowed all the rest. The first Ming emperors had their capital in Nanking and the proximity of Ching-tê Chên to the seat of government doubtless helped its development. At any rate from this time onwards the fine white porcelain of Ching-tê Chên was in general demand and the imperial factory there was rebuilt and reorganized to keep the court supplied with it; and Chinese ceramic writers thenceforward speak of Ching-tê Chên and little else.

The neighbourhood of Ching-tê Chên had long been noted for its excellent ceramic wares. It was ordered to supply goods to the court as early as the 6th century, and it received its present name in the Ching TC period of the Sung dynasty (1004–07). All that the industry required in the way of material was lavishly supplied by the neighbouring hills, kaolin (china clay) for the body of the porcelain and *petuntse* (china stone) to mix with it and to form the glaze, wood ashes to soften the glaze, and cobaltiferous ore of manganese to make the blue for the underglaze painting and the blue glazes. The staple product of Ching-tê Chên is the fine white porcelain which has made China a household word throughout the world; and as this ware lent itself peculiarly well to painted decoration, the vogue for painted porcelain rapidly replaced the old Sung taste for monochromes. They fall into three chief groups, namely blue and white, enamelled wares and three-colour glazed wares, all of which are essentially pictorial in their decoration.

Blue and White.—The beautiful cobalt blue is one of the few ceramic colours which will stand the high temperature required to melt the porcelain glaze, and which consequently can be used under the glaze. Thus the blue colour, painted on the body of the ware and covered with a transparent sheet of glaze, gives a perfectly protected picture which will last as long as the porcelain itself. The idea of painting porcelain in this fashion was not new in the Ming dynasty. It was known to the Sung potters, but it was only in the Ming dynasty that blue and white became fashionable. Nor is the idea necessarily of Chinese origin, for blue painting was certainly known to the Near-Eastem potters as early as the 9th century, and we have as yet no indication of its use in China at so early a date. In the Ming dynasty, however, the Ching-tê Chên potters made it specially their own, and their blue and white was not only supplied in large quantities to the imperial court but was exported all over the eastern hemisphere.

During certain reigns—Hsuan Tê (1426–35), Chêng Tê (1506–21) and Chia Ching (1522–66)—the native supplies of cobalt blue were supplemented by a superior blue imported from the Near East and known as Mohammedan blue. This imported material was scarce and costly and was at first reserved for the imperial factory, and even so it was usually diluted with the common native cobalt. Later on supplies of it found their way into the hands of the private manufacturers. According to Chinese accounts it varied much in tone, but the kind best known to us is the Mohammedan blue of the Chia Ching period which is a dark violet blue of great strength and intensity. In general the Ming blue is painted in one of two ways, either in finely pencilled line drawing or in strongly outlined designs filled in with flat washes. The better class of Ming porcelain, made for imperial and native use, was potted thin and finely shaped; and this is now rare and only to be acquired from Chinese collections. But there is a commoner class which was more strongly and roughly fashioned to meet the exigencies of the export trade, and this has been found in considerable quantities in India, the East Indies, Persia, Egypt and even in Europe. But all the Ming blue and white, whether made for home or foreign consumption, is distinguished by a freshness and freedom of design which make the commonest specimen a desirable possession.



BY COURTESY OF THE BRITISH MUSEUM
TURKISH POTTERY JUG

Another colour used, like the cobalt blue, under the glaze, is a red derived from copper. It was a difficult colour to control but it was used with success in several Ming reigns, notably the Hsuan Te (*see* page 363) and Ch'êng Hua, both as monochrome and in designs painted in the same way as the blue and white.

Ming Enamelled Wares.—Pictorial designs having become fashionable, means were found to paint them on the glaze as well as under it. The chief advantage in on-glaze painting lies in the wider range of colours available. The over-glaze colours, commonly distinguished as enamels, are made of coloured glass ground to powder and liquefied so as to be usable on a brush. They are "fixed" in a small stove, or muffle, at a low temperature which is sufficient to melt the enamel powder and make it adhere to the glaze without actually melting the latter.

The colours used are leaf green and turquoise green derived from copper, a brownish yellow derived from iron, and aubergine purple derived from manganese, besides which a dry black pigment was obtained from manganese and a thin tomato red (halfway between a pigment and an enamel) from iron. The Ming red is apt to become iridescent and lustrous; both it and the black are used for painting outlines, and the latter was sometimes washed on and covered with transparent green to form a composite black. Gilding was also used. With this palette the Ming potters produced richly coloured porcelain, decorated with pictorial designs and formal brocade patterns. In some cases the enamels were combined with underglaze blue and this colour scheme, though known in the 15th century, was so popular in the Wan Li period (1573–1619) that it has come to be known as the wan *li wu ts'ai* or Wan Li polychrome. Another type, known as the "red and green family," is characterized by the absence of blue and the predominance of red and green, and again there are effective combinations of two colours such as red and yellow, blue and yellow, blue and green, red and green, red and gold and more rarely green and gold.

Besides being painted on the glaze the enamel colours were sometimes painted on the biscuit, *i.e.*, the fired but unglazed porcelain body; but this technique was commoner in the succeeding dynasty and will be discussed later.

"Three-colour" Ming Wares.—There are few kinds of ceramic ware, Chinese or otherwise, that make such a brave show as the Ming three-colour (*san ts'ai*) porcelain. Though nominally combinations of three, the glazes which make up the colour scheme of this group are dark violet blue, turquoise, aubergine purple, yellow and a neutral white; and they are used in washes over designs set in single-colour ground'which is usually dark blue or turquoise. To prevent the colours from overrunning each other the designs are outlined by incised lines or by threads of clay, or they are carved in open work. The glazes themselves, though harder than the enamels discussed in the last section. do not require the full heat of the porcelain kiln to melt them, and consequently the ware has to be "biscuited" (subjected to a preliminary firing) and then, when the glazes have been applied, fired again in the cooler parts of the kiln.

They are, in fact, what the French call them, glazes *du demi-grand feu.*

The decoration of the three-colour ware is bold; it includes large floral subjects, lotus and cranes, peonies and peacocks, and a few set figure subjects such as the Eight Immortals paying court to the God of Longevity, Wang Chih watching the game of chess, etc. The details are often built up in slight relief, certain parts such as faces and hands of human figures being left unglazed. The glazes are thick and inclined to be opaque. Much of the three-colour ware dates from the 15th century. In the 16th century the glazes tend to become sleeker, smoother and more transparent, and incised decoration is used

The three-colour decoration was not confined to porcelain. Excellent specimens of it are seen on both stoneware and earthenware bodies. Indeed some of the most beautiful three-colour

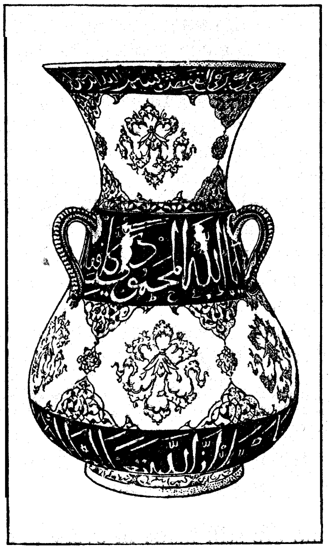
CHINESE VASE

Lang Yao sang-dedoeuf vase of the K'ang Hsi period (1662–1722). Height 17½ inches vases have a buff stoneware body and bold floral designs in minutely crackled glazes which include a peacock blue of peculiarly attractive tone. Where this group of fine pottery was made is not known; but it is found in widely separated parts of China and may have been made in several factories.

Other Ming Wares.—Though monochrome porcelains no longer held the premier position, they were still made in considerable quantity and some of them received special notice from Chinese writers. The sacrificial red (chi hung) of the Hsuan Te and Ch'êng Hua periods, a brilliant underglaze red derived from copper, was most noted; and next came the chi ch'ing, an intense blue glaae of the Hsuan Te period; and a lovely blue glaze of slightly mottled texture is found on some of the Chia Ching porcelains. There were, besides, celadon green, lustrous black and brown glazes; and all the denzi-grand feu glazes of the three-colour porcelains were used individually as monochromes, the turquoise blue being especially effective.



BY COURTESY OF THE BRITISH MUSEUM
LAMP FROM THE MOSQUE OF OMAR

Beautiful, too, are the pure white porcelains (white was the colour required in certain forms of ritual and also by the court during periods of mourning); and special mention is made of the exquisite white "egg-shell" bowls of the reign of Yung Lo (1403–24) and of the white altar cups of the Hsiian Te and Chia Ching periods. If any decoration was added to these white wares it was faintly carved, incised or traced in white slip under the glaze, a subtle form of ornament known as an hua or secret decoration. Another and more conspicuous form of slip decoration is traced in white on blue or green glazes in a manner resembling the modern *pâte* sur *pâte*. Reliefs in white biscuit and remarkably fine open work distinguish some of the later Ming porcelains, the open work being of such superhuman delicacy that it was called kuei kung or devil's work. A quantity of stoneware and earthenware was made all over China in the Ming period. The best known are the tile work and architectural pottery which are often finely modelled: they are usually glazed with green, yellow, aubergine purple, turquoise or blue. On parts of the famous Nanking pagoda, built in the beginning of the 15th century, white porcelain was also employed for the same purpose. Many vases and vessels of everyday use were also made as by-products of the tile works which existed in all large centres of population to supply local needs; but it is hard to distinguish the common pottery of the Ming from that of the earlier and later periods, except where there is a close analogy with some known type of Ming porcelain to help us.

In the early years of the 16th century direct contact was established between Europe and China; and Chinese porcelain, together with silk and tea, soon became an important item of European trade. From this time onwards we note the influence of European taste affecting the Chinese porcelain to a steadily increasing extent.

The **Ch'ing** Dynasty **(1644–1911)**.—The Ch'ing dynasty of the Manchus replaced the Ming in 1644; but it was not till about 1680 that its rule was firmly established over a pacified country. A succession of three able and enlightened emperors—K'ang Hsi (1662–1722), Yung Chêng (1723–35) and Ch'ien Lung (1736–95)—gave China a long period of good rule and the ideal conditions for the development of the arts, which indeed enjoyed at this time an unusual amount of imperial patronage. The imperial porcelain factory at Ching-tê Chên was managed by a series of exceptionally capable directors. Ts'ang Ying-hsüan, appointed in 1682, remained in charge till the end of the K'ang Hsi period. Nien Hsi-yao was appointed by the Emperor Yung Chêng and in 1728 he was given as an assistant the celebrated T'ang Ying, who succeeded him in 1736 and held the post with great distinction till 1749. T'ang Ying left behind him several treatises on the manufacture under his control, and in addition to these we have the letters of the Jesuit father d'Entrecolles which were written from Ching-tê Chên in 1712 and 1722, giving us an intimate picture of the life and industry of the great porcelain centre with its 3,000 furnaces.

The period from 1680 to 1749 must be regarded as the most fertile in the annals of Chinese ceramics. The porcelains of this time are distinguished by fine finish and perfect command of material and technique. They do not, however, differ basically from those of the Ming potters, who had little to learn in the essentials of their craft; and on the whole they suffer by comparison with the Ming in the matter of originality and freshness. The Ch'ing wares indeed are often a trifle stale and mechanical. Still they have enjoyed a long period of popularity in Europe, and their relative weakness has only recently become apparent; for we have only recently made acquaintance with the better types of Ming porcelain.

Ch'ing Blue and White.—Old Nanking is a household phrase in Europe for Chinese blue and white. None the less it is a misnomer, for while much of that ware was transhipped from Nanking, none of it was actually made there. Old Nanking is in fact the blue and white porcelain of Ching-tê Chên and chiefly that made in the K'ang Hsi period and imported into Europe by the Dutch and other East India merchants. It was justly famous, for never was more care expended on the preparation of the ware and the refining of the blue. The best K'ang Hsi blue is pure sapphire, without the tinge of violet or grey so often observable in the Ming blue; and it is usually laid on in graded washes which give it its splendid, vibrating depths. As to the painted designs they are mainly Ming themes, when they are not of the formal arabesque type; but some of them are of outstanding beauty, such as the design of ascending and descending branches of flowering prunus reserved in white in a ground of marbled blue which is netted over with lines suggesting cracked ice.

The prunus blossom falling on the breaking ice is a symbol of returning spring; and this motive is a favourite one for the decoration of the jars in which gifts of fragrant tea and sweetmeats were sent at the new year—a festival which falls in China three to seven weeks later than in our calendar. The vogue of blue and white seems to have died down at the end of the K'ang Hsi period, for after that time the ware in general sank into mediocrity, though exceptions must be made of two types. One is the close imitations of Ming blue and white made in the Yung Chêng period; and the other is the so-called "soft paste" blue and white, a ware prepared with "soapy rock" (hua shih), a kind of pegmatite, and exquisitely painted with the finest brushwork and the purest blue under a soft-looking crackled glaze. Another name given to this porcelain is "steatitic," in the belief that the hua *shih* was soap-stone or steatite. It was an expensive ware and chiefly used for small objects such as snuff bottles and the furniture of the writing table, in which the Chinese *literati* take special delight.

Famille Verte.—This is the name given to the K'ang Hsi porcelain decorated in transparent enamels. These enamels are in the main the same as those used in the Ming period, but there are a few differences. The iron red is a coral rather than a tomato red, the yellow is clearer than the brownish Ming yellow, there are additional shades of green, and the Ming turquoise green is replaced by a beautiful violet blue enamel.

The enamels are either painted over the glaze or are washed over black-outlined designs painted direct on the unglazed porcelain or biscuit. The latter process was not unknown in the Ming period, but most of the existing specimens, though often miscalled Ming, belong to the Ch'ing dynasty. Some of the finest Ch'ing porcelains are enamelled on the biscuit, such as the sumptuous vases with grounds of green-black (*famille noire*), figures and groups.

Not unlike the porcelain enamelled on the biscuit is that decorated with washes of coloured glazes, chiefly green, yellow and aubergine. This is the Ch'ing version of the Ming three-colour ware; but the Ch'ing glazes are sleek and transparent. Sometimes they are laid on in patches making a motley decoration which is known in the trade as "egg and spinach" glaze.

Ch'ing Monochromes.—The Ch'ing monochromes comprise the Ming types, close imitations of the old Sung glazes and many novelties.

Among the best known is the *lang yao* red, which follows the Ming *chi hung* but has a character of its own, varying from bright cherry red and deep ox-blood *(sang de boeuf)* colour to a dappled glaze of crushed strawberry tint. This red is called after a potter family of the name of Lang; and, though imitated in subsequent reigns, it was never so well controlled or so fine in colour as on the K'ang Hsi porcelain. Another success of the K'ang Hsi period was the "peach bloom" glaze. pinkish red in colour but flecked with russet spots and broken by passages of green. Between the peach red and *lang yao* are many shades of maroon and liver colour. Other K'ang Hsi glazes are the mirror-black, the powder-blue and the pale lavender or *clair de lune;* and Chinese writers mention turquoise, eel-skin yellow and snake-skin green as specialties of the period.

We need not dwell on the many other monochromes—whites. celadons, lustrous browns, aubergine purples, violet blues and so forth; but there is a group of composite glazes which requires notice.

They are formed by washes of enamel over a stone-coloured crackled glaze; and they include "apple-green," camellia leaf green, sage green and mustard yellow. Coral red was also used in monochrome, but this and many enamels of the *famille rose* types belong chiefly to the Ch'ien Lung period, as also do the splashed or *flambe' reds* which came at first by accident but which T'ang Ying succeeded in getting under perfect control.

Famille Rose.—In the third decade of the 18th century a revolution took place in the enamelled porcelains. A new palette of colours was introduced, opaque enamels among which rose pinks (derived from gold) are most conspicuous. The Chinese called these new colours *juan ts'ai* (soft colours) or *yang ts'ai* (foreign colours), and we have adopted for them the French name *famille rose.* The *famille rose* displaced the *famille verte,* and it brought with it a new and more effeminate type of decoration with delicate designs executed with a miniature-like refinement. The colours are seen at their best on the Yung Chêng porcelain with a few sprays of flowers thrown artistically across the white surface. The move elaborate ruby-back dishes and table services with crowded figure-subjects and complicated borders are less satisfactory; but these were painted in the Canton enamelling establishments and were destined for the European trade. At Canton. too. were decorated large quantities of Ching-tê Chên porcelain with coats of arms and other European designs directly ordered by the foreign merchants

The *famille verte* enamels, though eclipsed by the *famille* rose, were not entirely suppressed; and they emerged again in a mixed palette of transparent and opaque colours. These mixed enamels were effectively used by a school of painters who worked in the style of one Ku Yueh-hsiian, a maker and decorator of glass in the early years of Ch'ien Lung's reign. Good specimens are rare, for they are prized by Chinese collectors. Other specialities of the Ch'ien Lung period are "lace-work" porcelain with designs deeply incised and forming semi-transparencies; and "rice-grain" porcelain in which the designs are actually cut out of the side of the vessel though allowed to fill up with glaze. A third type, known as *graviafu,* has a covering of opaque *famille rose* enamel which is diapered with incised scroll-work.

The monochromes of the Yung Chêng and Ch'ien Lung periods include those of the K'ang Hsi with numerous additions, some of which have already been mentioned. Great ingenuity was exercised by the Ch'ien Lung potters in the imitation of naturai substances in glaze; the effects of tea dust, iron-rust and bronze are cleverly produced, and enamelled metal, shells, birds' eggs, grained wood, jade, ivory, etc., are copied so closely as to deceive the eye. But these *tours de force* are symptoms of an art which had passed its maturity; and after the 18th century the porcelain has little interest, being mainly of an imitative kind. Exceptions may be made of the Peking medallion bowls, the finer snuff bottles of the Tao Kuang period (1820–50) and some of the imperial porcelains which maintained a high standard of technique. The devastation of Ching-tê Chên during the T'ai-p'ing rebellion in 1853 was a crowning disaster to the ceramic industry of China.

Provincial Porcelains and Pottery.—The bulk of the Ch'ing dynasty porcelains which have reached Europe is of Ching-tê Chên make; but there were many provincial factories which supplied local needs and which also catered for the sea-borne trade to India and the East Indies. These provincial wares are generally of a coarse type; but a shining exception is the white porcelain made at Tê-hua in the province of Fukien. This is the *blanc de Chine* of the old French catalogues, which was freely exported from Amoy in the 17th and 18th centuries, and which served as a model for most of the early European porcelains. It is a beautiful, translucent ware with a soft-looking, melting glaze of milk or cream white, sometimes warmed with a pinkish tinge; and it was chiefly used for ornamental objects such as vases, libation cups, incense burners, figures and groups, less often for table wares. It is decorated, if at all, with slight, applied reliefs, moulded or incised designs, rarely with painted enamels. The TC-hua factories are known to have existed in the last half of the Ming dynasty, and they are still active to-day; and as the character of the ware has changed very little, the dating of specimens will always be difficult.

Immense quantities of earthenware and stoneware have been and are still made in every part of China. We know little of the individual potteries, but there are two centres which must be mentioned. Yi-hsing, on the west side of the Great Lake in Kiangsu, has been noted since the 16th century for a fine stoneware, chiefly red but also buff, grey and of other colours formed by clever blending of the local clays. The red tea ware of Yi-hsing came to Europe with China tea as early as the 17th century. It was classed at that time with the American *buccaro* ware; and it was copied closely by Dutch, English and German potters, notably by Bottger at Dresden and by Dwight and Elers in England. The Yi-hsing tea-pots were cleverly fashioned, often in fanciful shapes, and decorated with reliefs, moulded and incised designs and in some cases with glazes and even enamels.

The second centre lies in the province of Kwangtung, the principal potteries being at Shekwan near Fatshan, a few miles west of Canton. The Shekwan ware is a stoneware verging on porcelain; and the standard type has a thick flocculent glaze of brown mottled with blue and grey and sometimes with vivid red. Glazes of the Sung Chün type and celadon green, as already mentioned, besides *flambé* red were also used; and some of the Shekwan stoneware dates back to the Ming period, though the bulk of it is of comparatively recent date.

The reader is reminded that true Chinese decoration is never meaningless. Its meaning may be directly expressed in semi-religious emblems such as the Eight Buddhist Symbols, the attributes of the Eight Immortals, the Eight Precious Things, etc.; or indirectly by motives which suggest good wishes, such as the peach, crane, tortoise and pine (long life), the bat (hdppiness), the pomegranate (fertility). Again combinations of flowers, animals, etc., can be read rebus-fashion into auspicious phrases; for the Chinese language abounds in homophones and the Chinese delight in puns. They also delight in themes of religious and historical import; and the understanding of their decorative designs involves a deep study of their religion, history and folk-lore.

Numerous marks and seals are used on Chinese pottery and porcelain; but for these again the reader must consult special books. The most important and the most frequent of the marks are the reign-names *(nien hao)* of the emperors; but there are also potters' names, phrases of good omen, symbols and the names of halls and workshops, which it would be futile to enumerate without giving the actual marks and their readings.

KOREA

The geographical position of Korea makes it a natural link between China and Japan. In close contact with China the Koreans were ahsorhing Chinese influences from the Han dynasty onwards; and Chinese graves of the Han period excavated in Korea prove by their contents that the Koreans must have been familiar with the arts of their great western neighbour. But in actual fact the early Korean pottery, though doubtless its essentials were learnt from the Chinese, developed on lines of its own. It is a hard, slate-grey ware, unglazed except for an accidental smear of glossy brown which probably came from the wood ashes in the kiln, and ornamented with large perforations, rather crude reliefs and simple incised patterns. This is the ruling type found in the tombs of the Silla period, which is generally regarded as extending from the 1st to the 10th century, though the Silla state did not actually become paramount till the 7th century. Naturally the Silla pottery varies considerably in such a great space of time, and some of it is potted thin, fired hard and of a neat and almost ornamental appearance.

The Korai Period (918-1392).—But the heyday of Korean ceramics belongs to the succeeding Koryu or Korai period, when the Korean potters suddenly developed a skill which was the admiration of the Chinese themselves. There can be little doubt that this sudden change was wrought either by Chinese refugees or by Koreans who had gone to China to study. For the home of the new industry was in southern Korea, in the Zenra district; and, as Dr. Nakao has pointed out, this district is connected by the most convenient sea route with the coast of Chekiang, the home of the Chinese celadon in the imitation of which the Koreans specialized. The characteristic Korean ware of the Korai period is a porcellanous stoneware with a celadon glaze which at its best resembles blue green ice, but which varies in tone to olive green and brown. A Chinese writer, Hsü Ching, who visited Korea in 1125 compared this ware in one passage with the secret-colour (pi *sê*) ware of Yueh Chou and the contemporary Ju Chou porcelain, and in another passage with the celadon of Lung-ch'üan. The same writer adds that in form and style it resembled Ting Chou porcelain, a statement of which we quickly realize the truth in comparing the etched, engraved and moulded designs in the Korean bowls with those of the ivory white Ting ware Incidentally it may be mentioned here that a white porcelain of Ting type and a bluish white porcelain of *ying ch'ing* type have both been found in Korai tombs; but whether they were, all or some, made in Korea itself or imported from China are questions not yet decided. The finest Korai ware is undoubtedly the blue green celadon made in the best period which may be placed between 1050 and 1170; and it is either plain or delicately decorated with etched or carved designs. Sometimes the glaze is more grass green like the typical Lung-ch'iian celadon or olive green like the so-called northern celadon (see above).

Indeed there are specimens which could hardly be distinguished from this latter ware, were it not for the typical Korean finish of the base which is shallow and covered with glaze and almost always scarred with the marks of the spurs or sand on which the piece was supported in the kiln This rough finish of the base and a tendency to lose shape in the firing are two defects which are apt to mar even the best Korean ware.

It was probably in the last half of the 12th century that a typically Korean method of decorating the celadon ware was first used, namely inlaying the incised designs with black and white clays. Discreetly used this decoration produced a very charming effect; but it was overdone and soon became hackneyed. The easy but mechanical method of stamping the designs instead of drawing them with the stylus was adopted, and a stiff and crowded ornamentation resulted To this inferior class belongs the so-called "Mishima" ware with its radiating cord patterns which recalled to the Japanese the lines of their Mishima almanac.

Other less usual kinds of decoration on the Korai ware are painting in underglaze red, painting in bold, but often rather crude, designs in brown (rarely in white) in the style of the Chinese Tz'ŭ Chou pottery, and blending variously coloured clays so as to make a marbled body. Black- and brown-glazed wares of the "Honan *temmoku*" class are also found in Korea, but, as with the ivory white and ying *ch'ing* types, their native origin remains to be proved By the end of the 13th century the Korai pottery had become definitelv decadent: the beautiful celadon glaze had turned brown and cement-coloured, and the inlaid and brown-painted wares were coarse and clumsy.

The Korai dynasty was followed by the Yi which lasted from 1392 to 1910. The capital was removed from Song-do to Seoul and the name of the kingdom was changed to Chosen. But the country was impoverished by many calamities and the final blow to its prosperity came with the invasion of the Japanese under Hideyoshi at the end of the 16th century. From this time Korea was virtually closed to the outside world and became a veritable hermit kingdom. We know little of the early Yi pottery except so far as it is reflected in Japanese imitations. From these we would infer that it included a rough kind of red or grey pottery with translucent glaze varying from brown to light grey tinged with pink; coarse *mishima*, and brown-painted wares which the Japanese call e-gorai (painted Korean); a creamy buff ware with closely crackled glaze; and grey ware with opaque milk white glaze of thin paint-like appearance which the Japanese call koma-gai. For the rest, specimens of the 17th to 19th century wares in our collections comprise porcellanous stoneware with crackled grey or buff glaze, plain or painted with sketchy designs in dull underglaze blue; and white porcelain painted in underglaze blue and red, with occasional relief decoration and open work.

JAPAN

Japan, like every other country, has its primitive pottery, a rough hand-made material sometimes mat-marked like the primitive Chinese. A more advanced type is found in the dolmen burials which date from the 3rd century B.C. to the 7th AD. The dolmen-builders were invaders from the mainland, doubtless from Korea, and the dolmen pottery closely resembles the Korean wares of the Silla period The development of the potter's art in Japan was slow—perhaps it was retarded by the preference for other materials, such as lacquer, for the articles of every day use—and it seems at first only to have moved forward under the stimulus of foreign influences The first foreign influence was Korean. The next was Chinese, and this must have been felt as early as the 8th century, for the treasure of the Emperor Shomu, preserved at Nara, includes a few specimens of motley glazed pottery of T'ang type. In the 13th century Kato Shirazaemon is said to have gone to China to study the work of the Sung potters, and to have set up kilns in Seto on his return. Reputed specimens of his work are tea jars and tea bowls with thick treacly glazes of black, amber brown, chocolate and yellowish grey colour. This type of pottery took a firm hold in Japan and variations of the Seto glazes were subsequently made in many factories throughout the country. A second and more potent wave of Korean influence flooded Japan after Hideyoshi's campaigns in the 16th century, from which he brought back a large number of Korean captives. It happened too that about the same time the famous aesthete Senno Rikiu organized the tea ceremony, which has played ever since an important part in Japanese social life. The masters of the tea ceremony decided that pottery was the most fitting material for the tea vessels; and the Japanese potters soon learnt from the Koreans how to meet the demand satisfactorily. Hence the numerous imitations of Korean Yi dynasty wares to which allusion was made in the last section. Indeed many of the best known Japanese potteries, such as those of Karatsu, Satsuma, Shigaraki, Takatori and Hagi, owe most of their importance, and also very often their origin, to Korean teachers. From the 16th century onward Japanese pottery developed rapidly and many new and original types were invented, of which the *raku* ware is one of the most important (Plate XLII., fig. 8).

Though the credit for the invention of *raku* ware is given to a Korean family settled in the Kioto district, the ware itself is essentially Japanese. It is a soft, hand-made earthenware, requiring only a slight firing, and covered with a peculiarly waxen, treacly and semi-opaque glaze of various colours of which the black and salmon are the earliest and the yellow, green, cream white and mixed colours later.

Another successful Japanese creation is the antithesis of the *raku* ware. It is a hard reddish brown stoneware unglazed as a rule, except for an accidental smear, and evidently well suited for figure modelling. Its habitat is the province of Bizen, where the industry can be traced back to the 14th century. A fine, hard, buff pottery with closely crackled cream glaze is another Japanese specialty. It is a development of the Korean *koma gai,* or white ware; and it reached its finest expression in Satsuma. Here and at numerous factories in Kyoto it was used as the vehicle for enamelled decoration.

The art of enamelling on porcelain was learnt from China, the story being that Sakaida Kakiemon, an Arita potter, was instructed in it by a Chinese ship's master about the middle of the 17th century. One of the most celebrated Japanese potters, whose art-name is Ninsei, adapted its use to the cream glazed pottery and developed a special style of enamelling in purely Japanese taste. Ogata Kenzan, another of the great Japanese ceramic artists, at the end of the 17th century found a way of using enamelled decoration on the soft *raku* glazes (Plate XXVII., fig. 1). From this time onwards Chinese influence was discounted in the pottery which displays much originality and a true national style.

Japanese Porcelain. — Meanwhile the manufacture of porcelain had started in Japan. Needless to say the technique was learnt from the Chinese, a potter named Gorodayu go Shonzui visiting Ching-tê Chên itself to study in the 15th century. Shonzui's difficulty on his return to Japan was to find suitable raw material and he was forced to work with imported Chinese clays. Not till the beginning of the 17th century did the discovery of the important deposits of porcelain stone on Izumi Yama, in the Arita district of Hizen, permit the establishment of the Japanese porcelain industry on a firm basis. The Arita district was the chief centre of the manufacture; and it was here, at the seaport Imari, that the Dutch traders obtained the "Old Imari" porcelain with which they flooded Europe. Here too Kakiemon practised his new-found art of enamelling, in a style which is for ever associated with his name. The Kakiemon enamels were soft orange red, grass green and lilac blue, supplemented by pale primrose yellow, turquoise green, gilding and occasionally by underglaze blue; and his decorations are slight and in the best Japanese taste. A few blossoms, a floral medallion, a flowering prunus tree, a banded hedge with birds, quails and millet, a tiger and bamboos (Plate XXVII., fig. 3) a dragon and sometimes children are motives of the nicely balanced Kakiemon designs which have been imitated wherever porcelain has been made (Plate XLII., fig. 2). The "Old Imari" of the Dutch importers included another highly specialized but less artistic kind of porcelain. It was painted with masses of heavy impure blue supplemented by red and gold and to a less extent by enamel colours. The designs are irregular and confused, asymmetrical panels enclosed by mixed brocade patterns. Over-loaded, but not without decorative value, they appealed strongly to the Dutch taste.

Many factories were started in the Arita district, those of the princely houses of Hirado and Nabeshima being the most noted; and the industry soon spread to other provinces. It was early established in the Kutani district of the province of Kaga and at a little later period at Seto in Owari, Mino, Kioto and many other places. The Kaga potteries in the 19th century popularized a special kind of decoration in red and gold; but on the whole Japanese painted porcelain follows closely on Chinese lines, and the highest ambition seems to have been to make wares which could be mistaken for Ming porcelain. The Koto factory on the shore of Lake Biwa was noted for its enamelled porcelain in the middle of the 19th century; and good imitations of Chinese celadon were made in the Arita district at an early date and at Sanda and Kioto since the end of the 18th century. In the early 19th century remarkably fine porcelain of "egg-shell" thinness was made at Mikawachi, in Seto, Shiba and Mino.

Since the reopening of Japan to the foreigner in 1868 vast quantities of pottery and porcelain have been made for the Western market. These wares, usually overloaded with ornament, do not represent true Japanese taste, which requires that a piece of pottery be made strictly to serve its useful purpose and decorated soberly in a style appropriate to its form and use.

It is not practicable within the compass of this article to describe the work of individual potters, and the mere mention of famous names, such as Banko, Hozan, Dohachi, Eisen, Rokubei and Zengoro Hozen, cannot serve any useful purpose. The potteries are very numerous, being for the most part small family concerns; and as each had its individual mark or seal and a proper pride in using it, the list of Japanese potter's marks is a formidable one, for which the reader must consult works cited below.

PERSIA AND THE NEAR EAST

The ceramic history of the Near East between late Roman and Islamic times is still obscure. Little Sassanian pottery of any importance has been identified, and the excavations at Constantinople which should tell the Byzantine side of the story have hardly begun. But the continuity of ceramic tradition in these regions is not for a moment in doubt. The most'familiar of all the Persian glazes is the blue-green which appears on late Babylonian, Parthian and late Roman wares; while in Egypt there is no real break in the sequence of potters from early dynastic times to the present day, though the chain of evidence is very weak in the period immediately preceding the coming of Islam.

The "Gabri" Types.—What is reputed to be the earliest type of mediaeval Persian pottery has been called "Gabri" because it was believed to have been made by the pre-Islamic, fire-worshipping (Gabri) peoples. It is an earthenware with a reddish body which is usually concealed by a coating of white slip (liquid clay) and covered with a transparent lead glaze. The commonest form of decoration was effected by cutting or scratching a design through the slip coating so as to expose the red ware below; and by varying the naturally yellowish colour of the glaze by washes of green and purplish brown, derived respectively from copper and manganese. This technique is probably of Byzantine derivation, but it has been used since in every civilized country and at all periods. The Gabri ware, though often crude and bucolic, is attractive for its bold designs and warm colouring, and in the best specimens the rendering of animal forms among floral scrolls (Plate XXXIX., fig. 4) and of ornamental inscriptions is highly artistic. In point of date some of it may go back to the early days of Islam (7th century), but the bulk of it may safely be placed between the 10th and 13th centuries. In Egypt the same technique was largely used on the armorial pottery of the 15th century. Gabri ware has been excavated chiefly in northern Persia, at Zendjan, Rhages and Hamadan; and a kindred ware reputed to come from Amul, south of the Caspian, is distinguished by the additional colours, yellow and ochreous red. A rare type

PERSIAN POTTERY

1. Jug from Sultanabad, 13th century, decorated with metallic lustre and turquoise glaze. Height 7½″
2. Mihrab tile, 13th century, modelled in low relief and decorated with glaze and lustre. Length 12″
3. Dish, Rakka or Rhages, 12th century, incised and deaorated with glaze. Diameter 16¾″
4. Star tile, 13th century. Length 8″

reputed also to be of Amul make has painted designs in white on a background of black slip. A red ware with painting in coloured slips, as well as with incised ornament, has been found in some quantity as far east as Samarkand.

Samarra.—A shining exception to the usual haphazard excavation is the work done by Profs. Sarre and Herzfeld in the ruins of Samarra on the Tigris, a site which was occupied for about 50 years in the 9th century. The finds made here are of the utmost historic importance, and they include a variety of interesting pottery types. One is a thin reddish buff earthenware decorated in low relief with formal designs under a green lead glaze and strongly reminiscent of the lead glazed wares of the late Roman period. Another and more characteristic type is a close-grained, buff pottery with an opaque greyish white glaze which is sometimes painted with a dark cobalt blue, sometimes with lustre pigments of golden brown, green or blood red tones. The blue-painted ware is varied at times with patches of green and manganese brown. The same Samarra body is found with monochrome white, green and yellow glazes, and also with glazes splashed and mottled with green and yellow in the style of the Chinese T'ang wares with or without incised designs. Indeed it is clear that the Samarra potters deliberately set themselves to copy Chinese wares, fragments of which in company with white and celadon porcelain have been found on the site. But the most important of the Samarra fragments are those decorated with lustre.

Lustre painting is perhaps the chief contribution of the Near East to ceramic decoration. When and where it was first used are still debated questions, but one fact at any rate is established by the Samarra finds, namely that the process was fully developed in the 9th century. The lustre is applied in the form of a metallic salt (derived from copper or silver) which is painted on the glazed ware and developed at a low temperature in a special kind of kiln. This process deposits a film of metal on the surface of the ware, in colour golden brown, greenish or red, and when the film is thin enough to allow the light to penetrate it, it glows with beautiful rainbow reflections. The blue-painted and the lustred pottery of the Samarra type have been found at Susa certainly, and, according to report, at Rhages also; and examples of the lustred types have all been found in the waste heaps at Fostat in Egypt.

Rakka Ware.—Extensive pottery remains, including a number of kiln wasters, have been dug up at Rakka, in Syria, a place situated on the Euphrates about 100 m. E. of Aleppo. Rakka is a very ancient site and one which had considerable importance between the 8th and the 14th centuries. It includes ruins of several cities, one of which was the residence for a time of the Caliph Harun Al-Rashid. The pottery found at Rakka is of a type which became general in the Near East after the 10th or 11th century. It has a sandy, white or buff white body, loosely constructed and friable, and it is covered with a clear silicious glaze which became opaque when tinted with certain colours. A bowl of Rakka ware figured in Chatfield Pier's book is said to have a dated inscription of the year 831: it is painted in black under a pale blue glaze. Other Rakka wares are decorated with a characteristic brownish lustre; and some of these may date back to the 10th or 11th century. Others again have designs in bold relief which is lustred, or covered with opaque turquoise or translucent bluish green glaze. But the most characteristic type is painted in black under a pale blue glaze or in blue and black under a clear glare.

Sometimes the glaze is coloured a fine purplish brown with manganese. The blue and black painted ware is common to Syria and Egypt, whence its name Syro-Egyptian, and the bulk of it was made between the 13th and the 15th centuries.

Kiln sites have also been found at Rakka with remains of another kind of ware which appears to belong to the 11th or 12th century. It is white with engraved designs under a clear glaze which is sometimes coloured with dabs of blue. Probably other colours also were used, for specimens of this type reported to come from Rhages have the same features with the addition of green, yellow and manganese purple.

Rhages Ware.—To return to Persia, the ruins of Rhages have long been a happy hunting ground for pottery seekers, and they have produced wares of great variety and of many periods. There is little doubt that Rhages was an important centre of the ceramic industry, though very few waste pieces have been found to indicate the presence of kilns. The city, once the capital of the Djebal, was laid waste by the Mongols in 1220, and, though not completely abandoned till the 17th century, it never recovered from this disaster. The classic period of Persian pottery is from the 12th to the 14th century; and among the fragments found at Rhages are some of the most beautiful Persian wares. They are mostly made of the sandy white material; and the glaze is usually opaque and of a creamy tone, and much of it is finely painted with golden brown lustre with or without touches of blue. Another beautiful type, specially associated with the name of Rhages, is painted in enamel colours heightened by leaf gilding on a cream white or turquoise blue glaze. The Rhages enamels include blue, turquoise, manganese purple, red, green, mixed colours and white, and, with the exception of the blue, they generally have a mat appearance which gives a subdued splendour to the colour scheme. The designs on this Rhages enamelled ware are pencilled with miniature-like fineness recalling to a great extent the beautiful workmanship in the manuscript illuminations of the early 13th century. Indeed it has been thought that the court miniaturists may have assisted at the work. In some cases, especially with the more formal designs, parts of the pattern are built up in relief and these incrustations are jewelled with enamels and gilding.

Again the red, white and gold are effectively used in tracing formal designs on a fine dark blue glaze or on an opaque turquoise glaze which frequently covers moulded reliefs. Enamel colours too are sometimes used on the unglazed water jugs of porous buff earthenware, which are found all over the Near East and which are often decorated with artistic relief ornament.

The ruins of Sultanabad, in Kazvin, have also given us much fine pottery of the classic period, wares painted in lustre with or without blue, decorated in strong relief under blue, turquoise or green glazes, and painted in blue and brown under a clear glaze. The most characteristic Sultanabad type is a variety of the last mentioned, with animals, birds or human figures set in a background of close foliage, outlined in black and washed in with blue. The central motives are frequently speckled with black dots, and parts of the ornament are slightly raised.

The beauty of these specimens is further enhanced by the warm grey tone of the glazed ware in the remaining spaces. Chinese influence is frequently observable in the drawing of the figures, and pure Chinese motives such as the dragon and phoenix also appear. These features indicate a date in the second half of the 13th century after the Mongol conquest. Excavations at Khar have produced pottery of the best Rhages types, and it is probable that many other sites could be found equally productive, for there is no doubt that pottery centres were widely distributed throughout Persia and that Rhages and Sultanabad are only two of many.

Persian Tiles.—One of the most attractive forms of Persian pottery, the beautiful lustred wall tiles, have been found at Rhages Veramin, Koum, Natinz, Meshed and Kashan, and it is reasonable to suppose that such things were manufactured on the spot. But the wall tiles illustrate almost every phase of Persian ceramic art. Some of the earliest have ornamental inscriptions in strong relief and a coating of monochrome glaze, light blue or green. Next came the splendid lustred tiles, cut into star shapes and decorated with a complete design on each, chiefly consisting of ornamental foliage which sometimes encloses animals, birds and even human figures. An inscribed border usually completes the tile, and many of the inscriptions have the added interest of dates in the 13th and 14th centuries. The designs are sometimes painted direct in the lustre pigment, sometimes reserved in a lustred ground: details are etched with a needle point and parts of the design, especially the borders, are often touched with blue and occasionally with turquoise. It was soon discovered by the craftsmen that a slight relief gives additional play to the lustre, and reliefs were freely used, especially on the larger mihrab tiles. In place of lustre we also find traceries of red, white and gold on dark blue or turquoise glaze as on the Rhages wares. Another characteristic Persian mural decoration is in a mosaic composed of glazed pottery sawn in intricate patterns and embedded in mortar. There are fine examples of this work on buildings of the 14th century. Later the same general effect was produced by the easier method of painting the design in coloured glazes leaving the outlines dry to represent mortar.

Before leaving the classic period of Persian pottery mention should be made of the fairy-like effects obtained in the sides of bowls and vases by open work designs into which the glaze has been allowed to run, forming transparencies. This beautiful decoration is seen on white wares which may be as old as the 11th century and on the pottery found at Rhages, Sultanabad and Fostat. It reappears at a later date on the so-called Gombroon ware.

Later Persian Wares.—In the post-classical period, from the 15th century onwards, the fashions in Persian pottery underwent considerable change. Few of the older styles survived, and those which did are barely recognizable. The body of the ware is the same sandy white material; but it is more highly vitrified and quite often it is translucent in the thinner parts, a condition only occasionally noticeable in the early wares. It is in fact a kind of soft porcelain. Chinese influence is very strong in the decoration. Celadon greens and other colours are copied as monochromes or painted with traceries of white slip: the painted designs in blue and black, or in blue alone, under a clear glsze, so closely follow the Ming blue and white that they are often mistaken for it. The Persian potters even marked their wares with imitations of Chinese seals. Survivals of the old Persian types include decoration scratched through a black slip under a pale blue glaze, painting in black under a blue glaze, and lustre ware, but in every case the character of the designs has changed. As to the lustre ware it would perhaps be more correct to describe it as a revival, for we have no examples made during the century which preceded the reign of Shah Abbas (1587–1629). On the revived ware the lustre is greenish or reddish brown in colour and its reflections are generally coppery, but sometimes of a beautiful ruby tint. It is applied over a white, or a vivid blue, glaze, rarely over yellow; and the designs are freely drawn trees and plants, among which the cypress occurs frequently, animals and birds and formal patterns, arabesque scrolls, leaf medallions and cable borders. The old device of reserving the design in a ground of lustre does not seem to have been used. Though this ware is generally known as Shah Abbas lustre, the only published specimen with a date was made in the year 1651 (or 1673 according to the reading), and a jug in the British Museum has a metal mount of about 1700. The ware in fact seems to be a 17th century revival but there is no evidence that it continued beyond that period.

The effective use of pierced ornament filled with transparent glaze on the earlier wares has already been noted. After a long interval it reappears on the white translucent ware of the later periods. The incised patterns are of a simple kind and they are supplemented as a rule with a few sprays or arabesques in blue and black. This singularly light and elegant pottery has been called Gombroon ware, because it was believed to have been shipped from the port of Gombroon; but it was probably made in many places, and the material differs in no respect from the contemporary ware made all over Persia. The few known dated examples are of a rather coarse type and belong to the early years of the 19th century; but the ware was largely made in the 18th and some of it may date back to the 17th century.

The late Persian types are no easier to localize than the earlier. Chardin, who travelled in Persia in the 17th century, tells us that faience in Chinese style was produced all over the country, but that the best came from Shiraz, Meshed, Yezd, Zorende and Kerman. There is an interesting product of Yezd in the Eritish Museum, a kettle-shaped ewer of fine white ware well painted in blue in Chinese style and inscribed "The Work of Mahmûd Mi'mar of Yezd. The decorator of it the poor Zari. 102 j" (=A.D. 1616). Hannover describes a pottery decorated in blue, green and a red similar to that used on the Turkish wares (*see* below), which he believed to be of Kerman make. Kubatcha in the Caucasus is also credited with the manufacture of a ware painted in similar colours or in a greyish blue under a glaze which tends to crackle. A typical specimen of this ware is a dish with a female bust surrounded by floral ornament, while others have rather coarsely painted designs in the style of Chinese blue and white; but all that can be said with certainty is that pottery of this kind has been found in the neighbourhood of Kubatcha. With even less reason a considerable group of post-classical pottery with black designs under a transparent blue glaze, which is inclined to crackle, have been assigned to Kubatcha; but there is little doubt that this type was made in various parts of Persia and certainly at Damascus. Specimens exist with dates around the year 1500.

The later tile work tends to be pictorial, with hawking figures on horseback and the like in slight relief in a ground of landscape and flowers. One of the best examples of the 17th century tile work is in the Victoria and Albert Museum, a large panel made up of many plaques and representing a princess and court ladies in a garden of flowers and cypress trees.

In the middle of the 18th century overglaze enamel painting in the colours of the Chinese *famille* rose came into use on tiles and on ordinary pottery. But the late 18th century and the 19th century Persian wares are in the main coarse versions of older types.

Mention has already been made of the early lustred pottery, the *graffiato* wares, and the blue and black painted wares of Syrian type found in Egypt, and of the continuity of the potters' art there from early dynastic times to the present day. Most of the early Persian and Syrian types were made in Egypt in the neighbourhood of Cairo; and the finds at Fostat are specially rich in lustre wares of all kinds, in pottery painted in black and blue under a clear glaze, and in monochromes which imitate Chinese porcelain.

Turkish and Damascus Wares.—Little is known of the potteries of Asia Minor in the middle ages, but in the 16th century under Ottoman rule they became iamous for a pottery which is unsurpassed for its bold designs and powerful colouring. It is directly descended from Persian wares, but it has decided characteristics of its own which reflect the taste and temperament of the Ottoman peoples. It has the standard Near Eastern body of sandy whitish material, but in all the better specimens this body is dressed with a slip of fine white clay. On this the decoration is painted in black outlines which are filled in with brilliant blue, turquoise, green, and either manganese purple or thick red, under a clear glassy glaze. The colours are laid on with a full brush, and the Turkish designs have a distinctive character. They consist chiefly of sprays of certain flowers such as the narcissus, tulip, carnation, rose, fritillary, etc., naturalistically treated, or of arabesques of feathery leaves; and the dishes have borders of spiral clouds.

The transition from the old Persian types to the full-blown Turkish ware is abrupt; but a link may be found in the pottery of Damascus.

Outside this important city, kiln sites have been found with remains of a pottery of the 14th century Syro-Egyptian type, painted in blue and black under a clear glaze; and there is a vase with lustred decoration on a blue glaze, bearing legend "painted by Yussuf of Damascus" which implies a knowledge of the lustre technique among the Damascenes. Pottery painted in black under a blue glaze has been found in some quantity near Damascus and tiles of the same kind of ware adorn buildings in the city. Some of thcsc have delicate Persian scroll-work suggesting a date not later than the 15th century, while other specimens have the large feathery leaf designs which appear on the Turkish wares. Finally Damascus has been credited with the manufacture of the most refined of the wares of Turkish type, distinguished from the rest by soft colours which include a dull lilac in place of the thick Turkish red, a delicate turquoise blue and sage green, and also by a certain Persian flavour in its arabesque ornaments. It must be admitted, however, that the claims of Damascus to a monopoly of this ware are more than doubtful.

The most outstanding feature of the pure Turkish pottery is a brilliant red colour, made with Armenian bole, which is laid

14TH CENTURY SYRIAN VASE

Syrian vase with typical tapering neck, made of light buff pottery covered with a deep blue glaze and then decorated and refired with metallic lustre. Now in the Victoria and Albert Museum on in palpable relief. Its manufacture must have been widely spread over the Turkish dominions, for the ware is found effectively decorating the walls of mosques and public buildings from Adrianople to Cairo. Important centres of the manufacture were at Constantinople, Nicaea, Broussa and possibly in the island of Rhodes, though the old tradition that the ware came exclusively from Rhodes has been proved erroneous. The dating of the Turkish ware is established by the tiles on various buildings of which the history has been preserved. by a few specimens with European metal mounts and by still rarer pieces with dated inscriptions. From these sources we learn that the best period was in the 16th century, and that the quality of the ware had deteriorated by the last part of the 17th century, when the designs had become coarse and hackneyed and the ware itself dirty and yellowish. A beautiful mosque lamp of the finest Turkish ware in "Damascus" style in the British Museum bears the date 1549. A ware of such individuality could not fail to affect the pottery of other regions, and its influence can be traced on the Persian pottery of the 17th century, and particularly on the kind which is called Kubatcha.

Kutahia in Anatolia was till quite recent times a busy ceramic centre. From the 17th century onwards a pottery of Turkish type was made here, but painted with small patterns—palmettes, scrolls and flowers, scale and leaf diapers, etc.—in lively colours including blue, turquoise, green, yellow and the Turkish red. It is a crisp ware, thinly potted and sometimes engraved with criss-cross patterns in the paste. Dated specimens of the years 1719 and 1787 are known. A much more artistic ware painted in shades of blue has also been attributed to Kutahia; but this attribution rests on the reading of an inscription of a ewer in the Godman collection (Cat. Pl. LV., No. 35) which is given as follows: "This mass cruet commemorates the servant of God, Abraham of Kutahia, Anno Armen: 959" (=A.D. 1510). The date is interesting, but if the reading is correct it still leaves open the question whether the ewer was made at Kutahia or elsewhere.

UNITED STATES

It is difficult to write an accurate comprehensive story of pottery and porcelain in the United States. There are several reasons. First, local history is inadequate. In some parts of the country where the potters did not belong to the group considered socially important, it is almost impossible to trace accurately their activities because they mere seldom mentioned in newspapers or records. In other sections, the potters were among the leaders so that complete records are available. As a result, it is sometimes incorrectly supposed that certain parts of the country had practically no pioneer potters. The second reason is that until the 20th century, ceramic history centred attention on foreign developments. The third reason is that nowhere is terminology clear-cut, due to the fact that pottery began before there were printed records and has continued to spread and develop in many directions ever since so that each new development has been a gradual merging of one phase of expression into another. Such changes often took place simultaneously even in different parts of the same country. Twentieth century commercial practice added to the confusion of terms. Often manufacturers gave to their ware trade names which erroneously suggested classification within groups popularly considered valuable. Because of looseness in terminology, it was usually impossible to determine unquestionably where one classification ended and another began, or to list characteristics which could remain unchallenged as distinguishing qualities of a given group.

Historically, development of pottery and porcelain in the United States was practically a duplication of the progress of ceramic history of the world except that, due to an accumulated ceramic knowledge and new scientific and industrial processes, ceramic development in the United States took place within about 300 years, while the world development had been going on for many centuries. The history of American pottery and porcelain can be divided into three distinct periods. The first comprised pioneer pottery made by individual potters for utilitarian purposes. By gradual change, ceramics became an important industry supplying quantities of inexpensive ware made by mass production methods, and about the middle of the 19th century the decoration and making of pottery and porcelain began as an art.

Pioneer Pottery.—Pioneer pottery resulted from the use of natural local materials made simply and directly into articles needed in the everyday life of the group wherein the potter lived. As a result, the ware had a ruggedness, directness and simplicity which are usually lost as soon as civilization reaches the point where needs are less demanding.

Potteries were operated by three and four generations of the same family The principles and problems of the potter's life were similar to those of a carpenter or blacksmith--only materials and equipment were different. Often the potter was part farmer or tradesman. Usually, the red firing clay was baked at a comparatively low temperature so that the ware was porous and easily broken. Glazes were lead or a mixture of lead, flint and clay. Workshops were fitted with a wheel and a kiln. Near by was a clay pit with a paddle turned by a mule or horse for mixing. In most cases, ware was thrown on the wheel but occasionally it was pressed into or over moulds of fired clay or wood. Often pieces were decorated with quaint designs, mottoes or patriotic inscriptions. The drawing was childlike, the craftsmanship varied.

Decoration was done in various ways. In one method, slip (liquid clay) of a different colour was painted on by means of a brush or slip cup. This was called "slip painting." Sometimes a piece was partially or completely covered by slip and later, when the piece was "leather-hard." the design was scratched through the slip. This method was known as "sgraffito." At other times a design was cut or scratched into the clay without the coating of slip. Such objects as churns, crocks, pitchers, plates and toys were made. The colours were terra-cotta, white, dark brown and yellow, with touches of green and blue. Often the ware was distributed by boat, especially throughout the Ohio and Mississippi valleys as far south as New Orleans. At other times it was sold in local stores or peddled from door to door. Some pieces are valuable historically because important events were recorded and dated. Examples of this ware can be found both in museums and in private collections. One of the best displays is in the Pennsylvania museum in Philadelphia.

The term "pioneer" potter refers more to a point of view or a stage of development than to chronology. During the colonization period, pottery enterprises spread. In each case, the simplest use of local clays made into utensils was the most logical beginning.

By the early 17th century, many pioneer potteries were established, though the exact date and location of the first potter is not known. In 1641, John Pride was working in Salem, Massachusetts. There are indications that potteries were in Jamestown, Virginia, at the time of Captain John Smith and it is known that as early as 1650 several potteries had been established in Virginia. It appears that in 1684, a pottery was functioning in Burlington, New Jersey. Dr. Daniel Coxe of London, once governor of New Jersey, caused the pottery to be built. In eastern Pennsylvania, Germans settled as early as 1735, then spread southward and westward. Beginning about 1750, over 115 potteries were recorded in eastern Pennsylvania alone, making colourful slip-painted and sgraffito ware according to the German tradition. All were small. The Bell pottery of Waynesboro boasted six wheels. It was considered large. Peter Craven, the first of the Jugtown potters in North Carolina, is said to have come from Staffordshire, England, about 1750. From that time to the present date Jugtown potters have supplied the needs of that community. The ware is shaped on the wheel and glazed with simple glazes. The first pottery known west of the Alleghenies was built at Morgantown, West Virginia, by Foulke, about 1784, and continued until 1890. William McFarland went from Kentucky to Losantiville, later called Cincinnati, and many others followed to various parts of Ohio, Indiana, Illinois, Minnesota, Missouri and farther west. The Moravians were established in North Carolina about 1840. They were the same race and religion as the German settlers of Pennsylvania. Their ware was similar. One potter was named Brother Aust. He must have been successful because the authorities of the colonies complained that people came from a radius of 50 to 60mi. to buy. He was ordered to discontinue sales to outsiders "on account of the crowd it draws."

Refinement of Ware.—As communities became more established and there were time and money for more than bare essentials, pottery began to leave the pioneer stage. This took place as a gradual natural growth, affected tremendously by the development of the machine age and greater use of available scientific knowledge. These changes brought about increased refinement of clays, more expert workmanship, higher fire-effecting harder bodies and glazes—mould production, improved machinery and new decorative processes. Thus, generally speaking, one may say that pottery began with pioneer ware—soft, crude and red—and progressed by successive steps through Rockingham ware to a gray stoneware often glazed with salt, and on to white china and porcelain.

During the early part of the 18th century potteries sprang up in many places and great development followed. Two families, headed by John Remmey and William and Peter Crolius, established themselves at "Pot Baker's Hill" or "Potters' Hill," New York city, in 1745. The two families worked and lived as neighbours for several generations. Both families included members influential in public life. Connecticut, the birthplace of the beanpot, led in quantity production of pottery and earthenware from 1771 to 1850. In 1793, Captain John Norton, who had learned his trade in Litchfield, Connecticut, founded a pottery in Bennington, Vermont. It functioned over a century. The ware of this period was glazed in several ways; one was by throwing salt into the fire so it would volatilize and coat the piece with sodium silicate, thus making what is known as "salt glaze ware." In a second method, a stoneware clay was coated with Albany slip, a low-burning red clay. By firing the coated piece to a high temperature, the slip melted into a beautiful brown glaze.

Beginning of White Ware.—Next came interest in a whiter ware. During the last part of the 17th century and throughout the 18th, England, France and Germany were striving to produce ware equal to porcelains from China. In the Bodleian Library at Oxford an old record indicates that "white Chiney Ware" was made at the pottery established by Dr. Daniel Coxe near Burlington, New Jersey. It may have been the first white ware made in the United States. In 1745, William Cookworth, an important potter of England, wrote referring to a "china earth" discovered in Virginia. He said, "I have lately with me the person who hath discovered the china earth. He had samples of the china ware of their making with him, which were, I think, equal to the Asiatic. 'Twas found in the back of Virginia. He has gone for a cargo of it, having bought the whole country from the Indians." Some authorities believe the samples referred to were made in the United States; others think they were made in England from clay imported into England from the United States. In a patent taken out in 1774 by Edward Heylyn and Thomas Frye of the Bow Pottery in England for the making of "china ware" it was stated that the material was "an earth, the product of the Chirokee nation in America, called by the natives 'Unaker'." Samples found at the Wedgewood factory and tested by William Burton proved that "Unaker" was a china clay.

During the 18th century, after Philadelphia had become the social capital of the United States, there was a demand for better ceramic wares to supply the needs of a well-to-do class. With this background, more refined ware began to succeed. In 1765, Josiah Wedgewood was worried because potteries were being established in the American colonies. Referring to the colonial market, he wrote, "We cannot make anything too rich and costly"

For about 100 years, potters tried to make chinaware before they were able to record commercial success. During that time, numerous fortunes were lost. Many of these efforts took place in or near Philadelphia. Alexander Trotter was mentioned in 1808 as a leading manufacturer of Queensware (earthenware). Another Philadelphia potter was Abraham Miller, member of a family of potters, an expert modeller, member of the State senate, and a leading member of the Franklin Institute. In 1824, he exhibited a silver lustre pitcher and a specimen of porcelain. In 1842, he showed decorated plates, vases and ornamental flower pots. By the time he died in 1858, excellent American porcelain was being made, equal in quality to the best produced in England. Around 1850, American potters began to succeed in producing a vitrified earthenware and parian—a hard, unglazed white ware, which required fewer skilled workmen and presented no problems with glaze and cblour. Later, a modified parian appeared as a very thinly cast glazed ware. It was called Belleek. Although small amounts of high grade white ware had been made, it was not until about 1825 that porcelain was manufactured in any quantity. About 1820, William E. Tucker, a member of a Quaker family of educators in Philadelphia, undertook to decorate imported white ware by the overglazed process. Soon he became interested in making his own ware for decorating. The beginnings were crude, but several medals were earned. In 1825, he succeeded in making hard-paste porcelain. Eventually, there were financial struggles and changes in partnerships until, in 1832, Joseph Hemphill joined the firm, bringing financial backing and a great capacity for business. Soon Tucker died and Hemphill imported capable workmen from Europe. As a result, the firm experienced a period of producing excellent ware of expert workmanship and a better quality of design.

