Assistant Professor of Botany, Imperial College of Science and Technology, South Kensington. PLANTS (*in part*).

R. L. Ho. Robert Lockhart Hobson, C.B., B.A.
Former Keeper of Department of Oriental Antiquities and Ethnography, British Museum (retired). Author of *Worcester Porcelain; Chinese Pottery and Porcelain; The Later Ceramic Wares of China*. POTTERY AND PORCELAIN (*in part*).

R. L. Wi. Raymond Louis Wilder, Ph.D.
Assistant Professor of Mathematics, University of Michigan. POINT SETS.

R. M. Wh. R. Mortimer Wheeler
PUNCH.

R. N. B. Robert Nisbet Bain
Assistant Librarian, British Museum, 1883–1909. Author of *Scandinavia: The Political History of Denmark, Norway and Sweden, 1513–1900; The First Romanovs, 1613 to 1725; Slavonic Europe: The Political History of Poland and Russia from 1469 to 1796;* etc.
POLAND (*in part*); POTEMKIN, GRIGORY ALEKSANDROVICH.

R. P. René Poupardin, D-ès-L.
Secretary of the Ecole des Chartes. Honorary Librarian of the Bibliothèque Nationale, Paris. PROVENCE (*in part*).

R. R. Sir Richard Studdert Redmayne, K.C.B., M.Sc., F.G.S., M.Inst.C.E.
Past President, Institute of Mining and Metallurgy. Hon. Member, Surveyors' Institute. H.M. Chief Inspector of Mines, 1908–20. Author of *The British Coal Industry*. PULVERIZED FUEL.

R. R. M. Robert Ranulph Marett, M.A., D.Sc., F.R.A.I., F.B.A., LL.D.
Rector of Exeter College, Oxford, 1928–43. Formerly University Reader in Social Anthropology. Author of *Anthropology; Psychology and Folklore*. PRAYER.

R. S. Cl. R. S. Clay, B.A., D.Sc., F.Inst.P.
Principal, Northern Polytechnic, Holloway, London, 1902–31. Author of *Practical Exercises in Light; Treatise on Practical Light*. RADIOMETER.

R. S. Co. Robert Seymour Conway, M.A., D.Litt.
Former Hulme Professor of Latin, Victoria University of Manchester. Formerly Professor of Latin, University College, Cardiff, and Fellow of Caius College, Cambridge. PRAENESTE (*in part*).

R. Ta. R. Taylor, M.A., B.Sc.
Assistant, Chemical Research Laboratory, Teddington, Middlesex. PRESSURE CHEMISTRY.

R. W. P. Raymond William Postgate
Editorial Staff of the 14th Edition of the *Encyclopædia Britannica*. Author of *The Bolshevik Theory; Revolution from 1789–1906; The Builders' History;* ed. *Pervigilium Veneris*. RADICAL.

S. A. Samuel Alexander, O.M., M.A., Litt.D., F.B.A.
Hon. Fellow of Lincoln College, Oxford, 1918. Hon. Fellow of Balliol College, 1925. Hon. Professor (Professor, 1893–1924) of Philosophy, Manchester. Author of *Moral Order and Progress; Locke; Spinoza and Time;* etc. QUALITIES.

S. A. H. S. A. Hurren
Lecturer on Technology of Pianoforte Construction at Northern Polytechnic Institute. PLAYER-PIANO.

S. B. F. Sidney B. Fay, Ph.D., Litt.D., L.H.D.
Professor of History, Harvard University and Radcliffe College, Cambridge, Mass. Author of *Origins of the World War* (2 vols.); etc. PRUSSIA (*in part*).

S. F. H. Sir Sidney Frederic Harmer, K.B.E., M.A.
Director of Natural History Departments, British Museum, 1919–27. Hon. Fellow, formerly Fellow, Tutor and Lecturer, King's College, Cambridge. Joint-Editor of *The Cambridge Natural History*. POLYZOA; PTEROBRANCHIA.

S. Fr. Sigmund Freud, M.D., LL.D.
Professor of Neurology, Vienna University, 1902–38. Director of the *International Journal of Psychoanalysis*.
PSYCHOANALYSIS: FREUDIAN SCHOOL.

Sh. Thomas Shaw, Baron Shaw of Dunfermline, P.C., K.C., LL.D.
Former Lord of Appeal. Lord Advocate for Scotland, 1905–9.
PRIVY COUNCIL, JUDICIAL COMMITTEE OF THE.

S. K. L. Samuel K. Lothrop, A.B., Ph.D.
Anthropologist, Museum of the American Indian Heye Foundation, New York. Author of *Tulum: An Archaeological Study of Eastern Yucatan;* etc. POKOMAN; QUICHÉ.

S. Lea. Stephen Leacock, B.A., Ph.D., L.H.D., LL.D., D.C.L.
On staff of McGill University, 1901–36. Head, Department of Economics, 1908–36; Emeritus, 1936– . Author, *Elements of Political Science; Canada, The Foundations of Its Future; Montreal, Seaport and City; Nonsense Novels*, etc. PRINCE EDWARD ISLAND.

S. McC. L. Samuel McCune Lindsay, Ph.D., LL.D.
Emeritus Professor of Social Legislation, Columbia University, New York. President, Academy of Political Science, 1910–30. Author of *Social Aspects of Philadelphia Relief Work;* etc.
PROHIBITION.

S. Me. Stanley Melville, M.D., M.R.C.S.
Radiologist, St. George's Hospital, London. Radiologist, Charing Cross Hospital, West London Hospital and Hospital for Sick Children, Great Ormond St., London. RADIOTHERAPY.

S. Mo. Stanley Morison
Editor of *The Fleuron*, London, 1926–30. Typographical adviser. Author of *Four Centuries of Fine Printing;* etc.
PRINTING TYPE (*in part*).

S. Ru. Sidney Russ, C.B.E., D.Sc.
Professor of Physics, Medical School, Middlesex Hospital, since 1920. Fellow of University College, London. Co-Author of *Radium X-Rays and the Living Cell;* etc. RADIOLOGY.

S. T. H. W. Captain S. T. H. Wilton, R.N. (retired)
Late Assistant Director of Naval Ordnance, Admiralty, London.
PRESS GANG.

S. W. C. Sydney W. Cole, M.A.
Lecturer in Medical Chemistry, Trinity College, Cambridge.
PROTEINS.

T. A. Thomas Ashby, D.Litt., F.B.A., F.S.A.
Formerly Director of the British School at Rome. Author of *Turner's Visions of Rome; The Roman Campagna in Classical Times; Roman Architecture*. Revised and completed for press a *Topographical Dictionary of Ancient Rome* (by late Prof. J. B. Platner). POMPEII (*in part*); PRAENESTE (*in part*); PUTEOLI; etc.

T. A. C. Sir Theodore Andrea Cook
Late Editor-in-Chief of *The Field*, London. Author of *A History of the English Turf; The Fencers' Song;* etc. QUOITS.

INITIALS AND NAMES OF CONTRIBUTORS

T. E. G. **Theodor E. G. Gregory, D.Sc.**
Economic Adviser to Government of India since 1938. Sir Ernest Cassel Professor of Economics in the University of London, 1927–37. QUANTITY THEORY OF MONEY.

T. F. H. **Talbot F. Hamlin, B.A., B.Arch.**
Instructor in the History of Architecture, Columbia University, New York. Chairman, City Plan Committee of the Merchants' Association, New York. Author of *The Enjoyment of Architecture; The American Spirit in Architecture.*
PLATERESQUE; PORCH.

T. G. Ba. **T. Graham Bailey, M.A., B.D., D.Litt.**
Reader in Hindustani in the University of London.
PUNJAB *(in part).*

T. H. **Thomas Hodgkin, B.A.**
British Historian. Author of *Italy and Her Invaders; Tlzeodoric the Goth; Life of Charles the Great.* RAVENNA *(in part).*

T. H. H. **Colonel Sir Thomas Hungerford Holdich**
Superintendent, Frontier Surveys, India, 1892–8. H. M. Commissioner for Perso-Beluch Boundary, 1896. President, Royal Geographical Society, 1916–8. Author of *The Indian Borderland; The Countries of the King's Award; India; Tibet;* etc.
QUETTA.

T. J. E. **Major T. J. Edwards**
Secretary to the Honours and Distinctions Committee, War Office, London. Author of *The Perforated Map; The Non-Commissioned Officer's Guide to Promotion in the Infantry.*
QUARTERMASTER *(in part).*

T. L. H. **Sir Thomas Little Heath, K.C.B.**
Hon. Fellow of Trinity College, Cambridge. Assistant Secretary to the Treasury, 1907–13. Author of *A History of Greek Mathematics;* etc. PORISM; PTOLEMY *(in part);* PYTHAGORAS.

T. N. McC. **Thomas Nesbitt McCarter, A.M.**
Chairman of the Board, Public Service Corporation of New Jersey. Author of *District Court Pvactice of New Jersey; One Phase of a Jerseyman's Activities.*
PUBLIC SERVICE CORPORATION OF NEW JERSEY.

T. W.-D. **Theodore Watts-Dunton**
English Man of Letters. Author of *The Renascence of Wonder; The Coming of Love;* etc. POETRY *(in part).*

U. P. H. **Ulysses P. Hedrick, D.Sc.**
Director Emeritus of the New York State Agricultural Experiment Station, Geneva, New York. PLUM *(in part).*

V. Bu. **Vannevar Bush, M.S., Eng.D.**
President, Carnegie Institution of Washington. Professor of Electric Power Transmission, Massachusetts Institute of Technology, 1919–38. PRODUCT INTEGRAPH.

V. H. B. **Vernon Herbert Blackman, Sc.D., F.R.S.**
Director of Research Institute of Plant Physiology, Imperial College of Science and Technology, London.
PLANTS *(in part);* POLLINATION.

V. R. B. **Victor R. Boswell, M.S., Ph.D.**
Principal Horticulturist and Assistant Head of Division of Fruit and Vegetable Crops and Diseases, Bureau of Plant Industry, U.S. Department of Agriculture, Washington, D.C.
PUMPKIN; RADISH.

W. A. L. E. **Rev. William Alexander Leslie Elmslie**
Professor of Hebrew and Old Testament Literature in Westminster College, Cambridge. Fellow of Christ's College, 1911–7.
PROPHET.

W. A. R. **William Alfred Reid, LL.M.**
Former Foreign Trade Adviser, Pan American Union. Lecturer on International Commerce at the School of Business Administration, American University, Washington. Author of *Ports and Harbours of South America; History of the Pan American Union; Seeing South America;* etc. PLATA, RIO DE LA *(in part).*

W. A. S. H. **William Albert Samuel Hewins, M.A.**
Secretary of British Tariff Commission, 1903–17. Tooke Professor of Economic Science and Statistics at King's College, London, 1897–1903. Author, *Imperialism and Its Probable Effect on the Commercial Policy of the United Kingdom;* etc.
PROTECTION *(in part).*

W. B. Ho. **W. B. Honey**
Keeper in the Department of Ceramics, Victoria and Albert Museum, South Kensington, London.
POTTERY AND PORCELAIN *(in part).*

W. Bro. **William Brown, M.A.**
Professor of Plant Physiology, Imperial College of Science and Technology, London, since 1928. PLANTS *(in part).*

W. By. **Hon. Wilfrid Bovey, O.B.E., LL.D., D.Litt.**
Barrister at Law (England). Member, Legislative Council, Quebec. Author of *The French Canadians Today; Canadien—A Study of the French Canadians.* QUEBEC.

W. C. Be. **William Cabell Bruce, LL.D.**
Member of the United States Senate, 1923–9. Author, *John Randolph of Roanoke;* etc. RANDOLPH, JOHN.

W. C. Br. **Warren C. Browne**
Editor and Publisher, *The National Lithographer,* New York.
PRINTING TYPE *(in part).*

W. C. B. T. **W. C. B. Tunstall, M.A.**
Civilian Lecturer, Royal Naval College, Greenwich.
QUIBERON, CAMPAIGN AND BATTLE OF *(in part).*

W. C. Ha. **Sir W. Clarke Hall, B.A.**
Metropolitan Magistrate and Chairman of the Shoreditch Juvenile Court. Author of *The Law Relating to Children; Children's Courts;* etc. PROBATION *(in part).*

W. C. M. **Walter Conrad Muenscher, A.M., Ph.D.**
Professor of Botany, Cornell University. Author of *Weeds* (of the United States); *Poisonous Plants of the United States; Keys to Woody Plants,* etc. POISON IVY; POISOSOUS PLANTS.

W. C. S. **Walter C. Sanders**
General hlanager, Railway Division, The Timken Roller Bearing Company, Canton, Ohio. Author of *Railway Car Design and Construction.* RAILWAYS *(in part).*

W. de B. H. **W. de Bracy Herbert**
Barrister-at-Law. Former Recorder of Newcastle-under-Lynx.
QUARTER SESSIONS, COURT OF *(in part).*

W. E. D. **W. E. Dalby, M.A., B.Sc., M.Inst.C.E.**
Former Dean of, and London University Professor of Engineering, City and Guilds Engineering College of the Imperial College of Science and Technology. POWER TRANSMISSION *(in part).*

W. F. C. **William Feilden Craies, M.A.**
Late Barrister-at-Law, Inner Temple, and Lecturer on Criminal Law, King's College, London. Editor of Archbold's *Criminal Pleading* (23rd ed.). QUARTER SESSIONS, COURT OF *(in part).*

W. F. S. **William Fleetwood Sheppard, Sc.D.**
Senior Examiner in the Board of Education.
PROBABILITY AND ERROR.

W. G. A. **Walter Gordon Armstrong**
Assistant to the President, Youngstown Pressed Steel Co., Warren, Ohio. PRESSED METAL.

W. H. Sa. **William Henry Salter, M.B.E., M.A., LL.B.**
Treasurer and Joint Hon. Secretary, Society for Psychical Research, London. PSYCHICAL RESEARCH.

W. H. Wi. **Colonel Sir William Henry Willcox**
Physician and Lecturer on Chemical Pathology and on Forensic Medicine to St. Mary's Hospital, London, 1900–35. Medical Adviser to Home Office since 1919. POISON

W. J. C. **W. J. Cunningham, Hon.A.M.**
Professor of Transportation, Harvard University.
RAILWAYS *(in part).*

W. K. G. **W. K. Gregory, A.M., Ph.D.**
Curator of Departments of Comparative Anatomy and Ichthyology, American Museum of Natural History. Professor of Palaeontology, Columbia University. PRIMATES *(in part).*

W. La. **William Latey**
Of the Middle Temple. Barrister-at-Law, of the Probate and Divorce Courts. PRESS LAWS *(in part).*

W. Li. **Walter Lippmann, A.B.**
Special Writer, *New York Herald Tribune.* Formerly Editor of *The New York World.* Author of *The Political Scene; Liberty and the News; Public Opinion;* etc. PULITZER, JOSEPH *(in part).*

W. M. F. P. **Sir William Flinders Petrie, D.C.L., Litt.D., Ph.D., F.B.A., F.R.S.**
Emeritus Professor of Egyptology, University College, London, 1933–42. Excavator of Giza, Naucratis, Am and Daphnae.
PYRAMID.

W. N. K. **William N. Keeler**
General Manager, Sun-Maid Raisin Growers' Association, Fresno, California. RAISIN.

W. P. H. **Walter Page Hedden, A.M.**
Chief, Bureau of Commerce, The Port of New York Authority. Author of *How Great Cities Are Fed.* RAILWAYS *(in part).*

W. Po. **Wilson Popenoe, Sc.D.**
Director, Escuela Agricola Panamericana, Tegucigalpa, Honduras, C.A. Author of *Manual of Tropical and Subtropical Fruits.* POMEGRANATE.

W. R. I. **Very Rev. William Ralph Inge, K.C.V.O., D.D., F.B.A., Hon.D.Litt., Hon.LL.D.**
Dean of St. Paul's, 1911–34. Lady Margaret Professor of Divinity and Fellow of Jesus College, Cambridge, 1907–11. Gifford Lecturer, St. Andrews, 1917–8. Romanes and Hibbert Lecturer, 1920; etc. Author of *Lay Thoughts of a Dean; The Philosophy of Plotinus;* etc. PLOTINUS.

W. R. Sm. **William Roy Smith, M.A., Ph.D.**
Associate Professor of History, Bryn Mawr College, Pennsylvania. POLK, JAMES KNOX.

W. Sco. **Walter Scott**
Member of the Royal Sanitary Institute, Institution of Heating and Ventilating Engineers, and Advisory Committee on Plumbing. Ex-President, Associated Master Plumbers. Technical Editor, *The Plumber and Journal of Heating.* Examiner in Plumber's work and Allied Sanitary Engineering, City and Guilds of London Institute. Late Chief Lecturer on Plumbing, The Polytechnic, London. PLUMBING.

W. S. L. **W. S. Lewis**
Professor of Geography, University College, Exeter.
PRAGUE *(in part).*

W. S. L.-B. **Walter Sydney Lazarus-Barlow, M.D., F.R.C.P.**
Former Member of the Cancer Committee, Ministry of Health. Formerly Professor of Experimental Pathology, Middlesex Hospital Medical School, London University. Author of *A Manual of General Pathology; Elements of Pathological Anatomy and Histology for Students.* Editor of the Medicine section of the 14th Edition of the *Encyclopædia Britannica.*
PLEURISY OR PLEURITIS; PURPURA; QUACKERY *(in part).*

W. Sta. **William Staniar**
Mechanical Power Engineer and Division Head, Manufacturing Division, Dupont Engineering Company, Wilmington, Del. Author of *Mechanical Power Transmission.*
POWER TRANSMISSION *(in part).*

W. S. Wa. **W. S. Wallace, M.A.**
Librarian, University of Toronto. QUEBEC *(in part).*

W. T. C. **William Thomas Calman, C.B., D.Sc., F.R.S., LL.D., F.L.S.**
Keeper of the Department of Zoology, British Museum, 1927–36. Author of "Crustacea" in Lankester's *Treatise on Zoology.*
PYCNOGONIDA.

W. T. M. **Rt. Rev. William T. Manning, D.D., S.T.D., D.C.L.**
Bishop of New York since 1921.
PROTESTANT EPISCOPAL CHURCH.

W. V. B. **W. Valentine Ball, O.B.E., M.A.**
Barrister-at-Law. Master of the Supreme Court, King's Bench Division. PRACTICE AND PROCEDURE *(in part).*

W. W. Ch. **Winn W. Chase**
Associate Editor, *Textile World,* New York.
RAIN-PROOF FABRICS.

W. Wi. **William Wilson, Ph.D., D.Sc., F.R.S.**
Hildred Carlile Professor of Physics, University of London.
QUANTUM THEORY, THE.

W. W. P. **W. Wyatt Paine, J.P., F.S.A.**
Author and Editor of numerous legal textbooks.
POLICE *(in part).*

W. W. R. **William Walker Rockwell, Ph.D., D.Theol.**
Professor of Church History and Librarian, Union Theological Seminary, New York. PURITANISM.

W. Y. **Rev. William Young**
Minister, Higher Broughton Presbyterian Church, Manchester, 1877–1901. PRESBYTERIANISM *(in part).*

ENCYCLOPÆDIA BRITANNICA

VOLUME 18

PLANTS TO RAYMUND OF TRIPOLI

PLANTS. In the most generally used sense a plant is a member of the vegetable class of living things, plants and animals being the two classes into which living things (organisms) are roughly divided. With the higher forms the difference is very definite and leaps to the eye. In the case of lower forms of life the distinction is often very difficult and indeed an artificial one, since plants and animals have had common ancestors in evolution. The early use of the word was for a twig, shoot, cutting or sapling which is the meaning of the Latin *planta.*

Other meanings of the word are derived from the verb "to plant" *i.e.,* to fix in position or place. It is thus used of the fixtures, machinery or apparatus necessary for carrying on an industry or business; in colloquial or slang use it is applied to a swindle, a carefully arranged plot or trap laid to deceive. (Cf. also PLANTATION.) In the following sections the botanical sense of the term is followed. An outline of the classification of plants is given under BOTANY and the chief groups, Algae, Fungi, Gymnosperms, etc., are dealt with in separate articles.

CLASSIFICATION OF PLANTS

In the article BOTANY reference has been made to the earlier systems of classification and the evolution of the idea of a natural system in which families are grouped according to their affinities. Details of classification *within* the large groups are given in the special articles on these groups. An outline of the generally accepted system of classification of the groups themselves is given below.

Plants are usually divided into CRYPTOGAMS, in which there are no flowers producing seeds, the sexual reproductive organs being inconspicuous, and PHANEROGAMS, in which the plants bear flowers or flower-like structures from which seeds arise. The term SPERMOPHYTA is sometimes used for Phanerogams. To the more complex Cryptogams which show vascular strands (see PLANTS: Anatomy) the term Vascular Cryptogams is often applied.

Cryptogams.—The lower groups of Cryptogams are classified as THALLOPHYTA, *i.e.,* plants possessing a thallus or plant body which shows no differentiation into stem and leaves. The large groups of the Thallophyta are the PROTOPHYTA, the most primitive group of plants; ALGAE, a group mostly of aquatic plants, showing various coloured pigments (green, red, brown, etc.); BACILLARIALES or DIATOMS, a group of minute, brown plants sometimes classed with the Algae; and the FUNGI and BACTERIA, which are colourless parasitic or saprophytic plants probably derived by reduction from alga-like ancestors. To all these groups special articles are devoted, and also to the lichens, which are a peculiar group of composite plants, consisting of an alga and a fungus living in association.

The BRYOPHYTA (*q.v.*), which include the liverworts and the Musci or true mosses, are distinguished from the Thallophyta by the fact that the plant body often shows a distinction into stem and leaves, and the female reproductive organs are structures known as archegonia.

The group PTERIDOPHYTA, or fern-like plants, includes all the cryptogams higher than the Rryophyta. The plants often show a marked differentiation into leaves, some of these being of very great size and much divided. Furthermore they show well marked vascular strands (see p. 6) and their female reproductive organs are archegonia. This large group includes the Filicineae (true ferns), the Equisetineae (horsetails, etc.); the Lycopodineae (club-mosses, etc.) and the Pteridospermae (a fossil group) which are described under PALAEOBOTANY.

Phanerogams.—To this group, which is sometimes termed SPERMOPHYTA (or *Spermatophyta*), all the higher plants belong. It includes the GYMNOSPERMS, in which the seed is not enclosed in an ovary and the male and female reproductive organs are not found contained in a single flower, and the ANGIOSPERMS, in which the seed is not naked but enclosed in an ovary and the male and female reproductive organs (stamens and carpels) are usually associated in a single flower.

Classification of Angiosperms.—This very large group of plants falls into two classes, MONOCOTYLEDONS and DICOTYLEDONS. The first being characterised by an embryo with one cotyledon (seed-leaf), a stem which usually shows no secondary thickening, and flowers with parts in threes. The second shows an embryo with two cotyledons, a stem which exhibits secondary thickening, and flowers with parts in fours or fives. The classification of angiosperms which is now usually followed, is that of A. Engler, the monocotyledons and dicotyledons being divided into a number of classes termed orders (or cohorts or series), the name of each order usually terminating in -ales. Each order includes a number of families (formerly termed "natural orders") many of which are dealt with in special articles; the name of the family usually terminates in *-aceae.*

An outline of Engler's classihcation is given below, the orders (series) being printed in block type and the families in italics. For the 11 *orders of Monocotyledons a synopsis of the chief characteristics is given. A selection of the more important* families *is made in the case of the orders which include a large number of families.*

MONOCOTYLEDONS

Order 1. **Pandanales**—(Marsh *herbs or shrubs or trees with large narrow leaves and compound heads or spikes of flowers. Seeds rich in endosperm.) Typhaceae, Pandanaceae, Sparganiaceae.*

Order 2. **Helobieae**—(Water *or marsh plants with cyclic or hemicyclic flowers, often enclosed in a spathe. Embryo large with little or no endosperm.) Potamogetonaceae, Najadaceae, Alismaceae, Butomaceae.*

Order 3. **Triuridales**—(Saprophytes *with scaly leaves and small long-stalked flowers.) Triuridaceae.*

Order 4. **Glumiflorae**—(Usually *annual or perennial herbs with naked flowers covered by bracts. Ovary unilocular with one ovule.) Graminaceae, Cyperaceae.*

Order 5. **Principes**—(Plants *often trees, leaves of large size often fan-like or feather-like, male and female flowers usually in spikes enclosed in a spathe, ovary superior and fruit a berry or drupe with rich endosperm.) Palmaceae.*

Order 6. **Synanthae**—(Often *palm-like or climbers or large herbs with male and female flowers arranged alternately over the surface of a spike.) Cyclanthaceae.*

Order 7. **Spathiflorae**—(Herbaceous *or woody plants, sometimes climbing, flowers on a simple spike [spadix] more or less enclosed in a bract.) Araceae, Lemnaceae.*

Order 8. **Farinosae**—(Herbaceous *or sometimes grass-like in habit, flowers cyclic, hermaphrodite or unisexual, androecium often reduced, ovary usually orthotropous, endosperm mealy.) Bromeliaceae, Commelinaceae, Pontederiaceae.*

Order g. **Liliiflorae**—(Usually *herbs, often with bulb, corm or rhizome, perianth petaloid or glume-like; ovary* trilocular *superior or inferior; fruit a capsule or berry; ovule anatropous; endosperm fleshy or oily.) Juncaceae, Liliaceae, Amaryllidaceae, Dioscoreaceae, Iridaceae.*

Order 10. **Scitamineae**—(Tropical, *large, perennial herbs often with sheathing leaves; flowers hermaphrodite and irregular, androecium often reduced; ovary inferior usually trilocular; fruit, a berry or capsule with numerous seeds with much* peri*sperm, little or no endosperm.) Musaceae, Zingiberaceae, Cannaceae.*

Order 11. **Microspermae**—(Flowers *of a pentacyclic* trimer*ous type but often with great reduction in the stamens; ovary inferior; fruit, a capsule with numerous minute seeds containing a very small undifferentiated embryo.) Orchidaceae, Burmanniaceae.*

DICOTYLEDONS

Archichlamydeae.—(Flowers often *without* a *perianth, usually polypetalous; pollination entomophilous in the lower orders, anemophilous in the higher orders.)*

Order 1. **Verticillatae**—*Casuarinaceae.*
Order 2. **Piperales**—*Piperaceae*. Chloranthaceae.
Order 3. **Salicales**—*Salicaceae.* ·
Order 4. *Garryales — Garryaceae.*
Order 5. **Myricales**—*Myricaceae.*
Order 6. **Balanopsidales**—*Balanopsidaceae.*
Order 7. **Leitneriales**—*Leitneriaceae.*
Order 8. **Juglandales**—*Juglandaceae.*
Order 9. **Batidales**—*Batidaceae.*
Order 10. Julianiales — Julianiaceae.
Order 11. **Fagales**—*Betulaceae, Fagaceae.*
Order 12. **Urticales**—*Ulmaceae,* Moraceae, *Urticaceae.*
Order 13. **Proteales**—*Proteaceae.*
Order 14. **Santalales**—*Santalaceae,* Loranthaceae, *Balanophoraceae.*
Order 1j. **Aristolochiales**—*Aristolochiaceae, Rafflesiaceae,* Hydnoraceae.
Order 16. **Polygonales**—*Polygonaceae.*
Order 17. **Centrospermae**—*Chenopodiaceae,* Amarantaceae, Phytolaccaceae, Caryophyllaceae.
Order 18. **Ranales**—*Nymphaeaceae, Ranunculaceae, Berberidaceae, Magnoliaceae,* Lauraceae.
Order 19. **Rhoeadales**—*Papaveraceae,* Cruciferae, Resedaceae.
Order 20. **Sarraceniales**—*Sarraceniaceae, Nepenthaceae, Droseraceae.*
Order 21. **Rosales**—*Podostemaceae, Crassulaceae, Saxifragaceae,* Hamamelidaceae, *Platanaceae,* Rosaceae, *Leguminosae.*
Order 22. **Pandales**—*Pandaceae.*
Order 23. **Geraniales**—*Geraniaceae,* Oxalidaceae, *Tropaeolaceae, Linaceae, Rutaceae,* Meliaceae, *Polygalaceae, Euphorbiaceae, Callitrichaceae.*
Order 24. **Sapindales**—*Buxaceae,* Empetraceae, Aceraceae, Sapindaceae, Balsaminaceae.
Order 25. **Rhamnales**—*Rhamnaceae,* Vitaceae.
Order 26. **Malvales**—*Tiliaceae,* Malvaceae, Sterculiaceae.
Order 27. **Parietales**—*Dilleniaceae,* Ochnaceae, *Elatinaceae,* Cistaceae, *Bixaceae, Violaceae, Passifloraceae, Begoniaceae.*
Order 28. **Opuntiales**—*Cactaceae.*
Order 29. **Myrtiflorae**—*Thymelaceae,* Elaegnaceae, *Lythraceae,* Rhizophoraceae, Myrtaceae, Onagraceae, *Hippuridaceae.*
Order **30. Umbelliflorae**—*Araliaceae, Umbelliferae, Cornaceae.*

Sympetalae—(Flowers usually sympetalous, *i.e., with the* parts *of the corolla more or less united, often resulting in a tubular flower.)*

Order 1. **Ericales**—*Pyrolaceae,* Ericaceae, Epacridaceae.
Order 2. **Primulales**—*Myrsinaceae,* Priwzulaceae.
Order 3. Plumbaginales—*Plumbaginaceae.*
Order **4. Ebanales**—*Sapotaceae,* Ebenaceae.
Order 5. **Contortae**—*Oleaceae, Gentianaceae,* Apocynaceae, Asclepiadaceae.
Order 6. **Tubiflorae**—*Convolvulaceae, Polemoniaceae, Boraginaceae,* Verbenaceae, Labiafae, *Solanaceae, Scrophulariaceae,* Bignoniaceae, Orobanchaceae, Acanthaceae.
Order 7. Plantaginales—*Plantaginaceae.*
Order 8. **Rubiales**—*Rubiaceae, Caprifoliaceae,* Adoxaceae, *Valerianaceae,* Dipsaceae.
Order g. **Cucurbitales**—*Cucurbitaceae.*
Order 10. **Campanulatae**—*Campanulaceae,* **Compositae.**

Bibliography.—The *best survey of the classification of* Plants is *given by A. Engler and E. Gilg, Syllabus der Pflanzenfamilien (Berlin,* 1924); *see also the larger botanical text-books such as Strasburger, Lehrbuch der Botanik (Jena,*1923), *and the English translation, Text-book of Botany (London,* 1920). *For the classification of* phanero*gams see A. B. Rendle, The Classification of Flowering Plants* (Vol. i. 1904, *Vol. ii.* 1925); *also* J. C. Willis, *A Dictionary of the Flowering Plants and Ferns (Cambridge,*1925), *which not only includes an outline of classification but gives in alphabetical order a brief account of the families and genera of all gymnosperms and angiosperms and also of the ferns. The fullest account of the classification of the plant kingdom is given by A. Engler, Die naturlichen Pflanzenfamilien (Berlin* 1887–1908), *a work in over* 20 *volumes of which a new edition is now in progress. A good' introduction to the systematic botany of flowering plants is* D. B. Swingle, *A Textbook of Systematic Botany* (1928); *this explains the basis of taxonomy (classification) and the terms used, and gives a review* of *some of the important works in systematic botany.* (V. *H.* B.)

MORPHOLOGY OF PLANTS

The morphology of plants consists in their comparative study from the point of view of Form. It treats not only of the external contour of the plant-body, External Morphology; but also of the internal contours of the constituent tissues, as revealed by anatomical study, the Morphology of Tissues. For the full understanding of form it does not suffice to examine the adult state only. It was found early that difficult questions of comparison could be illuminated by observation of development of the individual, that is, of its Ontogeny. This led to views based upon comparison as to the historical origin and descent of the parts compared, or even of the plant as a whole. A further step to the study of the parts as organs, carrying out certain distinct functions, gives the aspect now designated as Organography. These methods of *enquiry are used collectively as a basis for evolutionary or* systematic conclusions. But such conclusions are apt in critical cases to take the form of expressions of opinion which may differ widely. In arriving at a decision the most positive source of knowledge is the evidence of geological succession in time, and comparison of the forms constituting that succession. This is yielded by the study of fossil plants, called *Palaeophytology* or *Palaeobotany* (*q.v.*). But its record is so incomplete as to leave many problems unsolved. The morphology of plants thus conceived bears within it the possibility of reconstructing the evolutionary history of the vegetable kingdom, which is the goal to which all such study converges. This is called *Phylogeny*.

Pre-evolutionary and Evolutionary Morphology.—The aspect of morphology thus sketched is modern, dating in its present form from the period of the *Origin of Species*. But with varying success pioneer efforts had been made to found a science of plant-form before 1859, when Darwin's book was published. At first these related to the parts that constitute the plant-body as seen in the higher flowering plants, The foundation of organography was traced to Aristotle by Vines. More recently classification of members of the plant-body by Jung (1657), and observations on their ontogeny by Wolff (1759) resulted in a view summarized by the latter in these remarkable words: "In the entire plant whose parts we wonder at as being, at the first glance, so extraordinarily diverse, I finally perceive and recognize nothing beyond leaves and stem, for the root may be regarded as a stem. Consequently all parts of the plant, except the stem, are modified leaves." With such a conclusion already before him it was an easy step for Goethe (1790) to enunciate his theory of Metamorphosis of Plants: in particular he visualized an ideal leaf of the nature of a foliage leaf, of which the bracts and floral parts were held to be metamorphosed types.

The theory of evolution, long entertained before but galvanized into active existence by the genius of Darwin, revolutionized morphology (*Origin of Species*, 1859). For those whose vision was clear it converted it at a single stroke from a deductive handling of abstract ideas based chiefly on the higher plants, to an inductive argument rising, as Bacon said, successively from particulars to axioms of the lowest generality, then to intermediate axioms, and so to the highest.

This newer evolutionary or phyletic morphology, better designated as organography, starts with simple unicellular and aquatic organisms, such as the Flagellates. Each is a minute naked protoplast of inconstant form. A first step towards definite plant-organization is *encystment* within a firm cell-wall: this state appears as an incident in the life of many Flagellates, the encysted cell taking an approximately spherical form. Growth of such a green cell gives better opportunity for nutrition, and for storage of the material acquired: and an enlarging spherical form may be retained by organisms that float in the uniform medium of water. But the relation of an enlarging body to external conditions not uniform is liable to result in *polarity*, with the fundamental distinction of *apex* and *base*. The latter commonly attaches itself to any solid substratum, even without division of the single cell. But usually cell-division follows upon increasing size. If polarity be strongly marked, and growth continued, a filamentous plant-body may result, consisting of a chain of cells attached at its base. This may be further elaborated by cleavage of cells and by branching, while still attached at its base. In this we see initiated another leading characteristic of plant-organization, viz., *fixity of position*.

The sacrifice of mobility consequent on a fixed position is seen in all but the simplest plants: it accords well with the requirements of a self-nourishing green organism, but it imposes limits upon certain of the essential functions of competitive life. The nourishment of the plant must be brought to it by external agencies, such as diffusion, and absorbed from the medium, molecule by molecule. A raptorial habit, as in animals, is then unnecessary, and is even precluded by the fixed habit. On the other hand, the propagative cells must either themselves be motile or must be easily spread by external forces: otherwise any extension of field would be impossible. Throughout descent these two facts have dominated the morphological evolution of plants.

Since all nutrition is primarily a function of surface, the larger the size of the organism and the more complicated its form, other things being equal, the better the nourishment of the individual, and the greater will be its propagative capacity. In simple organisms increase in size may be general throughout the plant-body. But in all larger plants *growth is localized*. Sometimes it is *intercalary* at some point between apex and base; but usually it is distal or apical. Where tissue-formation is thus localized the cells involved in it retain their youth as embryonic cells: this is especially marked at the distal tip, which has thus the character of a *growing point*, or *punctum vegetationis*. Here not only is provision made for continued growth of a central axis, but also for the initiation of successive branchings, which often mature as lateral appendages upon it. The result in the higher plants is the leafy shoot. These elaborations of the vegetative system may be seen illustrated either in the successive stages of an individual life, or by comparison of distinct organisms, such as a seaweed, a liverwort, a fern or a flowering plant. With varying detail these all share that distinctive feature of the more elaborated plant-body, its *continued embryology*. In all the higher animals the embryonic phase is a transient step towards full development, resulting in limbs definite in number and position: but plants have the power of forming an indefinite number of parts, in a succession theoretically without term or limit. Every bud of a forest tree or of a herb contains its own growing point deeply embedded among the successive leaves it has produced, and holds the potentiality of unlimited further development. *This continued embryology is the leading feature in the organization of the enlarging plant-body.*

Categories of Parts.—The vegetative system of the more highly organized plants consists of parts which have been classed as *stem, leaf, root, emergence* and *hair*. So long as the more highly organized plants alone are studied these categories appear fairly distinct. But when such comparison is applied to include forms lower in the scale, the less complete differentiation of their parts raises many questions touching the evolutionary origin of the several categories themselves. Here the fossil evidence takes its place: for conclusions based upon structure, position, individual development or comparison are liable to be checked by the discovery of some ancient form that may raise a doubt, or present even a firm negative. Thus the conception of a leaf as a lateral appendage upon a stem that is fixed at its base by roots, involves three categories of parts well marked in the higher vascular plants. How does this accord with the existence of the Devonian fossil *Hornea*, which is a vascular plant without leaves or roots? It is clear that those categories are not absolute, but are results of evolutionary history still incomplete in *Hornea*.

Many difficult questions as to the category of parts are apt to arise when we attempt their classification in plants at large. Mere comparison of external form or even of internal structure will not suffice: decisions must be based upon the origin and the place which the parts take relatively to other parts at the time when they first appear. Following this method, those parts of the individual, or of different individuals, species or genera, have been distinguished as *homologous* which bear the same relation to the whole plant-body, whatever their form or function or external conditions may be. On the other hand, parts may resemble one another in form and in function, though they may differ in their relation to the whole plant-body. Such parts have been described as *analogous* one with another. For instance, the flat green organs of the butcher's broom are by origin axillary buds, not leaves. Though their main function is like that of leaves, nutritional, they are only analogous to leaves.

Homology presents a more difficult problem, for in plants there may be various degrees of that closer correspondence of parts connoted by the term. The strictest conception of homology is that designated *homogeny*, which may be defined as including those structures which are genetically related in so far as they have a single representative in a common ancestor (Lankester). This implies repetition of an individual part bearing a definite relation to the whole organism. In plants with their continued embryology such correspondence is rarely possible, owing to the indefinite number of appendages produced. And yet the leaves of a shoot are comparable in other respects; but their homology can only be recognized in a less stringent sense than homogeny. Further, it may be held as doubtful whether all such parts as those designated "leaves" represent any essential plan of construction applicable to plants generally. The question arises whether leaf-like organs may not have originated independently in distinct phyletic lines: for instance, among the higher Algae, the Bryophytes, and the vascular plants. These diverse leaf-like organs may rather be regarded as being based upon such uniformity of results as has been achieved polyphyletically in descent, that is, by various types of organisms independently. In that case their likeness would be described as *homoplastic* (Lankester).

Limiting Factors.—Given a sufficient nutritive supply, continued growth of the plant-body may bring the organism up against certain limiting factors, of which the most obvious are concerned with mechanical stability, and the preservation of a due balance between surface and bulk, whether of the external contours, or of the internal tissue-surfaces. The size-factor may thus dominate not only the possible dimensions, but also the form of the plant-body and of its constituent tissues. The underlying principle is that of "similar structures," long ago recognized by Galileo, and familiar to architects and engineers. Applying it mechanically the strength of a structure varies as the square of the linear dimensions, and the mass or weight as the cube. Any plant endowed with continued growth, and with branching, is constantly approaching a size-limit defined by mass versus strength. Somewhat more than 300ft. is the extreme practicable height for a tree with the usual proportions and type of construction of the trunk, branches and twigs. A higher trunk would bend or break under the stress of wind.

The size-factor is also an effective influence on form; this is seen in respect of the proportion of surface to bulk. If the same form is maintained in an enlarging body, its surface increases as the square, whiie the bulk increases as the cube of the linear dimensions. Since nutrition and transit of materials are dependent upon surface action, the maintenance of a due proportion of surface to bulk in an enlarging organism may become critical. Its effect may be traced externally in the subdivision of submerged leaves, or indeed in foliar development itself: or it may appear internally in the complicated segregation of the vascular tracts in plants where cambium is absent or sluggish, as in the ferns or Lycopods. Such influences of the size-factor have long been recognized by animal morphologists: they are now beginning to find their place in the morphology of plants. (See F. O. Bower, Proc. Roy. *Soc.* Edin., vol. xli., xliii.)

Causal Morphology.—The influence of the size-factor may be offered as an example of causal morphology, that is, the relation of form to environmental influence. It must suffice here merely to mention those better known branches of its experimental study which deal with the relation of form to such influences as gravity and light. Hofmeister introduced experiment in this field in his *Allgemeine Morphologie* der Gewachse (1868) as a corrective to the idealistic morphology of the previous period. His observations dealing with the arrangement and final form of the parts constituting the shoot were the natural precursors of the later work of Sachs, who recognized that the form and manner of life of plants "must in great part have arisen through the perpetual operation of gravity and light." (*Vorlesungen,* zte *Aufl:* p. 545.)

Adaptation.—The scalyness or succulence of isolated species or genera under xerophytic conditions may be taken as examples of protective adaptation. Such characters are often hereditary: for instance, the succulence of a cactus or of a spurge appears in the seedling, even when grown in moist air: a seedling parasite, such as the dodder, produces parasitic seedlings that require attachment to the host for full development. Here the germ cell carries the character held as adaptive. On the other hand many formal characters that are specially related to climate or soil may be less marked, or even absent in the offspring grown under medium conditions. They have not been permanently stamped upon the germ-cells. Such differences raise the general question of the inheritance of adaptive form.

Inheritance of Adaptive **Characters.**—Direct experiments that adaptive or impressed characters may be inherited in plants have so far given indecisive or negative results. All such experiments necessarily range within the narrow limits of laboratory time. If, however, a sequence of events conducted with the latitude of geological time gives a positive result, it seems right to give such a positive conclusion precedence over observations limited to a brief period. More than one good case has recently been brought forward showing the establishment of an ontogenetic adjustment as a permanently inherited character, where a consecutive evolutionary sequence of steps in its appearance can be traced from early geological periods, and confirmed by comparison of living species and genera. (See F. O. Bower, Ferns, vol. iii., Cambridge, 1928.) The conclusion follows that, in plants at least, direct ontogenetic adjustments, if repeatedly imposed, may become hereditary. Other opinions are held on this point, especially by zoologists (see LAMARCKISM, HEREDITY). If such inheritance were wide-spread or general, an important factor would be supplied in explanation of the prevalent phenomenon of adaptation.

But it would not provide a full explanation. The nature of the organism is the more decisive factor in adaptation. It suggests a tendency of initiative in the organism itself, which would go far to explain certain broad features in evolution. Intensive study of the coherent class of the ferns has shown similar trends of advance in distinct phyla-parallel changes which constitute together a positive phyletic drift. This may be held as determined by the "nature of the organism": and to it, acting on differences in that nature, may be attributed the results which we see worked out in those distinct classes and divisions of the vegetable kingdom, which nevertheless may have evolved under conditions essentially alike.

A frequent consequence of homoplastic adaptation is convergent evolution, with a high degree of similarity, or even of standardization as the final result. Examples of this are frequent in the vegetative system: for instance, in the phyllodes of Acacia and *Oxalis,* and the xerophytic leafage of Veronica and *Cupressus:* also in the prevalence of trimerous and pentamerous flowers. But it is in the propagative organs that it is most remarkable; leading to the high uniformity of the archegonia seen throughout the higher cryptogams, of the megaspores of the heterosporous types, and of the embryo-sacs in Angiosperms. Such standardization of parts, which can hardly have been in any of these examples strictly homogenetic, greatly increases the difficulty of their phylogenetic treatment, so far as it is based upon features apparently so similar.

Alternation of Generations.—A few examples must suffice in illustration of the working out of the principies thus underlying the more recent developments of plant-morphology. The first is the phenomenon of Alternation of *Generations.* In mosses and ferns the life-history comprises two distinct phases, or generations, which appear in alternate succession. In the ferns the one is the leafy fern-plant, which as it bears sporangia containing spores, is called the *sporophyte:* the other is a small green scale, the prothallus, which bears the sexual organs, or gametangia, containing the gametes, known as the spermatozoid, and ovum or egg: it is therefore called the *gametophyte.* These alternate generations together constitute a life-cycle of two somatic stages, each limited by a unicellular state, for each spore may germinate to form a prothallus, and each fertilized egg may grow into a new fern-plant (see PTCRIDOPHYTA). Such a cycle exists in the life-history of all mosses and ferns, while its correlative stages appear also in modified form in seed-plants: moreover it is now proved that a like alternation exists also in many Algae and Fungi. In fact an alternating cycle, with varying proportion of somatic development, underlies the morphology of *all plants that* possess sexuality.

Strasburger (1897) related this cycle with the cytological state of the respective stages (see CYTOLOGY). Since in fertilization (syngamy) the number of chromosomes is doubled, the generation that springs from it is (zx) diploid (*e.g.,* fern-plant, moss sporogonium): in the tetrad-division that precedes spore-formation, a corresponding reduction (meiosis) is effected, and the generation that springs from the spore is (x) haploid (*e.g.,* fern-prothallus,

Cross-section of a vascular bundle from the leaf-stalk of a Fern. 7. Sections of the stele of a Fern (*Loxsoma*), from the juvenile to the adult stem: (a) solid protostele; (b) medullated protostele; (c) and (d) medullated protostele with inner phloem; (e) and (f) widening of the phloem cylinder; (g) and (h) pocket of inner endodermis joined to outer endodermis at a leaf gap; (i) a transitional state to (j), which shows solenostele of adult stem. 8. Cross-section of stem of young Bamboo, showing scattered bundles. 9. Transverse section of the root of a Fern (Pellaea), with diarch xylem and sclerotic cortex. 10. Transverse section of the aerial root of Vanilla, with polyarch xylem and numerous root hairs. 11. Radial longitudinal section, stem apex of an Angiospermio plant. 12. Radial longitudinal section, tip of root of the Onion, showing root cap. 13. Surface and sectional views of a stellate hair of an Angiosperm. 14. Examples of forms of hairs of Angiosperms. 15. Sectional and surface views of a stoma from the leaf of an Angiosperm stem. 16. Stages in formation of cork and phelloderm as seen in cross-section of an Angiospermio stem: (A) the first division of the sub-epidermal phellogen; (Lower) the completion of a layer of cork. 17. (A) Part of a Laticiferous Cell from the stem of a *Euphorbia*, containing bone-shaped starch grains; (B) Laticiferous vessels in the root of an Angiosperm

moss-plant). It is a morphological problem of the first rank to determine the evolutionary relation of these generations to one another, whether in the individual, the phylum, or in plants at large.

Whatever the historical origin of alternation may have been, certain features in its further development were probably as follows. The land-habit of the Archegoniatae appears to have encouraged or fixed a biological difference between the generations: the gametophyte is characteristically semi-aquatic, while sexuality which is its end depends upon external liquid water: the sporophyte is characteristically a land-living body, often rooted in the soil, while the dissemination of the spores depends normally on dry conditions. Thus the alternate generations of the Archegoniatae accord well with an amphibial life, one being distinctly sub-aerial, the other not fully freed from dependence on external water. But the tie of aquatic fertilization (zoidiogamic) is inconvenient for land-living organisms: hence it is no surprise to find that the higher flowering plants have broken loose from it, by adopting fertilization by a pollen-tube (siphonogamic). The gametophyte by successive steps of reduction loses its independence as a separare generation, while rile sporophyre becomes dominant. This state may be held as the last essential step in the adaptation of plant-life to a land-habit.

A second illustration of the working out of the principles summarised above may be taken from the leaf. Of all the vegetative organs the leaf raises questions most open to debate. In the older morphology an ideal leaf was envisaged, and other types of leaf were regarded as modifications of it. But the duty of an evolutionist is to look not to an idea, but to the facts supplied by the lower organisms. They show that, whether in the gametophyte or the sporophyte, a leafless state preceded foliar development. Moreover both fossils and living plants suggest that all leaf-like appendages did not spring from a common source, but polyphyletically.

The effect of such considerations is to relax the old rigid conception of "the leaf" as a morphological constant. Biologically a leafy shoot appears as a favourable advance on a simpler organization, bringing with it an increasing proportion of absorptive surface to bulk. The existence of a demand for this is common to enlarging organisms, and the foliar development appears as a consequence in any or all such. The facts indicate an independent response in many distinct phyletic lines, with the result that the leaves so produced would not be all homogenetic, but probably in high degree homoplastic.

Conclusions.——From the preceding sketch of current plant-morphology it is seen to be founded on the theory of evolution, used as a working hypothesis. Observed facts are interpreted from the point of view of phylesis, the argument leading towards the reconstitution of evolutionary history. The difference between the older idealistic and the newer inductive morphology has been well drawn by Sachs. He pointed out "that the former fits new facts into a scheme of old conceptions, the latter deduces new conceptions from new facts" (*History* of *Botany,* 1890). But morphologists are still bound by an idealistic evolution theory, for some preconceived type is in their minds. The remedy lies in a refusal to accept any conclusion from comparison as definitive, unless based upon consecutive data derived from actual organisms phyletically related one to another. The consequence of this would be a greatly increased recognition of polyphyletic sequences. But it is better to entertain a wide theory of polyphylesis, with that apparent indefiniteness of conclusion that follows in its train, than to accept questionable doctrines that bring satisfaction only to uncritical minds.

Finally therr remains the question of causality. The causes of development can best be unravelled and their relations to the environment established by experiment. On the other hand, experiment by itself cannot reconstruct history: for it is impossible to rearrange for purposes of experiment all the conditions exactly as they were in an earlier evolutionary period: and even if this were done, can it be assumed that the subjects of experiment will really be the same? Consequently there must always be a margin of uncertainty whether a reaction observed under experiment to-day mould be the exact reaction of a past age. Nevertheless there is a great future before experimental morphology: and though it cannot wholly unravel the history of form, this should still be approached experimentally as well as objectively.

Thus the way had already been prepared for Modern views, associated with "hormones," and their influence on individual development indicates from yet another angle how morphology is becoming ever more closely knit to physiology. It has been said that it deals with the stereotyped results of physiology. This is true in so far as it points towards the historical aspect of morphology, extending back as it does to the remotest fossil records: while physiology deals observationally with the reactions of the present time. But a better summing up of the relations of these two branches of biological science would be that morphology deals with all phenomena of form, including such as are not yet physiologically understood.

ANATOMY OF PLANTS

The term "Anatomy," originally employed in biological science to denote a description of the facts of structure revealed on cutting up an organism, whether with or without the aid of lenses for the purposes of magnification, is restricted in the present article, in accordance with a common modern use, to those facts of internal structure not concerned with the constitution of the individual *cell* or structural unit of the plant body.

An account of the anatomy of plants naturally begins with the cell which is the proximate unit of organic structure. The cell is essentially an individualized mass of protoplasm, of small dimensions, and containing a differentiated protoplasmic body, called a *nucleus.* Other protoplasmic bodies, known as plastids, and inanimate matter, mainly in solution or suspension, are present. But all cells which are permanent tissue-elements of the plant body possess, in addition, a more or less rigid limiting membrane or *cell-wall,* consisting primarily of cellulose or some allied substance excreted by the living cell-body and serving to connect the different cells of a tissue *(see* below). Upon the characters of constitution, thickness and sculpture of the cell-walls the qualities of a plant-tissue largely depend. The life of all the cells in a plant-body may be prolonged or a number of the cells may die and their protoplasm be removed. Thus a tissue may consist of living encysted units combined with an inanimate framework of cell-walls, enclosing in their cavities solely liquids and gases. In such cases the characters of the adult tissue largely depend on the proportion and distribution, the stature, form and contents of the living and dead units, and on the nature of their walls. It is customary in plant anatomy to speak of the cell-wall with its enclosed cavity as "the cell," and of the contained protoplasm or other substances as *cell-contents.*

In all but the simplest forms the plant-body is composed of a number of cells associated in more or less definite ways. In the higher or more complicated plants the cells come to differ greatly among themselves so that the adult body is composed of definite systems of units. Each system has its own characteristic structure, depending partly on the characters of the component cells and partly on the method of association. Such a system is called a *tissue-system,* the word tissue being employed for any collection of cells with common developmental, functional or structural characters to which it may be conveniently applied, and accepted by the general resemblance which was thought to exist between the texture of plant-substance and that of a textile fabric before the fundamental constitution of plant-substance was discovered.

It is convenient here to define the two chief types of cell-form which characterize the tissues of the higher plants. The term *parenchyma* is applied to tissues the celis of which are isodiametric or cylindrical in form. The term *prosenchyma* is applied to tissues consisting of long narrow cells with pointed ends.

The reader is referred to special articles on the anatomy of the lower plants (Thallophyta: Algae and Fungi, and Bryophytes: mosses and liverworts) in which the differentiation of tissues is comparatively slight. It must suffice here to mention that both Algae and Fungi range from the simplest unicellular forms with no external differentiation of the body to forms of greater stature and compiexity of organization. The progress in complexity is closely associated with division of physiological labour among the component cells and with the adaptation of the multicellular organism to the needs of its environment. But whatever are the various states attained by individual genera the majority of the cells of the adult bodies of both Algae and Fungi remain alive and the tissues are essentially parenchymatous.

In accordance with the greater complexity in the conditions of life on land for self-supporting plants, considerably more advanced tissue-differentiation is exhibited by the Bryophyta, which are mainly terrestrial plants. In a general way this greater complexity consists (1) in the restriction of regular absorption of water to those parts of the plant-body which are in close contact with the soil, and (2) in the more regular evaporation of water from the parts exposed to the air. It is, however, in the higher vascular plants that those two principles find their fuller expression, for in the bryophytes water is still absorbed, as, for example, from rain or dew, by the general plant-surface. The lowest liverworts have an extremely simple vegetative structure comparable to that of many of the simpler Algae, for as their bodies are small and normally live in damp air the demands of terrestrial life on them are at a minimum. Thus their bodies consist of true parenchyma, and the vast majority of the component cells remain alive. Rooting and absorbing thread-like cells (*rhizoids*) universally occur on their lower surfaces in contact with the soil, and considerable tissue-differentiation may occur within the body. Thus some possess a distinct assimilative system consisting of branched chains of thin-walled cells packed with green plastids (*chloroplasts*) and arising from the bases of large cavities directed towards their upper illuminated surfaces. These cavities are completely roofed by a layer of surface cells pierced by pores, surrounded by special cells, and through which aeration and evaporation are freely maintained. In certain forms in which the body consists of thick midribs and delicate lateral leaf-like appendages strands or bundles of long thick-walled fibre-like (*prosenchymatous*) cells with pointed ends run longitudinally through the midribs, which are devoid of special assimilative tissue. The walls of these cells are strongly lignified (*i.e.*, consist of woody substance) and are irregularly thick and thin so as to be closely studded by simple pits which are usually arranged in spirals running round the cells and often elongated in the direction of the spiral. There is much variety of detail in the differentiation of the tissues of the liverworts, but the general plan of construction resembles that adopted in the leaves of higher plants.

In the mosses the plant-body is generally more elaborate in accordance with its fuller commitment to terrestrial life. There is always a radially organized supporting and conducting axis (stem) bearing laterally throughout the greater part of its length thin, flat assimilating and transpiring appendages (leaves). To the base of the stem or to those parts in contact with the soil are attached branched rhizoids. In some cases the stem possesses a special surface or epidermal layer of cells, but usually all the outer layers of the stem are composed of brown, thick-walled, lignified, prosenchymatous, fibre-like cells forming a peripheral *stereom* (mechanical and supporting tissue) which forms the *outer* cortex. This passes gradually into the thinner-walled parenchyma of the *inner cortex.* The entire cortex is generally alive and its cells often contain reserve foods in the form of starch. The centre of the stem, in the forms which live on soil, is composed of a strand of narrow, elongated, thin-walled, unlignified, dead water-conducting cells (*hydroids*) which are seldom pitted. This hydrom strand has in most cases no connection with the leaves, but runs straight up the stem and spreads out locally below the reproductive organs. In the aquatic and semi-aquatic forms, and in those mosses which live under conditions of extreme drought the entire plant-surface absorbs water, perpetually in the first two cases, and during rain in the third. In such forms the hydrom strand is either slightly developed or altogether absent. The leaves of most mosses are flat plates, each consisting of a single layer of square or oblong assimilating cells containing chloroplasts. The marginal cells of the plates are frequently produced as teeth and their walls are thick. The centre of the leaf is often occupied by a midrib consisting of several layers of parenchymatous cells elongated in the direction of the long axis of the leaf and poor in chloroplasts. This midrib may be considered a primitive conductive foliar strand or leaf-bundle. Associated with this conducting parenchyma are frequently found hydroids like those of the central strand of the stem, and in some cases continued into the cortex of the stem as a leaf-trace *bundle* (the anatomically demonstrable trace of the leaf in the stem). In several cases the leaf-trace runs vertically downwards for some distance in the outer cortex and ends blindly in a fan-shaped expansion: in others it joins the central hydrom strand so that a connected water-conducting system is established between stem and leaf.

Further differentiation of tissues characterizes the highest family of mosses, the Polytrichaceae. In these elongated, living, nucleated cells with a thin lining of protoplasm surround the dead hydrom, and form the *leptom,* inferred to serve for the conduction of organic substances, since the entire cavity of a leptom cell is sometimes occupied by proteid contents. The ends of each leptom cell are slightly swollen and fit to the similar swollen ends of the next leptoids in a row. The end walls are usually very thin, and the protoplasm, on artificial contraction, commonly sticks to them though no perforations of the walls have been found. It is considered that these cells are in some measure comparable to the sieve-tubes of higher plants (see below). Associated with the leptoids are similar cells without swollen ends and with thick end walls, while between the hydrom and leptom is a cylinder of cell-layers, known as amylon, which may serve for the temporary reservation and in the distribution of carbohydrates, since they sometimes contain an abundance of starch. The underground portion of the stem (rhizome) bears rhizoids and simple scales. The aerial parts bear leaves, each with a simple midrib several cells thick with a strong band of stereom above and below a bundle of leptom, hydrom and amylon cells which join the central cylinder of the stem. Each midrib bears two wings, one cell thick, while above the midrib is a series of closely set, vertical, longitudinally-running plates of green assimilative cells.

Vascular Plants. — It is, however, in the higher vascular plants (Pteridophyta, *e.g.,* ferns, horse-tails, club-mosses and Phanerogama or flowering plants) that the greatest anatomical complexity is found, for these are the dominant land plants. Such plants are not exactly comparable with the bryophytes for while the body of the latter bears the sexual organs and is called a *gametophyte,* and later nourishes a simple spore-bearing body (*sporophyte*), the vascular plant is a sporophyte which later nourishes a simple and reduced gametophyte. Nevertheless the gametophytic bryophyte and the sporophytic vascular plant have similar physiological needs and are both fixed to the soil. The chief new feature in external conformation of the body of a vascular plant compared with that of a bryophyte is the presence of "true" roots, the first formed of which is a downward prolongation of the primary axis of the plant. From this and from various parts of the shoot-system other roots originate. The roots of Pteridophytes are structurally simple and uniform compared with those of Phanerogams, but all manifest a primary plan of construction in direct relation to their normally subterranean life and fixative and absorptive functions; they differ from aerial stems in the characters of their surface tissues, in the absence of the green assimilative pigment chlorophyll, in the arrangement of their vascular systems, and in their mode of apical growth. Great variety in stem- and leaf-form and structure is shown by the vascular plants.

But in spite of the many considerable differences of detail between Pteridophytes and Phanerogams, we can trace, alike in root, stem and leaf a threefold division of tissue systems, already indicated among the bryophytes, and expressive of the fundamental conditions of evolution of the bulky body of a land plant. Thus there is (1) a specializatiori of a surface layer of cells which regulates the immediate relations of the plant with its surroundings. while varying in expression in the subterranean and aerial parts. In the former the surface layer is pre-eminently absorptive and in the latter protective provision at the same time being made for the gaseous interchange of oxygen and carbon dioxide involved in respiration, and for such vital functions as assimilation and transpiration. This surface layer is known as the epidermis. On the other hand we have (2) an internal differentiation of conductive tissue, prefigured in the bryophytes, and collectively known in the vascular plants as the vascular system. The remaining tissue of the plant-body, which shows varied local differentiation and is concerned with special functions, is known by reason of its peripheral position in relation to the central conductive tissue as (3) the cortex. But besides absorption, assimilation, conduction and protection, provision is made for support and the storage of food. Thus locally in the cortex and vascular system special supporting tissues (stereom) may be developed according to the varied needs and the conditions of body-differentiation, and living cells of both the cortex and the vascular system may serve for temporary storage of foods and are specialized accordingly. The functions of aeration, assimilation and transpiration, by which the bulky tissues of the plant-body obtain oxygen for breathing and carbon dioxide for food-manufacture, and the removal of excess water is assured, are maintained by an extensive system of *intercellular* spaces communicating with the external air.

Epidermis.—The epidermis of the subaerial stems and leaves is primarily protective and usually consists of a single layer of living cells devoid of chloroplasts, and with thickened and cuticularized outer walls, defensive to slight shock and small parasites, but permitting controlled evaporation. At intervals it is interrupted by small pores (stomata) leading from the outer air to the system of cortical intercellular spaces, and serving for gaseous interchange between the primary tissues and the outer air. Each stoma is surrounded by a pair of peculiarly modified epidermal cells called guard cells which possess chlorophyll and open and close the pore, especially in accordance with the conditions of transpiration. The stomata of leaves are often situated at the bottom of pits in the leaf-surface. Thus transpiration is checked by the creation of a still atmosphere in the pit above the pore. Such an arrangement of the stomata is found especially in plants which require to economize their water supply if transpiration is in excess of absorption. In many plants living in conditions which tend to promote excessive transpiration at certain hours of the day, the epidermis is doubled or trebled and forms a water tissue which supplies the immediate needs of transpiration, and prevents the injury which would result in the epidermis if its cells were excessively depleted.

Hairs *and* Scales.—The epidermis of many species of vascular plants bears hairs or scales of varied form and function. Hairs are characteristic of stems and leaves of primitive pteridophytes and of many flowering plants, while scales characterize such pteridophytes as the advanced ferns. The simplest hairs consist of single elongated cells projecting above the general surface of the epidermis, while others consist of simple or branched cell-chains. The more complex scales are flat plates of cells commonly inserted on mounds or stalks, and may be placed parallel to the leaf-surface or projecting directly from it. By such emergencies transpiration is diminished by the stillness of the atmosphere between them. In other instances the hairs are glandular and excrete ethereal oils which tend to reduce transpiration, or they may be stinging, as in the common stinging nettle, in which the top of the hair is brittle, and when broken penetrates the skin and injects formic acid into the slight wound thus formed. In many cases both hairs and scales are shed before the stems and leaves are mature: in others they are retained throughout the life of the plant.

Hydathodes.—In many vascular plants special epidermal organs, known as hydathodes, are developed, especially on foliage leaves, and serve for the excretion of water in liquid form when transpiration is diminished so that the pressure in the water-channels of the plant has come to exceed a certain limit. Hydathodes are widely distributed in plants in certain tropical climates under which active root-absorption continues while the air is nearly saturated with water-vapour. In some cases the hydathodes are specially modified single epidermal cells or are multicellular hairs without direct connection with the vascular system. The cells concerned, like all excreting organs, have abundant protoplasm and large nuclei, and in many cases part of the cell-wall is perforated and resembles a filter. In others the hydathodes are associated with the ends of conductive strands and consist of groups of richly protoplasmic cells, as in the leaves of many ferns, while in flowering plants the hydathodes are most commonly directly connected with subjacent water-collecting cells known as *epithem* which act as intermediaries for the hydathodes and conductive strands. To illustrate, water expelled through hydathodes is often observable on the tips of grass leaves on a summer's evening and is commonly confounded with dew. Its expulsion as droplets is, however, due to the more rapid cooling of the air than of the soil as night approaches. Thus while active absorption continues by the roots, transpiration by the leaves is reduced in the evening and the conductive strands are overcharged with water which is expelled by the hydathodes. There are many other types of glands such as nectaries, *digestive-glands, resin-* and *mucilage-glands,* serving the most varied purposes in plant-life. Some involve epidermal cells, while others are more deeply seated, but as they are not involved in the primary activities of the epidermis they are here passed over. It will, however, be apparent that the epidermis of the stem and leaf of a vascular plant may be highly specialized.

Epidermis of Root.—The epidermis of the root is fundamentally different from that of the stem or the leaf. In relation to its normal function of water-absorption its cell-walls are not cuticularized and usually remain thin. The absorbing surface is increased by many of the cells being produced into tortuous, delicate, unicellular tubes (root-hairs) which aid in anchoring the root, and readily absorb the surface films of water from the soil particles. A root-hair thus corresponds in function with a rhizoid of a bryophyte. The hairs are normally definitely restricted to a more or less definite zone of the root a little removed from the growing root-tip. At the lower limit of this zone hairs are constantly being formed as the root advances in the soil, while at the upper limit they have passed maturity, are dying and are being destroyed. Thus beyond the zone which at any moment bears living absorbing hairs (the *piliferous* zone) the epidermis is extensively or completely destroyed, and its place is taken by the immediately subjacent cortical layer, which is not absorptive, but becomes protective like the epidermis of the stem or leaf. At the apex of the root, covering and protecting the delicate tissue of the growing point, is a special root-cap, consisting of a number of layers of cells produced by continual active local division of the apical epidermal cells, and which break down into mucilaginous products towards the outer surface of the cap, thus facilitating the passage of the apex as it pushes between the soil particles, and keeping the apex continually moist.

The **Cortex.**—The cortex consists primarily of living parenchyma, but its differentiation may be extremely varied, and in the complex bodies of vascular plants its functions are varied and may be modified. The cortex of a young stem is usually green as its cells possess chloroplasts, and a fine system of intercellular spaces communicates with the external air through stomata. With age the inner cortical layers may lose their chlorophyll and become storage tissue, and the outer layers may be extensively modified (see p. 10, secondary tissues). In many pteridophytes (*e.g.,* ferns) the mature outer cortical layers of the stem and root are hard sclerenchyma with thick brown walls, but in flowering plants, while the stems are still slender, the cells of the outer cortical layers elongate and become cylindrical so that their intercellular spaces are widened. Vertical bands of cellulose thicken those regions of the walls which are in contact with the intercellular spaces, but the remaining regions of the walls usually remain thin. Such a tissue is known as collenchyma. It provides peripheral support for the growing stem, and as its cells are alive, is open to later modifications with changing needs in stems which undergo annual increase in girth. The wonderful recovery, after bending and stretching, which is often observable in herbaceous stems, is in large measure due to the effective distribution of this elastic collenchyma. On the other hand sclerenchyma is commonly dead and provides a more rigid but usually unmodifiable supporting tissue. Its adequacy will be evident for stems such as those of modern ferns which do not increase annually in girth. Less commonly, scattered cells or cell-groups which increase little in length may become *stone* cells, with irregularly but inordinately thickened hard walls, while in some cases longitudinal rows of cells disintegrate thus forming canals, such as *resin canals,* the cortical wall-cells of which are excretory. Many such minor modifications of the original cortex of the stem occur in association with special localized functions.

Phloeotherma.—The innermost layer of the living cortex investing the central cylinder of the stem is, however, often early and peculiarly modified as a continuous cylinder called the *phloeotherma.* Throughout its entire course its cell-walls remain in close contact so that the system of intercellular spaces in the cortex is not continued into the central cylinder of conductive tissue. Towards the upper limit of the phloeothermal cylinder, while the stem is still young, the component cells may be rich in plastids in which starch grains are formed. In some localities the phloeotherma is known as a starch *sheath,* which is variously thought to play some rôle in the controlled conduction of carbohydrates from the assimilatory cortical cells to the vascular cylinder, or in some connection with the directional growth of the young stem. In the more mature regions of the stem starch grains are absent from the phloeothermal cells, the walls of which are somewhat thickened. In particular, a band of the lateral longitudinal and of the end walls is modified, being impregnated with a fatty substance which is thought to prevent radial transfer of foods in solution athwart the phloeotherma save under protoplasmic control of its cells. The phloeotherma is here known as an endodermis, and is thought to serve as a physiological barrier between the cortex and the central conductive cylinder.

Mesophyll.—The cortex of the leaf is primarily concerned with the primitive fundamental function of carbon assimilation, and to the active performance of this function the maximum exposure of living parenchymatous tissue containing chloroplasts is necessary. Thus the cortex of the leaf is essentially a green expanse of thin-walled parenchyma, known as the *mesophyll,* and is penetrated by a large and elaborate system of intercellular spaces which serve at one and the same time for the promotion of transpiration and respiration. The pathways for the gases which thus pass between the mesophyll and the outer air are the stomata, which in land plants with dorsiventral leaves are mainly or exclusively placed on the lower leaf-surface. By this means over-transpiration tends to be avoided, since the liberated water-vapour, being lighter than air, tends to remain in contact with the lower leaf-surface and checks evaporation. The stomata are in direct communication with the ample system of intercellular spaces in the mesophyll, the lower layers of which are commonly loosely arranged as *spongy tissue* with extensive intercellular spaces. This is the main transpiring tissue of the leaf, and in it chloroplasts may be comparatively few. It is protected from direct illumination and is at the same time liable to over-evaporation. The main assimilating tissue, on the other hand, is under the upper epidermis, is well illuminated, its cells are densely packed with chloroplasts, and are commonly oblong with their long axes perpendicular to the leaf-surface. The intercellular spaces are here narrow as between sticks in a bundle, and are in open communication with the spaces in the spongy tissue below. By reason of its resemblance to the boards in a fence, when viewed in a transverse section of the leaf, this portion of the mesophyll is called the palisade tissue. Leaves with blades held in a vertical position commonly possess palisade tissue on both sides or have little or no distinction in the form and arrangement of the cells of the mesophyll, since there is no difference in the illumination or other external conditions, while cylindrical or approximately cylindrical leaves may have palisade tissue all round. The leaves of shade plants have little or no differentiation of the palisade tissue. In fleshy leaves, which contain a great bulk of tissue in relation lo their chlorophyll content, the central mesophyll contains little or no chlorophyll and may consist of water-storage tissue, while locally a layer or mass of sub-epidermal cells may be thick-walled and fibrous.

The cortex of the leaf-stalk is transitional in structure to that of the stem and leaf-blade. The leaf-stalk is traversed by one or more vascular strands connected below to the central conductive system of the stem, and leading forward in the leaf-blade to a complex system of minor strands which ramify the mesophyll and run their course in the plane of junction of the spongy and palisade tissue. The layer of mesophyll immediately investing each bundle is phloeotherma and usually takes the form of a special parenchymatous sheath of elongated cells, distinguished otherwise from the rest of the mesophyll only by their poverty in chloroplasts. In a few rare cases the phloeothermal cells are rich in chlorophyll. These bundle-sheaths are considered important in the conduction of carbohydrates from the assimilative cells to the conductive strands and in the supply of water from the latter for transpiration. Their function is thus considered in some measure comparable with that of the phloeotherma of the stem.

The cortex of the roots of Pteridophytes is commonly extensively sclerotic at maturity, but in flowering plants the root-cortex generally remains a living parenchymatous food-storing tissue. Its innermost layer is invariably an endodermis.

VASCULAR SYSTEM

Among the most striking characters of Pteridophytes and Phanerogams is the possession of a double (hydrom-leptom) conducting system, such as has been noted in the higher mosses, but with more sharply defined and specialized features. This is the *vascular* system, and associated with it are other tissues consisting of parenchyma and special stereom. The whole tissue-system is known as the *stelar system* (from the way in which in its simpler forms it runs through the whole axis of the plant as a column). When it is remembered that the moss plant is a gametophyte while the vascular plant is a sporophyte it will be realized that the vascular system of the latter is not the result of elaboration of the conductive system of the former, but that these vascular systems are most readily interpreted as somewhat similar products of differentiation in plants fitted for life on land.

Tissue Elements. — The hydroid of a Pteridophyte (*e.g.,* a fern) is initially a living undifferentiated parenchymatous cell. As it dies it usually elongates and its wall is irregularly thickened and becomes woody (lignified). Its contents at maturity are watery solutions and air. The thickenings are on the inner wall-surface, are insufficient to line the wall entirely, and take the form of a spiral or complex network. The mature hydroid is called a *tracheid.* Its end walls persist and are commonly oblique. When the walls are mainly thickened their unthickened portions are called pits, and according to the varied distribution of the thickenings, the size, form, number and distribution of the pits depend. Thus in spiral *tracheids* a broad spiral band of unthickened wall persists, while when the thickenings on a wall-face are more or less transverse bars (often joined by short vertical bars) there is a resemblance to the rungs of a ladder, and we have a scalariform *tracheid.* All manner of transitions from spiral to scalariform tracheids may be found in a single plant. Spiral thickening is, however, characteristic of tracheids in which lignification begins and is completed while elongation of the cell is still in progress. Scalariform thickening is typical of tracheids which mature late or slowly, so that thickening may be continued after elongation is completed. The pits of scalariform tracheids are typically bordered pits, as the bars of thickening last deposited are widest. The pits on tracheid-walls which are in contact with each other are at similar levels so that at regular intervals the cavities of contiguous tracheids are only separated by a common thin area of wall (the pit-membrane). Sooner or later the pit-membrane disappears so that the mature tracheids come to consist of a framework of lignified bars with numerous small open communications between the cell cavities. Collectively with associated parenchyma the tracheids constitute the xylem or wood.

The leptoid of a Pteridophyte is also an elongated cell. It, however, remains alive, its wall is unlignified, it has a thin lining of protoplasm, but is destitute of a nucleus. It is always in communication with its neighbouring cells in a leptom strand by exceedingly minute wall perforations through which protoplasmic continuity is maintained. It is generally supposed that through these perforations organic substances are passed from cell to cell as through a sieve. The cells are accordingly called *sieve-tubes,* and collectively with associated parenchyma constitute the tissue called the *phloem,* or *bast.* The phloem is typically distributed at the periphery of the xylem when the latter is massed centrally, but may occur in other positions *(see* below). Between the phloem and the phloeotherma is a mantle of one or more layers of parenchyma forming the pericycle.

Arrangement **of the** Vascular System— In vascular plants the xylem and phloem are nearly always found in close association in strands or *bundles,* but as is to be expected in so complex and varied a group as the Pteridophytes the arrangement of such bundles is by no means stereotyped either in the group or in the different parts or members of the plant-body. A connected vascular system runs, however, through the entire body. In the roots and leaf-blades the vascular system is comparatively simple. In the former a solid. slender xylem core is virtually invested by phloem, with a single layer of pericycle as a mantle in direct contact with a continuous cylindrical endodermis, beyond which is the bulky and often sclerotic cortex. The arrangement is thus virtually radial. The bundles in the leaf-blade are on a somewhat similar plane of simplicity, but their phloem is directed downwards, their xylem upwards, the tracheids are dominantly spirally thickened, and the phloem is scanty or entirely absent towards the slender bundle-endings. Similarly throughout the entire length of stem there may be a solid xylem core, surrounded successively by phloem, pericycle and endodermis. Such a vascular system is a *solid protostele.* The slender stems of most juvenile Pteridophytes are protostelic and despite widening of the *stele* in the more bulky portions of the adult plant, this primitive protostelic state may be maintained throughout the entire stem. In many cases, however, as in advanced ferns, the vascular system of the juvenile stem alone is a solid protostele. When followed upwards the core of the xylem strand may remain entirely parenchymatous. This parenchymatous core is the *medulla* or *pith,* and the stele is here called a *medullated protostele.* At higher levels the stem may show a different vascular arrangement, sieve tubes being differentiated in the centre of the medulla, at first as a solid strand, but later or higher as a cylinder with parenchymatous pith at its core and parenchyma between it and the xylem. At a still higher level there may be an inner endodermis between the pith and the inner phloem so that the succession of tissues from within as viewed in a transverse section of the stem may be medulla, inner endodermis, parenchyma (or inner pericycle), inner phloem, parenchyma, xylem, parenchyma, outer phloem, outer pericycle and outer endodermis. Such a local arrangement of the stelar elements is said to be *siphonostelic,* is considered an evolutionary advance on the protostelic state, and may characterize the entire upper portion of the adult stem.