Moulds for Quantity Production.— In 1859, the demand for cheaper domestic ware had grown sufficiently to enable potters to establish themselves on a sounder financial basis. Mould making was being carried on as a trade by men who made and sold moulds, though exclusive rights mere not yet practised. Small potteries often purchased their moulds from a mould maker or a defunct potter. Probably no one person contributed as much practical information toward this change in production as William Bloor. In Trenton, New Jersey, from 1854 to 1859, he was associated with James Taylor and Henry Speeler who established the first pottery factory in Trenton in 1852. In 1856, a medal was awarded the firm by the Franklin institute of Philadelphia. In 1859, he went to East Liverpool from whence he had come in 1854. There, in 1860, he manufactured on a commercial scale the first white ware to be made in East Liverpool, Ohio, now one of the great pottery centres of the world. The ware was translucent and well vitrified. Most of it was made in moulds and skilfully decorated with designs painted by expert workmen. This success had a great influence on the production of moderately priced white ware. In 1865 he returned to Trenton, which at that time was America's pottery centre and helped establish the firm which later became the Eutreria pottery where a high quality Belleek china and fine ivory porcelain were made.

In 1870, he went back to East Liverpool where he supplied the potteries with materials from mines he had discovered and owned in New England, Maryland and Missouri. Later, he helped establish the Dresden pottery of which firm he was a member when he died in 1877. In the *Journal of the American Ceramic Society* it is stated of Bloor: "Giving information freely to competitors in Trenton and East Liverpool, the transition from yellow ware to white ware was quickly made under Bloor's tutelage. Americans were ready and able to purchase white ware made on Bloor's formulas and by Bloor's methods. Thus the white dinnerware industry of Trenton and East Liverpool was started by Mr. Bloor."

One pioneer in the manufacture of pottery in Trenton, New Jersey, told how he had travelled over the States of New York, Pennsylvania, Delaware and Ohio, searching for the best place to manufacture pottery. He had chosen Trenton because it mas between the two great markets—New York and Philadelphia—and because the section was healthy, abounding with fine clay and convenient for the collection of other materials by canal or river.

Referring to development during a few years following 1861, he wrote: "If the business increases at the same ratio, Trenton is destined to be the Staffordshire of America and in 50 years hence but little ware will need to be imported." In 1890, Mrs. Benjamin Harrison wished to buy domestic tableware for the White House but could find nothing suitable. It was not until 1918 that Lenox, Incorporated, Trenton, New Jersey, supplied the White House with the first American-made table service

Imported Workmen. — Far-sighted manufacturers often brought skilled workmen from France, England and Germany to improve the quality of their ware. About 1835, Joseph Hemphill of Philadelphia imported experts from Sevres who produced pieces more or less copies of Sevres ware. In 1843, Julius Norton, the third generation of potters at Bennington, Vermont, brought over John Harrison, modeller from Copeland; he brought many of the latest moulds and designs being used in England. About the middle of the 19th century, Charles Csrtlidge and Company of Green Point, New York, brought Josiah Jones from the Staffordshire pottery in England. He was a designer, modeller and ceramist. Soon after his arrival he imported Elijah Tatler, a decorator of great ability. In 1853, the firm sent ware to the International exhibit in New York. It included tea and dinner sets in bone china, as well as earthenware and statuettes, modelled by Jones. There are good specimens of these in the Metropolitan museum and the Pennsylvania museum.

Handicaps. — From the beginning, unfamiliarity with new materials was a definite handicap to the potter. One who had been a master workman in the old country might find himself bankrupt in the new country before he became accustomed to materials. Since there was little scientific ceramic knowledge he had to discover correct materials and proportions by the trial and error method before his funds were depleted. While the problems of new materials were being overcome, and better ware was being developed, a more sophisticated social life was evolving so that the potter had to deal with a public prejudice against American-made ware. Sometimes the cause of the prejudice was due to the fact that American-made ware was more crude, but often people considered it elegant to use imported ware. The European manufacturers encouraged that feeling. At times there was sabotage among the American workmen, sympathetic with the mother country. At other times the markets were temporarily flooded with ware to be sold at a price the local manufacturer could not meet, so that the potter had to go out of business or move to a section where there was less competition.

Toward the end of the 19th century, there were other handicaps. Both in Europe and the United States, emphasis had been placed upon improved techniques for mass production at the expense of sound design. As a result, many pieces were created primarily as demonstration of technical skill with little thought of good design. Eventually there was a reaction, especially in Europe where simpler and better design began to replace the extravagantly ornate. The designers in the United States still clung to the type of design traditional with the designers, who were usually old countrymen. Conservatism and prejudice against ware made in the United States lasted well into the 20th century.

Ceramics Becomes Scientific. — Up to the end of the 19th century, ceramic information had been guarded and handed on from generation to generation. New discoveries were kept secret and experimentation was carried on by rule of thumb. While working on the minerals from 1884 to 1894, Edward Orton, Jr., discovered a dearth of literature concerning the science of ceramics. Being a public spirited, practical man, he succeeded in getting sufficient support for a lam authorizing the establishment of a ceramic department at Ohio State university in Columbus in 1894. It was the first school in the United States for the scientific study of ceramic engineering. Not long after that the New York State College of Ceramics was established at Alfred, New York, with Charles F. Binns as its director. Dr. Binns had had life-long acquaintance with ceramics since his father was a factory superintendent in England and he himself was for some time superintendent in the Royal Porcelain Works at Worcester, England. Soon other States had established similar departments. At these schools scientific methods were developed for compounding efficient bodies and glazes and for solving problrms encountered by the potters. The ceramists turned more and more to the fields of chemistry, physics, geology, mineralogy, microscopy and other sciences to discover what those fields might contribute.

Under the leadership of Edward Orton, Jr., the American Ceramic Society was founded in 1898 to co-ordinate ceramic interests and further progress. Its work was carried on by meetings, by collecting, publishing, and distributing available ceramic information and by encouraging research. Thus ceramic knowledge became accumulative so that early in the 20th century a person successfully completing a four-year ceramic course had the opportunity of a better understanding of the science of ceramics than a master under the old system could have had after working a lifetime.

As trained ceramists were gradually absorbed into the potteries, they greatly influenced production — making better-wearing bodies and glazes and developing cheaper factory methods. However, because emphasis was put on science and technique, at the expense of good design in form, colour and decoration, the country was soon producing ware which was of the best technically but the designs were often copies of European patterns or a conglomeration of patterns produced under a variety of conditions. As a result, the ever-developing taste of the American public continued to be prejudiced in favour of imported ware, but this time for a different reason. It was no longer the quality of the ware or workmanship which was responsible for the prejudice but instead lack of beauty and distinction and the absence of that intangible quality which comes from the hand of a skilled creator but is lost by one who copies — regardless of how accurately the work is done.

Pottery and Porcelain as an Art. — About the middle of the 19th century, European women were interested in doing overglaze decorating. The idea spread to America where it became fashionable for women to go to Europe to study the subject. In 1879, the Cincinnati Pottery Club was formed by a group of women for the purpose of encouraging sound pottery production. They did under- and over-glaze decoration and made porcelain. Much credit is due this pioneer work. In 1891 the National Ceramic Association was founded. Ten thousand women were actively engaged in the United States working at ceramics. Five thousand earned a living doing over-glaze painting. The association was organized in Chicago where there were 1,000 pottery decorators. The object was to advance the art and secure the finest possible exhibition for the World's Fair. In 1892 Mrs. S. S. Frackelton of Milwaukee, Wisconsin, organized the "National League of Mineral Painters." Its aim was to bring into closer relationship the overglaze painters in order to define lines of study and to aid in the development of a national school of ceramic art. At one time the membership became as high as 500 women. They exhibited in many places and took part in international expositions, often winning recognition for exceptional achievement. Later, Mrs. Frackelton did excellent work with salt glaze in an effort to use a humble material as a medium for artistic expression. She received honours at home and abroad. Many of the decorators became interested in creating the forms they were to decorate. Some of those creating the forms continued to expand until a business or profession was established. As a result of the activity of the Cincinnati Pottery Club, the Rookwood pottery developed. The Pewabic pottery was established by Mrs. Stratton in Detroit. Mr. and Mrs. A. Robineau in Syracuse, New York, turned to porcelain, carved decoration, crystalline and other glazes. Also, they were in charge of a ceramic department at the University of Syracuse. Charles F. Binns in his work at the New York State College of Ceramics lent valuable support to the expression of ceramics as an art. Besides helping to organize the science of ceramics, he made excellent stone ware of the quality of the Chinese. He knew factory methods and was an expert craftsman who often explored the historical background of ceramics. Because of his broad interests and high standards, he was an inspiring teacher in the field of ceramic art. Many excellent ceramic artists were trained by him and valuable research was done under his direction.

It was only natural that the increased interest in the art expression of ceramics should result in new scientific developments among the artists and improved design for individual and manufactured ware. To study and further these ends, a section of the American Ceramic Society was organized which was known as the Art Division of the American Ceramic Society. Work of the division is carried on through regular meetings, exhibitions and research reports and other articles published in the *Journal of the American Ceramic Society*. The most important regular exhibition is organized annually at the Syracuse Museum of Fine Art as a Robineau Memorial Ceramic Exhibition. It was started in 1932 by Ann Wetherill Olmstead, director of the museum. Because of Miss Olmstead's work, American potters were invited to send an exhibition to museums in the Scandinavian countries, to England, and to many important museums and galleries of the United States. As a result of various efforts the quality and appearance of mork done by studio potters improved greatly during the first half of the 20th century and the design of ware for reproduction methods is given increasing attention.

After about 150 years of technical, financial and artistic struggle, it is encouraging to find that in 1940, the best of the United States pottery and porcelain is as good in quality and design as any made. Ceramic artists in many parts of the country mork as designers, studio potters and teachers; the number increases steadily and standards constantly improve as the general public learns to understand the beauty of fine ceramics.

Many States have tax-supported ceramic schools. Art schools advocating better designs for industrial use encourage the ceramic department to study mass production possibilities and methods along with the craft of the potter. Pottery work is taken more and more seriously in public schools. The national, State and local governments are sponsoring the making of pottery as an art expression. A U.S. ceramic experiment station is in the Tennessee Valley. *(See* also NORTH AMERICA: *Distribution of Cultures.)*

POTTER'S CLAY: *see* CHINA-CLAY,

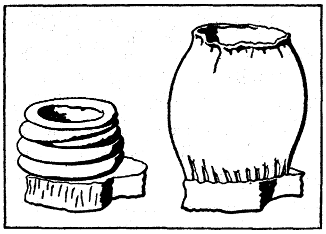
POTTERY, PRIMITIVE. Receptacles of some kind are essential to man, however primitive, and are made of basketry, skins, gourds and other suitable natural objects. But over all these pottery has an advantage, for it can be brought into contact with fire and not be destroyed, and it is therefore valuable for cooking purposes.

Pottery-making is not universal, however; partly because its construction is not easily carried on under certain cultural conditions, *e.g.,* a nomadic life; partly because it depends upon suitable materials being available, though sometimes potters obtain their clay from other districts. It is absent from large regions of America, and in certain islands of the west Pacific has become a lost art. The knowledge of pottery-making was, at one time, believed to mark a stage in the cultural development of mankind, but its presence among such peoples as the Andamanese, Eskimo, Bushmen and Hottentots, and its absence among the advanced Polynesians, make this questionable

The manufacture of pottery falls into five stages: preparing the *body* or raw material; shaping the pot; drying and firing it; decorating it; and varnishing or in some other way rendering it non-porous. This last is often lacking in the pot-making of primitive peoples, but the other four processes are found in the manufacture of the simplest wares.

As regards the raw material, it seems that the clay is frequently dug and seasoned for a while before using. Clays vary very greatly. Those which are highly plastic and hold the water, though convenient for working. are liable through excessive shrinkage to crack in the drying or firing of the pot and must therefore be *opened* by mixing them with non-plastic materials Sand is often used to this end, or carbonaceous materials such as chopped grass, cinders, dried cow or donkey dung; frequently old potsherds are ground up for this purpose. In mixing the *body,* the proportion of clay, *opener* and water necessarily varies greatly and is judged empirically by the potter.

Shaping.—The body having been prepared, the next stage is the shaping. There are three main ways of doing this: by hand, with the aid of a few simple implements; by moulding; and by throwing on the potter's wheel. Of these, the first is by far the most common. There are two hand techniques—modelled and coiled. The simplest way in which a pot is modelled is that used by the women of the Baronga in South Africa. Having kneaded the body into a very soft ball, the woman "makes a hole in it, which she enlarges by degrees, hollowing it out and gradually giving it the shape she wishes. . . . It is astonishing to see the beautiful symmetry of these utensils." (H. Junod, *The Life of a South African Tribe.)* If the pot is to be a big one, the initial lump of clay may not be enough and more is added to build up the walls of the vessel. Frequently the pot is modelled in parts, which are then welded together.



FROM DALE & SMITH, "THE ILA SPEAKING PEOPLE OF NORTHERN RHODESIA" (MACMILLAN)

FIG. 1.—STAGES IN PRIMITIVE POTTERY PRODUCTION

Left, rings of clay piled up. Right, walls completed by scraping the clay upwards

In the coiling technique, the raw material is rolled out into a slender rope which is coiled upon itself (fig. 1).

The coils are carefully worked together with the fingers and the unevennesses smoothed away, so that, when the pot is finished, no trace of them is visible except occasionally in faint ridges on the inner surface. The modelled and coiled techniques may be combined; the base of the pot is modelled from a lump and the coils built up on this.

Certain tribes used baskets for moulds. These were subsequently burned in the firing. A similar method is used by shaping the belly of the pot over a ring of vegetable fibre, then adding the neck and base. In these examples a mould is destroyed with every pot made. More advanced is the method by which one mould is made to serve several times. Among the Hausas of Nigeria, a pot is inverted and over this a sheet of clay is spread so as to form a bell-like dome. This is then removed from the mould and the shoulders and neck modelled by hand (fig. 2). A moulded pot may be made in two or more sections, then joined.

Shaping a pot by means of throwing on the wheel is little known among primitive peoples, because primitive potters can make by hand pots which rival those thrown and because it takes years to learn to throw expertly.

Drying and Firing.—When a pot is finally shaped, it is necessary to render the clay hard by firing it. The material of which a vessel is composed contains a certain amount of free water which can be removed by leaving it to dry or be sun-baked for a time; but it also contains a quantity of combined water which is only liberated at a temperature of from 350°–400° C. If only sun-baked, the vessel when filled with water would absorb this and after a short while collapse into a shapeless mass. But when the combined water has been liberated the clay is completely decomposed; it is impossible for it to become malleable again and it will hold water safely. Except, therefore, for certain pots which are destined only to contain grain and other dry goods, all vessels must be fired.

After being shaped the pot is set aside to dry for some hours, usually where there is a free current of air. Except in a few cases, ware is fired but once. Usually the firing is done in the open. The pyre is carefully built and the pots stacked so that the heat may circulate freely. A genuine kiln has only been recorded from the region of the Lower Congo. It seems to be a beehive shaped structure. The more common primitive practice is to bake the ware in a hole in the ground. The "oven" is fairly elaborate, for charcoal is used andopenings are therefore cut through the soil to the chamber that bellows may be employed to sustain the

necessary heat. The time taken for firing varies greatly, from about half-an-hour to two days. Pots which have been fired for only a short time are less durable than others. There is great diversity of shapes and an amazing similarity in wares widely separated from each other in time and space. Some elaborate forms have a utilitarian purpose, others a religious significance, while others appear to be the outcome of the artist's desire to create something beautiful. In many cases, the pots are modelled in imitation of natural or manufactured objects, which before the introduction of ceramics served the people as vessels.

Decoration and Colour.—In most primitive pottery decoration is done by means of incised lines, made with a pointed stick, thumbnail or coil of rope. Sometimes wooden stamps are used or the "beater" with the aid of which the pot is modelled is carved or wrapped about with string and the designs may be but the marks thus left on the surface. Where pots are moulded over baskets, the clay will be decorated by the impress of these. The most usual designs are bands of chevrons or other rectilinear skeuomorphs, though animal and plant, and occasionally human motifs, do occur. To increase the effect, the incisions are often filled with powdered lime or some other substance which shows up against the dark background of the vessel. Less common are ornaments applied to the surface such as knobs, scrolls and figurines. Raised designs are also produced by pressing out the wall of the pot from within. Another method, of restricted distribution, is that of scraping away the surface so as to leave the figures in relief.

The colour of a vessel is to a great extent dependent upon the composition of the body and the method of firing. Of materials present in bodies, iron is usually the only colouring element. This, on being subjected to heat under oxidizing conditions, is changed into a red iron oxide and gives a shade varying from yellow to an orange or red; under reducing conditions producing a colour which ranges from light bluish gray to a deep, sometimes metallic, black. Usually among primitive peoples no effort is

made to produce certain shades by regulating the conditions of the firing. A dark colour is often the result of a pot's being smoked; this may be an unintentional incident of the firing, but among the Ashanti it is brought about by setting the vessel, while still red-hot from the furnace, on a heap of dry tinder. This it ignites.' Water is then poured on and the pile is left smoking. The smoke permeates the heated clay and deposits on and sometimes through it a mixture of finely divided tar and carbon, rendering it non-porous. Decoration by means of slip is occasionally found, but true painted pottery is extremely rare among primitive peoples.

Varnishing.— Fired pots are nearly always porous. They are therefore frequently varnished and this varnish is often decorative as well as useful. Many different methods are employed to treat the surface with a resin, gum, fat or gelatinous substance. Similar in artistic effect to varnishing but without so great utilitarian value is the practice of polishing or burnishing the ware, but this is only possible where the clay is of a fine body. Though vessels are the most common pottery products of primitive peoples, other things are sometimes made, such as tobacco pipes, drums, toys and figurines.

Sociological and Religious Aspect.—Little attention has as yet been paid by ethnologists to the religious and sociological aspects of pot-making. Generally the craft is confined to one sex, usually the female, except where the potter's wheel is used, which is always operated by men. In so far as domestic utensils are naturally matters which concern women it is not strange that they should be the potters, but this does not explain why, in many cases, men are definitely prohibited from potting nor why their very presence during the manufacture is inimical to it. Thus among the Sema Nagas of Assam a man may not even speak to a woman thus engaged nor approach her work. The making of ceramics is often the prerogative of certain families or a certain district and any infringement of this may easily cause trouble. Even where this is not so, certain villages become famous for their wares. Theories of origins are necessarily speculative, but in evolving them it must not be forgotten that clay shaped and burnt does not produce a pot. The body must be properly prepared, the vessel properly dried and fired under suitable conditions. The accidental discovery of pottery, therefore, is not so easy as has sometimes been implied.

BIBLIOGRAPHY.—No work has yet been written on primitive pot-making, but the following monographs and articles contain more or less detailed accounts of the methods of individual tribes. POTTHAST, AUGUST (1824–1898), German historian, was born at Hoxter on Aug. 13, 1824, and was educated at Paderborn, Miinster and Berlin. He assisted G. H. Pertz, the editor of the *Monumenta Germaniae historica,* and edited the *Regesta pontificum romanorum, r198–1304* (1874–75). From 1874 to 1894 he was librarian of the German Reichstag. Potthast compiled the monumental and indispensable *Bibliotheca historica medii aevi* (1862; new enlarged ed., 1896), a guide to the sources of European history in the middle ages. The work, in the form of an index, gives particulars of practically all the historical writers of Europe and their work between 375 and 1500. Potthast died on Feb. 13, 1898.

POTTINGER, SIR HENRY (1789–1856), British administrator, was born in Ireland, Oct. 3, 1789. In 1804 he became attached to the British army in India and during the next 35 years served successively as collector of Ahmadnagar, resident of Cutch and resident of Sind. In 1840 he was appointed envoy and plenipotentiary to China, a war having broken out between Britain and that eountry over the opium trade. In 1842, the struggle having been successfully terminated, Pottinger was responsible for the drawing up of the treaty of Nanking, the terms of which included the cession of Hongkong to Britain. He was made governor and commander in chief of Hongkong in 1843, the first to hold that office under English rule. He held the governorship for a year and subsequently served for a short time as governor of the Cape of Good Hope (1846–47). In Aug. 1847 he was appointed governor of Madras, where he remained until 1854. He died at Malta, March 18, 1856.

POTTO, the name of the West African slow-lemurs, *Perodicticus,* popularly miscalled "sloths." The aborted condition of the index finger is their most distinctive feature. The ordinary potto (P. *potto*) is about the size of a squirrel, with large staring eyes and a stump of a tail; its colour is rufous brown. Bates's potto (P. *batesi*), of the Congo, is nearly allied; the awantibo (*P. calabarensis*), of Old Calabar, has no tail (see PRIMATES).

POTTSTOWN, a borough of Montgomery county, Pennsylvania, U.S.A., on the Schuylkill river, 40 mi. N.W. of Philadelphia; on federal highway 422; served by the Pennsylvania and the Reading railways. Pop. (1920) 17,431 (90% native white); (1940) 20,194. It is the centre for a population of 90,000; and has important manufactures, notably of iron and steel, but including a large variety of other industries. The aggregate factory output in 1939 was valued at $25,677,000; retail sales (1940) amaunted to $11,307,000. In a natural park 3.5 mi. N. are the "ringing rocks," covering about 150 ac., which give different tanes of the musical scale when struck. Pottstown was founded in 1753 by John Potts, and was called Pottsgrove until 1820. It was incorporated as a borough in 1815. In this neighbourhood the first commercially important iron furnace in America was established in 1716.

POTTSVILLE, a city of Pennsylvania, U.S.A., the county seat of Schuylkill county; on the Schuylkill river, go mi. N.W. of Philadelphia. It is served by the Lehigh Valley, the Reading and the Pennsylvania railways. Pop. (1920) 21,876 (92% native white); 1940 federal census 24,530. It ha5 a picturesque location (700 ft. above sea level) at the gap made by the river through Sharp mountain and is in the midst of the southern ("Schuylkill") region of the anthracite coal field. Besides its large coal-mining interests, it has railroad shops and a variety of manufacturing industries, with an output in 1939 valued at $8,000,000. Bank clearings for the year 1940 aggregated $14,528,601. The city operates under a commission form of government. The first white family that settled here was massacred by the Indians in Aug. 1780. Permanent settlement dates from about 1795, and soon after that an iron furnace was set up. In 1804 this furnace was bought by John Potts, founder of the borough. Coal was discovered in 1807. The town was laid out in 1816, incorporated as a borough in 1828, became the county seat in 1851 and was chartered as a city in 1911. It was a centre of the Molly Maguires (*q.v.*) disturbances (1854–77) and some of the leaders were tried here and convicted in 1876–77.

POUCHED MOUSE, any member of the polyprotodont marsupial genus *Phascologale* (see MARSUPIALIA). There are over a dozen species, none larger than a rat. They feed almost entirely on insects. Pouched mice are found throughout Australia, where all the species have uniformly coloured furs, and in New Guinea and the Aru islands; most of the Papuan forms are distinguished by striping on the back.

PQUGHKEEPSIE, a city of New York, U.S.A., the county seat of Dutchess county; on the east bank of the Hudson river, midway between New York city and Albany. It is on federal highway 9E, and is served by the New York Central and the New York, New Haven and Hartford railways, river steamers and ferry to Highland. Pop. (1920) 35,000 (82% native white); 1940 federal census 40,478. A cantilever railroad bridge, 6,767 ft. long, with approaches, and zoo ft. above the water, spans the Hudson at this point, and a highway bridge there was completed in 1930. Intercollegiate boat races are rowed on the river annually. The city is built on terraces rising to 200 ft. above the river. On its eastern boundary is the extensive campus of Vassar college (*q.v.*), and 2 mi. N. of the city is the Hudson River State Hospital for the Insane (1871). There are several private schools in the city. and several charitable institutions, including a hospital (1878) and a home for old men (1881) founded by the Vassar brothers. The manufactures (valued in 1937 at $25,042,259) are numerous and widely diversified. The city's assessed valuation for 1940 was $46,757,761. Poughkeepsie was settled by the Dutch about 1698. It was incorporated as a village in 1799 and as a city in 1854. The New York legislature met there in 1778, 1780, 1781, 1782, 1788 and 1795, and there on July 26, 1788, the State Convention ratified the Federal Constitution. The name is a modification of an Indian word, meaning the reed-covered lodge by the little water place.

POULENC, FRANCIS (1899–), French composer, was born in Paris on Jan. 7, 1899. His first important work, the *Rapsodie Nègre,* played in Paris in 1917, excited much interest as the work of so young a composer. It was followed by Le bestiaire and Cocardes (1919) and Quatre *poèmes* de Max Jacob (1921) for solo voice and chamber orchestra. In 1920–21 he wrote the comedy-bouffe, *Le gendarme incompris,* with an ensemble of one violin, one violoncello, one double-bass, one clarinet, one trombone and triangle. A ballet, Les Biches (1925) was followed by Concert *champêtre* (1927) and by his Aubade for orchestra (1929).

POULSEN, VALDEMAR (1869–1942), Danish engineer, was born at Copenhagen, Nov. 23, 1869. He became an assistant in the technical section of the Copenhagen telephone establishment and in 1898 invented the telegraphone, an electro-magnetic phonograph capable of registering human speech by the alternating magnetization of a wire. In 1900 Duddell (*q.v*) devised his singing "arc" by connecting an inductance and a capacity with an ordinary arc; and in 1903 Poulsen invented a modification of this by means of which he produced continuous oscillations of frequencies used in wireless telegraphy (*q.v.*), thus solving one of the greatest problems in the science of radio technique. The Poulsen arcs are used by radio stations throughout the world.

POULTRY AND GAME. The term poultry includes fowls, ducks (domestic), turkeys, guinea fowl and geese; the word game is usually applied to wild duck, partridges, grouse, pheasants, quails, deer (venison) and other edible wild birds and beasts. Rabbits, hare and pigeons are usually classed with game.

Poultry and game may be cooked in a variety of ways: roasted; boiled; grilled; stewed in various forms; boned and made into galantines; baked in pies, puddings, vol-au-vents, pasties, etc.; combined with cereals, jellies and special sauces, or pounded and used for spreading on pastry or bread and butter.

Preparation of Game and Poultry.—Poultry and feathered game should be plucked and then singed to remove any stray hairs or feathers. It is easier to pluck poultry when warm. The neck is cut off at the shoulder, leaving the skin. There are two ways to draw poultry. The English loosen the skin around the vent with the point of a knife, lay the bird on a board, back uppermost, make a small incision in the skin of the neck lengthwise, insert the fingers through the opening and draw out the entrails, being careful to avoid breaking the gall. Americans cut a slit from the vent of about two inches and draw out the entrails from there. The gizzard, from which the inner bag has been removed, heart and liver are saved for giblet gravy or used in the stuffing. The bird is then washed thoroughly inside and out with cold water. Chop off the ends of the claws and fold back the pinions in the form of a triangle; turn the bird over and bend back the legs towards the neck. Either pin in place with a skewer (if a small bird) or use a trussing needle and stitch through the bird under the knee-bones, at the same time, securing the flap and pinions Birds which need larding should then be covered with bacon fat.

Roasting. — Birds which require stuffing should be filled with a suitable forcemeat (chopped meat, spiced and seasoned) which ought, if possible, to include the pounded liver of the bird. Turkeys and large fowls (capons) are frequently stuffed with veal and ham forcemeat flavoured with lemon peel and nutmeg or with chestnuts; geese and ducks with sage and onions chopped finely and mixed with other forcemeat ingredients, and ducks are occasionally stuffed with prunes and apples. Roast wild duck, widgeon, teal and most small game birds are generally served without stuffing, though pheasants may be stuffed with chestnuts. To keep game birds moist while cooking, a small piece of butter or rump steak is often placed inside the bird. Small birds should be protected with a buttered paper or larding. To roast very small birds, *e.g.*, larks, place them on a skewer.

The best way to roast a haunch of venison is to wrap it in buttered paper and seal this over with a flour and water paste. Ordinary dripping is used for basting poultry and venison, but butter is preferable for basting game birds. About 10–20 minutes before poultry and game have finished cooking remove buttered paper or larding and dredge with flour.

A good gravy with roast poultry or game is essential. Stuffed birds need a thickened gravy. Bread, cranberry, mushroom or chestnut sauce may be served with turkey, and sausages or bacon is a common addition. Roast fowl, pheasant, partridge and grouse are all usually accompanied by rashers of bacon and bread sauce. Water-cress is used as a garnish. Fried breadcrumbs are served with partridge, pheasant and grouse. Red currant jelly should always accompany roast venison and hare. Apple sauce is substituted for bread sauce in serving roast goose.

Poultry is boned and stuffed to form a galantine. Remove the head and feet; then draw the bird. Divide the skin down the back with a sharp knife and turn down the flesh from the ribs, breast and side bones, leaving these as bare as possible. Pull legs and wings carefully out at the sockets, cutting the sinews through with a knife, and turn these inside out with the rest of the outside skin. Free the skeleton and turn the skin outwards again. Stuff the bird to restore its original shape.

Other Methods of Cooking. — All poultry may be boiled in the same way as butcher's meat, *i.e.*, in a well-flavoured stock (see COOKERY) and served with different sauces, *e.g.*, boiled chicken and egg sauce. As a general rule, game is not boiled. Both game and poultry are used for making entrées and these may take the form of elaborate stews (brown stews flavoured with special condiments, such as mushrooms, truffles, orange peel, vegetables, etc.); salmi of game; timbales (moulds of cold poultry and game); creams (purées with cream and egg liaison); fricassées; blanquettes; spatchcock of game (split bird grilled and served with melted butter to moisten); jellies (cold game and poultry purées formed into shapes and masked with aspic or white sauce. or both mixed together); minced game and poultry formed into rissoles or croquettes and dipped in batter, rolled in pastry or dipped in egg and breadcmmbs and fried in deep fat.

In the making of soups, game and poultry are also used as foundations, and any game or poultry may be used for making raised pies, ordinary pies, pasties and vol-au-vents. (See PASTRY.) Where sufficient giblets are available these may also be used for pie-making. To prepare giblets, first scald them and remove any outer skins, such as tough skin adhering to gizzards, etc., take out crop and remove gall. Cut into convenient pieces and partially stew before adding to the pie.

Rabbits and Hares. — For roasting, rabbits and hares are first cleaned and then filled with stuffing; after which they are sewn up. Extend the fore-legs straight along the sides and skewer through the body. Bring the hind-legs forward and bend back the head on to the shoulders and fix into place by passing a skewer through the mouth into the body. For stewing, brown the meat in the same way as for meat. Rabbits may also be curried. For jugged hare, skin and clean the hare, joint it and remove the liver; place in an earthenware pot and add a bunch of sweet herbs, onion stuck with cloves, blade of mace, piece of lemon rind, celery seed or stalk of fresh celery, carrot and a few button mushrooms. Cover with stock Cook slowly until the flesh is tender. Strain off the gravy and thicken with flour, pounded liver and some of the blood of the hare. Stir in one tablespoon of red currant jelly, one tablespoon of Worcester sauce and a dessertspoon of mushroom ketchup. A wineglass of port wine is frequently added to this dish. Serve with fried or poached forcemeat balls and red currant jelly.

POULTRY AND POULTRY FARMING. In practically all countries poultry farming for the purpose of producing meat and eggs for table use is carried on to some extent. In fact, few other agricultural enterprises are so widespread, and in Eire, China, Canada, Denmark, England, Australia and the United States and some other countries, the poultry industry is one of the leading branches of agriculture. Within each country the egg and chicken business is by far the most important branch of the poultry industry.

In most countries turkey production is carried on to a limited extent only, although in the United States it is a relatively important enterprise. The raising of ducks for eggs is an industry of moderate importance in England, the Netherlands and Belgium and for meat production primarily in the United States Geese are raised exclusively for meat, goose production being of limited importance in practically all countries except Germany and in one or two other European countries. The raising of guinea fowl for meat production is of relatively little importance in any country.

In all countries most flock owners of chickens are primarily interested in egg production because more income is obtained from egg production than from chicken-meat production. In certain sections of some countries, especially France, England and the United States, however, producers receive practically all of their poultry receipts from market poultry. It is true, of course, that on farms where egg production is the primary consideration most of the males raised each year are sold as broilers, fryers or roasters.

Domestic breeds of chickens descended from the jungle fowl of India. The numerous modern breeds of chickens known throughout the world may be conveniently classified into the following five classes, on the basis of their origin: English, Asiatic, American, Mediterranean and Continental European. The breeds belonging to the Mediterranean class are for the most part somewhat smaller in body size and more active than the breeds belonging to the other classes. Also, Mediterranean breeds lay white-shelled eggs, become broody relatively seldom, and have white ear lobes whereas most of the breeds belonging to other classes lay brown-shelled eggs, are likely to become quite broody, and have red ear lobes. The Mediterranean breeds are not as well suited for meat production as most of the other breeds. The Asiatic and some of the Continental European breeds have feathered shanks whereas other breeds have nonfeathered shanks.

Principal Breeds and Varieties.—Although there are more than 100 breeds and varieties of chickens, the number kept primarily for meat or egg production or both is very limited, several breeds and numerous varieties having been developed because of some unique structural character, such as an odd shape of comb or the presence of a crest on the top of the head, or because of the beauty of the plumage pattern. All birds belonging to the same breed have the same shape. Varieties within a breed differ with respect to colour of plumage. There are numerous Bantam breeds, kept by some poultrymen as novelties. Only the more popular breeds and varieties of outstanding economic importance can be discussed here.

Australorp.—This breed originated in Australia and was developed primarily as an egg producer, although its medium size makes it a good meat bird. The comb is single, the skin white and the plumage black. It is kept to some extent in the United States but is more popular in Australia.

Dorking.—The Dorking is an English breed and of the three varieties, the White, the Coloured, and the Silver Gray, only the last named variety has assumed importance in England. Dorkings have long, broad, deep and low-set bodies and five toes, most other breeds having four toes. The Silver Gray Dorking has a single comb and white skin, is an excellent meat bird and is used to a considerable extent in England for crossing with some of the Game breeds.

Leghorn.--Of the 12 different varieties of Leghorns, only the Single-Comb White is kept extensively in any country. The Leghorns belong to the Mediterranean class. White Leghorns have been bred to a high level of egg production in England, Canada, Australia and the United States and for years have occupied a very prominent place on commercial poultry plants devoted to market egg production. Its white-shelled egg and yellow skin enhance its popularity, although Leghorns do not make as good table birds as most of the larger sized breeds. For market egg production, exclusively, and for economy of production the Single-Comb White Leghorn is pre-eminent.

New Hampshire.—The New Hampshire is an American breed, with single comb and yellow skin, popular in the United States and Canada as an egg and meat producer. In both sexes the plumage over most of the body is chestnut red, and there is some black in wing and tail feathers; in the male the hackle and saddle feathers are reddish bay. Well bred New Hampshires grow fast and mature early and for that reason have been used extensively for the production of broilers and fryers. For this same purpose New Hampshire females are crossed with Barred Plymouth Rock males with good results.

Orpington.—This is a single-combed English breed of which there are four varieties: Buff, Black, White and Blue. The Buff and White varieties have enjoyed more popularity in England than the other varieties. The Orpington is an egg producer of moderate ability as compared with the Leghorn and the more popular American breeds. The white skin is largely responsible for the raising of the Buff variety in the middlewestern section of the United States, where a dressed carcass with a light-coloured finish is sometimes desired.

Plymouth Rock.—Among seven different varieties of this American breed, only the Barred and the White varieties have assumed a place of economic importance, although the Buff variety is kept to some extent. The comb is single and the skin is yellow. In the Barred variety the black and white bars should be of equal width in males, and the white bars should be one-half as wide as the black bars in females. In both sexes the end of each feather is black. In the United States Barred Plymouth Rock males are crossed extensively with New Hampshire females to produce chicks for commercial broiler and fryer raisers because some markets prefer a barred bird, barring being dominant to the New Hampshire plumage colour. After about 1935, White Plymouth Rocks increased in popularity, especially in the U.S. middlewest. The Plymouth Rock is a bird of good size, with good fleshing properties, and when properly bred lays well.

Rhode Island Red.—The Rhode Island Red is another American breed, the single comb variety being much more popular in England, Canada and the United States than the rose-comb variety. The skin is yellow. The plumage should be rich dark red over all parts of the body, there being black in the tail and parts of the wing feathers. The Single-Comb Rhode Island Red has been bred extensively for egg production and in the United States especially, and some strains lay as well as some of the best strains of Single-Comb White Leghorns. The Red is also a good meat producer.

Sussex.—This English breed contains the Light, Speckled and Red varieties, the Light variety being by far the most popular in England although but few of any Sussex varieties are kept in other countries. The comb is single and the skin is white. In plumage colouration the Light Sussex is similar to the Light Brahma. Sussex fowl have long been noted for the excellence of their flesh and are kept extensively in England for the production of roasters. After about 1925, English poultry breeders made considerable improvement in the laying qualities of the Light Sussex.

Wyandotte.—Among several varieties of this American breed, the White Wyandotte is the only variety bred extensively in England, the United States, or other countries. Wyandottes have rose combs and yellow skins. Like several other American varieties, they are a good general-purpose fowl, suitable for both meat and egg production. In England, egg production has been developed to a higher level among White Wyandottes than in other countries. In the United States White Wyandotte has largely been supplanted in popularity by the other previously mentioned American varieties.

Other Breeds *and* Varieties.--Of hundreds of other breeds and varieties of chickens kept in various countries, only a few can be mentioned. The Ancona is a Mediterranean breed with mottled plumage. The Dark Cornish is of English origin and has a very broad, compact body, ideal as a roaster type but a poor layer; it is sometimes used for crossing with other breeds. The Faverolle is a French breed with feathered shanks; in England the Salmon Faverolle is crossed extensively with the Light Sussex for roaster production. Old English and Modern Game breeds make excellent roasters but are poor layers and are kept largely by fanciers. The Jersey White Giant is the largest of the American breeds. developed primarily as a meat breed and is not noted for egg production. The Light Brahma has always been the most popular representative of the Asiatic breeds but is kept to a limited extent only. The Black Minorca is the largest of the Mediterranean breeds but has never been kept to any great extent in any country. The Black Sumatra is a native of Sumatra and is a fancier's breed exclusively.

Breeding for Meat and Egg Production.— Success in raising chickens for meat and egg production is largely a matter of good stock plus good management. Good stock can be secured only from carefully selected, well bred parents that are properly mated.

Meat Production Standards.— For profitable meat production, chickens must grow at a rapid rate and make good gains in body weight for the feed they consume. Usually the fewer pounds of feed consumed per pound of gain in body weight, the greater the profit in meat production. The characteristics which birds raised for meat production should possess include: (1) good health and vigour; (2) fast wing feathering at hatching time and fast tail feathering at 10 days of age; (3) well feathered over the back by 8 weeks of age; (4) rapid growth to marketing time; (j) well proportioned body, with good length and width and fair depth in proportion to shank length, body depth being uniform from front to rear; (6) good fleshing on breast and thighs. The selection of breeding stock on the basis of these six characteristics implies that the poultry breeder must carry on a definite selection program from hatching time to the time of mating.

Commercial poultrymen interested in poultry meat production exclusively frequently resort to crossbreeding with beneficial results, since crossbreeding tends to stimulate growth during the first 10 or 12 weeks, and mortality is usually less than among purebred chickens. However, the actual results secured from crossbreeding depend largely on the breeding quality of the parental breeds crossed. In England, and to a lesser extent in some other English-speaking countries, new breeds have been developed by crossbreeding for the purpose of enabling the sexes to be separated at hatching time according to differences in the colour of the down. This makes it possible for meat producers to purchase male chicks only and market egg producers to purchase female chicks only.

Egg Production Standards.— In addition to the six characteristics for meat production given previously, a pullet, to lay well, should possess the following four outstanding characteristics: (7) early sexual maturity; White Leghorns should commence to lay at about 150 days of age and Light Sussex, New Hampshires, Plymouth Rocks, Rhode Island Reds and other general-purpose birds at about 170 days of age; (8) pullets of all varieties should lay at a rate of at least 50% production, or a minimum of 15 eggs per month; (9) there should be little or no broodiness; White Leghorns usually do not exhibit much broodiness, but general-purpose varieties must be bred for non-broodiness or there will be numerous interruptions in laying; (10) pullets of all varieties should continue to lay for a period of approximately 10 months from the time they start to lay.

In order to develop a strain of birds noted for a high level of egg production, the poultry breeder must adopt a rigid prograrn

of selecting his breeding stock from year to year. The program of selection should be based on minimum standards for early sexual maturity, rate of laying, non-broodiness and persistence of production. Selecting birds with good pedigrees for future breeding purposes is an additional help in developing a good laying strain. The best help of all in selecting females for breeding purposes is to select them from among the families of full sisters that are outstanding in laying performance. Males for future breeding purposes should also be selected from the outstanding families but too close inbreeding should be avoided.

Additional Standards of a Good Strain.—In addition to the 10 desirable characteristics previously mentioned, a good strain of chickens should also possess the following essential characteristics: (11) good egg size, eggs attaining approximately standard weight (2 oz. each) within about 60 days from the time a pullet commences laying; (12) eggs of good interior quality; (13) hatchability of at least 75% of all eggs incubated; (14) low mortality among growing chickens and laying stock; the strain should possess the ability to resist disease to a marked degree; (15) long productive life.

Renewing the Flock—Whether chickens are raised for meat production or pullets are kept for egg production, the entire flock or part of it has to be renewed every year. Commercial producers of broilers and fryers renew their flocks several times a year, depending upon the number of lots produced annually. Market egg producers should plan each year to replace about two-thirds of the layers with a fresh lot of pullets because birds usually lay about 20% fewer eggs in their second than in their first laying year.

In practically all English-speaking countries it is possible for the great majority of poultry producers to secure from hatcheries the chicks necessary to renew their flocks. Hatching chicks in incubators rather than under broody hens makes it possible to secure larger numbers earlier in the season, which is a distinct advantage. Some farmers still hatch their own chicks in oil-heated incubators of limited capacity. The egg capacity of incubators used by a commercial hatchery operator may run up to several thousand eggs. these incubators being heated for the most part by gas, coal or electricity.

Hatchery operators may be divided roughly into two groups: (1) those who produce their hatching eggs with their own breeding flocks and (2) those who secure their hatching eggs from flocks owned by others. The hatchery operator who produces his own hatching eggs naturally has complete control over his flock and is thus in a position to do a great deal toward improving the quality of chicks hatched for customers. The most progressive hatchery operators who secure their hatching eggs from various flock owners adopt a system of close supervision concerning the management of the flocks and see to it that the females are carefully selected and are mated to males with as good breeding as possible.

Since many of the chickens raised in different countries each year are secured as chicks from hatcheries, it is quite apparent that they occupy a very important place in the poultry industry. The quality of chicks produced by hatcheries determines very largely the results secured by those who purchase the chicks for meat or egg production.

Rearing **Chickens.**—If a few chickens only are to be raised, they may be brooded with hens, hut if a few hundred or more are to be raised, they should be brooded artificially. hloreover, brooding chicks artificially makes it possible to raise a larger number at one time than with natural brooding so that a larger number of pullets of the same age may be placed in the laying house in the fall of the year.

There are several different types of brooders for artificial brooding, varying according to size, design and the kind of fuel used to supply heat. Brooders differ in size from those accommodating about 50 chicks to those accommodating several thousand chicks.

Most makes of brooders are portable and can be nioved from place to place. Many of the portable brooders are equipped with canopies or hovers for conserving the heat to a limited area near its source. There are colony brooders for lots of about 60 to a few hundred chickens, continuous brooders for brooding chickens by the thousands, and battery brooders for brooding in strict confinement. The kind of fuel used to supply heat in colony brooders may be kerosene, coal, wood, distillate oil, gas, or electricity. Continuous brooders are heated by burning coal, gas, or distillate oil. Battery brooders are usually heated electrically.

When only a few chickens are to be raised, some kind of lamp brooder is often justified, because the initial expense is relatively low. On the other hand, if a few hundred or more chickens are to be raised, one of the other types of brooders would undoubtedly be justified.

Most poultrymen use electric or wood-burning or coal-burning portable brooders. Best results are usually secured when not more than 250 chickens are brooded together.

For the first few days, the temperature under the hover of the brooder should be about 95° F. at about 2 in. above the floor. The temperature should be lowered about 5° each week depending upon the time of the year and the outside temperature. The temperature of the brooder house should be about 70° F. The most critical period in brooding is the first two weeks; thus the most careful attention should be given the brooder during this time. Drafts in the brooder house should be avoided and the litter should be kept dry to prevent the spread of disease. When the chickens are well feathered, they require little heat. They should be given access to a grass or other succulent green range when a few days old. Plenty of waterers and hopper feed space should be provided, larger sized waterers and dry mash hoppers being provided as the chickens grow.

A 10 ft. x 12 ft. or a 12 ft. x 12 ft. colony brooder house is large enough for brooding 250 chickens up to about eight weeks, when the sexes should be separated. The pullets may be moved to range shelters to be reared on range, and the cockerels may be kept until they attain broiler, fryer or roaster stage.

Feeding Problems.—Several different kinds of nutrients are required for growth and for egg production. Water, carbohydrates, fats, proteins, minerals and vitamins are all necessary. Ample supplies of carbohydrates and fats are supplied by the cereal grains and their by-products, since these ingredients constitute such a large part of the diet. Particular attention must be given to the selection of protein, mineral and vitamin supplements used to balance the diet.

White Leghorn chickens reared on range, both sexes in approximately equal numbers, should weigh about 2 lb. each at 12 weeks of age and would have consumed about 7.5 lb. of feed per bird; at 24 weeks they should average about 4.25 lb. each and would have consumed about 24 lb. of feed per bird. Chickens belonging to the general purpose breeds, both sexes in approximately equal numbers, should weigh about 2.75 lb. each at 12 weeks and would have consumed about 8.75 lb. of feed per bird; at 24 weeks they should average about 6 lb. per bird and would have consumed about 30 lb. of feed per bird.

Among laying birds of the same size, those that lay well consume more feed than those that lay poorly, but egg production is more efficient. For instance, a 4-lb. 100-egg bird consumes on the average about 71 lb. of feed in a year, whereas a 4-lb. 200-egg bird consumes about 85 lb. of feed in a year. Nevertheless, the 200-egg bird is much more efficient, because she consumes about 5 lb. of feed for every dozen eggs produced, whereas the loo-egg bird consumes about 8.5 lb. of feed per dozen eggs produced.

Laying birds averaging 4 lb. and laying at the rate of 30% consunie about 8 lb. of feed per dozen eggs produced, whereas the same birds laying at the rate of 70% consume about 4.5 lb. of feed per dozen eggs produced. Laying birds averaging 6 lb. and laying at the rate of 30% consume about 10 lb. of feed per dozen eggs produced, whereas the same birds laying at the rate of 70% consume about 5 lb. of feed per dozen eggs produced.

Housing the Laying Stock.—The purpose of housing is to give the layers protection and keep them comfortable so that they will be efficient egg producers. In extremely hot weather the layers are very likely to suffer considerably if they cannot secure relief in a cool house. The chicken has no sweat glands to assist in keeping the body cool. In extremely cold weather, chickens not only suffer from the cold in a poorly built house but use too much of the energy contained in their feed to conserve body heat instead of to produce eggs. The primary objective in housing laying stock, therefore, is to protect the birds against excessively high and low temperatures and especially against sudden changes in temperature. In addition, the proper housing of the layers makes it possible to manage them more efficiently.

The location of the laying house should be such as to provide for the proper circulation of air within the house and at the same time avoid unnecessary exposure to the wind. A southern, well-sheltered slope which offers good air and water drainage is usually the most desirable. The size of the house needed varies according to the size of the flock. For flocks of 15, 25 and 50 birds, houses should have about 70, 100 and 180 sq.ft. floor space, respectively. A flock of 125 birds should have about 400 sq.ft. floor space. A flock of several hundred or a few thousand birds should be divided into units of about 125 or 250 birds per unit, several units being housed in one long continuous house.

It costs less, on the average, to build a square house than a long narrow one, which is likely to be drafty. Houses for small flocks should be at least 10 ft. deep, and houses for large flocks should be at least 16 ft. or better still, 20 or 24 ft. deep. Large flocks may be kept in houses that are two, three or four stories high. A multistoried house reduces the labour required to manage a large flock, as compared with a single-storied house. A multistoried house simplifies ventilating problems to some extent and makes it possible to maintain more uniform temperatures in summer and winter.

A concrete floor is more durable and much more sanitary than a board floor. Insulating the walls and roof, especially the latter, helps greatly to keep the house cool in summer and warm in winter. The proper ventilation of the house is necessary in order to remove excessive moisture and provide fresh air but, at the same time, drafts should be avoided. Sunlight in the laying house is desirable not only because it brightens up the house but also because it tends to keep the house dry and is a good germicide, being effective in destroying disease organisms.

Moreover, sunlight is a good source of vitamin D. A good absorbent litter helps to keep the floor dry. How frequently the litter should be removed depends largely on the number of birds in the house, weather conditions, and the extent to which the house is properly ventilated.

Marketing Eggs.—Nearly all eggs at the time they are laid are of superior quality. They represent the kind of eggs that most consumers would like to purchase the year round. The proper steps to preserve fresh-laid egg quality are far more important than most producers realize. The proper preparation of eggs for market and marketing them to best advantage are just as important, in many respects, as producing them efficiently.

Since the germ of a fertile egg begins to develop at about 69" F., eggs for market should be kept at a temperature lower than 68° F., a temperature of 55° F. being desirable. All producers of market eggs should keep the males away from the females except during the breeding season.

Unless eggs are gathered frequently and cooled promptly in warm weather, they commence to deteriorate. In fact, the higher the temperature and the drier the air of the room in which eggs are held, the more rapid the deterioration. Some of the most striking changes that take place in eggs subjected to high temperatures and dry atmosphere are: (1) water evaporates through the porous shell, (2) the thick white tends to break down into thin white, (3) the yolk membrane becomes weaker, and (4) the yolk becomes more flaccid.

The excessive heating of eggs, whether from being exposed to the sun's rays or held for a long time in a warm room, results in a complete breakdown of the thick white, giving the entire white a watery appearance.

Clean litter and clean nests, one for every five hens, are essential for the production of clean eggs. The eggs should be gathered in wire baskets three or four times daily in warm weather and stored in a room in which the temperature is about 55° F. and the relative humidity about 75%.

Flock owners who only have a few layers often sell all of their surplus eggs direct to consumers. This is especially true of flock owners in villages or those living in areas adjacent to towns and cities. In the case of farm and commercial flock owners the eggs may pass through any one of several different marketing channels before reaching the consumer. Selling market eggs on a graded basis is in the best interests of producers, dealers and consumers. Eggs are graded according to size, shell cleanliness, size of air cell, and the quality of the yolk and white.

The method of packing eggs in different countries varies. In several European countries, for instance, long wooden boxes are used for packing eggs in straw whereas in Canada and the United States different kinds of containers are used, including cartons holding ½ doz. or 1 doz., fibre or cardboard boxes holding 15 or 30 doz., or wooden egg cases holding 30 doz. From the surplus producing areas in a country, eggs are shipped by express to consumers or retailers in consuming centres or they are shipped in refrigerated cars or trucks to wholesalers who sell them to retailers.

Co-operative egg marketing methods have been developed extensively in various English-speaking countries, especially Australia and the United States as well as in such countries as Eire and Denmark.

Prior to World War II some countries, including China, Denmark, Australia, New Zealand, South Africa and Eire, exported considerable quantities of eggs annually to Great Britain, which is primarily an importing country. (See also EGGS.)

Marketing Chickens.—Chickens are sold alive at various ages, ranging from those about 8 weeks old, weighing about 1 lb. each, to those that are several years old. They are all called "chickens" when one wishes to distinguish them from turkeys, guineas, ducks and geese. From the market standpoint, however, the term "chicken" is usually used to distinguish growing birds, except stags and capons, from cocks and hens, the latter usually being referred to as "fowl." Stags are older than chickens, have more prominent spurs, and the flesh is not so tender. Capons are male birds that were castrated while young, the flesh being relatively tender even when the birds are almost fully grown.

While the marketing of live chickens is an important industry in many countries, the proportion of dressed poultry marketed by live-poultry buyers increased considerably after about 1930. In all countries the great bulk of market poultry is sold to consumers either in the dressed, drawn or cut-up form. A dressed bird is one that has been killed and plucked. A drawn bird is a dressed bird from which the head, feet and entrails have been removed. A cut-up chicken is a drawn bird that has been cut up into parts suitable for frying.

Feed should be withheld from birds for about 15 hours before they are killed and plucked. The different methods of plucking chickens include dry plucking, hard-scald plucking, semiscald plucking, wax plucking, and machine plucking. Dry plucking must be done the moment the bird is killed, while the body is still warm. The hard-scald method involves immersing the bird for a few seconds, except the head and feet, in water kept at a temperature of 180° to 190° F. If the water is too hot or the birds remain in the water too long. the skin will have a scalded appearance. For semiscalding, the temperature of the water should be approximately 127° F. for broilers, 128° F. for fowl, and the birds should be kept in the water for 30 to 35 sec. Wax plucking is a somewhat involved process in which a special kind of melted wax is used to facilitate the removal of feathers, pinfeathers and hair. Plucking machines are used to some extent, especially in England and the United States. Some of the machines are equipped with a revolving disc or cylinder for dry plucking and others are equipped with a revolving cylinder to which rubber "fingers" are attached for plucking by the semiscald method.

After the birds have been plucked, the heads, feet and vents are cleaned thoroughly in order to give the dressed carcasses an attractive appearance. After the birds are dressed, they should be cooled thoroughly by immersing them in cold water for about an hour, or they may be held for about a day in a room for dry cooling at a temperature of 32° to 34° F. If the dressed birds are to be packed in boxes or other containers for shipment to market, the heads are wrapped in parchment or kraft paper waxed on one side.

In some countries, especially the United States, dressed birds are drawn in poultry-packing plants and after being inspected and cleaned are prepared so that they are ready to be placed in the consumer's oven for roasting. Such poultry is called quick-frozen full-drawn, the carcasses being frozen immediately after being drawn at temperatures which range as low as −20° F.

The practice of selling fresh-killed chickens cut in pieces suitable for frying has gained considerable impetus in Canada and the United States. Buying cut-up chicken is popular with many housewives, because practically no labour is necessary in preparing the poultry for the frying pan.

Great Britain is the principal importer of dressed poultry. Prior to World War II most of its imported supplies were obtained from Eire, France, Austria and Latvia.

Raising Ducks for Meat and Eggs.—Duck raising is practised on a limited scale in practically all countries. for the most part as a small farm enterprise; but in such countries as England and the Netherlands they are kept extensively for egg production, and in the United States a considerable number of commercial plants have been developed for meat production exclusively. The Runner duck, formerly called the Indian Runner, and the Khaki-Campbell are especially adapted for egg production, whereas the larger sized Pekin breed is a meat producer of exceptional merit. Some strains of Runners and Khaki-Campbells will lay better than many strains of chickens. Pekin ducks grown commercially for meat are marketed from about 8 to 12 weeks of age, when they weigh from about 43 to 7 lb. each. In England the Aylesbury is the kind kept for meat production. The Muscovy duck, of South American origin, is kept on farms for meat production to some extent because it does not "quack."

Goose Raising.—Goose raising is a farm enterprise of limited proportions in practically all countries, although in Germany, Austria, parts of France, and certain sections of other countries, goose raising on a commercial basis is carried on extensively. The Toulouse, predominantly gray in colour, and the Embden, a white breed, are the two outstanding meat-producing breeds. On some commercial plants, market geese are fattened by a special process, the forced-feeding of noodles sometimes being practised, resulting in a considerable enlargement of the livers.

Some goose raisers make a practice of plucking feathers from the live birds, usually just before the birds moult, up to one pound of feathers being obtained from a bird.

Guinea Raising.—Guineas are raised as a sideline on a few farms in various countries. In some cities there is a relatively good market for them, and they are often used as a substitute for game birds, such as quail, grouse, pheasant and partridge.

(M. A. J.)

POUND, SIR (ALFRED) DUDLEY (PICKMAN ROGERS) (1877–1943), first sea lord and admiral of the British fleet during World War II, was born Aug. 29, 1877, on the Isle of Wight. He was educated in grammar schools in Surrey and Greenwich until 1891, when he entered the navy. In 1913–14, Pound attended the Naval War college, and in 1914 was raised to the rank of captain and appointed naval assistant to Lord John Fisher, then first sea lord. He commanded H.M.S. "Colossus" during the battle of Jutland and for his part in the engagement was mentioned in dispatches. From 1922–25 he served in the admiralty as director of the plans division and in 1925 entered two years' service as chief of staff to the Mediterranean fleet's commander in chief, Admiral Sir Roger Keyes. In 1926 he was promoted to rear admiral and from 1927–29 was assistant chief of the naval staff. From 1929–31 he commanded a battle cruiser squadron. In 1932, having reached the rank of vice admiral, he was made second sea lord and chief of naval personnel at the admiralty, and in 1935 he was made admiral and temporary chief of staff of the Mediterranean fleet. From 1936–39 he was commander in chief of that fleet. On May 17, 1939, he was advanced to first sea lord and chief of the naval staff and in July 1939 was made admiral of the fleet. He resigned Oct. 4, 1943, because of ill health and died the following Oct. 21.

POUND, EZRA LOOMIS (1885–), U.S. poet, was born in Hailey, Idaho, Oct. 30, 1885. He was educated at the University of Pennsylvania and at Hamilton college, N.Y. He taught until 1907, when he left the United States to travel in Europe, and except for two brief return visits to the United States, he remained in Europe thereafter, living successively in London, Paris and Italy. Although Pound had written a number of works by 1912, his first important publication, *Ripostes,* was printed in that year. This volume contained five imagist poems by T. E. Hulme and its appearance was regarded as the beginning of the imagist movement. Pound gave further impetus to the movement in 1914 with *Des Imagistes,* an anthology of imagist poetry. From 1917–19 he was London editor of *The Little Review.* In 1924 he settled in Italy, where, in 1941, he began to make daily pro-Fascist broadcasts from Rome. In 1943 he was one of eight indicted in the United States for treason by a federal grand jury.

Pound was responsible for bringing to English poetry a number of new techniques as well as for introducing Chinese and Greek influences. His other writings include poems, operas, translations and a number of prose works, most of the last being political documents.