When the vascular system is entirely protostelic the decurrent bundles from the leaves join the vascular system of the stem without disturbing the continuity of the latter. Thus throughout the entire plant the endodermis is an unbroken mantle. But in the siphonostelic portions of the vascular system of the stem, the pith and cortex are commonly in open parenchymatous connection through *gaps* in the stele, and round the edges of these gaps the inner and outer endodermal cylinders are united by endodermal cells. Thus here again the endodermis is a continuous tissue, and isolates completely the pith and the cortex from the vascular tissues. The gaps which occur immediately above the level of insertion of the leaf-trace bundles on the stele of the stem are called *foliar gaps,* while those which occur elsewhere are called *perforations.* When there is no overlapping of leaf-gaps the siphonostele is said to be *solenostelic;* when two or more leaf-gaps overlap, the stele is *dictyostelir.* Thus locally the vascular system of a Pteridophytic stem may be solenostelic or dictyostelic: likewise it may be locally a *perforated solenostele* or a *perforated dictyostele.* Rarely among ferns is there more than a single vascular cylinder. The condition is described as *polycyclic,* and an outer and inner cylinder may be even united by oblique lateral strands. In such cases the leaf-rrace strands are joined to the outer cylinder, while the inner cylinder may best be considered concerned with internal conduction.

Structure **of** the Stele **in Seed-plants.**—The typical structure of the vascular cylinder of the adult primary stem of the Gymnosperms (firs and their allies) and Dicotyledons (the dominant group of higher flowering plants)—all of which are seed-bearing plants—is, like that of the higher ferns, a hollow cylinder of vascular tissue enclosing a central parenchymatous pith. But unlike the ferns the seed-plants have no internal phloem (except as a special development in certain families) and there is no internal endodermis. The xylem and phloem rarely form perfectly continuous layers as in the solenostelic ferns, for the vascular tissue is typically separated into distinct *collateral bundles,* the xylem of which is usually wedge-shaped in cross section with the first formed xylem (*protoxylem*) at the inner extremity, while the phloem forms a band on the outer side of the xylem, and is separated from the latter by a band of conjunctive tissue *(mesoderm).* These collateral bundles are separated from one another by bands of conjunctive tissue called *primary medullary rays,* which may be quite narrow or of considerable breadth.

When the pith is large-celled, the xylem of the bundles is often separated from it by a distinct layer of conjunctive tissue called the endocycle. and a similar layer, the *pericycle,* separates the phloem from the cortex. The inner layer of the cortex (phloeotherma) may form a well-marked *endodermis,* or may differ in other ways from the rest of the cortex. The pericycle, medullary rays, endocycle and mesoderm all form part of one tissue-system, the *external conjunctive.* The external conjunctive is usually a living and comparatively small-celled tissue, the cells of which are greatly elongated in the direction of the stem-axis and may be collenchymatous, sclerenchymatous, fibrous or food-storing. The conjunctive tissue of the stem is open to *secondary changes,* bound up with the thickening of the stem as it grows old. Most of the collateral bundles are leaf-trace bundles, *i.e.,* they can be traced upwards from any given point till they pass out of the cylinder, travel through the cortex of the stern, and enter the leaves. The remaining bundles *(compensation bundles)* which go to make up the cylinder, are united at some level with the leaf-trace bundles, and in turn form the traces of leaves at some higher level. Purely cauline vascular strands (*i.e.,* confined to the stem) are rare in the flowering plants, though common in Pteridophytes. The leaf-trace of any given leaf rarely consists of a single bundle only, the number of bundles in a trace is generally odd, and the median bundles of the trace are typically the largest.

Foliar- or *leaf-gaps* are formed in essentially the same way as in the ferns, but as the distribution of the bundles of a single trace may be wide and long, there may be a number of gaps in the cylinder associated with the insertion of the bundles of a single leaf-trace. The gaps are, however, often filled as they are formed by the development of external conjunctive tissue immediately above the points at which the bundles begin to bend out of the stele, so that sharply defined open gaps, such as occur in fern steles, are but rarely met with in flowering plants. The constitution of the stele of a flowering plant entirely from bundles as above described, which are either themselves leaf-traces or will form leaf-traces after junction with similar bundles, is the great characteristic of the stem-stele of flowering plants. These collateral bundles are obviously highly individualized. The external conjunctive tissue is often arranged in relation to each bundle separately, so that, for example,-there may be pericyclic fibres immediately outside the phloem-masses alone. In some cases the individualization is carried further, the cortex and pith becoming continuous between the bundles, which appear as isolated strands embedded in a general ground tissue. Each bundle has its own investment of tissue corresponding with external conjunctive. The bundles sometimes keep their arrangement in a ring corresponding with the stele, though there may be no continuous cylinder. This condition is known as *astely.*

The Monocotyledons, one of the primary divisions of Angiosperms, typically possess large leaves with broad sheathing bases, containing numerous bundles. This results in the number of bundles present at any given level of the stem being high. These bundles are scattered in a definite though not superficially obvious order through the conjunctive tissue of the stele, which occupies nearly the whole diameter of the stem, the cortex being restricted to a very narrow layer, or scarcely recognizable as a definite zone. The mass of conjunctive tissue is developed as a large-celled ground-tissue, and around each bundle there is a fibrous investment. In the stems of many water plants various stages of reduction of the vascular system, especially of the xylem, are met with, and very often this reduction leads to the-formation of a compact stele in which the individuality of the separate bundles may be suppressed, so that a closed cylinder of xylem surrounds the pith. The phloem is seldom so reduced, and there is normally a well-marked endodermis. In other cases the reduction goes much further till the endodermis comes to surround nothing but an intercellular channel, formed in place of the stelar tissue.

To the vascular tissue of the typical leaf and root of the Phanerogams reference is made below. But there are peculiarities of organization of the hydroids and leptoids of the bundles of flowering plants which here call for special mention. Generally the end walls of superimposed developing hydroids break down, so that the final product of differentiation is a continuous tube with lignified pitted walls. Such tubes are called vessels, and are characteristic of the vast majority of Phanerogams, though tracheids still dominate the Gymnosperms. There is every degree of transition between spirally thickened and reticulately thickened vessels. The sieve-tubes of Phanerogams in their most advanced forms which dominate the Angiosperms have the end walls or portions of the end walls specially perforated. Such walls are accordingly called sieve-plates. It is assumed that by such end sieve-plates the longitudinal movement of slimy foods is accelerated. Associated with the sieve-tubes are, in addition, cells of the same length as the sieve-tubes, generally narrow, thin walled and enucleate, and which are thought to co-operate in some intimate way with the sieve-tubes. They are known as companion cells, and a sieve-tube and its companion cell arise during tissue-differentiation from the same mother-cell. On the whole the leptoids and hydroids of the Phanerogams are considerably more specialized than those of the Pteridophytes.

Stelar Tissue of Leaf and Root.—In the leaf of the average Phanerogam the vascular tissue takes the form of a number of branching or approximately parallel, and usually anastomosing, strands, above and below which the mesophyll is raised so as to produce the so-called veins. The vein-system is typically very elaborate, and the bundle-system is concentrated in the leaf-stalk (petiole) as the tributaries of a river are massed in the main stream. The leaf-bundles are always collateral (the phloem being turned downwards and the xylem upwards), and the whole bundle may be protected above and below by fibrous cells. As the bundles are followed towards their blind endings in the mesophyll the fibres first disappear, the sieve-tubes are replaced by narrow elongated parenchyma which soon dies out, and the bundles usually end in short or long spiral or reticulate tracheids covered by the phloeothermic sheath.

The stele of the primary root of a Gymnosperm or Angiosperm is of radial structure. There are usually two or four xylem strands radially alternating with phloem strands (the stele being thus diarch or tetrarch), and the first formed xylem groups (protoxylem) are peripheral. A polyarch state is, however, common in adventitious roots (which arise on other stems or roots in "chance" positions), and the protoxylem groups are then numerous. The centre of the stele is seldom solid xylem, but is generally pithed, and sclerotic cells are by no means uncommon in the conjunctive tissue. The roots of some palms and orchids show a peculiar "polystelic" structure. Thus it will be seen that while the vascular systems of the stems of Phanerogams are highly individualized, those of the leaves and primary roots are of simpler organization, but are of varied structure.

Laticiferous Tissue.—There are, however, in certain families of Angiosperms peculiar tissues which are not met with in the Pteridophytes. Such, for example, is the laticiferous tissue found in Compositae and Euphorbiaceae, which takes the form of long, usually branched tubes which penetrate the other tissues of the plant in a general longitudinal direction. The tubes possess a delicate layer of protoplasm with numerous nuclei lining the walls, while the interior of the tube (corresponding with the cell-vacuole or cavity) contains a fluid called latex, consisting of an emulsion of fine granules and drops of very various substances, suspended in a watery medium, in which other substances (salts, sugars, rubber-producers, tannins, alkaloids and various enzymes) are dissolved. Of the suspended substances, grains of caoutchouc, drops of resin and oil, proteid crystals and starch grains may be mentioned. Of this varied mixture of substances some are undoubtedly plastic (*i.e.*, of use in constructing new plant tissue), while others are apparently end-products of metabolism, secreted within the plant-body. The relation of the laticiferous tissue to the assimilating cells, under which they often run, and the fact that where this tissue is richly developed the conducting parenchyma of the bundles, and sometimes also the sieve-tubes, are poorly developed, as well as various other facts, point to the conclusion that the laticiferous tissue has an important function in conducting plastic materials, in addition to acting as a reservoir for excreta. As a secondary function we may recognize, in certain cases, the power of closing wounds, which results from the rapid coagulation of latex in contact with the air. The use of certain plants as rubber-producers (notably Hevea *brasiliensis*, the Para rubber tree), depends on this property of coagulation. The trees are regularly tapped and the coagulated latex which exudes is collected and worked up into rubber. Opium is obtained from the latex of the opium poppy (*Papaver somniferum*) which contains the alkaloid morphine.

Laticiferous tissue is of two kinds: (1) laticiferous cells, which branch but do not anastomose, and the apices of which keep pace in their growth with the other tissues of the plant (Apocynaceae and most Euphorbiaceae), (2) laticiferous vessels, which are formed from rows of actively dividing (meristematic) cells. The end walls of these cells break down so that a network of laticiferous tubes arises (Papaveraceae, Hevea). In some cases, as in Allium and in the Convolvulaceae, rows of cells with latex-like contents occur, but the walls separating the individual cells do not break down.

Such facts serve to illustrate the advanced specialization of the higher plants compared with the land bryophytes, but by no means exhaust the anatomical peculiarities of the former. In particular, mention may be made of tissues which arise by modification of primary living tissues, and are accordingly known as secondary tissues.

CAMBIUM

Secondary Tissues.—In most of the modern Pteridophytes, Monocotyledons, and in annual plants among the Dicotyledons, there is no further growth of much structural importance after the tissues above considered have been differentiated. But in nearly all perennial Dicotyledons, and in all dicotyledonous and gymnospermous trees and shrubs, certain layers of cells retain the power of division, although they may be for long mature, and are apparently fixed elements of a tissue. By this power of growth and division they become the originators of new or secondary tissues, which bring in their train many modifications in the plant-body. Primary tissues which are thus awakened to new divisional activity become, like the growing points of stems and roots, meristems or the initials of tissues, but while the apical *meristems* of stems and roots give rise to the primary tissues above considered. these new meristems are secondary *meristems* since they give rise to secondary tissues. There are two chief secondary meristems, the cambium and the phellogen.

The cambium typically continues the formation of xylem and phloem, thus adding to the conductive tissue already produced. It is merely the cycle or band of parenchymatous tissue lying between the primary xylem and primary phloem. Its cell walls are generally thin, and as its cells enlarge by special nourishment, they are divided principally by tangential walls, thus producing radial rows of cells. The primary xylem remains stationary, but as the cell rows thus formed increase in number and the individual cells enlarge, the primary phloem and all the external tissues move outwards. The tracts of cambium between the strands of xylem and phloem are called *fascicular cambium,* while those which cross the primary medullary rays from bundle to bundle are called *interfascicular cambium.* The cells of the interfascicular cambium likewise divide mainly by tangential walls, and with the same frequency as the fascicular cambium. Thus radially within the interfascicular cambium the primary medullary rays are left stationary, while the surrounding tissue is pushed outwards. There is usually one cylindrical layer of actively dividing cells in the cambial cylinder, and it may be imagined that at any moment it has given rise by tangential division to two such layers. The products of the interfascicular cambium may first be considered. The inner products differentiate as parenchymatous cells which are added to the medullary rays; the outer products retain the power of division. Thus the cambium is moved slightly outwards and its cells divide as before by tangential walls into outer and inner layers. The inner layer thus formed differentiates as a parenchymatous addition to the medullary ray, and the outer layer retains the power of division. Thus a general outward movement of the cambium proceeds, leaving behind or within layers of cells which radially augment the medullary rays.

From time to time it is the outer layer of cells produced by cambial activity which becomes differentiated as parenchymatous cells, while the inner layer remains cambial. In this way the outward progress of the cambium is temporarily delayed but is not arrested. After a long period of cambial activity the interfascicular cambium has moved outwards to a considerable distance, having greatly augmented the medullary ray within and radially, and to a lesser extent, but also radially, without. It will be apparent that the interfascicular cambium is not a fixed or permanent layer of cells, but that the power of division is steadily transferred outwards, and the locus of the cambium is changed with time. It will be further evident that with each step in the outward movement of the cambium the circumference of the cambium must increase. The division of the cambial cells is accordingly not accomplished solely by tangential walls, but from time to time radial divisions also occur. Thus the cambial cylinder is widened and its integrity is maintained as it moves outwards. But while in the vast majority of higher plants the additions to the medullary rays thus produced are uniformly parenchymatous, and these *primary medullary rays* increase outwards as wedges, there is some complication in the products of cambial division between the primary xylem and phloem. The fascicular cambium is generally moved outwards with the same rapidity as the interfascicular cambium, so that the cylindrical form of the cambium is maintained.

Moreover, of the inner products of division in the fascicular cambium many differentiate as *segments of a vessel, tracheids, fibres* or *parenchyma,* which may be variously grouped, but which collectively constitute the *secondary xylem.* In many instances sooner or later one or more cambial cells, within which radially such elements have differentiated, produce exclusively radial rows of parenchyma. These rows have in general the characters of medullary rays, but are obviously purely of secondary origin, and continue neither inwards to the pith nor outwards to the cortex like the primary rays. They are indeed *secondary rays* of purely cambial origin. Of the outer products of division in the fascicular cambium many differentiate as *sieve-tubes* and *companion cells,* or as *fibres* or *parenchyma* arranged in various patterns and collectively constituting *secondary phloem.* With this tissue may also be associated minor *secondary rays,* reaching inwards to the cambium, often the direct radial continuations of similar rays in the xylem, but not reaching the cortex without. It will be apparent that the tangential dimension of each tract of fasicular cambium is steadily increased as the cambium mores outwards, so that the secondary wood increases as an outward widening wedge, while the secondary phloem appears as an inward widening wedge, the two wedges meeting at the cambium. It is not to be supposed that at any moment uniform behaviour is maintained by all the cambial cells in a longitudinal row. so that while at one level, and at various points in the fascicular cambium, secondary medullary rays are being formed in both xylem and phloem, immediately above and below this level, fibres, vessel-segments, sieve-tubes, wood-parenchyma and phloem-parenchyma are being produced. The secondary medullary rays are accordingly of no great depth, and may well be described as narrow bands of parenchyma placed radially in the xylem and phloem. Similarly the behaviour of the interfascicular cambium is not uniform at all levels or at all stages in its outward progress, for while for a time it may produce parenchyma exclusively, locally its products may be secondary phloem and secondary xylem. Thus after a time an island of secondary wood and phloem is seen in a cross section of the stem, dividing the primary ray into two branches, which, when followed outwards, reach the cortex. Nor are the primary rays of great depth, though on an average they are much deeper than the secondary rays, for the downward course of both xylem and phloem is tortuous, and fusion of strands occurs above and below the rays, which are accordingly of lenticular outline when seen in a tangential section of the stem.

Annual Rings.—In those plants whose annual activity is interrupted by a regular winter or dry season the limit of each year's increment of secondary wood, and to a less obvious degree of secondary bast, is marked by a more or less distinct line which is produced by the sharp contrast between the elements formed in the late summer of one year and those produced in the spring of the next. It is believed that in relation to the large and rapid supply of water and other substances to the unfolding leaves in spring and early summer, large vessels are produced by the cambium in the spring, while as summer advances and the need for water diminishes, the vessels formed are narrower. and as the supply diminishes still further, more abundant fibres, with greatly reduced cavities, arise. Thus in a single season of cambial activity a rough outward progression may be traced in the secondary wood of that season from wide vessels to narrow fibres, beyond which the transition to the wide vessels of the succeeding spring is sudden. Each zone thus recognized in a cross section of the stem is called an *annual ring,* and the lines of separation of successive rings mark the temporary halting places of the cambium at the end of successive seasons.

Sap-wood and Heart-wood.—The older wood of large trees, forming a cylinder in the centre of the trunk, frequently undergoes marked changes in character. The wood-parenchyma and medullary rays die, and the walls of all the cells often become greatly hardened, owing to the deposit in them of special substances. Wood thus altered is called *heart-wood* or *duramen,* as distinguished from the younger *sap-wood* or *alburnum,* which is nearer the cambium, carries on the active function of conduction, and retains its parenchymatous cells in life. The heart-wood ceases to be of any use to the tree except as a support, and owing to its dryness and hardness is much used for industrial purposes.

Phellogen and **Periderm.**—It will be obvious that secondary increase of xylem and phloem involves an outward movement of the primary phloem and of all the elements which surround the latter, and that the cortex, and particularly the epidermis, must accommodate for this movement, either yielding passively to a limit and being injured or destroyed by the outward pressure, or being to some extent modified so as to persist. In most cases the epidermis is unable to maintain the active radial division of its cells necessary for such expansion as occurs, is soon stretched to its limit, dies and is destroyed. Extensive radial division in the cortical cells is progressively less essential as the inner cortex is followed inwards, and as a rule, by a combination of radial and tangential divisions, the integrity of the cortex is maintained. Towards the periphery of the cortex, and commonly by modification of its outer layer, a secondary meristem, similar to the cambium, arises and produces external and internal secondary tissues. This meristem is the *phellogen,* and the whole of the tissue it gives rise to is known as *periderm.* The phellogen derives its name from the fact that its external product is the characteristic tissue known as *cork.* This consists typically of closely fitting layers of cells which quickly die, and when mature, have completely suberised walls which collectively serve to replace the epidermis as an external protective layer, when the former is ruptured. The outer layers of the cork are constantly being destroyed, but new layers are in progress of formation within. The internal tissue formed by the phellogen is known as *phelloderm;* it augments the cortex, and typically consists of living parenchymatous cells to some extent capable of further division. Indeed, an inward succession of phellogens may arise in the phelloderm and in even more deeply seated living layers. In certain cases the epidermis becomes the phellogen. To the great activity of the phellogen, and to the power of formation of a series of phellogens in deep layers, the value of the cork oak as a source of cork is due.

Cambium in Roots.—The cambium in the root, which is generally found in those plants which have a cambium in the stem, always arises in the conjunctive tissue internal to the primary phloem, and forms new (secondary) phloem in contact with the primary and secondary xylem internally. In roots which thicken but slightly, and whose cambium usually appears late, it is confined to these regions. If the development of secondary tissues is to proceed further, arcs of cambium are formed in the pericycle external to the primary xylem, and the two sets of cambial arcs join, forming a continuous, wavy line in transverse section, with bays opposite the primary phloems and promontories opposite the primary xylems. Owing to the resistance offered by the first formed secondary xylem, the bays are pushed outwards as growth proceeds, and the wavy line becomes a circle. Opposite the primary xylems the cambium either (a) forms parenchyma on both sides, making a broad, secondary (principal) ray, which interrupts the vascular ring and is divided at its inner extremity by the islets of primary xylem, or (b) forms secondary xylem and phloem, completing the vascular ring. In either case narrow secondary rays are formed at intervals, just as in the stem. Thus the structure of an old thickened root approximates to that of an old thickened stem, and so far as the vascular tissues are concerned, can often be distinguished from the latter only by the position and orientation of the primary xylem.

Growing Points.—The tissues above considered all owe their origin ultimately to the growing points or apical *meristems* defined in the embryonic plant-body. To the great variety of apical meristems found in vascular plants reference alone can here be made. It must suffice to note that in most Pteridophytes there is a single large apical cell at the end of each stem- and root-axis, that it usually has the form of a tetrahedron, that its base occupies the surface of the growing point, and that its apex points inwards. By definite and regular divisions of such a cell a mass of still undifferentiated cells is produced immediately behind the growing point, which is continuously occupied by a residual apical cell. From these undifferentiated cells the tissues above considered sooner or later arise by further growth, divisions and differentiation. In most Phanerogams the apical (or primary) *meristems,* instead of consisting of single apical cells or of a definite group of initials, are stratified, *i.e.,* there is more than one layer of initials. Throughout the Angiosperms the epidermis of the shoot originates from separate initials which never divide tangentially, so that the young shoot is covered by a single layer of dividing cells, the *dermatogen.* Below this are the initials of the cortex and the central cylinder. Whether these are always in layers which remain separate is not known, but it is certain that in many cases such-layers cannot be distinguished. This, however, may be due to irregularities of division and displacement of the cells by irregular tensions, destroying the obviously layered arrangement. In some cases there is a perfectly definite line of separation between the young cylinder (*plerome*) and young cortex (*periblem*), the latter having one or more layers of initials at the actual apex. The separation of layers in the apical meristem of the root is usually much more obvious than in the stem. The outermost layer is the calyptrogen, which gives rise to the root-cap, and in Dicotyledons to the piliferous layer as well. The periblem, one cell thick at the apex, produces the cortex, to which the piliferous layer belongs in the Monocotyledons; and the plerome, which is nearly always sharply separated from the periblem, gives rise to the vascular system.

There is generally some definite progression in the actual differentiation of the individual tissues, so that, for example, comparatively simple xylem and phloem elements may be recognized in certain portions of a stem or root before the differentiation of xylem and phloem is accomplished in the stele as a whole. Such first formed xylem and phloem elements are known respectively as *protoxylem* and *protophloem,* and serve for the initial conduction of food-materials, while the later formed elements of the primary xylem and phloem are called respectively metaxylem and *metaphloem.*

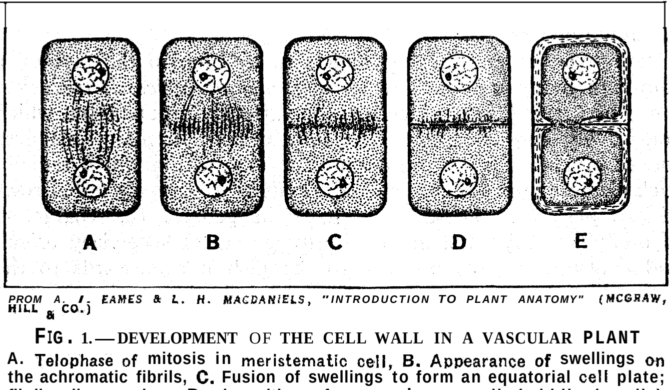
The branches of the stem arise by multiplication of the cells of the epidermis and cortex at a given point, thus forming a protuberance at the end of which an apical meristem is organized The vascular system is connected in various ways with that of the parent axis by the differentiation of bundles across the cortex of the latter. This is known as exogenous branch formation. In the root, on the other hand, the origin of branches is *endogenous.* The cells of the pericycle, usually opposite a protoxylem strand, divide tangentially and give rise to a new growing point, the outward path for which is prepared by digestion of the surrounding tissues. The connections of the stele of such a root with that of the parent axis are made across the pericycle of the latter. The cortex of the new root is never connected with that of the parent, but with its pericycle. *Adventitious* roots, arising from the stem, usually take origin in the pericycle, but sometimes from other parts of the conjunctive tissue.

Thus it will be seen that throughout the vascular plants thkre are definite and orderly methods of production and distribution of the tissues destined to play their parts in the major or minor processes of life, and that such organisms are well fitted for life on land. (J. McL. T.)

CYTOLOGY

The structure and development of the vegetable cell so far as the protoplasm and the nucleus are concerned are considered in their broader aspects in the article **Cytology.**

The recognition of the fundamental similarity of the cells of plants and animals and the identity in structure and functions of animal and vegetable protoplasm which formed the starting point in the study of cytology are conceptions which subsequent investigations have only broadened and confirmed. Nevertheless this agreement, whether it be in the minute structure of the protoplasm or in the details of nuclear mitosis, is accompanied by peculiarities in the cell structure of plants which have had a profound influence in the evolution of the vegetable body. Of these the most important, because far-reaching in their effects, are the presence of



FROM A. J. EAMES & L. H. MACDANIELS, "INTRODUCTION TO PLANT ANATOMY" (MCGRAW, HILL & CO.)

FIG. 1.—DEVELOPMENT OF THE CELL WALL IN A VASCULAR PLANT

Fusion of swellings to form an equatorial cell plate; fibrils disappearing, D. deposition of new primary wall (middle lamella) between the halves of the split cell plate, E. deposition of a secondary wall layer between the plasma membrane and middle lamella, except in region of a large pit. Primary wall. solid black: cytoplasm stippled, plasma membrane densely stippled; secondary wall shaded

plastids in the protoplasm and the existence of the cell wall. In the higher plants the egg is necessarily a naked cell, but when fertilization is accomplished the new cell secretes around itself a membrane—a cell wall—before it begins to grow and divide, and the myriad cells to which it gives rise in the course of its further development are from the first enclosed in a similar membrane.

The continuous development which is such a characteristic feature of the structure of the higher plants depends on the presence of persistent embryonic regions or growing points at such places *e.g.*, as the tips of stems and roots. This enables us to study in these regions the formation of new cells, and to trace their development and modification to form the adult tissues of the member to which they belong.

The individual cells appear rectangular in form and consist of a mass of protoplasm containing a large nucleus and separated from the neighbouring cells by a delicate membrane. It is unnecessary to refer to the detailed structure of the protoplasm and the nucleus, since these have already been fully described *(see* CYTOLOGY), but with suitable treatment it is possible to distinguish in the protoplasm of these merislem cells the rudiments of definite protoplasmic organs, the plastids. The nature, purpose and function of these important bodies will be considered below: for the present it is sufficient to say that they are differentiated portions of the protoplasm which perform definite functions.

From such embryonic cells all the tissues of the plant body are formed by processes of growth and differentiation. Growth involves an increase in size of the individual cells which may in some cases result in an enlargement to many thousand times their original volume. This enlargement does not however necessitate a proportional increase in all the parts of the cell. Increase in size is mainly the result of active extension of the cell wall. The protoplasm does not increase in volume in the same proportion and hence cavities appear in it which are filled with a watery fluid —the cell sap. As the wall enlarges these spaces or vacuoles increase in size and number and eventually coalesce to form one large central vacuole in the protoplasm which thus becomes restricted to a comparatively thin layer closely applied to the cell wall (fig. 1, E). The nucleus, which undergoes little change during this process or may even be reduced in size, is at all times embedded in the protoplasm and thus comes to lie close to the cell wall or in some cases it may be slung by delicate protoplasmic strands in a more or less central position in the cell. It is often possible to observe a circulation of the material in these strands, definite streams moving from the cell wall towards the nucleus and vice versa. It is, however, uncertain as to whether this is a general phenomenon.

The Cell Sap.—The cell sap which fills the vacuoles is water in which are dissolved substances of various kinds. some of which are food materials others products of the metabolism of the protoplasm. Its composition is constantly changing but among the substances of constant occurrence are inorganic salts, carbohydrates such as the sugars and soluble nitrogenous compounds; in addition the sap of fully developed cells may contain colouring matters such as the anthocyanins, which are red, violet, or blue and give their characteristic colour to the petals of many flowers, the leaves of such trees as the copper beech-and the tissue of the beetroot. The large proportion of the total volume of the cell occupied by the cell sap explains the large percentage of water present in soft vegetable tissues; *e.g.*, cabbage and spinach leaves, roots of turnip and beet and shoots of asparagus contain over 90% of water.

The cell wall and the protoplasm are both freely permeable to water and indeed the former is also permeable to the molecules of crystalloid substances. The living protoplasm, however, may be described as semi-permeable since it may restrict the passage of dissolved substances either into or out of the vacuole. One result of this property of the protoplasm is that, whereas at a given moment the pressure of molecules of water inside and outside the cell may be equal, there may exist in the vacuole in addition a pressure due to the molecules of the salts; the cell is in consequence distended, the wall is stretched and owing to its elasticity exerts a counter-vailing pressure. Such a cell is described as turgid and in this condition it acquires a certain rigidity analogous to that of a distended air bladder.

This characteristic of the vegetable cell has played an important part in the evolution of the plant body since it has rendered possible the development of plant organs of relatively large size with a minimum organization of skeletal tissue. Such structures as the leaves of herbaceous plants—though provided with a network of veins—maintain their form and position only by the turgidity of the living cells of which they are largely built up. Loss of water from the individual cells results in a shrinkage of the tissues as a whole, and the familiar appearance of wilting or flagging of plants deprived of water is brought about in this way.

Plastids.—The plastids or chromatophores are portions of the protoplasm which have become specialized for the performance of certain functions. They are readily distinguished in the adult cell by their size and definite form and they are often conspicuously coloured. Leucoplasts are colourless and occur in the cells of the deeper lying tissues where light cannot penetrate—if exposed to light they often become green. They are frequently concerned with the formation of starch grains. Chromoplasts are colour-carrying bodies giving red and yellow colours to the petals of Rowers, ripe fruits, etc.; they contain yellow and red pigments such as xanthophyll and carotin. The most important of all the plastids, however, are the green chloroplasts, chlorophyll bodies or chlorophyll corpuscles as they are variously termed. They contain chlorophyll and are of universal occurrence throughout the vegetable kingdom with the sole exception of the important group of the Fungi. It is by means of this pigment that the plastids are enabled in the presence of light to form carbohydrates from water and carbon dioxide.

The importance of this process cannot be overestimated, since it is the starting point in the manufacture of the food of all living organisms and its activity has made possible the existence of plants and animals upon the earth. *(See* PHYSIOLOGY.) Chlorophyll when extracted from plants by suitable solvents can be shown to contain a number of pigments. The green, blue-green, yellow and red have been already mentioned. In form the chloroplasts are extremely variable and the Algae (*q.v.*) show a rich variety of shape; in the higher plants however they are discoid in form. Like the leucoplasts they frequently show inclusions of starch grains. They may increase in number by dividing into two halves by simple constriction. They have been shown to be present in the egg cell of some plants and are, in these cases, thus passed on from one generation to another, but they have not been demonstrated in the sexual cells of all plants.

The Cell Wall.—The cell wall in meristematic cells is an extremely delicate membrane but, with the completion of the growth in size of the cell, it is increased in thickness and may in certain cases undergo considerable modification. It is commonly regarded as a secretion of the protoplasm and it is in living cells in intimate relation with the protoplasm which may interpenetrate the particles of its substance. This close relation can be readily appreciated when the process by which the wall is first laid down is considered. From the beginning of the plant's existence as a single cell, all new cell formation consists in the division of a pre-existing cell into two halves by the formation of a dividing wall. In this process the cytoplasmic spindle which functioned in the preceding nuclear division *(see* CYTOLOGY) plays an important part. The spindle fibres—increased in number—show swellings or thickenings in the middle of their length (fig. 1, B), which coalesce and form a continuous "cell plate" which is extended until it reaches the side walls of the mother cell. This cell plate is not however the cell wall; it is of protoplasmic nature and splits into two layers between which the true wall substance is laid down (fig. 1, D). The subsequent growth of the cell wall is facilitated by its intimate penetration by the protoplasm, which lays down fresh materials between the existing particles (intussusception), and later adds to its thickness by the deposit of fresh layers of material on the inner surface of the primary wall (apposition).

The primary wall, laid down in the manner above described, might be regarded as common to the two cells concerned in its formation, but many facts go to show that it is either a double membrane from its inception or that it readily splits into two. The result is that every cell is surrounded by its own individual wall. This is seen very clearly in the development of elongated cells such as fibres, which may grow to many hundred times their original length. In this process they may change their position, sliding over the surface of neighbouring cells and making contact with cells of different, and of more remote, origin. Such elongated cells as the fibres undergo considerable thickening of their walls when their growth is completed. This thickening is originally of cellulose, but it may undergo secondary changes becoming wholly or in part lignified, thus rendering the wall firm and hard and better adapted to serve the purpose of mechanical support. Thickening and lignification of the wall is also characteristic of the cells concerned in the formation of the water-conducting elements. With the completion of these changes in the cells of the strengthening and water conducting tissues the protoplasm disappears and the walls alone remain.

Plasmodesma.—The living cell in a complex multicellular plant body is a unit, but not an independent one, and its functions must be conditioned by, and related to, the activities of the organism as a whole. This must involve a close connection between the living protoplasm of neighbouring cells and this is effected by delicate connecting strands, the plasmodesma, which traverse the walls. These represent in some cases the persistence of the original continuity of the protoplasm of two sister cells, but for the most part they are probably new contacts established when growth is completed. The presence of these delicate connections has been established in a large number of cases, and it is probable that they are of universal occurrence in the higher plants. They play a part in the correlation of the functions of the cells, and they may also provide the means by which stimuli can be conveyed through long tracts of tissue in those cases, where the region stimulated is distant from that in which the response is shown.

(R. J. T.)

DISTRIBUTION AND ECOLOGY

The distribution of plants can be considered from two main aspects. The present or past distribution of species, genera and families, termed *floristic* plant geography, can be studied both for its own sake and as a factor in determining the location of human activities or features of the earth's surface. But besides this purely geographical aspect the facts of distribution can be considered in relation to their causes; the influences of climate, of topography, of the soil conditions, of other plants, of animals, and even of the past history of the superficial crust of the earth and of the species itself. It is this relation of plants to their environment, in its widest sense, and the mutual effect of environment and organism, which is the province of ecological plant geography, or briefly plant ecology.

Floristic Distribution.— The floristic distribution of species exhibits the greatest possible variation from the species which as a wild plant is confined to a limited area (endemic) to wide-ranging species such as many microscopic plants (*e.g.,* some bacteria) which are apparently universal in their occurrence. There are probably no vascular plants that are strictly cosmopolitan, but the common bracken (Pteridium *aquilinum*) and the reed (*Phragmites communis*), though far less common in the tropical regions, are feral species in the most diverse climes (the former, however, notably absent from oceanic islands). In striking contrast are such plants as the fern *Thyrsopteris elegans,*—an endemic confined to the Island of Juan Fernandez or Pringlea *antiscorbutica* restricted to the tempestuous shores of Kerguelen.

Endemics are an especial feature of oceanic islands as is shown by the flora of Madagascar, which comprises some 4,000 species of vascular plants and contains no less than 75% of endemics. In New Zealand the proportion of endemics is 74%, whilst in Hawaii the endemics constitute 80% of the entire flora. By contrast the floras of continental islands are practically destitute of endemics, as is shown by that of Britain, which amongst its flowering plants probably includes but one endemic of specific rank, namely, the wolf's-bane (Aconitum anglicum).

It is clear that when a new species originates it will not immediately attain its climatic limits but its spread will be a gradual process, occupying a longer or a shorter time according to the efficiency of the means whereby the dispersal of its seeds or other reproductive bodies is attained. It is the belief that this process is in general secular rather than rapid, which has led to the view that the area occupied by a species, genus, or family is roughly dependent upon its age. Willis has adduced evidence to show that the majority of endemics are species of recent origin which have either not had sufficient time to spread over a larger area (*e.g.,* local endemics in continental areas) or have been prevented, by the presence of natural barriers, extending beyond their place of origin. The latter explains the high proportion of endemics on oceanic islands. On the other hand, it is certain that some endemic species are relics of a former more extensive area of occupation, the remnants of a bygone vegetation. The fern genus *Matonia* is at the present day represented by three species, of which two are confined to Borneo and the third also occurs in the Malay Peninsula; yet fossil evidence indicates that ferns of this affinity had an almost cosmopolitan distribution in Mesozoic times. The Gleicheniaceae, the Schizeaceae, and Marattiaceae, families of ferns now practically absent from the northern hemisphere, furnish further examples of area diminishing with the lapse of time. Amongst the flowering plants the present restricted distribution of Ginkgo biloba, the tulip tree (Liriodendron tulipifera) and the sequoias, affords a marked contrast to the widespread occurrence of species of these genera in Tertiary times and shows the importance of the past history of a group in appreciating the significance of the existing representatives.

Frequently the members of a genus comprise one or more species which extend over a large area, whilst the remainder are of much more restricted distribution and occupy areas either included in or overlapping the range of their more widespread congeners. Illustrations are furnished by the she-oaks of Australia (Casuarina), with the littoral C. *equisetifolia* extending from east Africa and Madagascar to the Society islands and Burma and the Philippines to Tasmania, within which area occur a number of other species. Again the genus Mercurialis includes the dog's mercury (M. *perennis*) and M. annua, which are of wide range, whilst the five or six other species extend over comparatively small areas in the Mediterranean region and eastern Asia. It is probable that in such genera the species of more local occurrence are derivatives of the wide-ranging types, but it is also evident that were the widely dispersed parent types to die out the other species of restricted distribution would come to present the condition of discontinuous distribution which is a feature of many genera and families at the present day. The pipeworts (*Eriocaulon*) are chiefly found in tropical and sub-tropical regions, but E. *septangulare* is found in the eastern United States, the west of Scotland, and the west of Ireland. Of over 400 species of heath belonging to the genus Erica, the majority are concentrated in Cape Colony and the Mediterranean area. The Proteaceae and Cycadaceae, containing many very localized genera, now exhibit a discontinuous distribution in tropical and sub-tropical regions, but there is little doubt that the Cycadaceae extended over a large part of the world in Jurassic times and the Proteaceae were probably much more widely distributed in the Tertiary epoch than at the present day. Discontinubus distribution in the species may be the outcome of irregularities of dispersal, the result of extinction from parts of its former range, or even due to origin of the species in more than one locality.