POUND, ROSCOE (1870–), American jurist and educator, was born at Lincoln (Neb.), Oct. 27, 1870. He graduated at the University of Nebraska and studied law in the Harvard law school 1889–90.

On his admission to the bar in 1890 he commenced practice in Lincoln, Nebraska. He was commissioner of appeals of the supreme court of Nebraska 1901–03.

He was assistant professor of law at the University of Nebraska 1899–1903, and dean of the law faculty 1903–07; was professof of law at Northwestern university 1907–09, and at the University of Chicago 1909–10. In 1910 he accepted the Story professorship of law at the Harvard law school, becoming Carter professor of jurisprudence there in 1913 and dean from 1916 to 1936.

Pound has written *Phytogeography of Nebraska,* with F. E. Clements (1898); *Readings on Roman Law* (1906); *Lectures on the Philosophy of Freemasonry* (1915); *The Spirit of the Common Law* (1921); *Criminal Justice in the American City* (1922); *Introduction to the Philosophy of Law* (1922); *Interpretations of Legal History* (1923); *Law and Morals* (1924); *Readings on the History and System of the Common Law,* 3rd ed. (1927); *Criminal Justice* (1930); *The Fornzative Era of American Law* (1938); *History and System of the Common Law* (1939); *Organization of Courts* (1940); *Appellate Procedure in Civil Cases* (1941).

POUND (1) An enclosure in which cattle or other animals are retained until redeemed by the owners, or when taken in distraint until replevied, such retention being in the nature of a pledge or security to compel satisfaction for debt or damage done. Animals may be seized or impounded when (*a*) distrained for rent; (b) damage *feasant, i.e.,* doing harm on the land of the person seizing; (*c*) straying; (d) taken under legal process. The pound-keeper is obliged to receive everything offered to his custody and is not answerable if the thing offered be illegally impounded.

Where cattle are impounded the impounder must supply sufficient food and water (Cruelty to Animals Acts, 1849 and 1854); any person, moreover, is authorized to enter a place where animals are impounded without food and water more than 12 hours and supply them; and the cost of such food is to be paid by the owner of the animal before it is removed. Pounds are almost obsolete. (See DISTRESS; REPLEVIN.)

POUND (2)—(*a*) a measure of weight; (b) an English money of account. (a) The English standard unit of weight is the *avoirdupois* pound of 7,000 grains. The earliest weight in the English system was the Saxon pound, subsequently known as the Tower pound, from the old mint pound kept in the Tower of London. The Tower pound weighed 5,400 grains and this weight of silver was coined into 240 pence or 20 shillings, hence pound in sense (2) (a pound weight, of silver). The pound troy, probably introduced from France, was in use as early as 1415 and was adopted as the legal standard for gold and silver in 1527. The act which abolished the Tower pound (18 Hen. VIII.: the "pounde Troye which exceedeth the pounde Tower in weight iii. quarters of the oz.") substituted a pound of 5,760 grains, at which the pound troy still remains. There was in use together with the pound troy, the merchant's pound, weighing 6,750 grains, which was established about 1270 for all commodities except gold, silver and medicines, but it was generally superseded by the pound avoirdupois about 1330. There was also in use for a short time another merchant's pound, introduced from France and Germany; this pound weighed 7,200 grains. The pound avoirdupois has remained in use continuously since the 14th century, although it may have varied slightly at different periods—the Elizabethan standard was probably 7,200 grains. The standard pound troy, placed together with the standard yard in the custody of the clerk of the House of Commons by a resolution of the House of the 2nd of June 1758, was destroyed at the burning of the houses of parliament in 1834. In 1838 a commission was appointed to consider the restoration of the standards, and in consequence of their report in 1841 the pound avoirdupois of 7,000 grains was substituted for the pound troy as the standard. A new standard pound avoirdupois was made under the direction of a committee appointed in 1834 (which reported in 1854), by comparison with authenticated copies of the original standard (see *Phil. Trans.* 1856). This standard pound was legalized by an act of 1855 (18 & 19 Vict. c. 72). The standard avoirdupois pound is made of platinum, in the form of a cylinder nearly 1·35 in high and 1·15 in. in diameter. It has a groove or channel round it to enable it to be lifted by means of an ivory fork (for illustration see MEASURES AND WEIGHTS) and is marked "P.S. 1844. 1 lb." P.S. meaning Parliamentary Standard. It is preserved at the Standards Office, in the custody of the Board of Trade. Copies were also deposited at the Houses of Parliament, the Royal Mint, the Royal Observatory and with the Royal Society.

See the *Reports of the Standards Commission (6* parts, 1868–73).

POUND STERLING. Immediately prior to the outbreak of the World War the pound sterling circulated in the United Kingdom in two main forms, namely, gold sovereigns and Bank of England notes. Both were legal tender for any amount, but the latter were not issued in smaller denominations than five pounds. In addition, certain banks, mainly Scotch and Irish, issued their own notes.

The relative purchasing power of the pound in Britain is shown in the table below. Abroad, it would purchase $4.87; 25.22frs., and 20.43 marks. The Bank of England had a note issue of £55,000,000, of which £30,000,000 was in circulation and the remainder held in the Bank's own "Reserve." £38,000,000 in gold was held by the Bank, and an unknown number of sovereigns and half-sovereigns were held by the banks and the public. Gold was free to leave the country and the Bank was bound to redeem its notes in gold on demand.

War Results.—With the outbreak of the war, British bankers and financiers called their foreign funds home, and in so doing forced the American exchange for a day or two to above $5.00. Secondly, the public demand for gold ran the Bank's stock down from 38 to 27 millions, and its "reserve" of notes from 25 to 8 millions. Thirdly, a new form of pound had to be instituted to meet the public demand for currency. This was the currency-note, issued by the treasury in denominations of one pound and ten shillings, which, like the sovereign and the bank-note, was legal tender for any amount.

The rise of the pound against the dollar was short-lived, war expenditure, Government borrowing, and heavy purchases of munitions from abroad having their inevitable effect. The check upon inflation imposed by the Peel's Bank Act had been abolished by the institution of the currency-notes, which could be issued without limit. Artificial means were adopted to maintain gold stocks and the pound against foreign currencies. The export of gold and even its withdrawal from the Bank was discouraged, and the exchange on New York was "pegged" at parity. (See PEGGING THE EXCHANGE.) Foreign securities were mobilized and bought up by the British Government to pay for imports of food and munitions, and luxury imports were checked. At home, commodity prices were "controlled."

Great Britain came out of the war with over £320,000,000 in currency-notes and a huge floating debt, much of which was pure inflation, and when the props were removed from the pound the inevitable collapse followed, the relative purchasing power of the pound, wholesale, being as shown below:—

	Purchasing power of the pound					
	June 1914	Dec. 1919	Apr. 1925	Feb. 1928	Sep. 1931	Oct. 1935
Flour, lb.	200	126	113	145	294	209
Potatoes, cwt.	5	2	2	3	3	3
Beef, stone	4	2	3	4	4	4
Cotton, lb.	31	8	19	24	64	37
Wool, lb.	10	3	4	5	13	10
Steel rails, cwt.	3	1	2	2%	2½	2½
Copper, lb.	37	19	37	36	81	65
Steam coal, cwt.	28	10	21	27	26	26
Rubber, lb.	7	8	11	15	101	38
Dollars	4.87	*3.67	4.87	4.88	4.86	4.92

*Jan. 1920; the following month it fell to 3.2.

In round figures, in early 1920, the pound had lost two-thirds of its value, measured in its internal purchasing power, and one-third of its value as against the dollar. Furthermore, in 1919, when the exchange was "unpegged," the export of gold had to be prohibited, or else all Britain's gold stocks would have been lost within a short space of time.

Post-war Recovery.—April 1920 to April 1925 was a period of such drastic deflation that at the latter date the gold standard could be restored; but the currency note remained part of the monetary system; currency notes and bank-notes were made irredeemable in gold on demand; and the Bank of England was not required to sell gold in less quantities than 400 oz. fine (then equal to £1,700 in value). In 1928, the currency-note and bank-note issues were amalgamated under the Bank of England, and the normal fiduciary note issue was fixed at £260,000,000.

Between 1925 and 1931 world prices gradually fell while British costs failed to follow. The result was that British prices stood some 10 per cent above the world level, causing an unbalanced trade position and a steady drain of gold. Through this and other causes, accentuated by the crisis of 1931, Great Britain abandoned the gold standard on September 21, 1931.

Thereafter the Bank of England was not obliged to sell gold at all, and the pound was free to vary in terms of foreign currencies. After many vicissitudes, including the devaluation of the dollar in 1934, the pound settled down at approximately its old parity with the dollar, but at about 60 per cent of its 1925–31 parity with the franc. In 1932 the government established a special Exchange Equalisation Account to minimise fluctuation in the exchange value of the pound. In 1935 there was no prospect of an early return to gold, but British prices had ceased to be above the world level. (See also MONEY; CURRENCY.) (N. E. C.)

POURTALES, COUNT FRIEDRICH VON (1853–1928), German diplomatist, was born at Oberhofen, Switzerland, on Oct. 24, 1853. After a brief period of service in the army, he entered the German Foreign Office in 1880. He was for the seven years immediately preceding the World War, German ambassador at St. Petersburg. He published in 1927, Meine *letzte Verhandlungen in St. Petersburg Ende Juli 1914,* in which he relates his last effort to dissuade the tsar from mobilization in July 1914. He died at Bad-Nauheim on May 4, 1928.

POUSSIN, NICOLAS (1594–1665), French painter, was born at Les Andelys (Eure) in June 1594. He learned painting under Quentin Varin, a local painter, till he went to Paris, where he entered the studio of Ferdinand Elle, a Fleming, and then of the Lorrainer L'Allemand. He improved himself by studying prints after Raphael and Giulio Romano; and in 1624 he proceeded to Rome, where he stayed for six years, and married Anna Maria Dughet, a Frenchwoman. His intimacy with Du Quesnoy, afterwards celebrated under the name of Il Fiammingo, may have led Poussin to the careful study of antique reliefs, many of which he modelled. He also attended the academy of Domenichino, whom he considered the first master in Rome. Among his first patrons were Cardinal Barberini, for whom was painted the "Death of Germanicus" (Barberini palace); Cardinal Omodei, for whom he produced in 1630, the "Triumphs of Flora" (Louvre); Cardinal de Richelieu, who commissioned a Bacchanal (Louvre); Vicenzo Giustiniani, for whom was executed the "Massacre of the Innocents," now in the museum at Chantilly; Cassiano dal Pozzo, who became the owner of the first series of the "Seven Sacraments" (Belvoir castle); and Fiéart de Chanteloup, with whom in 1640 Poussin, at the call of Sublet de Noyers, returned to France. Louis XIII. conferred on him the title of "first painter in ordinary," and in two years at Paris he produced several pictures for the royal chapels (the "Last Supper," painted for Versailles, now in the Louvre) and eight cartoons for the Gobelins, the series of the "Labours of Hercules" for the Louvre, the "Triumph of Truth" for Cardinal Richelieu (Louvre), and much minor work. In 1643, disgusted by the intrigues of Simon Vouet, Feuquières and the architect Lemercier, Poussin withdrew to Rome. There, in 1648, he finished for De Chanteloup the second series of the "Seven Sacraments" (Bridgewater gallery), and also his noble landscape with Diogenes throwing away his Scoop (Louvre); in 1649 he painted the "Vision of St. Paul" (Louvre) for the comic poet Scarron, and in 1651 the "Holy Family" (Louvre) for the duke of Créqui.

The finest collection of Poussin's paintings, as well as of his drawings, is possessed by the Louvre; but, besides the pictures in the National Gallery and at Dulwich, England possesses several of his most considerable works. The "Triumph of Pan" is at Basildon (Berkshire). Other important works are in the collection of Sir Herbert Cook, Richmond; the duke of Bedford, the earl of Carlisle, the earl of Yarborough, the duke of Devonshire, Burdett Coutts and at Longford castle. The Prado, Madrid, the Dresden museum, the Eremitage at Leningrad, possess a number of representative pieces by this prolific master. The prints that have been engraved after his principal pictures amount to upwards of 200.

Nicolas Poussin was an eclectic, selecting and combining what he admired in the classic art of the past. He not only emulated Titian's glowing colour and the rhythm of Raphael's design; he also borrowed figures out of pictures by these masters (from Titian's "Bacchanal" and Raphael's "Stanze" for instance) and introduced them into his canvases. Yet he was no mere copyist. His conceptions are essentially French, and his characters might be staged in one of Corneille's dramas. His art is reasoned and intellectual. The Greek law of unity in space and time is realized. His statuesque figures are ranged parallel to the picture plane as in antique reliefs. The landscape background is similarly arranged; and he applied the principles of figure composition to his landscapes. His influence on French painting was great and lasting. It was felt in the work of successive generations—of David, Ingres, Delacroix, Chassériau, Puvis de Chavannes and Corot, down to modern times. He stands for the classical tradition, for the balance and harmony in things, for the rhythmic movement of line, for decorative arrangement in composition after which modern artists since Cézanne have been striving, in reaction to impressionism. Poussin's immediate follower was Gaspard Dughet, his brother-in-law and pupil, who through this double bond of relationship shared the name of Poussin,

GASPARD POUSSIN (1613–1675) devoted himself to landscape painting and rendered admirably the severer beauties of the Roman Campagna. He worked for three years in the studio of his brother-in-law and then came under the influence of Claude Lorrain. He worked mainly at Rome, thence making excursions to Milan, Perugia, Castiglione, Florence and Naples. A noteworthy series of works representing various sites near Rome is to be seen in the Colonna palace; other important works are in the Doria and Borghese palaces; but one of his finest easel-pictures, the "Sacrifice of Abraham," formerly the property of the Colonna, is now in the National Gallery, London. The frescoes executed by Gaspard Poussin in S. Martino di Monti are in a bad state of preservation. Gaspard died at Rome on May 27, 1675.

See G. P. Bellori, *Le Vite de Pittori, scultori ed architetti moderni* (1672); Sandrart, *Acad. nob. art. pict.*; *Lettres de Nicolas Poussin* (1824); Félibien, *Entretiens* (1666–88); P. Desjardins, *Poussin* (1903): W. Friedländer, *Nicolas Poussin* (Munich, 1914).

POUT or **BIB** (*Gadus luscus*), a small fish of the Mediterranean and the Atlantic coast of Europe, differing from its relative the cod, in the deeper body, larger eye, etc. It is coffee-coloured, with broad, dark transverse bands.

POVERTY LINE. The words "poverty line" have only come into use in comparatively recent years, and probably, to the general public, they merely represent a vague social cleavage between people living in varying degrees of security and comfort and people who are constantly exposed to actual privation. To the social student, however, the term has gradually acquired both greater content and greater precision.

It was first made familiar by Charles Booth, in his monumental *Life and Labour of the People,* commenced in 1886. In analysing the population of London, he divided it into eight classes, four of which he defined as poor, the other four as "above the line of poverty." "My 'poor,'" he wrote, "may be described as living under a struggle to obtain the necessaries of life and make both ends meet, while the 'very poor' live in a state of chronic want. It may be their own fault that this is so: that is another question; my first business is simply with the numbers who, from whatever cause, do live under conditions of poverty or destitution."

Booth found 30% of the population of London living under such conditions, or "below the line of poverty."

Illuminating, however, as were Booth's researches, they left the actual basis of the poverty line indefinite. In 1899 Seebohm Rowntree made a somewhat similar investigation into poverty in York, a city with a population at that time of about 76,000. The comparative smallness of the area covered enabled him to undertake a closer analysis of the poverty problem and to distinguish between "primary" and "secondary" poverty.

By the former he implied poverty due solely to lack of sufficient income to maintain a family of normal size in a state of physical efficiency, even though all the resources available were economically administered. "Secondary" poverty, on the other

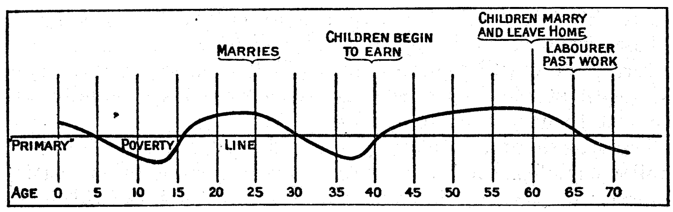

DIAGRAM SHOWING AGES AT WHICH THE POVERTY LINE VARIES

hand, was due to the expenditure of some part of the income on objects other than the maintenance of physical efficiency.

Requirements of Physical Efficiency.—In order to fix his primary poverty line it was necessary to calculate the bare minimum requirements of physical efficiency and the cost of satisfying these. The procedure was as follows:

The requirements of physical efficiency were classified under three headings: (1) Food, (2) House rent including rates, (3) Household sundries, such as clothing, light, fuel, etc. With regard to food, certain standards, in terms of calories per day, were established, in the light of the latest scientific evidence available, for adult males, adult females, and children of varying ages. The standard adopted for the adult male was 3,500 calories per day, this being the amount required for men doing moderate work. Due proportions of this were fixed for women, adolescents and children. In this way the food required by any given family could be expressed in the terms of a common unit, namely, the calories consumed "per man per day." The dietary selected by Rowntree to provide the necessary calories was based upon the cheapest rations falling within the Local Government board order for workhouses, and included no alcohol, no tobacco and no meat, with the exception of a little bacon, being less generous than the average dietary required for workhouse purposes. It was then priced according to the cheapest rate ruling in York at that time, and the following figures were adopted as representing the necessary minimum expenditure for food, viz., 3s. each per week for adults, and 2s.3d. each per week for children.

With regard to rent, the actual sums then paid were taken as the necessary minimum. As regards household sundries, the sum allowed for a family of father, mother and three children for clothing, fuel and all other sundries was 4s. 11d. per week—a figure arrived at after detailed investigation. Allowing 4s. for rent, these figures totalled up to £1 1s. 8d. a week for a family of five. With the prices ruling on Feb. 1, 1928, this figure becomes £2 1s. 11d., made up as follows:—food £1 3s. 11d.; clothing, fuel, and all other sundries 10s. 8d.; rent 6s., and compulsory insurance 1s. 4d. No allowance was made for so much as a tram ride or a postage stamp during the year, or for any expenditure whatever upon moral, mental, or social development, and even the sick club and the funeral club were excluded. The aim was simply to ascertain the lowest cost at which bare physical efficiency could be achieved, if the housewife were a woman of considerable experience, commonsense, and strength of will.

Having fixed the primary poverty line, the next step was to ascertain what proportion of the population of York were living in primary and secondary poverty respectively.

York's Ten Per Cent of Primary Poverty, 1899.—In order to do this trained investigators visited every working class house in York, and gathered together with other facts, information which enabled a reasonably accurate estimate to be made of the income of each family. In the course of the visits note was taken of every family which was evidently living in poverty as judged by the housing conditions and the signs of malnutrition. The number of those living in secondary poverty was ascertained by subtracting from the total population found to be living in poverty those whose incomes placed them below the primary poverty line. It was found that 10% of the total population of the city or 15½% of the working-class population were living in primary poverty, and 18% of the total population or 28% of the working-class population were in secondary poverty. It may be noted that when the two groups of "primary" and secondary poverty are taken together we have figures, namely, 43% of the working classes and 28% of the total population of York, which are readily comparable with the results obtained by Booth.

Rowntree, in analysing the immediate causes of primary poverty, showed that more than one half of it was due solely to the death of the wage earner, 22% to largeness of family, and the rest to miscellaneous causes.

The causes of secondary poverty do not lend themselves to similar classification, but Rowntree stated them as drink, betting, ignorant or careless housekeeping, and other improvident expenditure, and put drink as the predominant factor.

It may be added that subsequent investigators, such as Prof. A. L. Bowley and Miss Hogg, have practically ignored the existence of secondary poverty, concentrating rather on the endeavour to estimate the number of those who in any given area are compulsorily below the poverty line or are living in primary poverty.

Later Enquiries.—The enquiries of Booth and Rowntree were followed by other investigations of particular areas. In 1912 and 1913 investigations were made by Prof. A. L. Bowley and Prof. A. R. Burnett-Hurst into conditions in certain typical provincial towns, namely, Reading, Northampton and Warrington, and the mining area of Stanley. These were supplemented a little later by a similar enquiry into conditions in Bolton, and the results of these researches were published in *Livelihood and Poverty* in 1915. The lines followed were similar to those of Rowntree, save that the method of taking samples of each town was adopted, in place of the investigation of every household. The results were measured by Rowntree's "poverty line" and also by the authors' "new standard," based upon that of Rowntree, with certain minor variations—the general effect of which was to make the standard somewhat higher for an adult and somewhat lower for a child. The net difference per family between the two standards, however, was comparatively slight. With prices ruling on Feb. 1, 1928, Bowley's standard amounted to £2 1s. 2d., made up as follows:—food £1 2s. 6d.; clothing, fuel and sundries 9s. 4d.; rent 8s. 0d., and compulsory insurance 1s. 4d. This compares with Rowntree's £2 1s. 11d.

The conclusion reached by those adopting the new standard, assuming full time wages to be earned in every case, was that in these five towns 11% of working-class families were below the primary poverty line. It should be noted that this figure makes no allowance for loss of earnings due to unemployment, and therefore it cannot properly be compared with Rowntree's figures, which were based upon the actual average income over the year. The fundamental principle, however, that of a poverty line determined by the requirements of bare physical efficiency, remains precisely the same.

Investigation of 1924.—In 1924 a similar investigation was made in the same towns with a view to discovering whether poverty had diminished in the intervening period. The results of this appear in *Has Poverty Diminished?* by Prof. Bowley and Miss Margaret H. Hogg. Taking the "New Standard" as the basis of comparison, and allowing for the increase in the cost of living, the investigation showed that the proportion of the working-class population below the primary poverty line had fallen from 11% in 1912–14 to 3·6% in 1923–4, assuming full time wages to be earned in every case, or to 6·5%, assuming that the actual incomes of the families observed during the week of the investigation were equal to their average weekly incomes throughout the year. The latter basis is the more appropriate for purposes of comparison with Rowntree's figures.

Although not claiming exact accuracy, such figures afford strong evidence that the volume of poverty in Britain has continued to diminish throughout the first quarter of the 20th century. Probably the proportion of the population living below the primary poverty line in 1925 was less than half the proportion in 1900. At the same time the gravity of the position should not be underestimated. Taking 6·5% of the working-class population as representing 4% of the total population, we had in 1924 in the British Isles practically 2,000,000 persons living below the standard necessary for the maintenance of mere physical efficiency. Moreover, the number of different individuals who at one time or other fall below the poverty line is much greater than those who fall below it at a given moment.

From the national standpoint it is serious that in any given family the period of greatest want occurs before any of the children begin to earn. At that time those living near the poverty line are liable to fall below it, and the stress is most severe upon the younger children, and women who are bearing children. According to Bowley and Hogg, even in our improved post-war conditions, more than one child in six lives below the poverty line at some period, while a smaller proportion of children live below it for many years together.

Nevertheless, there has certainly been a striking reduction in the proportion of primary poverty. One of the outstanding characteristics of post-war conditions is the rise in the real wages of the lowest paid labour. Between 1913 and 1924 the wages of unskilled labour approximately doubled, whilst the cost of living was only 70% higher. A second characteristic is the reduction in the average size of the family. The census figures of 1921 showed the average number of children under 14 years of age per "family" to be 1·12 against 1·29 in 1911. Thus, the effect of increased wages in reducing poverty appears to be twice as great as the reduction in the size of families.

All the above figures refer to Great Britain only. There are no comparable figures for other countries—though undoubtedly the proportion of people below the poverty line is less in the British Dominions and in the United States than in Great Britain. It may possibly be less in Holland, Denmark and Switzerland; but, in the absence of figures, this is only guess-work. It is almost certainly greater in the other European countries, while in Japan, China and India it is enormously greater, even after making full allowance for differences in climate and national customs. To raise the standard of living in the East is perhaps the most urgent material task confronting civilisation.

POVINDAH, a class of warrior nomadic traders in Afghanistan, who belong chiefly to the Ghilzais. Their name, which designates their occupation, is derived from the same root as the Pushtu word for "to graze." They are almost wholly engaged in the carrying trade between India and Afghanistan and Central Asia.

See Census of India 1921, Vol. I. 1924, p. 96.

POWELL, FREDERICK YORK (1850–1904), English historian and scholar, was born in Bloomsbury, London, on Jan. 14, 1850. Much of his childhood was spent in France and Spain. He was educated at Rugby, and at Christ Church, Oxford, was called to the bar at the Middle Temple in 1874, and married in the same year. He became law-lecturer and tutor of Christ Church, fellow of Oriel college, delegate of the Clarendon Press, and in 1894 he was made regius professor of modem history in succession to J. A. Froude. He assisted Professor Gudbrandr Vigfússon in his *Icelandic Prose Reader* (1897), *Corpus poeticum boreale* (1887), *Origines islandicae* (1905), and in the editing of the Grimm Centenary papers (1886). He took a keen interest in the development of modern French poetry, and Verlaine Mallarmé and Verhaeren all lectured at Oxford under his auspices. He was also a connoisseur in Japanese art. York Powell befriended refugees after the Commune, counting among his friends Jules Vallès the author of *Les Réfractaires;* and he was also a friend of Stepniak. He died at Oxford on May 8, 1904.

See the *Life,* with letters and selections, by Oliver Elton (1906).

POWELL, JOHN WESLEY (1834–1902), American geologist and ethnologist, was born at Mount Morris, N.Y., March 24, 1834. His parents were of English birth, but had moved to America in 1830, and he was educated at Illinois and Oberlin colleges. He began his geological work with a series of field trips including a trip throughout the length of the Mississippi in a rowboat, the length of the Ohio, and of the Illinois. When the Civil War broke out he entered the Union Army as a private, and at the battle of Shiloh he lost his right arm but continued in active service, reaching the rank of major of volunteers. In 1865 he was appointed professor of geology and curator of the museum in the Illinois Wesleyan university at Bloomington, and afterwards at the Normal university.

In 1867 he commenced a series of expeditions to the Rocky Mountains and the canyons of the Green and Colorado rivers, during the course of which (1869) he made a daring boat-journey of three months through the Grand Canyon; he also made a special study of the Indians and their languages for the Smithsonian Institution, in which he founded and directed a bureau of ethnology. His able work led to the establishment under the U.S. Government of the geographical and geological survey of the Rocky Mountain region with which he was occupied from 1870 to 1879. This survey was incorporated with the United States geological and geographical survey in 1879, when Powell became director of the bureau of ethnology. In 1881, Powell was appointed director also of the geological survey, a post which he occupied until 1894. He died in Haven, Ma, on Sept. 23, 1902.

His principal publications were: *Exploration of the Colorado River of the West and its Tributaries* (1875), *Report on the Geology of the Eastern Portion of the Uinta Mountains* (1876), *Report on the Lands of the Arid Region of the United States* (1879), *Introduction to the Study of Indian Languages* (1880), *Canyons of the Colorado* (1895), *Truth and Error* (1898).

POWELL, VAVASOR (1617–1670), Welsh Nonconformist, was born in Radnorshire and educated at Jesus College, Oxford. About 1639 he became an itinerant preacher, and for preaching in various parts of Wales he was twice arrested in 1640. During the Civil War he preached in and around London. In 1646 he returned to Wales, and with a salary granted by parliament resumed his itinerant preaching. In 1650 parliament appointed a commission "for the better propagation and preaching of the gospel in Wales," and Powell acted as one of the principal advisers of this body. In 1653 he returned to London, and having denounced Cromwell for accepting the office of Lord Protector he was imprisoned. At the Restoration in 1660 he was arrested for preaching, and after a short period of freedom he was again seized, and he remained in prison for seven years. He was set free in 1667, but in 1668 he was again a prisoner, and he died in custody on Oct. 27, 1670.

See *The Life and Death of Mr. Vavasor Powell* (1671), attributed to Edward Bagshaw the younger; *Vavasoris Examen et Purgamen* (1654), by E. Allen and others; D. Neal, *History of the Puritans* (1822); and T. Rees, *History of Protestant Nonconformity in Wales* (1861).

POWER. The word "power," as used by the engineer, indicates energy under human control and available for doing mechanical work. The principal sources of power are the muscular energy of men and animals; the kinetic energy of the winds and of streams; the potential energy of water at high levels, of the tides and of waves; the heat of the earth and of the sun; and heat derived from the combustion of fuels. Of these sources of power the winds, waves and solar heat suffer the disadvantage of being essentially intermittent and therefore requiring some method of storage of power if the demand for power is continuous. From the point of view of the size and cost of the power plant, when large amounts of power are required, windmills, wave motors, and solar engines are not adaptable to large-scale power-generation; tidal power, while it may be developed in certain places for large power, usually entails excessive first cost; volcanic power or natural steam has been used in Italy and experimented with in California; hydraulic turbines and heat engines alone permit the construction of compact plants of practically unlimited capacity and of moderate first cost. The commonly accepted unit of power is the horse-power, which was defined by James Watt in 1783 as the equivalent of 33,000 ft.lb. of work per minute. This is about ten times as much work as can be done per minute by a labourer working eight hours per day.

The use of domesticated animals was the first enlargement of the power of man and the beginning of his civilization. The use of the wind for sailing vessels was an early development but its use in operating windmills dates from about the 12th century. Water-wheels were known in Greek times and are described by Vitruvius, but their capacity was very small. To the end of the 18th century the largest water-wheels for industrial use did not exceed 10 horse-power. The earliest operative heat engine is the cannon, used first at the end of the 13th century. The social consequences of its invention were momentous; it had a great part in the destruction of the feudal system. It represented a greater concentration of power than had been possible previously. Its indirect influence in stimulating the development of the art of cutting metals is of prime importance in the history of the heat engine.

The special incentive which gave birth to the steam engine was the desire to remove water from mines (particularly the tin mines of Cornwall). In 1698 Capt. Savery's engine was patented and a number of his engines were built. They were found to be extravagant in their use of coal. Four years later the first steam engine using a cylinder and piston was devised by Newcomen. It was while repairing a model of this engine that James Watt made the improvements that resulted in the modern steam engine. In 1782 Watt patented a double-acting rotative engine which, for the first time, made steam-power available for driving all kinds of mechanism. The result of this invention was the factory system and the industrial revolution. It became possible also to apply steam-power to navigation and to railroads.

The next important advance in power generation was the invention by Fourneyron of the hydraulic (reaction) turbine in 1827, for utilizing the energy of water available under high heads. Impulse water-turbines of the Pelton type, adapted to use the highest heads, were developed in California about 1860. Hydraulic turbines have now reached a high degree of perfection giving efficiencies in excess of 90%. The largest unit built up to 1928 has a capacity of 100,000 horse-power.

The thermal efficiency of a heat engine is a function of the maximum and minimum temperatures of the working substance and also of the cycle of operations. The cycle of maximum efficiency for given temperature limits is the Carnot cycle. Combustion, which is the source of heat in heat engines, either may occur outside the engine (external combustion) or may occur inside the engine (internal combustion). In external-combustion engines the working substance is distinct from the products of combustion and heat travels to it by conduction through containing walls such as boiler heating-surface. The maximum temperature of the working substance is then limited by the strength of the containing walls at high temperature; in 1928 the practical limit of temperature was about 900° F. With internal combustion the products of combustion are used as the working substance and there is no maximum temperature limit since the containing walls, piston and valves can be water-cooled. The theoretical thermal efficiency of the steam turbine, operating under the limiting conditions of 1928, is about 36%, of the Diesel engine about 50%. The brake thermal efficiencies actually realized are considerably lower. The internal-combustion engine is compact, of light weight, instantly available for use, has low labour cost and no stand-by losses. Its principal disadvantage is that it uses a fuel more costly than coal except in Diesel engines utilizing the cheapest grades of oil.

The first practical internal-combustion engine was that of Lenoir (1860). Two years later Beau de Rochas showed that for good efficiency it is necessary to compress the explosive mixture before igniting it; and in 1876 this idea was effectively realized in a successful explosion engine by Otto. The Otto cycle is the standard cycle in automobile, aeroplane and many stationary and marine engines. The fuel used by Lenoir and Otto was coal gas but in 1883 Daimler substituted volatile liquid hydro-carbon fuel (gasolene or petrol) and thereby made the engine available for automotive purposes. The use of less volatile hydro-carbon fuels (kerosene, fuel oil, etc.) was first successfully developed by Hornsby in the Hornsby-Ackroyd engine of 1894. A year later Diesel built his first engine, in which the air is brought up to the temperature of ignition of the fuel by the work of compression alone and fuel is injected in a finely atomized state after the compression is completed. It is possible to burn in it any fuel that can be atomized by high pressure air injection, by spraying under very high pressure through small openings, or by other means. It offers the combination of the cheapest fuel and the highest efficiency of utilization. The Diesel engine was slow in development at first because of many practical difficulties, especially from heat stresses. Its use in the automotive field is just beginning, particularly for trucks. In the aviation field it is particularly desirable in order to diminish the fire risk of the fuel.

The principal uses for power up to about 1890 were for driving shafting, pumps, compressors and hoists, for locomotives and for marine propulsion. With the improvements that had recently been made in the use of electricity the power station appeared. Electricity is a means for transmission of power and the only means which is economical for long distances and for complicated systems. The earlier power transmission systems by rope drives, compressed air and water under pressure, were too costly and cumbersome to survive. The maximum size of the electrical units installed increased rapidly from about 150 kw. in 1886 to 5,000 kw. in 1900.

The larger the engine the lower is its rotation speed. Large reciprocating engines are complex, heavy and costly, adapted only to special conditions. In 1884 Parsons had taken out a patent for a reaction steam turbine and in 1891 made it into a condensing unit and began to supply it to electric-power stations. In 1889 De Laval introduced the first practical impulse steam turbine. These turbines and those developed from them operate at high speeds of rotation, occupy little space, require no fly-wheels, are exceedingly simple, and have high steam efficiencies. The largest unit built up to 1929 is of 208,000 kw. capacity. This is equivalent to 279,000 h.p. or the work of 837,000 horses, or over 8,000,000 men working eight-hour shifts. Single power plants develop over 1,000,000 kilowatts.

In order to obtain high thermal efficiency it is desirable not only that the maximum temperature of the working substance should be high but also that the amount of thermal energy available at high temperature should be considerable. This condition exists with a saturated vapour because the abstraction of latent heat results in change of state without change in temperature. For this reason pressures of 1,400 lb. per square inch are now being used in a few plants, corresponding to a saturation temperature of nearly 600° F. At the critical pressure the temperature is only a little over 700° F, so that the limit of possible efficiency with steam is nearly reached; higher efficiencies with external-combustion engines can be obtained by the use of a combination of two working substances or the so-called binary-fluid system. A large-scale installation of a mercury-water system has yielded a brake thermal efficiency of about 35%, which is much more than is possible with any steam plant and practically the same as for a good Diesel engine. This system is still regarded as under development. The natural line of progress in power generation would seem to be the development of an internal-combustion turbine. Unfortunately all attempts along this line appear destined to fail until progress in metallurgy has produced some metal which will maintain adequate strength at high temperatures and also until the compression of the charge can be carried out much more efficiently than is possible with present-day centrifugal compressors.

The history of the development of power shows a constant striving for greater economy, greater compactness of the units and greater capacity of each unit. The present limits of capacity have already been indicated and they will certainly be extended. The cost of power is now becoming so low that no considerable improvement is to be anticipated. In a steam-turbine plant, with a consumption of 1 lb. of coal per hour per horse-power and with coal at \$5 per ton, the cost of the fuel is $\frac{1}{2500}$ of the cost of man-power when labour is paid \$5 per eight-hour day. The total cost of power, taking all costs into consideration, is only about $\frac{1}{800}$ of the cost of man-power. In a Diesel engine plant the cost of power is still lower.

POWER ALCOHOL: *see* Alcohol in Industry.

POWER AMPLIFIER. In radio work the ratio of the alternating-current power produced in the output circuit to the alternating-current power supplied to the input circuit is known as the power amplification. A power amplifier is an amplifier which is capable of producing relatively large power in an output circuit. (*See* Amplification.)

POWER OF ATTORNEY or Letter of Attorney is a written authority, usually, though not necessarily, under hand and seal, empowering the person named therein to do some act or acts on behalf of the principal, which otherwise could only be done by the principal himself. It is either general or special. A general power of attorney authorizes the agent to act for his principal in all matters, or in all matters of a particular nature, or generally in respect of a particular business. A special power of attorney authorizes the agent to represent his principal only in regard to some particular specified act. A power of attorney expires with death of the principal, and is revocable at his will, even by a verbal notice, unless it has been given for a valuable consideration to secure some interest of the donee. The law relating to powers of attorney is a branch of the law of agency. Powers of attorney are used freely in the United States where their form and usage follow that of England. (*See* PRINCIPAL AND AGENT.)

POWERS, HIRAM (1805–1873), American sculptor, the son of a farmer, was born at Woodstock, Vt., on June 29, 1805. In 1819 his father removed to Ohio, where the son attended school for about a year. After leaving school he found employment in a reading-room in the chief hotel of the town; but, being, in his own words, "forced at last to leave that place as his clothes and shoes were fast leaving him," he became a clerk in a general store in Cincinnati and afterwards a mechanic in a clock and organ factory. In 1826 he began to frequent the studio of Eckstein, and at once conceived a strong passion for sculpture. His proficiency in modelling secured him the situation of general assistant and artist of the Western museum in Cincinnati, where his ingenious representation of scenes in Dante's Inferno met with extraordinary success. At the end of 1834 he went to Washington, where his remarkable gifts soon awakened attention. In 1837 he settled in Florence, Italy, where he remained till his death. While he found it profitable to devote the greater part of his time to busts, his best efforts were bestowed on ideal work. In 1839 his statue of "Eve" excited the admiration of Thorwaldsen, and in 1843 he produced his celebrated "Greek Slave," which at once gave him a place among the leading sculptors of his time. Among the best known of his other ideal statues are the "Fisher Boy," "Il Penseroso," "Proserpine," "California," "America" (modelled for the Crystal Palace, Sydenham), and the "Last of his Tribe." He died on June 27, 1873.

POWER TRANSMISSION. The appliances connected with installations for the utilization of natural sources of energy may be classified into three groups:—(1) Prime movers, by means of which the natural form of energy is transformed into mechanical energy. To this group belong all such appliances as water turbines, steam turbines, steam engines and boilers, gas producers, gas engines, oil engines, etc. (2) Machinery of any kind which is driven by energy made available by the prime mover. To this group belong all machine tools, textile machinery, pumping machinery, cranes—in fact every kind of machine which requires any considerable quantity of energy to drive it. (3) The appliances by means of which the energy made available by the prime mover is transmitted to the machine designed to utilize it. The term *power* is used to denote the rate at which energy is transmitted. The unit of power in common use is the horse power, and one horse power means a rate of transmission of 550 foot-pounds per second.

In many cases the prime mover is combined with the machine in such a way that the transmitting mechanism is not distinctly differentiated from either the prime mover or the machine, as in the case of the locomotive engine. In other cases the energy made available by the prime mover is distributed to a number of separate machines at a distance from the prime mover, as in the case of an engineer's workshop. In this case the transmitting mechanism by means of which the energy is distributed to the several machines has a distinct individuality. In other cases prime movers are located in places where the natural source of energy is abundant, namely, near waterfalls, or in the neighbourhood of coal-fields, and the energy made available is transmitted in bulk to factories, etc., at relatively great distances. In this case the method and mechanism of distribution become of paramount importance, since the distance between the prime mover and the places where the energy is to be utilized by machines is only limited by the efficiency of the mechanism of distribution.

Prime movers are considered in the articles STEAM ENGINE; INTERNAL COMBUSTION ENGINES; DIESEL ENGINE; TURBINE, STEAM; MOTOR, ELECTRIC; HYDRAULIC MACHINERY, and machines are treated in various special articles. For the methods and mechanisms of distribution or transmission reference should be made to the following articles:

1. ELECTRICAL POWER TRANSMISSION
2. HYDRAULIC POWER TRANSMISSION
3. POWER TRANSMISSION, MECHANICAL
4. PNEUMATIC POWER TRANSMISSION

and to the articles ELECTRICAL POWER, NATIONAL AND REGIONAL SCHEMES; ELECTRICITY SUPPLY; ELECTRIFICATION OF INDUSTRY; POWER TRANSMISSION: VARIABLE GEARS. (X.)

POWER TRANSMISSION, MECHANICAL

Mechanical transmission of power is effected generally by means of belts or ropes, by shafts or by wheel gearing and chains. Each individual method may be used separately or in combination. The problems involved in the design and arrangement of the mechanisms for the mechanical distribution of power are conveniently approached by the consideration of the way in which the mechanical energy made available by an engine is distributed to the several machines in the factory. By a belt on the fly-wheel of the prime mover the power is transmitted to the line shaft, and pulleys suitably placed along the line shaft by means of other belts transmit power, first, to small countershafts carrying fast and loose pulleys and striking gear for starting or stopping each engine at will, and then to the driving pulleys (*q.v.*) of the several machines.

Quantitative Estimation of the Power Transmitted.—In dealing with the matter quantitatively the engine crank-shaft may be taken as the starting point of the transmission, and the first motion-shaft of the machine as the end of the transmission so far as that particular machine is concerned.

Let T be the mean torque or turning effort in ft.lb. which the engine exerts continuously on the crank shaft when it is making N revolutions per second. It is more convenient to express the revolutions per second in terms of the angular velocity ω, that is, in radians per second. The relation between these quantities is $\omega = 2\pi N$. Then the rate at which work is done by the engine crank shaft is $T\omega$ foot-pounds per second, equivalent to $T\omega/550$ horse power. This is now distributed to the several machines in varying proportions. Assuming for the sake of simplicity that the whole of the power is absorbed by one machine, let T_1 be the torque on the first motion-shaft of the machine, and let ω_1 be its angular velocity, then the rate at which the machine is absorbing energy is $T_1\omega_1$ foot-pounds per second. A certain quantity of energy is absorbed by the transmitting mechanism itself for the purpose of overcoming frictional and other resistances, otherwise the rate of absorption of energy by the machine would exactly equal the rate at which it was produced by the prime mover assuming steady conditions of working. Actually therefore $T_1\omega_1$ would be less than $T\omega$ so that

$$T_1\omega_1 = \eta T\omega,$$

where η is called the efficiency of the transmission. Considering now the general problem of a multiple machine transmission, if T_1, ω_1, T_2, ω_2, T_3, ω_3, $\cdots$ are the several torques and angular velocities of the respective first motion shafts of the machines,

$$(T_1\omega_1 + T_2\omega_2 + T_3\omega_3 + \cdots) = \eta T\omega \qquad (2)$$

expresses the relations which must exist at any instant of steady motion. This is not quite a complete statement of the actual conditions because some of the provided energy is always in course of being stored and unstored from instant to instant as kinetic energy in the moving parts of the mechanism. Here, η is the over-all efficiency of the distributing mechanism. We now consider the separate parts of the transmitting mechanism.

Belts.—Let a pulley A (fig. 1) drive a pulley B by means of a leather belt, and let the direction of motion be as indicated by the arrows on the pulleys. When the pulleys are revolving uniformly, A transmitting power to B, one side of the belt will be tight and the other side will be slack, but both sides will be in a state of tension. Let t and u be the respective tensions in pounds on the tight and slack side; then the torque exerted by the belt on the pulley B is $(t-u)r$, where r is the radius of the pulley in feet, and the rate at which the belt does work on the pulley is $(t-u)r\omega$ foot-pounds per second. If the horse power required to drive the machine be represented by h.p., then

$$(t-u)r\omega = 550 \text{ h.p.}, \tag{3}$$

assuming the efficiency of the transmission to be unity. This equation contains two unknown tensions, and before either can

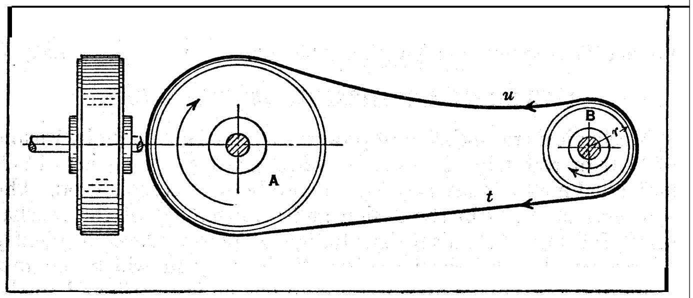

FIG. 1.— SHOWS BELT TORQUE

be found another condition is necessary. This is supplied by the relation between the tensions, the arc of contact θ, in radians (fig. 2), the coefficient of friction μ between the belt and the pulley, the mass of the belt and the speed of the belt. Consider an element of the belt (fig. 2) subtending an angle $d\theta$ at the centre of the pulley, and let t be the tension on one side of the element and $(t+dt)$ the tension of the other side. The tension tending to cause the element to slide bodily round the surface of the pulley is dt. The normal pressure between the element and the face of the pulley due to the tensions is $t\,d\theta$, but this is diminished by the force necessary to constrain the element to move in the circular path determined by the curvature of the pulley. If W is the weight of the belt per foot, the constraining force required for this purpose is $Wv^2d\theta/g$, where v is the linear velocity of the belt in feet per second. Hence the frictional resistance of the element to sliding is $(t-Wv^2/g)\mu d\theta$, and this must be equal to the difference of tensions dt when the element is on the point of slipping, so that $(t-Wv^2/g)\mu d\theta = dt$. The solution of this equation is

$$\frac{t-Wv^2/g}{u-Wv^2/g} = e^{\mu\theta}, \tag{4}$$

where t is now the maximum tension and u the minimum tension, and e is the base of the Napierian system of logarithms, 2.718. Equations (3) and (4) supply the condition from which the power transmitted by a given belt at a given speed can be found. For ordinary work the term involving v may be neglected, so that (4) becomes

$$t/u = e^{\mu\theta}. \tag{5}$$

Equations (3) and (5) are ordinarily used for the preliminary design of a belt to calculate t, the maximum tension in the belt necessary to transmit a stated horse power at a stated speed, and then the cross section is proportioned so that the stress per square inch shall not exceed a certain safe limit determined from practice.

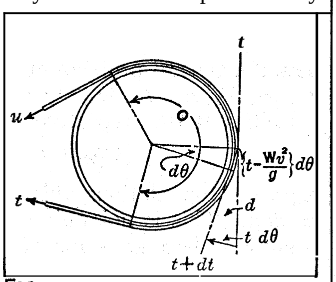

FIG. 2.— COEFFICIENT OF FRICTION

To facilitate the calculations in connection with equation (5), tables are constructed giving the ratio t/u for various values of μ and θ. (See W. C. Unwin, Machine *Design*, 12th ed., p. 377.) The ratio should be calculated for the smaller pulley. If the belt is arranged as in fig. 1, that is, with the slack side uppermost, the drop of the belt tends to increase θ and hence the ratio t/u for both pulleys.

Example of Preliminary Design of a Belt.—The following example illustrates the use of the equations for the design of a belt in the ordinary way. Find the width of a belt to transmit 20 h.p. from the flywheel of an engine to a shaft which runs at 180 revolutions per minute (equal to 18·84 radians per second), the pulley on the shaft being 3 ft. diameter. Assume the engine flywheel to be of such diameter and at such a distance from the driven pulley that the arc of contact is 120°, equal to 2·094 radians. and further assume that the coefficient of friction $\mu = 0{\cdot}3$. Then from equation (5) $t/u = e^{2.094\times 0\cdot 3} = 2.718^{0.6282}$; that is $\log_e t/u = 0.6282$, from which $t/u = 1{\cdot}87$, and $u = t/1{\cdot}87$. Using this in (3) we have $t(1-1/1{\cdot}87)\ 1{\cdot}5\times 18{\cdot}84 = 550\times 20$, from which $t = 838$ lb. Allowing a working strength of 300 lb. per square inch, the area required is 2.8 sq.in., so that if the belt is $\frac{1}{4}$ in. thick its width would be 11·2 in., or if $\frac{3}{16}$ in. thick, 15 in. approximately.

The effect of the force constraining the circular motion in diminishing the horse power transmitted may now be ascertained by calculating the horse power which a belt of the size found will actually transmit when the maximum tension t is 838 lb. A belt of the area found above would weigh about 1·4 lb. per foot. The velocity of the belt, $v = \omega r = 18{\cdot}84\times 1{\cdot}5 = 28{\cdot}26$ ft. per second. The term Wv^2/g therefore has the numerical value 34.7. Hence equation (2) becomes $(t-34{\cdot}7)/(u-34{\cdot}7) = 1{\cdot}87$, from which, inserting the value 838 for t, $u = 464{\cdot}5$ lb. Using this value of u in equation (1)

$$\text{H.P.} = \frac{(838-464{\cdot}5)\times 18{\cdot}84\times 1{\cdot}5}{550} = 19{\cdot}15.$$

Thus with the comparatively low belt speed of 28 ft. per second the horse power is only diminished by about 5%. As the velocity increases the transmitted horse power increases, but the loss from this cause rapidly increases, and there will be one speed for every belt at which the horse power transmitted is a maximum. An increase of speed above this results in a diminution of transmitted horse power.

Belt Velocity for Maximum Horse Power.—If the weight of a belt per foot is given, the speed at which the maximum horse power is transmitted for an assigned value of the maximum tension t can be calculated from equations (3) and (4) as follows:—

Let t be the given maximum tension with which a belt weighing W lb. per foot may be worked. Then solving equation (4) for u, subtracting t from each side, and changing the signs all through: $t-u = (t-Wv^2/g)\ (1-e^{-\mu\theta})$. And the rate of working U, in foot-pounds per second, is

$$U = (t-u)v = (tv - Wv^3/g)(1-e^{-\mu\theta}).$$

Differentiating U with regard to v, equating to zero, and solving for v, we have $v = \sqrt{(tg/3W)}$. Utilizing the data of the previous example to illustrate this matter, $t = 838$ lb., $W = 1{\cdot}4$ lb. per foot, and consequently, from the above expression, $v = 80$ ft. per second approximately. A lower speed than this should be adopted, however, because the above investigation does not include the loss incurred by the continual bending of the belt round the circumference of the pulley. The loss from this cause increases with the velocity of the belt, and operates to make the velocity for maximum horse power considerably lower than that given above.

Flexibility.— When a belt or rope is working power is absorbed in its continual bending round the pulleys, the amount depending upon the flexibility of the belt and the speed. If C is the couple required to bend the belt to the radius of the pulley, the rate at which work is done is $C\omega$ foot-pounds per second. The value for C for a given belt varies approximately inversely as the radius of the pulley, so that the loss of power from this cause will vary inversely as the radius of the pulley and directly as the speed of revolution. Hence thin flexible belts are to be preferred to thick stiff ones. Besides the loss of power in transmission due to this cause, the bending causes a stress in the belt which is to be added to the direct stress due to the tensions in the belt in order to find the maximum stress. In ordinary leather belts the bending stress is usually negligible; in ropes, however, especially wire rope, it assumes paramount importance, since it tends to overstrain the outermost strands and if these give way the life of the rope is soon determined.

Rope Driving.— About 1856 James Combe, of Belfast, introduced the practice of transmitting power by means of ropes run-

Whitworth's quick return motion principle. S. Triple and single friction drives. T. Eccentric friction drive

2. PRINCIPLE OF RATCHET PAWLS AND SAWS

A. Pawls of various forms used on ratchet wheels to prevent backward motion. B. Intermittent circular motion from constant rotary motion. C. Pawl giving intermittent circular motion from reciprocating circular motion. D. Double pawl ratchet wheel, with lever, used in non-concentric shaft. E. Double pawl ratchet using claw movement. F. Intermittent circular motion from reciprocating circular motion used on concentric shafts. G. Geneva movement giving intermittent circular motion from constant circular motion used on the motion picture machine. H. Intermittent circular motion employing bell crank. I. Intermittent rotary motion from a shaft at right angles. J. Vibrating toothed wheel giving quick return rectilinear motion. K. Wave motion given to bell crank from constant circular motion. L. Double pawl ratchet in different form as (E.) M. Ratchet head with spring pawls. N. Ball and roller bearings for reducing friction. O. Intermittent circular motion from pendulum motion of a lever by friction pawls. P. Band saw for scroll sawing. Q–R. Jig saw for scroll sawing. This has a reciprocating motion: (Q) jig saw; (R) source of power. S. Vertical and circular gang saws, for multiple work. T. Drum cam giving reciprocating motion ning in grooves turned circumferentially in the rim of the pulley (fig. 3). The ropes may be led off in groups to the different floors of the factory to pulleys keyed to the distributing shafting. A groove was adopted having an angle of about 45°, and this is the angle still used in the practice of Messrs. Combe, Barbour and Combe, of Belfast. A section of the rim of a rope driving wheel showing the shape of the groove for a rope of $1\frac{3}{4}$ in. diameter is

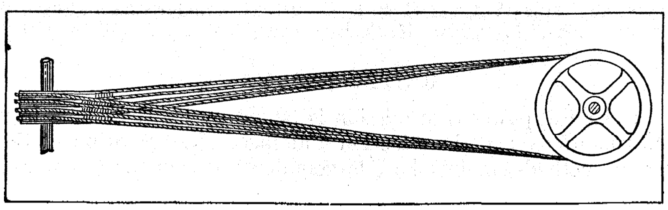

FIG. 3.— GROUP SYSTEM OF ROPE DRIVE

shown in fig. 4, and a rope driving pulley designed for six $1\frac{3}{4}$ in. ropes is shown in fig. 5. A rope is less flexible than a belt, and therefore care must be taken not to arrange rope drives with pulleys having too small a diameter relatively to the diameter of the rope. The principles of §§ 3, 4, 5 and 6, apply equally to ropes, but with the practical modification that the working stress in the rope is a much smaller fraction of the ultimate strength than in the case of belting and the ratio of the tensions is much greater. The following table, based upon the experience of Messrs. Combe, presents the practical. possibilities in a convenient form:—

Diameter of rope	Smallest diameter of pulley, which should be used with the rope	H.P. per rope for smallest pulley at 100 rev. per minute
In.	In.	
$\frac{3}{4}$	14	$\frac{5}{8}$
1	21	1
$1\frac{5}{8}$	42	8
$2\frac{1}{8}$	66	16

The speed originally adopted for the rope was 55 ft. per second. This speed has been exceeded, but, as indicated above, for any particular case there is one speed at which the maximum horse power is transmitted, and this speed is chosen with due regard to the effect of centrifugal tension and the loss due to the continual bending of the rope round the pulley Instead of using one rope for each groove, a single continuous rope may be used, driving from one common pulley several shafts at different speeds. For further information *see* Abram Combe, *Proc. Inst. Mech Eng.* (July 1896). Experiments to compare the efficiencies of rope and belt driving were carried out at Lille in 1894 by the *Société Industrielle du Nord de la France*, for an account of which *see* D. S. Capper, *Proc. Inst. Mech. Eng.* (October 1896). Cotton ropes are used extensively for transmitting power in factories, and though more expensive than Manila ropes, are more durable when worked under suitable conditions.

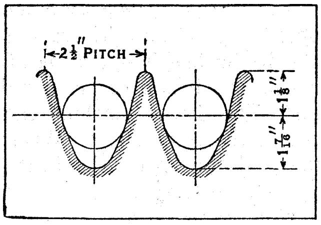

FIG. 4 —SECTION OF RIM FOR ROPE PULLEY DRIVE

Shafts.—When a shaft transmits power from a prime mover to a machine, every section of it sustains a turning couple or torque T, and if w is the angular velocity of rotation in radians per second, the rate of transmission is $T\omega$ foot-pounds per second, and the relation between the horse power, torque and angular velocity is

$$T\omega = 550\,\text{H.P.} \tag{6}$$

The problem involved in the design of a shaft is so to proportion the size that the stress produced by the torque shall not exceed a certain limit, or that the relative angular displacement of two sections at right angles to the axis of the shaft at a given distance apart shall not exceed a certain angle the particular features of the problem determining which condition shall operate in fixing the size. At a section of a solid round shaft where the diameter is D inches, the torque T inch-pounds, and the maximum shearing stress f pounds per square inch, the relation between the quantities is given by

$$T = \pi D^3 f/16, \tag{7}$$

and the relation between the torque T, the diameter D, the relative angular displacement θ of two sections L inches apart by

$$T = C\theta\pi D^4/32L, \tag{8}$$

where C is the modulus of rigidity for the material of the shaft. Observe that θ is here measured in radians. The ordinary problems of shaft transmission by solid round shafts subject to a uniform torque only can be solved by means of these equations.

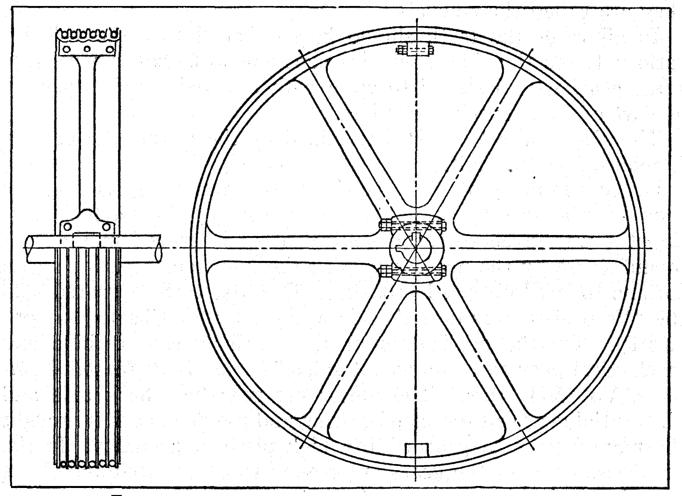

FIG. 5.— DESIGN OF PULLEY FOR SIX ROPE DRIVE

Calculate the horse power which a shaft 4 in. diameter can transmit, revolving 120 times per minute (12.56 radians per second), when the maximum shearing stress f is limited to 11,000 lb. per square inch. From equation (7) the maximum torque which may be applied to the shaft is $T = 138{,}400$ inch-pounds. From (6) $\text{H.P.} = \dfrac{138{,}400 \times 12\cdot 56}{12 \times 550} = 264$. The example may be continued to find how much the shaft will twist in a length of 10 ft. Substituting the value of the torque in inch-pounds in equation (8), and taking 11,500,000 for the value of C,

$$\theta = \frac{138{,}400 \times 120 \times 32}{11{,}500{,}000 \times 3\cdot 14 \times 256} = 0\cdot 057 \text{ radians,}$$

and this is equivalent to 3·3°.