Effects **of** Glaciation.— It is quite impossible to appreciate the present distribution of species in either North America or northern Europe without recognition of the profound changes consequent upon the last glacial epoch. During Cretaceous times there would appear to have been a remarkable uniformity in the character of the vegetation of the world, with warm temperate types as far nor'th as Greenland. This uniformity was succeeded by a differentiation in the Tertiary period. On either side of the tropical belt there probably existed a zone of forest presenting a mixture of temperate and subtropical types, southern types being present in the northern hemisphere and northern types, such as the true beeches and the common oak (Quercus Robur), being present in the southern hemisphere. Mrs. Clement Reid has admirably demonstrated, by a comparison of successive floras of the Pliocene period of Europe, the gradual disappearance of exotic types as the Pleistocene approached, probably accompanying a diminution of temperature. It is due to the work of Heer on the arctic fossil flora, the writings of Asa Gray, Saporta and Hooker that the fossil floras of the past have been so ably utilized in the elucidation of the peculiarities of the distribution of the present. The holarctic distribution of a large assemblage of species prior to the glacial refrigeration is the clue to the resemblances between the American and east Asiatic floras. Of these migrants, driven southwards by the increasing cold, relics remain in the genus *Sequoia,* now only represented by two north-west-American species, in *Ginkgo biloba,* confined to western China, in the American genus *Liriodendron* and the Chinese *Glyptostrobus.* The magnolias no longer occur wild in Europe as they did in the past, but still survive both in Asia and America. Of the genera cited Depape has recorded Pliocene remains from the valley of the Rhone of *Sequoia sempervirens, Liriodendron tulipifera, Ginkgo biloba,* and *Glyptostrobus heterophyllus.* The elimination of these and many others from the European flora is probably to be attributed mainly to the presence of natural barriers against the southward retreat, such as the Mediterranean, whereas in Asia and America there was a continuous land bridge to a climatic sanctuary, the temporary home of some, the permanent retreat of others.

During the Ice age itself the flora consisted of definitely arctic types and a considerable number of other hardy species which survived the cold in the areas, probably of considerable extent, which were not actually covered by ice. Judged by the frequency of the remains in sub-fossil deposits of the glacial period in Europe the commonest species were the mountain dryas (*Dryas octopetala),* the dwarf birch *(Betula nana)* and various willows of mat-like habit, such as *Salix reticulata,* S. *polaris,* etc. It is noteworthy that the species cited and a number of others prevalent at that period are now most characteristic of arctic regions but also occur in warmer climates on what may be termed arctic islands, namely, the summits of the higher mountains, a discontinuous distribution that can be attributed to survival from glacial times. With the final retreat of the ice, which in northern Europe probably took place somewhere about 14,000 years ago, the recolonization of the glaciated areas by the less hardy species began.

The colonization thus begun has continued ever since. The fact that Ireland possesses but two-thirds of the vascular plants of Britain whilst the flora of England, though richer than that of Scotland, is less varied than that of the neighbouring areas of France emphasizes the importance of the facilities for dispersal of fruits and seeds in determining the distribution of species. The rapid spread of the Canadian pondweed *(Elodea canadensis)* from Market Harborough, where it first appeared in England in 1847, of *Veronica persica,* or more recently of the rayless mayweed *(Matricaria suaveolens),* a native of Oregon, all of which have become abundant over a great part of Britain; or, again, the spread of the prickly pear (*Opuntia inermis*) at the rate of a million acres a year in Australia and the choking of the waterways of Florida by the water hyacinth *(Eichornia crassipes*) all bear witness that area is not necessarily a criterion of age and that the process of colonization is still going on, a process in which the disturbing influence of the hand of man plays no small part.

Ecological Factors.—The most superficial observation shows that species are not uniformly distributed throughout their range and that certain conditions favour one kind of plant rather than another. In the ecological concept the idea of competition is never absent and the effect of the external conditions upon the constituents of the vegetation of any region is largely dependent upon their selective action. The sum total of the external circumstances surrounding the plant is termed the *habitat* and the various conditions that together determine distribution are termed the habitat *factors,* of which some are physical and others biological.

Climatic Factors.—Of the physical factors the most important are climatic and of these temperature would appear to play the major rôle. Hence we find that the main vegetation zones on the earth's surface have a latitudinal distribution and that the species which has an extensive north and south range has commonly a wide range in the east and west direction also. Whilst some species, as already noted, are almost cosmopolitan, it is true of the majority that they do not occur both in tropical and arctic regions. In some cases it has been shown that the species comprises several geographical races with different capacities for endurance of climatic extremes, but there is little evidence to show that species can become adapted to climatic extremes that they could not initially endure. Many garden plants are cultivated in the open beyond the limits of their natural range, showing that the climatic conditions need not be lethal in order to delimit the area of a species.

By diminishing the rate of growth or inhibiting reproduction temperature may effectually prevent the maintenance of a species in competition with other plants although there is a considerable margin before the lethal limit is reached. Extremes of temperature, however, cause death in many plants by coagulation of the living cell contents, and in general the susceptibility to such extremes is directly proportional to the amount of water which the plant or part of the plant contains. Hence seeds which have a very low content of water are exceptionally resistent whilst succulent shoots are especially susceptible. Rapid changes of temperature are far more liable to prove fatal than changes of the same amplitude which occur slowly.

In tropical and sub-tropicai regions where there is no dry season the vegetation consists of broad-leaved evergreen forests, but where, as in temperate latitudes, a warm and cold season alternate, the characteristic type is deciduous woodland; whilst in still higher latitudes, where the growing season, or frostless period, is of short duration, the prevailing types of forest consist of narrow-leaved evergreen conifers. A similar zonation to that presented from the Equator to the Poles is seen in the altitudinal zonation on the higher mountain masses. Such is well illustrated in Corsica where the olive characterizes the belt from sea-level to 400 metres, the chestnut from 400m. to 1,000m., pines *(P. Pinaster* and *P. Laricio)* and beech from 1,000m. to 1,600m.; the alder (*Alnus suaveolens)* the sub-alpine zone from 1,600m. to 1,900m. and scrub of the dwarf juniper (*Juniperus nanus)* with *Berberis aetnensis* up to 2,000 metres.

The importance of temperature and the length of the growing season is further shown by the altitudinal distribution of individual species, which varies markedly in correspondence with the latitude. For example, *Polygonum viviparum* attains to 1,230m. in Scotland at 56·48 N. Lat., on the Swiss alps it is found at over 2,850m. (9,000ft.), and on Mt. Everest (27·59 N. Lat.) reaches an elevation of 4,460m. (14,500ft.). Study of comparative altitudes in different latitudes shows that the upper limits tend to rise on the higher mountains and in areas of large mountain masses, which indicates the importance of exposure conditions.

The extreme conditions tolerated by living vegetable organisms is shown by the fact that spores of bacteria can endure immersion in liquid air whilst certain blue-green algae (*Phormidium laminosum, Mastigocladus laminosus)* occur in water at temperatures above 49°C. Even amongst the flowering plants the resistance of some species to cold is considerable, *Larix siberica* for instance growing where temperatures of —70°C are not unknown, whilst seeds are particularly resistant to both heat and cold. Here, too, attention may be called to the extreme altitudes attained by some flowering plants, *Arenaria muscosa* being found at 20,400ft. on Mt. Everest, the highest recorded station for a member of this class.

Precipitation.—Of almost equal importance to temperature is the amount and seasonal distribution of precipitation either in the form of rain or snow or as dew and fog. In regions of equivalent temperature forests will in general occupy the areas of highest precipitation, deserts the areas of lowest precipitation, and grasslands the areas of intermediate humidity. In the United States, for instance, the mean annual rainfall in the desert region ranges from 0–30in., in the prairies from 20–30in., and in the regions of forest from 30–90in. In any estimate of the influence of rainfall, however, the humidity of the air is necessarily a considerable factor and the efficacy of a given precipitation will be largely influenced by the temperature changes, upon which the rate of water-loss from the surface of the plant and from the soil in which it grows so largely depends. Further, this water-loss will be greatly augmented by wind, and so the velocity and frequency of air movements have an important influence on the limits of species and plant-communities. The frequent incidence of high winds inhibits the gro th of trees near the summits of mountains, both by their drying action and mechanical effect, whilst the strong winds and low temperature together determine the distribution of arctic Tundra.

Illumination.— Since all green plants manufacture their organic food by means of the radiant energy absorbed from sunlight, the intensity and duration of this illumination naturally aifects the distribution of species. Many woodland plants are so constituted as to function best in this respect when growing in comparatively weak illumination, whilst others, such as many littoral species, attain their optimum rate of food production in full sunlight. Even the weak light which reaches the floor of a woodland is sufficient for the requirements of some mosses, but when the shade is too intense the vegetation is confined to parasites and saprophytes and so the rich fungus flora of a dense beechwood or pinewood becomes one of its salient characteristics. It has, moreover, been found that the length of the period of daily illumination may be an important factor in influencing reproduction. Some species appear to be indifferent to the length of the period of daylight, except in so far as the amount of organic food they manufacture is dependent on the total radiant energy they receive. Other species respond to a shorter daily illumination by earlier flowering and fruiting, whilst with still other species the effect is a retardation in the reproductive process.

Nevertheless, though the individual climatic factors play each their separate part, it is mainly upon their interaction that distribution of species depends. Thus it is that some are particularly associated with oceanic climates characterized by small amplitude of temperature and high humidity, whilst others are found in the drier and more extreme conditions of continental areas. Examples of the former are furnished by the petty whin (*Genista anglica)* and the wild hyacinth (*Scilla nutans*), features of the west of Europe, whilst the latter are represented by various species of *Eryngium* and *Artemisia* of the Russian steppes.

The Soil.—The character of the soil is chiefly important as to its physical structure, except where the chemical constitution exhibits extreme conditions. For upon the size of the constituent mineral particles and the proportion of organic material which the soil contains depends in large part its capacity to retain the water which reaches it in the form of precipitation or by capillarity. It is the feeble power of such retention that renders the conditions on a sand dune or a shingle beach comparable to those of a desert even in regions of high precipitation and humidity. It is in great measure differences in *water capacity,* as this power of water retention is termed, that are responsible for the different types of vegetation on clay, sand, and peat, within an area of uniform climatic conditions. Nevertheless, other soil factors, such as the chemical nature, the reaction, the nature of the soil atmosphere and the constitution of the teeming population of micro-organisms, etc., all play a part in determining the relative suitability of soils for one species or another. The soil conditions in untouched vegetation, however, present a very different distribution from the comparative uniformity of agricultural land, a definitely stratified organization, as a consequence of which species growing intermingled but with root systems of differing depths of penetration may be occupying very different types of soil both as regards chemical and physical constitution. The direct influence of the chemical nature of the soil is often difficult to separate from its indirect influence on water supply, absorption of soluble salts, etc. This is well seen in the vegetation of calcareous and non-calcareous soils. The so-called calcicole species which frequent the former may prefer calcareous soils either because of their physical qualities, because of their neutral or slightly alkaline reaction, or because of their chemical properties. Further, such association may be obligatory or merely preferential. Preference for a particular soil type is sometimes a feature of an entire genus, as that of *Clematis* for calcareous soils, whilst in other groups closely allied species may have very different requirements.

Biological Factors.—These comprise the effects of plant on plant and the relation between animals and plants. Of these biological factors, however, the most important is the influence of man. It is largely due to man that the present tree limit in the alps is considerably below its former altitude, whilst even in comparatively unsophisticated regions of the tropics considerable changes have resulted from the practice of migratory cultivation and the artificial extension of grassland at the expense of forest, both for domestic animals and the encouragement of wild game. The profound effect of rabbits on natural vegetation has been well exemplified in New Zealand and Australia, whilst the attacks of field mice, mollusca and various parasitic fungi, *inter alia,* considerably affect the efficiency of reproduction in many wild species. On the other hand, the beneficial effects of earthworms, moles, ants, etc., is analogous in nature to tht action of the plough in maintaining adequate aeration of the soil. Many flowers depend upon insects for their pollination, and hence the area of a species may be restricted by that of its pollinating agent.

In addition to the effects of climatic, edaphic (soil), and biotic factors, there are the historical factors to which allusion has already been made, and in this connection it must be recognized that the vegetation of yesterday has in large part been responsible for the conditions which determine the vegetation of to-day. The habitat is not static, but dynamic, and the present is but the link which joins the conditions of the past to those of the future.

Autecology.—The success or failure of the individuals of the species in one area will depend not merely on its ability to flourish in the environment there present but also on its capacity to modify that environment and itself to become modified. The study of this relation of the individual to its surroundings is termed *autecology.* A few examples will serve to illustrate the importance of the life history and structure of the organism in determining its fitness for a particular station or habitat. Thus annuals are an especial feature of deserts, where the short relatively wet season is occupied in rapid growth and reproduction whilst the dry hot season is passed in the seed state. The same quality has enabled many plants to become weeds of arable land and others to survive the rigours of a cold season. By contrast the vegetation of arctic regions is characteristically rich in perennials, for the growing season is so short and the temperature so low that growth is a slow process, and the annual species which occupies a considerable period in attaining the reproductive state is at a disadvantage in competition with perennial types in which the flower rudiments are often formed already in one season preparatory to their expansion in the next. Many of the herbaceous plants of woodlands exhibit exceptionally early leaf expansion, and hence their leaves are receiving light and manufacturing food material for weeks, and sometimes months, before the canopy of foliage of the shrubs and trees is formed above. This quality of precocious leaf development has enabled its possessors to occupy woodlands in which the light intensity during the summer months may be less than 1% of that in the open.

The possession of a relatively small leaf surface, a tufted habit, low growth, or hairy leaves are a few amongst many external features which tend to reduce the rate of water loss from the leaf surface (transpiration) and thus enable their possessors to occupy drier areas than would be possible for them in their absence. Such features are often accompanied by a microscopical internal structure also tending to check the rate of water loss, and plants having an aggregate of such feature are often termed *xerophytes,* from their capacity to grow in arid situations. Many plants, on the other hand, are entirely devoid of such transpiration checks and even exhibit features which tend to promote water loss, and often possess means of secreting liquid water. Such plants are quite unsuited to dry situations, but are admirably adapted for the humid situations in which they flourish.

Some species owe their success to a remarkable capacity for vegetative spread, as, for example, *Mercurialis perennis* and *Epilobium angustifolium,* others to a copious seed output, as, for instance, the foxglove *(Digitalis purpurea*), of which one plant may produce a million seeds in a single season. Contrast this with the seed output of another woodland species, *Allium ursinum,* which often does not exceed 40 seeds per annum. The rosebay willowherb (E. *angustifolium*) will often spread at the rate of 60cm. a year by means of its rhizomes and at the same time produce some 50,000 seeds, whereas its congener, *E. montanum*, only produces from 4,000 to 13,000 seeds in a season and spreads vegetatively about 1·1cm. per annum. The equipment of species in the struggle for existence is thus very unequal.

Seed Dispersal. — Many seeds and fruits are dependent on wind action for their distribution, and some, such as the parachute-like fruits of the goatsbeard *(Tragopogon)*, the plumed seeds of the willows and willowherbs, or the winged seeds of the tropical *Bignoniaceae*, are wonderfully fitted for this mode of dispersal. Others, such as the burr-fruits of the goose-grass *(Galium aparine)*, enchanter's nightshade *(Circaea)* and herb bennett *(Geum urbanum)*, become attached to the coats of animals by means of their hooked appendages, whilst the seeds of many berries are swallowed by animals and deposited in their droppings. often at great distances from their source. Here, however, it should be noted that the crops of birds on migration are usually empty and their plumage remarkably clean, so that bird carriage is not so important an agent as might be supposed. Still other seeds or fruits, like those of many waterside plants, have a buoyant structure and are carried to new habitats by means of streams and ocean currents. The efficacy of this means of dispersal is shown by the carriage of seeds of *Entada scandens* from South America by ocean currents, which frequently deposit them along the west European seaboard in a viable condition.

The Social Life of Plants (Synecology).—The foregoing considerations lead naturally to the conception of definite communities of plants, and it is the study of these social groupings which is the particular domain of *synecology*. The largest groupings that can be recognized are related to the broad climatic features of the earth's surface; such are termed *formations* and are well represented by the tropical *rain forest*, a community characteristic of areas within the tropics with high and continuous rainfall, consisting of a luxurious vegetation in which there are a great variety of broad-leaved evergreen trees, numerous woody climbers *(lianes)*, and epiphytic plants, the whole presenting a great complexity of structure. Other examples of formations are the deciduous forests of temperate regions, the grassland formations of the American prairies and the African veld, or the deserts of arctic and tropical regions. These formations can be further subdivided, according to the species which play the major rôle in the plant community, into *associations*, where several species take a leading rôle, or *consociations*, where there is one predominant species. Since even in these the subordinate species vary from one part to another, *societies* within the association can be recognized.

The deciduous forest formation of America presents in Indiana and Missouri associations in which oak and hickory are the chief features, whilst in the region of the great lakes it is represented by an association of birch and maple. In central Europe the same formation is represented by the very mixed forests of beech, hornbeam oak, etc., of the Danube region, by the Mediterranean chestnut forests, by the oak forests of Austria and other types. In Britain consociations are the rule, each characterized by a single dominant tree and associated with particular soil conditions. Thus the ashwoods are chiefly found on limestone soils, where the conditions are moist; beechwoods on dry soils, particularly those derived from chalk; birchwoods constitute the uppermost zone of woodland in mountain districts and also occur as a temporary phase on felled areas; alderwoods occupy the wettest soils; oakwoods of *Quercus Robur* are a feature of the moister and more fertile clays and loams, and oakwoods of *Q. sessiliflora* of the less fertile, acid, and usually drier non-calcareous soils, especially on the valley slopes of the west. Within an English oakwood some areas are covered with a carpet of *Mercurialis perennis* and *Scilla nutans*, others with *Anemone nemorosa* or *Ficaria verna*, furnishing examples of societies within the consociation. Such illustrations serve to indicate the use of these synecological terms; but for an account of the plant communities of the world the reader is referred to the works cited on p. 18.

Every plant community has something of the attributes of an organic unit, in that it possesses a more or less definite structure and has a life history in which juvenile, adult, and senile phases can be recognized. The structural organization is well illustrated in the temperate deciduous woodland, where three definite strata are usually present, respectively consisting of trees, shrubs and herbs, whilst beneath the lowest tier or ground flora there is often a carpet of mosses and the surface soil is rich in fungi and bacteria. Although less conspicuous, these flowerless plants are just as important a part of the community and have as definite a floristic composition. Beneath the surface the root systems of the higher plants exhibit a stratification comparable to that of the aerial organs, and the differing depths to which the roots of different species penetrate, as also the different periods at which they make their maximum demands on the food supply in the soil solution, are features which tend to reduce the competition between species and render possible that dense intermingling which results in the succession of seasonal changes. It must, however, be realized that the architecture of any community necessarily connotes different conditions in its various parts so that the environment occupied for example by the ground flora of a tropical or temperate forest, or by the lowest stratum of a fen is markedly different, as to humidity and illumination, from that of the tree layer in the one or the tall reed; in the other.

The different associations in a plant formation show an analogous structure often built up by very diverse species, and no better example of this could be furnished than by the desert vegetation of Texas and Mexico, characterized by succulent Cactaceae, and that of Africa, characterized by succulent Euphorbiaceae. Some of the members of these totally unrelated groups are so similar when not in flower as to be most readily distinguished by wounding, since the euphorbias possess milky juice which the cacti do not. Each association is distinguished by the presence and relative abundance of certain species and the absence of others. Those which are almost invariably present in a community are termed *constants*, but their diagnostic value is often low owing to their constancy in more than one association. Examples are furnished by *Mercurialis perennis* in the beechwoods of Britain and *Viola sylvestris* in the oakwoods. Of greater significance are the *characteristic* species which occur more or less exclusively in a particular community, as *Hordeum sylvaticum* and *Monotropa hypopitys* in the beechwoods of Britain or *Psamma arenaria* on European sand-dunes. Such characteristic species may be at the same time constants but are often of local occurrence. Many of the subordinate or accessory species are found in a variety of communities but have their characteristic frequency in each.

Succession. — Careful observation shows that, quite apart from the periodic rhythm of the seasonal changes, no community is stable. The physical environment itself is slowly altering, partly as a consequence of climatic action, partly through the influence of the living covering. Commonly, these changes are too secular in character to be readily appreciated, and it is only where the alterations in the physical environment are unusually rapid that the existence of a definite life-history in the plant community can be easily observed. In general, the tendency is for communities characterized by extreme conditions, as of dryness or wetness, to approach the mean. The process is well illustrated by the formation of sand-dunes, where the early stages consist of sandy accumulations around plants of marram grass (*Psamma*) or other pioneer species; these by their continued growth, as fresh layers of sand are added, not only stabilize the sand but by the decay of their older parts add organic material and so materially increase the water-retaining capacity of the soil. With the consequent amelioration of the extreme desert conditions species less specialized than the first colonizers can become established, and so there is a cumulative increase in the stability and quality of the habitat. The original dune-units increase in size and coalesce. so that the "yellow dune" gives place to the "grey dune," carpeted with continuous vegetation, and ultimately comes to bear scrub or even forest. Similarly the first occupation of the submerged mud in some estuary by almost microscopic seaweeds is the vanguard of a sequence of plants which progressively raise the level of a salt-marsh till it becomes pasture often of high economic value. The zones of vegetation which can be seen bordering the margin of a shallow lake present a sequence in space from within outwards which corresponds closely with the sequence of changes in time which led to the present condition of the outermost. Another familiar example is the passage of enclosed pasture to scrub and finally woodiand. In such *successions,* as these sequences are termed, each phase is distinguished by the presence of certain species, and the number and size of these tends usually to increase as the succession proceeds. Frequently in the final stages, however, one or two species again come to predominate, and since these often determine the physiognomy of the community they are frequently referred to as the *dominants.* Successions have been extensively studied by American ecologists and F. E. Clements has utilized this aspect as the basis for a classification of plant communities.

Competition.—Except perhaps in the so-called "open" communities such as those of deserts, where the individual plants are separated by bare soil, there is probably always direct competition between the constituent members. The conditions of the habitat exert a selective action, stimulating the development of certain species and depressing the vigour of others. If protected from competition many species can grow in habitats where they do not occur naturally. Many aquatics can survive under terrestrial conditions, and a large proportion of alpines succeed under cultivation in the lowlands. It is thus commonly not a question of whether or not a species can grow, but whether it can grow well, and competition often resolves itself into a capacity to obtain the requisite share of such essentials as light, air, water and mineral salts. In competition for light the naturally taller species is at an advantage; it can grow above and shade its competitor. Thus, wherever soil and climate can support forest vegetation, this tends to be the end phase or "climax" in the succession. So, too, trees which cast a deep shade are usually successful in competition with those having a light canopy. The birch, which by reason of its light wind-born fruits readily colonizes denuded woodland areas, eventually gives place to trees of heavier canopy such as the oak. Large size, however, is usually associated with delay in reproductive activity and the prolonged life-history renders the arboreal habit less successful than the herbaceous under the stress of conditions imposed by the presence of man. This is reflected in the steady diminution of the area occupied by natural forests.

Almost any feature in the organization or life-history of the individual which fits it for its particular habitat is at the same time a passive agent in its survival; but amongst the features which may be regarded as of importance in aggressive competition may be mentioned especially the rate of vegetative spread, the annual output of seeds, the efficiency of the mechanism of dispersal, and the extent and character of the root and shoot systems.

Economic Aspects.—Finally, mention should be made of the importance of the study of plant communities and their successions for the proper control and exploitation of forests and the maintenance of high yielding pastures. The naturally occurring species of an area serve as a valuable guide to agricultural practice, since their presence is in effect a product of the complex built up of soil and climate. A study of the natural relations of species is, moreover, a useful guide to their artificial juxtaposition in the practice of agriculture, forestry and horticulture (*qq.v.*).

PHYSIOLOGY OF PLANTS

The physiology of plants deals with the functions of the living plant as morphology and anatomy deal with form and structure. Physiology aims to explain the functions of an organism in terms of physical and chemical processes. Physiology thus considers the living organism solely from the mechanistic standpoint, *i.e.,* from the standpoint that the organism is a machine albeit a very complex one. In this attempt to explain the organism in the terms of a machine the physiologist is supported by the fact that the organism appears to obey so-called physical laws in much the same way as does dead material. The living organism for example obeys the law of the conservation of energy, the amount of energy given out by the organism being equal to the amount taken in in food; again the plant or animal conforms also to the second law of thermodynamics which relates to the use of free energy.

Characteristics of Living Organisms.—Although it is impossible to give an exact definition of a living organism some of its characteristics may be pointed out. Whether one is dealing with a plant or animal of a single cell, or of a large organism such as an elephant or a tall tree, it is evident that it is a machine constructed to carry on certain processes, such as the absorption or building up of food; the process of respiration (*see* below) and the processes of growth and reproduction. One great difference between the living machine and any other machine is that the living machine is infinitely more complex than any man-made machine. Then again the processes going on in the organism are not independent of one another but are to a high degree, what is called, *integrated.* All the processes are interlinked or related, the finished material of one process being often the raw material of the next, and all being so closely associated as to lead to movement or growth or reproduction or some other activity of the organism. Another marked characteristic of the living machine which distinguishes it from all other machines is its power, to put it colloquially, to build itself up as it goes along. In other words the growing organism is a functioning unit which adds to itself and increases the size of the machine by its own functicnal activity. Another characteristic of the plant or animal is its constant reaction to the environment and its constant adaptation to changes in the environment. It is true that a carefully dried seed kept at a low temperature may appear to be quite inert, though still alive as is shown by its power of germination under suitable conditions; yet all active organisms show a constant interchange with their environment. Even in the case of the seed it is probable that some interchange, such as respiration, is still going on though at such a slow rate that our present methods of analysis are too coarse to recognize it. Another characteristic of the organism is that any apparent steady state or equilibrium is not a *static* but a *dynamic* one. If the normal organism appears to be in an inactive state it is simply that the constructive processes just balance the destructive processes, not that the processes are at a standstill. The living organism is like a battery which is constantly running down and requires constant recharging, though the recharging goes on at the same time as the discharging. The majority of cells require oxygen for their mere continued existence even in a resting condition and additional oxygen when in a state of activity. This need of oxygen even during quiescence indicates that a quiescent state of the cell is only an apparent quiescence, a state of dynamic not static equilibrium. Again the giving out of heat by all living organisms even when apparently inactive indicates the dynamic equilibrium of chemical processes going on in the cells. These exceedingly intricate processes continue unceasingly throughout the life-period of every cell in the simplest as well as in the most complex organisms.

Organization of Cell.—A11 living cells contain, or consist of, a viscous, glairy material (somewhat akin in consistence to unboiled white of egg) known as protoplasm. Protoplasin is not of course a single substance but a very complex system; it has been described as the "physical basis of life" since life as far as we know, does not appear to exist apart from protoplasm. An analysis of an active plant tissue, like lettuce or beet leaves, shows that it contains about 90% water. Of the dry material we should find carbon 38·19%, hydrogen 5·1%, oxygen 30·8%, nitrogen 4·5% and ash 21·5%. Similar results would be found for most plant material in the dry state though resting materials such as the potato tuber and the wheat grain would have only 2–4% of ash. Active protoplasm, and living material generally, is characterised by a high percentage of carbon owing to the large amount of organic matter, and in plants by a high percentage of oxygen owing to the large amount of oxygen-rich materials as carbohydrates (sugars, starch). A small proportion of nitrogen is also always present in living material. In ordinary analyses of plant material the protoplasm is only a small proportion of the material, a large proportion is dead cell-wall material, the contents of the cell vacuole (see above, Cytology), and protoplasmic inclusions. The nearest approach to an analysis of protoplasm is that which has been made of certain myxomycetes (see FUNGI) which exist as naked masses of protoplasm. Kiesel (1925) has examined Reticularia lycoperdon. He finds in a hundred parts of the dry weight.—protein, 29·1, other nitrogenous substances, 12·0, nucleic acid, 3.7, oil 19·1, carbohydrates generally 9 9, glycogen 15·2, also lecithin and cholesterol. This analysis is of course very incomplete; 6% of the material was not determined and a large number of substances present in small quantities only must have been overlooked. We note, however, the large amount of protein and this is a general phenomenon; just as we find life associated with protoplasm so we find protoplasm associated with protein.

It is clear that protoplasm must be a material, or rather a system of materials of very special nature since the enormous number of chemical reactions associated with life processes go on within it, and are apparently controlled and brought by it into proper co-ordination. Protoplasm also is concerned with the hereditary process, with the handing on to the male and female cells and from cell to cell in the body of the plant or animal, of the special qualities which cause the offspring to resemble their parents. (*See* CYTOLOGY)

The modern theory of the special peculiarities of protoplasm associated with its life activities may be termed the *physico*-chemical theory. In this view stress is laid not so much on any special organization of the protoplasm as on its peculiar physico-chemical condition.

It is pointed out that proteins are colloidal in nature or rather exist in the colloidal state (see COLLOIDS) and that, on one hand, many of the peculiarities which distinguish chemical processes in the living organism from the same processes occurring in the laboratory, and the peculiar co-ordination of processes which marks the living cell—and indeed of the whole organism for the harmony of the working of the plant or animal body is a commonplace—are related in some way with the colloidal nature of the protoplasmic substratum in which they occur. It cannot be said, however, that the colloidal theory carries us very far. We know that material in the colloidal state exhibits an enormous extension of surface and that substances may accumulate on this extended surface (by a process known as adsorption) and react together at a much faster rate than would otherwise be the case. The theory, however, does not explain how the numerous chemical processes going on in the cell are on the one hand kept from interfering with one another, and yet on the other hand are brought into close interrelationship and co-ordination. Still less can a colloidal theory explain the even more complicated processes of growth, of *differentiation* (the development of new and different parts as the plant or animal develops), and of heredity. It is clear also that the protoplasm is not a simple colloid of two phases, such as are found in gamboge in water where the particles of gamboge are the one phase and the water surrounding them the other phase. In the protoplasm there is not only protein material but oily material (so-called lipin material) appears to be essential and probably also carbohydrates play a part. We know furthermore, that various salts (of potassium, calcium, etc) are necessary. The physical relationship of the colloidal protoplasm must therefore be far more complex than that of any colloidal material studied in the laboratory. Any attempt to explain the peculiar relationship of the processes occurring in living organisms by reference to the behaviour of a complicated, dead, colloidal medium is largely speculation since the behaviour of such a medium is unknown.

Enzymes.—When dealing with the colloidal organization of the cell reference must be made here to the substances known as enzymes (*q.v.*). These are substances of unknown nature which can be extracted from dead cells whether plant or animal, and they must certainly play a very large part in the chemical processes going on in the living cell. They have three marked characteristics; they can act as catalytic agents, *i.e.,* they cause many chemical processes to go on at a much faster rate than would otherwise be the case; in chemical language they accelerate; they can thus cause rapid changes to occur which in their absence require a high temperature or the action of strong acids or alkalis. Secondly they act in very minute quantities and do not themselves appear to be used up in the process which they accelerate, for example invertase can break down 1,000,000 times its weight of cane sugar. Thus they partake of the nature of chemical catalysts Thirdly they are usually sensitive to heat (thermolabile) their activity being usually destroyed by temperatures well below that of boiling water. It is to be noted that the processes they accelerate may be either breaking down processes or building up (synthetic) ones, and that they can accelerate both such processes. Enzymes have been very actively investigated of late years especially by Willstatter and his pupils, but their nature is still obscure. They seem to be a part of the mechanism of the living cell by which the rate of various chemical processes are controlled. These enzymes seem to be of colloidal nature, or to have a colloidal carrier, though apparently they are not of protein nature; and furthermore their action is markedly specific, that is, the enzyme which affects the rate of one chemical process is unable to affect the rate of another process of marked chemical similarity. For example, sugars closely related in chemical composition require different enzymes to bring about changes in them. This is one of the puzzling aspects of cell physiology for it seems difficult to believe that the cell has a battery of enzymes to carry on the very numerous chemical processes with which it is concerned. Enzymes can, of course, only be studied outside the cell and it may be that the conditions in the living cell are different.

In relation to the cell organization it must be pointed out that many of the processes going on in the cell are *balanced* or reversible reactions, that is reactions which are capable of going in either direction; a good example of this is the formation of fats. These substances consist of glycerol (glycerin) combined with a fatty acid. In the presence of a special enzyme, lipase (found in castor oil seeds and in the animal body), this reaction is capable of going either way, the fat may be split up into glycerol and acid, or the acid and glycerol may be combined to form fat; the lipase accelerates both these processes. Whether the reaction goes in the direction of synthesis or analysis depends not on the lipase but on the concentration of the substances taking part, *i.e.,* fat, glycerol, fatty acid and water. It is probable that by controlling the amount of water available for particular reactions the cell is able to control the direction in which such a reversible process shall go.

WATER RELATIONS OF THE PLANT

It is well known that water is essential for all life processes. A seed may be thoroughly dried and still be capable of germination but it is in a dormant state; for its germination and ordinary activities water is necessary. It seems essential that the colloids of the protoplasm should be swollen (imbibed) with water in order that it may be active. Furthermore all the chemical processes of the cell go on in a watery medium and water is necessary for the solution and reaction of the substances concerned. The more active tissues of the plant generally contain particularly large quantities of water as was seen in the case of the green leaf; in the older and less active parts the percentage of water is less because many of the cells have been reduced to dead husks of cell wall material.

WATER RELATIONS OF THE CELL

As is shown above, under the heading of Cytology, the mature cell consists of a cell-wall lined inside with a thin layer of protoplasm, which itself encloses a central space, the *vacuole,* filled with cell sap. *(See* above, *Cytology.)* The sap contains various dissolved substances, sugars, nitrogenous materials, a variety of inorganic salts and other substances which are sometimes of colloidal nature. Curiously enough the majority of the substances are highly soluble in water and yet if a slice of beetroot is placed in water the amount of material passing out from the sap of the living cells is comparatively small as long as the cells remain alive; the cells on the other hand are capable of taking up water. We have then a peculiar condition of affairs in which water can enter the cell but the passage out of soluble substances present inside the cell is hindered. This effect is due, not to the cell wall which appears on the whole to be dead and inert, but to the living layer of protoplasm which is often known as the *plasma membrane.* This exhibits when living a condition of *semipermeability* since it lets water readily pass in and out, but hinders the passage of certain dissolved substances such as those in the sap. Water is attracted into the cell by the dissolved substances inside just as it would be into a sugar solution enclosed within a pig's bladder, which also roughly is semipermeable allowing water to enter freely but being more or less impermeable to the sugar. As a result of the entry of water the cell becomes swollen up and turgid and exerts what is known as *osmotic pressure* on the elastic cell wall or membrane which is thus stretched. Whole tissues of the plant are thus given a rigidity which is not due to their actual mechanical strength. The dependence of this rigidity on plentiful supplies of water is well seen in the case of leaves and the stems of herbaceous plants which often wilt, *i.e.,* become soft and flaccid, on a hot summer's day. Directly so much water is lost that the wall is no longer expanded, the rigidity of the cell must completely disappear.

Plasmolysis.—That the cell allows water to pass both ways and that the plasma membrane hinders not only the exit but also the entry of various substances into the cell is shown by the action on the living cell of a solution of cane sugar or of some salt such as potassium nitrate, or calcium chloride. If 'the living cell is placed in a solution of one of these substances of a concentration greater than that of the cell sap, water is drawn out of the cell and the cell collapses; this process is known as plasmolysis. It gives a convenient method of measuring the osmotic pressure of the cell. We find that concentration of cane sugar which brings about what is called "incipient plasmolysis," that is, the stage at which the plasma membrane has just begun to be withdrawn from the cell wall at one point. In this condition the osmotic pressure inside and outside the cell must be the same and since the osmotic pressure of the sugar solution can be determined the pressure of the cell sap is known. Osmotic pressure is generally expressed in terms of atmospheres; if a cell has an osmotic pressure of 5 atmospheres, the pressure exerted on a given area of the cell wall is five times as great as the downward pressure exerted by the atmosphere on the same area, which is about fourteen pounds to the square inch. Pressures of 5 to 40 atmospheres are common in plant cells and those of the order of 150 atmospheres have been observed. These pressures seem large but owing to the very small size of the cell the actual forces concerned are small.

Osmotic Pressure, Turgor Pressure and Suction Pressure.—When a cell is supplied with water it goes on absorbing and at the same time expanding with the result that the *backward* pressure of the stretched and elastic cell wall becomes greater and greater, until finally it equals the osmotic pressure of the cell contents; this backward pressure of the cell wall is known as *turgor pressure.* The cell is then fully expanded and fully imbibed and can absorb no more water. If on the other hand the cell is not fully imbibed the osmotic pressure is greater than the turgor pressure and the cell will tend to suck or draw water into the cell. When the cell is flaccid, as in the plasmolysed condition, there is no turgor pressure. It is clear that the difference between the osmotic pressure and the turgor pressure measures the pull with which the water is drawn into the cell; this difference is known as *suction pressure.* The term water absorbing power is sometimes employed but the first is by far the more satisfactory term since we arc dealing with a pressure and not a power. If P=the osmotic pressure of the cell sap, T= the turgor pressure, and S the suction pressure, then $P-T=S$. We see then that the suction pressure is that fraction, if any, of the osmotic pressure left over from balancing the turgor pressure (backward pressure of the wall). When the cell is fully imbibed with water then $P=T$ and so $P-T=0$ and there is no suction pressure. When the cell is flaccid $T=0$ and therefore $P=S$, *i.e.,* the suction pressure is equal to the full osmotic pressure.

As the suction pressure is such an important quantity the question arises as to its measurement. As it represents the pressure with which water is drawn into cell from outside it is evident that if we just balance this pressure inside the cell by an equal pressure outside, the cell will neither take in nor give out water, and therefore will neither expand nor contract, *i.e.,* will remain unaltered in volume. This consideration is the basis of the method of measurement. The cell, the suction pressure of which is to be determined, is placed in purified paraffin oil under the microscope and its volume measured; this gives its normal volume since it does not absorb the oil nor does it lose water while immersed in the oil. The cell is then removed and placed in various strengths of cane sugar solution or some other plasmolysing agent until a concentration is found at which the volume is the same as measured in the oil. If the cell does not change in volume while lying in a watery solution it must be that its suction pressure is opposed by an equal pressure in the opposite direction. This counter pressure must be the osmotic pressure of the-cane sugar solution which just keeps the cell at its original volume. The osmotic pressure of this solution thus gives the suction pressure of the cell in the state in which it was investigated; like the osmotic pressure it is usually expressed in atmospheres.

ABSORPTION OF WATER BY THE PLANT BODY

Water plants are surrounded by a very dilute solution of salts, as in the case of fresh water or a somewhat stronger solution in the case of sea water. Being surrounded by a watery medium the loss of water, and accordingly the need for absorption of water, does not play any very large part in their economy. The conditions are very different with land plants which, in the case of higher plants, often expose very large surfaces to the air and consequently lose great quantities of water in the form of vapour, which passes through the pores in their leaves in the process of *transpiration (see* below). Such land plants must therefore take up larger quantities of water from the soil and the rate at which they can take up water will depend upon the forces with which the water is held in the soil for it is these forces which the *suction pressure* of the cells in contact with the soil have to overcome.

Soil Conditions. — The soil is a very complex material consisting of (a) mineral particles of various sizes and varied chemical composition, *(b)* of organic matter usually in the form of a dark brown material known as *humus* which is derived for the most part from the decomposition of remains of dead plants which formerly grew upon the soil, *(c)* water, which is held by colloidal adsorption in films on the mineral and humus particles and also, to a certain extent, within spaces of the soil, (d) air which is found in the spaces between the soil particles. The air can, of course, be displaced by water, as in the case of a water-logged soil where all the pore spaces of the soil are filled with water. Soils differ very much in what is called their *mechanical* composition, *i.e.,* in the relative amount of particles of large and small size. A sandy soil has a large proportion of large particles, a clay soil has a large proportion of small particles, and to this is due their great difference in behaviour both in relation to water-retention and their response to mechanical treatment (*e.g.,* ploughing) and to fertilizers. The relation of size of soil particles to the water holding power of the soil is particularly important in reference to the physiology of the water absorption of the plant from the soil, and attempts have been made to estimate the relative forces with which the water is held by different soil constituents. Briggs and McLane working in America determined the amount of water held back by various soils when they were whirled round with enormous rapidity in a centrifuge;

the centrifugal force resulting from the rapid rotation at first causes water to be thrown off but it is finally balanced by the water retaining forces of the soil particles. By comparing the behaviour of a number of different soils of different compositions they deduced that if the water holding capacity (moisture equivalent) of the particles of size 2.0 to 0·05 mm. diam. (*i.e.,* coarse and fine sand) be taken as unity, the corresponding equivalent for the particles of below 0·05 to 0·005 mm. diam. (silt) is 12, while that for the particles of less than 0·005 mm. (*i.e.,* clay) is 57. The silt is partly colloidal, and the clay highly colloidal, and the high water-holding power is due to the colloidal properties. The humus also is of colloidal nature and of marked water-retaining power and its capacity in that respect may be taken as about the same as that of the colloidal clay. The forces with which the water is held in different soils and in the same soil with different amounts of water has been investigated by Shull by what may be termed a biological method. It is well known that dry seeds will take up water actively and often with considerable force, the amount they can take up depends upon the force with which the water is held in the medium from which it is being taken. The method consists then in placing dry seeds in different soils with different content and determining the amount of water taken up after a given period, say 48 hours. Similar seeds are then placed at the same temperature, (a) in concentrated solutions of lithium chloride and sodium chloride of high osmotic pressure, or (b) over sulphuric acid of different concentrations. If the seed takes up in the same time the same amount of water from a given soil as from the salt solution or from the moist air over sulphuric acid the water retaining power of the materials in which the seed is placed should be the same. Now the osmotic pressures of the solutions—which represent the forces against which the water-absorbing forces of the seeds are acting—are known and so the water holding power of the soil can be expressed in atmospheres. The results show that the water absorbing power of the seeds is very high, for they will take water from a saturated solution of lithium chloride which has an osmotic pressure of nearly a thousand atmospheres. They show also, as was to be expected, that in an ordinary loam soil the forces with which the water is held go up markedly as the water becomes reduced in amount. In a silty loam investigated the forces holding water were negligible when there was 20% of water in the soil, but when it was reduced to 15% the forces were several hundred atmospheres and when reduced to about 10% of the order of 1,000 atmospheres pressure. With sand the condition is very different for the material is non-colloidal and the water is only loosely held; only when the water content is reduced to a very small amount does the pressure become considerable.

Dynamic Relations of Water Absorption.—The observations which have been described above only gives us a picture of static equilibrium between the plant and the soil. They show what the conditions are when there is a balance between the forces pulling water into the seed (or root of the plant) and the forces holding the water in the soil, that is they show us the condition when water is no longer taken up. This, however, though helpful, as giving some measure of the forces which the root has to overcome, gives us a very imperfect picture of the relationship to the plant. The plant is continually giving off water in the process of transpiration and unless the rate of absorption keeps pace with the rate of loss of water the water content of the plant will begin to fall. The plant will flag when this difference in the two rates has existed for a short period and the plant will be dead long before the rate of absorption has fallen to zero. The equilibrium between absorption on the one hand and loss of water by transpiration on the other is thus, like the equilibrium in the living cell, a dynamic not a static one.

TRANSPIRATION

The term transpiration is applied to the process of loss of water vapour from the aerial part of a land plant; it is of the nature of controlled evaporation. The transpiratory losses take place mainly from the leaf surface since these organs expose a large surface for evaporation and are supplied on the epidermal surface with pores known botanicaiiy as stomata. (See above, *Anatomy.*) These pores interrupt the otherwise continuous layer of *cuticle* which covers the surface. In its absence the loss of water from the leaf surface would be very large and uncontrollable. The cuticle is, however, not completely waterproof so that we can distinguish cuticular transpiration and *stomatal* transpiration. The second is very much the larger, being usually 80–97% of the whole, though under special conditions, as in a tropical rain forest, the cuticular transpiration may be as high as the stomatal.

Measurement of Transpiration.—That transpiration occurs can be shown by the loss of weight of a potted plant, when the pot and surface of the soil are protected from water-loss by rubber sheeting; this gives a convenient method for measuring the rate of transpiration. It is not applicable to plants growing in the ground; for such plants paper dipped in a cobalt chloride solution, dried and applied to the leaf may be employed. On the absorption of the water vapour coming from the leaf the colour of the cobalt chloride paper changes from pink to blue, and the rate of this change gives some measure of the rate of transpiration.

Size and Arrangement of Stomata.—The stomata are more commonly confined to the lower surface of the leaf—the cuticle on the upper surface being then continuous, though leaves with stomata on both sides frequently occur. The stomata are very small pores, those of the sunflower leaf being about $\frac{1}{100}$ of a millimeter (*i.e.,* about $\frac{1}{2500}$ of an in.) in diameter. They are very numerous, varying from 40 to 300 per square mm.; a sunflower leaf may thus bear 13,000,000 of them. The pore is bounded by two special cells known as guard cells (as described in the anatomy of plants) and open below into a chamber which is bounded by the walls of the green cells (*mesophyll*) of the leaf. These cells are full of water and from their wet cell walls water naturally evaporates into the space, and by the physical process of gaseous diffusion passes out of the stomatal pore into the drier air outside. As the stomata occupy a very small proportion of the total surface it might be supposed that the rate of passage of a gas or vapour out or in would be very slow. It was shown, however, by Brown and Escombe in 1900 that such very small pores allow of a much greater rate of diffusion than might be expected. It is found that provided the pores are not too close to one another the rate of diffusion is proportional to their diameter and not to their area.

Effect of *Various* Conditions on the Rate of Transpiration.—Transpiration like most physiological processes is markedly affected by external conditions. Since the process is essentially one of evaporation, one of the most important factors (the term factor is applied to a particular condition affecting the rate of a process) is the humidity or relative dryness of the air to which the plant is exposed. The drier the air the more rapid, on purely physical grounds, will be the rate of diffusion of the water vapour through the stomatal pore. This is due to the big difference of the water content (humidity) of the air below and above the pore. The proper measure of the evaporating power of the air is not the actual relative humidity (or percentage saturation of the air) but the saturation deficit and this is markedly affected by temperature. Air 70% saturated at 10° C has only about half the saturation deficit of air 70% saturated at 20° C, and so its evaporating power is only half. Temperature itself has very little effect on transpiration or evaporation except in so far as it affects the evaporating power of the air. Atmospheric pressure has only a slight effect since evaporation tends to go up with a fall in barometric pressure but it is so small that it can under ordinary conditions be neglected Wind is a very important factor in transpiration. It is well known that plants suffer very much in windy situations and "wind-breaks" are often put up for plant protection. The ill effect is mainly due to the enhanced rate of transpiration, which is the direct physical effect of the removal by the wind of the layers of air in contact with the leaf.

Effect of Light.—If the rate of transpiration is measured, say by weighing a potted plant under appropriate conditions, it is found that the water loss is much greater by day than by night and this occurs even if the evaporating power of the air and the temperature are kept constant. It is a well known effect of light upon the higher terrestrial plants. This effect occurs in an ordinary diffused light so it cannot be due to the heating effect of the rays, for in such circumstances such effect is practically negligible. The effect produced by the light must be due to some change in the leaf itself since the factors affecting evaporation have remained unaltered. As the transpiratory water loss is through the stomata we should expect some change in the size of the pore, and it is found that in the majority of leaves light causes a widening of the stomatal pore and darkness a partial closure.

Stomatal Action.—As already stated the stomatal pore is bounded by two guard cells and it is by changes in their shape that the alteration of the pore is brought about. Their shape, the relative thickness of their inner and outer walls, and their attachment to the epidermal cells are such that when they become more turgid their inner walls—those facing the pore—move apart and so the pore widens, while on a reduction of turgor these walls approach one another and the pore becomes less in size. When the cells become collapsed, as in drying or by plasmolytic agents, the size of the pore is very much reduced though probably not to zero.

The mechanism by which light brings about alterations of turgor in the guard cells has been much disputed. It has often been held that the stomata open in light owing to the increased turgor due to the accumulation of sugars produced by the assimilatory activity of the chloroplasts of the guard cells. This view is quite untenable for the guard cells open in the light in the absence of external supplies of carbon dioxide. Lloyd (1908) also has shown that guard cells containing only leucoplasts behave similarly to normal ones. It was shown also by the same observer that the guard cells in the early morning, when the pore is closed, show much starch, which disappears during the day to reappear again in the evening when the stoma closes. This led to the view that the light affected the starch-sugar ratio in the guard cells. In the day insoluble starch would change into soluble sugar and the turgor of the cell rise, in the night the sugar would change back to starch and the turgor fall. The turgor changes would bring about the corresponding changes in the size of the stomatal pore. This view received support from the observations of the osmotic pressure of guard cells. In *Rumex* patientia, for example, it was found that the osmotic pressure of the guard cells is 23 atmospheres when they are fully open, about midday, while only 13–14 atmospheres when the pore is closed at night. It is found that in addition to light other factors such as neutral salts and acids and alkalis affect the starch-sugar relation and so stomatal movement. This is rather what might be expected since the change from starch to sugar and the reverse is almost certainly an enzymic one. Further work by G. W. Scarth in 1926 indicate that acetic acid and ammonia, *i.e.*, both acid and alkali, will cause the opening of the stomata; in an intermediate range where there is slight acidity the guard cells remain closed. This suggests that what the guard cells respond to is a change in the concentration of free hydrogen ions (*i.e.*, the free hydrogen parts of the acid molecule when it is dissociated in water) of the solution. In this view light affects the "acidity" of the leaf as a whole either by altering the content of organic acids in the cells, or the concentration of carbonic acid by affecting the rate of assimilation. There are indications that the effect is more complex and that the change in the starch-sugar ratio is too slow to explain the rapid turgor changes that occur. It is probable that there is present in the cell sap of the guard cells some colloidal material which absorbs water and that the amount of water the colloid takes up is altered by changes in the concentration of the hydrogen ions of the cell.

Control of *Transpiration* by *Stomata*.—The question of the control of the rate of transpiration by the stomata has also been much debated. The older view was that the opening and closing of these pores had an important controlling effect. This view was abruptly called in question by Lloyd in 1908 who denied the regulation of water loss of leaves through stomatal closure. It is clear from later work that the stomatal aperture may vary widely while the rate of transpiration shows no corresponding change; thus the stomata may go on opening in the middle of the day while the transpiration rate falls. The matter is again complicated by the fact that the rate of loss of water vapour by the stomata is also affected by the accumulation of moist layers of air upon the surface of the leaf. If the stomata open more widely when such layers are present there may be little possibility of any faster diffusion of water vapour through the pores. Calculations indicate that in still air the layers of moist air on the leaf exert the most effect, and it is only when the stomatal pores have become very narrow that the pores can have a controlling action. In wind, however, these moist layers are removed and the stomatal pore can exert a controlling action at any degree of opening. It must be borne in mind however that the stomata are very sensitive to light but their response to losses of water by the leaf are slow, so that they cannot keep the water content of the leaf constant by controlling the stomatal pore.

Direct Action of Light on Leaf Cells.—As already described light markedly increases transpiration by causing the stomata to open, but the question arises as to any possible direct effect on the mesophyll. It was claimed by Francis Darwin (1914) that in a leaf which had been vaselined on both sides, to block the stomata, and then slit so that the mesophyll cells transpired directly into air, light still increased the rate of water loss by as much as 36% in the case of the leaf of ivy. Such a huge increase seemed very unlikely, so the matter was again investigated by Henderson (1926), who showed that, when all allowances were made for possible changes of temperature, light did produce an increased rate of evaporation from the mesophyll cells of the leaf to the extent of about 5%. The exact mechanism of this is obscure; it is probably some effect on the resistance of the protoplasm to the passage of water through it to the surface of the cell. In the light the cell wall would be more fully imbibed, *i.e.*, wetter than in the dark.

Advantages and Disadvantages of Transpiration.—This question is often debated, the extreme positions being (1) that the process is an *unavoidable* evil, (2) that it is a physiological necessity. The idea of its physiological necessity is mainly based on the view that the water and the inorganic salts that the plant requires are taken in together in the form of the very weak solution which occurs in the soil, and that the excess water must be got rid of in transpiration. This view is based on the erroneous assumption that water and salts enter the plant together. As a matter of fact the forces bringing about the entry of water and the entry of dissolved salts into the root cells are of an entirely different nature; the two must enter quite independently. Whether transpiration is an "evil" may be debated but it is perfectly clear that given the necessity of taking in gases from the air, the loss of water by plants is quite unavoidable. The same pores which allow the entry of gases must also allow of the passage out of water vapour. The plant could only stop such water loss by having a continuous cuticle, and then the supply of carbon dioxide for the manufacture of sugar and starch would almost completely be cut off. The loss of water by transpiration is a necessary result of the construction of the plant. It has been suggested that a rapid stream of water rising in the wood (see below) is necessary to convey the salts to the leaves, but it is found that a reduction of transpiration does not necessarily reduce the accumulation of salts in plants. It may be that some *minimum* rate of upward water flow is necessary to transport the salts to the higher parts of the plant. Transpiration may also play some small part in keeping down the temperature of plants exposed to the direct rays of the sun.

MOVEMENT OF WATER IN THE PLANT BODY

The water that enters the plant from the soil ultimately escapes from the leaf surface passing through the stomatal pores in the form of water vapour. The question arises as to the path taken by this water. It has been known a long time that the main body of the water passing through the vascular plants travels by way of the xylem, *i.e.*, the wood. (See above, Anatomy.) The evidence for this is various. It is found that if the trunk of a tree is "ringed," *i.e.*, cut through right down to the wood throughout the circumference of the tree, water continues to pass up the tree for a long time and apparently unhindered. Again if cut shoots are placed in a solution of a dye such as eosin, the wood alone is deeply stained showing that the dye solution has travelled up through this tissue. The frequent occurrence in the wood of wide open tubes containing no protoplasm also indicate its function as a conducting channel.

Passage of Water Across the Root.—The root as anatomical studies show, usually exhibits elongated outgrowths from certain of its superficial cells. These outgrowths are known as *root-hairs* and serve to increase the surface of the root available for absorption. These hairs are in contact with the films of water on the soil particles and they can withdraw water from the soil if their suction pressure *(see* above) is greater than the imbibition forces of the soil, *i.e.,* the forces tending to retain the water in the soil. The water thus absorbed, if it is to reach the leaves, must pass across the root to the xylem strands and the question arises as to the mechanism of this transport. It has been shown by the work of Ursprung and Blum that there is a *gradient of increasing pressure* from the root hair to the endodermis; by this means the water will pass from cell to cell across the cortex. At the endodermis there appears to be some abnormal condition for in the absorbing root of the broad bean it is found that while the suction pressure rises from outside to the sixth cortical cell from 0·7 to 3·0 atmospheres, yet at the endodermis it falls to 1.7 atmospheres; as a result the direction of movement of the water should be reversed and the water pass back again; this cannot be the case so the matter requires further investigation.

Ascent of Water in the Wood.—That the water rises in the wood to supply the needs of transpiration is well established, but the mechanism of this rise has been much disputed. It is clear that any explanation must meet the extreme case of the tall leafy tree. Now a single tree may lose many gallons of water a day in transpiration and a blue gum tree (Eucalyptus) of Australia or a Sequoia of N. America may reach a height of 300 ft. or more. A mechanism has thus to be found which will not merely hold up a column of water at a height of 300 ft.—this is merely a problem in statics—but one that will drive (or pull) many gallons of water a day to this height. Many different forces have been invoked to explain the rise. The force of capillarity has been called in but measurements of the size of the wood vessels show that capillarity will not explain the rise of water to the height of a tall tree, let alone the continued movement of the water upward. Then again atmosphere pressure has been suggested as concerned in the movement, but such a pressure would only explain the rise of water to a height of a little over 30 ft. "Root pressure" has been called in as the motive power for the rise of the transpiration stream. When the stem of a wood plant is cut across near the ground a flow of sap under considerable pressure may occur from the wood of the cut stump; the pressure bringing about this flow is known as root pressure. Unfortunately for this explanation no pressures have been observed which are adequate to explain the rise of water to the top of a tall tree. Again root pressure is found most active in the spring, while the transpiration stream flows most actively in the summer. Then again we have the so-called *vital theories* of the cause of the ascent of sap in all trees. In these theories the living parenchyma cells which are so characteristic of the wood are supposed to exert a pumping action. They are assumed to take water from a lower wood vessel and pump it into a higher vessel with which they are in contact.

The objections to these vital theories are mainly twofold; they are inconsistent with experimental data and also with the known structure of the wood. The strongest experimental evidence against vital theories is obtained from the results of poisoning experiments. E. Strasburger carried out in 1893 some classical experiments with an oak tree over 70 ft. high and with tall climbers like wistaria and hop. The oak was cut off at the base and the cut end placed in a tub of picric acid, a highly poisonous yellow solution, which was found to be taken up in considerable quantities. After three days in this fluid the trunk was placed in a solution of a reddish dye (fuchsin) and there left for another six days. The oak trunk was then split down the middle when it was found that the yellow poison had been drawn up to 70 ft., and among the yellow stained wood were red patches showing that the dye had been drawn up *after* the picric acid, *i.e.,* through the *dead* wood. In the case of the two climbers lengths of 30–40 ft. were killed by heat when it was found that, as in the oak, coloured solutions were drawn up through the stems in spite of the killing of the living cells. These experiments seem to show clearly that fluids will rise in the wood of tall plants without the intervention of the living cells of the wood.

Cohesion Theory of the Ascent of Sap.—It is evident that in the absence of a pumping mechanism in the wood itself the water rising must *either be pushed from below or pulled from above.* Since water will rise even in tall trees when they are severed at the base some pulling force from above would appear to be acting and it can be demonstrated that a cut leafy shoot does exert a pulling or sucking force on a column of water. If a glass tube is fixed with an airtight junction to the lower end of a small leafy branch of a tree (the wood being bared at the point of junction), water will naturally rise in the tube. If the tube is filled with boiled water and the lower end placed in a dish of mercury, the mercury will be drawn up after the water. Under favourable conditions when no air bubbles develop in the system the mercury column will be raised *to a height above that of the barometric column.* This demonstrates that the cut branch exerts a definite sucking force on the water column. The same fact could be demonstrated without mercury using water alone in the tube, if the space above the water in which the tube dipped was exhausted of air. More elaborate experiments of this type show that a transpiring branch will exert a pull of 7 to 8 atmospheres. Such experiments demonstrate not only the sucking force exerted by *a* cut leafy shoot but also a peculiar physical property of a fluid such as water and mercury, namely, its cohesion or tensile strength. If a column of water or mercury is held up in a vertical tube without being supported from below, it must evidently be held by a pull from above. If, however, the fluid is transmitting a pull its particles must cohere together like the particles of a steel wire. Now it is found that if a fluid, like water, be free from air bubbles and is enclosed in a rigid tube to the wall of which the fluid *adheres,* it can then transmit a very considerable tension, owing to the attraction of the water particles for one another which is spoken of as their *cohesion.* Under conditions spoken of, with the fluid adhering to the walls of a rigid tube, the fluid is unable to change its shape and hence, as the result of its cohesion, is able to transmit a pull like a steel wire. By experiment it has been shown that in the case of water this cohesion or tensile strength is very great, for it requires over 200, and probably over 300, atmospheres to rupture a column of water.

The cohesion theory of the ascent of sap asserts that the water threads in the water channels of the wood are adhering to the wet walls of these vessels (and of the tracheids) and that these water threads can transmit any pull exerted on them at the top. Any cross-walls in the wood channel do not interfere with the practical continuity of the water columns since these walls are fully soaked with water. As has already been explained transpiration losses take place from the cells abutting on the intercellular spaces in the leaf, with a consequent increase in their suction pressure. As a result they take water from neighbouring cells and those with rising suction pressure will take water from the tracheids found in the fine vascular bundles (veins) of the leaf. The water columns in these dead tracheids are continuous with those in the rest of the wood channels in the plant, and the result of the withdrawal of water by the leaf cells is that these columns fall into a state of tension which is transmitted throughout the plant and thus down to the roots. The pull of the mesophyll cells in the leaf is thus felt by the cortical cells of the absorbing root, and water is drawn from them into the wood and their suction pressure goes up. This leads to water being taken from cells farther and farther towards the outside of the root, and so to loss of water from the root-hair which takes water from the soil; thus the chain of cohering particles extending from the soil to the leaf is complete.

Difficulties in the Cohesion Theory.—The cohesion theory certainly provides the most satisfactory explanation of the rise of the transpiration stream in tall trees. There are one or two difficulties, however, presented by the theory, one of which is in respect of air bubbles in the woody tracts. If sections of the wood are cut with great precaution a certain number of the wood channels are always found to contain air bubbles and therefore to be out of action. If the number of these air-containing channels went on increasing from year to year the proportion of blocked channels might be very high, though the new ring of wood laid down each year would start without air bubbles. It is suggested by Dixon that root pressure which develops in the spring would compress the air bubbles, by pushing the columns from below, and so cause their solution. It is doubtful, however, if root pressures occur of the magnitude necessary to bring about the solution of the bubbles at the top of a tall Sequoia tree. On the other hand the bubbles found in sections of the wood may be artefacts, *i.e.,* produced in the cutting of the sections. From the observations of H. R. Bode it seems doubtful if bubbles exist at all in the water-conducting tracks of herbaceous plants under normal conditions, and the case may be the same in woody plants, though the bubbles seem to develop very easily; this question of air bubbles in the wood requires further investigation. Another difficulty lies in the behaviour of dead leaves. The cohesive theory it must be remembered is a *purely* physical theory. All it requires is one membrane evaporating into dry air, another membrane in contact with a water supply, and the two connected by a continuous water thread under such conditions that it can support a tensile stress. Accordingly if we kill a leaf with chloroform vapour while still attached to the plant it should continue to draw up water as its cell walls are still directly continuous with the water supplies of the stem. One would expect the leaf cells to collapse owing to the loss of osmotic pressure but not to dry up; we find, however, that such a dead leaf soon dries. This suggests that though the cohesion theory rightly envisages the main factors in the rise of water there are other subsidiary factors which play a part.

ABSORPTION OF SALTS AND PERMEABILITY

As is well known the plant contains considerable quantities of inorganic salts of sodium, potassium, calcium, magnesium and iron and the only source of these is the soil from which nitrates, sulphates and phosphates are also obtained. The water in the soil is not pure but is a weak solution of inorganic salts known as the *soil* solution. The exact composition of the soil solution is doubtful. It must vary much from soil to soil and from time to time in the same soil and it is a matter of great difficulty to separate it from the soil. Estimations give a concentration of total solids in the soil solution from a wet soil of 0·1 to 0·025 per cent or less; a manured soil gives a stronger soil solution than an unmanured one. It is from the soil solution that the ordinary land plant takes up the salts necessary for its growth; unless the essential salts can be supplied in sufficient quantity growth will suffer. It must be added however that a sufficient supply of water and appropriate salts together with a sufficient aeration of the root system are not in themselves sufficient; in addition, the reaction of the soil must be suitable. The soil must be neither too acid nor too alkaline, or to put it more accurately, the concentration of hydrogen ions in the soil must be correct. Olsen (1923) in studying Swedish vegetation demonstrated a remarkable agreement between the concentration of hydrogen ions in the soil and the distribution of various plants. The presence of lime or chalk in the soil is of great importance in relation to soil reaction since lime neutralizes acidity. The addition of lime will often raise an infertile "sour" soil to a fertile level. The striking response of some plants to lime-rich or lime-poor soils may be related to the hydrogen ion concentration of the soil.

The Essential Salts.—Plants which normally grow in the soil can be grown successfully in water cultures, *i.e.,* in a solution of salts, or in quartz sand watered with such a solution. A solution of this kind may consist of water 1,000 grams, potassium nitrate 1 gm., calcium sulphate 0·5 gm., magnesium sulphate 0·5 gm., calcium phosphate and ferric phosphate each 0·25 gm. In this or similar solutions plants may be grown successfully for many generations. If any of the elements, nitrogen, sulphur, phosphorus, potassium, calcium, magnesium and iron are absent, the plant suffers, indicating that these elements are essential to the plant. The sodium and chlorine which plants absorb from the soil do not seem to be essential for plant growth. Moreover, small quantities of boron are absolutely necessary for the proper growth of such a plant as the broad bean. We know, in addition, most of the essential salts appear to be poisonous when given alone and that salts have an antagonistic action to one another, each neutralizing the toxicity of the other. The culture solution has thus to be a balanced solution in which the various toxicities cancel out.

Absorption of Salts.—When the water relations of the cell were discussed it was pointed out that the plasma membrane of the cell was of a semi-permeable nature, in that it held back soluble substances in the cell sap while showing a permeability to water. The fact that plants contain inorganic salts which they have taken up from the soil shows that the cell is not completely impermeable to dissolved substances, as does the fact that such substances as sugar travel about the plant. It is found, as we should expect that when salts (such as potassium nitrate or sodium chloride), or even cane sugar, are used as plasmolysing agents that the substance enters sooner or later and plasmolysis disappears. The entry of salts into the cell raises the whole question of the nature of the living plasma membrane and the forces which are concerned in bringing about the passage of substances in and out of the living cell. The subject, however, is as yet a very confused one and has recently been reviewed by Stiles. On simple physical principles a salt should go on entering and accumulating in a cell until the concentration inside and outside the cell is the same. If, however, a slice of carrot is placed in a solution of potassium chloride the salt goes on accumulating in the cell until the concentration inside is apparently many times (even 25 times) that outside. Again as Osterhout has shown, if the sap of the large cells of the seaweed Valonia is analysed it is found that the concentration of potassium inside the cell is over 40 times that of the sea water outside. On the other hand the concentration of sodium is five or six times as great in sea water as it is in the cell sap. The fact that the living plasma membrane can keep permanently between its two sides so great a difference of concentration as that of potassium shows that it must be of very peculiar nature.

Changes of Permeability.—As might be expected from the fact that the accumulation of substances in a cell is a fluctuating quantity one finds that the permeability of a cell is not constant; in other words the rate of entry or exit of a given substance may be changed by external conditions. For example the permeability of a cell to a particular dye may be markedly affected by the nature and concentration of a neutral salt in the dye solution. Since the plasma membrane contains a high percentage of protein and the physical condition of such substances is altered by many salts, the change in permeability is not unexpected. Then again we find that the rate of entry of one salt into a cell is altered by the presence of another salt. Weak solutions of sodium chloride and calcium chloride, which by themselves do not plasmolyse a cell, will do so when mixed. The effect seems to be due to the calcium ion altering the membrane in such a way as to hinder the entry of the sodium ion—another example of antagonistic action. Again it has been claimed that light increases the permeability of the cells in the leaf of the lime. Illumination has been definitely shown (Brooks, 1927) to increase the rate of entry of a dye into the *Valonia* cell, and also to increase the rate of diffusion of the salts from the cut surface of a tissue, such as that of the swelling at the base of the leaf-stalk in the sensitive plant (Mimosa). We have probably to view the permeability of active cells as constantly varying, though how the changes in permeabilities of neighbouring cells are related so as to cause material to travel in any particular direction in a tissue is still obscure.

Transport of Salts and of Organic Substances.—The mechanism of the transport upward of mineral salts and the transport downwards of organic substances (such as sugar from the leaves), is still imperfectly known. Owing to the apparent slowness of diffusion of salts from cell to cell the supplies of salts required by the leaves would seem necessarily to move in the transpiration stream. There are, however, no data available showing that the rate of the stream and the concentration of salts in it are sufficient to transport the necessary supplies. A reduction of the rate of the transportation stream by shading leaves does not appear to reduce the salt content of the plant, at least in the herbaceous plants investigated. It may be that a certain critical rate of the stream is required and that in the experiments mentioned the rate was always above this.

GENERAL METABOLISM OF THE PLANT

The term metabolism is applied to the whole complex of chemical changes going on in the plant, the building up of more complex organic substances from simpler ones being spoken of as anabolism, and the breaking down of complex to simpler ones being termed Katabolism. It has already been noted that very many of the chemical reactions in the plant are balanced or reversible ones, so that according to the conditions (*e.g.,* the concentration of the reacting substances) the process may at one time be anabolic, another time katabolic. A balanced reaction ultimately reaches an equilibrium point where the rate of the process iii one direction is equal to the rate in the other; the equilibrium is thus a dynamic one. In those balanced reactions in which there is an energy exchange, *i.e.,* heat is taken in or given out, the equilibrium point is altered by a change of temperature. Experiment in the laboratory shows that the rate of many chemical processes is markedly affected by a rise of temperature, the rate of many of them doubling for each rise of 10° C. The marked effect of temperature on the metabolism of plants is no doubt partly one of acceleration, and partly a shifting of the equilibrium points of reversible reactions. There is a further point in relation to balanced reactions; if such a reaction is proceeding in a particular direction and material A is being converted into material B, then the mere accumulation of B tends to slow down the reaction and ultimately brings it to a standstill; should then the amount of B be increased further the reaction will proceed in the other direction, *i.e.,* from B to A. A similar result is very common in reactions caused by enzymes, the accumulation of the products of the reaction tending to bring the reaction to a standstill.

Stress must be laid on the fact that the chemical processes going on in the living plant take place not in a simple homogeneous medium like water but in the protoplasm, which is what is called a heterogeneous system, having many colloid phases. (See above.) The enzymes which seem to play so large a part in metabolism also appear to be colloidal at least in part; thus many of the reactions may take place on their surfaces and on the surfaces of the protoplasmic medium. The system in which the chemical changes occur being thus heterogeneous and of so complex a nature, we should naturally expect that a variation of conditions (such as of temperature, illumination, etc.) would affect differently the processes in the plant and similar processes occurring in the laboratory.

The metabolism of the green plant, to which our brief review must be confined, shows two main anabolic processes, (a) the manufacture of carbohydrates in the process of photosynthesis (carbon *assimilation*), (b) the building up of complex nitrogenous substances such as proteins from nitrates absorbed from the soil and from organic material such as carbohydrates. In addition there is a main metabolic process, that of *respiration,* which is akin to the process of alcoholic fermentation by yeast.

PHOTOSYNTHESIS (CARBON ASSIMILATION)

The whole life of the globe is dependent on this photosynthetic power of green plants for they alone are able to manufacture food material for themselves. The green plant may be described as the great alchemist which alone of living things has mastered the secret of converting the sun's rays into food material. The process of assimilation is associated with certain pigments which absorb the incident light; the energy so obtained is employed in the building up of complex organic substances from carbon dioxide and water, oxygen being at the same time evolved. In the case of the higher plants the pigments of the green Ieaf, as we know mainly from the work of Willstätter and his collaborators, are four in number—*Chlorophyll* a, $C_{55}H_{72}O_5N_4Mg$, a blue-black crystalline substance, greenish blue in solution; *Chlorophyll* b, $C_{55}H_{70}O_6N_4Mg$, a green-black substance, green in solution; *Carotin,* C_4OH_{56}, an orange-red substance found also in carrots, and *Xanthophyll,* $C_{40}H_{56}O_2$, a yellow substance. The two first are the green pigments and are often termed "chlorophyll," the other two are the yellow pigments. The amounts of these do not vary greatly in different leaves. The average amounts are given below:—

	Percent of fresh weight	Percent of dry weight
Chlorophyll a	0·2	0·63
Chlorophyll b	0·075	0·24
Carotin	0·017	0·05
Xanthophyll	0·033	0·09

In green algae the same four pigments are present; in the brown and red algae and blue-green algae chlorophyll is present in association with other pigments which give these plants their peculiar colour. The assimilating pigments are not dissolved generally in the cell but are associated with denser portions of the protoplasm of definite form, known as plastids; it is apparently in these plastids that the special physical and chemical processes characteristic of photosynthesis occur. It is generally accepted that the two green pigments are the most important in the process of photosynthesis. One of the functions of the green pigments is clearly that of absorbing the necessary energy for the decomposition of carbon dioxide, and their solutions show very characteristic absorption bands, particularly in the red-orange and the violet end of the spectrum. Whether in addition the chlorophyll reacts chemically with the carbon dioxide is still in doubt. Willstatter and Stoll hold that the carbon dioxide combines with the chlorophyll to form a definite compound on which light acts; it is thus converted into a substance of the nature of a peroxide which can be acted upon by an enzyme.

Products of Photosynthesis.— Sachs (1862) was the first to relate the carbohydrates appearing in the leaf to the process of assimilation; he was responsible for the dictum that starch was the "first visible product of assimilation." This was based on the fact that in the case of many plants starch appeared in the plastids of the leaf in the light and disappeared again in the dark. It is now generally agreed that carbohydrates of some kind are the main products of photosynthesis, though many monocotyledons form little or no starch, but much sugar in the form of glucose, fructose and cane sugar. Which carbohydrate is first formed is a matter in dispute. In green leaves exposed to light cane sugar accumulates markedly; this has led to the view that it is the first formed sugar. A much more plausible hypothesis would seem to be that hexose sugars (glucose and fructose) are first produced, and that when these reach a certain concentration cane sugar is formed from them; this view is supported by the work of Weevers (1924). The starch arises in all probability from glucose and it would seem likely that there is a critical concentration of sugar in the chloroplast above which starch is formed from the sugar, and below which the starch is converted back into sugar. This is confirmed by the fact that by floating leaves on sugar solutions of high concentration even those which are normally starch-free will produce that substance in their chloroplasts.

Effect of Various Conditions on the Rate of Photosynthesis.—The rate of this process is affected by the concentration of carbon dioxide available, by the amount of water, by the intensity of the light and by its wave length, by the chlorophyll content, by the supply of oxygen and of mineral salts, and also by many other internal conditions, or factors as they are called. It used to be supposed that all these factors acted independently, but it was shown by the work of F. F. Blackman (1905), that the factors are closely interrelated. He put forward the "theory of limiting factors," that in any set of conditions the rate of a physiological process was determined by the factor present at the lowest intensity. The view that under any set of conditions it was only by the increase of the intensity of one factor that the rate of the process could be increased requires some modification in the light of recent work. It is clear, however, that if any factor A is present at very low intensity it will prevent an increase of another factor B having the marked effect upon the rate of the process which it would have produced if the factor A were acting at a higher intensity. Bearing this relationship of the factors in mind, we find that with increasing concentration of carbon dioxide the rate of assimilation goes up proportionally, if the concentration is not too high and light and temperature are sufficient. Similarly with increasing light-intensity the rate of assimilation goes up proportionally if the temperature and concentration of carbon dioxide are sufficient. With high light intensities there is probably a falling off in the rate, as with higher concentrations of carbon dioxide. With a moderate temperature, if other conditions are favourable, the rate of assimilation obeys the Van't Hoff rule, approximately doubling for each rise of temperature of 10° C. At higher temperatures, somewhere in the neighbourhood of 25° C, with some plants, the injurious effect of high temperature appears and the rate begins to fall off. The process of assimilation is little sensitive to the concentration of oxygen, reduction to $\frac{1}{100}$ of the normal amount having no effect, but complete absence of oxygen acts injuriously. A number of *internal* factors must markedly affect the rate of photosynthesis, but the only one that has been closely investigated is that of the chlorophyll-content, by Willstatter and Stoll. It was found that the photosynthetic rate per unit of chlorophyll (the "assimilation number") varied markedly in different plants and even in the same plant. Leaves of yellow varieties were found to show very high rates in proportion to the amount of chlorophyll present, though the rate in these leaves is less influenced by temperature than is that of fully green leaves. Clearly there is some internal factor (or factors) other than chlorophyll content which is controlling the rate. This may be termed the "protoplasmic factor"; Willstatter and Stoll conclude that this factor is enzymic.

Quality of Light and Photosynthesis.— The question of the effectiveness in photosynthesis of light of different wave lengths has been hotly debated by physiologists for many years. The question is a complicated one since in white light there are great differences in the energy-value of the rays of different wave lengths, and the different rays are absorbed to a very different degree by the chlorophyll and the colourless parts of the leaf. In the case of the leaf there is little doubt that with equal intensity of incident light the red rays are more effective than the blue. The work of Warburg and Negelein quoted below indicates also that for equal quantities of light-energy *absorbed* by *the chloroplast,* the red rays are considerably more effective than the blue.