In the case of hollow round shafts where D is the external diameter and d the internal diameter equation (7) becomes

$$T = \pi f(D^4 - d^4)/16D, \tag{9}$$

and equation (8) becomes

$$T = C\theta\pi(D^4 - d^4)/32L. \tag{10}$$

The assumption tacitly made hitherto that the torque T remains constant is rarely true in practice; it usually varies from instant to instant, often in a periodic manner, and an appropriate value of f must be taken to suit any particular case. Again it rarely happens that a shaft sustains a torque only. There is usually a bending moment associated with it. For a discussion of the proper values of f, to suit cases where the stress is variable, and the way a bending moment of known amount may be combined with a known torque, *see* STRENGTH OF MATERIALS. It is sufficient to state here that if M is the bending moment in inch-pounds, and T the torque in inch-pounds, the magnitude of the greatest direct stress in the shaft due to the effect of the torque and bending moment acting together is the same as would be produced by the application of a torque of

$$M + \sqrt{(T^2 + M^2)} \text{ inch-pounds} \tag{11}$$

It will be readily understood that in designing a shaft for the distribution of power to a factory where power is taken off at different places along the shaft, the diameter of the shaft near the engine must be proportioned to transmit the total power transmitted whilst the more remote parts of the shaft are made smaller, since the power transmitted there is smaller.

Gearing. Pitch Chains.—Gearing is used to transmit power from one shaft to another. The shafts may be parallel; or inclined to one another, so that if produced they would meet in a point; or inclined to one another so that if produced they would not meet in a point.

In the first case the gear wheels are called spur wheels, sometimes cog wheels; in the second case bevel wheels, or, if the angle between the shafts is 90°, mitre wheels; and in the third case they are called skew bevels.

In all cases the teeth should be so shaped that the velocity ratio between the shafts remains constant, although in very rare cases gearing is designed to work with a variable velocity ratio as part of some special machines.

The size of the teeth is determined by the torque the gearing is required to transmit.

Gearing is noisy at high speeds unless special care is taken in the manufacture to secure exact uniformity in pitch. Great impetus was given to the development of improved methods of manufacture by the need of gearing the high speed marine steam turbine to the low speed propeller. The first turbine geared ship the "Vespasian" was described in a paper by Sir Charles Parsons entitled "On the application of the marine steam turbine and mechanical gearing to merchant ships." *Proc. Inst. Naval Architects,* Vol. LII. 1910. The motor car gear box, back axle and differential gear call for silent gearing and the demand has brought the manufacture of gearing to a high pitch of accuracy. In the best class of work the gears are ground to exact pitch and shape after hardening,

Pitch chains are closely allied to gearing; examples are offered by many automobile engines, *e.g.,* the pitch chain often found driving the large shaft, etc Pitch chains ane used to a limited extent as a substitute for belts, and the teeth of the chains and the teeth of the wheels with which they work are shaped on the same principles as those governing the design of the teeth of wheels.

If a pair of wheels is required to transmit a certain maximum horse power, the angular velocity of the shaft being ω, the pressure P which the teeth must be designed to sustain at the pitch circle is 550 $\mathrm{H.P.}/\omega R$, where R is the radius of the pitch circle of the wheel, whose angular velocity is w.

In the case of transmission either by belts, ropes, shafts or gearing, the operating principle is that the rate of working is constant, assuming that the efficiency of the transmission is unity, and that the product Tw is therefore constant, whether the shafts are connected by ropes or gearing Considering therefore two shafts, $T_1\omega_1=T_2\omega_2$; that is $\omega_1/\omega_2=T_2/T_1$; *i.e.,* the angular velocity ratio is inversely as the torque ratio. Hence the higher the speed at which a shaft runs, the smaller the torque for the transmission of a given horse power, and the smaller the tension on the belts or ropes for the transmission of a given horse power.

Long Distance Transmission of **Power.**—C. F. Hirn originated the transmission of power by means of wire ropes at Colmar in Alsace in 1850. Such a telodynamic transmission consists of a series of wire ropes running on wheels or pulleys supported on piers at spans varying from 300 to 500 ft. between the prime mover and the place where the power is utilized. The slack of the ropes is supported in some cases on guide pulleys distributed between the main piers. In this way 300 h.p. was transmitted over a distance of 6,500 ft. at Freiberg by means of a series of wire ropes running at 62 ft. per second on pulleys 177 in. diameter. The individual ropes of the series, each transmitting 300 h.p., were each 1·08 in. diameter and contained 10 strands of g wires per strand, the wires being each 0.072 in. diameter. Similar installations existed at Schaffhausen, Oberursal, Bellegarde, Tortona and Zürich. For particulars of these transmissions with full details *see* W. C. Unwin's Howard Lectures on the "Development and Transmission of Power from Central Stations" (*Journ. Soc. Arts,* 1893, published in book form 1894). The system of telodynamic transmission would no doubt have developed to a much greater extent than it has done but for the advent of electrical transmission, which made practicable the transmission of power to distances beyond the possibilities of any mechanical system.

Orcutt, "Characteristics and uses of Ground Gears," *Proc. Inst. Mech. Eng.* (1925 Vol. 2). (W. E. D.)

UNITED STATES

Mechanical power transmission is bound by many assumptions and conditions, and the selection and successful operation of the various methods employed are largely dependent upon: (1) source and kind of power; (2) character of equipment to be driven; (3) horse-power, speeds and ratios; (4) supports and foundations; (5) bearings—their construction, type and spacing; (6) lubrication; (7) shafting—size, quality and material; (8) belting—type, width, thickness and method of joining; (9) manner of loading and unloading the power to be transmitted; (10) mechanical and atmospheric conditions involved; (11) relation of distribution to prime mover; (12) alignment; (13) available space; (14) maintenance facilities.

Modern Methods.—Recent years have brought efficient and economical small-powered prime movers and improvements in mechanical power mechanisms. These developments have segregated the transmitting of mechanical power into certain groups which, when employed in proper relation to other essential operating factors, make for economy, efficiency and low maintenance. Modern mechanical transmission systems can be classified as follows: (1) direct motor coupled connection; (2) direct motor belt connection; (3) direct motor chain connection; (4) belt and line shaft group system; (5) gear reduction unit system; (6) open gear connection system; (7) multiple fabric or manila rope systems; (8) the variable speed connection unit; (9) the combination of one or more of the above systems.

Direct motor coupled connections afford compactness and are most extensively employed for the driving of modern machine tools (*q.v.*). The connection medium between motor and the power-receiving shaft should be a flexible coupling.

Direct motor belt connections employ a belt as the connection between the motor and power-receiving shaft of the mechanism and are extensively employed for various apparatus and machine tool driving. With this method any ratio up to 6 to 1 is practicable from the motor to machine.

Direct motor chain connections employ chain of various types as the connection between the motor and power-receiving shaft of the mechanism. It is successfully operated on machine tools and line shaft drives. Ratios up to 7 to 1 on short centres are practicable.

The group system is extensively used in modern industrial operations. Group driving is most practicable from 5 to 50 h.p. and if the line is operating at the normal speeds of 150 to 300 r.p.m., one belted or chain reduction is sufficient from motor to line. The driven machine can be belted from the line through countershafts or direct. With this system, the size of the prime mover is based on the aggregate of the running loads of the machines driven.

Gear reduction unit systems. The electric motor has the inherent characteristic of operating at high speed. In many industrial operations the power-receiving shaft of apparatus or machine to be driven must run at slow speed. Ratios of 50 to 1 and 100 to 1 are frequent from prime mover to apparatus, therefore the use of the modern gear reduction unit. Ratios such as these if attempted by the belting and shafting method would require a large amount of transmission equipment. Spur gear reducers are manufactured with ratios up to 500 to 1 and reduce in a straight line. The worm gear reducer has reached a high state of perfection. The single unit can be employed on drives requiring speed reductions of 100 to 1.

The open gear connection system is employed where extremely close centres and moderate ratios are desired such as on small

Windmill and grinder. O. Chinese tread wheel for power. **P.** Sloping tread wheel platform machine tools and large apparatus. Composition or non-metallic gears are used on the prime mover shaft to eliminate the noise of high speed metallic gears meshing together. Large apparatus at slow speeds are frequently direct geared to the motor and where a greater ratio is necessary than is practicable with one reduction, a back geared motor is employed. This type of motor combines one geared reduction integral with itself.

The multiple fabric rope system is of recent development. The ropes are of "V" shaped endless construction and operate on "V" grooved wheels. Ratios up to 7 to 1 and extremely short centres are possible. It is applicable for direct driving of almost any class of machine or apparatus where adjustment between driver and driven is possible. There are now in use two systems of *manila rope driving:* the American or continuous method and the English or multiple method. The American system employs but one continuous rope winding over all of the grooves with the rope on the slack side forming a loop over an idler sheave and a travelling tightener which automatically regulates the tension of all the wraps of the rope. The English system employs separate and independent endless ropes in each groove of the wheels. The American system will transmit power for great distances and in any direction. The English system is most adaptable for direct high power driving.

Variable speed connection units are used to meet the requirements of numerous industrial operations. Variations in applied speed are absolutely necessary, and the control of this speed change must be smooth or without shock. In modern practice this is accomplished by variable speed motors or by mechanical speed change devices. It frequently happens that it is necessary to employ a *combination of methods* of driving because of limited space. The compactness of modern methods is then an advantage.

Mechanical Consideration. — Consideration affecting power methods are space, speed, ratios and method of control. Mechanical driving requires *space,* the amount being dependent on the method employed. If ratios are low and ample centres are available the "group" system of belt driving should be employed. If space is limited and ratios are high, the close coupled installations such as chain, worm or spur gear reducers, multiple rope and direct gear connections should be used. Space governs moderate *speed ratios,* but available area does not warrant the use of shafting and belting when ratios of 25, 30, 50 and 100 to 1 are necessary. For these ratios gear reduction units should be used.

The method of control is an important factor since it is frequently necessary to change speeds or shut down the machine during operation and then start under load. Unless a slip ring motor is employed, direct connection by any rigid means should not be used. Shafting should be employed for this service equipped with belting or chains controlled by either clutch or shifters.

Plant Considerations. — Plant considerations affecting power methods are power sources and costs. In industry where power is either purchased or generated, the *power source* has no effect on the problem, but in plants where natural power has been harnessed by cumbersome methods and modernizing is desired, the problem is somewhat difficult. Here power is distributed by long lines of shafting and numerous wide belts. If the plant is large, the friction load is high and maintenance excessive. By the installation of gear reduction units and short centre devices much shafting and belting can be removed. *First cost* of mechanical transmission equipment should not be considered to such an extent that the cheapest method is the best. In many instances high initial expenditures are economical. In large industrial operations, *maintenance costs* are of necessity high, but when good quality transmission equipment is installed it should be given care and attention. Careless joining, wrong type and size of belting and injurious dressings are all causes of high maintenance. Inattention to lubrication, poor adjustments, careless installing and overloading cause the maintenance bills to rise on transmission appliances such as bearings, clutches, pulleys and shafting.

Belting. — Power belting is the medium of delivering a given amount of power at a given point at the least cost per unit of time, which should result in the transmission of power at the lowest cost per horse power per year over the longest period of useful service. If the belting fails, the mechanism stops. If the belting slips, the mechanism slows down. It is necessary that the user have some knowledge of the attributes and characteristics of the various power belting materials and the correct atmospheric and mechanical conditions. (*See* BELTING.) The open belted short centre driving installation is not efficient. Its faults have led to the development of modern methods for driving at close centres by flexible shock absorbing non-metallic mediums.

The Automatic idler system is a development of the ordinary tightener pulley. Its chief function is to increase the arc of contact on the driving pulley. The fulcrum or idler pulley is applied to the belt so as to equal the belt tension and to increase the arc of contact both permanently and automatically and in accordance with the load transmitted. The permanent increase is attained by the proper location of the idler fulcrum. The automatic increase is accomplished by wrapping every possible inch of belting around the smaller of the two pulleys. The elongation or stretch of the belt due to its elasticity is in synchronism with the variations in the power transmitted; when the power is maximum, the arc and the grip of the belt on the pulley is also maximum.

The multiple "V" shaped rubber and fabric rope drive is an adaptation of the English multiple endless rope-driving method with the exception that it employs "V" shaped ropes made of rubber and fabric composition operating on multiple "V" grooved wheels. It is an excellent transmitter of power at close range. The greater the load tension, the greater the adhesion to the grooves of the wedge-shaped belting sheaves, therefore, slip is almost entirely eliminated. This method of driving is successful on short centre work, with centre distances up to 12 feet. It has a range in power capacity from $\frac{1}{2}$ h.p. to 2,000 h.p., depending on the number and size of "V" ropes employed.

High Ratio Short Centre Device. — There are occasions for ratios from 15 to 1 to 30 to 1. Solving such reductions by shafting and belting may be out of the question. Worm gear or spur gear reduction units may be too rigid. To meet such requirements a new device has been recently developed, which gives a compact, flexible, short-centre and high-ratio drive. It is composed of a gear, pinion, pulley, spindle and fulcrum arm. The pulley and pinion are keyed to the spindle which is supported by the fulcrum arm centred on the shaft to be driven. The gear is keyed on the shaft to be driven and meshes with the pinion on the spindle. Thus, in the rotation of the spindle by the aid of a belt drive to the spindle pulley, the pinion tends to make an epicyclic movement around the gear wheel with which it meshes, but such movement is restrained when the belt has been tensioned and the continued rotation of the pinion will rotate the gear wheel and operate the apparatus or lineshaft. The degree of tension on the driving belt depends upon the inertia to be overcome in starting the load and in the continued running, so that the belt always retains the correct tension for the power requirements. The chief feature of this method of driving is the absolute automatic load tension on the ordinary open driving belt without the aid of spring or weight controlled idler pulleys. The belt is always in correct tension because the load controls it.

Power Shafting Bearings. — There are various types of bearings manufactured for industrial power transmitting. They are designed to support shafting and the factors which determine the selection of any given design are: (1) diameter and speed of shaft; (2) power transmitted and kind of load; (3) supporting structure; (4) lubrication; (5) space limitations; (6) operating conditions. Bearings are made of iron or steel, bushed or lined with brass, bronze and various anti-friction metals. (*See* BEARINGS.) When bearings are lined with babbitt metal, as is common practice, the shaft beds itself down and distributes its weight uniformly over the entire bearing surface. Industrial bearings are subjected to "moderate" or "excessive" pressures. Moderate pressures exist in industrial head, line, jack and counter shaft operations if the correct number of bearings are employed for the load demand. Standard bearings for this class of work have ample bearing surface for the pressures involved. Excessive pressures on bearings are due to extreme weight, pull or thrust conditions. Excessive dead load causes extreme weight. Excessive pull is due to high belt or rope tension. Excessive thrust is due to abnormal duty or to faulty mechanical adjustments.

Solid babbitted bearings of babbitted cast iron should be used on slow speed shafting under $4\frac{7}{16}$ in. diameter. Lubrication is by grease cup or plain oiling. *The split flat box* type of babbitted cast iron, furnished with a cap, is employed where moderate powers and speeds are involved, but not on shafting over $3\frac{15}{16}$ in. diameter. Grease or oil is used as a lubricant.

The self-oiling rigid pillow block type of babbitted cast iron is designed to feed the oil to the shaft, by the ring, chain, collar or capillary method. This type should be lubricated by the ring, chain or collar method up to 110 r.p.m. Above this speed the capillary system should be used.

The angle self-oiling rigid pillow block type is similar to the self-oiling rigid pillow block except that the split is at an angle of approximately 45°. This bearing should be employed when a severe power pull is directly on the cap.

The ball and socket self-oiling pillow block type is of cast iron construction, is equipped with ring or capillary oiling features, accommodates itself to shaft movement and possesses vertical adjustment. It is made in sizes from $1\frac{7}{16}$ in. to $4\frac{15}{16}$ in. diameter. It is employed for shafting supported from concrete piers or timbers and particularly on line shafting supported from walls of buildings.

The adjustable drop hanger is designed to support line shafting. It can also be used for head, jack or counter shafting. It is constructed of cast iron and equipped with a self-oiling bearing. The ball and socket type has vertical adjustment through threaded plungers and side adjustment through slotted holes. in the base. The 4-point suspension type can be adjusted both vertically and horizontally but the bearing is held more rigidly than that of the ball and socket type. These types of hangers are manufactured for shafting $\frac{15}{16}$ in. to 6 in. diameter.

The adjustable ball and socket post hanger type is of cast iron and is equipped with a self-oiling bearing. It is designed for head and line shafting that must be supported from columns. It has vertical adjustment and the bearing can arrange itself to the shaft movement. It is made for shafting $\frac{15}{16}$ in. to 6 in. diameter. (*See* BEARINGS.)

Transmission by chain has progressed to the extent that there is a type of chain for most any service. The general advantages of chain driving are: (1) very high efficiency; (2) relatively high speeds available; (3) reversability; (4) unaffected by heat, cold or moisture; (5) wide power transmitting range; (6) a positive velocity ratio; (7) utility on short or long centres; (8) security from slippage.

Detachable malleable iron chain is composed of individual malleable iron links so designed as to allow ease of assembly. It finds application in practically every form of industry where the speeds and ratios are held within 400 r.p.m. and under, and the ratio held to not more than j to 1.

Steel Roller Chains.—While malleable iron chains have given satisfactory service for the transmission of power in their field, a demand for chains which will operate at higher speeds and carry heavier loads was responsible for the development of a more accurate steel chain. These chains range from a rugged low speed class to machine finished high speed chains.

Light steel roller chain is an accurately pitched chain of light construction, three times the tensile strength of the malleable iron type and operates on the same cast tooth sprockets. It is constructed with medium carbon hot rolled steel side bars. The pins and bushings are of hardened steel and the rollers are of either malleable iron or hardened steel. It is applicable where the speeds and ratios are held within 700 r.p.m. and under, and the ratio held to not more than 5 to 1.

Finished steel roller chain is intended for general power transmission purposes and operates on accurately cut sprocket wheels. This chain is manufactured in a number of pitches ranging from $\frac{1}{2}$ to 4 inches. It is constructed with special rolled steel, heat-treated side bars. The pins are made from alloy steel hardened and the bushings are steel, case hardened. The rollers are high carbon steel. heat treated and can either be made curled or solid. It can be had either riveted or detachable and is made in single or multiple widths. It is possible to operate this chain at 1,000 f.p.m. and with ratios up to 10 to 1, but it is more desirable from an economical and long life standpoint to limit its operating speed to approximately 700 r.p.m. and its ratio to 7 to 1.

The silent chain is manufactured for any reasonable power capacity, and is designed for high speeds. It is therefore employed in connection with motor applications. The silent chain is an assembly of specially designed links which operate on cut tooth sprockets, generally termed pinion and gear. The silent chain drive is applicable in all channels of industrial operations. It is particularly adaptable for direct chain connection between motor and machine or motor and line, head or counter shafting. The most desirable speed for this type of chain is 1,200 to 1,500 r.p.m. and ratios of 1 j to 1 have proven successful. (*See* CHAIN MANUFACTURE.)

Gear **Reduction** Units.—Motor speeds of 500 to 1,800 revolutions per minute are too high for industrial purposes, therefore, some mechanical reduction medium must be interposed between the motor and driven machine. The modern speed reduction gear unit has made possible the elimination of a multiplicity of chains, gears, shafting and belting for ratios such as 15 to 1 and higher. It utilizes four general types of gearing, namely, the worm, the spur, the herringbone and the bevel. Reduction units using these various types are available in suitable sizes and ratios for almost any power and speed reduction required. Each type has inherent limitations, therefore, care should be exercised based on a knowledge of the units in question before a selection is made for a particular requirement. One of the most important factors in the successful operation of a speed reduction gear whether it be the worm, spur, herringbone or bevel type, is the connection to the motor and the connection to the shaft of the driven machine or apparatus. The flexible type of coupling is imperative at these points, because it is not mechanically possible to line two shafts perfectly, each supported on its own bearings, so that both will revolve about the same axis.

The efficiency of a modern *worm gear speed reducer* is entirely dependent in many cases on the helix angle of the thread of the worm. The greater the helix angle (up to about 42°) the greater the efficiency; and the smaller the angle, the greater the power loss. The worm of a modern reducer is usually integral with an alloy steel shaft with threads hardened and ground. This combination is rigidly supported on ball or roller bearings, the rear bearing being of the double row maximum type, capable of carrying the full thrust load of the worm in either direction as well as one half the radial load. The other half of the radial load is taken by the forward bearing. The worm gear usually consists of a chilled cast bronze rim shrunk on and pinned to a high grade cast iron centre. The housing of the reducer is cast iron, compact and sealed tight so that the oil in which the gearing operates can be perfectly maintained.

Ratios of 60 or 70 to 1 are common, but beyond this the efficiency drops rapidly. To obtain higher reductions and stih retain the right angle feature of the worm drive, two methods may be employed. One is to provide an auxiliary shaft supported independently, on which is mounted a pinion which in turn meshes with another gear. Another more recent method is to employ a reduction unit specially designed with suitable bearings to permit the mounting of the pinion directly on the slow speed shaft. For special applications and ratios up to 10,000 to 1, the double reduction worm gear unit may be employed. Modern worm gear reduction units can be operated at worm speeds up to 4,000 r.p.m. and are therefore, suitable for direct connection to steam turbines.

The spur gear reduction ***unit*** has been evolved to cope with ratios as high as 500 to 1 and reduces in a straight line. The spur gear reducer can be classified into two distinct types, the planetary and the non-planetary. The planetary type is capable of giving the largest speed reduction because it consists of spur gears or idlers radially disposed about a central pinion and in turn mesh with a stationary internal gear. The planetary reducer with single reduction is satisfactory for ratios between 4 and 8 to 1, but shouid not be considered for ratios of less than 3 to 1. High ratios such as

100, 200, 400 and 500 to 1 are obtainable in the planetary type by the reductions being doubled or tripled and coupled in series in the same cast iron housing. The non-planetary type of spur gear reducer has the advantage of giving comparatively low reductions and keeping the rotational speeds at minimum. Ratios as low as 1 to 1 and as high as 300 to 1 are practical with the non-planetary system. This type consists usually of spur gears radially disposed about a central pinion. Each of the spur gears is keyed directly to pinions which in turn mesh with a central gear mounted upon the slow speed shaft.

***The** herringbone gear speed reducer* does not possess the right angle feature of a worm drive nor the "shafts in line" feature of the spur gear reduction unit. It reduces in parallel. The single reduction type is manufactured up to a ratio of 8 to 1. In ratios over this the reduction is obtained in two steps. There are two distinct types of the double herringbone reduction unit. One type consists of two sets of herringbone gears arranged in series. In the other type, the first set of gears is split, one set being cut right and the other left hand. They are mounted far enough apart to allow the insertion of the final drive pinion between the helical gears This form of construction equalizes the loads of all bearings as well as making a more compact drive. These two types are manufactured in ratios up to 60 to 1.

Variable Speed Mechanisms.—Methods both electrical and mechanical have been devised for varying applied speed to apparatus. For many operations of this character, the variable speed motor is ideal, but generally, this type of motor possesses a certain definite range of speed alterations, and therefore is not suitable for close speed adjustment. Fine adjustment is possible with modern mechanical speed transformers. These devices operate in connection with constant speed motors and are most efficient. There are certain phases of industrial operations where speeds must be gradually increased or decreased, otherwise destruction of the product results. For operations such as this, the mechanical speed transformer is imperative. (W. STA.)

VARIABLE GEARS

This article is concerned with variable transmission of power, and not merely variable speed transmission, otherwise it would have to include the consideration of a multitude of appliances such as speed indicators, integrators and many kinds of calculating machines.

Power transmission gears may be divided into two classes (1) that in which there is a step by step change and (2) that in which the change is gradually effected and an infinite range of velocity ratio is possible.

Step by step variable gears are familiar to all who have passed through an engineer's workshop, in which lathes, drilling machines and other tools are operated by stepped belt pulleys or trains of wheels of different size, these devices being used to effect variable transmission. A familiar example on the roads is the motor-car, in which with very rare exceptions the change of speed is effected by means of a gear box containing a number of different sized pairs of tooth wheels, arranged so that a change of speed can be effected at will by operating a gear lever. On the other hand infinitely variable transmission is less familiar and until comparatively recent times had no particular application except for very light powers. The increasing employment of infinitely variable transmission is due to the fact that the electric motor, steam turbine, and most of all the internal-combustion engine (*q.v.*) have for many purposes superseded the steam engine. One feature of the greatest value in the steam engine is its flexibility; the inferiority in this direction of other kind; of motive power being very marked. For this reason there have been attempts in recent years to find either by frictional, electric, hydraulic or other mechanical means some practicable and effective form of infinitely variable transmission.

Before proceeding to describe various types of variable transmission it must be understood that it is quite possible to vary the speed of transmission by a slipping clutch and claims are often put forward for such a clutch as effecting infinitely variable transmission. This, however, is not correct, being only a case of variation in speed by a direct loss of energy and not true variable transmission. The true test of variable transmission is as to whether it fulfils, at any rate approximately, what is called the Law of Work that "what is lost in force is gained in speed" and vice versa. Thus, for instance, apart from the unavoidable loss of efficiency due to friction, either a train of wheels or a combination of belt pulleys obey the law of work and overcome a greater resistance by a corresponding reduction of speed. On the other hand, if a lesser resistance is to be overcome the rate of operation can be proportionately increased by suitable alteration of the train of wheels employed.

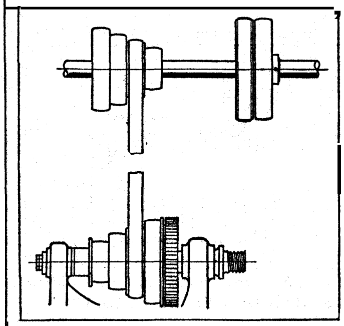

FIG. 1.— DIAGRAM SHOWING STEP PULLEY SYSTEM OF BELT DRIVE FOR AN ORDINARY LATHE

Classification of Methods.—In order to understand the different types of variable transmission they may be classified under the following heads; Frictional, Mechanical, Pneumatic, Electric, and Hydraulic.

Frictional.—Fig. 1 shows the step pulley system, the lower series operating in the headstock of the lathe, and the upper deriving motion from the driving shaft. As the belt is shifted from right to left off and on the different pulleys the speed of the lathe can be increased; or when from left to right the opposite effect is obtained. Corresponding to step by step movement, fig. 2 shows an infinitely variable transmission by pulleys which forms part of the cotton spinning device of Houldsworth invented just a century ago. Here the variation of speed between the driving and driven pulleys is obtained by shifting the belt to and fro along drums of nearly conical form. A modern form of variable transmission was in 1910 and later applied successfully to motor bicycles. Each pulley has a groove of "V" shape, the driving and driven pulleys being both capable of expansion and contraction. This expansion or contraction is effected by shifting in one direction or another the conical movable side of the pulley. The closer the sides come together the greater will be the effective diameter of the pulley. Powerful springs ensure that the driving belt shall be gripped on both pulleys, an idle wheel running between two pulleys accurately to secure the correct location of the conical surface.

A development is now taking place of this type of variable transmission for larger powers. In a useful form variation of the distance apart of the conical sides of a driving and driven pulley is effected when much power has to be transmitted by a hand wheel that operates a combination of worm and worm wheel so as to turn to other worms and thereby move levers, which respectively operate the movable cheeks of the conical pulleys either inwards or outwards. In all probability the oldest type of infinitely variable gear is that in which a friction roller is moved edgeways to and fro on the disk or circular flat plate. If, as in a certain type of motor-car the speed of the driven disk is least when the roller 'is nearest the edge, the greatest driving force is then obtained. On the other hand, when the roller has approached towards the centre of the disk p the greatest speed is obtained with corresponding reduction of driving force. The power transmitted with this gear is however comparatively small as it depends entirely on frictional contact of the surfaces and the wear of the frictional surfaces is considerable.

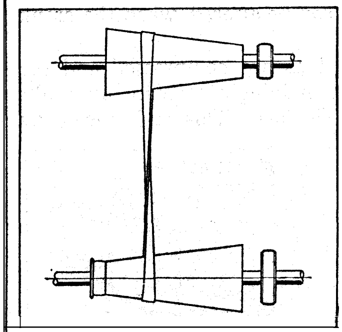

FIG. 2.— DIAGRAM OF A VARIABLE TRANSMISSION BY PULLEYS

Mechanical.——Variable transmission of mechanical kind can be said to be practically confined to the employment of trains of toothed wheels. The most familiar case of mechanical gearing is that of a lathe headstock, in which by coupling up the largest step pulley to the spur wheel to the spindle of the headstock a direct drive is obtained from the speed pulleys. If this coupling is released and by means of a handle shown in the figure the back axle is approached to the main spindle so as to bring into engagement the two pairs of tooth wheels, the driving now takes place through the pinion driven by the step cone pulley through the axle shaft, and back to the lay spindle. Increase of driving force with corresponding reduction of speed is thus obtained which in the present example is nine times as great as by the direct drive.

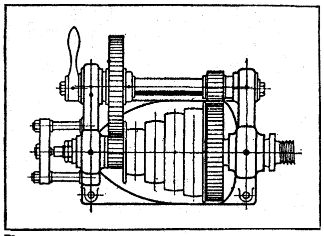

FIG. 3.— VARIABLE TRANSMISSION AS USED IN A LATHE HEADSTOCK

In a standard type of motor car change speed gear box, the engagement of different ratios of spur wheels and pinions is obtained by sliding the teeth sideways into mesh with each other. This is called the "clash" engagement. In another type of gear box no such sideway sliding takes place, the teeth of the respective wheels being always in mesh with each other. Change of gear in this case is effected by sliding the different jaw clutches into engagement with each other.

Pneumatic. — Many attempts have been made to introduce pneumatic variable transmission since 1900 by Dunlop, Lenz, Lebach and others The best account of these pneumatic devices as applied on a large scale to locomotives was given in La Revue *Générale* des *Chemins* de Fer, May 1923, by Brillé. Up to the present these devices, though extremely interesting and ingenious, have not proved efficient in practice.

Electrical. — Various inventors have suggested continuously variable electric change speed gear As already explained a mere reduction of effort by interposed resistance is not a true variable transmission, and all the most important examples of real variable electric transmission as on electric railways, is of essentially a step by step nature. Locomotive systems such as Crochat's mine locomotive, the loco-tractor of Moyse, those of Westinghouse, of Sultzer Diesel and Dewa are on the same fundamental principle as the Tilling-Stevens electric transmission, namely, production of electrical current by a dynamo from an internal-combustion engine and the operation by an electric motor of some form of gearing to turn the wheels.

Hydraulic. — The last form of transmission, and in its development the most recent, is hydraulic transmission. A beautiful device by Hastie was described as long ago as 1881. By means of two springs the stroke of the crank can be altered, when the crank pin slides in a groove

When the effort is great the springs are compressed and the stroke is increased correspondingly, enabling a constant hydraulic pressure to overcome a variable resistance. This resistance may vary within wide limits, with the corresponding econom) in the matter of the fluid employed. In the foregoing case the working fluid was water supplied by a high-pressure hydraulic main on the principle first introduced by Armstrong. Modern hydraulic variable gear in which oil is the working fluid has been brought into extensive operation chiefly to enable electrical power to overcome very variable resistance without causing a rise in the amperes transmitted. The principle of operation is exactly identical with the generation of electrical current by a dynamo, which current is transformed into mechanical effort by an electrical motor. In the case of hydraulic transmission, however, a variable stroke pump is employed to produce a flow of incompressible fluid, generally oil, which operates in a hydraulic motor. Thus it is only necessary to effect a change in the stroke of the pump when any required hydraulic pressure can be obtained with the great advantage of not unduly increasing the driving effort on the pump.

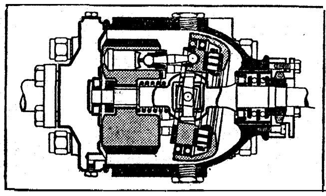

FIG. 4.— SECTION OF ONE ELEMENT OF THE JANNEY-WILLIAMS HYDRAULIC VARIABLE GEAR

Hydraulic variable gear has been employed for a great variety of purposes such as cranes, lifts, winches, tipping wagons, rail cars, gun mountings, planing and broaching machines, swing bridges, etc. The chief types of these gears may be distinguished as parallel and radial. Fig. 4 shows a section of the Janney-Williams gear (either pump or motor) which is an example of the former type, and it will be seen that the variation in effort is attained by varying the angle of what is known as a swash plate, with the result of altering the stroke of the pistons. As the stroke is reduced the working pressure can be increased; thus when the stroke is very small a very great pressure can be produced and consequently great resistance can be overcome. The necessary valve action is obtained by causing the opening at the inner end of the cylinders to pass in succession the supply and exhaust ports.

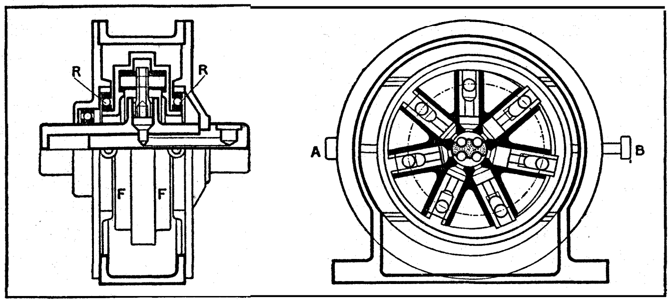

FIG. 5.— THE HELE-SHAW RADIAL STROKE PUMP

In the operation of the one radial type pump, the cylinder body revolves about a fixed axis which forms a cylindrical valve. As the cylindrical body revolves, the working fluid is alternately admitted from and exhausted into the two ports respectively. The fluid comes in under no pressure from the port and is driven out under any required pressure from the port along the shaft. In order to obtain any required variation of pressure the frame to which the connecting rod ends are attached is made to pivot about the fixed centre by a rod attached to the upper end of the frame. In the middle position there is obviously no stroke, and when the neutral position is passed the direction of flow is reversed.

Two views of another type of radial stroke pump are shown in fig. 5 (Hele-Shaw Pump), the left-hand view being in half section, the lower portion of which shows *ff* a revolving case called the "floating ring." The sectional portion in the view shows that this floating ring is carried on ball races *r* and *r*, their object being to reduce the frictional wear of the rollers or slippers by allowing the floating ring to rotate freely with the cylinder body, in which the pistons are carried. If the floating ring is moved bodily along guides on the line *a-b* (shown in the other view) the stroke of the pistons and the fluid pressure can be varied as required, just as in the previous example.

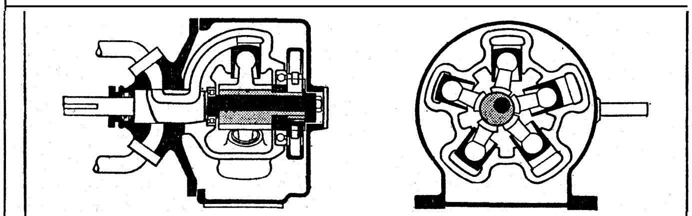

FIG. 6.— THE HELE-SHAW BEACHAM PUMP

An improvement in the foregoing pump has been devised, the Hele-Shaw Beacham pump, in which a central valve is employed, a radical change being effected by what is known in mechanical science as "inversion." Instead of pistons operating outwardly and obtaining their stroke from contact with an eccentric enclosing the whole cylinder body, the pistons are operated from a fixed crank, the cylinder body surrounding the crank and the pistons working inwardly. The variable stroke is obtained by altering the throw of the crank, which is otherwise fixed. The crank is in the form of a live ring mounted with roller bearings on a compound eccentric.

Steam engine with oscillating cylinder dispensing with valve and valve mechanism. D. Oscillating piston engine. E. Double oscillating piston steam engine, early form. F. Eccentric rotary pump or engine, commonly used for positive pressure pumping. G. Gear pump or engine. H. Cross-section of a vertical steam engine with simple sliding valve. I. Steam engine governor, centrifugal type. J. Cross-section of a horizontal slide valve steam engine. K. Cross-section of a triple expansion compound steam engine. L. Steam engine governor, centrifugal type. M. Pelton wheel type steam turbine. N. Hand reversing mechanism for single cylinder steam engine. O. Stephenson link reversing mechanism for steam engines. P. Reaction type steam turbine, commonly used in electrical power plants

2. CLOCK ESCAPEMENTS, HAMMERS, ETC.

A. Early form of clock escapement used in wooden clocks. B. One form of clock escapement. C. Common form of clock escapement. D. Watch escapement mechanism with balance wheel and hair spring. E. Four way link movement. F. Stop wind for watches and clocks. G. Early form of watch showing movement of balance wheel. H. Hand bailing press. I. Gravity trip hammer used in early forging methods. J. Gravity gear drop hammer. K. Gravity cam drop hammer. L. Pneumatic air hammer for light drop forgings. M. Centrifugal air blower. N. Pile driver. O. Conveyor using the principle of Archimedes screw. P. Hand punch using toggle joint

The compound eccentric consists of two parts of equal eccentricity, the stroke-varying mechanism being arranged to effect rotation of these two parts in opposite directions with the result that the resultant eccentricity may be varied at will from zero to maximum in either direction. This gear was fully described in Engineering, Oct. 16, 1925.

Another important feature of the new pump is the fact that instead of the central plane of the valve ports coinciding with the central plane of the revolving cylinder body, it is displaced so that the central planes of the cylinders and that of the valve ports are separated from each other. Fig. 6 is a diagrammatic figure which will make the explanation clear. One remarkable effect is the improvement in the matter of silence. The opening and closing of the ports causes water-hammer blows due to the high pressure in an incompressible fluid. These blows are no longer transmitted so as to cause sound vibrations in the enclosing cylinder body.

POWHATAN. This group of Algonkin Indian tribes in the tide-water portion of Virginia and southern Maryland had been welded into a confederacy by the conquests of an able chief known by the same name, shortly before the settlement of Jamestown in 1607. His daughter Pocahontas married John Rolfe. After Powhatan's death they massacred 347 British settlers in 1622. Fourteen years of relentless warfare followed until the Indians submitted, only to rise again in 1641 and slay 500 whites. This war broke them, and though in 1669 2,100 remained of the original 8,000, they have now dwindled to some 700, mixed with negro and white blood, and known as Chickahominy, Pamunkey, etc. (A. L. K.)

POWIS, EARLS AND MARQUESSES OF. Before the Norman Conquest the Welsh principality of Powis, comprising the county of Montgomery and parts of the counties of Brecknock, Radnor, Shropshire, Merioneth and Denbigh, was subject to the princes of North Wales. Early in the 12th century it was divided into upper and lower Powis. In 1283 Owen ap Griffin, prince of upper Powis, formally resigned his princely title (*nomen* et *circulum principatus*) and his lands to the English king Edward I. at Shrewsbury, and received the lands again as an English barony. (See Montgomeryshire Collections, 1868, vol. i.) This barony of Powis passed through female inheritance to the family of Cherleton and in 1421 to that of Grey. It fell into abeyance in 1551.

In 1587 Sir Edward Herbert (d. 1594), a younger son of William Herbert, earl of Pembroke, purchased some of the lands of the barony, including Red castle, afterwards Powis castle, near Welshpool, and in 1629 his son William (c. 1573–1656) was created Baron Powis. William's grandson, William, the 3rd baron (*c.* 1629–1696), was created earl of Powis in 1674 and Viscount Montgomery and marquess of Powis in 1687. The recognized head of the Roman Catholic aristocracy in England, Powis was suspected of complicity in some of the popish plots and was imprisoned in the Tower of London from 1678 to 1684. He followed James II. into exile and was created duke of Powis by the dethroned king. William, 2nd marquess, who had a somewhat chequered career as a Jacobite, died in October 1745, and when his son William, the 3rd marquess, died in 1748 the titles became extinct.

In 1748 Henry Arthur Herbert (d. 1772), who had been made Baron Herbert of Cherbury in 1743, was created Baron Powis and earl of Powis. The titles became extinct a second time when his son George Edward died in January 1801. George's sister and heiress, Henrietta Antonia (1758–1830), married Edward Clive (1754–1839), son and heir of the great Lord Clive. In 1804, he was created Baron Powis and earl of Powis.

POWNALL, THOMAS (1722–1805), British colonial statesman and soldier, born at Saltfleetby, Lincolnshire, was educated at Lincoln and at Trinity College, Cambridge, where he graduated in 1743. In 1753 he went to America as private secretary to Sir Danvers Osborn, just appointed governor of New York. Osborn committed suicide soon after reaching New York (Oct. 6), but Pownall remained in America, devoting himself to studying the condition of the American colonies. In 1756 he came home, and presented to Pitt a plan for a campaign against the French in Canada, to begin with the investment of Quebec. In 1757 Pitt appointed him governor of Massachusetts; he was transferred to South Carolina in February 1760. This office he held nominally for about a year; but he never went to South Carolina, and in June 1760 he returned to England. In 1762–1763 he was commissary-general of the British troops in Germany. He sat in parliament from 1768 to 1780, and died at Bath on Feb. 25, 1805. In 1764 he published (at first anonymously) his famous Administration of the Colonies advocating a union of all British possessions upon the basis of community of commercial interests.

POYNINGS, SIR EDWARD (1459–1521), lord deputy of Ireland, was the only son of Robert Poynings, second son of the 5th Baron Poynings. His mother was a daughter of Sir William Paston, and some of her correspondence is to be found in the *Paston* Letters. Robert Poynings was implicated in Jack Cade's rebellion, and Edward was himself concerned in a Kentish rising against Richard III., which compelled him to escape to the Continent. He attached himself to Henry, earl of Richmond, afterwards Ring Henry VII., with whom he returned to England in 1485. By Henry VII. Poynings was employed in the wars on the Continent, and in 1493 he was made governor of Calais. In the following year he went to Ireland as lord deputy under the viceroyalty of Prince Henry, afterwards King Henry VIII. Poynings immediately set about Anglicizing the government of Ireland, which he thoroughly accomplished, after inflicting punishment on the powerful Irish clans who supported the imposture of Perkin Warbeck. He then summoned the celebrated parliament of Drogheda, which met in December 1494, and enacted the "Statutes of Drogheda," famous in Irish history as "Poynings's law," subordinating the Irish legislature to that of England, till its repeal in 1782. After defeating Perkin Warbeck at Waterford and driving him out of Ireland, Poynings returned to England in 1496, and was appointed warden of the Cinque Ports. He was employed both in military commands and in diplomatic missions by Henry VII., and later by Henry VIII., his achievement being the negotiation of the "Holy League" in 1513.

See Sir Francis Bacon, *The History of the Reign of King Henry VII.* (1641); Richard Bagwell, *Ireland under the Tudors* (2 vols., 188;); J. T. Gilbert, *History of the Viceroys of Ireland* (Dublin, 1865); J. A. Froude, *The English in Ireland* (3 vols., 1872–74); Wilhelm Busch, *England under the Tudors,* ed. *by* James Gairdner (1895).

POYNTER, SIR EDWARD JOHN, 1ST BART. (1836–1919), English painter, son of Ambrose Poynter, architect, was born in Paris on the 20th of March, 1836. He pursued his art studies in England and in Paris (under Gleyre, 1856–1859), and exhibited his first picture at the Royal Academy in 1861. In 1869 he was elected an A.R.A., and in 1876 R.A.

In the decorative arts he practised freely as a designer in fresco, mosaic, stained glass, pottery, tile-work and the like. He was elected to the Royal Society of Painters in Water Colours in 1883.

As director for art in the Science and Art Department, and principal of the National Art Training Schools (now the Royal College of Art) at South Kensington Poynter proved himself a vigorous and successful administrator. He resigned his office in 1881, and in 1894 became director of the National Gallery. Under his rule the National Gallery of British Art, at Millbank, presented by the late Sir Henry Tate, became a department of the National Gallery. He edited the great Illustrated Catalogue of *the* National Gallery (1889- goo), in which every picture in the collection is reproduced.

On the death of Sir John Millais in 1896, Poynter was elected president of the Royal Academy, and was knighted. He was made a baronet in 1902. Poynter died in London on July 26, 1919.

See Cosmo Monkhouse, "Sir E. J. Poynter, P.R.A.: His Lift and Work." *Art Annual* (1897); *M.* H. Spielmann, "Sir E. J. Poynter. P.R.A., and his Studies," *The Magazine of Art* (1897).

POYNTING, JOHN HENRY (1852–1914), British physicist, was born at Monton, near Manchester, on Sept, 9, 1852. He studied at Owens college, Manchester, and at Trinity college, Cambridge. He was bracketed third wrangler in 1876. Poynting went as demonstrator in physics to Owens college, but returned to Cambridge in 1878 on his election as fellow of Trinity college. In 1880 he was appointed professor of physics at the Mason college, which afterwards became the University of Birmingham. He retained this post until his death at Birmingham on March 30, 1914.

Poynting carried out experiments over a period of 12 years to determine the gravitational constant and the mean density of the earth. He used a balance method and during the course of his experiments added considerable knowledge to the technique of accurate weighing. Poynting's best known work is that in the papers "On the Transfer of Energy in the Electromagnetic Field" (*Phil. Trans. A.*, 1884) and "On Electric Currents and the Electric and Magnetic Induction in the Surrounding Field" (*Phil. Trans. A.*, 1888). In the first paper Poynting showed that the flow of energy at a point could be expressed by a simple formula in terms of the electric and magnetic forces at that point. This is known as Poynting's theorem and the vector is also called by his name. Poynting also wrote papers on radiation and the pressure of light and several books.

Poynting's interests were very wide; he served as a justice of the peace, was chairman of the Birmingham Horticultural Society and acted as dean of the Faculty of Science. He was elected F.R.S. in 1888.

See his *Collected Scientific Papers,* edit. *by G.* A. Shakespear and G. Barlow (1920).

POZAREVAC or **PASSAROWITZ,** the capital of the Pozarevac department of Serbia, Yugoslavia. Pop. (1931) 14,055. It lies 8 m. from its harbour, Dubravitsa, on the Danube. The town has no special industry, but being a road centre, is the principal market of a large and fruitful plain. At Lubichevo, 2 m. W. is a State model farm, a stud farm, and a nursery for mulberries. Lignite is worked at Kostolats, 7 m. N. by E., and the hills in this district show many traces of Roman mines. Roman coins, sarcophagi and inscriptions are also found. The famous Treaty of Passarowitz between Austria and Turkey was signed here in 1718. The town was taken by the Serbs under Kara George in 1804, and in 1815 Prince Milosh of Serbia again defeated the Turks here. Germans occupied it in April 1941.

POZNAN or **POSEN,** a Polish province, bounded north by the province of Pomorze, east by the provinces of Warsaw and Lodz, south and west by Germany. The province was conquered by Germany in Sept. 1939. Area 9,243 sq.mi.; pop. (1931) 2,115,000; in 1935 92% were Poles, 7·9% Germans and 0·1% Jews. The Jews were formerly numerous in the province, but migrated to America in the second half of the 19th century, when the peasants organized co-operative societies. The Germans, who had settled under Government support, left after the reconstitution of the Polish state, in large numbers. The province, which contains 38 districts, has always formed a territorial unit since the dawn of history as Great Poland (Wielka Polska), the seat of the tribe which organized the Polish monarchy, and has always been one of the most enlightened, influential and patriotic parts of Poland. It is part of the central Polish plain, and consists of a low plateau intersected by the beds of the rivers Notec, Warta and Obra. These three rivers drain into the Oder, with which the Warta is also connected by the Obra canal. The east part of the province is in the basin of the Vistula, which is connected with the Notec by the Bydgoszcz canal. The surface is dotted with small lakes and ponds, and there are many broad fens and swamps. The soil is light and sandy, but much of the land reclaimed in the marshy districts is very fertile. The greater part of the province is under tillage, but 17·3% is occupied by forests. The principal crops are rye, wheat, oats, barley, potatoes, beets and hops. The vine is cultivated in the south-west corner, and tobacco is also grown. A feature of the country until World War II was the efficient organization of agricultural co-operative societies, culminating in the great union under Father Wawrzyniak, which enabled the Polish peasants to hold their own against their German competitors, and the fact that education made illiteracy, so prevalent in the "Congress Kingdom," a rarity in Poznan. The marshy tracts afford excellent pasture and support large numbers of cattle, horses, sheep and goats. The mineral resources of the province are small, but the industries, at first purely agricultural, such as distilling, brewing, sugar and tobacco, increased with the development of the Polish state. Locomotives are built at Poznan, while Bydgoszcz became the centre of the timber trade for all Poland. A timber exchange was established there, and the first paper mills in Poland. Trade is facilitated by the network of navigable rivers, canals and railways, while the roads are the best in the country. Trade after World War I suffered from the change of markets due to the transference of Poznan from Germany to Poland. There are several large towns: Poznan (272,000 in 1939), Bydgoszcz (141,000) and Gniezno (29,924 in 1931). Other towns are Inowroclaw, Ostrów, Leszno, Krotoszyn, Rawicz and the most ancient town of Poland, Kruszwica.

(A. B. Bo.; X.)

HISTORY

The history of the province of Western or "Great" Poland, of which Poznan (called by the Germans Posen) is the principal city (*see* p. 397), falls within the scope of the article POLAND. One of the oldest towns of the province is Gniezno (German Gnesen), originally the capital of the whole country, and still the seat of the primate of Poland. The tide of German immigration into the province flowed strongly in the 13th and the following centuries. The industrious German settlers were the principal factor in the development of trade and manufacture in the towns; they also did much to improve agriculture in the country. Since the re-union of the kingdom of Poland in the 14th century, the province of Poznan shared the fate of the united country.

During the 17th century, a Swedish invasion ruined the province, the commercial importance of the city began to suffer in consequence of the one-sidedly agrarian spirit of Polish legislation, and the strenuous efforts of the Jesuits, directed against the growth of Protestantism, introduced into the life of Poman the unrest of religious feuds, which were prolonged till the 18th century.

At the first partition of Poland, in 1772, the districts to the north of the river Notec (German, Netze) fell to the share of Prussia. The rest of the province followed in 1793 and 1795, and was united with the territory acquired in 1772 to form the province of South Prussia. In 1807, after the peace of Tilsit, the province was incorporated with the grand duchy of Warsaw, but in 1815 it reverted to Prussia as the grand duchy of Posen,

The Prussian regime, during the first decades after the Congress of Vienna, was conciliatory: a Polish nobleman, prince Anthony Radziwiłł, was appointed lieutenant-governor of the province; there was a provincial assembly, and there were local representative bodies. About 1830, however, a new current set in with the presidency of Flottwell: the experiment of settling subsidized German colonists on Polish soil—started by Frederick the Great in the 18th century—was resumed, and the Polish language deprived of its position of equality with German in the Government offices, the law-courts, and the schools. In the '40s, the revolutionary movement spreading throughout Europe, manifested itself in Prussian Poland and an armed rising in 1848 was suppressed by military force. A highly reactionary Prussian Government arose out of the turmoil of the revolutionary year, and measures of repression against Polish organizations followed. But a resolutely anti-Polish policy on a large scale was only originated by Bismarck, and was carried out in earnest after the creation of the new German empire in 1871. To the landed gentry and the clergy, who had been the mainstay of Polish nationalism so far, there were now added a body of increasingly prosperous and enlightened peasants in the country, and a growing, wealthy Polish middle class in the towns,—all these ranks of society being united in organized opposition to the policy of Germanization. Bismarck aimed cruel blows at the Polish clergy in conducting his *Kulturkampf* against the Catholic element in the ***Reich;*** but the effect was only to rally the Polish masses more effectually round the clergy, who became their leaders in economic as well as in political organization. More success was achieved by the measures in the field of education which gradually made the school system of the province thoroughly German while rendering it at the same time democratic, progressive and highly efficient. Similarly, in the development of the administrative system, improved efficiency and thorough Germanization went together. The powers of resistance of the Polish element, however, rapidly increased with its numbers and its prosperity; and the Prussian Government soon realized that only economic means would serve its ends. In 1888, the Colonizing Commission was established for the purpose of buying up Polish land for German colonists, and it was equipped with 100,000,000 marks (£5,000,000). The Polish element countered the attack by co-operative credit organizations, in which both the peasants and the middle class of the town took a prominent share; and soon the Poles succeeded in buying more land than they lost. The creation of a subsidized society—the Society of the Eastern Marches (known as the H.K.T. from the initials of its founders)—for the promotion of German advance in the east, the great increase of the funds at the disposal of the Colonizing Commission, the creation of a special fund of nearly half a million marks a year towards a campaign against the Polish middle class in the towns—all proved insufficient, and Bulow, Bismarck's most zealous successor, brought new legislative means into play: a bill in 1904 forbidding Poles to establish new peasant farms on soil of their own, and one in 1907 authorizing the Government to dispossess Polish landowners by force. These measures were accompanied by no less drastic ones in the field of education and administration: in 1901, much scandal was roused by the discussion in the Prussian parliament of the incidents at Wrzesnia (Wreschen), where Polish children had been beaten by German schoolmasters for refusing to say the Lord's Prayer in German; and in 1906, the Prussian Government was made somewhat ridiculous by the strike of some 100,000 Polish school-children, which, in spite of severe proceedings against their parents, continued for nearly a whole school year. In 1908, the notorious "Gagging bill" limited to a minimum the right of Polish citizens to form societies, and altogether forbade the use of Polish at public meetings.

The anti-Polish policy of Prussia, although occasionally criticized in the Reichstag, had, on the whole, both a majority of German opinion and the authority of the supreme power in the Reich behind it. But it was largely rendered futile by the disciplined organization of the entire Polish element, as well as by its large and continuous increase in numbers. While the German birth-rate began to fall rapidly, the birth-rate among Polish peasants remained very high; and the political struggle for the land in Prussian Poland resulted in a measure of agricultural prosperity which—in spite of drastic expulsions of foreign subjects, inaugurated by Bismarck in 1885—continued to attract immigrants from other parts of Poland. Prussian Poland shared in the material progress of Germany after 1870, and World War I found this province the most advanced and uniformly wealthy of all the three sections of Poland.

Even after all the losses and privations which the province, however out of sympathy with the German cause, had to undergo with the rest of Germany in 1914–18, the Prussian sector of Poland, when it shook off German domination shortly after the Armistice (Dec. 27, 1918), emerged as still the most prosperous of the three; its territory had not been devastated by actual warfare, as large portions both of Austrian and Russian Poland had. This gave the former Prussian Poles a certain advantage over the others; and they naturally clung to this advantage in the new and united Polish republic after the Peace of Versailles. A customs barrier continued, for a time, to separate the former Prussian province from the body of the new Poland; and a special "Ministry for former Prussian Poland" came into being, which existed for several years.

Such separatism was grounded on a somewhat distinct mentality which the struggle against Prussian rule had developed. The Poles under Prussia had acquired something of that crude belief in sheer force which was characteristic of Germany after 1870. They had not had the opportunities for intellectual refinement which home rule under Austria had given to their Galician brethren; but their peasantry had reached a much higher level of enlightenment than that of either Austrian or Russian Poland. In the new Polish State, in consequence of all this, the former Prussian province represented a solid block of hard-and-fast Nationalism as well as of uncompromising devotion to the Catholic Church, whose services to the national cause in Prussian times were gratefully remembered. Gradually, however, the ties of common political life began to produce their effect, and the parliamentary elections later found the population of former Prussian Poland differentiated politically on the same party lines as the rest of the republic. The new Polish university of Poznan (which had taken the place of a German academy), and other Polish educational and cultural institutions, worked for amalgamation.

Poznan, with half its borders along the German frontier, was difficult to defend in World War II and fell rapidly to the German army in Sept. 1939.

BIBLIOGRAPHY.—The German case, at the height of the anti-Polish policy on the eve of World War I, was summed up in an elaborate work by L. Bernhard, *Das polnische Gemeinwesen im preussischen Staate* (Leipzig, 1907). From the Polish point of view, the history of Prussian policy in Poznan has been told by Professor J. Buzek in *Historja polityki narodowościowej rządu pruskiego 1815–1908* (Lwów, 1909). For the history of the city of Poznan, *see* N. Pajzderski, *Poenan* (Lwów, 1922, ill.). **(R. DY.)**

POZNAN or **POSEN,** capital of the province of Poznan, in Poland, situated in a wide and sandy plain on the Warta, 180 mi. W. from Warsaw and 150 mi. E. from Berlin. Pop. (1939) 272,000. Germany conquered the province in Sept. 1939. Before World War I, half the population were Germans, who had been encouraged to settle by the Prussian government, and who returned to Germany after the restoration of Poland. The city is the centre of a network of railways connecting it with Warsaw, Berlin, Breslau and Torun. It is the centre of one of the five ecclesiastical provinces of the Catholic Church in Poland, and the seat of the most ancient Polish bishopric, founded in the 10th century. The old town (Stare *Miasto*) and the new town lie on the left bank of the Warta, with large suburbs on the right bank. There are 15 Roman Catholic churches, of which the cathedral contains many works of art and the tombs of the two first rulers of Poland. The town hall (Ratuse), rebuilt in 1552, is a magnificent building in the Romanesque style. A legacy of the former Prussian rule is the castle built by William II. There is a large library, the Raczynski library, two museums and a university. Industries are mainly connected with agriculture, such as distilling, brewing, sugar milling, agricultural machinery. The manufacture of locomotives was established after 1918. An annual fair was inaugurated in 1922, and there is an active trade, both by river and rail, in corn, cattle, wood, wool and potatoes.

Poznan is one of the oldest cities in Poland and the residence of the first king, Boleslaw the Brave, and of the first Polish bishop. The original settlement was on the right bank of the river, but German settlers in 1250 made the new town on the opposite bank a flourishing commercial centre. A charter in 1394 gave the city staple right for all wares passing from Poland into Germany, and from Germany into Poland. The German element was assimilated, though many foreigners settled there, including a colony of Scots. After the fires of 1536 and 1590, Poznan, formerly Gothic, was rebuilt in Renaissance style. The prosperity of Poznan declined with the economic decline of Poland in the 17th century, but revived in the 19th century, partly as the natural centre of a great agricultural region, partly as a bulwark of the Poles in their struggle against German penetration.

POZOBLANCO, a town of southern Spain in the province of Córdova, near the head-waters of the Guadamatillas and of other small sub-tributaries of the Guadiana. Pop. (1930), 15,843. Its fairs are famed for their live stock and agricultural products. There are zinc and argentiferous lead mines near by, and manufactures of cloth and leather in the town itself.

POZZO DI BORGO, CARLO ANDREA, COUNT (1764–1842), Russian diplomatist, was born at Alata, near Ajaccio, of a noble Corsican family, on March 8, 1764, some four years before the cession of the island to France. He was educated at Pisa, and in early life was closely associated with Napoleon and Joseph Bonaparte, the two families being at that time closely allied in politics. Pozzo was one of the two delegates sent to the National Assembly in Paris to demand the political incorporation of Corsica in France, and was subsequently a Corsican deputy to the Legislative Assembly, where he sat on the benches of the right until the events of August 1792. On his return to Corsica he was warmly received by Paoli, but found himself in opposition to the Bonaparte brothers, who were now veering to the Jacobin party. Under the new constitution Pozzo was elected *procureur-général-syndic*, that is, chief of the civil government, while Paoli commanded the army. With Paoli he refused to obey a summons to the bar of the Convention, and the definite breach with the Bonaparte family, who actively supported the revolutionary authorities. dates from this time. Eventually Paoli and Pozzo accepted foreign help, and from 1794 to 1796, during the English protectorate of Corsica, Pozzo was president of the council of state under Sir Gilbert Elliot. When Napoleon sent troops to occupy the island he was excepted from the general amnesty, and took refuge in Rome, but the French authorities demanded his expulsion, and gave orders for his arrest in northern Italy. After a short stay in London he accompanied in 1798 Elliot (now become Lord Minto) on an embassy to Vienna, where he lived for six years.

In 1804 through the influence of Prince Adam Czartoryski he entered the Russian diplomatic service. In 1805 he was Russian commissioner with the Anglo-Neapolitan, and in 1806 with the Prussian army. He was entrusted with an important mission to Constantinople in 1807, but the conclusion of the alliance between Alexander I. and Napoleon at Tilsit in July interrupted his career. He returned to Vienna, but on the demand of Napoleon for his extradition Metternich desired him to leave the capital. He then retired to London again and remained in England until 1812, when he was recalled by Alexander. He diligently sought to sow dissension in the Bonaparte household, and in a mission to Sweden he secured the co-operation of Bernadotte against Napoleon. On the entry of the allies into Paris he became commissary general to the provisional government.

At the Bourbon restoration Pozzo di Borgo became Russian ambassador at the Tuileries, and sought to secure a marriage between the duke of Berry and the Russian grandduchess Anna, Alexander's sister. He was present at the Congress of Vienna, and during the Hundred Days he joined Louis XVIII. in Belgium, where he was instructed to discuss the situation with Wellington. The tsar dreamed of allowing an appeal to the people of France on the subject of the government of France in accordance with his vague liberalizing tendencies, but Pozzo's suggestions in this direction were met by violent opposition, the duke refusing to make any concessions to what he regarded as rebellion; in St. Petersburg, on the other hand, Pozzo's attachment to the Bourbon dynasty was considered excessive. During the early years of his residence in Paris Pozzo laboured tirelessly to lessen the burdens laid on France by the allies and to shorten the period of foreign occupation. That his French sympathies were recognized in Paris is shown by the strange suggestion that he should enter the French ministry with the portfolio of foreign affairs.

Pozzo's influence at the Tuileries declined with the accession of Charles X., whose reactionary tendencies had always been distasteful to him; but at the revolution of 1830, when the Tsar Nicholas was reluctant to acknowledge Louis Philippe, he did good service in preventing difficulties-with Russia. In 1832 he visited St. Petersburg; the next year he was in London renewing his relations with Wellington, and early in 1835 he was suddenly transferred to the London embassy in succession to Prince Lieven. Although he did not lose in official standing, Pozzo was aware that this change was due to suspicions long harboured in various quarters in St. Petersburg that his diplomacy was too favourable to French interests. In London his health suffered, and he retired from the service in 1839 to Paris, where he died on Feb. 15, 1842. He had been made a count and peer of France in 1818.

See Ouvaroff, *Stein et Pozzo* (St. Petersburg, 1846); *Correspondance diplomatique du comte Pozzo di Borgo et du comte de Nesselrode*, ed. by Charles Pozzo di Borgo (2 vols., Paris, 1890–1897); Vicomte A. Maggiolo, *Corse, France et Russie. Pozzo di Borgo, 1764–1842* (Paris, 1890); J. B. H. R. Capefigure, *Les Diplomates européens* (4 vols., 1843–1847).

POZZUOLI (anc. PUTEOLI, *q.v.*), a seaport and episcopal see of Campania, Italy, in the province of Naples, $7\frac{1}{2}$ mi. W. of it by rail. Pop. (1936), 24,594 (town); 29.690 (commune). It is on the base of a hill projecting into the Bay of Pozzuoli, separated from the main portion of the Gulf of Naples by the promontory of Posilipo. The volcanic *pozzolana* earth (also found near Rome), used now as in Roman times for making cement and concrete, derives its name from the place. In the middle ages Pozzuoli was frequently sacked and also damaged by the natural convulsions of 1198 and 1538. It has large ironworks and melting furnaces; while to the west is a large artillery factory.

PRABHU, the writer caste of Western India, corresponding to the Kayasth of Bengal. Numbering only 21,941 in Bombay in 1921, they stand high socially and professionally.

PRACTICE AND PROCEDURE. The practice and procedure of the High Court of Justice in England is now regulated by the Judicature Act, 1925 (which repealed and consolidated nearly all the former Judicature Acts), and the various rules of court made pursuant to various Acts passed in and since 1883. Lest the Judicature Acts and Rules as so framed should not provide for every contingency, it was expressly provided by rule in 1883 that "where no other provision is made by the Judicature Act or Rules the procedure and practice existing in 1883 should remain in force." The object of the Judicature Acts and the Rules made thereunder was to improve a system of practice and procedure which had grown up through the centuries. Although those concerned to defend the ancient order were wont to say that it made for precision — particularly in the matter of pleadings there can be no doubt that its advantages were, or became, hidden under its chief defects — prolixity and technicality.

The following is an attempt to state, in outline, the practice and procedure in the High Court in England. In the performance of his task the writer has kept one fact constantly in mind, namely, that if the *reason* for a particular rule or canon of procedure is appreciated, the rule will be better understood. The rules of procedure did not spring into being in a single day: they are the result of years of experience. And it will always be found, that whether it be sound or not there *is* a reason for every rule, howsoever technical it may appear to be.

Some Technical Terms. — He who is minded to study the modern rules of practice and procedure must understand the meaning of various words (often Latin words), and phrases some of which are now obsolete. The following brief glossary may suffice. *Act on Petition* was a term used for a part of the procedure in the probate, divorce and admiralty division, now of infrequent occurrence. It was more freely used in the old admiralty and divorce courts before the Judicature Acts became law. *Answer* in English law was, prior to the Judicature Acts, the statement of defence especially as regards the facts and not the law. It is still applied in divorce proceedings to the reply of the respondents, and it occurs in the phrase "answer to interrogatories." (*See* "Discovery" below.) *Assets* in English law mean the property of a debtor in the hands of his representative sufficient for the satisfaction of his creditors or legatees; the word also occurs in the phrase "administration of assets." (*See* O. 55, r. 3, 4.) An *Associate* is an officer of the supreme court, whose duties are to draw up the list of causes, enter verdicts, hand the records to the parties, etc., and generally to conduct the business of trials. *Assumpsit* (Lat. "he has undertaken") was a word applied to an action for a breach of contract, and was always used in pleadings by the plaintiff to set forth the defendant's undertaking or promise. Hence the phrases "bring *assumpsit*" or "sue in *assumpsit*."

Declaration in an action of English law was formerly the first step in pleading — the precise statement of the matter in respect of which the plaintiff sued. It is also used in other legal connections, *e.g.*, declaration of insolvency, declaration of title. declaration (statutory) in lieu of an affidavit; and dying declaration. *In formâ pauperis* is the legal phrase for a method of bringing or defending a case in court on the part of persons without means. *Information* (*q.v.*) is a proceeding on behalf of the Crown against a subject otherwise than by indictment. Certain suits might formerly be filed in chancery by way of information in the name of the attorney-general. Informations are still filed by the attorney-general in revenue cases in the king's bench, Judgment summons is a summons issued under the Debtors Act 1869, citing a defendant against whom judgment has been entered to appear and be examined as to his means, and to show cause why he should not be committed for non-payment of his debts, *Summons* is, in English law, (1) a command by a superior authority to attend at a given time or place or to do some public duty; (2) a document containing such command. and not infrequently also expressing the consequence entailed by neglect to obey.

Various Forms of "Proceeding."—In the High Court of Justice, civil actions are begun by obtaining from the officers of the court a document known as a "writ of summons." In this document are stated the names of the parties and the nature of the claim made (which in the case of liquidated sums of money must be precise and particular). It is sealed and issued to the party suing it out, and served on the opposing party, not by an officer of the court but by an agent of the plaintiff. The tenor of the writ is to require the defendant to appear and answer the claim, and to indicate the consequences.

Many proceedings in the High Court are initiated by forms of summons different from the writ of summons. Of those issued in the High Court three classes merit mention:—

1. For determining interlocutory matters of practice and procedure arising in "a pending cause or matter." These are now limited as far as possible to a general summons for directions, introduced in 1883 so as to discourage frequent and expensive applications to the masters or judges of the High Court on questions of detail. These summonses are sealed and issued on application at the offices of the High Court. The matters raised are dealt with by a master with an appeal to a judge in chambers summarily. In matters of practice and procedure there is no appeal from a judge at chambers without leave from him or from the court of appeal.

2. For determining certain classes of questions with more dispatch and less cost than is entailed by action or petition. This kind of summons is known as an "originating summons," because under it proceedings may be originated without writ for certain kinds of relief specified in the rules (R.S.C., O. 55, r. 3). The originating summons may be used in all divisions of the High Court, but is chiefly employed in the chancery division, where it to a great extent supersedes actions for the administration of trusts or of the estates of deceased persons, and for the foreclosure of mortgages a similar but not identical procedure was created with reference to questions of title, etc., to real property. In the king's bench and probate divisions the originating summons is used for determining summarily questions as to property between husband and wife, or the right to custody of children, and many other matters (0. 54, rr. 4 B–4 F), but there is nothing to prevent a summons of this kind issuing in the king's bench for the determination of some such question as the construction of a bill of lading. The proceedings on an originating summons are conducted summarily at chambers without pleadings, and the evidence is usually written. In the chancery division when the questions raised are important the summons is adjourned into court. An appeal lies to the court of appeal from decisions on originating summonses. The forms of summonses and the procedure thereon in civil cases in the High Court are regulated by the Rules of the Supreme Court.

3. Certain proceedings on the Crown side of the king's bench division are begun by summons, *e.g.,* applications for bail; and in vacation writs of habeas corpus, *mandamus,* prohibition and certiorari are asked for by summons as the full court is not in session. (*See* Crown Office Rules, 1906.)

Mandamus has always been regarded as an exceptional remedy to supplement the deficiencies of the common law, or defects of justice. The writ is used to compel inferior courts to hear and determine according to law cases within their jurisdiction, *e.g.,* where a county court or justices in petty or quarter sessions refuse to assume a jurisdiction which they possess to deal with a matter brought before them. It has in recent years been employed to compel municipal bodies to discharge their duties as to providing proper sewerage for their districts, etc. The courts do not prescribe the specific manner in which the duty is to be discharged, but do not stay their hands until substantial compliance is established.

Besides the prerogative common law writ there are a number of orders, made by the High Court under statutory authority, and described as, or as being in the nature of, mandamus, *e.g.,* mandamus to proceed to the election of a corporate officer of a municipal corporation (Municipal Corporations Act 1882, s. 225); orders in the nature of mandamus to justices to hear and determine a matter within their jurisdiction, or to state and sign a case under the enactments relating to special cases.

At common law mandamus lies only for the performance of Acts of a public or official character. The enforcement of merely private obligations, such as those arising from contracts, is not within its scope. But now a mandamus may be granted by an interlocutory order of the High Court in all cases in which it shall appear to the court just or convenient that such an order should be made. (O. 53). The remedy which is thus created is an attempt to engraft upon the old common law remedy by damages a right in the nature of specific performance of the duty in question. It is not limited to cases in which the prerogative writ would be granted; but mandamus is not granted when the result desired can be obtained by some remedy equally convenient. beneficial and effective, or a particular and different remedy is provided by statute. An action for mandamus does not lie against judicial officers such as justices. The mandamus issued in the action is no longer a writ of mandamus, but a judgment or order having effect equivalent to the writ formerly used. (*See* INJUNCTION.)

The jurisdiction of the High Court, derived from the court of chancery, to decree specific performance of contracts has some resemblance to mandamus in the domains of public or quasi-public law.

Action at Law.—In English law the term "action" at a very early date became associated with civil proceedings in the court of common pleas, which were distinguished from pleas of the Crown, such as indictments or informations and for suits in the court of chancery or in the admiralty or ecclesiastical courts. The English action was a proceeding commenced by writ original at the common law. The remedy was of right and not of grace. As a result of the reform of civil procedure by the Judicature Acts the term "action" in English law now means at the High Court of Justice "a civil proceeding commenced by writ of summons or in such other manner as may be prescribed by rules of court" (*e.g.,* by originating *summons*). The proceeding thus commenced ends by judgment and execution. The stages in an English action are the *writ,* by which the persons against whom relief is claimed are summoned before the court; the pleadings and interlocutory steps, by which the issues between the parties are adjusted; the trial, at which the issues of fact and law involved are brought before the tribunal; the judgment, by which the relief sought is granted or refused; and *execution,* by which the law gives to the successful party the fruits of the judgment.

The procedure varies according as the action is in the High Court, a county court, or one of the other local courts of record which still survive; but there is no substantial difference in the incidents of trial, judgment and execution in any of these courts.

An action is said to "lie" when the law provides a remedy for some particular act or omission by a subject which infringes the legal rights of another subject. An act of such a character is said to give a "cause of action." When the rights of a subject are infringed by the illegal action of the State, an action lies in England against the officers who have done the wrong, unless the claim be one arising out of breach of a contract with the State, or out of an "Act of State." For a breach by the State of a contract made between the State and a subject the remedy of the subject is, as a general rule, not by action against the agenrs of the State who acted for the State with reference to the making or breach of the contract, but against the Crown itself by the proceeding called Petition of Right.

The Writ of Summons.—This is the universal means of commencing an action in the High Court. It is addressed to the defendant, and may be either generally or specially indorsed with a statement of the nature of the claim made. The latter form of indorsement is allowed in certain cases of debt or liquidated demand, and gives the plaintiff the great advantage of entitling him to sign judgment in default of appearance by the defendant, and even in spite of appearance unless the defendant can satisfy a judge that he ought to be allowed to defend. No statement of claim is necessary in case of a specially indorsed writ, the indorsement being deemed to be the statement. The writ may be issued out of the central office or out of a district registry, and the plaintiff may name on his writ the division of the High Court in which he proposes to have the case tried. There are special rules governing the issue of writs in probate and admiralty actions. The writ remains in force for 12 months, but may be renewed for good cause after the expiration of that time. Application for renewal should, however, be made before the expiration of 12 months from the date of the writ. Service must be personal, unless where substituted service is allowed, and in special cases, such as actions to recover land and admiralty actions. Service out of the jurisdiction of a writ or notice of a writ is allowed only by leave of a judge. Notice of the issue of a writ, and not the writ itself is served on a defendant who is neither a British subject nor in British dominions. The law is contained in the Rules of the Supreme Court, especially Orders ii.–xi. and xiv.

Appearance.—Every writ has upon it a memorandum pointing out to the defendant rhat he must, in due course, enter an appearance, otherwise judgment may be signed against him in default. Appearance is entered by the defendant delivering to the proper officer a memorandum stating the name of his solicitor or that he will defend in person (O. 12, r. 8). He must give notice of appearance to the plaintiff or his solicitor. He must give his address for service which, if he has entered appearance in London, must be within 3 m. of the Royal Courts of Justice, and if in a district Registry, the address must be within the district. In the vast majority of cases the defendant leaves it to his solicitor to enter appearance for him. He may enter a conditional appearance if he disputes the jurisdiction of the court, or desires to allege some informality or irregularity in the service of the writ (O. 12, r. 30).

If the defendant does not enter an appearance and the writ has been specially indorsed (*i.e.*, for a liquidated demand) the plaintiff may sign judgment in default for his debt and costs (O. 13, r. 3). But this rule does not apply where the defendant is an infant or a lunatic—the court, in the exercise of its parental jurisdiction, prohibiting such litigants from compromising without leave. Where, however, a defendant does not appear to a writ in which the plaintiff claims damages or other relief which cannot be claimed in a specially indorsed writ, the plaintiff can only sign on what is called interlocutory judgment, which leaves the *quantum* of the damages to be assessed in such manner as the court may think right (O. 13, r. 5). But judgment for the possession of land may be obtained owing to default in appearance. These rules as to default, however, are subject to this—that any judgment by default may be set aside on such terms as to costs or otherwise as to the court shall seem just (O. 13, r. 10). As a general rule, however, if the judgment has been regularly signed, it will only be set aside on very stringent terms, and the defendant must show that he has a meritorious defence.

Application for Summary Judgment.—Appearance having been entered, the next step is taken by the plaintiff. He issues either a summons for summary judgment or a summons for directions. A summons for judgment *can* only be issued, properly speaking, where the action is brought for a liquidated sum, *e.g.*, for money lent, the amount due, or for a cheque or bill of exchange, or where an action is brought by a landlord to recover possession from a tenant whose term has expired or has been duly determined by notice to quit. In all these cases the application must be supported by an affidavit to the effect that the money, etc., is due, and that, in the belief of the plaintiff there is no defence. If the defendant does not appear, or if he appears and shows no cause to the contrary, judgment will be given forthwith by the master in chambers. Where, however, the defendant appears in answer to the summons and shows by affidavit or otherwise that he has a defence, going to the whole cause of action, leave to defend will be given, and the master will then give directions as to the further conduct of the suit. Sometimes it will appear that the defendant has no answer to part of the claim. In that case the master generally orders payment to the plaintiff's solicitors in a certain time, or judgment in default, and gives directions as to the balance. In rare cases the master will order some part of the money sought to be recovered to be brought into court as a condition of leave to defend. But a plaintiff ought not to proceed for summary judgment unless he has substantial grounds for believing there is no defence to the action. Should it turn out that there is a defence of which he must, or ought to, have known, he runs the risk of having to pay the costs.

This (which has just been described) is the celebrated procedure under Order 14. Unknown to the public, and to a large section of the legal profession, enormous sums of money change hands each year in consequence of orders made by masters in chambers. The successful plaintiff receives a fixed sum for costs, the amount of which varies according to the amount of the claim, Claims for £20 and over may be prosecuted in this way. In its essence, this procedure, which allows a litigant to defend himself only when he swears to a defence, is a survival from ancient times when it was competent for a plaintiff to cause his debtor to be imprisoned unless he could show a defence. Consequently the court always takes a lenient view of any defence which may be put forward, acting on the principle that if the defendant swears to that which, if true, would constitute*a defence, he must not be precluded from putting his case before the court.

Having decided to give leave to defend, the next duty of the master is to say how the case shall be tried. If the issue is clear and simple he has power to send it for trial into the short cause list. In that case it is set down for trial without pleadings, and it comes on for trial before a judge alone in a very short space of time. Where, however, service issues are raised necessitating an order for discovery and pleadings, directions are given providing for those matters and settling the place of trial—whether in London or at assizes. If the amount is under £100, however, the case is generally remitted for trial in the county court, the costs being left to the county court judge. If it involves a technical or scientific enquiry, or the examination of accounts, the master may send it to an official referee. Finally, if the parties agree, he may order it to be tried before a master, who fixes a time and day and hears the whole case with witnesses. His decision on a reference of this kind is subject to an appeal to a divisional court.

From the decision of a master on a summons for judgment, an appeal lies to the judge in chambers, who may reverse or vary the master's order. It not infrequently happens that the party who is unsuccessful before the master carries in fresh evidence before the judge in chambers. From the judge an appeal lies (with leave) to the court of appeal, subject to this, that where the judge has given unconditional leave to defend, there is no further appeal of any kind.

Summons for Directions.—In all other cases commenced by writ and subject to an exception to be presently mentioned, the plaintiff in every action must take out a summons for directions. After the defendant has appeared, and before taking any fresh step in the action, other than applying for an injunction as receiver, or the entering of judgment in default of defence (O. 30, r. 1, [a] and [b]). In so far as it is compulsory, this rule does not apply to admiralty actions, nor to an action where the writ is specially indorsed, nor to any proceeding commenced by originating summons (O. 30, r. 1 [a]). The plaintiff must issue the summons within 14 days of the defendant's appearance, and if he does not do so, the defendant may apply to dismiss the action for want of prosecution. On the hearing of that application, however, the master may give direction (O. 30, r. 8).

The master generally deals in the first instance with the following matters: pleadings, discovery, and place and mode of trial. Either party may make application under it to the master on two days' notice for further directions, and every interlocutory application in an action which has to be made before judgment is so made (O. 30, r. 5). Even an application for leave to discontinue proceedings is so made.

Generally speaking, the effect of the order made on the application for directions is to set the case on its career through the courts.

Parties.—All persons may be joined in one action as plaintiffs in whom any right to relief arising out of the same transaction is alleged to exist, whether jointly or severally, or in the alternative where, if such persons brought suit separately, a common question of law or fact would arise (O. 16, r. 1). Should it appear, however, that any such joinder may embarrass or delay the trial, separate trials may be ordered (ib.). Again, if an action is by accident brought by the wrong plaintiff a new plaintiff may be substituted or added (O. 16, r. 2). As regards defendant, all persons may be joined as such against whom the right to any relief is alleged to exist, whether jointly or severally or in the alternative (O. 16, r. 4). If numerous persons having the same interest in the cause or matter desire to assert or defend their rights, the court may authorize one or more of them to represent all (O. 16, r. 9). As a corollary to the above rules it is important to notice that the court has ample power to strike out parties improperly joined, and to add others who should be before the court in order that the matters in dispute may be effectually determined (O. 16, r. 11). As regards lunatics and infants the rules are strict to prevent anything in the nature of a settlement or compromise of an action save with the consent of the court or a judge. Money recovered by an infant or lunatic may be kept in court or otherwise protected for the benefit of the party concerned.

It has been the law since the days of Henry VIII. that a man may sue in *formâ pauperis.* Formerly he had to show that he was not worth more than £25, his wearing apparel, tools of trade, etc. not being taken into account. He could have a solicitor and counsel assigned to him. Now any poor person (*i.e.,* a person who is not worth more than £50 or such larger sum not exceeding £100 as may be allowed in special circumstances or a person whose usual income is not more than £2 or in special cases £4 a week) may sue or defend without paying court fees and may have a solicitor and counsel assigned to him free of charge. (See generally O. 16 and 22 et *seq.)*

Third Party Procedure.—It is obvious that where A has a claim against B, B may have a claim against C which arises, or which he desires to assert, only because A has brought an action against him. It would be unfortunate, and would involve unnecessary expense to all parties if B were bound to refrain from suing C until A had sued him. A remedy for this is provided by what is known as third party procedure (O. 16, r. 48) under which, where a defendant claims contribution or indemnity against a person not a party to the action, he may, by leave, issue a third party notice. To that notice (which corresponds to a writ) the third party must appear, otherwise judgment may go against him by default (O. 16, rr. 49, 50). If he does appear, suitable directions may be given so that all the questions between all the parties may be tried in the same action (O. 16, r. 52). The third party may bring a fourth party from whom he seeks indemnity subject to the same rules as prevail in relation to third parties (O. 16, r. 54B).

An action does not abate because of the marriage, death, or bankruptcy, etc., of any party thereto, if the cause of action survives (O. 17, r. 1), and where any marriage, etc., takes place, or there is any devolution of estate by operation of law, the court may order that the husband, personal representative, trustee, or other successor to interest of any party shall be made a party and served with notice of the proceedings (O. 17, r. 2). Similarly, any person, who by reason of a marriage, death, bankruptcy or assignment after action brought acquires an interest in the dispute may apply to be made a party (O. 17, r. 4).

Several causes of action may be joined in the same action; but the court may order that there shall be separate trials if the various causes of action which appear upon the record cannot be conveniently tried together (O. 18, r. 1). This rule is subject to one notable exception. namely, that no other cause of action can be joined with an action for the recovery of land, except by leave of the court (O. 18, r. 1).

The Pleadings.—Normally, in an action tried in the king's bench divisions, "pleadings" are ordered to be delivered. They consist of a statement of claim, the defence (and counterclaim, if any), and reply, and, in rare cases, a rejoinder. No pleading subsequent to defence can, however, be delivered without leave.

A pleading is the term applied in English law to the preparation of the statement of the facts on which either party to a civil action founds his claim to a decision in his favour on the questions involved in the proceeding; and also to the document in which these statements are embodied. The term "pleadings" is used for the collected whole of the statements of both parties; the term "pleading" for each separate part of the pleadings.

The object of the pleadings is to secure that both parties shall know what are the real issues between them. A plaintiff must (in certain cases) deliver a statement of claim; a defendant must put in a defence and he may also plead a setoff or counterclaim. The plaintiff must (in certain cases) reply to the defence, and must put in a defence to the counterclaim. The rules of pleading are so framed as to restrict the length of pleadings as much as possible. So "every pleading shall contain, and contain only, a statement in a summary form of the material facts on which the party pleading relies for his claim or defence, as the case may be, but not the evidence by which they are to be proved." The pleader must confine himself to material facts—but an allegation may be material though it is not necessary. He must confine himself, too, to facts material at that stage of the action.

With a view to avoiding prolixity, the rules p ovide that a contract which is to be implied from a series of letters or conversations, or from various circumstances, may be referred to as a fact without setting out all the letters, etc., in detail. But reference to those letters, etc., and the substance of material conversation must be given. Matters of law need not be pleaded to. But even though it may necessitate a long and elaborate statement, all material facts must be set out in a pleading. If material, dates, names and items are not given, the pleader may be ordered to give particulars. A pleading may contain alternative and inconsistent allegations.

As indicated above, particulars may be ordered if a pleading is not sufficiently explicit. Particulars may be necessary to indicate to the opponent the nature of the evidence required by him.

A few examples must suffice. In an action for libel where the defendant has alleged that the plaintiff is a "swindler," or a "felon," pleads that the words are true, he must give particulars showing the nature of the alleged swindle or felony. In an action in which a plaintiff, suing for the balance of monies alleged to be due, gives credit for a lump sum, he must give particulars showing how the lump sum is made up. Where the plaintiff claims general damages (*e.g.,* in an action for personal injuries) "£1,000," he need not give particulars showing how he arrives at that figure; but if he claims special damage, *e.g.,* "£100 for medical expenses," consequent upon the injury, particulars will be ordered. It is no answer to a claim for particulars that they are within the applicant's own knowledge. He may still desire to know what facts the other party is going to rely upon in support of his case. Sometimes, however, a litigant asked to give particulars will be allowed to interrogate his opponent before complying with the order.

But where particulars would be in vain they will not be ordered. If the plaintiff, for example, asks for an account to be taken between him and the defendant, it is obvious to the defendant that all his dealings with the plaintiff will have to be enquired into. But if the plaintiff claims an account and £100 which he alleges will be due when the account is taken, it is clear that the defendant is entitled to know how that figure is arrived at. If, when asking for an account, he also asks particulars of money had and received, they will be refused, as the facts will emerge on taking the account.

With regard to the defence, it is seldom enough merely to traverse (*i.e.*, deny or refuse to admit) the matters in the statement of claim. For example, if the plaintiff sets up a contract which was in fact made, it would be idle for the defendant merely to deny the existence of a contract. He should confess (*i.e.*, admit) the contract and **avoid** the effect of that confession by setting up the Statute of Fraud or Limitations or by setting up (a) that the contract has been duly performed or rescinded; or (b) that it was illegal; or (c) that some condition precedent to his liability has not been performed. In an action of debt a mere denial of the debt is expressly declared by the rules to be inadmissible; and in an action for liquidated sums the defence must deny the order or contract, the delivery, or the amount claimed. Again, in an action for money had and received, the defence must deny the receipt of the money, or the existence of those facts which are alleged to make such receipt by the defendant a receipt to the use of the plaintiff. If the defendant desires to deny the right of a plaintiff to sue in a representative capacity, he must do so specifically (O. 21, r. 5). While the defendant should make every denial which is really necessary, he should avoid denying matters which are really immaterial. If he does so, the court has power to make him pay any extra costs occasioned thereby (O. 21, r. 9).

With regard to counterclaims, a defendant may counterclaim not only against the plaintiff but against other parties to the action, and against a person who is not a party (O. 21, r. 11). But whereas a counterclaim against a plaintiff and a person already a party is merely delivered, a counterclaim involving a "third party" must be served on him like a writ. Such third party must appear as if he were a defendant to an action, and, having done so, may deliver a defence without any leave from the court (O. 21, r. 14). It s competent for any person who is made defendant to a counterclaim to apply to the court for an order to exclude the counterclaim, on the ground that it cannot be conveniently or properly tried with the original action (O. 21 r. 15). If there is a counterclaim on the record, and the original action is stayed, discontinued or dismissed, the counterclaim can nevertheless be proceeded with (O. 21, r. 16). As to defences generally, one or two survivals from ancient times are to be found in the rules. Thus it is still competent for a defendant, in certain cases, to plead "not guilty by statute" — as when for example an action is brought for illegal distress. But it is unsafe to use this plea, as no other plea can be added save by leave (See O. 19, r. 12 ; O. 19, r. 20.) Again, a plea "in abatement" (*e.g.* that a third person should have been added as plaintiff) is not allowed. Finally in an action for the recovery of land against a defendant who is in possession by himself or his tenant the defendant (unless he has some equitable defence) need only plead that he is in possession. This puts everything in issue and enables him to raise any defence--even the Statute of Limitations (O 21, r. 21). The reason assigned for this (by Lord Justice Brett) is that the plaintiff in an action for recovery of land must recover on the strength of his own title and not through any defect in the defendant's title. "Possession is nine points of the law."

Payment into Court. — There is no part of the procedure in civil actions more important to the litigant than that which enables a defendant to pay money into court. By a judicious payment into court a defendant may bring proceedings to an end, and so avoid the costs of what may be an expensive action. Further, if he pays in enough or more than enough to satisfy the plaintiff's claim, the plaintiff will have to bear all costs incurred subsequent to the date of payment in.

The rules provide that in any action for debt or damages (not, *e.g.*, a mere action for an account) including actions for libel or slander, the defendant may, before defence, or with defence not denying liability, pay money into court in satisfaction of the whole or a specified part of the claim (O. 22, r. 1). By so paying in, he admits liability to that extent. The plaintiff may then take the money out and proceed with the action (O. 22, r. 5), or accept it in full satisfaction (O. 22, r. 5). In the latter case, if he accepts it within a certain time (prescribed by O. 22, r. 7) he may proceed to tax and recover his costs. If he does not so accept it but goes on with his action, and fails to recover anything more, the defendant will be entitled to all the costs incurred subsequent to the date of payment in.

There is one case in which the defendant ought certainly, in his own interest, to pay money into court. This is where in answer to a claim for a liquidated sum, he has made a tender before action. Tender of what is due is a complete defence to an action; but where there is a plea of tender upon the record, it will not avail the defendant unless he has brought the amount tendered into court. And this is good sense, because the defendant's attitude must be that he always was and still is ready and willing to pay his debt. But where money has been paid into court with a plea of tender, the plaintiff cannot terminate the action by taking that money out of court; for he will thereby admit the defence and the costs of the whole action will be the defendant's.

But it is not always necessary for a defendant to admit liability for the sum paid in. In any action of debt he may pay in without admitting liability (except when he pleads tender). This is a mere offer to secure peace, which may appear with any other defence, *e.g.*, a denial of the contract or a plea of performance. The plaintiff may accept it in satisfaction and take it out of court (O. 22, r. 6) and tax his costs (O. 22, r. 7). If he does not accept it in satisfaction, the money remains in court to abide the result of the action (O. 22, r. 6). The danger of denying liability, however, lies in this, that it puts the plaintiff to the proof of his case, and although he may recover no more than the sum paid in, the defendant may not get his costs of contesting those issues. In action for damages (except for libel or slander) the rule is very similar (O. 22, r. 1), but in libel and slander cases, payment in can only be made in satisfaction (*i.e.*, with an admission of liability) or else by way of compensation and amends, under the Libel Act 1843. If necessary, as where, for example, the claim involves several causes of action, particulars will be ordered showing how much of a payment in is to be applied to each cause of action.

Neither the fact of a payment into court having been made nor the amount of such payment must be revealed to a jury (O. 22, r. 22). If there has been such a revelation, the court will stop the case and discharge the jury. If more than enough has been paid in, the excess will be ordered to be repaid to the defendant.

To the general rule that it rests with plaintiff to say whether he will or will not accept money paid into court, there is an exception in any case where the plaintiff is an infant or a person of unsound mind. Acceptance of a sum paid in involves (or may involve) a compromise of the action, and the court, exercising a parental jurisdiction in such matters will refuse to allow a compromise which may not be fair to the plaintiff. And so the court has power, not only to refuse to allow a compromise, but it may provide, by order, for the money being retained in court and invested or otherwise disposed of for the benefit of the infant (until he attains the age of 21) or lunatic as the case may be. (See generally O. 22, r. 15.)

Reply and Subsequent Pleadings. — The defence having been delivered, the plaintiff may find it necessary to deliver a reply. Under the old rules a plaintiff was always entitled to reply — even if it was only to join issue. But now a mere joinder of issue is unnecessary and (O. 27, r. 13) no reply or subsequent pleading (*e.g.*, rejoinder, sur-rejoinder, etc.) can be delivered without order except in certain admiralty cases (O. 23). But a reply may be essential, *e.g.*, where there is a counterclaim (to which the reply is really a defence) or where the defendant has pleaded the Statute of Limitation, and the plaintiff desires to prove a payment which takes the case out of the statute. He must not, however, suggest a new cause of action in his reply, for that would be what the old pleaders called a "departure." And the reason is plain. To a new cause of action the defendant must be enabled to put in a defence in accordance with the rules. A new cause of action must therefore appear in an amended statement of claim.

Cases may occur in which, although the plaintiff had a good cause of action when he issued his writ, something happened afterwards to satisfy his claim or discharge the cause of action. For example, he may accept payment of the debt sued for, or a sum of money by way of compromise of a claim for damages. Such acceptance or compromise would constitute a defence. If it takes place before the expiration of the time limited for defence, the defendant may raise it in his defence, signifying that it arose since action brought (0. 24, r. 1). And even if it arises after that time, the defendant may raise it by leave (0. 24, r. 2). The plaintiff may thereupon "confess" such defence and tax his costs up to the time when it was delivered (0. 24, r. 3) unless the court shall otherwise order. A similar rule obtains with reference to a reply which sets up new matter in defence to a set off or counterclaim. A counterclaim may be founded on facts which have arisen since action brought, but it must be phrased as so arising.

Discontinuance. — In certain circuinstances an action may be discontinued, or a defence withdrawn. Thus at any time before receipt of defence, or after receipt thereof before taking any proceeding other than interlocutory (*e.g.*, a summons for particulars), the plaintiff may, *without* leave, by notice in writing discontinue the whole action, or withdraw any part of it as against all or any of the defendants, subject to the payment of costs (O. 26, r. 1).

Proceedings in Lieu of Demurrer. — In former days it was competent for a defendant to "demur" to the statement of claim on the ground that it disclosed no cause of action. The result was that many a claim was defeated and costs were often incurred merely because the plaintiff had not put his case in proper form. Now, however, demurrer is abolished (O. 25, r. 1) but any party may raise a point of law by his pleading, and the point so raised shall be disposed of at or after the trial subject to this, that if the parties consent or the court so orders the point may be set down for hearing and disposed of before the trial (0. 25, r. 2). If the decision substantially disposes of the whole action, the action may be dismissed (0. 25, r. 3). This course may be conveniently adopted where it is obvious that a serious question arises as to whether the statement of claim as drafted discloses any cause of action, or the defence any answer in law to the claim.

Striking Out Pleadings. — The court may order a pleading to be struck out on the ground that it discloses no reasonable cause of action or answer (O. 25, r. 4). In any such case, or if the action or defence be shown by *the pleadings* to be frivolous or vexatious, it may be stayed or dismissed, or judgment may be entered for the defendant accordingly as may be just (ib.). To succeed in such an application, an objecting party must be able to point to some defect in the pleading itself. The rule is only acted upon in plain and obvious cases. So if in an action on a contract it be clear that there is no contract between the plaintiff and the defendant; or no contract valid in law; or that the matter is already res *judicata,* or where the statement of claim on the face of it shows that there is a good defence, it will be struck out.

But the court will generally give a party leave to amend a pleading before striking it out. Apart from the rule above mentioned (and O. 19, r. 25, which enables anything scandalous or vexatious, or which tends to delay, etc., the trial of an action, to be struck out) the court has inherent jurisdiction to stay all proceedings before it which are obviously frivolous or vexatious or an abuse of its process. Discontinuance by the plaintiff does not alter a counterclaim, but a counterclaim cannot be set up after discontinuance.

A defendant may by leave, and only by leave, and upon terms, withdraw the whole or part of his defence or counterclaini. If the defence is withdrawn, the plaintiff can sign judgment in default of defence. An application so to withdraw may be made at any time. A cause entered for trial may be withdrawn by either plaintiff or defendant upon producing a consent in writing to the proper officer (0. 26, r. 2). The plaintiff must pay the defendant's costs if he discontinue an action (0. 26, r. 3); and if he bring another action for the same or substantially the same cause, it may be stayed if the costs of the former action are not paid (0. 26, r. 4).

Default of Pleading. — The rules of pleading are enforced by this — that if a party does not plead as and when required, he may if he is a plaintiff have his action dismissed, if he is a defendant have judgment signed against him. Thus if a plaintiff being bound to deliver a statement of claim does not do so within the time allowed, the defendant may apply to have the action dismissed for want of prosecution, and on the hearing of the application the court may either dismiss the action or make such order as shall be thought just (O. 27, r. 1). Where the plaintiff delivers his statement of claim after the application has been made, the court will generally make no order save that he pay the costs. The plaintiff need not deliver a statement of claim save under an order for directions, for which he must himself apply. If he does not so apply within 14 days of the defendant's appearance the defendant may have the action dismissed (0. 30, r. 8). A plaintiff may be in default in delivering a reply and defence to a counterclaim. If so, the defendant's only remedy is to move for judgment under O. 27, r. 11, even when the counterclaim is for a liquidated demand, and even if some other person has been made a defendant to the counterclaiin.

A defendant may make default either in not entering an appearance, or in not putting in his defence. If he has not appeared, and, the writ not being especially indorsed (*i.e.,* with a claim for a liquidated sum), he has had a statement of claim filed against him in default, he must appear and deliver his defence within ten days of the filing of the statement of claim. Otherwise he may have judgment signed against him with costs (O. 21, rr. 2–9). In such a case, however, if the plaintiff could have signed judgment merely in default of appearance, he can only have such costs as he would have had in that case. In other words, he will not be allowed the costs of the statement of claim. If a defendant has appeared to the writ other considerations arise. If the writ was specially indorsed he must deliver a defence within ten days unless the plaintiff has proceeded for summary judgment (O. 21, r. 6) and in other cases if a separate statement of claim has been delivered he must deliver his defence within the time limited by the summons for directions (O. 21, r. 8).

The procedure to be adopted if the defendant has not put in a defence depends upon the nature of the action. (See APPEARANCE, p. 400.)

Close of Pleadings. — There comes a time in every action when the pleadings are deemed to be closed. Where no reply or subsequent pleading is ordered then within four days of the delivery of the last pleading, or where a reply has been ordered within a certain time, at the end of that period the pleadings are to be deemed closed and all statements therein put in issue (0. 27, r. 13). This, however, does not apply to a reply to a counterclaim which is really a defence. Unless the plaintiff obtains leave to reply to a counterclaim, the statements of fact which it contains shall be deemed to be admitted after the expiration of ten days, unless a reply has been ordered, in which case, if the order is not complied with, the facts will be deemed to be admitted.

Amendment. — In former times the ends of justice were often defeated, and the litigant was put to an enormous amount of unnecessary expense, because the powers of the court to allow amendment of pleadings were greatly restricted. Now, however, the court or a judge may at any time, and on such terms as to costs or otherwise as may be thought right, amend any deficit in any proceedings, and all necessary amendments shall be made for the purpose of determining the real question or issue raised by or depending on the proceedings (0. 28, r. 12).

Amendment of Pleadings. — The court or a judge may at any stage of the proceedings allow either party to alter or amend his indorsement or pleadings in such manner and on such terms as may be just, and all such amendments shall be made as may be necessary for the purpose of determining the real question in controversy between the parties (0. 28, r. 1). Under this rule amendment will always be allowed, if it can be made without injustice to the other side. While a new cause of action may be introduced into the statement of claim by amendment, if the plaintiff, at the same time seeks to stand on his original claim, leaving his writ unamended, this is practically a discontinuance, for the new claim is wholly unsupported by the writ. Such an amendment will only be allowed on the terms that the plaintiff pays all costs down to the time of the amendment, and that all proceedings are stayed until those costs are paid.

A petition of right cannot be amended unless the amendment is such that if the petition had been presented as amended, the *fiat* of the attorney-general would have been granted.

To allow an amendment of a petition of right would be to derogate from the prerogative of the Crown. A common informer is but seldom allowed to amend his statement of claim in an action for penalties. Amendment is often allowed on an application to strike out a pleading as embarrassing or because it discloses no cause of action—*ut res magis valeat quam pereat*. Although, when a statement of claim is delivered the plaintiff may therein alter, modify or extend his claim without any amendment of the writ, he cannot add a claim on a wholly new and different cause of action except by leave; and if leave be given the writ should be amended. The writ or the statement of claim must be amended in one case, *i.e.,* where the plaintiff recovers by verdict of a jury more than the amount he has actually claimed. Otherwise he cannot recover the amount of the verdict. Amendment may be allowed at any time but it should obviously be made at the earliest possible moment. A defendant may have no answer to the claim as amended. A plaintiff may find it necessary to confess an amended defence and stop his action; or, where the amendment involves *a* payment of money into court, he may be content with the amount paid in.

A plaintiff may, in certain cases, and within a certain time amend his statement of claim, whether indorsed on the writ or not, without leave (O. 28, r. 2). But he cannot, in the exercise of this privilege, add a cause of action which has accrued to him since the writ—although he can do that by leave. Nor can he add new parties. If he has delivered particulars with the statement of claim he can amend them under this rule; but particulars delivered otherwise can only be amended by leave. Under this rule a special indorsement can be amended provided the claim is one which can be specially indorsed. A similar rule (O. 28, r. 3) applies to a counterclaim. But it is important to notice that any amendment so made without leave may be disallowed—or only allowed upon terms—on the application of the other side if the justice of the case so requires (O. 28, r. 4).

It has been stated that amendment to statement of claim or counterclaim without leave can only be made within a certain time. All other amendments to claim or defence, or to any other pleading, can only be made by the leave of the court or a judge and upon such terms as to costs as may be just (O. 28, r. 6). If an order giving leave to amend be made and the amendment is not made within the time limited or within 14 days of the date of the order, the order is void, unless the time be extended by the court or a judge (O. 28, r. 7). Moreover the amended pleading must be delivered to the opposite party within the time allowing the same (O. 28, r. 10).

Actions By or Against Firms.—If a firm desires to bring an action, or anyone desires to bring an action against a firm, in the firm name, especial considerations arise. Broadly speaking, a firm consisting of more than one person carrying on a business within the jurisdiction may sue or be sued in the firm name, but subject to this—that the names of the partners must, if required, be revealed to the other side. Where, however, a man carries on business in a name other than his own, he can only sue in his own name, but he may be sued in the name of his firm. He must, however, reveal his true name if required. Service of process on a firm may be effected either upon any one of the partners, or upon the manager at the place of business of the firm. The person served must be told, at the time, whether he is served as a partner or as manager. A firm cannot enter an appearance as such: it must appear by one of the partners personally; but an alleged partner may appear with a denial that he is a partner. The property of the firm within the jurisdiction can be seized in execution of a judgment against the firm, and so can the property of individual partners. This is but a summary of O. 48A which provides a complete code of rules on the subject. It must be carefully studied by anyone who is concerned in an action by or against a firm.

Discovery.—The pleadings having been closed, the parties in most cases proceed to have discovery, either of facts or documents or both. The English common law courts were originally unable to compel a litigant before a trial to disclose the facts and documents on which he relied. In equity, however, a different rule prevailed, there being an absolute right to discovery of all material facts on which a case was founded. Now the practice is regulated by the Rules of the Supreme Court, 1883, Order 31. Discovery is of two kinds, namely, by interrogatories and by affidavit of documents, provision being also made for the production and inspection of documents. Where a party to a suit can make an affidavit stating that in his belief certain specified documents are or have been in the possession of some other party, the court may make an order that such party state on affidavit whether he has or ever had any of those documents in his possession, or if he has parted with them or what has become of them. A further application may then be made by notice to the party who has admitted possession of the documents for production and inspection. Copies also may be taken of the more important documents. There is also discovery of facts obtained by means of interrogatories, *i.e.,* written questions addressed on behalf of one party, before trial, to the other party, who is bound to answer them in writing upon oath. In order to prevent needless expense the party seeking discovery used to have to secure the cost of it by paying into court a sum of money, generally not less than £5, but this rule has been abolished. Objection may be taken to discovery either of a fact or a document on the ground of privilege or that the matters sought to be discovered are criminatory.

Thus all documents and communications passing between a litigant and his legal advisers are absolutely privileged and need not be disclosed. Again, where an admission of a fact or the production of a document might involve the admission of a criminal offence, the litigant may refuse to give discovery. Where the opposite party is not satisfied with an affidavit of documents, or the answer to an interrogatory, he may, in certain cases apply for a further and better affidavit or answer, and in some cases the master to whom the application is made will himself examine a document in order to see whether it shall be disclosed or not. The advantage of discovery lies in this—that it forces a litigant to reveal his case on oath. It is one thing to make a statement or deny a fact in a pleading. That merely has effect to put the matter in issue. It is a much more serious matter to have to swear to a fact in an affidavit, because, in the case of the answer to an interrogatory, it may be put in evidence by the opposite party at the trial. Many an action is brought to a speedy end by an order for discovery, because the litigant is wholly unable to swear to the truth of the claim or defence which he has put upon his pleadings. Discovery will not be allowed if the remedy sought to be inforced is of a penal nature, or if the plaintiff is relying on a forfeiture.

Evidence on Commission.—Cases often arise in which it is impossible owing to illness or absence to secure the attendance of a witness at the trial. In such circumstances the court has power (conferred by O. 37, r. 5 et *seq.*) to direct that the evidence be taken anywhere before an officer of the court or any other person. It must be shown, however, that the witness will be unable to attend, either because of illness or because he is out of the jurisdiction, and cannot be compelled to attend by *subpoena*. Even a plaintiff may be allowed to give evidence on commission, but this is a privilege seldom granted. The evidence of the witness is written down and signed by him and can be put in at the trial. In certain foreign countries, where evidence cannot be taken on commission, it is secured by letters of request, which are sent through the Foreign Office.

Admission.—Although the pleadings show that everything is in issue in an action, it is competent for either party to give notice that he admits the truth of the whole or part of his opponent's case (O. 32, r. 1). This secures the costs of proving those facts, and, if the whole cause of action is admitted, enables the party to whom the admission is made to apply for judgment (O. 32, r. 6). Apart from this, either party may give notice to the other to admit facts and if he refuses to do so unreasonably he may have to pay the costs of the necessary proof of those facts (ib. [4]). Similarly notice may be given to admit documents; indeed the costs of proving any document may be disallowed if the notice is not given (O. 32, r. 3).

Special Case.—The parties to any cause or matter may concur in stating the questions of law arising therein in the form of a special case for the opinion of the court (O. 34, r. 1), and the court may order a question of law to be decided either by special case or otherwise before any question of fact is tried (O. 34, r. 2).

Transfer *and Consolidation* of Action.—Action may be transferred from one division of the High Court to another, or from one judge to another by order of the lord chancellor but subject to the consent of the president of the division (O. 59, r. 1). Causes depending in the same division may be consolidated with each other (O. 59, r. 8).

Application and *Proceedings* at *Chambers*.—All applications at chambers (*i.e.*, before a master or a judge) are made by summons unless they are made ex parte, that is to say, by one side only. Applications at chambers generally are regulated by O. 54, while O. 55 prescribes the rules observed in chambers in the chancery division.

Proceedings in District Registries.—To meet the convenience of suitors who do not live in or near London, district registries have been established in various parts of the country. Proceedings can only be taken in a district registry, in an action in which the writ has been issued out of that registry. Broadly speaking, the powers of a district registrar are similar to those of a master of the supreme court. In certain cases, however, where an action has been commenced in a registry the defendant can as of right have it moved to London, and the court has power in all cases to move an action from a registry to London or vice versa. (See generally O. 35.) As to appeals from district registries see APPEAL. Proceedings by poor persons under the Matrimonial Causes Acts in district registries are provided for by O. 35a.

Trial.—The places and mode of trial having been fixed by the order made on a summons for directions, the plaintiff must give notice of trial (O. 36, r. 11), and if he fails to do so, within the time prescribed by the rules, the defendant may do so, or else apply to have the action dismissed for want of prosecution (O. 36, r. 12). Trial follows upon the completion of the steps necessary to bring the parties before the court and to adjust the issues upon which the court is to adjudicate, which may be summed up in the term pleading. In England the trial is usually in open court, and it is rare to try cases in camera, or to attempt to exclude the public from the hearing. In practice hearing in camera is only ordered where to try in open court would be to defeat the ends of justice. The essential part of the trial is that there should be full opportunity to both sides for evidence and argument on the questions in dispute. At present in England, as distinguished from the rest of Europe, the evidence is ordinarily taken *viva voce* in court, and affidavits and depositions are sparingly accepted, whereas under the continental system the bulk of the proofs in civil cases are reduced to writing before the hearing.

In the High Court of Justice in England several modes of trial are now used:—

1. Trial by judge with a jury used in the king's bench division and in probate and matrimonial cases. There is a right to have a jury as a matter of course in actions of defamation, false imprisonment. malicious prosecution, seduction and breach of promise of marriage.

2. Trial by a judge without a jury is invariable in the chancery division and now common in other divisions. Cases in the chancery division are not tried with a jury unless a special order is made (O. 36, r. 3); and the High Court in cases in which trial without jury could be ordered without consent still retains the power of so trying them, and has also acquired power to direct trial without a jury of any issue requiring prolonged examination of documents or accounts or scientific or local investigation.

3. Trial with assessors, usually in admiralty cases (the assessors being nautical) but rare in other division?.

4. Trial by an official referee in certain cases involving much detail (R.S.C., O. 36).

5. Where the parties consent, trial may be had of any case in the king's bench division before a master in chambers.

A speedy trial may be ordered in certain cases (O. 36, r. 1A), but the power conferred by this order is sparingly exercised. The parties may be represented in the High Court by counsel or may conduct their case in person. The trial is carried on by stating to the court the pleadings if any and by opening the plaintiff's case. This is followed by the evidence of the witnesses, who are sworn and examined and cross-examined. On the completion of the plaintiff's case and evidence, the defendant's case is stated and evidence adduced in support of it. The plaintiff or his lawyer has, as a rule, the reply or last word unless the defendant has called no evidence. If when the trial is called on the plaintiff appears and the defendant does not, the plaintiff may prove his case (O. 36, r. 31). If the plaintiff does not appear, the delendant may have judgment dismissing the action, and may prove his counterclaim if he has one (O. 36, r. 32). But any judgment by default may be set aside on terms.

At the conclusion the judge sums up the law and facts of the case to the jury and their verdict is returned, or if there is no jury the judge gives judgment stating his conclusion on the law and the facts involved. He then directs that judgment shall be entered as he thinks right (O. 36, r. 39), and a memorandum is endorsed on the judgment pointing out that if it is not obeyed, the defendant will be liable to process of execution (O. 41, r. 5).

Juries.—In England the trial jury (also called petty jury or traverse jury) consists of 12 jurors, except in the county court where the number is eight. Women are now summoned as jurors, but a husband and wife cannot be summoned on the same occasion. A woman may, however, claim exemption on the ground that by reason of pregnancy or some other feminine condition or ailment she is or will be unfit to serve. Either party to the suit may apply to the court for an order that the jury shall consist wholly of men or wholly of women. In civil but not in criminal cases the trial may by consent be by fewer than 12 jurors, and the verdict may by consent be that of the majority.

The jurors are selected from the inhabitants of the county, borough or other area for which the court to which they are summoned is commissioned to act. In criminal cases, owing to the rules as to venue and that crime is to be tried in the neighbourhood where it is committed, the mode of selection involves a certain amount of independent local knowledge on the part of the jurors. Where local prejudice has been aroused for or against the accused, which is likely to affect the chance of a fair trial, the proceedings may be removed to another jurisdiction, and there are a good many offences in which by legislation the accused may be tried where he is caught, irrespective of the place where he is alleged to have broken the law.

Exemptions from juries include members of the legislature and judges, ministers of various denominations, and practising barristers and solicitors, registered medical practitioners and dentists, and officers and soldiers of the regular army. Persons over 60 are exempt but not disqualified. Lists of the jurors are prepared by the overseers in rural parishes and by the town clerks in boroughs, and are submitted to justices for revision. When jurors are required for a civil or criminal trial they are summoned by the sheriff or, if he cannot act, by the coroner.

For the purpose of civil trials in the superior courts there are two lists of jurors, special and common. The practice of selecting special jurors to try important civil cases appears to have sprung up, without legislative enactment, in the procedure of the courts.

The jurors are the judges of fact upon the evidence laid before them. Their province is strictly limited to questions of fact, and within that province they are still further restricted to matters proved by evidence in the course of the trial and in theory must not act upon their own personal knowledge and observation except so far as it proceeds from what is called a "view" of the subject matter of the litigation.

While the jury is in legal theory absolute as to matters of fact, it is in practice largely controlled by the judges. Not only does the judge at the trial decide as to the relevancy of the evidence tendered to the issues to be proved, and as to the admissibility of questions put to a witness, but he also advises the jury as to the logical bearing of the evidence admitted upon the matters to be found by the jury. The rules as to admissibility of evidence, largely based upon scholastic logic, sometimes difficult to apply, and almost unknown in continental jurisprudence, coupled with the right of an English judge to sum up the evidence (denied to French judges) and to express his own opinion as to its value (denied to American judges), fetter to some extent the independence or limit the chances of error of the jury.

The appellate court will not upset a verdict when there is substantial and conflicting evidence before the jury. In such cases it is for the jury to say which side is to be believed, and the court will not interfere with the verdict. To upset a verdict on the ground that there is no evidence to go to the jury implies that the judge at the trial ought to have withdrawn the case from the jury. Under modern procedure, in order to avoid the risk of a new trial, it is not uncommon to take the verdict of a jury on the hypothesis that there was evidence for their consideration, and to leave the unsuccessful party to apply for judgment notwithstanding the verdict. The question whether there was any evidence proper to be submitted to the jury arises oftenest in cases involving an imputation of negligence—*e.g.,* in an action of damages against a railway company for injuries sustained in a collision.

This statement indicates existing practice but scarcely determines what relation between the facts proved and the conclusion to be established is necessary to make the facts evidence from which a jury may infer the conclusion. The true explanation is to be found in the principle of relevancy. Any fact which is relevant to the issue constitutes evidence to go before the jury, and any fact, roughly speaking, is relevant between which and the fact to be proved there may be a connection as cause and effect. As regards damages the court has always had wide powers, as damages are often a question of law. But when the amount of the damages awarded by a jury is challenged as excessive or inadequate, the appellate court, if it considers the amount unreasonably large or unreasonably small, must order a new trial unless both parties consent to a reduction or increase of the damages to a figure fixed by the court; see Watt v. Watt (1905), App. Cas. 115.

Judgment and Execution. — Execution is allowed as a matter of course after judgment except where it has for some reason been stayed, *e.g.,* where an appeal is pending. (See generally R.S.C. O. 42.) A judgment for the recovery of money or costs is enforced, as a rule, by writ of *fieri* facias addressed to the sheriff, and directing him to cause to be made (*fieri* facias) of the goods and chattels of the debtor a levy of a sum sufficient to satisfy the judgment and costs, which carry interest at 4% per annum. The seizure effected by the sheriff or his officer, under this writ, of the property of the debtor, is what is popularly known as "the putting-in" of an execution. The seizure should be carried out with all possible dispatch. The sheriff or his officer must not break open the debtor's house in effecting a seizure, for "a man's house is his castle"; but this principle applies only to a dwelling-house, and a barn or outhouse unconnected with the dwelling-house may be broken into. The sheriff on receipt of the writ endorses it on the day, hour, month and year when he received it; and the writ binds the debtor's goods as at the date of its delivery, except as regards goods sold before seizure in market overt, or purchased for value, without notice before actual seizure (Sale of Goods Act 1893, s. 26, which supersedes s. 16 of the Statute of Frauds and s. 1 of the Mercantile Law Amendment Act 1856).

This rule is limited to goods, and does not apply to the money or bank-notes of the debtor which are not bound by the writ till seized under it (Johnson v. Pickering, Oct. 14, 1907, C.A.). The mere seizure of the goods, however, although, subject to such exceptions as those just stated, it binds the interest of the debtor, and gives the sheriff such an interest in the goods as will enable him to sue for the recovery of their possession, does not pass the property in the goods to the sheriff. The goods are in the custody of the law. But the property remains in the debtor who may get rid of the execution on payment of the claim and fees of the sheriff. The wearing apparel, bedding, tools, etc., of the debtor to the value of £5 are protected. Competing claims as to the ownership of the goods seized are brought before the courts by the procedure of "interpleader." In the king's bench division, the sheriff issues a summons before a master in chambers calling upon the execution creditors and claimant to appear and state their respective cases. If the claim is not admitted by the execution creditor, an issue is directed to try the merits and either party may ask the master to try the issue himself. This he generally does at the earliest possible opportunity, for the sheriff being in possession, costs are mounting up. Otherwise the "issue" is reported for trial to the High Court or county court, the claimant being directed to bring the amount of the sheriff's valuation into court. That money being in court, the sheriff withdraws. After seizure the sheriff must retain possession, and, in default of payment by the execution debtor, proceed to sell. Where the judgment debt, including legal expenses, exceeds £20, the sale must be by public auction, unless the court otherwise orders, and must be publicly advertised. The proceeds of sale, after deduction of the sheriff's fees and expenses, become the property of the execution creditor to the extent of his claim.

Under the law of bankruptcy, the sheriff, in case of sale under a judgment for a sum exceeding £20 is required to hold the proceeds for 14 days in case notice of bankruptcy proceedings should be served upon him. (See BANKRUPTCY.) Imprisonment for debt in execution of civil judgment is now abolished except in cases of default in the nature of contempt, unsatisfied by judgments for penalties, defaults by persons in a fiduciary character, and defaults by judgment debtors.

Writ of *Elegit*.—The writ of *elegit* is a process enabling the creditor to satisfy his judgment debt out of the lands of the debtor. It derives its name from the election of the creditor in favour of this mode of recovery. It is founded on the Statute of Westminster (1285, 13 Ed. I. c. 18), under which the sheriff was required to deliver to the creditor all the chattels (except oxen and beasts of the plough) and half the lands of the debtor until the debt was satisfied. By the Judgments Act 1838 the remedy was extended to all the debtor's lands, and by the Bankruptcy Act 1883 (now replaced by the Bankruptcy Act 1914) the writ no longer extends to the debtor's goods. The writ is enforceable against legal interests whether in possession or remainder but not against equitable interests in land. When the debtor's interest is equitable recourse is had to equitable execution by the appointment of a receiver or to bankruptcy proceedings. (See R.S.C., O. 43.)