Efficiency of the Photosynthetic Process.—It is known that the green leaf is comparatively inefficient as a producer of assimilation material. Brown and Escombe (1905) attempted to determine the efficiency of the green leaf by comparing the energy of the light absorbed with the absorption of carbon dioxide, the assumption being made that glucose was produced in the leaf from the carbon dioxide. Their results are only very approximate but they indicate that the efficiency is only about 1%, increasing however with low intensities of light to about 4%. A large proportion of the energy absorbed is used in transpiration, and with the higher intensities of light the concentration of carbon dioxide in nature is too low to allow of the light being fully effective. The most accurate experiments on the efficiency of the photosynthetic process are those of Warburg and Negelein (1922 and 1923) with the minute unicellular fresh water alga, *Chlorella.* With such a plant there is no question of transpiration, and the experimental arrangements were such that practically the whole of the light received was absorbed by the chloroplasts of the cells; in the case of the leaf a considerable amount of the light passes through it and a certain amount is reflected. Warburg and Negelein show that with decrease in the intensity of the light the efficiency goes up, *i.e.,* a larger proportion of the light absorbed is made use of in photosynthesis, the rate of the latter process being measured by the production of oxygen. In their earlier experiments they obtained an efficiency of 71% when using yellow and yellow-red rays; the methods employed for calculating this were, hcwever, not altogether satisfactory. In their later work they obtained results of 59% for red light, and 34% for blue light. Whether these percentages are the maxima that can be obtained is not yet certain.

Cosmic Relations of the Photosynthetic Process.—As already stated this process is the fundamental chemical process on which the life of all animals and plants depend. A study of the land plant's relation to the sun shows it as a machine of comparatively low efficiency, since only a small part of the sun's energy is stored by the plant, crops such as cereals and potatoes retaining only 2 to 3% of the energy received. This uneconomical working is in part due to the fact that so much of the sun's energy consists of invisible heating rays which the plant cannot use for food production. Furthermore the plant is somewhat more efficient than first appears as part of the material manufactured during the day is burnt up again in respiration and so lost. The proportion so lost is very variable, depending largely on the temperature at night; it may be taken as 20–50 per cent. Another cause of the low efficiency of the plant, as has already been pointed out, is the low concentration of the raw material (the carbon dioxide) available for the process. It has been suggested that in early Carboniferous times when coal was formed, the concentration of this gas was higher. However this may be it is clear that the energy available from our rapidly lessening stores of coal and oil is really the energy of sunlight received by the earth many thousands of years ago.

RESPIRATION AND FERMENTATION

Respiration and fermentation are closely allied processes. Both consist in the breaking down, generally by an oxidation, of complex organic compounds, commonly sugar, into simpler ones with a liberation of energy. In respiration oxygen is usually necessary and the breakdown is complete, carbon dioxide and water being formed. In the second oxygen is not necessary and the chemical degradation is not complete, some organic substance such as alcohol being the end product. As is to be expected the release of energy for a given amount of sugar consumed is much greater in respiration than in fermentation, the first being a much more economical process than the other. By means of these two processes the plant gains supplies of available energy from the food material consumed. Such supplies of energy are necessary to maintain the dynamic equilibrium of the cell and to carry on various chemical processes in which energy is absorbed. In the higher plants some of the energy is also used in mechanical work.

Aerobic Respiration.— As has already been stated absorption of oxygen and the production of carbon dioxide are characteristic of the majority of plants as they are of animals. The carbon dioxide is not the only product for if sugar is oxidized an equal number of molecules of carbon dioxide are formed together with a certain amount of heat. The term *aerobic* respiration is applied to this process in contrast with the one in which oxygen is not necessary, which is termed *anaerobic* respiration and is akin to fermentation. Various substances appear capable of being oxidized in respiration, sugars, fats, proteins, sulphur, ammonia, nitrites, methane, (CH_4) hydrogen, etc., but in the higher plants sugar seems to be the substance most commonly consumed. The action is an oxidation and may be expressed thus:—

$$C_6H_{12}O_6+6O_2=6CO_2+6H_2O$$

together with a release of 674,000 calories of energy.

The intensity of respiration varies enormously in different plants and different organs of the same plant. Actively growing tissues such as meristematic tissues show the most intense respiration, in some cases as in the developing spadix of arum *(see* ARACEAE) the rate is as high as in warm blooded animals and the heat generated is sufficient to raise perceptibly the temperature of the inflorescence. Developing seeds also show active respiration; poppy seeds at 16° C give out in 24 hr. 122 cc. per gram of *dry* weight. Leaves pressed together in a receptacle where heat losses are small may in the process of respiration raise the temperature so much as to bring about their death. When sugar is used in respiration the amount of carbon dioxide given out is equal to the amount of oxygen taken in; the *respiratory quotient* (CO_2/O_2) is then one. In other cases it is widely divergent from unity especially when fats or proteins are being consumed.

Effect of Conditions on Respiration.— The rate of this process is markedly affected by various external and internal conditions. Temperature is one of the most active as is to be expected, since a rise of temperature tends to accelerate chemical processes generally. The effect on respiration is very similar to that on assimilation *(see* abovr) and again markedly depends on the duration of exposure to higher temperatures. The respiration rate is very low round about the freezing point, but rises with increase of temperature, being very approximately doubled for a rise of temperature of 10° C. After a time, however, an injurious effect with rise of temperature sets in—no doubt an effect on the protoplasmic mechanism, since high temperatures affect colloids.

The rate of respiration is also affected by the amount of the available material. Increase in the concentration of sugar supplied tends to raise the rate, as can be shown by adding or subtracting sugar from the food supply of a fungus in culture. A reduction of the amount of oxygen in the air has not much effect on respiration until the amount is considerably reduced. On the other hand the accumulation of carbon dioxide—a product of respiration—has a definitely depressant effect on the rate of both aerobic and anaerobic respiration.

Anaerobic Respiration and Fermentation.— Green plants which normally show aerobic respiration are still able to give out carbon dioxide when kept in an atmosphere free from oxygen; at the same time alcohol is produced in small quantities indirectly showing kinship between fermentation and this type of respiration. The alcoholic respiration of yeast has been the subject of much investigation and is known to be associated with an enzyme-zymase, and the production of a compound of sugar and phosphoric acid (known as hexosephosphate) and an enzyme which acts on this compound. *(See* FERMENTATION.) The work of Neuberg and his collaborators indicates that pyruvic acid is an intermediate product between sugar and alcohol.

Mechanism of Respiration.— The peculiarity of respiration as a chemical process lies in the fact that the plant (and animal) is able to oxidize at quite ordinary temperatures such a substance as sugar, which in the laboratory can only be burnt at high temperatures. The question arises as to the peculiar conditions in the plant responsible for this. Oxidizing enzymes have been claimed as the key to the problem, but while these will readily oxidize certain aromatic compounds they will not act on the respiratory substances such as sugars. Wieland has brought forward an entirely different theory of physiological oxidation in which water is the real source of the oxygen used. In this view the first step in the process is the combination of the respiratory material with water, which is followed by a process of *dehydrogenation,* probably under the action of an enzyme, in which hydrogen is split off leaving the material oxidized. The hydrogen is in an active state and in ordinary aerobic respiration combines with the oxygen of the air to form water; the oxygen of the air thus acts as a *hydrogen acceptor* as it is called. In the absence of air other substances, such as methylene blue or hydroquinone, can take its place. Thus the oxidation of acetic acid to alcohol can go on without oxygen•if methylene blue is present. Glucose also can give carbon dioxide at ordinary temperatures when water and some catalyst, such as palladium black, are present and some acceptor of hydrogen is available. Another theory is that of O. Warburg, who holds that respiration is essentially a surface reaction. He has shown that various substances such as oxalic acid, amino acids, and even sugars are respired in the living organism. The effect of narcotics on the "respiration" of the surface is very similar to that on the respiration of the living organism. Quastel's theory of the activation of the respiratory substances and the discovery by Sir Frederick G. Hopkins of the important sulphur-containing substance glutathione must be referred to. The various theories of oxidation are discussed in the English edition of Kostychev's book on plant respiration *(see* references).

GROWTH

The term growth is generally applied to the increase in size of an organism, In unicellular organisms it applies only to the inciease of the single cell; in multicellular organisms it is generally associated with the formation of new cells as well as with the increase in size of cells already existing. In the growth of the cell we may find an increase in all the cell constituents, cell-wall, protoplasm, etc., though frequently an increase in volume is brought about by the enlargement of the volume of the cell without any increase of protoplasm. Of the manner of growth of protoplasm we know very little. Bacteria (which are unicellular and consist of little else than a mass of protoplasm) when placed under the more favourable conditions of temperature and food supply will multiply so rapidly that each cell divides into two new ones every 20 minutes. The protoplasm thus grows at such a rate that its mass becomes multiplied *eight times every hour.* This shows that the production of protoplasm from non-living material may go on at an astonishing rate, but of the details of this production we are quite ignorant. In cells invested with a cell wall the growth of the latter is due to the activity of the protoplasm. The new wall which divides the parent-cell into two new ones is formed across the nuclear spindle. *(See* above, *Cytology.)* There has been considerable dispute as to the method of thickening of a wall already formed, whether it is by the addition of new layers, *i.e.,* apposition, or by the intercalation of new particles of cell wall material among the old—the so-called *intussusception.* It is probable that the first process is the more common but that both occur.

Effect of External Conditions on Growth.—It is found that on the whole light has a retarding effect on growth. When illuminated the actual length attained by the organ and the rate of growth are both less than in the dark. Dicotyledonous plants grown in the dark have generally much elongated stems and also small leaves but the actual amount of light required to prevent the *etiolated* condition is very small. Light is of course indirectly necessary for the growth of the green plant, as without it the leaves are unable to build up the food material. *Temperature* is the factor which has the most marked effect on the rate of growth, as is to be expected since the temperature so largely controls the rate of the processes on which growth depends. There is a *minimum* temperature below which the growth of the plant or organ does not occur at all, a *maximum* above which the growth stops as a result of injury to the plant, and an *optimum* temperature, the one at which the rate is greatest. These, however, are not absolute terms for, as with all effects of temperature, the degree of temperature cannot be separated from its duration. This is so particularly in relation to higher temperatures which may be injurious only when the duration is prolonged. In the case of the roots of the cress plant, which have been closely investigated, the minimum is found about freezing point, 0° C; the optimum, however, was found to vary with the duration of the exposure. If the roots were tested by means of an exposure of $3\frac{1}{2}$ hours to various temperatures, the optimum was at 30° C; with an exposure of 7 hr. at 29° C, while with an exposure of 14 hr. the optimum was pushed back to 27° C. The maximum also was found to fluctuate in a similar manner being higher with shorter times of exposure. Both light and temperature have also a *formative* effect on the plant in that these factors may affect the shape of plant organs; plants grown at high temperatures in weak lights are noticeably different in appearance from plants grown at a lower temperature and a higher light intensity. The formative effects of chemical substances is also often marked at least in the case of the lower plants. Another external condition necessary for the growth of most plants is a supply of oxygen.

Periodicity of Growth.—Organs of limited growth usually show what is called a "grand period of growth," the rate of growth being at first slow then gradually increasing to a maximum and then slowing down again to zero. This may be illustrated by a zone on the main root of a bean seedling which in *successive days* showed the following increases, the results being expressed in millimetres, 1·8, 3.7, 17·5, 16·5, 15·5, 14·5, 7·0, 0·0. If we express the total length of the root section graphically we have an S shaped curve; the organ or plant body starts as a small structure, grows at first slowly and then with increasing rapidity, and then the rate of growth begins to slow down and finally stops.

Correlation of Growth.—One of the most striking phenomena in the growth of the plant body is the correlation of growth. The thickness of the trunk is related to the size of the branches which it bears, and the size of the root-system is correlated with that of the shoot-system. A good example of correlation is seen in the bending up in a side-shoot to replace the loss of the top of the main stem in the tree trunk of a conifer. It has been known for some time that in the animal body hormones (chemical messengers) are produced by certain glands and that these hormones circulating about the body may control growth and other processes. It has of recent years been demonstrated that the plant possesses growth-promoting substances which can diffuse through the plant and so control growth at some distance from the point of production of the substances.

IRRITABILITY

The term irritability is often applied to the visible reactions which the plant makes to its environment. The particular action of the environment is known as the stimulus, and irritable responses as responses to a stimulus. The stimulus may, for example, be some change in the intensity of light or temperature or gravity or electricity. Some stimuli are necessary for the normal growth of the plant such as a suitable degree of temperature, light, etc.; without such conditions acting more or less continually on the plant body as a whole the organism would not be in a state to react to stimuli. The term stimulus is to a large extent a term serving as a cloak for our ignorance. We do not speak of the stimulus of light causing assimilation because we have some physio-chemical picture of this process. When a shoot turns in response to unilateral light we speak of the light as a stimulus, largely because we are unable to picture the course of events which cause difference of illumination to bring about curvations of the shoot or root. Stimuli have, however, usually one point in common that the stimulus does not itself supply the energy employed in the response to the stimulus, but the energy used in the response comes from a store pre-existing in the plant. The stimulus seems thus to be a releasing mechanism, in which the amount of energy employed has no relation to the energy released. The firing of a gun is a good example where the energy used in pulling the trigger has no relation at all to the amount of energy released in the explosion; irritable mechanisms of this kind are therefore sometimes called trigger mechanisms.

GEOTROPISM

It is well known that the plant body takes up a definite position in space. The main stem of a tree usually stands quite vertically and its branches stand out more or less horizontally. The main or tap root also grows vertically downwards and the rootlets at various angles. It is well known also that if a seedling is placed with its stem and its root horizontal the stem proceeds to curve upwards and the root downwards.

Geotropic Response.—This response is known as a geotropic response. that of the stem being negatively geotropic and the root positively geotropic. We note that the curvature is usually confined to the tips of the organs, *i.e.*, to the growing points of the stem and the root. That the curvature is due to the action of gravity was shown as long ago as 1806 by Knight, the English experimenter. He fixed a number of seedlings in different positions on the edge of a wheel rotating in a vertical plane, that is, on a horizontal axis. The wheel was rotated at a considerable speed so that at its edge there was considerable centrifugal force. The result he observed was that the roots, in whatever direction they had started growing, soon grew outwards at right angles to the direction of the axis. The stems, however, grew in the opposite direction to that in which the centrifugal force was acting and they soon all met in the centre of the wheel. This experiment shows that plants do not distinguish between gravity and centrifugal force, and that the root grows in the direction of the force while the stem grows in the opposite direction. About 70 years later Sachs invented his *klinostat*, an apparatus by which plants are rotated on a disc in a vertical plane, but the speed of rotation is very slow, once in 10–20 minutes. As a result centrifugal force is negligible but the one-sided action of gravity is abolished as every side of the organ in turn faces downwards; the effect of gravity is not annulled but the curving (*tropistic*) effect is abolished. It is evident that the curvature results from the difference in the elongation of the two sides.

Geotropic Curvature is not confined to plant organs which are still in active growth. It may occur in organs which have normally ceased to grow as in the case of the stems of grasses. If a short piece of wheat or barley stem is placed in a horizontal position, the base of the node, to the growth of which the elongation of the node is mainly due, will start into growth again as a result of the stimulus of gravity and the stem turns upward. That such curvature is not a simple weight effect on the plant is shown by the *upward* curvature of the stem, and by the fact that the root often will grow downwards into mercury although in such a dense fluid the root tends to be forced upwards.

Reaction and Presentation Time.—As we are dealing with a stimulus we should expect the effect to be related to the duration, intensity and direction of the force; this we find to be the case When a stem or root is laid horizontal the time taken for the organ to show a visible curvature is 10 to 20 minutes, according to the sensitiveness of the object and the external conditions, such as the temperature. This period is known as the reaction *time*. It is found that this length of time is not necessary to produce a curvature. If after a much shorter time the plant is removed from the horizontal position and placed on a klinostat, the curvature follows later. The minimum time to which the plant must be exposed to the gravitational stimulus in order to show later a curvature is known as the *presentation* time. This is much shorter than the reaction time and varies from as short a period as 2 min. for the inflorescence stalk of the plantain and the hypocotyl of the sunflower, to 25 minutes for some other plants. There is naturally a marked difference in the presentation times exhibited by individuals of the same species. In the oat shoot, for example, the mean time was 32 minutes, but some reacted in less than 14 minutes, while others required more than 49 minutes. It is found that the stimulation applied during the presentation time need not be given all at once. A series of short exposures, each less than the presentation time, may by summation become effective. If the pauses between stimulation are only five times as large as the periods of stimulation the presentation time is not lengthened by the intermittent nature of the treatment. Thus, if the normal presentation time of a shoot is 10 minutes, it will react if placed horizontal for five successive 2 minute periods, with a period of 10 minutes in the vertical position in between. If, however, the period between one stimulation and the next is 20 minutes, then more than 5 of the two-minute periods will be required. The effect of the stimulation thus slowly weakens during the pauses.

The presentation time and reaction time are naturally affected by the intensity of the applied stimulus. We cannot alter the effect of gravity, but we can use instead a centrifugal force which can be increased at will and to which, as has been shown above, plants respond as to gravity. The table below gives the intensity of the centrifugal force measured in terms of gravity (G), the presentation time, and the products of the time by the intensity.

Intensity	Presentation time	Product
46 G	7 secs.	322
24 ,,	12 ,,	287
4·84 ,,	60 ,,	290
0·76 ,,	415 ,,	315
0·14 ,,	2·230 ,,	322
0·04 ,,	7·800 ,,	312

We see from the third column that the geotropic reaction obeys what is called the product *law*—the time of stimulation is inversely proportional to the intensity of the stimulus, so that the product of the two is constant. This product law is also clearly shown when the root or stem is placed at various angles with the horizontal. The horizontal position is found to give the most intense stimulus, the intensity being proportional to the sine of the angle with the vertical at which the organ is placed.

PHOTOTROPISM

The fact that plants growing near a window will bend their shoots towards the light is familiar to everyone. This reaction is known as *phototropism*, which means a turning towards light; the term has replaced *heliotropism*, which means a turning towards the sun, since the reaction is shown in relation to almost any light. As in the case of geotropism there are two types of response, *positive* and *negative*, where the turning is towards or away from the source of light respectively. The first is found strongly marked in most shoots of the higher plants and is also found in a few roots. The positive phototropism of most roots is to be expected, since without some such response the light needs of the plant could hardly be satisfied. It is also to be noted that with the ordinary diffuse light of the sun the phototropic reaction is much more powerful than the geotropic. A seedling developing from a seed underneath a stone in a position to which light reaches, will not, under the influence of gravity, push its shoot fruitlessly against the stone above, but will show a phototropic curvature and so reach the light. Negative phototropism is found in some underground roots but markedly in the aerial roots found in many orchids. There are also plant organs which tend to set themselves at right angles to the direction of the incident light; these show *transverse* phototropism. The phototropic reaction is usually a growth reaction like the geotropic one. The side which becomes convex grows faster than the normal, and the concave side less fast. Also, as in the case of geotropism, unilateral light may cause a curvature in a mature organ by starting growth in length afresh. All light curvatures are, however, not due to growth changes but in the case of some leaves to the turgor changes of special cells.

Phototropism and the Product Law.—As with geotropism we find that the product law holds; the effect depends on the amount of light received, *i.e.*, on the product of the intensity of light multiplied by the time of illumination. The time required with different intensities of light to start a reaction, *i.e.*, the *presentation time*, is given below for the coleoptile (the seedling sheathing leaf) of the oat:—

Presentation time	Intensity (metre-candles)	Product
6 (hours)	0·00085	18·6
1	0·00477	17·2
4 min.	0·0898	21·6
4 (seconds)	5·46	21·8
1/100 (second)	1,902	19·0

It is seen that the product varies about the number 20, which means that the oat coleoptile will respond to 20 metre-candle-seconds. The principle of summation is also found with phototropism; stimuli too weak to cause a reaction will act if repeated. The intensity of the light required to produce an effect for a given time is found to vary with the colour, in other words, with the wave-length. It is found that *visible* light of all wave lengths will act, but the violet light is the most effective.

Conduction of Stimulus.—Charles Darwin showed as long ago as 1881 that the light stimulus might be perceived at one place and the curvature result at quite another place, showing that the stimulus was conducted. This is well seen in certain grass seedlings (such as those of *Setaria*), where the apical cotyledon soon stops growing, while the hypocotyl below continues to elongate for some time. Illumination of one side of the *cotyledon alone* will bring about a marked curvature of the hypocotyl below. In the same way unilateral illumination of the *tip* of the coleoptile of the cereal seedling, such as oat, will cause a curvation of the *lower* part. In relation to the conduction of the phototropic stimulus in this plant a very surprising result was obtained by Boysen-Jensen in 1913. He found that if the tip of the coleoptile be cut off and stuck in again with a thin layer of gelatine and the tip be then exposed to one-sided light a curvature will ensue in the darkened lower region. Later this was shown to be true for other grasses and also for the conduction of a stimulus due to injury. Snow in 1923 was able to show that the same held for the geotropic response of bean roots. If the tip is cut off and is fixed on again with gelatine the roots curve when placed horizontal. This suggests something which can pass a layer of gelatine, *i.e.*, very definitely a soluble growth-promoting substance which differs from the illuminated tip and causes the curvature. It has also been found that the slowing of the growth of a vertical coleoptile caused by decapitation can be largely removed by replacing the coleoptile in position. Such observations as these have led to a large amount of work, particularly in Holland and Germany. The most striking of the results obtained has been that of F. Went (1927), who has shown that by placing cut off illuminated coleoptile tips on small blocks of agar (a gelatine-like material obtained from seaweed) the growth-promoting substance diffuses into the agar. Blocks of this agar when placed on the cut surface of the coleoptile are able to cause curvatures.

Nature of Phototropic Reaction.—The earlier view of the positive response of stems to unilateral light was that the side towards the light being more highly illuminated had its growth rate reduced more than did the other side, with the result that the stern bent towards the source of light. Later, however, when the negative response of other plant organs was observed, and the response of transparent structures like root hairs and fungal hyphae, the view was widely held that the plant responded to the *direction* of the incident light. A. H. Blaauw was the first to return to the simpler theory; he showed that simple unicellular structures like the sporangiophone of *Phycomyces* and the complex hypocotyl of the sunflower exhibited a complicated but definite "light-growth reaction" when equally illuminated all round, the rate of growth being increased in *Phycontyces* and reduced in the sunflower. Light *apart from direction* has thus an accelerating effect in the one case and a retarding effect in the other. The turning of the hypocotyl of the sunflower towards the light is easily explicable as the side towards the light would be more illuminated and so grow more slowly. In *Phycomyces*, however, a negative phototropism might be expected, since the "light-growth reaction" is one of retardation, but in fact the curvature is towards the light. Blaauw, however, pointed out that the glass-like cylindrical structure of the sporangiophore acts like a lens and focuses the light on the further side, which is thus more intensely illuminated than the nearer. As a result of his work Blaauw put forward the view that in general the phototropic reaction is simply a growth response to differences of light intensity on the two sides of the organ.

The chemotactic movements of antherozoids and bacteria and the chemotropic movements of roots cannot here be dealt with, but a few words must be said on the so-called *nastic* movements of plant organs. These are movements which may be called out by a change in external conditions, but, as already stated, the nature of the movement is not determined by the stimulus from outside. The perianth leaves of the tulip exhibit a *thermonastic* movement, for when the temperature is raised these leaves open as a result of the greater growth of the upper sides. Many flowers show *nyctinastic* movements, opening and closing in response to changes of light intensity. Similar movements, the so-called *sleep movements*, are also known in leaves, especially in the leaves of Leguminosae.

Photoperiodism.—A very interesting reaction to light, which is in no sense a phototropic response, has been discovered of late years. It is a familiar fact that at least in temperate climates many plants flower only at certain periods of the year; there are so-called spring flowers, autumn flowers and plants which flower in the summer. This marked seasonal effect must be due to some varying external condition or set of conditions. It has often been supposed that, temperature plays a large part in the development of flowers, and a certain degree of warmth is essential for growth, yet altering the temperature alone will not markedly alter a plant's flowering period. Asters and chrysanthemums cannot be made to flower in summer by lowering the temperature, nor irises in winter by putting them in a greenhouse.

Apart from temperature there is one regular cyclical change associated with the march of the seasons and that is the change in length of the day and night, the day in the latitude of London varying from $16\frac{1}{2}$ hours in June to a little under eight hours in December. It was shown by Garner and Allard that in the case of many plants it is the length of the day which is the decisive factor in fixing the season of flowering. The discovery was made in the United States, where the behaviour of a valuable variety of tobacco, known as Maryland Mammoth, was being studied. It had been found impossible to obtain seeds from this variety since it went on growing steadily through the season, sometimes reaching a height of 12 ft., being eventually cut down by frost before it had formed flowers. One autumn a specimen was transplanted to a greenhouse, where it promptly flowered and set seed. This was at first thought to be an effect of temperature, but further investigation showed that it was impossible to cause the plants to flower in summer. It was soon found that the *dominating factor was length of day;* if growth conditions were favourable it would flower in the short days of late autumn or winter but not in the long days of summer. By artificially shortening the day to 12 hours, by placing the Maryland Mammoth plants in the dark during some of the daylight hours, flowering could be brought about at any time of the year. Following up this discovery Garner and Allard investigated at Washington the behaviour of a large number of plants. These were grown in pots which were borne upon light trucks running on lines so that the pots could be run in and out of sheds and thus be illuminated for various fractions of the daylight period. Many plants, such as the tobacco variety mentioned above, soya beans, asters, chrysanthemums, poinsettia, were found to be "short day" plants, and would only flower when the period of daylight was reduced to 12 hours or less. If the time of illumination is suitably adjusted the plants will flower and fruit when they are quite diminutive, while other individuals exposed to full daylight grow to a large size without any trace of flower production. Other plants such as grasses have been shown to be "long day" plants, which require a long daily period of illumination for the initiation of flowering.

PATHOLOGY OF PLANTS

Plant pathology (or Phytopathology) is that branch of biological science which treats of the diseases of plants. While there can be no doubt that diseases of plants, and in particular of cultivated plants, have manifested themselves from time immemorial, it is only within comparatively recent years that their study has been taken up in an organized and scientific manner. The application of the scientific method generally to the study of practical agricultural problems is a development scarcely older than the 19th century.

Historical.—In view of the devastating effects of plant disease, especially when the particular plant attacked is of primary importance as food for mankind or his domestic animals, it is not surprising to find that references to epidemics of disease are not uncommon in historical writings, even of remote times. The earliest records are to be found in the Old Testament (*e.g.*, Deut. xxviii., 22, 1 Kings viii., 37) under such terms as "blasting" and "mildew." The precise nature of the diseases referred to cannot now be determined but there is little doubt that some of the epidemic diseases of cereals, such as rust or mildew, are indicated. The ravages of insects are frequently noted, such as for instance plagues of locusts, caterpillars and canker-worms.

In Greek literature we find references to plant diseases in the writings of Aristotle, and more particularly in those of his pupil Theophrastus, the father of botany. The latter describes diseases of a number of cultivated crops, such as various legumes, cereals, fig, olive, etc., and observes that varieties of the same crop may show different degrees of resistance to disease. This is probably the first mention of the idea of "resistant varieties" which figures so largely in present day writings on the subject. Among Roman writers the younger Pliny, who flourished in the 1st century of our era, devotes some attention to the subject and makes a number of well-founded observations regarding the incidence of certain plant diseases.

The middle ages were for plant pathology, as for all other sciences, dark ages and we have to come down to the Renaissance, with its general quickening of interest in all intellectual pursuits, to find evidence of further progress. The 17th and 18th centuries witnessed considerable activity in the study of plant diseases. The new studies proceeded in the main from two different directions. The practical gardener or agriculturalist was chiefly concerned in describing the various diseases to which his crops were subject and in attempting to evolve methods of treatment. On the other hand, the student of human pathology was interested in the diseases of plants from the possible analogies to his own problems which such a study might offer. The whole science of botany had in the old days a distinct medical bias. It is not surprising, therefore, that the study of plant diseases has been to a large extent modelled upon the older science of human pathology, the terminology of which has been freely borrowed.

The elucidation of the real nature of plant disease, from the point of view of the causal agent, is mainly dependent upon the perfection of the microscope. But even the extended powers of observation which the use of that instrument brought to bear on the subject did not at once lead to a correct appreciation of the true nature of plant disease. Various structures were observed and accurately figured in detail as being associated with the diseased parts, but they were interpreted as portions of the plant which had become changed by the disease and not as belonging to a distinct organism which was responsible for the disease. The first incontestible proof that a specific plant disease was due to the invasion of the tissues of the plant by a definite parasitic organism was furnished by the German scientist, De Bary, whose pioneer researches prepared the way for a host of other workers, at first chiefly in Germany, and later in all civilized countries. The 20th century has witnessed an extraordinary activity in the study of problems of plant disease, most strikingly, perhaps, in the U.S.A. The economic importance of the subject, as a branch of scientific agriculture, has become increasingly recognized and the prosecution of plant disease researches is being more and more taken up by Government departments in all countries possessing a progressive agriculture

Finger-and-toe or club root disease of cabbage. D. Canker of apple tree. E. Spike disease of hop (Central branch diseased, lateral climbing branches healthy). F. Spotting of fruit disease "Anthracnose" of bean

Definition and Scope.—While it is true that the distinction between a healthy and a diseased plant is often perfectly obvious, it is not easy to frame a definition of the diseased condition which will meet all cases. The border line between health and disease is not always sharply marked. It will be shown below that the majority of plant diseases result from the invasion of the plant tissues by a definite organism, the parasite. Nevertheless, the presence of a parasite does not always necessarily mean disease in the common acceptation of the term. For example, the root-nodules of leguminous plants (pea, bean, clover, etc.) are produced by the attack of an organism—a bacterium—and far from producing damage, the presence of the bacterium is essential to the proper development of the plant. The important part played by certain fungi in the germination and subsequent growth of many plants, such as orchids and heaths, is a further illustration. The living together of two organisms does not necessarily produce injury to either partner, in which case one speaks of a symbiotic relationship. Every gradation may be traced from the purely symbiotic type, in which the two partners are benefited or not obviously injured, to the distinctly parasitic type in which one partner thrives at the expense and to the detriment of the other. In fact both types of relationship may be shown between the same two partners—that is, a symbiotic or harmonious relationship is at first set up, but by and by one of the partners suppresses the other and the relationship becomes one of parasitism. There is thus a gradual transition from a condition of health to one of disease.

So far reference has only been made to the diseases of parasitic nature. Over and above these there is a class of diseases in which no parasite is present at all, viz., the so-called plzysiological diseases. The existence of the latter increases the difficulty of defining disease in terms of the causal agent.

Perhaps the most adequate definition is obtainable by considering the normal development of a plant. Over a certain range of conditions, which one reckons as normal, a particular species of plant develops in a certain way—*e.g.,* has a certain appearance, reaches a certain size, and so on—all of which are the reflection of a normal physiology or functioning of the plant. If now a particular individual diverges from the normal and if the abnormality impairs the functioning and more especially imperils the life of the plant, that plant may be considered as being diseased.

From the purely practical or economic point of view, a satisfactory definition of disease presents no great difficulties. Any given crop is grown in the expectation of a certain yield, both as regards quality and quantity. Disease in its economic aspects may therefore be defined as a condition of the crop in consequence of which it fails to give a satisfactory yield.

General Classification.—Diseases, whether of plants or animals, may be classified on the basis of the symptoms produced or of the causal agent concerned. For reasons given more fully below, the latter system of classification is more generally adopted in connection with plant diseases, and it is convenient to give at this point a general classification along such lines in order to limit the scope of the present article. Classified on the basis of the causal agency, plant diseases are as follows:—

(1) Diseases due to the non-living environment.

(2) Diseases due to so-called internal causes.

(3) Diseases due to living agencies, which may be plants or animals.

The first two groups constitute the plzysiological diseases. In group (1) the disease symptoms can be related to certain physical or chemical features of the environment. In group (2) no such association has yet been demonstrated, nor has it been possible to explain the symptoms as being due to the presence of a parasite. The second group is thus defined on purely negative characters, and is in fact a kind of limbo into which are put all diseases the cause of which is still obscure. Some of these may prove, with advancing knowledge, to be referable to either of the other groups.

The members of the third group constitute the parasitic diseases. The plant, technically termed the host, is attacked by another organism called the parasite. The animal parasite may be various—mammal, bird, snail, insect, eelworm, etc. The attack of a crop by such an animal as a rabbit is not usually described as a disease, though there is no difference in kind between such attack and that produced by mites or greenflies. Economically the most important diseases of animal origin are those produced by insects, and these constitute in the main the province of the entomologist. (See ENTOMOLOGY: Economic.)

Plant parasites may be bacteria, algae, fungi (including slime-fungi) or higher plants. Plant diseases of bacterial origin were at one time believed not to exist, on account of the supposed fact that the acidity of plant juices is inimical to bacterial growth. Many bacterial diseases of plants are now known, some of great economic importance. The recorded cases of parasitism due to algae are few and unimportant. Diseases caused by higher plants, some of which will be cited later, are on the whole of greater scientific interest than of economic importance. The fungi (*q.v.*) are by far the most important group of disease-producing organisms, so far as plants are concerned.

Broadly speaking, therefore, the plant pathologist is by training either an entomologist or a mycologist. As far as diseases of parasitic type are concerned, only those caused by plants, and therefore chiefly of fungal origin, will be dealt with in the present article. At the same time it is important to note that the two aspects of the study of plant disease, the entomological and the mycological, cannot in practice always be separated.

Symptoms of Disease.—The study of symptoms is the first step in the examination of a disease problem. By symptoms one means the total of the modifications shown in the plant as the result of disease. In the majority of plant diseases of parasitic type the true symptoms are accompanied at one stage or other of the disease by certain appearances such as the fructifications of the parasite.

A very important difference between the typical plant disease and the typical animal disease is as regards the definiteness of the symptoms shown. In animals and especially in man disease symptoms are usually very characteristic, so that it is often possible to identify (or diagnose) a particular disease from a study of the symptoms alone. With plants this is not generally possible. Disease symptoms in the latter are much more generalized, *i.e.,* the same or approximately the same symptoms can be produced by a great variety of causes. Wilting of the foliage, for example, is a symptom of disease in plants and its cause may be most varied—damage to the roots by fungal or insect attack, damage to the stem, presence of injurious salts in the soil, scarcity of water, and so on. Hence it follows that while a study of the symptoms may give valuable indications of the nature of a particular plant disease, it is in general necessary to discover the cause or aetiology of the disease before the latter can be definitely identified. Determination of the causal agent may be difficult and usually involves considerable expense of labour and time.

While the main symptoms of plant disease are of a rather generalized nature, a number of different types may be distinguished. The more important of these are given in the following list:

(a) Change of colour, such as paleness, silvering, reddening, blackening of leaves. The change of colour may be shown over the leaf or even over the whole plant, or it may be limited to spots, streaks or patterns, such as the well-known "mosaic" appearance.

(b) General wilting of the shoot, as when the plant suffers from drought, or from "damping off" disease, or from the effects of a parasite which destroys the roots or is present in the water-conducting system.

(c) Premature shedding of leaves, blossoms, fruits, etc.

(d) Abnormal *retention* of leaves, which is especially well shown in certain diseases of deciduous trees. The autumnal shedding of leaves is a vital or physiological process, due to the action of a definite absciss or cutting-off layer at the base of the leaf. If this layer is prevented from functioning, as for example by the killing action of a parasite which has invaded it, the leaves cannot be shed in the normal way.

(e) Dwarfing or *stunting,* which may be general to the whole plant or may only be shown in particular organs.

(f) Abnormal enlargement or multiplication of parts (hypertrophy) resulting in the formation of such structures as galls, turnours, knots, warts, etc. (fig. 1). Hypertrophy is generally accompanied by distortion or malformation as in the rolling or puckering of leaves and the twisting of shoots. Frequently it takes the form of an abnormal development of buds, the majority of which would normally have remained dormant. The structures called "witches' brooms" (fig. 1) which are common on certain trees (*e.g.,* willow, birch) are produced in this way.

(g) Replacement of one organ by another, as for example the change of petals into foliage leaves. Some changes of this type, though properly speaking malformations, may be economically desirable and are therefore not considered as diseases. An example is the "doubleness" of some flowers.

(h) Change of habit of growth, *e.g.,* from the prostrate to the erect, from the climbing to the non-climbing type of growth (fig. 1).

(i) Change in the periodicity relationships of the plant, as for example the premature flowering ("bolting") of a biennial plant in its first year of growth, or the opening of foliage or Aoral buds at the wrong time of year.

(j) Replacement of parts of the plant by structures belonging to the parasite, such as the conversion of the rye grain into the resting organ (sclerotium) of the Ergot fungus (fig. 1). "Mummification" of certain fruits is another example of this type.

(k) More or less rapid killing (necrosis) of the plant or parts of it. Killing is often accompanied by more or less pronounced rotting, as in the decay of fruits, buds, etc. (fig. 1). Localized killing of leaves results in the formation of dead spots The killed tissue may remain as such or may dry up and fall out, thereby producing a "shot-hole" effect.

(*l*) Formation of deep-seated wounds or cankers (fig. 1). In a canker, the parasite slowly eats into the plant tissue, the part invaded being killed and to a large extent disappearing. Associated with this type of wound there is usually a certain amount of hypertrophy of the tissue which still remains alive round the margin of the invaded part.

(*m*) Various kinds of exudations, as in the gumming of plum trees or the abnormal flow of resin in certain conifers.

METHOD OF STUDYING PLANT DISEASE

Though the investigation of a plant disease is a matter for the specialist, a short account of the methods adopted will serve to indicate the type of problems encountered. The parasitic type of disease is in practice the one most frequently met with, and therefore in actual study it is usually assumed in the first instance that the disease under investigation is of parasitic origin.