Writs of Possession and Delivery. — Judgments for the recovery or for the delivery of the possession of land are enforceable by writ of possession. The recovery of specific chattels is obtained by writ of delivery (R.S.C., O. 47, 48).

Writ of *Sequestration*.—Where a judgment directing the payment of money into court, or the performance by the defendant of any act within a limited time, has not been complied with, or where a corporation has wilfully disobeyed a judgment, a writ of sequestration is issued, to not less than four sequestrators, ordering them to enter upon the real estate of the party in default, and "sequester" the rents and profits until the judgment has been obeyed (R S.C., O. 43, r. 6).

Equitable Execution. — Where a judgment creditor is otherwise unable to reach the property of his debtor he may obtain equitable execution, usually by the appointment of a receiver, who collects the rents and profits of the debtor's land for the benefit of the creditor (R.S.C., O. 1, rr. 15A–22). But receivers may be appointed of interests in personal property belonging to the debtor by virtue of the Judicature Act 1873, s. 25 (8). The plaintiff may apply ex parte, for leave to issue a summons for the appointment of a receiver and for an injunction to restrain the defendant from parting with his property pending the hearing of the summons. Such an application may be heard by a master.

Attachment.—A judgment creditor may "attach" debts due by third parties to his debtor by what are known as garnishee proceedings. A garnishee order *nisi* may be made by a master of the king's bench on the application of the judgment creditor. It must be supported by an affidavit in which the judgment creditor or his solicitor swears positively that there is a debt owing by the garnishee to the judgment debtor—a debitzim in *praesenti,* which may however be *solvendum* in futuro. Enormous sums of money are "garnisheed" in the course of the year to answer judgments from the king's bench division. Stock and shares belonging to a judgment debtor may be charged by a charging order, so as, in the first instance, prevent transfer of the stock or payment of the dividends, and ultimately to enable the judgment creditor to realize his charge. A writ of attachment of the person of a defaulting debtor or party may be obtained in a variety of cases akin to contempt (*e.g.,* against a person failing to comply with an order to answer interrogatories, or against a solicitor not entering an appearance in an action, in breach of his written undertaking to do so), and in the cases where imprisonment for debt is still preserved by the Debtors Act 1869 (R S.C., O. xliv.). *Contempt* of *Court* (*q.v.*) in its ordinary forms is also punishable by summary committal.

Another form of execution analogous to the attachment of a debt is a charging order. This directs that any stock, funds or shares of a public company in England, standing in the name of a debtor in his own right or in the name of any person in his trust for him, shall stand charged with the payment of the judgment debt and interest. The charge cannot be enforced for six calendar months after the order (0. 46, r. 1).

Interpleader.— This in English law is the form of action by which a person who is sued at law by two or more parties claiming adversely to each other for the recovery of money or goods wherein he has no interest, obtains relief by procuring the rival claimants to try their rights between or among themselves only. Originally the only relief available to the possessor against such adverse claims was by means of a bill of interpleader in equity. The Interpleader Act 1831 enabled the defendant in such cases, on application to the court, to have the original action stayed and converted into a trial between the two claimants. The Common Law Procedure Act of 1860 further extended the power of the common law courts in interpleader; and the Judicature Act 1875 (repealed and re-enacted by the Judicature Act 192j) provides that the practice and procedure under these two statutes should apply to all divisions of the High Court of Justice. The Judicature Act also extended the remedy of interpleader to a debtor or other person liable in respect of a debt alleged to be assigned, when the assignment was disputed. In 1883 the Acts of 1831 and 1860 were embodied in the form of rules by the *Rules* of the *Supreme Courts* (1883), O. 47, by reference to which all questions of interpleader in the High Court of Justice are now determined. Interpleader is the equivalent of multiplepoinding in Scots law.

Costs.—When giving judgment in England, the judge usually deals with the costs of the action. The term "costs" denotes the expenses incurred (1) in employing a lawyer in his professional capacity for purposes other than litigation; (2) in instituting and carrying on litigation whether with or without the aid of a lawyer.

The retainer of a solicitor implies a contract to pay to him his proper charges and disbursements with respect to the work done by him as a solicitor. In cases of conveyancing his remuneration is now for the most part regulated by scales ad valorenz on the value of the property dealt with (Solicitors' Remuneration Order 1882), and clients are free to make written agreements for the conduct of any class of non-litigious business, fixing the costs by a percentage on the value of the amount involved. So far as litigious business is concerned, the arrangement known as "no cure no pay" is objected to by the courts and the profession as leading to speculative actions, and stipulations as to a share of the proceeds of a successful action are champertous and illegal. An English solicitor's bill drawn in the old form is a voluminous itemized narrative of every act done by him in the cause or matter with a charge set against each entry and often against each letter written. Before the solicitor can recover from his client the amount of his charges, he must deliver a signed bill of costs and wait a month before suing.

The High Court has a threefold jurisdiction to deal with solicitors' costs:—(I) by virtue of its jurisdiction over them as its officers; (2) statutory, under the Solicitors Act 1843 and other legislation; (3) ordinary, to ascertain the reasonableness of charges made the subject of a claim.

The client can, as a matter of course, get an order for taxation within a month of the delivery of the solicitor's bill, and either client or solicitor can get such an order as of course within 12 months of delivery. After expiry of that time the court may order taxation if the special circumstances call for it, and even so late as up to 12 months after actual payment.

Costs as between solicitor and client are taxed in the same office as litigious costs, and objections to the decisions of the taxing officer, if properly made, can be taken for review to a judge of the High Court and to the court of appeal.

The expenses of litigation fall in the first instance on the person who undertakes the proceedings or retains and employs the lawyer. It is in accordance with the ordinary ideas of justice that the expenses of the successful party to litigation should be defrayed by the unsuccessful party, a notion expressed in the phrase that "costs follow the event." But there are many special circumstances which interfere to modify the application of this rule. The action, though successful, may be in its nature frivolous or vexatious, or it may have been brought in a higher court where a lower court would have been competent to deal with it. On the other hand the defendant, although he has escaped a judgment against him, may by his conduct have rendered the action necessary or otherwise justifiable. In such cases the rule that costs should follow the event would be felt to work an injustice, and exceptions to its operation have therefore been devised. In the law of England the provisions as to litigious costs, though now simpler than of old, are still elaborate and complicated, and the costs themselves are on a higher scale than is known in most other countries.

Except as regards appeals to the House of Lords and suits in equity, the right to recover costs from the opposite party in litigation has always depended on statute law or on rules made under statutory authority. "Costs are the creature of statute." The House of Lords has declared its competence to grant costs on appeals independently of statute.

In the judicial committee of the privy council the power to award, in its discretion, costs on appeals from the colonies or other matters referred to it, is given by s. 15 of the Judicial Committee Act 1833; and the costs are taxed by the registrar of the council.

The general rule now in force in the Supreme Court of Judicature is as follows:—"Subject to the provisions of the Judicature Acts and the rules of the court made thereunder, and to the express provision of any statute whether passed before or after Aug. 14, 1890, the costs of and incident to all proceedings in the Supreme Court, including the administration of estates and trusts, shall be in the discretion of the court or judge, and the court or judge shall have full power to determine by whom and to what extent such costs are to be paid. Provided (1) that nothing herein contained shall deprive an executor, administrator, trustee or mortgagee who has not unreasonably carried on or resisted any proceedings of any right to costs out of a particular estate or fund to which he would be entitled under the rules hitherto (*i.e.,* before 1883) acted upon in the chancery division as successor of the court of chancery; (2) that where an action, cause, matter or issue is tried with a jury, the costs shall follow the event unless the judge who tried the case or the court shall for good cause otherwise order." (R.S.C., O. 65, r 1.)

The rule above stated applies to civil proceedings on the Crown side of the king's bench division, including mandamus, prohibition *quo warranto,* and certiorari (*R.* v. *Woodhouse,* 1906, 2 K.B. 502, 540); and to proceedings on the revenue side of that division (0. 68, r. 1); but it does not apply to criminal proceedings in the High Court, which are regulated by the Crown office rules of 1906, or by statutes dealing with particular breaches of the law, and as to procedure in taxing costs by O. 65, r. 27, of the Rules of the Supreme Court.

The rule is also subject to specific provision empowering the courts to limit the costs to be adjudged against the unsuccessful party in proceedings in the High Court, which could and should have been instituted in a county court, *e.g.*, actions of contract under £100 or actions of tort in which less than £10 is recovered, unless the plaintiff, claiming a liquidated sum, has taken proceedings under O. 14 in the High Court, in which case he *may* get High Court costs if he recover over £20.

Costs of interlocutory proceedings in the course of a litigation are sometimes said to be "costs in the cause," that is, they abide the results of the principal issue. A party succeeding in interlocutory proceedings, and paying the costs therein made "costs in the cause," would recover the amount of such costs if he had a judgment for costs on the result of the whole trial, but not otherwise. But it is usual now not to tax the costs of interlocutory proceedings till after final judgment.

When an order to pay the costs of litigation is made the costs are taxed in the central office of the High Court, unless the court when making the order fixes the amount to be paid (R.S.C., O. 65, r. 23). Recent changes in the organization for taxing have tended to create a uniformity of system and method which had long been needed.

The taxation is effected, under an elaborate set of regulations, by reference to the prescribed scales, and on what is known as the lower scale, unless the court has specially ordered taxation on the higher scale (R.S.C., O. 65, rr. 8, 9, appendix N).

In the taxation of litigious costs two methods are still adopted, known as "between party and party" and "between solicitor and client." Unless a special order is made the first of the two methods is adopted. Until very recently "party and party" costs were found to be a very imperfect indemnity to the successful litigant; because many items which his solicitor would be entitled to charge against him for the purposes of the litigation were not recoverable from his unsuccessful opponent. The High Court can now, in exercise of the equitable jurisdiction derived from the court of chancery, make orders on the losing party to pay the costs of the winner as between solicitor and client. These orders are not often made except in the chancery division. But even where party and party costs only are ordered to be paid under the present practice (dating from 1902), the taxing office allows against the unsuccessful party all costs, charges and expenses necessary or proper for the attainment of justice or defending the rights of the successful party, but not costs incurred through over-caution, negligence, or by paying special fees to counsel or special fees to witnesses or other persons, or by any other unusual expenses (R.S.C., O. 65, rr. 27, 29). This practice tends to give an approximate indemnity, while preventing oppression of the losing party by making him pay for lavish expenditure by his opponent. The taxation is subject to review by a judge on formal objections carried on, and an appeal lies to the Court of Appeal.

See ADMIRALTY; APPEAL; ARBITRATION; EVIDENCE; COUNTY COURT. (W. V. B.)

THE UNITED STATES

The practice and procedure of the courts in the varous jurisdictions of the United States is derived, in the main, from the English common law system of court administration. But since each State or Territory and the Federal Government, in addition, has its own system of courts and its own procedure, a considerable diversity exists. In general, a reform of the common law procedure has occurred in many ways similar to the English reforms of the 19th century. The extent of the reform varies in the different jurisdictions. The most important change is that of the so-called code reform of procedure inaugurated by the code of civil procedure adopted in New York in 1848 and now in force in 30 American jurisdictions.

The Code Reform. — In 1847 the New York legislature instructed a commission "to provide for the abolition of the present forms of actions and pleadings in cases at common law; for a uniform course of proceeding in all cases whether of legal or equitable cognizance, and for the abandonment of all Latin and other foreign tongues, so far as the same shall by them be deemed practicable, and of any form and proceeding not necessary to ascertain or preserve the rights of the parties" (N.Y. Laws, 1847, C. 59 § 8). During the following year, the commission reported a code which was adopted on April 12, 1848. This measure, which has served as the model for other codes in the United States, was largely the work of David Dudley Field, a member of the commission. It is often called the "Field Code."

The chief characteristic and most fundamental part of the code is its single form of action for all cases. The distinctions of the common law actions and *of their forms* were abolished; the separation in procedure of equitable from legal relief was abandoned. As a substitute, the codifiers planned a blended system of law and equity with only one form of action to be known as the *civil action.* In effect, this is the same step taken in England a generation later in the Supreme Court of Judicature Act (1873). The full benefits of this reform have not been attained in all the States, for many courts considered the ancient forms of action to rest upon distinctions fundamental in the law. Furthermore, some courts have taken a hostile attitude towards the attempted union of actions at law and suits in equity. Here the history and tradition of the separate systems of law and equity have proved strong obstacles to a complete amalgamation. It has therefore often been held that the theory of the action, whether legal or equitable, must be pointed out in the pleadings. In fact, however, the difference between law and equity actions to-day is chiefly in the remedy to be granted and this should not be an objection to the single action or the simpler forms of pleading.

Perhaps the obstacle which has seemed greatest to the courts in preventing a complete union of law and equity is the requirement common to the State Constitutions that the right of trial by jury shall remain inviolate. This is construed to mean a preservation of the jury trial right substantially as it was at the time of the original adoption of the Constitutions. In view of the historical practice of jury trials in courts of law, this means in effect that in modern substitutes for action at law, jury trial is a matter of right, while in equitable claims no such right exists. Many courts in protecting the constitutional right continue to force a division of all actions into "law actions" and "equity actions." A more convenient rule and one more in keeping with the code principle is followed in some States, where the question of the form of trial is not allowed to affect the pleading in advance of the trial. If an issue arises at the trial as to the existence of a right to jury trial in either party, it is then determined by the nature of the issues developed in the pleadings in the light of the historical method of trying such issues.

Another important characteristic of the code is its emphasis upon pleading facts, not conclusions of law or evidence. *Fact pleading* was to be substituted for the *issue pleading* of the common law. This part of the code reform has been comparatively unsuccessful, because no clear line of demarcation exists between statements of fact and statements of law. An additional change wrought by the code is the adoption of the equity principles of greater freedom of joining parties and of rendering judgments in part for or against the various parties, as the justice of the case may require (the *split judgment* of equity). In spite of the fact that the code reform has not met with the same degree of success in all the States, it seems in general to have been in accord with the desires of the people for simpler judicial procedure. Modern plans for further reform are all in the direction of a greater simplification of practice.

The system inaugurated by the New York Code of 1848 has been adopted in the following jurisdictions: Alaska (1900); Arizona (1864); Arkansas (1868); California (1850); Colorado (1877); Connecticut (1879); Indiana (1852); Iowa (1851); Idaho (1864); Kansas (1859); Kentucky (1851); Minnesota (1851); Missouri (1849); Montana (1865); Nebraska (1855); Nevada (1860); New Mexico (1897); New York (1848); North

Carolina (1868); Korth Dakota (1862); Ohio (1853); Oklahoma (1890); Oregon (1854); Porto Rico (1904); South Carolina (1870); South Dakota (1862); Utah (1870); Washington (1854); Wyoming (1869); Wisconsin (1856); a total of 28 States and two Territories. Of the above States four — Arkansas, Iowa, Kentucky and Oregon — still retain a formal distinction between actions at law and suits in equity, although both are heard in the same court and by the same judge or judges. The code was adopted in Florida in the reconstruction days following the Civil War, but on restoration of the former Government it was supplanted by a modified common-law system. This is the only case where code pleading, once adopted, has been repudiated.

The non-code States are generally classified as common-law States and as "quasi code" or "quasi common law" States according to their nearness of resemblance to the common-law system or to the code system. But in no jurisdiction is the common-law system in force in its entirety. All the States have made some approach to the code principles. In the non-code States in general, the formal distinctions between law and equity actions are maintained, although considerably broken down, especially by the presence of statutes allowing "equitable defences" in actions at law. Often, in these States some distinctions between the forms of action are maintained. as between tort and contract; but even here the minute distinctions of the common law as between trespass and trespass on the case have been abolished.[1] The following may be treated as the "quasi code" or "quasi common-law" States: Massachusetts, Mississippi, Alabama, Maryland, Tennessee, Georgia, Texas and Michigan. The following may be treated as common-law States: Delaware, District of Columbia, Florida, Illinois, Maine, New Hampshire, New Jersey, Rhode Island, Vermont, Virginia and West Virginia. In New Jersey where the equity and law courts are entirely distinct, a practice act was adopted in 1912 for the law courts, which was an advanced system based on the English practice (N.J. Laws, 1912, p. 377). This act has had a salutory effect on a recent New York revision of the code (1920). The code of practice in Louisiana is based upon the civil law of that State.

Federal Procedure. — In the Federal courts, jurisdiction at law and in equity, though administered by the same court, has not been blended, partly because of a belief that under the Federal Constitution the separation of the two systems is necessary. This belief, in the light of the decisions, does not seem well founded. A statute passed in 1915 allows equitable defences in actions at law, and to some extent lessens the difficulties due to the divided system.

A uniform simplified procedure in equity for the Federal courts throughout the country has been established under statutes which enact that "the forms and modes of proceeding in suits of equity and of admiralty and maritime jurisdiction in the district courts shall be according to the principles, rules and usages which belong to courts of equity and of admiralty respectively," and which also authorizes the U.S. Supreme Court to establish rules of practice. U.S. Rev. St. § 913 (28 U.S.C.A. § 723 [U.S. Comp. St. § 1536]); U.S. Rev. St. § 917 (28 U.S.C.A. § 730 [U.S. Comp. St. §1543]). In 1912, by use of this rule-making power the Court succeeded in greatly simplifying the equity practice of the lower Federal courts.

On the law side of the Federal courts, difficulties arise because the controlling "Conformity Act" (originally passed in 1872) provides that "the practice, pleadings, and forms and modes of proceeding in civil causes, other than equity and admiralty causes, in the (federal) district courts shall conform as near as may be, to the practice, pleadings and forms and modes of proceeding existing at the time in like causes in courts of record of the state within which such district courts are held" (U.S. Rev. St. § 914 [28 U.S.C.A. § 724; U.S. Comp. St. § 1537] [not applicable to the circuit courts of appeal or to the U.S. Supreme Court]; Camp v. *Gress*, 250 U.S. 308, 39 Sup. Ct. 478, 1919). The question when conformity is to be had presents a difficult problem. As the Federal courts constitute an entirely independent judiciary system, there can be no conformity in conflict with positive Federal legislation; in any event, the conformity is only "as near as may be." Another difficulty is the lack of a unified practice for all the Federal courts as in Federal equity procedure. In attempting to apply all the differing rules followed in the various States, the conformity practice has served to emphasize the discord. To remedy the situation the American Bar Association has urged the passage of an act by Congress establishing a uniform system of Federal practice in law and equity under rules made by the Supreme Court, similar to the procedure adopted in 1912 as to equity.[2]

Revisions and Future Pleading Reform. — General revisions of the code have been infrequent. In New York, however, prior to 1920 some changes were made resulting in an increase of the bulk of the code. In 1920 the New York Civil Practice Act was adopted, incorporating certain provisions, such as those fur joinder of parties, from the English practice, but retaining many of the undesirable features of the old procedure (N.Y. Laws, 1920, C. 925). While the Practice Act materially reduced the bulk of the code, it continued the policy of legislative control of the details of practice. Authorities generally agree that procedural law requires constant revision and that a fundamental step in procedural reform is the placing of power in the judges to make and alter rules of practice, as under the English system.[3] This should be accompanied by a centralized system of court administration with the chief justice or other official as directing executive head. Among desirable incidental reforms of practice may be noted freer joinder of parties and of claims in a single action, greater facility in waiving jury trial, as by failure of a party affirmatively to claim it, pleading in the alternative, clearer provisions as to when jury trial may be had, abolishment of the demurrer, freer amendment of pleadings, procedure for entering judgments summarily in the absence of a *bona fide* defence (the summary judgment) and procedure for declaring the rights of the parties even though no wrong has actually been committed (the declaratory judgment).

The Function of Pleading. — In pleadings under the code. emphasis was originally placed upon stating the facts rather than conclusions of law on the one hand or mere evidence on the other. It has been urged that this system of *fact pleading* should now give way to a plan of *notice pleading,* a very brief statement designed merely to give notice of the plaintiff's claim to the opponent and to the court (C. B. Whittier, "Notice Pleading," 31 *Harv.* L. *Rev.* 501). Notice pleading differs from fact pleading in the main in the degree of generality of statement permitted. Thus, instead of describing the particulars of an accident, only the time and fact of the accident are alleged. While brevity to this extent is not generally followed in courts of general jurisdiction in the United States, the modem tendency is to place increasing emphasis upon the notice function of all pleadings. This is desirable not only because of the great difficulty in distinguishing facts from law and evidence, but because it comports more with modern ideas of the place of pleading in the judicial system. The legal profession to-day recognizes to an increasingly greater degree that pleading is not an end in itself but only a means to an end, and that end the administration of justice between litigants. The office of pleading and practice is only as an aid in bringing out the substantive legal relations of the parties.

Course of Proceedings in a Legal Action. — Notice to the defendant at the institution of suit and an opportunity to present his side of the case are essential to the American, as to any system of justice. In many of the States (some of which have

[1] This is true even in Illinois, whose "pleading and practice are not only derived from the common-law system, but they are in fact that system, modified, however, by some legislation, which still leaves them the nearest approach to the English law of procedure, as it existed before the passage of the Judicature acts, now remaining anywhere in the world" (35 N.Y. State Bar Assn. Rep. 850). Some States provide merely for the joining of counts in trespass and case (Ala. Code, 1907, § 5,329; R.I. Gen. Laws, 1923, § 4,874).

[2] For the history of the movement and copy of the bill see Rep. of Committee on Uniform Judicial Procedure of Am. Bar Assn., 5 A.B.A.J. 468 (1919); 6 *ibid.*, 509 (1920); 48 A.B.A. Rep. 343 (1923); and later reports of the Association to date.

[3] *See* authorities collected in Clark, Code Pleading, 33, note 103 (1928).

adopted the code procedure), the traditional practice of issuing a writ in the name of the State directing the sheriff to make the summons is followed. In others, however, the writ of the sovereign is supplanted by a simple written summons to appear, signed by the plaintiff or his attorney and served upon the defendant by anyone not a party—usually by a clerk in the office of the plaintiff's attorney. Even in these jurisdictions, when the plaintiff claims some extraordinary or provisional remedy, such as attachment of the defendant's property, arrest of the defendant or an injunction, notice is given in the form of a court order served by some public officer, such as the sheriff. It is necessary that proper *service* of the summons be had, for unless the defendant is legally notified of the action, no *jurisdiction* is acquired over his person. Moreover, unless the action is brought to the proper court, *jurisdiction over the subject matter* does not exist. Next come the pleadings, the first step being the filing by the plaintiff of his *complaint* or *petition* (the *declaration* or *count* of the common law). This contains the names of the parties and the court, a statement of the facts constituting the plaintiff's cause of action and a demand for the judgment to which he thinks himself entitled. The complaint is served upon the defendant with the summons or after the parties are in court or else is supplied to the defendant by the court clerk. If the defendant desires to defend, his first move is to enter an *appearance* which may be done, without his presence in court, by a written notice of appearance by his attorney, or by filing an *answer* to the complaint. By *demurring,* the defendant may question the legal sufficiency of the complaint. But if the demurrer is abolished as in New Jersey and New York, he moves for judgment and thus raises the same issue. In the defendant's *answer* he may deny the plaintiff's allegations or he may admit them and allege new matter in his defence or as a basis for a *counterclaim* against the plaintiff. To this the plaintiff under most codes may file a *reply* (corresponding to the common-law *replication)* and at this stage the pleadings are generally required by the statute to come to an end. Thereafter follows the actual trial with the production of evidence by the parties, followed by the verdict, if a jury is present, and judgment. If the defeated party so desires he may then take an appeal to some appellate tribunal. *(See* APPEAL: *In the United States.)* When the judgment is finally effective, extensive proceedings are available to secure its enforcement.

Criminal Procedure.—Here again the English practice is the source. Indictment by a grand jury is still an essential step in a criminal prosecution in many jurisdictions for capital and many other serious crimes. This body varies in number in the different jurisdictions but usually consists of not less than 12 and not more than 23 persons, at least 12 of whom must concur in presenting an indictment. It may act upon its own knowledge, upon an information of the prosecutor or upon a complaint made under oath by a private person before a committing magistrate. The indictment, which is usually prepared beforehand by the prosecutor and given to the grand jury for its consideration, serves as the prosecution's complaint at the trial. A number of technical rules apply to the indictment, making criminal procedure very rigid. Thus in many jurisdictions unless the indictment describe the offence with great particularity, including its time and place of occurrence and the accused's name, it may be quashed. Such technicalities are a relic of ancient common-law times when the accused was favoured because of the serious penalties imposed for minor offences. But as the reason for these rules is now gone, authorities to-day advocate a procedure requiring only that reasonable notice of the ground of complaint be given the accused. In a considerable number of States an information by the prosecutor has been substituted for the indictment by the grand jury. An information suffices in the Federal courts except in offences punishable by more than one year's imprisonment. Trial by jury is usually a constitutional guarantee except in minor offences. But in Maryland and Connecticut the accused may elect a trial to the court if he so chooses. The American Law Institute, an organization of judges, lawyers and law teachers with headquarters in Philadelphia, Pa., is now engaged as a part of its activities in preparing a model code of criminal procedure. Its first tentative draft, dated April 9, 1928, indicates that a noteworthy attempt is being made by it to simplify the administration of the criminal law.

PRADIER, JAMES (1792–1852), French sculptor, was born at Geneva. He was a member of the French Academy, and a popular sculptor of the pre-Romantic period, representing in France the drawing-room classicism which Canova illustrated at Rome. His chief works are the Niobe group (1822), "Atalanta" (1850), "Psyche" (1824), "Sappho" (1852) (all in the Louvre), "Prometheus" (Tuileries Gardens), a bas-relief on the triumphal arch of the Carrousel, the figures of "Fame" on the Arc de l'Etoile, and a statue of J. J. Rousseau for Geneva. Beside the above noted works mention should be made of his "Three Graces" (1821).

PRADILLA, FRANCISCO (1848–1921), Spanish painter, was born at Villanueva da Gallago (Saragossa). He studied first at the Fernando academy, and then at the Spanish academy in Rome, of which he was afterwards director, and became the leading historical painter of modern Spain. In 1896 he was appointed director of the Madrid museum. Though he is best known for such large historical compositions as "Joan the Mad" (gold medal, Paris, 1878), and "The Surrender of Granada" (gold medal, Munich, 1883), in which he discarded the heavy colouring of Laurens for a lighter and more atmospheric key, he has painted many excellent genre pictures in the manner of Fortuny, and some decorative compositions in which he follows the example of Tiepolo. The best of these are his decorations in the Murgo Palace in Madrid. Among his best known works are "Elopement," "Strand at Vigo," "Procession in Venice," "La Fiorella," "Reading on the Balcony," "Don Alfonso the Warrior," and "Don Alfonso the Scholar." He became member of the Berlin academy and died in Madrid on Oct. 30, 1921.

PRAED, WINTHROP MACKWORTH (1802–1839), English poet, was born in London on July 26, 1802, son of William Mackworth Praed, serjeant-at-law. His mother belonged to the New England family of Winthrop. At Eton Praed founded a ms. periodical *Apis matina,* which was followed by *The Etonian* (1820–21). After a brilliant career at Trinity college, Cambridge, he joined the Middle Temple, was called to the bar in 1829, and went to the Norfolk circuit. He entered parliament in 1830, and was a member of the short Peel administration in 1834. He died on July 15, 1839, in London.

Praed's lighter poetry was the perfection of ease. Austin Dobson has justly praised his "sparkling wit, the clearness and finish of his style, and the flexibility and unflagging vivacity of his rhythm" (Ward's *English Poets).* It abounded in happy allusions to the characters and follies of the day. His humorous verse found numerous imitators.

His poems were first edited by R. W. Griswold (New York, 1844); another American edition, by W. A. Whitmore, appeared in 1859; an authorized edition with a memoir by Derwent Coleridge appeared in 1864; *The Political and Occasional Poems of W. M. Praed* (1888).

PRAEFECT, the title of various Roman officials, civil and military *(praefectus).* A praefect was not a magistrate proper; he was the deputy of a superior magistrate.

City **Praefect.**—The city praefect *(praefectus urbis)* acted at Rome as the deputy of the chief magistrate or magistrates during his or their absence from the city. He represented the consul or consuls when he or they were absent on a campaign or on other public duties, such as the celebration of the annual Latin festival on the Alban Mount. The absence of all the chief magistrates for more than a single day rendered the appointment of a praefect obligatory; after the institution of the praetorship (367 B.C.) the necessity only arose exceptionally, as it rarely happened that both the consuls and the praetor were absent simultaneously. But a praefect was appointed during the enforced absence of all the higher magistrates at the Latin festival. The right of appointing a praefect belonged to the magistrate whose deputy he was. No formalities in the appointment and no legal qualifications on the part of the praefect were required. The praefect had all the powers of the magistrate whose deputy he was, but his office expired on the return of his superior.

Under the empire a new city prefecture was introduced. Augustus occasionally appointed a city praefect to represent him in his absence from Italy, although the praetors, or even consuls, remained in the capital. In the absence of Tiberius at Capreae during the last 11 years of his reign (A.D. 26–37), the city prefecture, hitherto temporary, became a permanent magistracy; henceforth the praefect held office even during the presence of the emperor in Rome. He was chosen by the emperor; his office might be held for years or for life. The praefect was not allowed to quit the city for more than a day at a time. His duty was the preservation of peace in the capital; he was, in fact, the chief of the police, with the superintendence of the streets, markets and public buildings. He was entrusted by Augustus with a summary criminal jurisdiction over slaves and rioters, which was gradually extended until it embraced all offences by whomsoever committed. In the 3rd century A.D., appeals to the emperor in civil cases were handed over to the praefect. An appeal lay from the praefect to the emperor. The praefect commanded the city cohorts (cohortes urbanae), which formed part of the garrison of Rome and ranked above the line regiments, though below the guards (see PRAETORIANS). The military power thus placed in the hands of the chief of the police was one of the most sorely-felt innovations of the empire. The changes of Diocletian and Constantine extended the power of the praefect, in whom, after the removal from R'ome of the highest officials, the whole military, administrative and judicial powers were centred.

Judicial Praefects.—Under the republic judicial praefects (praefecti *iuri* dicendo) were sent annually from Rome as deputies of the praetors to administer justice in certain towns of the Italian allies. These towns were called prefectures (*praefecturae*). After the social war (90–89 B.C.), when all Italy had received the Roman franchise, such prefectures ceased to exist.

Praetorian Praefects.—Under the empire the praetorians or imperial guards were commanded by praefects (praefecti *praetorio*), who were chosen by the emperor and held office at his pleasure. In course of time the command seems to have been enlarged so as to include all the troops in Italy except the corps commanded by the city praefect (cohortes urbanae). Further, the praetorian praefect acquired a criminal jurisdiction which he exercised as the representative of the emperor. A similar jurisdiction in civil cases was acquired by him not later than the time of Severus. Hence a knowledge of law became a qualification for the post, which was held by the first jurists of the age (*e.g.*, Papinian), while the military qualification fell into the background. Under Constantine the institution of the *magistri militum* deprived the praetorian prefecture of its military character, but left it the highest civil office of the empire.

Various Other Praefects.—The title of "praefect" was borne by various other Roman officials, of whom we may mention the following:—

(1) Praefectus *Aegypti* (afterwards Praefectus *augustalis*).—The government of Egypt was entrusted to a viceroy with the title of "praefect" and was surrounded by royal pomp instead of the usual insignia of a Roman magistrate. He was under the immediate orders of the emperor. The exceptional position thus accorded to Egypt was due to its peculiar character and status as an imperial domain and to its very high importance as the granary of Rome.

(2) *Praefectus Vigilum,* the commander of the cohortes *vigilum,* a night police force instituted by Augustus (A.D. 6). One of the principal duties of this force was that of serving as a fire brigade. The *praefectus vigilum* besides commanding the cohortes *vigilum* exercised criminal jurisdiction in cases of incendiarism and offences committed during the night.

BIBLIOGRAPHY.—The different praefects are fully discussed in Mommsen, *Römisches Staatsrecht* (1887), vols. II., III.; see also T. M. Taylor, Constitutional and Political History of Rome **(1899)**; **A.** H. J. Greenidge, Roman Public Life (1901); J. E. Sandys, Companion to Latin Studies (1921).

For the French pre'fet see **PREFECT.**

PRAEMUNIRE, in English law an offence so called from the introductory words of the writ of summons issued to the defendant to answer the charge, "Praemunire facias A.B.," etc., *i.e.*, "cause A.B. to be forewarned." From this the word came to be used to denote the offences, usually ecclesiastical, prosecuted by means of such a writ, and also the penalties they incurred. From the beginning of the 14th century papal aggression had been particularly active, more especially in two forms. The one, the disposal of ecclesiastical benefices, before the same became vacant, to men of the pope's own choosing; the other, the encouragement of resort to himself and his curia rather than to the courts of the country. The Statute of Provisors (1306), passed in the reign of Edward I., was, according to Coke, the foundation of all subsequent statutes of praemunire. This statute enacted "that no tax imposed by any religious persons should be sent out of the country whether under the name of rent, tallage, tribute or any kind of imposition." A much greater check on the freedom of action of the popes was imposed by the Statute of Provisors (1350–51) and the Statute of Praemunire passed in the reign of Edward III. The former ordained the free election of all dignities and benefices elective in the manner as they were granted by the king's progenitors. The Statute of Praemunire (the first statute so called), 1353, enacts "that all the people of the king's ligeance of what condition that they be, which shall draw any out of the realm in plea" or any matter of which the cognizance properly belongs to the king's court shall be allowed two months in which to answer for their contempt of the king's rights in transferring their pleas abroad. Many other statutes followed that of 1353, but that passed in the 16th year of Richard II.'s reign is usually referred to as the Statute of Praemunire. The Royal Marriage Act, 1772, is the last which subjects anyone to the penalties of a praemunire. A peer charged with praemunire is not entitled to trial by his peers, but is to be tried by a jury. The most famous historical instance of a prosecution of the Statute of Praemunire was that of Cardinal Wolsey in 1529.

See E. Coke, Institutes **(1628,** etc.); **J.** Reeves, History of English Law (1783–84); **H.** Hallam, Middle Ages **(1818)**; T. **E.** Tomlin, Law Dictionary (1838); H. J. Stephen, Commentaries on the Laws *of* England (1841–45); W. Stubbs, Constitutional History **(1866)**; J. **F.** Stephen, History oj Criminal Law of *England* **(1883).**

PRAENESTE (mod. Palestrina), a very ancient city of Latium, lies 23 m. E. of Rome by the Via Praenestina (see below), on a spur of the Apennines facing the Alban hills. To the natural strength of the place and its commanding situation Praeneste owed in large measure its historical importance. Objects in metal and ivory discovered in the earliest graves prove that as early as the 8th or 7th century B.C. Praeneste had reached a considerable degree of civilization and stood in commercial relations not only with Etruria but with the East. In 499 B.C., according to Livy, it formed an alliance with Rome. After Rome had been weakened by the Gallic invasion (390) Praeneste joinec in a long struggle with Rome which culminated in the great Latin War (340–338), in which the Romans were victorious, and Praeneste was punished by the loss of part of its territory. It continued in the position of a city in alliance with Rome down to the Social War, when it received the Roman franchise.

As an allied city it furnished contingents to the Roman army and possessed the right of exile (ius *exilii*), *i.e.*, persons banished from Rome were allowed to reside at Praeneste. The nuts of Praeneste were famous and its roses were amongst the finest in Italy. The Latin spoken at Praeneste was somewhat peculiar, and was ridiculed by the Romans, *e.g.*, by Plautus. In the civil wars the younger Marius was blockaded in the town by the Sullans (82 B.C.); and on its capture Marius slew himself, the male inhabitants were massacred in cold blood, and a military colony was settled on part of its territory, while the city was removed from the hill-side to the lower ground at the Madonna dell' Aquila, and the temple of Fortune enlarged so as to include the space occupied by the older city. Under the empire Praeneste, from its elevated situation and cool salubrious air, became a favourite summer resort of the wealthy Romans, whose villas studded the neighbourhood. Horace ranked it with Tibur and Baiae, though as a fact it never became so fashionable a residence as Tibur or the Alban hills. Still, Augustus resorted thither; here Tiberius recovered from a dangerous illness, and here Hadrian and Marcus Aurelius had villas. Amongst private owners were Pliny the younger and Symmachus.

But Praeneste was chiefly famed for its great temple of Fortune and for its oracle, in connection with the temple, known as the "Praenestine lots" (sortes *praenestinae*). The oldest portion of the sanctuary was, however, that situated on the lowest terrace but one. Here is a grotto in the natural rock, containing a beautiful coloured mosaic pavement, representing a sea-scene — a temple of Poseidon on the shore, with various fish swimming in the sea. To the east of this was a basilica in two storeys. As extended by Sulla the sanctuary of Fortune occupied a series of five vast terraces, which, resting on gigantic substructions of masonry and connected with each other by grand staircases, rose one above the other on the hill in the form of the side of a pyramid, crowned on the highest terrace by the small round temple of Fortune. This immense complex, probably by far the largest sanctuary in Italy, must have presented a most imposing aspect, visible as it was from a great part of Latium, from Rome, and even from the sea.

The modern town of Palestrina, a collection of narrow alleys, stands on the terraces once occupied by the temple of Fortune. On the summit of the hill (2,471 ft.), nearly a mile from the town, stood the ancient citadel, the site of which is now occupied by a few poor houses (Castel San Pietro) and a ruined mediaeval castle of the Colonna. Considerable portions of the southern wall of the ancient citadel, built in very massive Cyclopean masonry of blocks of limestone, are still to be seen; and the two walls, also polygonal, which formerly united the citadel with the town, can still be traced. The calendar set up by the grammarian M. Verrius Flaccus in the forum of Praeneste was discovered in 1771. Excavations made in the ancient necropolis, which lay on a plateau surrounded by valleys at the foot of the hill, have yielded important results for the history of the art and manufactures of Praeneste. The famous Ficoroni casket, engraved with pictures of the arrival of the Argonauts in Bithynia and the victory of Pollux over Amycus, was found in 1738. Most of the objects discovered in the necropolis are preserved in the Roman collections, especially in the Villa Giulia, the Museo Pigorini (Collegio Romano) and the Vatican.

Fr.; R. S. Co.; T.A.)

PRAENESTINA, VIA, an ancient road of Italy, leading from Rome east by south to Praeneste, a distance of 23 m., Gabii being situated almost exactly half-way. At the ninth mile the road crosses a ravine by the well-preserved and lofty Ponte di Nona, with seven arches, the finest ancient bridge in the neighbourhood of Rome. In the stretch, for a few miles beyond Gabii it is now only used as a track, and well preserved.

See T. Ashby in Papers of the British School at Rome, i. 149 sqq.

PRAESEPE, a loose star-cluster in the constellation Cancer having a "bee-hive" shape. It is a favourite object for telescopes of low power.

PRAETOR, originally a military title (a leader; Lat. prae . . . ire), was the designation of the highest magistrates in the Latin towns.

Under the republic the Roman consuls were at first called praetors; by the Licinian law of 367 B.C., a new magistrate was created who was to be a colleague of the consuls, though with lesser powers. This new magistrate was entrusted with the jurisdiction in civil cases; in other respects his powers resembled those of the consuls. His title was the city praetor (praetor urbanus), and when the number of praetors was increased, the city praetor always ranked first. To this new magistrate the title of "praetor" was thenceforward restricted. About 242 B.C. the increase of a foreign population in Rome necessitated the creation of a second praetor for the decision of suits between foreigners (*peregrini*) or between citizens and foreigners (praetor *peregrinus*). About 227 two more praetors were added to administer the provinces of Sicily and Sardinia. The conquest of Spain occasioned the appointment of two more in 197. The number of praetors remained stationary until Sulla's time (82 B.C.). Eut in the interval their duties multiplied. On the one hand, five new provinces were added to the Roman dominions; on the other new and permanent jury courts (quaestiones perpetuae) were instituted at Rome, over which the praetors were called on to preside. To meet this increase of business the tenure of office of the praetors and also of the consuls was practically prolonged from one to two years, with the distinction that in their second year of office they bore the titles of propraetor and proconsul instead of praetor and consul. The prolongation of office formed the basis of Sulla's arrangements. He increased the number of the praetors from six to eight, and ordained that henceforward all the eight should in their first year administer justice at Rome and in their second should as propraetors undertake the government of provinces. The courts over which the praetors presided, in addition to those of the city praetor and the foreign praetor, dealt with the following offences: oppression of the provincials by governors (repetundarum), bribery (ambitus), embezzlement (*peculatus*), treason (maiestatis), murder (de *sicariis* et *veneficis*), and forgery (falsi). Later, more provinces were added and more courts constituted, including that of *Gallia Cisalpina.* Iulius Caesar increased the number of praetors.

The praetors were elected, like the consuls by the *comitia* centuriata (see COMITIA) and with the same formalities. They held office for a year. The insignia of the praetor were those of the higher Roman magistrates — the purple-edged robe (toga praetexta) and the ivory chair (sella *curulis*); in Rome he was attended by two lictors, in the provinces by six. The praetors elect cast lots to determine the department which each of them should administer. A praetor as a civil judge at or before his entry on office published an edict setting forth the rules and law procedure by which he intended to be guided. These rules were often accepted by his successors, and corrected and amplified from year to year, became, under the title of the "perpetual" edicts, one of the most important factors in moulding Roman law. Their tendency was to smooth away the anomalies of the civil law by substituting rules of equity for the letter of the law.

Under the Empire. — Under the empire various special functions were assigned to certain praetors, such as the two treasury praetors (*praetores* aerarii), appointed by Augustus in 23 B.C.; the ward praetor (praetor *tutelaris*), appointed by Marcus Aurelius to deal with the affairs of minors; and the liberation praetor (praetor de *liberalibus causis*), who tried cases turning on the liberation of slaves. Of the praetorships with special jurisdiction (especially the ward praetorship and the liberation praetorship) some lasted into the 4th century and were copied in the constitution of Constantinople.

Besides their judicial functions, the praetors as colleagues of the consuls, possessed the consular powers, which they exercised in the absence of the consuls; but in the presence of a consul they exercised them only at the command either of the consul or the senate. (For the praetor as provincial governor see PROVINCE.)

BIBLIOGRAPHY.—A full account of the praetorship will be found in Mommsen, Romisches staatsrecht (1887); T. M. Taylor's Constitutional and Political History of Rome (1899) will also be found useful. See also A. H. J. Greenidge, Roman Public Life (1901); J. E. Sandys, Companion to Latin Studies (1921); W. E. Heitland, The Roman Republic (1923).

PRAETORIANS. In the early Roman republic, praetor (*q.v.*) meant commander of the army: later praetor and propraetor were the usual titles for provincial governors with military powers. Accordingly, the general's quarters in a camp came to be called *praetorium*, and one of the gates *porta* praetoria, and the general's bodyguard *cohors* praetoria. Under the empire cohortes pvaetoriae formed the imperial bodyguard. This, as founded by Augustus, consisted of nine cohorts, each 1,000 strong, some part of which was always with the emperor, whether in Rome or elsewhere. Tiberius concentrated this force on the eastern edge of Rome in fortified barracks. The men were recruited voluntarily, in Italy or Italianized districts, and enjoyed better pay and shorter service than the regular army; they were commanded by *praefecti prae*torio. This force was the only body of troops in Rome (save a few *cohortes urbanae* and some non-Roman personal guards of the emperor), or, indeed, anywhere near the capital. Accordingly it could make or unmake emperors in crises—at the accession of Claudius in A.D. 41, in 68–69, and again late in the second century.

See J. E. Sandys, Companion to Latin Studies (1921).

PRAETORHUS, MICHAEL (1571–1621), German musical historian, theorist and composer, was born at Kreuzberg, Thuringia, on Feb. 1j, 1571. His father's name was Michael Schultze, and the name was latinized as Praetorius. He studied philosophy at Frankfort-on-Oder, and on the death of his brother, on whose support he relied, he was given a post as organist in the town. He was organist and later kapellmeister and secretary to the duke of Brunswick-Wolfenbüttel, and was rewarded for his services with the priory of Ringelheim, near Goslar. He died at Wolfenbüttel on Feb. 1j, 1621. The most important of his compositions are: *Polyhymnia* (15 vols.), *Musae Sioniae* (16 vols.), and *Musa* Aonia (9 vols.), all written partly to Latin and partly to German words. But more precious than all these is the Syntagma *musicum* (3 vols. and a cahier of plates. 4to, Wittenberg and Wolfenbuttel, 1615–20).

For a full description of the work see Grove's Dictionary *of* Music (3rd ed., 1927).

PRAETUTTII, also called Πραιτεττιοί, a tribe of ancient Italy inhabiting the south of Picenum (*q.v.*). Their territory lay between the rivers Vomanum and Tessinnus (Pliny iii. §110), and therefore included Castrum Novum, Interamnia and the Truentus, as well as probably the original of Hadria.

PRAGMATIC SANCTION, originally a term of the later Roman law, is found in the Theodosian and Justinian codes (Lat. *pragmatica* sancfio, from the Gr. πρᾶγμα, business). It was a decision of the state dealing with some interest greater than a question in dispute between private persons, and was given for some community (*universitas hominum*) and for a public cause. In more recent times it was adopted by those countries which followed the Roman law, and in particular by despotically governed countries, to signify an expression of the will of the sovereign defining the limits of his own power or regulating the succession. Justinian regulated the government of Italy by pragmatic sanctions after it had been reconquered from the Ostrogoths. In after ages the king of France, Charles VII., imposed limits on the claims of the popes to exercise jurisdiction in his dominions by the pragmatic sanction of Bourges in 1438. The emperor Charles VI. settled the law of succession for the dominions of the house of Habsburg by pragmatic sanction that was first published on April 19, 1713 (see AUSTRIA). Philip V., the first of the Bourbon kings of Spain, introduced the Salic law by a pragmatic sanction, and his descendant, Ferdinand VII., revoked it by another. The term was not used in England.

PRAGMATISM, in philosophy, a theory or method of dealing with real things (Gr. πράγματα: cf. πραγματικός versed in affairs). "Pragmatic," as here employed is not used in the common colloquial sense of "pragmatical," *i.e.*, "fussy and positive," nor in the historical sense, as in "Pragmatic Sanction," of "relating to affairs of state," but in the sense of practical or efficient. Pragmatism, as a general philosophic doctrine or mental attitude, can only be understood as part of a reaction against the intellectualistic speculation which has characterized most of modern metaphysics. It arises from a general awakening to the fact that the growth of our psychological and biological knowledge must profoundly transform the traditional epistemology. It follows that "pragmatic" lines of thought may originate from a multiplicity of considerations and in a variety of contexts. These, however, may be conveniently classified under four main heads—psychological, logical, ethical and religious—and the history of the subject shows that all these have contributed to the development of pragmatism.

1. Psychologically, pragmatism starts from the efficacy and all-pervasiveness of mental activity, and points out that interest, attention, selection, purpose, bias, desire, emotion, satisfaction, etc., colour and control all our cognitive processes. It insists that all thought is personal and purposive and that "pure" thought is a figment. A judgment which is not prompted by motives and inspired by interest, which has not for its aim the satisfaction of a cognitive purpose, is psychologically impossible, and it is, therefore, mistaken to construct a logic which abstracts from all these facts. Nor is the presence of such non-intellectual factors in thinking necessarily deleterious: at any rate they are ineradicable.

2. In its logical aspect pragmatism originates in a criticism of fundamental conceptions like "truth," "error," "fact" and "reality," the current accounts of which it finds untenable or unmeaning. "Truth," for example, cannot be defined as the agreement or correspondence of thought with "reality," for how can thought determine whether it correctly "copies" what transcends it? Nor can our truth be a copy of a transcendent and absolute truth (Dewey). If it be asked, therefore, what such phrases mean, it is found that their meaning is really defined by their use. The real difference between two conceptions lies in their application, in the different consequences for the purposes of life which their acceptance carries. When no such "practical" difference can be found, conceptions are identical; when they will not "work," *i.e.*, when'they thwart the purpose which demanded them, they are false; when they are inapplicable they are unmeaning (A. Sidgwick). Hence the "principle of Peirce" may be formulated as being that "every truth has practical consequences, and these are the test of its truth." It is clear that this (1) implicitly considers truth as a value, and so connects it with the conception of good, and (2) openly raises the question—What is truth, and how is it to be distinguished from error? This accordingly becomes the central problem of pragmatism. This same issue also arises independently out of the breakdown of rationalistic theories of knowledge (F. H. Bradley, H. H. Joachim). Logical analysis, after assuming that truth is independent and not of our making, has to confess that all logical operations involve an apparently arbitrary interference with their data (Bradley).

3. The ethical affinities of pragmatism spring from the perception that all knowing is referred to a purpose. This at once renders it "useful," *i.e.*, a means to an end or "good." Completely "useless" knowledge becomes impossible, though the uses of knowledge may still vary greatly in character, in directness, and in the extent and force of their appeal to different minds. This relation to a "good" must not, however, be construed as a doctrine of ethics in the narrower sense; nor is its "utilitarianism" to be confused with the hedonism of the British associationists. "Useful" means "good for an (any) end," and the "good" which the "true" claims must be understood as cognitive. But cognitive "good" and moral "good" are brought into close connection, as species of teleological "good" and contributory to "the Good." Thus only the generic, not the specific, difference between them is abolished. The "true" becomes a sort of value, like the beautiful and the (moral) good. Moreover, since the "real" is the object of the "true," and can be distinguished from the "unreal" only by developing superior value in the process of cognition which arrives at it, the notions of "reality" and "fact" also turn out to be disguised forms of value. Thus the dualism between judgments of fact and judgments of value disappears: whatever "facts" we recognize are seen to be relative to the complex of human purposes to which they are revealed. It should further be noted that pragmatism conceives "practice" very widely: it includes everything related to the control of experience. The dualism, therefore, between "practice" and "theory" also vanishes; a "theory" unrelated to practice (however,

indirectly) is simply an illusion.

4. Pragmatism has very distinctly a connection with religion, because it explains, and to some extent justifies, the faith-attitude or will to believe, and those who study the psychology of religion cannot but be impressed with the pragmatic nature of this attitude. If the whole of a man's personality goes to the making of the truth he accepts, it is clear that his beliefs are not matters of "pure reason," and that his passional and volitional nature must contribute to them and cannot validly be excluded. His religion also is ultimately a vital attitude which rests on his interests and on his choices between alternatives which are real for him. It is not however asserted that his mere willing to believe is a proof of the truth of what he wishes to believe, any more than a will to disbelieve justifies disbelief. His will to believe merely recognizes that choice is necessary and implies risk, and puts him in a position to obtain verification (or disproof). The pragmatic claim for religion, therefore, is that to those who will take the first step and will to believe an encouraging amount of the appropriate verifications accrues. It is further pointed out that this procedure is quite consonant with the practice of science with regard to its axioms. Originally these are always postulates which have to be assumed before they can be proved, and thus in a way "make" the evidence which confirms them. Scientific and religious verification therefore, though superficially distinct, are alike in kind.

The *pragmatic doctrine of truth*, which it is now possible to outline, results from a convergence of the above lines of argument. Because truth is a value and vitally valuable, and all meaning depends on its context and its relation to us, there cannot be any abstract "absolute" truth disconnected from all human purposes. Because all truth is primarily a claim which may turn out to be false, it has to be tested. To test it is to try to distinguish between truth and falsity, and to answer the question—What renders the claim of a judgment to be true, really true? Now such testing, though it varies greatly in different departments of knowledge, is always effected by the consequences to which the claim leads when acted on. Only if they are "good" is the claim validated and the reasoning judged to be "right": only if they are tested does the theory of truth become intelligible and that of error explicable. If, therefore, a logic fails to employ the pragmatic test, it is doomed to remain purely formal, and the possibility of applying its doctrines to actual knowing, and their real validity, remain in doubt. By applying the pragmatic test on the other hand, it is possible to describe how truths are developed and errors corrected, and how in general old truths are adjusted to new situations. This "making of truth" is conceived as making for greater satisfaction and greater control of experience. It renders the truth of any time relative to the knowledge of the time, and precludes the notion of any rigid, static or incorrigible truth. Thus truth is continually being made and re-made. If the new truth seems to be such that our cognitive purposes would have been better served by it than they were by the truth we had at the time, it is antedated and said to have been "true all along." If an old truth is improved upon, it is revalued as "false." To this double process there is no actual end, but ideally an "absolute" truth (or system of truths) would be a truth which would be adequate to every purpose.

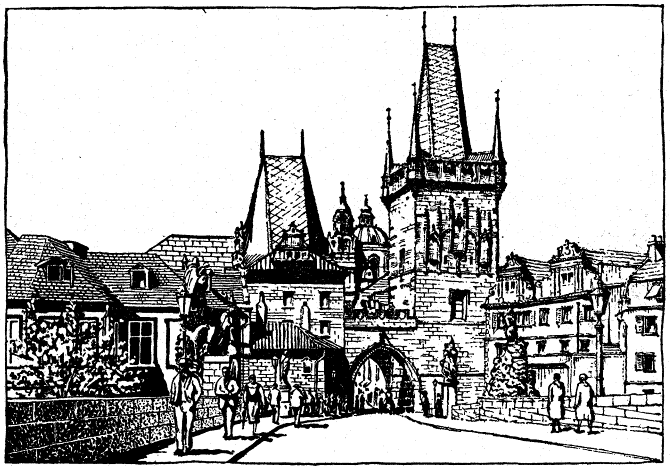
PRAGUE (prāg; Czech *Praha;* Ger. *Prag),* capital of Bohemia and Czechoslovakia, situated on both banks of a large meander of the Vltava. There is ample evidence that the site has been continuously inhabited since Palaeolithic times but its fixed population dates from the Neolithic period, when the advantages of a more open plant association in the valley slopes were exploited by an agricultural people. A fertile soil, mild climate, the shelter of surrounding heights and terraced valley slopes contributed to establish a strong and flourishing settlement which avoided the floor of the valley, subject to inundations.

History.—The early history of the town is obscure and legendary but the site was doubtless selected by Slav chieftains as a



BY COURTESY OF G. K. GEERLING

THE WEST END OF CHARLES BRIDGE, IN PRAGUE. CZECHOSLOVAKIA

convenient central position from which to govern their dominions. Historical records after the 10th century indicate a large settlement protected by two castles, one on a hill of the right bank—the Vyšehrad, and a later one on the Hradčany hill of the opposite bank. Geographically the town has never formed a perfect route centre and its supremacy as a political centre is largely the artificial creation of the successive rulers of Bohemia, who systematically furthered its growth. German colonists, invited to settle by King Vratislav during the 11th century, founded a settlement on the right bank at a place known as Pořič, now forming part of the "New Town" (Prague II.), and later a second settlement, the "Old Town" (Prague I.), was built and walled in by them. About the same period the Jews had a separate settlement first under the shadow of the Vyšehrad but later between the Old Town and the river, and now known as Prague V. or Josef's Town.

In the early part of the 19th century Prague, which had become almost a German city, felt the stirrings of a movement to revive the Czech nationality. At first purely literary and fostered by the "Society of the Bohemian Museum," founded 1822, it gradually assumed a political character. In 1848 a Slav congress was held in Prague. Trouble and conflict occurred between students and soldiers of the garrison, and barricades were erected but the town surrendered after a short bombardment. From that time on the history of Prague was the history of the rebirth of the Czechoslovak nation. Once more it was occupied by the Prussians in 1866, this time without resistance, and here the treaty of peace between Austria and Prussia was signed. Czech feeling and cultural life in Prague grew rapidly until its triumph resulted in the establishment of the republic of Czechoslovakia in 1918, with Prague as the capital. But in March 1939 Prague was occupied by Germans, and Hitler established a protectorate.

Topography!—The larger part of the modern town lies on the east or right bank of the Vltava, the houses spreading up the terraced slopes, often interrupted by parks, and overflowing into side-valleys. This is predominantly the commercial and industrial side of the town, though the "Old Town" and the adjacent parts of the "New Town" retain their ancient appearance. The former is remarkable for several features. Here is the "Ring" or market place with the fine old 14th century town hall, faced by the Týn church (14th–15th centuries) memorable as the religious centre of the Hussite movement and for its tomb of Tycho Brahe, the astronomer. Leading from the town hall to the limit of the old town is the Celetna ulice, at the extremity of which is the so-called powder tower, an elaborate building occupying the site of one of the old gates, at the corner of the Piikopy, which, with its continuations, is on the site of a trench that once encircled the fortifications of the old town. These and the fortifications around the new town are now laid out as parks. The new town lacks the crooked streets and quaint relics of the old, which surpasses it in romantic beauty and interest, but has much that is worth notice, *e.g.,* the National museum (1891) at the head of the Wenceslas place, and the 14th century Karlov church, restored in the 18th century.

The districts on the western bank of the river are mainly residential, with the exception of Holešovice-Bubna, and are dominated by Hradčany hill, on the summit of which lies the vast fortified palace of the ancient kings of Bohemia, now the headquarters of the government and the residence of the president. In the centre of the palace area stands the cathedral of St. Vitus, founded in 930 by the prince-saint Wenceslas, rebuilt by Charles IV and restored in recent times; castle and cathedral epitomize the history of the Czech state.

Industries, Education, **etc.**—Prague is pre-eminently the financial centre and the first manufacturing town of Czechoslovakia, including in its varied industries flour-milling, sugar-refining, brewing, tanning, the preparation of fertilizers and chemicals and the manufacture of furniture, foodstuffs and all types of heavy machinery, notably agricultural implements, rolling stock and river-barges. The re-orientation of the railways in Czechoslovakia has centralized traffic upon the capital, where electrification and enlargement are in progress, while it is also the terminus of Elbe-Vltava shipping; rapid progress is also being made in the direction of making it a centre of commercial aviation. The trade of the city was stimulated in 1920 by the establishment of a sample fair held twice a year and through which it is recovering much of its early importance as a leading centre of European trade.

Culturally too Prague is recovering its ancient leadership through its Czech and German universities and technical schools, while the charm of its numerous handsome buildings and monuments with historical associations, and the attraction of their architecture, even of the many flamboyant examples of Baroque style, are responsible for a growing number of foreign visitors.

The population numbered 676,657 in 1921, 94·2% Czech and 4·6% German. Of the total 468,375 live on the right, the remainder on the left bank of the river, 395,119 are Roman Catholics, 30,961 Protestants, 85.960 belong to the Czechoslovak church, 31,751 are of the Jewish faith and 127,676 are without any confession. In 1930 the total population was 848,823.

Boháč, *Hlvavní Město Praha* (Prague, 1923). (W. S. L.)

Battle of Prague, May *6,* **1757.**—This, the first great victory of Frederick the Great over the Austrians in the SEVEN YEARS' WAR, is described under the latter heading. The town also gives its name to other battles, notably that of 1620, the first important battle in the THIRTY YEARS' WAR (*q.v.*).

PRAGUERIE, THE, a revolt of the French nobility against King Charles VII, in 1440. It was so named because a similar rising had recently taken place in Prague, Bohemia, at that time closely associated with France through the house of Luxemburg, kings of Bohemia, and it was caused by the reforms of Charles VII. at the close of the Hundred Years' War, by which he sought to lessen the anarchy in France. The instigator was Charles I., duke of Bourbon, who three years before had attempted an unsuccessful rising. He and his bastard brother, Alexander, were joined by the former favourite, Georges de la Trémoille, John V., duke of Brittany, who allied himself with the English, the duke of Alençon, the count of Vendôme, and captains of mercenaries like Antoine de Chabannes, or Jean de la Roche. The duke of Bourbon gained over to their side the dauphin Louis — afterwards Louis XI. — then sixteen years old, and proposed to set aside the king in his favour, making him regent. Louis was readily induced to rebel; but the country was saved from a serious civil war by the energy of the king's officers and the solid loyalty of his "good cities." The constable de Richemont marched with the king's troops into Poitou, his old battleground with Georges de la Trémoille, and in two months he had subdued the whole country. Charles VII. then attempted to ensure the loyalty of the duke of Bourbon by the gift of a large pension, forgave all the rebellious gentry, and installed his son in Dauphin6 (see LOUIS XI.).

PRAIRIE, a level tract of grassy and generally treeless country, generally restricted to tracts so characterized in the central parts of North America (adopted from the Fr. prairie, a meadow-tract). In the United States the prairies may roughly be taken to extend from southern Michigan and western Ohio over Illinois (especially designated the Prairie State), Indiana, Missouri, Iowa, Wisconsin and Minnesota, and west of the Missouri to the foothills of the Rocky mountains. In Canada they extend from the same mountains to a line somewhat to the east of Winnipeg. The word prairie is used in a large number of compound names referring to natural and other features, flora, fauna, etc., characteristic of the prairies. Examples are: prairie-chicken or prairie-hen, a name for the pinnated grouse, also applied to the sharp-tailed grouse; prairie-dog, a rodent of the squirre! family.

For detailed description of the prairie scenery and its distinctive types of life *see* D. A. Dondore, ***The*** *Prairie and the Making* of *Middle America: Four Centuries* of *Description* (1927); *B.* Shimek, *Papers on the Prairie* (Iowa City, 1925).

PRAIRIE CHICKEN or **PRAIRIE HEN** (*Tympanuchus americanus*), **a** North American grouse inhabiting the prairies of the Mississippi valley north to Manitoba and south to Louisiana and Texas. The male has a neck-tuft cf ten or more rounded feathers, much reduced in the female. The lesser prairie hen (T. *pallidicinctus*) is smaller and has more buff above. It is confined to south-west Kansas and western Texas The Attwater prairie hen (T. a. attwateri) inhabits the coast districts of Louisiana and Texas.

PRAIRIE-DOG, a North American burrowing rodent allied to the marmots. There are several species in the western United States, ranging as far south as Mexico. The common prairie-dog (Cynomys *ludovicianus*) of the Great Plains region is a plump, short-tailed, squirrel-like animal of social habits. It makes a raised funnel-shaped entrance to its burrows, and congregates in colonies, sometimes many miles in extent and containing many thousands or even millions of individuals. Prairie-dogs feed chiefly upon grass. Rattlesnakes, burrowing owls and weasels are also found in the burrows but this does not indicate a "happy family" arrangement, as these animals prey on the young "dogs," and the prairie-dogs destroy the young owls and sometimes bury the rattlesnakes alive. (See MARMOT; RODENTIA.)

PRAIRIE DU CHIEN, a city of southwestern Wisconsin, U.S.A., on the Mississippi river, 3 mi. above the mouth of the Wisconsin; the county seat of Crawford county. It is on federal highway 18, and is served by the Burlington route and the Chicago, Milwaukee, St. Paul and Pacific railways. Pop. (1930) 3,943; in 1940, 4,622. It is the seat of St. Mary's academy for women (Roman Catholic; 1872) and has various manufacturing industries. Historically it is one of the most interesting spots in the state. In 1680 it was visited successively by Father Hennepin and the trader Du Lhut. In 1685 the French built a fort (St. Nicholas) of which the British assumed possession after the close of the French and Indian war. In 1816, Ft. Crawford was erected, and in 1820 Joseph Rolette established a permanent depot of the American Fur company. The first U.S. court in what is now Wisconsin was opened there in 1823 by Judge James Duane Doty. The "Milwaukee" railroad reached this point in 1857. The city was chartered in 1872.

PRAKRIT LANGUAGES, term applied to the vernacular (*prakṛta,* natural) languages of India as opposed to the literary Sanskrit (*saṁskṛta,* purified). There were two main groups of ancient Indo-Aryan dialects, or Primary Pkakrits; viz., the language of the Midland or Āryāvarta, and that of what is called the Outer Band. The language of the Midland was crystallized in the shape of literary Sanskrit before 300 B.C. Beside it, all the Primary Prakrits continued to develop under the usual laws of phonetics, and, as vernaculars, reached a secondary stage marked by a tendency to simplify harsh combinations of consonants and the broader diphthongs, the synthetic processes of declension and conjugation remaining as a whole unaltered. Although the literary dialect of the Midland became fixed, the vernacular of the same tract continued to develop along with the other Primary Prakrits, but owing to the existence of a literary standard by its side its development was to a certain extent retarded.

The Secondary Prakrits, in their turn, received literary culture. In their earliest stage one of them became the sacred language of Buddhism, under the name of Pali (*q.v.*). In a still later stage several Secondary Prakrits became generally employed for a new literature, both sacred and profane. Three of them were used for the propagation of the Jaina religion (see JAINS), and they were also vehicles for independent secular works, and largely employed in the Indian drama, in which Brahmans, heroes and people of high rank spoke in Sanskrit, while the other characters expressed themselves in some Secondary Prakrit according to nationality or profession. This later stage of the Secondary Prakrits is known as the Prakrit par excellence. In its turn it was fixed by grammarians, and as a literary language ceased to grow, while as a vernacular it went on in its own course. This further development was looked upon as corruption, and its result hence received the name of *Apabhraṁśa*. Again in their turn the *Apabhraṁśas* received literary cultivation and a stereotyped form, while as vernaculars they went on into the stage of the Tertiary Prakrits and become the modern Indo-Aryan languages.

In the Prakrit stage of the Secondary Prakrits we see as before —a Midland language, and the dialects of the Outer Band. The Prakrit of the Midland was known as ŚaurasEni, from Sūrasēna, the name of the country round Mathurā (Muttra). It was the language of the territories having the Gangetic Doab for their centre. To the west it probably extended as far as the modern Lahore and to the east as far as the confluence of the Jumna and the Ganges. Conquests carried the language to Rajputana and Gujarat. The development of SaurasEni was retarded by the influence of its great neighbour Sanskrit. Moreover, both being sprung from the same original—the Primary Prakrit of the Midland—its vocabulary, making allowances for phonetic changes, is the same as in that language.

The Prakrits of the Outer Band, all more closely connected with each other than any one of them was to SaurasEni, were Māgadhī, Ardhamāgadhī, Māhārāṣṭrī, and an unknown Prakrit of the North-west. Māgadhī was spoken in the eastern half of the Gangetic plain. Its proper home was Māgadha, the modern South Bihar, but it extended far beyond these limits at very early times. Judging from the modern vernaculars, its western limit must have been about the longitude of the city of Benares. Between it and Saurasēnī (*i.e.*, in the modern Oudh and the country to its south) lay Ardhamāgadhīmī "half Magādhī." Māhārāṣṭrī was the language of Māhārāṣṭra, the great kingdom extending southwards from the river Nerbudda to the Kistna and sometimes including the southern part of the modern Bombay Presidency and Hyderabad. Its language therefore lay south of SaurasEni. West of SaurasEni, in the Western Punjab, there must have been another Prakrit of which we have no record, although we know a little about its later *Apabhraṁśa* form. Here there were also speakers of Dardic (see INDO-ARYAN LANGUAGES), and the local Prakrit, to judge from the modern Tertiary vernacular, was a mixed form of speech. We have a detailed description of only one *Apabhraṁśa*—the Nāgara—the *Apabhraṁśa* of the Śaurasēnī spoken in the neighbourhood of Gujarat, and therefore somewhat mixed with Māhārāṣṭrī. We may, however, conclude that there was an *Apabhraṁśa* corresponding to each Prakrit, so that we have, in addition to Śaurasēna, a Māgadha, an Ardhamāgadha and a Māhārāṣṭra *Apabhraṁśa*. Native writers describe more than one local *Apabhraṁśa*, such as Vrācaḍa, the ancient dialect of Sind. There were numerous Prakrit subdialects to which it is not necessary to refer. These *Apabhraṁśas* are the direct parents of the modern vernacular.

Māhāraṣṭrī is the Prakrit best known to us. It early obtained literary pre-eminence, was the subject of long treatises by native grammarians, and became the language of lyric poetry and of the formal epic (kavya). Dramatic works have been written in it, and it was also the vehicle of many later scriptures of the Jaina religion. The older Jaina writings were composed in Ardhamāgadhī. The Māgadhī we have brief accounts by native grammarians and short sentences scattered through the plays. Saurasēnī is the usual prose dialect of the plays, and is also employed for the sacred writings of one of the Jaina sects.

The following is a list of the Indo-Aryan vernaculars, showing, when known, the names of the *Apabhraṁśas* from which they are sprung:—

Apabhraṁśa.	Modern language.
	A. Language of *the* Midland.
Śaurasēna . .	Western Hindi
	B. Intermediate Languages.
Āvanta . .	Rājasthānī
" . .	Pahārī Languages
Gaurjaia . .	Gujarātī
Śaurasēna . .	Pañjābī
Ardhamāgadha	Eastern Hindi
	C. Outer *Languages.*
	(a) *North-Western Group.*
Unknown . .	Kāshmīrī (with a Dardic basis)
" . .	Kōhistānī (with a Dardic basis)
" . .	Lahndii or Western Pañjābī
Vracada . .	Sindhi
	(*b*) Southern Language.
Māhārāṣṭra .	Marāṭhī
	(c) Eastern Group.
Māgadha . .	Bihārī
" . .	Oriyā
" . .	Bengali
" . .	Assamese

Language.—Originally real vernaculars with tendencies towards certain phonetic changes, the dialects were taken in hand by grammatical systematizers.

Subsequent writers followed these rules and not the living speech, even though they were writing in what was meant to be a vernacular. Moreover, at an early date, the Prakrits, qua literary languages, began to lose their characteristics as local forms of speech. A writer composed in Māhārāṣṭrī because it was the particular Prakrit employed for lyrics and in formal epics. In dramatic literature, SaurasEni and Miigadhi were put into the mouths of characters in particular walks in life, whatever the nationality of the dramatist might have been.

(Contractions: Skr.=Sanskrit. Pr.=Prakrit. S.= SaurasEni. Mg.=Māgadhī. AMg.=Ardhamāgadhī. M.=Māhāraṣṭrī. Ap.= Nāgara Apabhraṁśa.)

Vocabulary.—The vocabulary of S. is to all intents and purposes the same as that of Skr. In the languages of the Outer Band there are numerous provincial words (dēśī or dēśya), the originals of which belonged to Primary Prakrits other than those of the Midland. In the Outer Band there is also a rich variety of grammatical forms, many of which are found in the Veda and not in classical Sanskrit, and some which cannot be traced to any known Primary Prakrit form, but which must have existed in that stage and preceding it, far back into ancient Indo-European times.

An elaborate system of phonetics was developed by the grammarians. They are of interest as showing the tendencies at work and bring out especially in the case of compound consonants the substitution, mainly by a process of assimilation, of a slurred for a distinct pronunciation.

Declension.—Pr. has preserved the three genders of Skr., but has lost the dual number. As a rule, the gender of a noun follows that of the Skr. original, though in AMg. there is already a tendency to substitute the masculine for the neuter, and in Ap. these two genders are frequently confused, if the distinction is not altogether neglected. In the formation of cases, the phonetic rules just given are fully applied, but there are also other deviations from the Skr. original. The consonantal stems of Skr. declension are frequently given vocalic endings, and there is a general tendency to assimilate their declension to that of *a*-bases, which is helped by the free use of pleonastic suffixes ending in *a,* which are added to the base without affecting its meaning. Of these the most common are *-ka-*, *-ḍa-*, and *-alla-*, *-illa-* or *-ulla-*. The first of these was also very common in Skr., but its use was much extended in Pr. In accordance with the general rule, the *k* is liable to elision. It may even be doubled. *-Ḍa-* is confined to Ap., and may be used alone or together with the other two. *-Illa-* is most common in the Outer languages, and especially so in AMg. and M.

All the Skr. cases are preserved except the dative which has altogether disappeared in the Midland, but has survived in the singular number in the Outer languages. Everywhere the genitive can be employed in its place. Most of the case-forms are derived from Sanskrit according to the phonetic rules, but Ap. has a number of dialectic forms which cannot be referred to that language (*cf.* the remarks above about *-hi* = *θĭ*). It also rarely distinguishes between the nominative and the accusative.

The declension of neuter *a*-bases closely resembles the above, differing only in the nominative and accusative singular and plural. Ap. has almost lost the neuter termination in the singular. Feminine *a*-stems are declined on the same lines, but the cases have run more into each other, the instrumental, genitive and locative singular being identical in form. Very similarly are declined the bases ending in other vowels. The few still ending in consonants and which have not become merged in the *a*-declension, present numerous apparent irregularities.

All the Skr. pronouns appear in Pr., but often in extremely abraded shapes. There is also a most luxuriant growth of by-forms, the genitive plural of the pronoun of the second person being, *e.g.,* represented by no less than 25 different words in M. alone. We also find forms which have no original in classical Skr.

Conjugation.—The Pr. verb shows even more decay than does the noun. With a few isolated exceptions, all trace of the second, or consonantal, conjugation of Skr. has disappeared, and all verbs are now conjugated after the analogy of the *a*-conjugation, which falls into two classes, the first being the *a*-conjugation proper, and the second the *ē*-conjugation, in which the *ē* represents the *aya* of the Skr. 10th class and of causal and denominative verbs. The present participle is the only form which has everywhere survived. All the past tenses (imperfect, perfect and aorists) have fallen into disuse, leaving only a few sporadic remains, their place being supplied, as in the case of the tertiary vernaculars, by the participles, with or without auxiliary verbs. The present tense of the verb substantive has survived from Skr., but it is usual to employ *atthi* (= Skr. *asti*) for both numbers and all persons of the present, and *āsī* (= *āsīt*) for both numbers and all persons of the past. The latter has survived in the modern Punjabi *sī*, was. Another verb substantive (Skr. √ *bhū*) has also survived, generally in the form *hōi* or *huvaï* for *bhavati.* Its usual past participle is *hūa-*, or Mg. *hūda-*, S. *bhūda.* The forms given here are important when the history of the Tertiary Prakrits comes under consideration. These two verbs substantive make periphrastic tenses with other participles, and, in the case of the past participles and gerundives of transitive verbs (both of which are passive in signification), the agent or subject is put into the instrumental case, the participle being used either personally or impersonally, as in the tertiary languages. The gerundive, or future passive participle, is also used impersonally in the case of intransitive verbs.

Besides the participles, the infinitive and the indeclinable participle (gerund) have also survived. So also the passive voice, conjugated in the same tenses as the active. The causal has been already mentioned. There are also numerous denominative verbs (many of them onomatopoeic), and a good supply of examples of frequentative and desiderative bases, mostly formed, with the necessary phonetic modifications, as in Skr. Many direct representatives of Skr. participles in *-ta-* (without the *i*) and *-na-* also appear. As usual there is a tendency to simplification, and the termination *ia* is commonly added to the Pr. present base, instead of following Skr. analogy. All the three forms of the future passive participle or gerundive in *-tavya-*, *-anīya-* and *-ya-* have survived. The infinitive has survived, not only with the form corresponding to the classical Sanskrit termination *-tum,* but also with several old Vedic forms. The same is the case with the gerund, in which both the classical forms in *-tvā* and *-(t)ya* have survived, but with the loss of the distinctive use which obtained in Sanskrit. Besides these there are also survivals of Vedic forms, and even of Primary Prakrit forms not found in the Veda. The passive is generally formed by adding *-jja* or, in S. and Mg., *-īa-* to the root or, more often, to the present stem.

The only tenses which are fully conjugated in Pr. are the present, the imperative, the future and the optative. Except in Ap., the personal terminations in general correspond to the Skr. ones, but in Ap. there are some forms which probably go back to unrecorded Primary Prakrits. The imperative similarly follows the Skr. imperative. The base of the optative is generally formed by adding *-ejja-* in the Outer languages and *-ēa-* in S. The Skr. future termination *-isya-* is represented by *-issa-* or *-ihi-*.

Prakrit Literature.—The great mass of Prakrit literature is devoted to the Jaina religion. The oldest Jaina *sūtras* were in Ardhamāgadhī, while the non-canonical books of the Svētāmbara sect were in a form of Māhārāṣṭri, and the canon of the Digambaras appears to have been in a form of Saurasēnī. Prakrit also appears in secular literature. In artificial lyric poetry it is pre-eminent. The *Sattasaī* (*Saptaśaptikā*) was compiled at some time between the 3rd and 7th centuries A.D. by Hāla. It has had numerous imitators, both in Sanskrit and in the modern vernaculars, such as the Satsaī of Bihārī Lāl (17th century A.D.). Hāla's work is important as showing the existence of a large Prakrit literature at the time when it was compiled. Most of this is lost. In Prakrit we have the *Rāvaṇavaha* or *Sētubandha* (attributed to Pravarasēna, before A.D. 700), dealing with the subject of the *Rāmāyaṇa;* the *Gaüḍavaha* of Vākpati (7th–8th century A.D.), celebrating the conquests of Bengal by Yásōvarman, king of Kanauj, and the *Kumārapālacarita,* or the last eight cantos of the huge *Dvyāśraya Mahākāvya* written by Hēmacandra (A.D. 1150), to serve as a series of illustrations to the author's Sanskrit and Prakrit grammar, the *Sidda-hēmacandra.* The cantos are in Prakrit, and illustrate the rules of that portion of his work. Dramatic literature has also an example in the *Karpūra-mañjarī* ("Camphor-cluster," the name of the heroine) by Rāja-śēkhara (A.D. 900), a comedy of intrigue. An important source of our knowledge of Prakrit, and especially of dialectic Prakrit, is the Sanskrit drama. In works of this class many of the characters speak in Prakrit, different dialects being employed for different purposes. Generally speaking, Śaurasēnī is employed for prose and Māhārastri (the language of lyric poetry) for the songs, but special characters also speak special dialects according to their supposed nationality or profession. The result is that in the Sanskrit drama we have a valuable reflection of the local dialects.

BIBLIOGRAPHY.—*See* R. Pischel's *Grammatik der Prākritsprachen* (Strasbourg, 1900). As an introduction to the study of the language, the best work is H. Jacobi's *Ausgewählte Erzählungen in Mâhârashṭrî zur Einführung in das Studium des Prâkrit, Grammatik, Text, Wörterbuch* (Leipzig, 1886). The best editions of the grammars are E. B. Cowell's of Vararuci's *Prākṛta-Prakāśa* (1868), R. Pischel's of Hēmacandra (Halle, 1877, 1889), and E. Hultzsch's of Śiṁharāja's *Prākṛtarūpāvatāra* (1909). For *Dēśya* words, *see* Pischel's *The Dēśînâmamâlâ of Hemachandra* (Bombay, 1880). For *Apabhraṁśa,* in addition to his edition of Hēmacandra's grammar, *see* the same author's *Materialen zur Kenntnis des Apabhraṁśa* (1902). For *Apabhraṁśa* texts published in Europe, mention may be made of Dhanavāla's *Bhavisatta Kaha* (Munich, 1918), and Haribhadra's *Sanatkumāsacaritom* (Munich, 1921), both edited by H. Jacobi with valuable introductory essays, dealing with the whole question of Prakrit. For the mutual relationship of the various Prakrits, *see* S. Konow, "Mâhârâshṭrî and Mârâthî," in the *Indian Antiquary* (1903), xxxii., 180 *sqq.* For Jaina Prakrit, *see* under JAINS. In the secular texts the best editions are: A. Weber, *Das Saptataçatakam des Hāla* (Leipzig, 1881); another edition by Durgāprasād and Kāśīnáth Pāṇḍurang Parab under the title of *The Gâthasapataśatî of Śâtavâhana* (Bombay, 1889) [a good commentary]; S. Goldschmidt, *Rāvaṇavaha oder Setubandha* (Strasbourg, 1880–83) [text and translation]; Sivadatta and Parab, *The Setubandha of Pravarasena* (Bombay, 1895); Shaṅkar Pāṇḍurang Pandit, *The Gaüḍavaho, a Historical Poem in Prâkrit, by Vâkpati* (Bombay, 1887); the same editor, *The Kumârapâla-charita* (Bombay, 1900); *Rajaçekhara's Karpūramañjari,* edited by S. Konow,

translated by C. R. Lanman (Cambridge, Mass., 1901).

The literature of the Sanskrit drama is given under SANSKRIT.

PRAM, the name of a flat-bottomed boat or barge used as a "lighter" for discharging and loading cargo in the ports of the Baltic and North Sea. The word, which is common in various forms to all the languages bordering on those seas, is Slavonic.

PRANTL, KARL VON (1820–1888), German philosopher, was born at Landsberg on the Lech on Jan. 28, 1820, and died on Sept. 14, 1888, at Oberstdorf. In 1843 he became doctor of philosophy at Munich Observatory, where he was made professor. His best known work is the Geschichte der Logik *im Abendland* (Leipzig, 1855–70).

PRASEODYMIUM, a metallic element (symbol Pr, atomic number 59, atomic weight 140·9), of the rare-earth group, was discovered in 1885 by von Welsbach when he separated "didymium" into praseodymium and neodymium. This metal occurs along with lanthanum, cerium, neodymium, etc., in monazite, cerite and allanite. It is usually separated by fractional crystallization, employing first the double magnesium nitrate, and finally the double ammonium nitrate. The oxide is an almost black powder, the composition of which varies according to the method of preparation. It is usually considered to be Pr_4O_7; reduction in hydrogen gives Pr_2O_3. The oxides are soluble in acids giving green salts such as $Pr_2(SO_4)_3,8H_2O$, which show a strong characteristic absorption spectrum. The metal is prepared by the electrolysis of the fused chloride. It melts at 940° C. (See RARE EARTHS.)

(C. J.)

PRATI, GIOVANNI (1815–1884), Italian poet, was born at Dasindo and studied law at Padua. An ardent partisan of the house of Savoy, in 1862 he was elected a deputy to the Italian parliament, and in 1876 a senator. He died at Rome on May 9, 1884. Prati's work ranged from his romantic narrative *Ermenegarda* (1841) to the 500 sonnets collected in Psiche (187;) and the poems entitled *Iside* (1878). His *Opere varie* were published in five volumes in 1875, and a selection in one volume in 1892.

PRATINAS, a tragic poet of Athens, was a native of Phlius in Peloponnesus. About 500 B.C. he competed with Choerilus and Aeschylus, when the latter made his first appearance as a writer for the stage. Pratinas was also the introducer of satyric dramas as a species of entertainment distinct from tragedy. Pratinas was also a writer of dithyrambs and the choral odes called *hyporchemata* (a considerable fragment of one of these is preserved in Athenaeus xiv. 617).

See Pausanias ii. *13;* Suidas (*q.v.*) ; fragments in T. Bergk, Poetae *lyrici graeci,* vol. iii.

PRATINCOLE, a name for the bird Glareola *pratincola,* forming the type of a genus belonging to the order Limicolae. The pratincoles, of which eight or nine species have been described, are small birds, slenderly built and delicately coloured, with a short stout bill, a wide gape, long pointed wings and a forked tail. In some of their habits they are thoroughly plover-like, running swiftly and breeding on the ground, but on the wing they have much the appearance of swallows and, like them, feed, at least partly, while flying. The pratincole of Europe, G. pratincola, breeds in many parts of Spain, Barbary and Sicily, along the valley of the Danube and in southern Russia. In the south-east of Europe a second and closely allied species, G. nord*manni,* which has black instead of chestnut inner wing-coverts, accompanies or, farther east, replaces it; other species occur in Asia, Africa and Australia.

PRATO IN TOSCANA, a town and episcopal see of Tuscany, Italy, in the province of Florence, 11 m. by rail N.W. of Florence, 207 ft. above sea-level. Pop. (1936), 28,646, town; 70,206, commune. It is situated on the Bisenzio, and was dominated by a castle built by Frederick II. (c. 1250). The cathedral was begun in the 12th century; to this period belongs the narrow nave with its wide arches; the raised transepts and the chapels were added by Giovanni Pisano in 1317–1320; the campanile dates from 1340, while the façade, also of alternate white sandstone and green serpentine, belongs to 1413. It has a fine doorway with a bas-relief by Andrea della Robbia over it and a lovely open-air pulpit, erected in 1439 by Donatello and Michelozzo for displaying the Virgin's girdle, brought from the Holy Land by a knight of Prato in 1130. The pulpit itself has beautiful reliefs of dancing children; beneath it is a splendid bronze capital. The Chapel of the Girdle has a statue of the Virgin by Giovanni Pisano, and a handsome bronze open-work screen. The frescoes in the choir, with scenes from the life of St. John the Baptist and St. Stephen, are by Fra Filippo Lippi (1456–1466) and are his best work.

The massive old Palazzo Pretorio (13th century) contains a small but good picture gallery. A beautiful Madonna by Filippino Lippi (1498) is in a small street shrine at the corner of the Via S. Margherita. The Madonna del Buon Consiglio has some good reliefs by Andrea della Robbia, by whom is also the beautiful frieze in the Madonna delle Carceri. This church, by Giuliano da Sangallo (1485–1491), is a Greek cross, with barrel vaults over the arms, and a dome; it is a fine work, and the decoration of the exterior in marble of different colours (unfinished) is of a noble simplicity. The industries of Prato embrace the manufacture of woollens (174 establishments in the Val Bisenzio), straw-plaiting, etc.

See E. Corradini, *Prato* (Bergamo, 1905) ; R. Papini, *Prato* in *Toscana, 1910.*

PRATT, a city of southern Kansas, U.S.A., on the headwaters of the Ninnescah river, at an altitude of 1,916 ft.; the county seat of Pratt county; on federal highways 54 and 281; served by Rock Island and Santa Fe railways. Pop. (1940) 6,591. Pratt is a well built, well kept city, surrounded by a highly developed agricultural region of gently rolling land. It has a commission form of government, a city-planning commission and zoning regulations. Founded in 1884, Pratt was chosen as the county seat in 1886. It is the home of the Kansas State Fish hatchery.

PRAWN, a name applied to the larger shrimp-like Crustacea, in Great Britain usually to Leander *serratus.* (See SHRIMP.)

PRAXITELES, of Athens, the son of Cephissodotus, the greatest of the Attic sculptors of the 4th century B.C., who has left an imperishable mark on the history of art.

Though Praxiteles may be considered as in some ways well known to us, yet we have no means for fixing his date accurately. It seems clear that he was no longer working in the time of Alexander the Great, or that king would have employed him. Pliny's date, 364 B.C., is probably that of one of his most noted works. We possess one undisputed original work of Praxiteles, that of the marble statue of Hermes carrying the infant Dionysus (GREEK ART, Plate VI., fig. 3). The young child can hardly be regarded as a success; he is not really childlike. But the figure of the Hermes, full and solid without being fleshy, at once strong and active, is a masterpiece, and the play of surface is astonishing. In the head we have a remarkably rounded and intelligent shape, and the face expresses the perfection of health.

This statue is our best evidence for the style of Praxiteles. It altogether confirms and interprets the statements as to Praxiteles made by Pliny and other ancient critics. Gracefulness in repose, and an indefinable charm are also the attributes of works in our museums which appear to be copies of statues by Praxiteles. Perhaps the most notable of these are the Apollo Sauroctonus, or the lizard-slayer, a youth leaning against a tree and idly striking with an arrow at a lizard, and the Aphrodite at the bath (GREEK ART, Plate VI., figs. 5, 6) of the Vatican, a copy of the statue made by Praxiteles for the people of Cnidus. There is a story that Phryne, who was supposed to have been Praxiteles' model, induced him to name his two finest works by telling him his studio was on fire. He named the Eros and the Satyr. The "Capitoline Faun" at Rome has been identified as a copy of this, and a torso in the Louvre may even be the original.

Excavations at Mantineia in Arcadia have brought to light the basis of a group of Leto, Apollo and Artemis by Praxiteles. This basis was doubtless not the work of the great sculptor himself, but of one of his assistants. Nevertheless it is pleasing and historically valuable. Pausanias (viii. 9, 1) thus describes the base, "on the base which supports the statues there are sculptured the Muses and Marsyas playing the flutes." Three slabs which have survived represent Apollo, Marsyas, a slave and six of the Muses, the slab which held the other three having disappeared.

Four points of composition may be mentioned, which appear to be in origin Praxitelean: (1) a very flexible line divides the figures if drawn down the midst from top to bottom; they all tend to lounging; (2) they are adapted to front and back view rather than to being seen from one side or the other; (3) trees, drapery and the like are used for supports to the marble figures, and included in the design, instead of being extraneous to it; (4) the faces are presented in three-quarter view.

The subjects chosen by Praxiteles were either human beings or the less elderly and dignified deities. It is Apollo, Hermes and Aphrodite who attract him rather than Zeus, Poseidon or Athena. And in his hands the deities sink to the human level, or, indeed, sometimes almost below it. They have grace and charm in a supreme degree, but the element of awe and reverence is wanting. Between them Scopas with his gift for expressing emotion, and Praxiteles, with his delicacy and grace, changed the whole aspect of such sculpture, and the development of later ages derives largely from these two.

See Klein, *Praxiteles* (Leipzig, 1838); Perrot, *Praxitèle* (Paris, 1905).

PRAYER, a term used generally for any humble petition, but more technically, in religion, for that mode of addressing a divine or sacred power in which there predominates the mood and intention of reverent entreaty (from Lat. *precari*, entreat; Ital. *pregaria;* Fr. *prière*).

Prayer and its Congeners.—Prayer in the latter sense is a characteristic feature of the higher religions, and we might even say that Christianity or Mohammedanism, ritually viewed, is in its inmost essence a service of prayer. At all stages of religious development, however, and more especially in the case of the more primitive types of cult, prayer as thus understood occurs together with, and shades off into, other varieties of observance that bear obvious marks of belonging to the same family.

Confining ourselves for the moment to forms of explicit address, we may group these under three categories according as the power addressed is conceived by the applicant to be on a higher, or on much the same, or on a lower plane of dignity and authority as compared with himself. (1) Only if the deity be regarded as altogether superior is there room for prayer proper, that is, reverent entreaty. Of this we may perhaps roughly distinguish a higher and a lower type, according as there is either complete confidence in the divine benevolence and justice, or a disposition to suppose a certain arbitrariness or, at any rate, conditionality to attach to the granting of requests. In the first case prayer will be accompanied with disinterested homage, praise, and thanksgiving, and tends to lose its distinctive character of entreaty or petition, passing into a mystic communing or converse with God. In the second case it will be supported by pleading, involving on the one hand self-abasement, with confession of sins and promises of repentance and reform, or on the other hand self-justification, in the shape of the expression of faith and recitation of past services, together with reminders of previous favour shown. (2) If the worshipper place his god on a level with himself, so as to make him to some extent dependent on the service man contracts to render him, then genuine prayer tends to be replaced by a mere bargaining, often conjoined with flattery and with insincere promises. This spirit of do *ut* des will be found to go closely with the gift-theory of sacrifice (*q.v.*) and to be especially characteristic of those religions of middle grade that are given over to sacrificial worship as conducted in temples and by means of organized priesthoods. So when the high gods are kind for a consideration, the lower deities will likewise be found addicted to such commerce; thus in India the hedge-priest and his familiar will bandy conditions in spirited dialogue audible to the multitude (cf. W. Crooke, Things Indian, *s.v.* "Demonology," pp. 132, 134). (3) Lastly, the degree of dependency on human goodwill attributed to the power addressed may be so great that, instead of diplomatic politeness, there is positive hectoring, with dictation, threats, and abuse. Even the Italian peasant is said occasionally to offer both abuse and physical violence to the image of a recalcitrant saint; and antiquity wondered at the bullying manner of the Egyptians towards their gods (cf. Iamblichus, *De* mysteriis, vi. 5–7). Westermarck supplies many instances from Morocco of *'âr* the "conditional curse," applied to saints in order to make them attend, on pain of disaster if they are recalcitrant (History and Development of the Moral Ideas, passim). This frame of mind, however, is mainly symptomatic of the lower levels of cult. Thus the Zulu says to the ancestral ghost, "Help me or you will feed on nettles"; whilst the still more primitive Australian exclaims to the "dead hand" that he carries about with him as a kind of divining-rod, "Guide me aright, or I throw you to the dogs."

So far the forms of address are explicitly directed towards a power that, one might naturally conclude, has personality, since it is apparently expected to hear and answer. At the primitive stage, however, the degree of personification is, probably, often far slighter than the words used would seem to suggest. The verbal employment of vocatives and of the second person may have little or no personifying force, serving primarily but to make the speaker's wish and idea intelligible to himself. When the rustic talks in the vernacular to his horse he is not much concerned to know whether he is heard and understood; still less when he mutters threats against an absent rival, or kicks the stool that has tripped him up with a vicious "Take that!"

These considerations may help towards the understanding of a second class of cases, namely, forms of implicit address shading off into unaddressed formulas. Wishings, blessings, cursings, oaths, vows, exorcisms, and so on, are uttered aloud, partly that they may be heard by the human parties to the rite, but in many cases that they may be heard, or at least overheard, by a consentient deity, perhaps represented visibly by an idol or other cult-object.

From Suggestion to Prayer.—To address and entreat a fellow-being is a faculty as old as that of speech, and, as soon as it occurred to man to treat sacred powers as fellow-beings, assuredly there was a beginning of prayer. We are not likely to know how religion first arose, and the probability is that many springs went to feed that immense river. Thus care for the dead may well have been one amongst such separate sources. It is natural for sorrow to cry to the newly dead "Come back!" and for bereavement to add "Come back and help!" Another source is mythologic fancy, which, in answer to child-like questions: "Who made the world?" "Who made our laws?" and so on, creates "magnified non-natural men," who presently made their appearance in ritual (for to think a thing the savage must dance it); whereupon personal intercourse becomes possible between such a being and the tribesmen, the more so because the supporters of law and order, the elders, associate themselves as closely as possible with the supreme law-giver. From Australia comes a certain amount of evidence showing that, in the two ways just mentioned, some inchoate prayer is being evolved. On the whole, the absence of prayer from the magico-religious ritual of the Australians is conspicuous. Uttered formulas abound; yet they are not forms of address, but rather self-sufficient pronouncements charged with *mana* (*q.v.*). They involve a wonder-working recognized as such, the core of the mystery consisting in the supposed transformation of suggested idea into accomplished fact by means of that suggestion itself. To the man endowed in the opinion of his fellows (and doubtless of himself) with this wonderful power of effective suggestion, the output of such power naturally represents itself as a kind of unconditional willing. When he cries "Rain, rain," or otherwise makes vivid to himself and his hearers the idea of rain, expecting that the rain will thereby be forced to come, it is as if he had said "Rain, now you must come," or simply "Rain, come!" and we find that suggestional formulas mostly assume the tone of an actual or virtual imperative, "As I do this, so let the like happen," "I do this in order that the like may happen," and so on. Now it is easy to "call spirits from the vasty deep," but they do not always come. Hence such imperatives have a tendency to dwindle into optatives. "Let the demon of small-pox depart!" is replaced by the more humble "Grandfather Smallpox, go away!" where the affectionate appellative (employed, however, in all likelihood merely to cajole) signalizes an approach to the genuine spirit of prayer. Again, the user of suggestion conscious of his limitations will seek to supplement his *mana* by tapping, so to speak, whatever sources of similar power lie round about him. A notable method of borrowing power from another agency involving *mana* is simply to breathe its name in connection with the spell that stands in need of reinforcement; as the name suggests its owner, so it comes to stand for his real presence. Even the more highly developed forms of liturgical prayer tend, in the recitation of divine titles, attributes and the like to present a survival of this formalist use of potent names. *(See* NAME.)

Prayer as a Part of Ritual. — By an exactly converse process prayer actually generates formalism, instead of growing out of it. In advanced religion, indeed, prayer is the chosen vehicle of the free spirit of worship. Its mechanism is not unduly rigid, and it is largely autonomous, being rid of subservience to other ritual factors. In more primitive ritual, however, set forms of prayer are the rule, and their function is mainly to accompany and support a ceremony the nerve of which consists in action rather than speech. Hence, suppose genuine prayer to have come into being, it is apt to degenerate into a mere piece of formalism; and yet, whereas its intrinsic meaning is dulled by repetition according to a well-known psychological law, its virtue is thereby hardly lessened for the undeveloped religious consciousness, which holds the saving grace to lie mainly in the repetition itself. But a formula that depends for its efficacy on being uttered rather than on being heard is virtually indistinguishable from the purely suggestional type of utterance, though its origin is different. A good example of a degenerated prayer-ritual comes from the Todas *(see* W. H. R. Rivers, *The Todas,* ch. x.). The prayer itself tends to be slurred over, or even omitted. On the other hand, great stress is laid on a preliminary citation of names of power followed by the word *idith.* This at one time seems to have meant "for the sake of," carrying with it some idea of supplication; but it has now lost this connotation, seeing that it can be used not merely after the name of a god, but after that of any sacred object or incident held capable of imparting efficacy to the formula. Even the higher religions have to fight against the tendency to "vain repetitions" (often embodying a certain sacred number, *e.g.* three), as well as to the use of prayers as amulets, medicinal charms, and so on. Throughout we must carefully distinguish in theory, though hard in practice, between legitimate ritual understood as such, whether integral to prayer, such as its verbal forms, or accessory, such as gestures, postures, incense, oil or what not, and the formalism of religious-decay, such as generally betrays itself by its meaninglessness, by its gibberish phrases, sing-song intonation and so forth.

Silent Prayer. — A small point in the history of prayer, bearing on the subject of its relation to magic, is concerned with the custom of praying silently. Charms and words of power being supposed to possess efficacy in themselves are guarded with great secrecy by their owners, and hence, in so far as prayer verges on spell, there will be a disposition to mutter or otherwise conceal the sacred formula. Thus the prayers of the Todas already alluded to are in all cases uttered "in the throat," although these are public prayers, each village having a form of its own. At a later stage, when the distinction between magic and religion is more clearly recognized and an anti-social character definitely assigned to the former, on the ground that it subserves the sinister interests of individuals, the overt and, as it were, congregational nature of the praying comes to be insisted on as a guarantee that no magic is being employed, a notion that suffers easy translation into the view that there are more or less disreputable gods with whom private trafficking may be done on the sly. Thus, in accordance with the outlook of the classical period, Plato in his *Laws* (909–910) prohibits all possession of private shrines or performance of private rites; "Let a man go to a temple to pray, and let anyone who pleases join with him in the prayer." Nevertheless, instances are not wanting amongst the Greeks of private prayers of the loftiest and the most disinterested tone *(cf.* L. R. Farnell, *The Evolution of Religion,* p. 202 *seq.).* Finally, in advanced religion, at the point at which prayer is coming to be conceived as communion, silent adoration is sometimes thought to bring man nearest to God.

The Moralization of Prayer.——As to the moral quality of the act of prayer, this contrast between the spirit of public and private religion is fundamental for all but the most advanced forms of cult. In its public rites the community becomes conscious of common ends and a common edification. Even a very primitive people such as the Arunta of Australia behaves with the greatest solemnity at its ceremonies, and professes to be made "glad" and "strong" thereby. Of his countrymen, whom he would not trust to pray in private, Plato testifies that in the temples during the sacrificial prayers "they show an intense earnestness and with eager interest talk to the gods and beseech them" *(Laws,* 887). In acts of public worship at any rate, therefore, prayer and its magico-religious congeners are at all stages resorted to as a "means of grace," even though such grace does not constitute the expressed object of petition. Poverty of expression is apt to cloak the real spirit of primitive prayer, and the formula under which its aspirations may be summed up, namely, "Blessings come, evils go," covers all sorts of confused notions about a grace to be acquired and an impurity to be wiped away, which, as far back as our clues take us, invite interpretations of a decidedly spiritualistic and ethical order. To explicate, however, and purge the meaning of that "strong heart" and "clean" which the savage after his fashion can wish and ask for, remained the task of the higher and more self-conscious types of religion. A favourite contrast for which there is more to be said is that drawn between the magico-religious spell-ritual, that says in effect, "My will be done," and the spirit of "Thy will be done" that breathes through the highest forms of worship. Such resignation in the face of the divine will and providence is, however, not altogether beyond the horizon of primitive faith, as witness the following prayer of the Khonds of Orissa: "We are ignorant of what it is good to ask for. You know what is good for us. Give it to us." (Tylor, *Prim. Culture,* 4. 369). At this point prayer by a supreme paradox virtually extinguishes itself, since in becoming an end in itself, a means of contemplative devotion and of mystic communing with God, it ceases to have logical need for the petitionary form. Thus on the face of it there is something like a return to the self-sufficient utterance of antique religion; but, in reality, there is all the difference in the world between a suggestion directed outwardly in the fruitless attempt to conjure nature without first obeying her, and one directed towards the inner man so as to establish the peace of God within the heart.

PRAYER, BOOK OF COMMON, the title of the official service book of the Church of England. One of the most important steps taken at the Reformation was the compilation and provision of a comprehensive service book for general and compulsory use in public worship throughout the Church of England. The following main advantages were achieved.

(1) The substitution of the English language for the Latin language, in which all the old service books were written.

(2) Unification and simplification. The Prayer Book represents in a much condensed and abbreviated form the four chief ancient service books, viz.: the Missal, Breviary, Manual and Pontifical. In addition to a multiplicity of books there was much variety of use. Although the Sarum Use prevailed far the most widely, yet there were separate Uses of York and Hereford, and also to a less degree of other dioceses and cathedral churches as well. Cranmer's preface "Concerning the Service of the Church" expressly mentions the abolition of this variety as one of the things to be achieved by a book of Common Prayer. It says: "And whereas heretofore there hath been great diversity in saying and singing in Churches within this Realm; some following Salisbury Use, some Hereford Use, and some the Use of Bangor, some of York, some of Lincoln; now from henceforth all the whole Realm shall have but one Use." On the sources from which the Prayer Book was compiled, *see* F. Procter and W. H. Frere, *New History of the Book of Common Prayer* (2nd ed. 1902), and the works mentioned below.

Of changes preceding the first Prayer Book we may note: (a) The compiling and publishing of the Litany in English by Cranmer in 1544. (b) Royal injunctions in Aug. 1547 ordering the Epistle and Gospel to be read in English at High Mass. (c) A royal proclamation, dated March 8, 1548, imposing for use at the coming Easter *The* Order *of the Communion.* This was an order or form of service in English for the communion of the people in both kinds. It was to be inserted into the service after the communion of the priest, without making any other alteration in the Latin Mass. It comprised the long exhortation or notice to be given on Sunday, or on some other day, previous to the Communion, the longer exhortation, and the shorter invitation, the confession, absolution, comfortable words, prayer of humble access, formulae of administration and the concluding peace, much as they exist at present.

The First Complete Prayer Book.—The first complete vernacular Book of Common Prayer was issued in Jan, 1549. An Act of Uniformity made its use compulsory on and after the following Whit-Sunday. Some of the chief points of difference between this and subsequent Prayer Books were the following: Matins and Evensong began with the Lord's Prayer, and ended with the third collect; the Athanasian Creed was introduced after the Benedictus on six festivals only, and in addition to the Apostles' Creed; to the Communion service an alternative title was given, viz.: "commonly called the Mass." Introits were provided for use on every Sunday and Holy-Day; in the prayer for the whole state of Christ's church, the blessed Virgin Mary was commemorated by name; prayer for the dead was explicitly retained; also an invocation of the Holy Spirit before the words of institution, the prayer of oblation immediately following them; the mixed chalice was ordered to be used, and the Agnus Dei to be sung during the Communion of the people; unleavened bread was to be used and placed in the mouth of the communicant; the sign of the cross was frequently to be made; reservation for the sick and unction of the sick were retained; and exorcism, unction, trine immersion and the chrisom were included in the baptismal service. As to vestments, at Holy Communion the officiating priest was to wear "a white albe plain with a vestment or cope," and the assistant clergy were to wear "albes with tunicles." Whenever a bishop was celebrant he was to wear, "beside his rochette, a surplice or albe, and a cope or vestment"; the mitre was not mentioned.

The ordinal was added to this Prayer Book in 1550 by another act of parliament. It included the deliverance to the newly ordained priest of the chalice or cup, with the bread.

Second Prayer Book.—In 1552 a new and revised edition was introduced by an act of parliament which ordered that it should come into use on All Saints' Day (Nov. 1). This represents the most Protestant position ever reached in the Prayer Book. The chief alterations were: (1) the introductory sentences, exhortation, confession and absolution were to be read at the beginning of the order for morning and evening prayer; (2) in the order for Holy Communion the alternative title "commonly called the Mass" was left out; the introits were omitted, the Gloria in Excelsis was transferred from near the beginning to near the end of the service; the ten commandments with an expanded Kyrie eleison were introduced; the long new English canon of 1549 was split up into three parts—the prayer for the church militant, the prayer of consecration and prayer of oblation, becoming a post-Communion collect; the epiklesis or invocation of the Holy Ghost upon the elements was entirely omitted; the mixed chalice, the use of the sign of the cross in the consecration prayer; the coinmemoration of the blessed Virgin Mary and of various classes of saints were omitted; the words of administration in the 1549 book were abolished, viz.: "The body of our Lord Jesus Christ which was given for thee, preserve thy body and soul unto everlasting life," and "The blood of our Lord Jesus Christ which was shed for thee preserve thy body and soul unto everlasting life," and the following words were substituted: "Take and eat this in remembrance that Christ died for thee, and feed on him in thy heart by faith, with thanksgiving," and "Drink this in remembrance that Christ's blood was shed for thee, and be thankful;" a long rubric was added at the end of the service explanatory of the attitude of kneeling at the reception of Holy Communion, in which it was stated that "it is not meant hereby that any adoration is done, or ought to be done, either unto the sacramental bread and wine there bodily received, or to any real and essential presence there being of Christ's natural flesh and blood," etc.; exorcism, unction, trine immersion and the chrisom were omitted from the baptismal service; unction and communion with the reserved sacrament were removed from the services for the visitation and the communion of the sick; prayers for the dead and provision for a celebration of Holy Communion at a funeral were removed from the burial service; the vestments retained and ordered under the Prayer Book of 1549 were abolished by a new rubric which directed that both at the time of Communion and at all other times of ministration a bishop should wear a rochet and that a priest or deacon should have and wear a surplice only; on the other hand, the directions as to daily service were extended to all clergy and made much stricter, and the number of days on which the Athanasian Creed was to be used was raised from six to thirteen.

The main objects of these drastic alterations have been thought to have been two-fold: to abolish all ritual for which there was not scriptural warrant; and to make the services as unlike the pre-Reformation services as possible. The alterations were violent enough to alarm and offend the Catholic party, but they were not violent enough to satisfy the extreme Puritan party, who would no doubt have agitated for and would probably have obtained still further reformation and revision. This Prayer Book only lived for eight months. It came into use on All Saints' Day (Kov. 1) 1552, and on July 6, 1553, Edward VI. died and was succeeded by his sister Mary, under whom the Prayer Book was abolished and the old Latin services and service books resumed their place.

Act of Uniformity.---On the death of Queen Mary and the accession of her sister Elizabeth (Nov. 17, 1558) all was reversed, and the Book of Common Prayer was restored into use again. The Act of Uniformity, which obtained final parliamentary authority on April 28, 1559, ordered that the Prayer Book should come again into use on St. John the Baptist's Day (June 24, 1559). This was the second Prayer Book of King Edward VI., with few but important alterations, which, like all the alterations introduced at subsequent dates into the Prayer Book, were in a Catholic rather than in a Protestant direction. Morning and Evening Prayer were directed to be "used in the accustomed place of the church, chapel or chancel," instead of "in such place as the people may best hear"; the eucharistic vestments ordered in the first Prayer Book of Edward VI. were brought back by a new rubric which directed that "the minister at the time of the communion and at all other times in his ministration, shall use such vestments in the church as were in use by authority of parliament in the second year of the reign of Ring Edward the VI. according to the act of parliament set in the beginning of this book; in the Litany the following petition found in both the Edmarclian Prayer Books was omitted "from the tyranny of the bishop of Rome and all his detestable enormities, good Lord deliver us;" in the Communion service the two clauses of administration found in the first and second Prayer Books of King Edward's reign were combined; the rubric explanatory of "kneeling for reception," commonly known as "the Black Rubric" was omitted; in the Ordinal in the rubric before the oath of the queen's sovereignty the words "against the power and authority of all foreign potentates" were substituted for "against the usurped power and authority of the Bishop of Rome," and in the oath itself four references to the bishop of Rome, by name, were omitted.

A smouldering and growing Puritan discontent with the Prayer Book, suppressed with a firm hand under Queen Elizabeth, burst out into a flame on the accession of King James I. in 1603. A petition called the millenary petition, because signed by no less than 1,000 ministers, was soon presented to him, asking, among other things, for various alterations in the Prayer Book and specifying the alterations desired. As a result the king summoned a conference of leading Puritan divines, and of bishops and other leading Anglican divines, which met under his presidency at Hampton Court in Jan. 1604. After both sides had been heard, certain alterations were determined upon and were ordered by royal authority, with the general assent of Convocation. These alterations were not very numerous nor of great importance, but such as they were they all went in the direction of catholicizing rather than of puritanizing the Prayer Book; the one exception being the substitution of some chapters of the canonical scriptures for some chapters of the Apocrypha, especially of the book of Tobit. Alterations were introduced into the service for the private baptism of children in houses, with the object of doing away with lay baptism and securing the administration by the minister of the parish, or some other lawful minister; and the concluding portion of the Catechism, consisting of 11 questions on the sacraments, was now added.

The next important stage in the history of the Prayer Book was its total suppression in 1645 for a period of 15 years, "the Directory for the Public Worship of God in the Three Kingdoms" being established in its place. The restoration of King Charles II. in 1660 brought with it toleration at once. Nonconformists pressed upon the king, either that the Prayer Book should not be re-introduced, or that if it were re-introduced, features which they objected to might be removed. The result was that a conference was held in 1661, known from its place of meeting as the Savoy Conference. The objections raised from the Nonconformist point of view were numerous and varied, but they were thoroughly discussed between the first meeting on April 15 and the last on July 24, 1661; the bishops agreeing to meet the Puritan wishes on a few minor points but on none of fundamental importance. Later in the year, between Nov. 20 and Dec. 20, Convocation assembled and undertook the revision of the Prayer Book. In the earlier part of the following year the book so revised came before parliament. No amendment was made in it in either house and it finally received the royal assent on May 19, 1662, being annexed to an Act of Uniformity which provided for its coming into general and compulsory use on St. Bartholomew's Day (Aug. 24).

The alterations thus introduced were very numerous, amounting to many hundreds and many of them were more important than sny which had been introduced into the Prayer Book since 1552. Their general tendency was distinctly in a Catholic as opposed to a Puritan direction, and the 2,000 Puritan incumbents who vacated their benefices on St. Bartholomew's Day rather than accept the altered Prayer Book bear eloquent testimony to that fact. Among the important alterations, the following may be named as of special interest.

(a) The preface "It hath been the wisdom of the Church of England," etc., composed by Sanderson, bishop of Lincoln, was prefixed to the Prayer Book. (b) The authorized version of the Bible of 1611 was taken into use, except in the case of the Psalms, where the great Bible of 1539–1540 was retained as much smoother for singing, and in parts of the Communion service. (*c*) The rubric preceding the absolution in Morning and Evening Prayer, viz.: "The absolution to be pronounced by the minister alone," was altered into "The Absolution, or Remission of Sins, to be pronounced by the priest alone, standing; the people still kneeling." (d) In the Litany the phrase "Bishops, Pastors and Ministers of the Church," was altered into "Bishops, Priests and Deacons," and in the clause commencing "From all sedition and privy conspiracy," etc., the words "rebellion" and "schism" were added. (e) In the Communion service two rubrics were prefixed to the prayer "for the whole state of Christ's Church militant here in earth" ordering the humble presentation and placing of the alms upon the Holy Table, and the placing thereon then of so much Bread and Wine as the priest shall think sufficient; and the commemoration of the departed was added to the prayer itself. (f) The rubric explanatory of the posture of kneeling for reception, known as the Black Rubric, which had been added in 1562, but omitted in 1559 and 1604, was re-introduced; but the words "to any real and essential presence there being of Christ's natural flesh and blood" were altered to "unto any Corporal Presence of Christ's natural Flesh and Blood"—a very important and significant alteration which affected the meaning of the whole rubric. (g) A new office was added for the Ministration of Baptism to such as are of riper years. (*h*) A rubric was prefixed to the Order for the Burial of the Dead, forbidding that order to be used "for any that die unbaptized, or excommunicate, or have laid violent hands upon themselves." (i) In the "Ordering of Priests," and "the Consecration of Bishops," in the formula for ordination, after the words, "Receive the Holy Ghost," these words were added "for the Office and Work of a Priest (or Bishop) in the Church of God, now committed unto thee by the Imposition of our hands."

No substantial alteration has been made in the Prayer Book since 1662. But in 1859 the special services prescribed for Nov. 5, Jan. 30 and May 29 (which had an essential political significance) were abolished by royal warrant, chronicled as having obtained the sanction of the Convocations of Canterbury and York, and also legal force by act of parliament. In 1871 a revised Lectionary was substituted for the previously existing one, into the merits and demerits of which it is not possible to enter here; and in 1872, by the Act of Uniformity Amendment Act, a shortened form of service was provided instead of the present form of Morning and Evening Prayer for optional use in other than cathedral churches on all days except Sunday, Christmas Day, Ash Wednesday, Good Friday and Ascension Day; provision was also statutably made for the separation of services, and for additional services, to be taken, however, except so far as anthems and hymns are concerned, entirely out of the Bible and the Book of Common Prayer. In 1901 new forms of prayer, with Thanksgiving, were prepared by Convocation and authorized by royal warrant, and in 1922 a new Lectionary was issued for use in morning and evening prayer throughout the year.

Movements **for** Revision.—Since 1910 there has been a great movement for the revision of the Prayer Book in almost all branches of the Anglican Church. In Scotland some suggestions were made in the Synod of 1911, when a schedule of permissible variations to, and deviations from, the Prayer Book was drawn up, and a revised text of the Scottish liturgy was authorized. In 1919 a more complete revision was undertaken by the consultative council on Church legislation, a body consisting of bishops, clergy and laity sitting together without legislative power. The result of its labours from 1919 to 1924 was contained in a series of reports. In America revision was inaugurated in 1913 by the appointment of a Revision Commission of the General Convention, consisting of seven bishops, seven presbyters and seven laymen. The work had been going on continuously since then until, in 1925, the last stages were reached. A considerable number of the changes have been already ratified, and, after the ratification of the changes, approved in Oct. 1925, at New Orleans by the General Convention, in 1928 a Prayer Book according to the standard of 1928 will be published. In *South* Africa two tentative alternative uses for the Communion Office were put forward. This was followed by the definite issue of an alternative liturgy, which was sanctioned for use in the province at a provincial synod held in 1924, to be used when desired by the priest and people in the parish. In Canada a new Prayer Book has betn issued. It carefully avoids making any changes in the Communion Office or any changes involving doctrine, but adds a large number of services adapting the worship of the Church to the needs of the day. In *Ireland* a new revision is being undertaken for which a committee was appointed in 1909.

Proposals were made for a revision of the English Prayer Book on the accession of William III. in 1689, but they came to nothing. The subject was much to the fore between 1857 and 1863. Revision proposals were made in 1879, but came to nothing. The later movement for revision dates from the Royal Commission which was appointed on April 23, 1904, to inquire into "the alleged prevalence of breaches or neglect of the law relating to the conduct of Divine Service in the Church of England." This reference inevitably led to the consideration of a general revision of the book; and Convocation took up this task in 1906, though it was stated that it is not desirable at present to introduce into the text of the Prayer Book any changes, but they should be embodied in another volume to be sanctioned for optional use for a determined period. The work of revision went on for many years. The whole matter went through the hands of each House of Convocation separately, of the Joint Committee of both Provinces and then of each House again.

The result of this work was taken up by the Church Assembly when it was formed. A committee was appointed and the report of the Assembly on the revision of the Prayer Book was ultimately published under the auspices of the National Assembly (N.A.84). But when the moderate and somewhat conservative proposals which had been put forward by Convocation appeared in the fuller light of the Assembly many new factors came into consideration and different groups or parties in the Church took the matter of revision up with great keenness, so there was issued a series of new proposals. These were contained in the Green Book, issued by the English Church Union, the Grey Book, issued by a committee which was supposed to represent the Life and Liberty Movement, the Yellow Book, issued under the auspices of the Alcuin Club, an attempt to embody these suggestions in one book, and some white papers, representing a still more extreme view.

Reasons for Revision. — It may be convenient to sum up the reasons for the amendment of the Prayer Book. Speaking generally, they are the desire to adapt a book which dates from 1662 to the needs of the time. (1) A desire to do away with old-fashioned expressions, phrases unsuitable to the taste of the time, and statements inconsistent with modern thought. On this point there is considerable variation of opinion, many being attached even to the archaisms of the Prayer Book, others finding them difficult or even offensive. (2) A desire to adapt the Prayer Book to the changed usages of the Church which have gradually grown up, to accommodate law to custom. (3) Some desire that the Prayer Book should be revised so as to make the restoration of law and order in the Church possible. It is recognized that the existing Prayer Book cannot reasonably be obeyed in various points. It is proposed that there should be a rule of worship adapted to the present time with a reasonable latitude in the way of variations allowed, and that this should be enforced on the clergy. (4) There is a great desire to adapt the Prayer Book to the far wider religious and social aspirations of the present day. There is a great demand that religious worship should be brought much more closely into touch with the life of the people. (5) A desire felt, particularly by one party in the Church, arising from the great growth among them of sacramental ideas of worship. It is desired to give far greater opportunity for this in the new Prayer Book, and to accommodate it more closely to the traditional liturgical customs of the Church.

The final proposals embodied in the revised Prayer Books submitted to parliament in 1927 and 1928, and the events which ensued, are dealt with in *The Church* in the Twentieth Century, under article ENGLAND, CHURCH OF.