Identification of the Parasite.—The first problem which arises is the determination of the nature of the parasite (assuming that such is actually present). The tissues of the plant which show the symptoms of disease are examined, after suitable preparation, under the microscope and if the disease is actually due to a parasite it is usually not difficult to demonstrate its presence. Definite indications of its nature and identity may also be obtained at this stage. In a number of cases, the parts of the plant which show the symptoms of disease may appear to contain no parasite, even though further study may confirm that the particular disease is of truly parasitic nature. Thus the parasite may be so small as to be beyond the range of microscopic vision (see Virus diseases, below), or, as occasionally happens, the parasite is located elsewhere but is able to produce symptoms in parts of the plant remote from it. The mere presence of a fungus or bacterium within the diseased part (or lesion) is not, however, a certain indication that the disease is caused in that way. Direct proof can only be obtained by inoculating healthy plants of the species showing the disease with the organism in question and observing whether the disease is thereby produced. The details of the procedure involved in the carrying out of such artificial inoculations will vary much in different cases. In general it is necessary, as a first step, to prepare "pure cultures" of the organism, that is, to grow the latter in such a way that no other organism is present. These pure or unmixed cultures of the organism are then tested separately by inoculations on the host plant, and by this means evidence is obtained as to which is the active parasite concerned. The active parasite being isolated and its pathogenicity

FIG. 2.—THE FINER STRUCTURE OF SOME PARASITIC FUNGI (MAGNIFIED)

A. Surface view of plant leaf, showing rust spore germinating, B. Section of leaf showing entrance of rust fungus through a stoma, C. Penetration of cuticular layer of plant by fungus, D. Haustorium or abortive process of mildew within plant cell, E. Fructification of potato blight fungus with egg-shaped spores, F. Fructification of Black Rot fungus embedded in the tissue of an apple, rupturing outer skin of the fruit

(or capacity to produce disease) proved, one is now able to identify the particular disease in terms of the parasite which is responsible for it.

Identification of the disease is of value inasmuch as it enables the investigator to correlate his work with similar work done elsewhere, and of which a record is obtainable in the scientific literature. But mere identification is not the most important part of the study. It is essential to work out the *life-history* of the fungus—*i.e.,* to know where and in what form it occurs throughout the year. The same fungus may exist in a variety of forms in different situations or at different times of the year, and it is essential to connect up the various stages. In particular it is very important to establish the manner in which the fungus passes the winter (or equivalent) season. In temperate climates, for example, a summer growing season alternates with a period of dormancy during the winter. Often it is only on the actively growing crop in summer that the disease is observable. It reappears each spring, spreads during the summer, and becomes more or less latent during winter, The considerations which arise in this connection vary much in the different cases. A few examples will illustrate this. Annual crops pass the winter season in the form of seed. Is the disease therefore carried over the winter by means of the seed, and if so is it present within the seed, or is it carried on the surface? Or does it persist in the soil, or is the new crop infected afresh from dead remains (stubble, trash, etc.) of the preceding year's crop? Or again, do various perennial plants, such as certain weeds, serve to carry the disease through the winter? With perennial crop plants such as fruit trees, there is the further possibility that the disease may overwinter in a resting form on or in the plant itself. The determination of the exact method of overwintering which obtains in any particular case is obviously of the greatest practical importance.

The further examination of a disease problem from the point of view of the parasite would take into consideration the geographical range of the latter. Plants showing the particular symptoms would be obtained from different localities and the parasites isolated and compared. Thus a general idea would be obtained of the geographical distribution of the parasite and of the range of host plants which it could parasitize.

The complete elucidation of a plant disease involves much more, however, than the determination of the existence and habits of a parasite as outlined above. The presence of the parasite is only one of the conditions essential for the appearance of a specific parasitic disease. The more important factors and the manner in which they operate will now be indicated.

Temperature.—First as regards temperature. This factor determines in large measure the rate of growth and general vigour both of parasite and host. There is a certain temperature *(minimum)* below which an organism will not grow, a *maximum* above which it will not grow, and an *optimum* at which it grows best. These three temperatures constitute the so-called *cardinal points* for the particular organism. The cardinal points for the parasite are not in general the same as for the host plant, and the cardinal points for the disease itself are not the same as those of either host or parasite. Usually the range of temperature over which disease takes place is distinctly narrower than that over which either of the two organisms concerned will grow. The optimum temperature is well known in many cases to be different for host and parasite, and thus it is clear that the possibility exists of finding a temperature at which the host plant grows well but which is unfavourable for the development of the disease. The precise relationships are somewhat complex and have been fully worked out for a limited number of diseases only, but it is possible in general terms to classify diseases into the two main types, high temperature and low temperature diseases. An example of each will show the difference. The root-rot disease of tobacco is one of the low temperature type. Susceptible varieties of tobacco when grown in infected soil are badly diseased if the temperature rules low, whereas in the same soil the disease would not occur at a higher temperature. The wilt disease of cabbage is of the high temperature type, and only occurs in seasons when the general ground temperature is high.

Water.—The water-relationships of the crop are of equal importance with those of temperature and are to be studied in terms of the amount and distribution of rainfall, the water-retaining capacity of the soil, drainage, etc. Two factors which are of great importance in the initiation of parasitic attack are the relative humidity of the air surrounding the plant and the percentage of moisture present in the soil. The parasite requires the presence of a certain amount of moisture to start its growth processes. So it will often be possible for the plant pathologist to explain the occurrence of disease at one time or place and not at another in terms of these factors. The percentage of moisture in the soil affects not only the capacity of the parasite to grow but also the growth of the roots of the plant. It may therefore also influence the capacity of the roots to resist the attacks of the parasite.

Light.—Light is also a factor which influences the susceptibility of a plant to disease. The quantity of light received by the plant determines in large measure its vigour of growth, not merely as regards the amount of new tissue formed, but also as regards the mechanical strength and to a certain extent the chemical composition of the tissues of the plant. These qualitative differences influence the degree of resistance which the plant can offer to the attack of a parasite. For example the weak, pale, rather juicy, "forced" type of growth which results when plants are grown under conditions of feeble illumination — as when plants are grown in glasshouses during winter or when they shade each other by standing too closely together — predisposes them to attack by a variety of fungi ("damping-off" diseases). On the other hand, certain fungi (*e.g.,* some of the rusts) attack their hosts with vigour only when the latter are growing under conditions of good illumination. Again, the symptoms of certain diseases (*e.g.,* some mosaics) will only appear when the plant is exposed to light of a certain range of intensity.

The three fundamental factors, temperature, humidity and light are, in the open field, to a large extent beyond control. Nevertheless, it is often possible, in agricultural practice, materially to modify their action. By suitable methods of cultivation — draining, subsoiling, ridging, manuring — the amount of soil water can be regulated. By the provision of shade trees — as is usual in many tropical cultivations — or by suitable spacing of the crop itself or by pruning, the intensity of light or humidity of the air can be adjusted so as to approximate to the needs of the plant.

Soil Factors. — Reference has been made to soil moisture as a factor of importance in connection with plant diseases. This is merely one of the many soil factors which influence plant growth and which therefore require to be considered in dealing with the liability of plants to disease. The physical texture of the soil and the presence or absence of certain chemicals are of importance mainly inasmuch as they influence soil humidity. But there are in addition a number of soil factors which act otherwise. Thus the amount of certain constituents present in the soil (*e.g.,* nitrogen, potash, phosphate) influences not only the quantity of plant growth but also, to an appreciable degree, its quality — and in particular its susceptibility to disease. The presence or absence of lime, by controlling the reaction of the soil, is in some cases the factor which determines whether a particular disease will develop or not. Soil aeration is a factor in itself, though in practice it is often difficult to separate its effects from those due to soil humidity.

Internal Factors. — So far the discussion of the factors which influence plant disease has been limited to the environment. The latter, however, merely modifies the result which is in the main conditioned by the structure and physiology of the host plant itself. These "internal" factors are more elusive than those already discussed and in their fundamental aspects are practically unmapped. A few examples of internal factors and of their manner of functioning will be given in the following section. Nevertheless, though very little is known of the underlying factors which determine immunity or susceptibility, certain phases of the problem are open to direct observation and experiment.

From the foregoing sketch it is clear that the complete investigation of a plant disease may ramify into various branches of agricultural science. The plant pathologist is thus much more than a mycologist, or student of fungi, though in practice the two names are often used as equivalent. Plant disease investigations may call for the joint work of the mycologist (or entomologist), the soil chemist, the physicist and the practical agriculturalist, and lastly — as will be shown more clearly later — the co-operation is required of the geneticist for the breeding of resistant varieties, and of the pure chemist for the preparation of chemical means of combating the disease.

NATURE OF DISEASE; PHYSIOLOGY OF PARASITISM

The discussion under this heading will be confined almost wholly to diseases of parasitic nature. The problems presented in parasitic disease are simpler inasmuch as the interactions of parasite and host plant can be studied under the microscope, and to a certain extent at least are amenable to chemical and physical analysis. For simplicity, the description will be confined to a disease of fungal origin.

The earliest phase of such a disease is the entrance of a fungal thread or *hypha* (see FUNGI for account of fungal structure). The fungus, usually in the form of a spore, germinates on the surface of the plant, or otherwise comes in contact with the latter. It then enters, either by naturally occurring openings (stomata, water pores) (fig. 2) on the surface or by boring directly through the skin or cuticle of the plant (fig. 2). Certain parasites, known as *wound* parasites, are only able to enter through openings or wounds which have been made by other agencies; *e.g.,* insect bites, bruises due to processes of cultivation, frost cracks, wind damage, pruning wounds, etc. Then again dispute exists as to whether the actual process of penetration is effected by purely mechanical means or by the agency of some chemical substance which softens or dissolves the cuticular layer of the plant. Once inside the plant, the fungus progresses by sending hyphae through the tissue, either between the cells (*intercellular*) or into the cells (intracellular). The particular relationship shown — *i.e.,* whether the hyphae are between or actually in the host cells — is more or less characteristic of individual diseases. In many cases the hyphae of the fungus ramify between the cells of the host and here and there send characteristic outgrowths (haustoria) into the cells themselves (fig. 2). These outgrowths are clearly the organs which enable the parasite to abstract its nutriment from the host cells.

While the fungus is progressing through the plant, the cells of the latter in the neighbourhood of the parasite, or even at some distance from it, show a number of more or less characteristic changes. The total sum of these changes, it should be noted, constitute the symptoms of the disease. The details of the changes shown vary much from one disease to another, but broadly speaking one can distinguish two main types of disease, each with a characteristic set of host changes associated with it.

Generalized Parasites. — In the first type, the fungus pours out certain chemical substances into the surrounding host cells, with markedly destructive effects to the latter. The living contents (protoplasts) of the cells are killed and the walls which separate the individual cells (and which form the mechanical skeleton of the living plant) are softened or partially dissolved. The destructive principle exuded by the fungus is able to diffuse out into the host tissue and thus bring about killing of the latter well ahead of the growth of the fungus. Fungi of this type are therefore not parasites in the strict sense of the term, inasmuch as they are growing all the time, not on the living plant, but on parts of it they have previously killed.

This type of parasitism is relatively simple and crude. The fungus, so to speak, is in the nature of an assassin who kills and then plunders his victim. The essential part is the killing and this merely entails that the fungus must possess the necessary battery of substances for carrying out this process. In these respects such fungi and the diseases to which they give rise stand in marked contrast to the type which will now be described.

Specialized Parasites. — In the second type of disease, there is no rapid killing or rotting effect produced by the parasite on the host cells in the neighbourhood. The cells of host plant and parasite live side by side for a considerable time with no apparent damage to the former. Indeed it frequently happens that the presence of the parasite stimulates the host cells to unusual growth and activity. Thus the cells in the neighbourhood of the parasite, some of which are actually penetrated by the food-absorbing processes of the latter, are often found on examination to be more richly supplied with food reserves than are the normal cells removed from the zone of influence. If the part of the plant affected is a leaf or other green part, the stimulating effect produced by the parasite may often be seen in the more intense green round the margin of the invaded spot than elsewhere. The stimulating action in many cases takes the form of renewed growth on the part of cells which normally would not have grown further. In this way are produced the tumours, galls, warts, witches' brooms, etc., frequently associated with diseases of this type. Such parasitism illustrates the **symbiotic** relationship to which reference has already been made. The symbiotic relationship may persist for a considerable time, but by and by injurious effects supervene, leading to more or less extensive destruction of the host tissue.

The second type of parasitism is much more subtle in nature than the first. The method of attack adopted has no resemblance to that of the assassin but savours rather of the blackmailer whose interests would not be well served by the premature death of his victim. Up to a point the interests of blackmailer and victim are identical, and if the association leads to unusual industry on the part of the latter the final harvest is all the richer. In diseases of the second type an analogous behaviour is shown. The analogy can in fact be pressed more closely still. Fungi which produce the first type of disease are, like the assassin, not selective in their action. In diseases of the second type, on the other hand, a high degree of selectivity is typically shown.

Fungi which produce this specialized type of disease show specialization in other respects. Their food requirements are of a very particular nature, and on this account it is generally impossible to cultivate them on any medium other than the living plant to which they are specialized. The symbiotic relationship is apparently necessary, and if this is not developed, no effective parasitism ensues.

As fungal attack progresses, one usually finds that the parasite makes provision for its further distribution by the development of a fruiting or sporing stage. The spores may be formed within the tissue of the parasitized plant and are disseminated only when the latter is decomposed, as for example by rotting on the surface of the soil. More generally the fructifications of the fungus are developed on or towards the outside of the plant, either emerging from the stomata or bursting through the outer skin (fig. 2). Many fungal parasites develop two kinds of spore. One of these is produced in profusion during the growing period and serves to spread the disease rapidly to new plants. This is the so-called summer spore, which is usually short-lived and germinates with great readiness when the environmental conditions are suitable. The second type of spore is usually produced later in the season. This is a resting form which typically will not germinate until after a certain interval has elapsed, and which in some cases requires exposure to winter cold before it is capable of germination. The resting spore is usually provided with a thick protective wall, and is capable of enduring long exposure to atmospheric conditions. Its function is to carry the fungus over the winter.

Immunity. — The preceding sketch of the progress of a successful parasitic attack would be incomplete without some reference to those features of the plant which confer resistance or immunity to disease. These are the "internal" (as apart from environmental) factors to which reference was made above. It was also pointed out that immunity to certain highly specialized fungi was really due to over-susceptibility.

It may be noted in the first instance that a plant may be immune in the practical sense for the reason that it merely *escapes* disease. Internally it may be just as susceptible as other plants which become badly diseased. The presence of water-drops on the surface, which enable germination of the fungal spores, is a necessary antecedent to attack. Many plants are enabled to escape attack on account of a property of their outer surface which prevents the adherence of water.

With fungi which penetrate the cuticle, the strength of the latter is obviously of importance, at least if the mechanical view of penetration is accepted. In many cases there is definite evidence that this factor comes into play. Thus certain fungi are only able to attack the young leaves in which a mature, fully thickened cuticle is not yet present.

When the fungus has actually entered the tissues of the plant, it must, if parasitism is to be effected, be able to live in the sap with which it comes into contact. Attempts have therefore been made to explain the susceptibility or resistance of a tissue in terms of the properties of the plant juices. Certain difficulties of a technical nature are met with in such investigations; *e.g.*, it is not certain how far an extract which is pressed out from a plant is a true representation of the ceii-sap originally present in the cells. Up to the present it has been possible only in a few cases to correlate the resistance of the host tissue to fungal attack with the anti-fungal properties of the plant juice.

The method by which the "killing" type of fungus breaks down the resistance of the host tissue is by excreting certain enzymes which partially dissolve the cell walls and kill the protoplast. These ferments are highly specific in action; *i.e.*, they are active on some tissues and not on others. The main factor in this connection seems to be the chemical composition of the cell walls.

So far we have dealt with possible chemical measures of defence. Many plants adopt a mechanical means of defence by laying down a protective layer of cork in advance of the parasite. The corking-over of an exposed or wounded surface is a common reaction of plants, and the same often takes place in response to the wound caused by a parasite. One or more layers of corky cells are formed somewhere along the line of separation between diseased and healthy tissue, and these act as a mechanical barrier to further progress. Any condition of the invaded plant which tends to accelerate this formation of cork increases the resistance to attack, and conversely. Similarly it has been shown in one case (the "silver leaf" disease of plum trees) that resistance depends on the formation, as a wound response, of a layer of hard gum which mechanically shuts off the parasite.

No reliable evidence exists as yet of any formation of antibodies such as play a fundamental part in the arrest of certain animal diseases. Here we meet with another illustration of the essential difference between plant and animal diseases.

ECONOMIC IMPORTANCE OF PLANT DISEASES

The number of known plant diseases is very great, and even if those occurring on non-economic plants are ignored, there is still a large residue. A glance at the disease lists of economic crops, such as are published from time to time by departments of agriculture and other bodies, will show as many as twenty or more diseases occurring on particular species of cultivated plants. The majority of these appear, for the present at any rate, to be of little economic importance, but one may say generally that more or less all cultivated plants are subject to two or three diseases of major importance, which at various times or places interfere seriously with their profitable cultivation. Thus in the case of the potato, one may cite four important diseases, blight, wart, common scab and virus disease, all of which afford serious problems to the grower. Of the many diseases reported on the apple, one may mention mildew, scab, canker, brown rot, bitter pit and scald as of the greatest economic importance; and so on, for other crop plants. In any one year and in a given locality, certain of these diseases may do little damage or may even appear to be absent, but over a wide area and over a period of years the aggregate loss is very great. One might forecast that the seriousness of the losses due to plant disease will tend to become greater as the gradual increase in the world's population makes it less possible for the supply of any product to outstrip the demand.

Though the farming class as a whole may in certain cases reap an advantage from the prevalence of plant disease, to the individual farmer the occurrence of disease in his crops can only bring loss. He therefore adopts certain measures with a view to protecting his crops and submits to various legislative restrictions, the object of which is to prevent or limit the spread of plant diseases. All these measures have as their ultimate result an increased cost of production of the article concerned, and this in the long run represents a loss to the community.

Epidemics. — It is, however, when plant disease comes on in epidemic form that the most striking damage is produced. The general public which is unaware of the widespread and ever-continuous frittering away of plant products as a result of disease, sees then the disease in its most concentrated form. Such epidemics have at one time or other produced enormous losses. They have profoundly influenced the economic development of certain countries, and have led frequently to acute distress and famine. The following examples will serve to illustrate these statements.

The rust diseases of cereals are present in all cereal-producing countries and the annual loss in many of them runs into millions of pounds sterling. The estimated loss from the stem-rust disease of wheat in 13 of the northern United States for the ten-year period 1915–24 is given as about 550 million dollars, half of which loss was incurred in a single "rust" year, 1916. The rust epidemic of 1891 cost Prussia about three-quarters of the whole cereal crop. Similar disasters have occurred in India, Australia, South Africa and other wheat-growing countries. It is simply the fact that wheat is cultivated in so many widely separated countries—in all of which a rust epidemic is not liable to occur in any one year—which acts as a safeguard against a serious bread famine.

The coffee disease, also caused by a rust, is a striking example of the effect which a disease may have on the economic history of a country. In the earlier part of the second half of the 19th century, the coffee industry was the mainstay of the prosperity of Ceylon. About 1870 a hitherto unrecorded leaf disease appeared on the coffee bushes. As with many important plant parasites, the seriousness of this disease was not recognized at first. Within a few years the fungus had spread over the whole island and the coffee industry soon disappeared from Ceylon.

Perhaps the most outstanding instance of distress caused by a fungal disease is afforded by the great Irish potato famine in 1845 and 1846. The potato disease ("blight") had only appeared in Europe a few years previously, the causal fungus being, like the potato itself, a native of South America. The disease spread like wildfire over western Europe and in the seasons 1845 and 1846 almost completely destroyed the potato crop in Ireland. As the potato at that time constituted the staple food of the peasant population, the result of the epidemic was a famine of unprecedented severity.

The story of the coffee leaf disease in Ceylon has in recent years found a very close parallel in that of the chestnut blight in the United States. This disease first appeared in 1904 on a few trees in the neighbourhood of New York. Subsequent investigation showed that the causal fungus was a native of Eastern Asia where it occurs on certain native species of chestnut, but without causing appreciable damage. It had apparently been introduced into the United States on a consignment of chestnuts from the East, and there is every probability that if its importance had been recognized, the disease could have been stamped out in the early stages. As it was, the disease began to spread over the New England States and it soon became apparent that the fungus was much more destructive to the American sweet chestnut (*Castanea* dentata) than to the Asiatic forms. Control methods of the most elaborate nature were put in operation, but too late to be effective. At the present time, this disease has destroyed practically all the native chestnuts in the United States. (See CHESTNUT.)

Records of the complete extermination of an industry by fungal disease are fortunately not numerous. On the other hand it would be possible to multiply examples in which fungal diseases are an ever-present menace to particular cultivations. The most important single factor in the cultivation of many economic plants is the liability to certain fungal diseases.

METHODS OF CONTROLLING PLANT DISEASE

The checking of a plant disease, so that if not actually eliminated it is reduced to manageable proportions, is spoken of as its "control." This may be complete or partial. The methods of control may be divided into two main groups, first those which are put into practice by the grower himself, and second those which are enforced upon him by legislation. In the following discussion these will be considered separately.

Voluntary Control.—The adoption of control measures by the grower is subject to a number of severe restrictions. It is only with a certain number of crops that individual treatment of plants is possible, and in all but exceptional cases the economic consideration of cost is all-important. It is idle for the plant pathologist to suggest measures of control if the requirements of time and labour involved in the treatment are such as cannot be satisfied or if the ultimate gain to the grower is not obviously greater than the cost of the measures adopted. The control methods adopted may be directed to increasing the resistance of the plant to disease, or in the case of a parasitic disease may also be directed against the parasite. The former will be dealt with first.

Resistance.—For every plant there is a certain range of environmental conditions within which it grows best. If the conditions vary widely in any important respect from those which are ideal, the plant grows badly. A weakly growing plant is in general more susceptible to parasitic attack than is a strongly growing one, and the abnormal condition of the plant resulting from the unfavourable environment may in itself be so pronounced as to be called diseased. Good cultivation, therefore, which aims at giving the plant the optimal conditions for its growth, is the first line of treatment to be adopted with a view to lessening the incidence of disease.

The most approved methods of husbandry will not however guarantee freedom from plant diseases, nor are they always practicable. More special methods must therefore be adopted. In recent years it has become increasingly recognized that the main line of defence against many important diseases consists in the development of *immune* or resistant varieties of the host plant.

To obtain varieties of a crop plant which are resistant to a particular disease is in many cases not difficult. These may in fact exist among the varieties already in cultivation. If the resistant forms possess high merits in other respects—*e.g.,* in yielding power, in quality of product, etc.—then the problem of the particular disease is in large measure solved. Often, however, the resistant varieties which are already known to occur show certain disadvantageous features, and these may be so great as to outweigh the benefits conferred by the high disease resistance shown.

One method of obtaining a resistant strain from a commercial variety consists in growing the plants under conditions in which they are exposed to infection and selecting out for propagation those individuals which stand up successfully against the disease. This method has been adopted with great success in the development of strains resistant to some of the important wilt diseases (cotton, cabbage, etc.).

A more elaborate method consists in the artificial crossing of parents of known characteristics, followed by the sorting out of the different types which occur among the progeny. (See PLANT BREEDING.) This is the application to problems of disease of the principles of Mendelism (*q.v.*). Resistance to disease behaves as a single or multiple Mendelian factor, and is usually dominant in the immediate offspring.

Destruction of the Parasite.—The control of plant diseases by the adoption of measures against the fungus is best considered with reference to the life-history of the fungus and in particular to the manner in which it reinfects the growing crop after each period of winter dormancy.

If the fungus is a soil parasite, it may be possible to starve it out by ensuring that it does not come in contact with the particular crops on which it grows and multiplies. This involves a system of rotation of crops. The practice of crop rotation is justified for other agricultural reasons and is of great value in that it tends to check the multiplication of specific soil (and other) parasites. Some soil parasites however are able to live indefinitely on the humus material of the soil so that they cannot be starved out (*e.g.,* some wilt diseases), others may persist so long in the dormant form that the interval required between successive susceptible crops is too long to be economically practicable (*e.g.,* wart disease of potato).

The elimination of a parasite from the soil by any process of sterilization is generally impracticable on account of the expense involved. In greenhouse cultivation or in those cases where the main source of infection is the seed-bed, soil sterilization may be attempted. For this purpose, heat (*e.g.,* steam-heat as obtained from a boiler) or a fungicidal chemical such as formalin is generally used.

Preventive Measures.—If the disease is carried by the seed, the practical method of control consists either in the selection of seed known to be free from contamination or in some process of seed treatment devised to destroy the parasite without appreciably affecting the germinating capacity of the seed. If the fungus is present merely on the surface of the seed, treatment is generally simple. This consists in steeping the contaminated seed in solutions of various chemicals—formalin, copper sulphate, mercuric chloride, organic salts of mercury, etc.—for a suitable time. The fungus is killed by this treatment whereas the seed is little damaged on account of the protection afforded by its seed coat. Dusting the seed with various chemical powders is similarly effective.

A general palliative measure in the treatment of plant disease is to reduce the amount of infective material available. If the fungus overwinters on the dead remains of the previous year's crop, the latter should be disposed of, either by burning or by digging into the ground. Crop rotation, by segregating to some extent the current year's crop from last year's, is likewise useful.

One of the most important methods of protecting plants against the attack of air-borne parasites is by the use of fungicidal chemicals which are sprayed or dusted over the plants. The object aimed at here is to coat the surface of the plant with a thin but more or less continuous film of the fungicidal substance so that, when the air-borne spores of the parasite arrive, they are unable to initiate attack. Spraying or dusting, if properly carried out, prevents attack but is ineffective if the disease has already established itself. Thus an intimate knowledge of the life-history of the fungus with special reference to the date at which it emerges from its winter resting stage is of the greatest importance for success in spraying operations. The leaves and young shoots of the plant are readily injured by the action of poisonous chemicals, so that great care is necessary in the preparation and use of fungicides, otherwise greater damage may be done than that which it is intended to prevent. The spray, which consists of a very fine suspension in water of the fungicidal substance, is discharged under pressure in the form of a mist so that as far as possible the whole plant surface is covered. In practice various inert substances ("spreaders") are added in order to facilitate wetting of the leaves and adhesion of the spray. The basis of most sprays in commercial use is either copper or sulphur. To the former class belong the well known Bordeaux and Burgundy mixtures, prepared by adding solutions of copper sulphate to lime and soda respectively. To the latter belong such preparations as "liver of sulphur," "lime sulphur" and "colloidal sulphur."

Legislative Control.—The legislative enforcement of certain measures for the control of plant diseases actually dates back for several hundred years. Witness for example the Rouen act of 1660 for the control of wheat rust by the eradication of barberry bushes (see later). The full development of these measures however has only come about within the last twenty years. The Destructive Insects and Pests Act was passed by the British parliament in 1907 and a similar law, the National Plant Quarantine Act came into force in the United States in 1912. Practically all civilized countries adopted the same type of regulations and at much the same time.

Restriction of Imports.—As between one country and another, the effect of these enactments is to limit free trading in such plants or plant products as are considered likely to bring dangerous parasites into the importing country. The restrictions may amount to a complete embargo, as applies for instance to the import of English potatoes into the United States (on account of the wart disease) or of American gooseberry bushes into England (on account of mildew). In other cases import is allowed provided the material has been inspected by a responsible authority in the exporting country and warranted free from certain diseases. Such material is subjected to further inspection at the port of entry and if found contaminated may be destroyed. From the port it may be liberated directly to the trade or may be sent to a quarantine station, where it is grown in an isolated situation for such time as enables its freedom from disease to be fully established. These restrictive regulations may also be in force between different parts of the same country, as for instance, between the different states of the United States.

Domestic Control Measures.—Within the limits of any one country, legislative control may take the form of compulsory notification of certain diseases. The latter will then be inspected, and the appropriate measures—such as destruction of the infected material—enforced. A further measure is the placing of restrictions on the kind of crop which may be grown within certain infected areas. The legislation against wart disease of potato in England is an illustration of this type of control measure. Within an infected area (called a "scheduled" area) only immune varieties of potatoes may be grown. The enforcement of this kind of measure is very difficult unless suitable immune varieties or other substitute crops are available.

Legislative control of the type outlined above has naturally led to the creation of an inspection service, and further to a wide extension of facilities for advisory work and for the carrying out of research. This increased interest in problems of plant disease, arising from government intervention, is perhaps the most striking development in plant pathology which the 20th century has produced.

CLASSIFICATION OF PLANT DISEASES AND SPECIAL ACCOUNT

In the present section a brief account will be given of some of the more important plant diseases and under the following headings—

(a) Physiological Plant Diseases.
(b) Plant Diseases due to Bacteria.
(c) Plant Diseases due to Viruses.
(d) Plant Diseases due to Fungi and Slime-Fungi.
(e) Plant Diseases due to Higher Plants.

Physiological Plant Diseases.—Plants, like animals, may show deficiency diseases due to the lack of some important chemical constituent in their food supply. Thus a lack of iron salts in the soil produces the condition called "chlorosis," in which the green pigment of the plant, chlorophyll, fails to develop. Lack of potash, such as often occurs in poorly manured soils or in light soils leached by heavy rainfall, produces very characteristic symptoms of disease in certain plants, *e.g.*, potato, tobacco and cereals. Similarly for other essential food elements such as magnesium, phosphate and nitrogen. Conversely disease conditions may result from the presence of an excess of certain chemicals in the soil. To this class belong various kinds of chlorosis, due to excess of lime or manganese in the soil. The most important diseases of this type are those associated with the accumulation of soil alkali. These are met with in irrigated regions where they often constitute the chief agricultural problem.

Among diseases due to unsuitable environmental conditions may be cited those caused by too high temperature, such as sunscorch of leaves, heat canker, etc. The effects of too low temperature are familiar as frost injury to leaves, young shoots, fruit, etc., but a more important illustration is seen in the winter killing of trees in those countries which experience severe winter freezing. The development of "winter-hardy" varieties of cultivated plants is of great importance in countries possessing the continental type of climate.

Injuries due to noxious chemicals in the air are well shown by plants growing in industrial areas. The more important chemicals in this connection are gases, such as coal gas and sulphur dioxide, fumes such as sulphuric acid, and dusts such as soot and cement dust. The latter act by choking up the breathing pores of the plants, but this action is often accompanied by the poisonous effects of gases associated with the dust. In this connection should also be mentioned the injuries which arise from the injudicious use of chemical protective agents such as sprays.

Plant Diseases Due to Bacteria.—The most important diseases of this type are the fire blight (Bacillus *amylovorus*) of apples, penrs and similar fruits; the angular leaf spot or black-arm disease of cotton (*Pseudomonas malvacearum*); the olive tubercle (P. *Savastanoi*); citrus canker (P. cifri); various wilt diseases (*Bacillus tracheiphilus* in cucurbits, *B. solanacearum* in tomato, potato, etc.); soft rots of a number of vegetables (B. *carotovorus* and allied species); two leaf spot diseases of tobacco (*Bacterium angulatum* and B. tabaci); and crown gall (P. *tume*faczens) on a large variety of herbaceous and woody plants.

Plant Diseases Due to Viruses.—This important group was formerly placed among the physiological diseases, but it is now known that they are of infectious or contagious nature. Detailed investigation has failed to show the presence of a visible parasite, but in other respects the resemblance to the parasitic type of disease is very close. The disease can in many cases be transmitted by the inoculation of the juice of a diseased plant into a healthy one. Where this simple method of transmission fails, infection of a healthy plant can be obtained by grafting on it a shoot of a diseased plant. In certain cases it has been proved that the juice of a diseased plant is able to convey infection after it has been filtered through a porcelain cup, whence the current view with regard to these diseases is that they are caused by filter-passing organisms. The symptoms of virus disease are confined to the shoot portions of the plant, and take the form typically of mottling ("mosaic") of the leaves, with as a rule a certain amount of puckering, distortion or inrolling. The habit of growth may aiso be affected, and often there is dwarfing, premature death, and a marked diminution in the yield. The chief agents of transmission are various leaf-biting or leaf-sucking insects, particularly aphides. The number of crop plants which are known to show virus diseases is very large and includes potato, tomato, tobacco, cucumber, clovers, spinach, hop, sugar cane, sugar beet, peach and many others. Certain kinds of ornamental variegation are also infectious and are thus not distinguishable from virus disease.

Diseases Due to Fungi and Slime-fungi.—These constitute by far the most numerous group of plant diseases. The species of fungi which cause plant disease are to be numbered by thousands and occur in all the main divisions into which fungi are classified (see FUNGI). In the majority of text books on plant pathology, these diseases are classified according to the systematic relationship of the causal fungus, but in some cases a grouping according to the crop plant affected or according to the type of symptom produced may offer certain advantages. In the present article, any systematic review of even the more important diseases is impossible. Ail that can be attempted is to indicate some of the more important groups or types.

The Slime-Fungi. (Myxomycetes) are responsible for a few diseases of economic importance. The best known example is the finger-and-toe or club root of crucifers (turnip, swede, cabbage, etc.) due to the organism *Plasmodiophora* brassicae. This disease is remarkable for the large size of the hypertrophies produced on the roots of the affected plants.

The group of the Lower Fungi (Phycomycetes) includes two important disease-producing families. The more important of these is the *Peronospora* family or downy mildews which cause important diseases of a great number of crops, potato, vine, hop, lettuce, several grasses and many others. The downy mildew of the potato (Phytophthora infestans) produces the most important disease of all, the potato blight, to which reference has already been made. Many-seedling diseases ("damping off") also belong here. The most important member of the second family is the organism *Synchytrium* endobioticum, the cause of the black scab or wart disease of potato.

Within the group of the Ascomycetes there are numerous important parasites. Species of *Sclerotinia* produce the brown-rot or "mummy" diseases of apple, plum and similar fruits, being among the most destructive orchard parasites. The family of the Erysiphaceae comprises the powdery mildews. These fungi cause the abundant formation on the plant of a powdery mass of summer spores, whence the name of the group. Crops of economic importance which are attacked by powdery mildews include cereals, clover, vine, hop, gooseberry, stra berry, apple, rose and oak. Species of Exoascus produce the leaf-curl disease of peaches and almonds and a number of interesting if economically unimportant diseases such as witches' brooms on cherry and birch. To the group of Ascomycetes also belong such important diseases as ergot of grasses (Claviceps *purpurea*), apple canker (*Nectria galligena*), wheat scab (*Gibberella* saubinetii), black knot of plum (*Plowrightia* morbosa), chestnut blight (Endothia *parasitica*), and apple scab (Venturia *inaequalis*). The group Basidiomycetes includes three families of parasites of very great economic importance: the smuts, the rusts and the bracket fungi.

The smuts (Ustilagineae) are a peculiar group of parasites which live almost wholly within the host plant and usually direct their attack to the developing flower and fruit. The latter in the typical case is converted into a black powdery mass of spores which constitute the "smutted" head so characteristic of this type of disease. The most important examples are met with among the grasses—viz., the loose and covered smuts of barley, wheat, oats, rye, rice, maize, etc.

The rusts (Uredineae) include perhaps the most important of all plant parasites. The cereal rusts (*Puccinia graminis* and allied forms) are the best known and economically the most serious, but important parasites occur on apple, plum, coffee, Weymouth pine, and many others, especially herbaceous plants. A striking feature in the life history of some of these rusts is that they pass from one host species to another. Thus some forms of the wheat rust parasite have a stage on the barberry; the Weymouth pine blister rust passes to various species of currant. The elimination of the so-called "alternate host" offers a means of control for certain of these rusts. Hence the "barberry eradication campaign" which is being actively prosecuted in certain wheat-growing countries.

The bracket fungi (Polyporaceae) are a• group which attack living trees and timber. These are generally wound parasites which gain entrance through broken branches or other injuries, destroy the wood of the tree, and from time to time produce the well-known bracket-like fructifications on the surface. Species of Polyporus and Fomes attack a large variety of growing trees.

Diseases due to Imperfect Fungi make up an enormous and miscellaneous list, including such as the following: many fruit rots (Botrytis, *Penicillium*), wilts (Fusarium), stripe disease of cereals (*Helminthosporium*), and an almost infinite number of leaf, stem and fruit spots (Phoma, *Septoria, Gloeosporium*, etc.).

Diseases Due to Higher Plants.—Parasites of this type are of great botanical interest, but as a rule of little economic importance. Well known examples are the mistletoe (which is a semi-parasite only, being able to manufacture its carbonaceous food from the air by means of its green leaves) and the dodder or love vine. These attach themselves to and parasitize the stems of other plants.

BIBLIOGRAPHY.—F. D. Heald, *Manual* of Plant Diseases (New York and London, 1926), gives a full bibliography (pp. 20–24) of general and specialized text-books. Current literature: Phytopathology (American Phytopathological Society, 1911 onwards); Journal of Agricultural Research (Washington, D. C.. 1913 onwards); *Annals* of Applied Biology (London, 1914 onwards); *Zeitschrift* fur *Pflanzenkrankheiten*, (Stuttgart, 1891 onwards); Review of Applied Mycology (Kew, England, 1922 onwards). The journal last mentioned gives full abstracts of all the current plant pathological literature. (W. BRO.)

PLANUDES, **MAXIMUS** (c. 1260–1330), Byzantine grammarian and theologian w-ho flourished during the reigns of Michael VIII. and Andronicus II. Palaeologl, spent the greater part of his life as a monk in Constantinople. On entering the monastery he changed his original name Manuel to Maximus. Possessing a knowledge of Latin remarkable for 'his time he was sent by Andronicus II. in 1327 on an embassy to remonstrate with the Venetians for their attack upon the Genoese settlement in Pera. Planudes, especially by his translations, paved the way for the introduction of the Greek language and literature into the West.

He is the author of a Greek grammar, a biography of Aesop and a prose version of his fables, certain scholia, various original poems. His numerous translations from the Latin included Cicero's Somnium *Scipionis* with the commentary of Macrobius: Caesar's Gallic War; Ovid's *Heroides* and Metamorphoses; Boetius, De *consolatione philo*sophiae; Augustine, De *trinitate*. He also edited a supplement to the Anthology known as Appendix *Planudea*.

Krumbacher, *Geschichte* der byzantinischen *Literatur* (1897); J. E. Sandys, *Hist.* of Class. *Schol.* (1906), vol. i.