PRAYERS FOR THE DEAD. Wherever there is a belief in continued existence through and after death, religion naturally concerns itself with the relations between the living and the dead. In the ancient practices and doctrines of the Judaeo-Christian tradition prayers for the dead have an important place. The practice of the Old Testament Jews is expressed in II Mac. xii:43–44, where it is related that Judas sent "twelve thousand drachmas of silver to Jerusalem for sacrifice to be offered for the sins of the dead. . . . It is a holy and a wholesome thing to pray for the dead that they may be loosed from sin." The Gospels are not explicit in the matter but indications of early Christian practice are found in the letters of St. Paul. In I Cor. xv:29, he refers to the custom of Christians being baptized for those who had died without baptism. This at least bears witness to their belief in the efficacy of works for the dead. In II Tim. i:16–18 Paul seems to pray for Onesiphorus, then dead. Outside the Bible, early use of prayers for the dead is found in the inscription on the tomb of Abercius of Hieropolis in Phrygia (see Lightfoot, Apostolic Fathers, vol. i): "Let every friend who observeth this pray for me," *i.e., Abercius,* who died in the latter part of the second century. The inscriptions in the Roman catacombs bear similar witness to the practice, by the occurrence of such phrases as "Mayest thou live amongst the saints" (3rd century); "May God refresh the soul of . . ."; "Peace be with them." Among Church writers Tertullian is the first to mention prayers for the dead: "The widow who does not pray for her dead husband has as good as divorced him" (beginning of the 3rd century). Subsequent writers similarly make incidental mention of the practice as prevalent, but not as unlawful or even as disputed (until Aerius challenged it towards the end of the 4th century). The most famous instance is St. Augustine's prayer for his mother, Monnica, *Confessions* (Bk. ix).

An important element in the liturgies of the various churches consisted of the diptychs or lists of names of living and dead who were to be commemorated at the Eucharist. To be inserted in these lists was an honour, and it was out of this practice that the canonization of saints grew. In the third century we find Cyprian enjoining that there should be no oblation or public prayer made for a deceased layman who had broken a Church rule by appointing a cleric trustee under his will: "He ought not to be named in the priest's prayer who has done his best to detain the clergy from the altar." The universal occurrence of these diptychs and of definite prayers for the dead in all parts of the Church in the 4th and 5th centuries tend to show how primitive such prayers were. The language used in the prayers reflects the Old Testament, suggesting the continuance of an ancient Jewish tradition. We may cite from the so-called liturgy of St. James: —

> "Remember, O Lord, the God of spirits and of all flesh, those whom we have remembered and those whom we have not remembered, men of the true faith, from righteous Abel unto to-day; do thou thyself give them rest there in the land of the living, in thy kingdom, in the delight of Paradise, in the bosom of Abraham, Isaac and Jacob, our holy fathers, from whence pain and sorrow and sighing have fled away, where the light of thy countenance visiteth them and always shineth upon them."

Public prayers were offered only for those who were believed to have died as faithful members of Christ. This restriction on public prayers is still enforced by the laws of the Roman Catholic Church. But where there is no danger of scandal, permission is explicitly given to offer prayers and the sacrifice of the mass privately for heretics and schismatics (Coder *Juris Canonici,* 809; 2262). Theologians commonly teach that this permission extends also to the case of mass, and a fortiori prayers, offered for infidels (cf. Cappello, De Sacramentis (1928), vol. i, n. 619).

With the development of doctrine in the Catholic Church the foundations for the practice of prayers for the dead became more clearly defined. It is seen as the consequence of (a) the doctrine that purification from sin requires, beyond divine forgiveness, a satisfaction on man's part that is offered by good works in life or by a period of suffering after death; and (b) the doctrine that the prayers and good works of the living can benefit the souls of the dead who have not offered complete satisfaction for the sins whose guilt has been remitted. The authoritative statement of the Catholic Church's doctrine is in the *Decree for the Greeks* from the Council of Florence: "Likewise, if those who have truly repented of their sins have died in the charity of God before they have satisfied with fruits worthy of penance for their sins . . . , their souls are cleansed after death by purifying pains; of great benefit to them for relief from these pains are the suffrages of the faithful still alive, *i.e.*, the sacrifice of the mass, prayers and alms-deeds and other good works. . . ." (Denzinger, *Enchiridion Symbolorum,* 693). These doctrines on the existence of purgatory and the related doctrine on indulgences (*q.v.*) were opposed by the leaders of the Protestant reformation; consequently, they were inclined to disuse all prayers for the dead.

In the English communion service of 1549, after the offering of praise and thanks for all the saints, came the following: "We commend into thy mercy all other thy servants, which are departed hence from us with the sign of faith and now do rest in the sleep of peace: grant unto them, we beseech thee, thy mercy and everlasting peace." The burial service of the same date also contained explicit prayers for the deceased. In 1552 all mention of the dead, whether commemorative or intercessory, was cut out of the Eucharist; the prayers in the burial service were brought into their present form; and the provision for holy communion at a burial was omitted. The thankful commemoration of the dead in the Eucharist was restored in 1662, but prayers for them remained, if they remained at all, veiled in ambiguous phrases

The Church of England has, however, never forbidden prayers for the dead. It was proposed in 1552 to condemn the Roman doctrine *de precatione pro defunctis* in what is now the nand of the Thirtv-Nine articles, but the proposal was rejected. And these intercessions have been used in private by a long list of English divines, *e.g.,* Andrewes, Cosin, Ken, Wesley and Keble. In a suit (1838) as to the lawfulness of an inscription "Pray for the soul of . . .," the Court held that "no authority or canon has been pointed out by which the practice of praying for the dead has been expressly prohibited."

See H. M. Luckock, *After Death* (1886); E. H. Plumptre, *The Spirits in Prison* (1886); H. B. Swete, "Prayers for the Departed in the First Four Centuries," *Jour. Theol. Stud,* viii.; Arts. "Prayers for the Departed" in Hastings' *Encyc. Rel. Etk.* and "Dead, Prayers for the" in *Catk. Encyc.*

BRAYING WHEEL, used by the Buddhists of Tibet as a means of offering invocations. The smallest kind consists of a cylinder of metal or other substance turning on a handle as pivot. Outside it and on strips of paper within is inscribed the invocation to Avalokiteśvara or his consort, *Oṃ Maṇipadme hūṃ.* A weight hangs at the side, and with a slight movement of the hand the cylinder revolves. Larger wheels are made to revolve by means of wind or water.

PREACHING, the proclamation of a Divine message, and the regular instruction of the converted in the doctrines and duties of the faith, is a distinctive though not a peculiar feature of the Christian religion. The Mohammedans exercise it freely, and it is not unknown among the Buddhists. The history of Christian preaching with which alone this article is concerned has its roots (1) in the activity of the Hebrew prophets and scribes, the former representing the broader appeal, the latter the edification of the faithful, (2) in the ministry of Jesus Christ and His apostles, where again we have both the evangelical invitation and the teaching of truth and duty. Whichever element is emphasized in preaching, the preacher is one who believes himself to be the ambassador of God, charged with a message which it is his duty to deliver.

The Patristic **Age,** to the Death of St. Augustine, **430.**—From the Acts of the Apostles we gather something as to the methods adopted by St. Peter and St. Paul, and these we may believe were more or less general. The Apostles who had known the Lord would naturally recall the facts of His life, and the story of His words and works would form a great deal of their preaching. It is not until we come to Origen (d. 254) that we find preaching as an explanation and application of definite texts, a usage that Christianity adopted from Greek rhetoricians. The fourth century marks the culmination of early Christian preaching. In an age of doctrinal controversy, the intellectual presentation of the Christian position was thus developed. Preaching flourished chiefly in the East; especially noteworthy are the three Cappadocians, Basil (*q.v.*) of Caesarea, cultured, devout and practical; his brother Gregory (*q.v.*) of Nyssa, more inclined to the speculative and metaphysical; and Gregory (*q.v.*) of Nazianzus, richly endowed with poetic and oratorical gifts, the finest preacher of the three. Foremost of all stands John of Antioch, Chrysostom (q v.), who in 386 began his 12 years' ministry in his native city, and in 398 the six memorable years in Constantinople, where he loved the poor, withstood tyranny and preached with amazing power. In the West the allegorical method of Alexandria had more influence than the historical exegesis cultivated at Antioch. This is seen in Ambrose of Milan and in Hilary of Poitiers. But the only name of first rank in preaching is that of Augustine, and even he is curiously unequal. His fondness for the allegorical and his manifest carelessness of preparation disappoint as often as his profundity, his devout mysticism and his practical application attract and satisfy. Augustine's De *doctrina Christiana,* bk. iv., is the first attempt to formulate the principles of homiletics.

The Middle Ages.—After the days of Chrysostom and Augustine there was a great decline of preaching. The West did better than the East: at Rome Leo the Great and Gregory the Great could preach, and the missionaries Patrick, Columba, Columbanus, Augustine, Wilfrid, Willibrord, Gall and Boniface are known by their fruits. Then came the age when the papacy was growing out of the ruins of the old Roman empire, and the best talents were devoted to the organization of ecclesiasticism rather than to the preaching of the Word. But certain forces were at work which were destined to bring about a great revival, *e.g.,* the rise of the scholastic theology, the reforms of Pope Hildebrand and the preaching of the First Crusade by Pope Urban II. (d. 1099) and Peter the Hermit. In the 12th century the significant feature is the growing use of the various national languages in competition with the hitherto universal Latin. The most eminent preachers of the century were Bernard of Clairvaux (1091–1153), the two mystics of St. Victor, Hugo and Richard, and Peter Waldo of Lyons, who preached a plain message to the poor and lowly. The 13th century saw the culmination of mediaeval preaching, especially in the rise of the two great mendicant orders of Francis and Dominic. Representative Franciscan names are Antony of Padua (d. 1231), who travelled and preached through southern Europe; Berthpld of Regensburg (d. 1272), who, with his wit and pathos, imagination and insight, drew huge crowds all over Germany; and Francis Bonaventura, the schoolman and mystic, who wrote a little book on The *Art* of *Preaching.* Of the Dominicans Thomas Aquinas (d. 1274), the theologian, was perhaps also the greatest preacher. With the 14th century a new note, that of reformation, is struck; but on the whole there was a drop from the high level of the 13th. Among the popular preachers vigour was often blended with coarseness and vulgarity. Mysticism is represented by Suso, Meister Eckhart, above all Johann Tauler (*q.v.*) of Strasbourg (d. 1461), a true prophet in an age of degeneration. Towards the close of the century comes John Wycliffe (*q.v.*) and his English travelling preachers, who passed the torch to Hus and the Bohemians, and in the next age Savonarola.

The Reformation Period, 1500–1700.—The Reformers gave the sermon a higher place in the ordinary service than it had previously held, and they laid special stress upon the interpretation and application of scripture. The controversy with Rome, and the appeal to the reason and conscience of the individual, together with the spread of the New Learning, gave preaching a new force and influence which reacted upon the old faith. Most of the Reformation preachers read their sermons, in contrast to the practice of earlier ages. The English Book of Homilies (see HOMILY) was compiled because competent preachers were comparatively rare.

The 17th-century preaching was, generally speaking, a continuation of that of the 16th century, the pattern having been set by the Council of Trent and by the principles and practice of the Reformers. In Spain and Germany, however, there was a decline of power, in marked contrast to the vigour manifested in France and England. In France, indeed, the Catholic pulpit now came to its perfection, stimulated, no doubt, by the toleration accorded to the Huguenots up to 1685 and by the patronage of Louis XIV. The names of Bossuet, Fléchier, Bourdaloue, Fénelon and Massillon, all supreme preachers, despite a certain artificial pompousness, belong here, and on the reformed side are Jean Claude (d. 1687) and Jacques Saurin (d. 1730). In England, among Anglicans, are Andrewes, Hall, Chillingworth, Jeremy Taylor, Barrow and South; among Puritans and Nonconformists, Baxter, Calamy, the Goodwins, Howe, Owen and Bunyan. The sermons of these men were largely scriptural, the cardinal evangelical truths being emphasized with reality and vigour, but with a tendency to abstract theology rather than concrete religion.

The early years of the 18th century were a time of torpor as regards preaching. Generally speaking, sermons were unimpassioned, stilted and formal presentations of ethics and apologetics, seldom delivered extempore.

The Modern Period.—This dates from 1738, the year in which John Wesley began his memorable work. The example and stimulus given by him and by Whitefield were almost immeasurably productive. In their train came the great field preachers of Wales, like John Elias and Christmas Evans, and later the Primitive Methodists, who by their camp meetings and itinerancies kept religious enthusiasm alive when Wesleyan Methodism was in peril of hardening. Mean hile. in America the Puritan tradition, adapted to the new conditions, is represented by Cotton Mather, and later by Jonathan Edwards, the greatest preacher of his time and country. Whitefield's visits raised a band of pioneer preachers, cultured and uncultured, men who knew their Bibles but often interpreted them awry.

Preaching, in modern times, has been so varied, depending, as it largely does, on the personality of the preacher, that it is not possible to speak of its characteristics. Nor can one do more than enumerate a few outstanding modern names, exclusive of living preachers. In the Roman Catholic Church are the Italians Ventura and Curci, the Germans Diepenbrock and Foerster, the French Lacordaire, Dupanloup, Loyson (Pkre Hyacinthe) and Henri Didon. Of Protestants, Germany produced Schleiermacher, Claus Harms, Tholuck and F. W. Krummacher; France, Vinet and the Monods. In England representative Anglican preachers were: Newman (whose best preaching preceded his obedience to Rome), T. Arnold, F. W. Robertson, Liddon, Farrar, Magee; of Free Churchmen, T. Binney, R. W. Dale, Joseph Parker and J. H. Jowett (Congregationalist); Robert Hall, C. H. Spurgeon, Alexander Maclaren and John Clifford (Baptists); W. M. Punshon, Hugh Price Hughes, Peter Mackenzie and W. L. Watkinson (Wesleyan); James Martineau (Unitarian). The Scottish churches gave Edward Irving, Thomas Chalmers, R. S. Candlish, R. M. McCheyne and John Caird. In America, honoured names are those of W. E. Channing, Henry Ward Beecher, Horace Bushnell, Phillips Brooks, Harry Emerson Fosdick (1878–), to mention only a few.

See A. E. Garvie, The Christian Preacher (1920), a comprehensive survey with full bibliography. (A. J. G.)

PREADAMITES, a term signifying either (1) human races existent before Adam or (2) a 17th century Christian sect that professed belief in such races. The sect was inspired by Isaac La Peyrkre's Prae-Adanzitae (1655), which interpreted Paul's Epistle to the Romans (v. 12–14) to mean that, since "sin was in the world" before the law (that given to Adam), then there must have been human beings to sin. These were the Gentiles, whose creation is described in Genesis i., while Adam ("man") the first of the Jews, is not mentioned until Genesis ii.

PREAMBLE, a term particularly applied to the opening paragraph of a statute which summarizes the intention of the legislature in passing the measure. The procedure in the British parliament differs in regard to the preambles of public and private bills. The second reading of a public bill affirms the principle, and therefore in committee the preamble stands postponed till after the consideration of the clauses, when it is considered in reference to those clauses as amended and altered if need be (Standing Order 35). On the other hand, the preamble of a private bill, if opposed, is considered first in committee, and counsel for the bill deals with the expediency of the bill, calls witnesses for the allegation in the preamble, and petitions against the bill are then heard; if the preamble is negatived the bill is dropped, if affirmed it is gone through clause by clause. On unopposed private bills the preamble has also to be proved, more especially with regard to whether the clauses required by the standing orders are inserted (see May, Parliamentary Practice).

PREANGER (PRIANGAN), a district in the southwest of Java, Netherlands Indies, part of the province of West Java. Formerly one residency—the Preanger Regencies—it was divided into two residencies, Buitenzorg and Preanger. They are bounded north by Cheribon and Batavia, west by Bantam, east by Banjumas and Cheribon and south by the Indian ocean. Pop. (1930): Buitenzorg 2,212,997, Preanger 3,448,796. The natives are Sundanese. The whole district is mountainous, and contains a large number of both active and inactive volcanoes, including the well-known Salak and Gedeh in the north, and bunched together at the eastern end the Chikorai, Papandayan, Wayang, Malabar, Guntur, etc., ranging from 6,000 to 10,000 ft.

The greatest rivers are the Chi Manuk and the Chi Tarum, both rising in the eastern end of the province and flowing northeast and northwest respectively to the Java sea, and the Chi Tandui, flowing southeast to the Indian ocean. Crater lakes are Telaga (lake) Budas, in the crater of the volcano of the same name in the southeast, and Telaga Warna, on the slopes of the Gedeh, famous for its beautiful tinting. There are also other small lakes—Bagendit, Leles, Penjalee, etc. On the side of the Gedeh is the health resort of Sindanglaya (3,500 ft.), with a mineral spring containing salt.

Numerous warm springs are scattered about this volcanic region. The soil is in general very fertile, the principal products being rice, maize, cassava and pulse (kachang) and rubber in the lower grounds, and cinchona, coffee and tea. as well as cocoa, coca, tobacco and fibrous plants in the hills. The coffee cultivation has, however, diminished considerably. Irrigation works have been carried out in various parts. The principal towns are Bandung, the capital of Preanger; Buitenzorg, the site of world-famous botanical gardens; Sukabumi (34,191); Tasikmalaja (25,605) with its native wicker industry and Chianjur (20,812), Sumedang, Chibatu, Chichalengka, Garut and Manon Java; all with the exception of Sumedang connected by railway. The Preanger became Dutch in 1704, after the trouble with Susuhunan, Amangku Rat II. From the time of the British reform of the administration in Java by Sir Stamford Raffles (1811–16), it was known generally as the Preanger Regencies.

The district of Preanger was occupied by the Japanese in March 1942.

PRE-CAMBRIAN. Pre-Cambrian and Archaean, in geology, are used synonymously by certain authors and are so employed in this article. The term Archaean, however, is often used in a restricted sense to include only the oldest rocks, the Keewatin and Laurentian, for example, in North America.

Age and Features.—The pre-Cambrian includes all formations below the beds containing *Olenellus* fauna. A great unconformity, or time break, generally separates the Cambrian from the pre-Cambrian, although in a few regions there seems to be no unconformity, and the Olenellus beds appear to pass downwards conformably into underlying beds holding a few fossils older than the *Olenellus*.

The pre-Cambrian rocks are believed to underlie everywhere the Palaeozoic and all later formations; and wherever erosion has penetrated deeply enough the pre-Cambrian formations have been brought to light. They are the most ancient of any exposed on the crust of the earth, and may have required more than half of all geological time for their formation. Their age can be only approximately estimated, the estimate varying within wide range —48,000,000 to 1,710,000,000 years. These venerable formations, which are now exposed over one-fifth of the land surface of the earth, consist dominantly of granitic rocks, massive gneissoid, or banded in texture. Sediments and lava flows, while occurring in great thickness in some regions, are subordinate. In many parts of the world the rocks have been tremendously altered, and now consist of schists and gneisses of almost infinite variety.

Fossils are exceedingly rare and poorly preserved. Indeed, certain geologists consider that the evidence for the occurrence of fossils is hardly conclusive. This sparsity of fossils is the main feature which distinguishes the pre-Cambrian from Palaeozoic and later eras. On the whole, too, the rocks are more altered and metamorphosed than are those of later formations. On account of their generally metamorphosed state their structural and age relationships are complex and difficult to unravel, and much work remains to be done. Owing to the almost total absence of fossils no satisfactory way has been discovered of definitely correlating pre-Cambrian formations of one continent with another. Nevertheless it may be pointed out that the very oldest known rocks possess pronounced similarities, chief of which is the fact that they consist in many regions of lava flows of basic and intermediate composition. Moreover, the flows are interbanded in many areas with very striking beds of brilliant red jaspilite and banded hematite-magnetite-quartz rock commonly called iron formation. In Canada these lava flows have been named Keewatin. Certain writers have cautiously suggested that the Keewatin might, be correlated, tentatively, with similar rocks in South Africa, India and West Australia.

For much of pre-Cambrian time conditions on the surface of the earth appear to have been similar, in some respects at least, to conditions in later eras. Water played the same role then as it does to-day; rocks were deeply eroded, and conglomerates, sandstones and other sediments were deposited in the same manner as at the present time. It is believed, too, by certain geologists that ice ages occurred in north-eastern Ontario, China, India, Australia, and elsewhere; but in the first mentioned this has not yet been definitely established. Volcanic activity was intense, and lava flows in enormous thickness were poured out. Indeed, in the earliest (Keewatin) epoch of geological history volcanic activity as indicated by lava flows appears to have reached an intensity possibly never afterwards rivalled. The base on which these old flows were laid down has not been discovered.

Economic Importance. — The pre-Cambrian is economically of much importance on account of the valuable mineral deposits which it contains. The greatest gold mines in the world, those of the Transvaal, occur in these rocks, as do also the gold mines of India, Ontario, West Australia, Southern Rhodesia, Brazil and South Dakota. The pre-Cambrian, too, contains the greatest iron and nickel mines in the world, the latter at Sudbury, Canada, the former in the Lake Superior region of the United States. Copper is found in immense deposits. A variety of useful, non-metallic products also occur, including mica, talc, graphite, corundum, felspar, marble and other materials. The mineral production from the pre-Cambrian throughout the world is increasing, and our knowledge of these ancient complex rocks is advancing.

Canada. — The most extensive region of pre-Cambrian rocks is exposed in Canada, over a stretch of country estimated at 1,800,000 sq. miles. This great expanse surrounds Hudson Bay on the E., S. and W., and from its shape has been named the Canadian Shield; its southern fringe extends into the United States mainly around Lake Superior. Canada was the first country in which the pre-Cambrian formations were systematically studied and subdivided, the pioneer work having been accomplished during the middle of the last century by Sir William Logan, the father of pre-Cambrian geology, and owing to the great importance of the gold, silver, nickel, copper and cobalt mines, detailed geological mapping has been done, particularly since 1900 in the province of Ontario. The result has been that the pre-Cambrian formations of this region have been more closely studied and mapped than has any other of similar magnitude, and the classification so laboriously worked out in Ontario may be used as a guide or standard by geologists working on similar rocks elsewhere.

Though the rocks of Ontario have been studied in much detail practically only the southern fringe of the pre-Cambrian of Canada has been touched, and it will probably be many years before the vast inland regions will be mapped and the stratigraphy worked out. In N.-E. Ontario the rocks have been divided into three major divisions, upper, middle, and lower, based on two major periods of erosion. A great unconformity alike separates the upper from the middle and the middle from the lower. Granites of at least three ages have been recognized, viz., commencing with the oldest, the Laurentian, Algoman and Killarnean. On account of their similarity it has not been found possible to separate these three granites over large areas.

The following classification has been adapted by the Ontario Department of Mines, the youngest rocks being shown at the top of the column:—

Classification of Pre-Cambrian Rocks at Cobalt and Lake Timiskaming, in North-Eastern Ontario, Canada

Upper	KEWEENAWAN Nipissing diabase, etc. ANIMIKEAN Cobalt series—conglomerate, etc.
	GREAT UNCONFORMITY
Middle	MATACHEWAN Diabase, etc. ALGOMAN Lorrain granite. HAILEYBURIAN Lamprophyre, diabase, ctc. TIMISKAMIAN Conglomerate, etc.
	GREAT UNCONFORMITY
Lower	LAURENTIAN Represented by granite pebbles in Timiskamian conglomerate. LOGANIAN Grenville—iron formation, etc., in minor quantity; elsewhere much crystalline limestone, etc. Keewatin—Basic lavas, etc.

The classic name Huronian is not used in this classification, confusion having arisen owing to its employment in different senses.

The most ancient rocks in N.-E. Ontario, the Keewatin series, constitute one of the greatest outpouring of lavas in the history of the earth's crust, and are of immense thickness. The flows, which are in part at least of submarine origin, are composed dominantly of basalts and andesites in which pillow structure is commonly developed. Dacites and rhyolites are subordinate. Interbedded with the flows are subordinate bands of volcanic ashes and brilliant red jaspilites. In S.-E. Ontario crystalline limestones, known as the Grenville series, occur in great volume; this series is believed to have been deposited mainly towards the close of the Keewatin, there being no unconformity between the two. The basement on which the lava originally rested has nowhere been positively recognized. In W. Ontario there is a highly altered sedimentary series, known as the Coutchiching, which is believed by certain workers to be older than the Keewatin lava flows, but its stratigraphic position has not been generally agreed on, and the subject is still controversial.

The Keewatin occupies many isolated areas in the Canadian shield varying from a few to about 10,000 sq. miles. These isolated masses are surrounded and, apparently, supported by granite, which occurs in by far the greater volume. Wherever the contacts with the Keewatin and granites have been closely studied the granites have been found to be intrusive, and therefore younger than the Keewatin. The Laurentian includes only those granites which rest unconformably below the Timiskamian sediments. As detailed work progressed it was found that the Laurentian granites were difficult to recognize, 'and, indeed, in N.-E. Ontario have not as yet been discovered. The Timiskamian sediments, which occur in narrow sharply folded synclines, contain many granite pebbles and boulders. In N.-E. Ontario the granite (Laurentian) from which these granite fragments were derived has not as yet been recognized. The unconformity at the base of the Timiskamian is profound. The Timiskamian sediments are intruded by the basic Haileyburian rocks, and both Haileyburian and Timiskamian have been intruded by widespread masses of granites known as Algoman. The Matachewan basic intrusives, which cut the Algoman, are found in small volume. Above the Algoman and all the other rocks mentioned rest the Animikean sediments, of which the Cobalt series at Cobalt, Ontario, forms a part. These sediments rest in horizontal or gently inclined positions, and differ in this respect from the closely folded Timiskamian. The unconformity at the base of the Cobalt series is, like that at the base of the Timiskamian, very great.

On the north shore of Lake Huron there is a thick series of sediments to which the name Huronian was given by Sir Wm. Logan. These have not as yet been satisfactorily correlated with the Timiskamian or Cobalt series; unconformities have been found within them but these are of minor importance compared with that at the base of the Timiskamian or that at the base of the Cobalt series.

The Keweenawan in N.-E. Ontario is represented by the Nipissing diabase at Cobalt and by the nickel eruptive (norite-micropegmatite) at Sudbury. On the shores of Lake Superior the Keweenawan consists of a great thickness of sediments and lava flows. A minor unconformity has been found to exist between the Keweenawan and the Animikean. Granites are found in the Sudbury area, Ontario, cutting the Keweenawan nickel eruptive, and they belong to the third period of granitic intrusion, named the Killarnean. The pre-Cambrian era in North-Eastern Ontario was closed by the intrusion of fresh olivine diabase dikes which intersect all the older rocks and which in certain regions may be traced for many miles.

In that almost unexplored region of the Canadian Shield between the Atlantic on the E. and Great Slave and Great Bear lakes on the W. there is very little known regarding the rocks. They appear to consist largely of granites and gneisses; and a few isolated areas may correspond to the Keewatin and Timiskamian series. Late pre-Cambrian sediments relatively undisturbed occur along the Labrador coast, inland to the South of Ungava Bay, on the E. coast of Hudson Bay, on the Belcher Islands of that coast, on the S. side of Athabaska Lake, and in the Coppermine River area—where the rocks attain the thickness of over g miles and are known as the Coppermine River series. They resemble the Keweenawan series on the S. shore of Lake Superior, and like that series the Coppermine River group also contains deposits of native copper.

In the western part of Canada, including British Columbia and the Yukon, there are areas of pre-Cambrian rocks. In southern British Columbia the pre-Cambrian sediments attain great thickness, the Purcell series consisting of more than 20,000 ft. of sediments, mostly argillaceous quartzites.

United States.—In the Lake Superior region, where the pre-Cambrian rocks have been intensively studied by Leith and Van Hise, they have been sub-divided as follows, commencing with the youngest:

Algonkian	Keweenawan	w Proterozoic
	Huronian	
Archaean	Laurentian	
	Keewatin	

There have been, as in Ontario, three periods of granitic intrusions, namely, at the close of the Archaean, at the close of the Lower—Middle Huronian, and in Keweenawan times. The first has been called the Laurentian. The other t o are not specifically named, but in general correspond respectively to what has been called Algoman and Killarnean in Ontario. The Huronian is divided into three unconformable series, lower, middle and upper. The lower appears to correspond, in certain areas, with the Timiskamian of Ontario. Two major unconformities are recognized, one at the base of the upper, and one at the base of the lower (Knife Lake Series). Two others, at the base of the Keweenawan and at the base of the middle Huronian, are distinct but not conspicuous. The two major unconformities appear to correspond with those in Ontario at the base of the Animikean and of the Timiskamian respectively.

In Montana and northern Idaho there is a very thick series, consisting largely of sandstones and shales, known as the Beltian series; the pre-Cambrian sediments in the Grand Canyon of Arizona—the Grand Canyon series—are magnificently exposed; in the Adirondacks (New York State) the Grenville sediments are found; and in Pennsylvania, Maryland and Northern Virginia the Glenarm series of metamorphosed pre-Cambrian sediments.

British Isles.—In the British Isles the pre-Cambrian rocks have their greatest development in Scotland, but isolated areas of considerable interest and importance are also known in the Isle of Anglesey, N. Wales, S. Wales, the Welsh Borderland and the English Midlands.

Taken as a whole they fall into two main groups, an older group composed mainly of highly crystalline Schists and Gneisses, separated by a great unconformity from a younger relatively unaltered group of sediments and volcanic rocks. The older group of Schists and Gneisses has its most extensive development in the Highlands of Scotland of which it forms by far the larger part; here it includes the Glen Elg Schists, the Lewisian Gneisses, a highly altered plutonic complex, the Moinian, and the Dalradian Schists. The Glen Elg Schists, like the Moinian and Dalradian, consist in the main of a series of highly metamorphosed sediments of various kinds, though the Dalradian also contains schists of volcanic and hypolysed origin. The relative ages of these Schist Groups has afforded a matter for considerable controversy, and the matter cannot yet be regarded as definitely settled.

Crystalline Schists are also developed in the Isle of Anglesey, and on the coasts of Devon (Start), and Cornwall (Lizard).

The younger group of pre-Cambrian rocks is represented in N.W. Scotland by the Torridonian rocks, red felspathic sandstones and conglomerates, usually held to have accumulated under arid conditions, and believed to show considerable resemblance to the Keweenawan sandstones of America and the Jotnian sandstones of Fennoscandia.

In southern Britain a wider range of rock types is found; in W. Shropshire rocks of Torridonian type are found overlying with apparent unconformity a series of sandstones, grits, flags and shales predominantly grey in colour, the whole being referred to the Longmyndian Series. Elsewhere the pre-Cambrian rocks are mainly volcanic in origin, and include a series of lavas and tuffs of varied composition referred collectively to the Uriconian Series.

The relation of the Uriconian to the Longmyndian is difficult of determination; it possibly intervenes between the "red" and the "grey" Longmyndian.

Fennoscandia.—J. J. Sederholm bases his classification of pre-Cambrian rocks in Fennoscandia (*i.e.,* Scandinavia and Finland regarded as a geological unit) on the relations of sedimentary and other rocks to four great intrusions of granites, named (commencing with the youngest) Rapakivi, post-Kalevian, post-Bothnian and Katarchean. The oldest rocks, called Svionian, consist in part of schisted lavas, tuffs and crystalline limestones and are penetrated by the Katarchean granites. Unconformably overlying the Svionian and Katarchean granites is the Bothnian, the coarse conglomerates of which are reminiscent of the Timiskamian conglomerates of Ontario. The Bothnian is penetrated by the post-Bothnian granites. The Jatulian-Kalevian formations, which resemble the Huronian in Ontario, rest with great unconformity on the older rocks referred to above. The Jatulian-Kalevian sediments have been metamorphosed by post-Kalevian granites which are said to be analogous to the Algoman granites of Ontario. The Rapakivi granites are younger than all of the rocks just described. The youngest series of pre-Cambrian sediments belong to the Jotnian, the beds of which rest unconformably and generally almost horizontally on the older rocks. The Jotnian red sandstones have been compared with the Keweenawan of N. America.

South Africa.—Cambrian fauna have not as yet been recognized in South Africa; but, although the oldest fossils known are Devonian, it is believed that the pre-Devonian rocks are certainly largely pre-Cambrian. The pre-Devonian formations occupy an enormous stretch of country but in the central part they are almost entirely covered by vast areas of sand. Du Toit classifies them as follows:—

WATERBERG SYSTEM	Waterberg, Matsap and Umkondo Systems
ROOIBERG SERIES	Felsites and Sediments
TRANSVAAL SYSTEM	Pretoria and Griquatown Series Black Reef, Dolomite and Campbell Rand Series and Lomagundi System
NAMA SYSTEM	Fish River and Ibiquas Series Kuibis, Nieuwerust, Schwarzkalk, Otavi Dolomite and Malmesbury Series
VENTERSDORP SYSTEM	Zoetlief and Pniel Series.
WITWATERSRAND SYSTEM	Upper and Lower WWR.
PRIMITIVE SYSTEMS	Rhodesian Schists, Eldorado, Moodies, Pongola, Kheis, Kraaipan, Chanse, etc.

The oldest rocks have been named Primitive by Du Toit, and they are also known as the Swaziland system. In Rhodesia, the basal rocks—the Rhodesian schists—of the Primitive system are altered basic lava flows, commonly showing pillow structure, associated with bands of brilliant red jaspilite and banded ironstones; they are intruded by "old granite," and resting unconformably on them and "old granite" is a series of folded sediments known as the Eldorado series. The latter is intruded by younger granite. In Barberton and neighbouring portions of Swaziland the Jamestown and Onverwacht series of the Primitive system consists of basic lavas with subordinate cherty bands. The Moodies series of sediments is apparently 20,000 to 30,000 ft. thick; its age relation to the lavas is not definitely known. The Jamestown, Onverwacht and Moodies series are intruded by the "old granite."

In the Transvaal the Witwatersrand series rests with marked unconformity on the Primitive system. The Witwatersrand has a maximum thickness of almost 25,000 ft. and consists of quartzites, slates, and conglomerates. Certain conglomerate beds, regarded as placer in origin, contain gold, and these constitute the greatest known gold deposits in the world.

The Ventersdorp system, made up of lavas and minor amounts of sediments, rests unconformably on the Witwatersrand system; the Transvaal-Nama system of sediments, including a great dolomite formation, overlies this unconformably. The felsites of the Rooiberg series are regarded as the upper part of the Transvaal system.

The Waterberg system is the youngest of the pre-Cambrian. The rocks are mainly of sandstones and rest unconformably on the Transvaal. The Torridonian of Scotland compares with it.

India.—The pre-Cambrian of India consists of two main groups (a) a great mass of gneisses, crystalline schists, and plutonic rocks, named by T. H. Holland the Vedic, and (b) a group of unfossiliferous sedimentary rocks named by Holland the Purana group and suggestive of the Animikean and Keweenawan of Canada. Group (b) includes many isolated areas of sediments, of great thickness, little disturbed and resting with great unconformity on the Vedic group. Holland has tentatively classified the Vedic rocks as follows, commencing with the youngest:—5, Post-Dharwar, eruptives; 4, Dharwar systems; 3, Bundelkhand type of deformed eruptives; 2, Bengal type of Schists; 1, oldest gneisses.

There appear to be at least two periods of granitic intrusions, one (the Bundelkhand) cutting the Bengal schists, and the younger (post-Dharwar eruptives) cutting the Dhanvar system. It has been cautiously suggested that the Bundelkhand granites may be comparable with the Laurentian of Canada, and the post-Dharwar eruptives with the Algoman of Canada. The Bengal Schists are thought to be comparable with the Keewatin of Canada. The Dharwar system is much altered and folded, and contains lava flows, and banded jaspers characteristic of the Keewatin iron formation of Canada; sediments possibly corresponding to the Timiskamian may be recognized when further work is accomplished. The chief gold mines in India, those of the Kolar gold field, occur in rocks belonging to the Dharwar system. The post-Dharwar eruptives include granites and the elaeolite-syenites of Coimbatore.

Western Australia.—In the pre-Cambrian rocks of Western Australia no general sequence has yet been established, although in restricted areas the age relationships have been worked out. The rocks consist dominantly of gneisses, schists and granites; amphibolites everywhere play an important part, and bands of chert and brilliantly coloured jaspers constitute noticeable features and are identical with those in India, Rhodesia and East Transvaal.

The crystalline schists, some of which bear a close resemblance to the Keewatin of N. America, are divided into two groups: (a) an older group made up of mica-quartz-schist and marble associated with basic rocks which have in certain localities been converted into greenstone-schists, and (b) a younger group of conglomerates, arkoses, quartzites, slates and phyllites (the Mosquito Creek and other series). They have been intruded by great batholiths of granite covering some hundreds of sq. miles.

A younger series of little altered rocks, known as the Nullagine formation, consists of sandstones, quartzites, conglomerates, and dolomitic limestones, together with a series of lavas, ashes and agglomerates. The beds generally repose at horizontal or inclined angles, and rest with great uncomformity on the older rocks.

Brazil.—The pre-Cambrian covers large areas in Brazil, but little detailed work has been done. The oldest rocks have been named Archaean and consist of gneiss, granite and schist. There are also metamorphosed sediments, classed as Algonkian, made up of quartzites, iron formation, argillaceous schists and limestones. These Algonkian sediments contain great deposits of iron ores. One of the deepest gold mines, the Morro Velho mine of the St. John Del Rey Mining Company, occurs in pre-Cambrian calcareous schists and slates.

China.—In China there is a basal group of rocks consisting of gneisses and schists, including green schists, to which the name T'ai-shan complex has been given and which may correspond, in part, with the Keewatin of the N. American continent. The T'ai-shan complex is intruded by granites. Resting with great unconformity on these rocks is a highly altered, folded series of sediments known as the Wu-T'ai system, the conglomerates of which contain granite pebbles, proving the existence of granite older than this system. There are believed to be unconformities within the Wu-T'ai system; and granites are intruded into it. Some of the more altered sediments of the Wu-T'ai are suggestive of Lower Huronian rocks of the Lake Superior region.

Overlying the Wu-T'ai rocks with marked unconformity is the little altered Hu-t'o system, consisting of conglomerate, quartzite, shale and limestone. The Wu-T'ai and Hu-t'o systems have been classified by Bailey Willis as Proterozoic. (C. W. K.)

PRECEDENCE. This word in the sense in which it is here employed means priority of place, or superiority of rank. In Great Britain the crown is the fountain of honour, and has the undoubted prerogative to confer such rank and place as to it may seem convenient. In the old time all questions of precedence came in the ordinary course of things within the jurisdiction of the court of chivalry.

In 1539 an Act "for the placing of the Lords in Parliament" (31 Hen. VIII. c. 10) was passed at the instance of the king, and by it the relative rank of the members of the royal family, of the great officers of State and the household, and of the hierarchy and the peerage was definitely and definitively ascertained. Subsequent modifications were enacted in 1563 (5 Eliz. c. 18), and in 1689 (1 Will. and Mary c. 21). The Acts of Union with Scotland (1707) and Ireland (1800) laid down rules of precedence for the Scottish and Irish peers. At different times too, statutes for the reform and extension of the judicial organization have affected the precedence of the judges, more especially the Judicature Act of 1873. But the statute of Henry VIII. "for the placing of the Lords" remains the only measure dealing with any large section of the scale of general precedence; and the law, so far as it relates to the ranking of the sovereign's immediate kindred, the principal ministers of the Crown and court, and both the spiritual and temporal members of the House of Lords, is to all practical intents what it was made by that statute.

General Precedence of Men.—The sovereign; (1) prince of Wales; (2) younger sons of the sovereign; (3) grandsons of the sovereign; (4) brothers of the sovereign; (5) uncles of the sovereign; (6) nephews of the sovereign; (7) archbishop of Canterbury, primate of all England; (8) lord high chancellor of Great Britain or lord keeper of the great seal; (9) archbishop of York, primate of England; (10) prime minister; (11) lord high treasurer of Great Britain; (12) lord president of the privy council; (13) speaker of the House of Commons; (14) lord keeper of the privy seal; (15) lord great chamberlain of England, (16) lord high constable of England, (17) earl marshal, (18) lord high admiral, (19) lord steward of the household, (20) lord chamberlain of the household, (21) master of the horse, above peers of their own degree; (22) dukes; (23) eldest sons of dukes of the blood royal; (24) marquesses; (25) dukes' eldest sons; (26) earls; (27) younger sons of dukes of the blood royal; (28) marquesses' eldest sons; (29) dukes' younger sons; (30) viscounts; (31) earls'eldest sons; (32) marquesses' younger sons; (33) bishops; (34) secretaries of State of baronial rank; (35) barons; (36) lords commissioners of the great seal; (37) treasurer of the household; (38) comptroller of the household; (39) vice-chamberlain of the household; (40) secretaries of State; (41) high commissioners in London; (42) viscounts' eldest sons; (43) earls' younger sons; (44) barons' eldest sons; (45) knights of the Garter; (46) privy councillors; (47) chancellor of the Exchequer; (48) chancellor of the duchy of Lancaster; (49) lord chief justice of England; (50) master of the rolls; (51) president of the probate, divorce and admiralty division; (52) lords justices of appeal; (53) judges of the High Court of Justice; (54) viscounts' younger sons; (55) barons' younger sons; (56) sons of lords of appeal; (57) baronets; (58) knights grand cross of the Bath, Grand Commanders of the Star of India, grand cross of St. Michael and St. George, grand commanders of the Indian Empire, grand cross of the Royal Victorian Order, and of the Order of the British Empire; (59) knights commanders of the Bath, the Star of India, etc.; (60) knights bachelors; (61) judges of the county court direct; (62) serjeants-at-law; (63) masters in chancery; (64) masters in lunacy; (65) companions of the Bath, of the Star of India, of St. Michael and St. George, of the Indian Empire, commanders of the Royal Victorian Order, and of the Order of the British Empire; (66) companions of the Distinguished Service Order; (67) members of the Royal Victorian Order (4th class); (68) officers of the Order of the British Empire; (69) companions of the Imperial Service Order; (70) gentlemen of the privy chamber; (71) eldest sons of the younger sons of peers; (72) eldest sons of the baronets; (73) eldest sons of the knights of the Garter; (74) eldest sons of the knights of the Bath, of the Star of India, etc., (eldest sons of the knights grand cross taking precedence of eldest sons of knights of the second degree); (75) members of the Royal Victorian Order (5th class); (76) members of the Order of the British Empire; (77) younger sons of baronets; (78) younger sons of knights; (79) esquires; (80) gentlemen.

General Precedence of Women.—The Queen; (1) the queen dowager; (2) the princess of Wales; (3) daughters of the sovereign; (4) wives of the sovereign's younger sons; (5) granddaughters of the sovereign (with style of Royal Highness); (6) wives of the sovereign's grandsons; (7) sisters of the sovereign; (8) wives of the sovereign's brothers; (9) aunts of the sovereign; (10) wives of the sovereign's uncles; (11) nieces of the sovereign; (12) wives of the sovereign's nephews; (13) granddaughters of the sovereign (without style of Royal Highness); (14) wives of dukes of the blood royal; (1j) duchesses; (16) wives of sons of dukes of the blood royal; (17) marchionesses; (18) wives of the eldest sons of dukes; (19) dukes' daughters; (20) countesses; (21) wives of the younger sons of dukes of the blood royal; (22) wives of the eldest sons of marquesses; (23) marquesses' daughters; (24) wives of the younger sons of dukes; (25) viscountesses; (26) wives of the eldest sons of earls; (27) earls' daughters; (28) wives of the younger sons of marquesses; (29) baronesses; (30) wives of the eldest sons of viscounts; (31) viscounts' daughters; (32) wives of the younger sons of earls; (33) wives of the eldest sons of barons; (34) baron's daughters; (35) maids of honor to the Queen; (36) wives of knights of the Garter; (37) wives of the younger sons of viscounts; (38) wives of younger sons of barons; (39) daughters of life barons; (40) wives of the sons of life barons; (41) baronets' wives; (42) dames grand cross of the Order of the British Empire; (43) wives of the knights grand crosses of the Bath, grand commanders of the Star of India, grand crosses of St. Michael and St. George, grand commanders of the Indian Empire, grand crosses of the Royal Victorian Order, and of the order of the British Empire; (44) dames commanders of the Order of the British Empire; (45) wives of knights commanders of the Bath, Star of India, etc.; (46) wives of knights bachelors; (47) commanders of the Order of the British Empire; (48) wives of the companions of the Bath, of the Star of India, of St. Michael and St. George, of the Indian Empire, of commanders of the Royal Victorian Order, and commanders of the Order of the British Empire; (49) wives of companions of the Distinguished Service Order; (50) wives of serjeants-at-law; (51) officers of the Order of the British Empire; (52) wives of members of the Royal Victorian Order (4th class); (53) wives of officers of the Order of the British Empire; (54) companions of the Imperial Service Order; (55) wives of companions of the Imperial Service Order; (56) wives of the eldest sons of the younger sons of peers; (57) daughters of the younger sons of peers; (58) wives of the eldest sons of baronets; (59) baronets' daughters; (60) wives of the eldest sons of knights; (61) knights' daughters; (62) members of the Order of the British Empire; (63) wives of members of the Royal Victorian Order (5th class); (64) wives of members of the Order of the British Empire; (65) wives of the younger sons of the younger sons of peers; (66) wives of the younger sons of baronets; (67) wives of the younger sons of knights; (68) wives of esquires; (69) wives of gentlemen.

A special table of precedence in Scotland is regulated by a royal warrant dated March 16. 1905, and a special table of precedence in Ireland was set forth by authority of the lord lieutenant (Jan. 2, 1895). Both contain errors and will probably be revised.

Personal precedence belongs to the royal family, the peerage and certain specified classes of the commonalty. Official precedence belongs to such dignitaries of the church and such ministers of State and the household as have had rank and place accorded to them by parliament or the Crown, to the speaker of the House of Commons and to the privy council and the judicature. Substantive precedence, which may be either personal or official, belongs to all those whose rank and place are independent of their connection with anybody else, as by the archbishop of Canterbury, the iord high chancellor or the lord great chamberlain, peers and peeresses, baronets, knights and some esquires. Derivative precedence, which can only be personal, belongs to all whose rank and place are determined by their consanguinity with or affinity to somebody else, as the lineal and collateral relations of the sovereign, the sons, daughters and daughters-in-law of peers and peeresses in their own right, and the wives, sons, daughters and daughters-in-law of baronets, knights and some esquires. The precedence of the sovereign is at once official and personal, the precedence of peeresses by marriage is at once derivative and substantive. In the case of the sovereign it is his or her actual tenure of the office of king or queen which regulates the rank and place of members of the royal family, and in the case of peeresses by marriage, although their rank and place are derivative in origin.

What are termed "titles of courtesy" are borne by all the sons and daughters of peers and peeresses in their own right. The eldest sons of dukes, marquesses and earls are designated by the names of one or other of the inferior peerages of their fathers, usually a marquessate or an earldom in the first, an earldom or a viscounty in the second and a viscounty or barony in the third case. The rule applicable in former times, still adhered to by the older English dignities, was that a duke's eldest son was styled earl, the son of a marquess, viscount, the son of an earl, baron. No such rule obtained in Scotland. But, whatever it may be, it is without effect on the rank and place of the bearer, which are those belonging to him as the eldest son of his father. The younger sons of dukes and marquesses are styled "lords," followed by both their Christian names and surnames. The younger sons of earls and both the eldest and the younger sons of viscounts and barons are described as "honourable" before both their Christian names and surnames. The daughters of dukes, marquesses and earls are styled "ladies" before both their Christian names and surnames. The daughters of viscounts and barons are described as "honourable" before both their Christian names and surnames. If the eldest son of a marquess or an earl marries a woman of rank equal or inferior to his own, she takes his title and precedence; but if she is of superior rank she retains, with her own precedence, the prefix "lady" before her Christian name followed by the name of her husband's title of courtesy. Again, if the younger son of a duke or a marquess marries a woman of rank equal or inferior to his own, she is called "lady," with his Christian and surname following, and is placed in his precedence, but, if she is of superior rank, she retains, with her own precedence, the prefix "lady" before her Christian name and his surname. If the daughter of a duke, a marquess or an earl marries the younger son of an earl, the eldest or younger son of a viscount or baron, a baronet, a knight or an esquire, etc., she retains, with her own precedence, the prefix "lady" before her Christian name and her husband's surname. If the daughter of a viscount marries the younger son of an earl or anybody of inferior rank to him, or the daughter of a baron marries the younger son of a viscount or anybody of inferior rank to him, she retains her own precedence with the prefix "honourable" before the addition "Mrs." and his surname or Christian name and surname. But, if her husband is a baronet or a knight, she is called the Honourable Lady Smith or the Honourable Lady Jones, as the case may be. The wives of the younger sons of earls and of the eldest and younger sons of viscounts and barons, if they are of inferior rank to their husbands, take their precedence and are described as the Honourable Mrs., with the surnames or Christian names and surnames of their husbands following. The judges were placed by James I. before the younger sons of viscounts and barons and accorded the title of "honourable" (*q.v.*). But this does not apply to their wives.

Some Criticisms. — It is manifest on even a cursory examination of the tables we have given that they are in many respects very imperfectly fitted to meet the circumstances and requirements of the present day. In both of them the limits prescribed to the royal family are inconveniently narrow, in contrast to the ample bounds through which the operation of the Royal Marriage Act (12 Geo. III. c. 11) extends the disabilities but not the privileges of the sovereign's kindred. Otherwise the scale of general precedence for women compares favourably with the scale of general precedence for men, which is now in nearly the same condition as that in which it has been for between two and three centuries, and the political, to say nothing of the social, arrangements to which it was framed to apply have undergone an almost complete transformation. It is true that in the professional classes definite systems of subordination are established by either authority or usage, which are carefully observed and enforced in the particular areas and spheres to which they have reference. As an example of precedence, major-generals and rear-admirals are of equal rank, and with them are placed commissaries-general and inspectors-general of hospitals and fleets; in India along with civilians of 31 years' standing they immediately follow the vice-chancellors of the Indian universities, and in relation to the consular service they immediately precede agents-general and consuls-general. But there is nothing to aid us in determining whether in England they should be ranked with, before or after deans, king's counsel or doctors in divinity, who likewise are destitute of any recognized general precedence, and, as matters now stand, would certainly have to give place to the younger sons of baronets and knights and the companions of the knightly orders

No foreigner has any legal precedence in Great Britain, but it is suggested that it being proper courtesy to accord to guests the precedence due to the rank they bear in their own countries, they should rank in society with and immediately before those of the relative rank in England. It should, however, be remembered that the younger sons of counts and other nobles bear the title of count with the addition of the Christian name, and they should be ranked with younger sons of British earls, etc., whatever title they bear.

It has now become usual to recognize ecclesiastical rank derived from the pope, even when held by subjects of the king. Cardinals, therefore, rank by international usage above archbishops, as princes of the blood royal, and in Ireland, Roman Catholic and Protestant bishops rank as such by warrants there in force.

An order respecting precedence was sent by the secretary of State for the colonies to the governor-general of Canada (July 24, 1868). Precedence in India is regulated by a Royal Warrant dated May 6, 1871.

See the peerages of Burke, Debrett etc.

THE UNITED STATES

Since there is no hereditary ranking in the United States precedence in official functions and ceremonies is purely according to official position. No statutes determine the order, so courtesy is the only law which rules. Custom, however, has set an order generally as follows: The President, Vice-President, Ambassadors in order (*i.e.,* according to the date when their credentials were presented), Chief Justice, Justices, Ministers in order, Speaker of the House of Representatives, The Cabinet in order (Secretary of State, Secretary of the Treasury, Secretary of War, Attorney General, Postmaster General, Secretary of the Navy, Secretary of the Interior, Secretary of Agriculture, Secretary of Commerce, and Secretary of Labor), Senators, Chief of Staff of the Army, Chief of Operations of the Navy, Representatives, Chargé d'Affaires, major-generals and rear-admirals, counsellors and military and naval attaches, Solicitor General, foreign first secretaries, American under-secretaries and first-assistant secretaries, Federal Reserve Board members, Interstate Commerce Commission members, members of other quasi-independent boards and commissions, Secretary of the Smithsonian Institution and heads of other quasi-independent bureaus and institutions, foreign second and third secretaries, second and third secretaries of the United States.

PRECESSION OF THE EQUINOXES, in astronomy, an effect connected mainly with a gradual change of the direction of the earth's axis of rotation. There is a general resemblance between the motion of the earth and that of a spinning top. It is well-known that when a top is slightly disturbed its axis precesses round the vertical so that it traces out a cone; the earth's axis similarly describes a cone at the rate of one revolution in about 26,000 years. In applying this analogy we must take the ecliptic (*i.e.,* the plane of the orbit of the earth round the sun) to correspond to the horizontal; the axis about which the earth spins is inclined at $23\frac{1}{2}°$ to the "vertical," and keeping this inclination it turns slowly round the "vertical." It must be emphasized, however, that this correspondence between the earth and a top is superficial, the cause of the precessional motion being upon different principles.

In this way the north pole of the celestial sphere describes among the constellations a circle of $23\frac{1}{2}°$ radius, making a revolution in 26,000 years. At present it is near the star *a* Ursae Minoris, which is therefore called the Pole Star; but it has travelled a considerable distance within historic times. About 3000 B.C. the star *a* Draconis would have served as pole star; in 13000 B C., also in AD. 13000 Vega would be near enough to the pole to mark roughly its position. By this displacement the part of the sky visible from a particular terrestrial station gradually changes; certain constellations cease to rise above the horizon and others appear for the first time. In the time of the early Chaldean astronomers it was not necessary to travel so far south to see the Southern Cross as it is now.

Cause of Precession.—This was first explained by Isaac Newton. It is due to the attraction of the sun and moon on the equatorial protuberance of the earth, the moon being responsible for about $\frac{2}{3}$ and the sun for $\frac{1}{3}$ of the motion—the same proportion as the lunar and solar tides. Treating the equatorial bulge as an extra ring of matter surrounding a spherical earth, the attraction of the sun and moon on this ring gives a couple tending to turn the ring into the plane of the ecliptic, since both disturbing agents are in or near the ecliptic. If the earth were not spinning this would turn the earth over until the equator coincided with the ecliptic, but the spinning earth behaves like a gyrostat, so that its axis moves at right angles to the plane of the couple—just as the couple which would upset a top at rest gives the axis of the spinning top a conical motion.

The moon's orbit is inclined at about 5° to the ecliptic, but it does not remain still; its nodes travel round the ecliptic in 18·6 years. Averaged over a long period of time the deviations of the moon from the ecliptic cancel out; but at any moment the precession caused by the moon may be greater or less than the average, according to the position at the time of the lunar orbit. In fact the path of the pole among the stars is a slightly sinuous curve. Astronomers distinguish the average secular motion as precession and the periodic fluctuations or sinuosities as *nutation* (*q.v.*).

As the pole (corresponding to the equator) moves round the pole of the ecliptic, so the equinox or intersection of the equator and ecliptic moves round the ecliptic once in 26,000 years. Both right ascensions and longitudes are reckoned from the equinox as zero-point; stellar longitudes on this account iccrease steadily by nearly a minute of arc every year; the effect on the right ascensions is more complicated, but these also continually increase. The vernal equinox is commonly called the First Point of Aries, but it has already moved away from that constellation and is now in Pisces. It should be understood that the precession of the equinoxes has no effect on the seasons, and, for example, has no connection with the gradual departure of the spring equinox from March 21 which occurred in the old Julian calendar.

Planetary Precession.—Besides the foregoing luni-solar precession, a phenomenon of much smaller magnitude, known as planetary precession, is recognized. It is due to perturbations by the planets which cause slow changes in the plane of the earth's orbit. Planetary precession changes the position of the ecliptic, whereas luni-solar precession changes the position of the equator; either change affects the equinox, which is the intersection of the two planes. Corrections for precession and nutation are of great importance in most branches of positional astronomy, and their computation is very burdensome. For details of the theory of the precessional motions see Newcomb's *Spherical* Astronomy, ch. ix.

PRECIPITATION, in chemistry, is the separation of a solid in a condition to be insoluble in the solution from which it is removed. Precipitation is an important step in many chemical processes. It may be accomplished by the concentration of the solution to the point where it is supersaturated, when, upon cooling, a part of the solid separates out, though this process is usually described as crystallization (*q.v.*). It may also be accomplished by the addition of reagents which may combine with the material to form an insoluble compound, or which may displace the material from the original solution. The application of heat may cause coagulation, as with certain proteins, and the removal of gas may also alter conditions sufficiently to cause precipitation. A change of temperature is another method. The salting out process as employed in the soap industry is a familiar example of precipitation. The formation of the fibre from a solution of cellulose by causing it to pass into a setting bath is a case of precipitation used in the artificial silk industry.

PRECISION GAUGES AND COMPARATORS. The World War was responsible for a considerable development and improvement of apparatus intended for the measurement of engineers' gauges and products.

Whitworth and Johansson's Gauges.—Improvement in accuracy of measurement necessarily goes hand in hand with improvement in accuracy and perfection of manufacture of the articles to be measured. The original measuring machine of Sir Joseph Whitworth would have been of little value apart from the system of accurate standards (both end gauges and cylindrical gauges) which he produced for use with it. The next great advance was the introduction by the Swedish firm of Johansson, in 1908, of flat parallel faced slip and block gauges, of such perfection of workmanship that any two of them, when cleaned, would "wring" together. (See METROLOGY.) The gauges were made in series differing by definite small amounts, so chosen that by wringing together a suitable combination of pieces, any desired size, to the nearest 0·0001 in., could be produced. To ensure this accuracy, it is necessary that the individual pieces should each have a guaranteed accuracy of (say) 0·00001 in., in order that the cumulated error of a group of four or'five should not exceed 0·00005 inch. And in order to assert with confidence that this degree of accuracy is, or is not, in fact attained in an individual piece it is necessary to be able to measure with an accuracy of the order of 0·000001 inch. When the Johansson gauges were first introduced no appliances were available which could be relied on to give measurements of an accuracy of the order of 0·000001 inch. Three entirely different methods have since been developed, however, which enable it to be done, and which, with due precautions, give mutually consistent results. These are:—

Tilting Level Comparator.—The "tilting level" comparator, due to A. J. C. Brookes, in which the two gauges, or groups of gauges, to be compared are stood side by side on a level surface plate, and the difference in their heights is determined by the reading of a highly sensitive level, which rests by point contact upon their upper surfaces, through two ball feet.

Millionth *Comparator.*—The "millionth" comparator, due to J. E. Sears, jun., wherein measurements are made between two flat parallel anvils, giving a local surface contact, the one anvil being fixed, and the other connected, through a series of spring suspensions designed to eliminate all frictional effects, with a sensitive tilting mirror which causes a spot of light to move across a scale, giving a magnified image of the displacement of the anvil on a scale of about 30,000 to 1.

Optical Interference.—The method of optical interference developed at the Bureau of Standards, Washington, wherein the whole surfaces of the gauges under comparison may be inspected, being marked out into contours of approximately 0·00001 in. difference in height by the alternate light and dark bands forming the interference pattern.