PLAQUE, a small flat plate or tablet, applied particularly to rectangular or circular ornamental plates or tablets of bronze, silver, lead or other metal, or of porcelain or ivory. Small plaques, called plaquettes, in low relief in bronze or lead, were produced in great perfection in Italy at the end of the 15th and beginning of the 16th centuries, and were usually copies of ancient engraved gems, earlier goldsmith work and the like.

PLAQUEMINE, a city of southeastern Louisiana, U.S.A., located on the Mississippi river 14 mi. S.W. of Baton Rouge. It is the parish seat of Iberville parish. Pop. (1940) 5,049, a decrease of 75 from the 1930 figure. Plaquemine is served by the Texas and Pacific railroad and by state highways 30 and 168. Its principal industries include sugar, lumber and oil. The town's chief importance, however, derives from the fact that it is the site of the Plaquemine locks, constructed in 1909. The locks are located in a channel which connects the Mississippi with the Grand river, the Grand in turn being connected with the Atchafalaya, which flows into the Gulf of Mexico.

The function of the channel was at one time assumed by Plaquemine bayou, no longer navigable. The name Plaquemine, given first to the bayou and later to the town, is said to be a derivation of the Indian word for persimmon, a fruit which thrives in the vicinity.

Plaquemine was incorporated in 1838 and became the parish seat four years later.

PLASSEY (Palāsi), village of Bengal, scene of Clive's victory on June 23, 1757, over the forces of the namab Suraj-ud-Dowlah. Clive, with 1,100 European and 2,100 native troops, and 10 field-pieces, took the field against the nawab, who had 50,000 men, 53 heavy guns, and some French artillery under M. de St. Frais.

Only the river Bhagirathi separated Clive's little force from the entrenched camp of the enemy, when the English leader, for once undecided, called a council of war.' Clive and the majority were against fighting, Major Eyre Coote, of the 39th Foot, and a few others for action.

Coote's soldierly advice powerfully impressed Clive, and after deep consideration he altered his mind and issued orders to cross the river.

After a fatiguing march, the force bivouacked in a grove near Plassey early on the 23rd. The nawab's host came out of its lines and was drawn up in a huge semi-circle almost enclosing the little force in the grove, and St. Frais's gunners on the right wing opened fire.

Clive replied, and was soon subjected to the converging fire of 50 heavy guns. For hours the unequal fight was maintained, until a rainstorm stopped it. The English covered up their guns, but the enemy took no such precaution.

Mir Mudin, the only loyal general of the nawab's army, thinking that Clive's guns were as useless as his own, made a disastrous cavalry charge upon them; he lost his own life, and his colleagues then had the game in their hands. Mir Jagar persuaded the nawab to retire into the entrenchments. St. Frais stood fast until one of Clive's officers, Major Kilpatrick, successfully drove him in. Clive followed up this success by cannonading the camp at close range.

But the rank and file of the native army, ignorant of the treachery of their leaders, made a furious sortie. For a time Clive was hard pressed, but his cool generalship held its own against the undisciplined valour of the enemy, and, noticing Mir Jagar's division in his rear made no move against him, he led his troops straight against the works.

After a short resistance, made chiefly by St. Frais, the whole camp fell into his hands. At a cost of 23 killed and 49 wounded this day's work decided the fate of Bengal. Although the historic grove has disappeared, a monument has been erected to commemorate the victory.

PLASTER OF PARIS, $2CaSO_4, H_2O$, a hemihydrated variety of gypsum (dihydrated calcium sulphate, $CaSO_4, 2H_2O$) which forms a cement when treated with water (see CEMENT). It obtained its name in consequence of being manufactured by the calcination of gypsum in the neighbourhood of Paris.

PLASTER-WORK. Piastering is one of the most ancient of handicrafts employed in connection with building operations, the earliest evidence showing that the dwellings of primitive man were erected in a simple fashion with sticks and plastered with mud. Soon a more lasting and sightly material was employed to take the place of mud or slime, and that perfection in the compounding of plastering materials was approached at a very remote period is proved by the fact that some of the earliest plastering which has remained undisturbed excels in its scientific composition that nhich is used at the present day. The pyramids in Egypt contain plaster-work executed at least 4,000 years ago (probably much earlier) and yet existing. hard and durable. Indeed the principal tools of the plasterer of that time were practically identical in design, shape and purpose with those used to-day. For their finest work the Egyptians used a plaster made from calcined gypsum just like the plaster of paris of the present time, and their methods of plastering on reeds resemble in every way our "lath, plaster, float and set" work. Hair was introduced to strengthen the "stuff," and the whole finished somewhat under an inch thick.

Very early in the history of Greek architecture we find (*e.g.*, at Mycenae) the use of plaster of a fine white lime stucco. The art had reached perfection in Greece more than five centuries before Christ, and plaster was frequently used to cover temples externally and internally, in some cases even where the building was of marble. It formed a splendid ground for decorative painting, which at this period of Grecian history had reached a very high degree of beauty. The temple of Apollo at Bassae, built of yellow sandstone about 470 B.C., is an excellent example. Pavements of thick, hard plaster, stained with various pigments, were commonly laid in Greek temples. In England the walls of large houses were formerly plastered above the wainscoting and coloured, while the ornamented plaster ceilings of the time of Henry VIII, Elizabeth and James I, are still the admiration of lovers of the art. Still earlier specimens of the plasterer's skill are extant in the pargeted and ornamented fronts of half-timbered houses. With regard to the smaller buildings, comprising small dwelling houses and cottages, the general application of plaster is of comparatively late date; for wainscoted walls and boarded ceilings or naked joists alone are frequently found in houses of not more than a century old both in England and on the continent.

Wood and Metal Lathing.—Wood laths are narrow strips of some straight-grained wood, generally Baltic or American fir, in lengths of from two to four or five feet to suit the distances at which the timbers of a floor or partition are set. Laths are about an inch wide, and are made in three thicknesses; "single" ($\frac{1}{8}$ to $\frac{3}{16}$ in. thick), "lath and a half" ($\frac{1}{4}$ in. thick), and "double" ($\frac{3}{8}$ to $\frac{1}{2}$ in. thick). The thicker laths should be used in ceilings, to stand the extra strain, and the thinner variety in vertical work such as partitions, except where the latter will be subjected to rough usage. Laths are nailed with a space of about $\frac{3}{8}$ in. between them to form a key for the plaster, and they must be nailed so as to break joint in bays three or four feet wide with ends butted one against the other. By breaking the joints of the lathing in this way, the tendency for the plaster to crack along the line of joints is diminished and a better key is obtained. Every lath should be nailed at each end and wherever it crosses a joist or stud. All timbers over three inches wide should be counterlathed, that is, have a fillet or double lath nailed along the centre upon nhich the laths are then nailed. This is done to preserve a good key for the plaster. Walls liable to damp are sometimes battened and lathed in order to form an air cavity between the damp wall and the plastering.

Lathing of metal, either of wire or in the form of perforated sheets, is extensively used on account of its fireproof and lasting quality. There are very many kinds of this material made in different designs under various patents. A lathing has been introduced formed of thin wooden rods wired together at $\frac{1}{4}$-in. intervals. This can be fixed around curves, and economizes plaster.

Lathing nails are usually of iron, cut, wrought or cast—and in the better class of work they are galvanized to prevent rusting. Zinc nails are sometimes used, but are costly.

Materials for Plaster.—The lime principally used for internal plastering is that calcined from chalk or other nearly pure limestone, and is known as fat, pure, chalk or rich lime. Hydraulic limes (see BRICKWORK and MORTAR IN BUILDING) are also used by the plasterer, chiefly for external work. Perfect slaking of the calcined lime before use is very important as, if used in a partially slaked condition, it will "blow" when in position and blister the work. Lime should therefore be run as soon as the building is begun, and at least three weeks should elapse between the operation of running the lime and its use.

Hair is used in plaster as a binding medium, and gives tenacity to the material. Ox-hair, which is sold in three qualities, is the kind usually specified; but horsehair, which is shorter, is sometimes substituted in its stead or mixed with the ox-hair in the lower qualities. Good hair should be long, strong, and free from grease and dirt, and before use must be well beaten to separate the lumps. In America, goats' hair is frequently used, though it is not so strong as ox-hair. The quantity used in good work is one pound of hair to two or three cubic feet of coarse stuff.

Manila hemp fibre has been used as a substitute for hair. As a result of experiments to ascertain its strength as compared with that of other materials, it was found that plaster slabs made with Manila hemp fibre broke at 195 lb., plaster mixed with sisal hemp at 150 lb., jute at 145 lb., and goats' hair at 144½ lb. Another test was made in the following manner. Two barrels of mortar were made up of equal proportions of lime and sand, one containing the usual quantity of goats' hair, and the other Manila fibre. After remaining in a dry cellar for nine months the barrels were opened. It was found that the hair had been almost entirely eaten away by the action of the lime, and the mortar consequently broke up and crumbled quite easily. The mortar containing the Manila hemp, on the other hand, showed great cohesion, and required some effort to pull it apart, the hemp fibre being apparently quite uninjured. Sawdust has been used as a substitute for hair and also instead of sand as an aggregate. It will enable mortar to stand the effects of frost and rough weather. It is useful sometimes for heavy cornices and similar work, as it renders the material light and strong. The sawdust should be used dry.

Some remarks are made on the ordinary sands for building in the articles on BRICKWORK and MORTAR IN BUILDING. For fine plasterer's work special sands, not hitherto referred to, are used, such as silver sand, which is used when a light colour and fine texture are required.

In England this fine white sand is procured chiefly from Leighton Buzzard.

External Work.—For external work Portland cement is undoubtedly the best material on account of its strength, durability and weather resisting properties. The first coat or rendering is from ½ to ¾ in. thick, and is mixed in the proportions of from one part of cement to two of sand to one part to five of sand. The finishing or setting coat is about $\frac{3}{16}$ in. thick, and is worked with a hand float on the surface of the rendering, which must first be well wetted.

Stucco is a term loosely applied to nearly all kinds of external plastering, whether composed of lime or of cement. The principal varieties of stucco are common, rough, trowelled and bastard. Common stucco for external work is usually composed of one part hydraulic lime and three parts sand. The wall should be sufficiently rough to form a key and well wetted to prevent the moisture being absorbed from the plaster. Portland cement is used for all but the commonest external work. White Portland cement, made in the United States and France, is very successfully used with white sand to give an excellent stucco closely resembling stone and very durable.

Rough stucco is used to imitate stonework. It is worked with a hand float covered with rough felt, which forms a sand surface on the plaster. Lines are ruled before the stuff is set to represent the joints of stonework. Trowelled stucco, the finishing coat of this work, consists of three parts sand to two parts fine stuff. A very fine smooth surface is produced by means of the hand float. Bastard stucco is of similar composition, but less labour is expended on it. It is laid on in two coats with a skimming float, scoured off at once, and then trowelled. Stucco may be executed in colours, the desired tints being obtained by mixing with the lime various oxides. Black and grays are obtained by using forge ashes in varying proportions, greens by green enamel, reds by using litharge or red lead, and blues by mixing oxide or carbonate of copper with the other materials.

Rough-cast or Pebble-dash plastering is a rough form of external plastering in much use for country houses. In Scotland it is termed "harling." It is one of the oldest forms of external plastering. In Tudor times it was employed to fill in between the woodwork of half-timbered framing. When well executed with good material this kind of plastering is very durable. Rough-casting is performed by first covering the wall or laths with a coat of well-haired coarse stuff composed either of good hydraulic lime or of Portland cement. This layer is well scratched to give a key for the next coat, which is also composed of coarse stuff knocked up to a smooth and uniform consistency. While this coat is still soft, gravel, shingle or other small stones are evenly thrown on with a small scoop and then brushed over with thin lime mortar to give a uniform surface. The shingle is often dipped in hot lime paste, well stirred up, and used as required.

Sgraffito (Italian for "scratched") is scratched ornament in plaster. Scratched ornament is the oldest form of surface decoration, and at the present day it is much used on the continent, especially in Germany and Italy, in both external and internal situations. Properly treated, the work is durable, beautiful and inexpensive. The process is carried out by applying a first coat or rendering of Portland cement and sand, in the proportion of one to three, laid on about ½ in. thick; then following with the colour coat, which is sometimes put on in patches of different tints as required for the finished design. When this coat is nearly dry, it is finished with a smooth-skimming, $\frac{1}{12}$ to ⅛ in. thick, of Parian, selenitic or other fine cement or lime, only as much as can be finished in one day being laid on. Then by pouncing through the pricked cartoon, the design is transferred to the plastered surface. Broad spaces of backgrbund are now exposed by removing the finishing coat, thus revealing the coloured plaster beneath, and following this the outlines of the rest of the design are scratched with an iron knife through the outer skimming to the underlying tinted surface. Sometimes the coats are in three different colours, such as brown for the first, red for the second and white or gray for the final coat. The pigments used for this work include Indian red, Turkey red, Antwerp blue, German blue, umber, ochre, purple brown, bone black or oxide of manganese for black. Combinations of these colours are made to produce any desired tone.

Internal Plastering.—Lime plastering is composed of lime, sand, hair and water in proportions varying according to the nature of the work to be done. In all cases good materials, well mixed and skilfully applied, are essential to a perfect result. When brickwork is to receive plaster, it is all-important that its surface should be rough enough to form a key, or, alternatively, that the joints should be well raked out. Plaster is applied in successive coats or layers on malls or lathing, and gains its name from the number of these coats. "One coat" work is the coarsest and cheapest class of plastering, and is limited to inferior buildings, such as outhouses, where merely a rough coating is required to keep out the weather and draughts. This is described as "render" on brickwork, and "lath and lay" or "lath and plaster one coat" on studding. "Two coat" work is often used for factories or warehouses and the less important rooms of residences. The first coat is of coarse stuff finished fair with the darby float andscoured. A thin coat of setting stuff is then laid on, and trowelled and brushed smooth. "Two coat" work is described as "render and set" on walls, and "lath, plaster and set," or "lath, lay and set" on laths. "Three coat" work is usually specified for all good work. It consists, as its name implies, of three layers of material, and is described as "render, float and set" on walls and "lath, plaster, float and set," or "lath, lay, float and set," on lathwork. This makes a strong, straight, sanitary coating for walls and ceilings. The process for "three coat" work is as follows: For the first coat a layer of well-haired coarse stuff, about ½ in. thick, is put on with the laying trowel. This is termed "pricking up" in London, and in America "scratch coating." It should be laid on diagonally, each trowelful overlapping the previous one. When on laths the stuff should be plastic enough to be worked through the spaces between the laths to form a key, yet so firm as not to drop off. The surface while still soft is scratched to give a key for the next coat, which is known as the second or "floating coat," and is $\frac{1}{4}$ to $\frac{3}{8}$ in. thick. In Scotland this part of the process is termed "straightening" and in America "browning," and is performed when the first coat is dry, so as to form a straight surface to receive the finishing coat. Four operations are involved in laying the second coat, namely, forming the screeds; filling in the spaces between the screeds; scouring the surface; keying the face for finishing. Wall and ceiling screeds are plumbed and levelled. Screeds are narrow strips of plastering, carefully plumbed and levelled, so as to form a guide upon which the floating rule is run, thus securing a perfectly horizontal or vertical surface, or, in the case of circular work, a uniform curve. The "filling in," or "flanking," consists of laying the spaces between the screeds with coarse stuff, which is brought flush with the level of the screeds with the floating rule.

The "scouring" of the floating coat is of great importance, for it consolidates the material, and, besides hardening it, prevents it from cracking. It is done by the plasterer with a hand float which he applies vigorously with a rapid circular motion, at the same time sprinkling the work with water from a stock brush in the other hand. Any small holes or inequalities are filled up as he proceeds. The whole surface should be uniformly scoured two or three times, with an interval between each operation of from six to twenty-four hours. This process leaves the plaster with a close-grained and fairly smooth surface, offering little or no key to the coat which is to follow. To obtain proper cohesion, however, a roughened face is necessary, and this is obtained by "keying" the surface with a wire brush or nail float, that is, a hand float with the point of a nail sticking through and projecting about $\frac{1}{8}$ in.; sometimes a point is put at each corner of the float. After the floating is finished to the malls and ceiling, the next part of internal plastering is the running of the cornice, followed by the finishing of the ceiling and walls.

The third and final coat is the "setting coat," which should be about $\frac{1}{8}$ in. thick. In Scotland it is termed the "finishing," and in America the "hard finish" or "putty coat." Considerable skill is required at this juncture to bring the work to a perfectly true finish, uniform in colour and texture. Setting stuff should not be applied until the floating is quite firm and nearly dry, but it must not be too dry or the moisture will be drawn from the setting stuff.

The coarse stuff applied as the first coat is composed of sand and lime, usually in proportions approximating two to one, with hair mixed into it in quantities of about a pound to two or three cubic feet of mortar. It should be mixed nith clean water to such a consistency that a quantity picked up on the point of a trowel holds well together and does not drop. Floating stuff is of finer texture than that used for "pricking up," and is used in a softer state, enabling it to be worked well into the keying of the first coat. A smaller proportion of hair is also used. Fine stuff mixed with sand is used for the setting coat. Fine stuff, or lime putty, is pure lime which has been slaked and then mixed with water to a semifluid consistency, and allowed to stand until it has developed into a soft paste. For use in setting it is mixed with fine washed sand in the ratio of one to three.

For cornices and for setting when the second coat is not allowed time to dry properly, a special compound must be used. This is often "gauged" stuff, composed of three or four parts of lime putty and one part of plaster of paris, mixed up in small quantities immediately before use. The plaster in the material causes it to set rapidly, but if it is present in too large a proportion the work will crack in setting.

The hard cements used for plastering, such as Parian, Keene's and Sirapite, are laid generally in two coats, the first of cement and sand $\frac{1}{2}$ to $\frac{3}{4}$ in. in thickness. the second or setting coat of neat cement about $\frac{1}{8}$ in. thick. These and similar cements have gypsum as a base, to which a certain proportion of another substance. such as alum, borax or carbonate of soda, is added, and the whole baked or calcined at a low temperature. The plaster they contain causes them to set quickly with a very hard smooth surface, which may be painted or papered within a few hours of its being finished.

Mouldings. — Plain, or unenriched, mouldings are formed with a running mould of zinc cut to the required profile. Enrichments to suit a scheme may be added after the main outline moulding is set. being cast in moulds of gelatine or plaster of paris. For a cornice moulding two running rules are usual, one on the wall, the other on the ceiling, upon which the mould is worked to and fro by one workman, while another man roughly lays on the plaster to the shape of the moulding. The mitres at the angles are finished off with joint rules made of sheet steel of various lengths, three or four inches wide, and about $\frac{1}{8}$ in. thick, with one end cut to an angle of about 30°. In some cases the steel plate is let into a "stock" or handle of hardwood.

Cracks in plastering may be caused by settlement of the building, and by the use of inferior materials or by bad workmanship, but apart from these causes, and taking the materials and labour as being of the best, cracks may yet ensue by the too fast drying of the work, caused through the laying of plaster on dry walls ahich suck from the composition the moisture required to enable it to set, by the application of external heat or the heat of the sun, by the laying of a coat upon one which has not properly set the cracking in this case being caused by unequal contraction, or by the use of too small a proportion of sand.

For partitions and ceilings, plaster slabs (often of fibrous plaster) are in very general use when work has to be finished quickly. For ceilings they require simply to be nailed to the joists, the joints being made with plaster, and the whole finished with a thin setting coat. In some cases, with fireproof floors. for instance, the slabs are hung up with wire hangers so as to allow a space of several inches between the soffit of the concrete floor and the ceiling. For partitions the slabs frequently have the edges tongued and grooved to form a better connection; often. too, they are holed through vertically, so that, when grouted in with semifluid plaster, the whole partition is bound together as it were, with plaster dowels. Where very great strength is required the work may be reinforced by small iron rods through the slabs. This forms a very strong and rigid partition which is at the same time fire-resisting and of light weight, and when finished measures only from two to four inches thick. The slabs may be obtained either with a keyed surface, which requires finishing with a setting coat when the partition or ceiling is in position, or a smooth finished face, which may be papered or painted immediately the joints have been carefully made. Partitions are formed with one or other of the forms of metal lathing referred to, fixed to iron uprights and plastered on both sides.

Fibrous Plaster. — Fibrous plaster is given by plasterers the suggestive name ('stick and rag," and this is a rough description of the material, for it is composed of plaster laid upon a backing of canvas stretched on wood. It is much used for ceilings, partitions, mouldings, circular and enriched casings to columns and girders, and ornamental work, which, being worked in the shop and then nailed or otherwise fixed in position, saves the delay often attendant upon the working of ornament in position.

Desachy, a French modeller, took out in 1856 a patent for "producing architectural mouldings, ornaments and other works of art, with surfaces of plaster," with the aid of plaster, glue, wood, wire and canvas or other woven fabric. The modern use of this material may be said to have started then, but the use of fibrous plaster was known and practised by the Egyptians long before the Christian era; for ancient coffins and mummies still preserved prove that linen stiffened with plaster was used for decorating coffins and making masks. Cennino Cennini, writing in 1437, says that fine linen soaked in glue and plaster and laid on wood was used for forming grounds for painting. Canvas and mortar were in general use in Great Britain up to about 1850. This work is also much used for temporary buildings.

It is a notable fact that after World War I the rise of plasterers' wages in Great Britain and the United States, combined with the great scarcity of skilled workmen and other considerations, led to a considerable increase in the use of substitutes for plaster-work.

Various "boards," made of woodpulp and other materials, plywood and asbestos-cement sheets, have come largely into use for the finishing of walls and ceilings.

Jourdain, *English Decorative Plaster Work* (1926); A. H. Telling, *A.B.C. of Plastering* (1927). (X.; L. C. M.)

PLASTICS. The beginnings of the plastics industry have been variously ascribed to widely divergent geographical points—early developments are associated with Henri Braconnot, a Frenchman, C. F. Schonbein, a German, and Alexander Parkes, an Englishman, who all worked independently in the middle of the 19th century toward the development of a cellulose nitrate material. For all practical purposes however, it might be safely stated that the first real plastic was evolved by a young U.S. printer, John Wesley Hyatt. In 1863 the great elephant herds began to be decimated, and the excess demand for natural ivory was causing the price of all commodities made from ivory to rocket sky-high. It was then that Phelan and Collander, manufacturers of ivory billiard balls, sponsored a $10,000 award for the person who could develop an adequate substitute for the rapidly disappearing ivory. John Wesley Hyatt determined to win this award (an ambition which ironically was never realized), and thus started the plastics industry on its way. For it was in pursuit of the substitute billiard ball that Hyatt, working with his brother Isaiah, discovered cellulose nitrate plastic, later to be called by the trade name Celluloid. Hyatt did succeed in developing some very acceptable billiard balls coated with a collodion solution, and on April 6, 1869 the brothers were granted their first patent for the making of a solid collodion with very small amounts of solvent, dissolving the pyroxylin under pressure and thus securing great economy of materials and a saving of time. Improvements in the process of mixing the pyroxylin and camphor mere noted in patents issued in 1870 and 1872 to the Hyatts. Subsequent patents, 75 in all, were taken out as they developed progressive improvements in their process for mixing pyroxylin and camphor to produce cellulose nitrate plastic, the material which became the base for the plastics industry. In 1870 the Albany Dental Plate company was organized by Hyatt to handle the first commercial applications of cellulose nitrate plastic, and this venture was followed in 1871 by the formation of the Celluloid Manufacturing company, immediate predecessor of the Celanese-Celluloid corporation.

The far-reaching effects of the discovery of this material, its contribution to the plastics industry, and its influence upon many phases of American life, were manifold and enduring. Its principal use, immediately following the billiard ball era, was for dental plate blanks. One of the most important of the early applications was its use in sheet form for automobile side curtgins, not to mention that nostalgic symbol of a way of life—the famous celluloid collar.

Flexibility and resistance to wear were significant virtues of cellulose nitrate plastics, but its susceptibility (in the transparent form) to ultra-violet light resulted in rapid discolouration and deterioration. It was later used as the first bonding material for laminated "safety" glass, and although it was subsequently superseded by the more light-stable plastic materials, it served as an invaluable factor in establishing the importance of safety glass to the automotive industry. Cellulose nitrate was also used as a pigmented lacquer to provide both protection and colour to automobile bodies until the development of more suitable resins. Large quantities of the material were used for early photographic film. The miscellaneous applications cover a wide range of uses from spectacles, frames, buttons, combs, brush handles, heel coverings for ladies' shoes, typewriter and adding machine keys, radio and automobile dials to babies' rattles, and endless novelty and decorative items.

The cellulose nitrate or pyroxylin plastics are available in a wide range of colours and decorative effects. They may be moulded, extruded into rods, tubes and other uniform shapes, or sliced into sheets. By means of dyes and pigments which can be incorporated in the plastic mass by kneading, rolling, pressing, sheeting, restacking and re-sheeting, a wide variety of transparent and opaque colours as well as mottled and variegated effects may be produced. Its toughness, ease of fabrication, excellence and variety of colours, water resistance and good chemical resistance to solvents other than alcohols, ketones and esters contributed to the widespread and continued use of this earliest plastic. One of its chief drawbacks was its flammability, and the fact that light and heat tend to decompose and discolour it. Its use, however, was an important factor in paving the way for advances in the formulation and pigmentation of all thermoplastics, and for the pioneering in the mechanical and operative means of manufacture and fabrication of other plastic materials. Most important of all, it was in the vanguard of developments which created the later market for plastics, and indicated the direction for so many of its uses.

From the first, the search for a thermoplastic material, with the properties of cellulose nitrate but without its high degree of flammability, was pursued diligently. Strictly speaking, the discovery of such a material actually preceded Hyatt's, with Paul Schutzenberger's record of its preparation in 1865, and more fully in 1869. But it wasn't until 1894 that a patent was granted to C. F. Cross and E. J. Bevan for a process of preparation of a high acetyl chloroform soluble type of material. The first mention of a *plastic* of the cellulose acetate type occurred in 1903 in a patent issued to A. Eichengrun and T. Becker. Its first Practical commercial use was for safety photographic film in 1909, and for 17 years (through 1926) this new material was confined almost exclusively to the photographic field. Late in 1926 the work of the Dreyfus brothers in collaboration with the Celanese-Celluloid corporation bore the fruits of success, and cellulose acetate began to be used extensively as a base for the manufacture of commercial thermoplastics.

The same basic process that produced cellulose nitrate plastics is employed in the manufacture of cellulose acetates with the important difference that acetic acid and acetic anhydride instead of nitric acid is used to treat the cotton linters. For two years following its introduction for commercial consumption, cellulose acetate plastic material was available only as sheets, rods and tubes supplied for fabrication by the established method used for pyroxylin plastics. But general mass production from this material was given new impetus with the development in 1929 of a cellulose acetate moulding powder. The advent of the injection moulding press at that time greatly increased the speed with which moulded articles could be produced from this new thermoplastic material.

The products available from this material became legion, and the cellulose acetate plastics and moulding powder soon outstripped cellulose nitrate materials both in over-all quantity and dollar value of annual production. It became widely used in the automotive industry for interior accessories, such as knobs, handles, switches, escutcheons, steering wheels, instrument panels, dials, etc. Its high resistance to impact made it an ideal material for protective goggles, workmen's lanterns, gas mask lenses and plane parts. Its mechanical toughness suited it admirably for tool handles, pen and pencil containers, oil gauges, etc. Excellent electrical properties made it a first-rate insulating material for winding wires, laminating insulations, and for all types of telephone equipment including telephone bases and handles. Cellulose acetate became one of the outstanding materials in laminated or "safety" glass development because of its superiority to cellulose nitrate as a glass binder by virtue of its resistance to ultra-violet light and general weathering. Its toughness, light weight and transparency made the acetate materials a primary component in the aircraft industry, and during World War II these plastic materials assumed the importance of war essentials used extensively for cockpit enclosures, windows and numerous other parts of planes where visibility and strength are important.

Shellac, Phenolic and Bituminous Plastics.—It might be fitting in a chronicle of plastic development, to begin with a

COMMON SMALLER ARTICLES OF PLASTICS

From left to **right,** top to bottom: kitchen clock (acetate), fabric (saran), trays (acetate), electric shaver (phenol and urea), small juice extractor (styrene), date stamp (phenol), measuring cup (urea), egg holders (acetate), salad spoon and fork (acetate), strainer (acetate and urea), salt and pepper shaker (acetate), doorknob (styrene), keyhole flashlight (below salad fork) (urea), fishing tacklebox (to right of salad spoon and fork) (acetate), card box (acetate), strips of extruded moulding (acetate and butyrate), cigarette holder (acrylic), transparent funnel (polystyrene)

discussion of shellac, the source of which is a humble and natural one. It is a little red bug, the *laccifer lacca,* which thrives in India and southern Asia and is directly responsible for the production of shellac, a product known and utilized for centuries as a constituent of sealing wax, varnishes, lacquers, etc. However, the first practical efforts directed toward developing this material for commercial use as a plastic was by a contemporary of John Wesley Hyatt's, John Merrick, who obtained the first patent for shellac in 1868. In the same year a second patent was issued to John M. Gardner, but it was not until 1895 that Emile Berliner developed the use of shellac moulding composition for phonograph records, still one of its chief outlets today.

Its first important use for moulded electrical insulation came in 1900, and shellac is still widely employed today for the manufacture of high-voltage insulators. One of its early functions mas in the ignition system of motor cars, but its low softening point and tendency to distortion from heat, led to its replacement in this application by thermosetting resin compositions. Later developments were primarily in connection with its use as a resinous binder for cloths, paper, silk, mica and other insulating components. It is also a first-rate binder for laminated sheets and for tubing, to which it imparts a good bond and high-quality electrical insulation.

Its ease of mouldability, toughness, hardness, fidelity of reproduction, low cost and possibility of re-use as scrap are outstanding properties of shellac. It has both thermosetting and thermoplastic properties, and may be used for both types of work. The long heating required during the curing cycle to utilize its thermosetting properties increases its electrical quality.

It was the "fruitless" quest for a substitute for natural shellac that resulted in the discovery by Dr. Leo H. Baekeland of one of the most versatile of all plastic materials, the first phenol formaldehyde resin, Antedating Dr. Baekeland's discovery in 1907, was the work of Adolf von Baeyer, who reported in 1872 that the union of phenols and aldehydes led to the formation of a resin, but it was his inability to control the reaction as well as the failure of successive investigators to recognize the implications of the "insoluble" mass that resulted from the union of these ingredients, that prevented industrial development and exploitation of this plastic. In 1909 Baekeland was granted a patent in which it was recorded that a heat hardened resin could be produced by using an alkaline catalyst. A heat and pressure patent subsequently granted Dr. Baekeland attested to the technique for converting this resin in a relatively short time into a moulded article of excellent mechanical and electrical properties. The manufacture of Bakelite, as Dr. Baekeland called his discovery, was begun in 1907 in his Yonkers laboratory. In 1910 the General Bakelite company was organized which subsequently merged with two other companies to form the Bakelite corporation. After 1926, following the expiration of the basic patent, many other firms marketed phenolic resins under a variety of trade names to supply the enormous demands.

To Dr. Baekeland, for his outstanding contribution of this general utility plastic material, belongs much of the credit for the amazing growth of the radio and automotive industries, not to mention the field of plastics itself. For it was the discovery of this insulating material that made possible the growth of radio as a mass production item. The most general application of phenolic plastics in automotive vehicles is in those parts of the electric system where material with good dielectric properties is required—in distributor heads, coil parts, switches, junction boxes, etc. These parts must be held to close tolerances, must be impervious to intense heat, and must be tough enough to withstand the abuse of normal service conditions. They were made possible in a large measure by this phenolic resin. Other applications of this plastic in the automotive field are for the impregnation of brake linings, and in phenolic resin-bonded grinding wheels. Magnetos, switches, instrument housings, terminal sleeves and conductor terminals are a few of the aircraft uses of this material, as are plane radio sets, panels, tubes, sockets, condensers, mountings, coils, binding posts, knobs and dials. Moulded canvas base phenolic material is used for cable pulleys, bushings, pilot seats and helmet liners. Phenolics are also used for radio parts, photographic equipment, closures, telephone parts, corrosion resistant apparatus, electrical insulating materials, heavy industrial units, etc.

Not the least important of uses for phenolic resins are in laminates. A laminated structure is formed from layers of sheet material which are bonded together into a solid substance. The synthetic resins perform the function of bonding individual layers into single, fused pieces of laminated material. When unusual hardness, dielectric strength, chemical resistance and low thermal conductivity are desirable factors, the laminates perform invaluable functions. Power transformers, automobile timing gears, cams, clutches, industrial fan blades and heavy indoor truck wheels are all made from laminates using phenolic resins. Laminated materials have terrific impact resistance, and are usually impervious to mineral or vegetable oils and to most acids, alcohol, benzol and gasoline. (See also RESINS: *Synthetic Resins.*)

In 1909, at the same time that Dr. Baekeland was working on his formula for shellac, a third plastic material, the bitumen or cold-moulded type, was launched by Emile Hemming, one of the earliest pioneers in the field. Asbestos, asphalts, coal tar, stearin, pitches, natural and synthetic resins and oil are the raw materials used in the preparation of this plastic. Because of the presence of volatile solvents and drying oils in the composition, the conditioning and storing of this plastic, prior to moulding, must be closely supervised.

Early applications of this material were chiefly in the field of electrical devices, and for use in moulding automotive products. However, reductions in the cost of phenolic materials and in the cost of moulding phenolics limited the use of cold-moulded materials to situations where the high temperature and flame-resisting properties could not be matched by the phenolics. Their chief uses are for electrical switch parts which may be subjected to open flame or arc when the circuit is broken, and for cooking utensil handles placed inside the oven or subjected to an open flame in use. These products will not burn at cooking temperatures. Battery boxes are one of the chief automotive products made from this material, and wire connectors, valve wheels and cores for high heat-resistant units are other products. Low cost and rapid moulding cycle are outstanding properties.

Casein.—At the end of the 19th century, Dr. Adolf Spitteler was working in Hamburg to develop a "white blackboard." Toward this end he united sour milk with formaldehyde and achieved a tough, insoluble hornlike mass, which led to the first patent grant for casein in 1900 to Dr. Spitteler and a colleague, W. Krische. Production of this material began almost immediately in Germany and France under the trade name of Galalith, which means milkstone, and manufacture began in England soon after, in 1914. In the United States, the first successful casein plastic development was undertaken by the Aladdinite company in 1919.

Casein plastics are largely used to manufacture such items as beads, buttons, ornaments and similar novelties and accessories. The limitations on its more extensive use are imposed by its hygroscopicity or poor moisture resistance.

Urea Formaldehyde Resins.—Although it was known as early as 1897 that urea could combine with formaldehyde to form a resinous product, few advances in the direction of a practical development of this material were recorded until the granting of the Hanns John patents in 1920. This first patent was for a transparent urea formaldehyde resin product which had the appearance but not the fragility of glass. Fritz Pollak and Kurt Ripper investigated this material further, and patents for their developments were issued in 1923. In 1928 this "synthetic organic glass" appeared on the U. S. market under the trade name Aldur, but it soon proved to have little practical value because of a tendency to crack. It was demonstrated by Carleton Ellis, however, that the addition to the resin of a slightly hygroscopic filler such as wood flour, or bleached pulp or alpha cellulose resulted in a moulding composition that could be formed into stable articles. In 1929 two such moulding powders were introduced, one known as Beetle and the other as Aldur. In 1931 Plaskon was placed on the market.

From the first, this plastic enjoyed immediate acceptance and widespread usage. The unlimited range of permanent colours, dimensional stability, handiness, absence of taste and odour, excellent insulating qualities, lightness of weight and shock resistance made it a highly desirable material for lighting fixtures, tableware, bottle closures, scales, illuminated dials, piano keys, reflectors, toys, novelties, dress accessories and a aide variety of other products. Laminated sheet materials using urea formaldehyde resins are used for doors, wall panelling, table tops, decorative murals and a wide variety of interior and architectural applications, also as a resin for impregnation of fibres.

Cast Phenolic Resins.--In 1928 there appeared a new phenolic resinous product, known as the cast phenolic, which differed from the earlier phenolic resins in appearance, processing and range of applications. These new resins were prepared in the form of a viscous syrup which was poured into a lead or rubber mould and hardened by heating. Since these resins are produced in liquid form, it is possible to mix two or more colours which flow together. Cast phenolic products are machined and polished after casting to give them brilliance and depth. Although a considerable portion of their popularity was established on aesthetic grounds, their expanded use was also attributed to their ease of fabrication, smooth finish, low thermal conductivity, electrical insulating qualities, hardness and durability. Developments which resulted in a heat-resistant, nonabsorbent, nonreactive grade of cast phenolic resin extended its use to the manufacture of corrosion-resistant equipment such as impeller parts, rotor parts of pumping and piping, and forming tools or dies for aircraft parts.

Vinyl Resins.—These resins were known as early as 1838. but their commercial development in the U.S. dated from 1928. nhen the Carbide and Carbon corporation began to work with polyvinyl ester resins, and introduced them commercially as a product called Vinylite. The most important of these resins. estimated by industrial values, are the polyvinyl acetates, polyvinyl chloride, co-polymers of vinyl chloride, vinyl acetate and the polyvinyl acetals. At about the same time, Shawinigan Chemicals Ltd. in Canada began the manufacture of polyvinyl acetate under the trade name Gelva. The extraordinary superiority of polyvinyl butyral for use as a plastic binder for laminating safety glass resulted in the establishment of three plants for its manufacture in 1937. In 1940 the Dow Chemical company entered the vinyl field with its vinylidene chloride resin for chemically resistant applications and coating, and for synthetic products known as Saran. The vinylidene chloride plastics in extruded form are used as tubing or piping to replace copper, and as extruded fibres for furniture and household upholstery fabrics.

Polyvinyl acetate plastics achieved great success as coatings. as adhesives for all types of materials, including paper, metal, mica, glass, plastic sheets, wood and porcelain.

Polyvinyl chloride plastics are endoned with considerable resistance to chemicals and moisture. They are used widely for gaskets and protective coatings, and as an insulating material for uires. The vinyl resins assumed new importance during World War II as insulation, and substitutes for rubber and other scarce materials.

Polystyrene.——More than 100 years before it was produced commercially in the United States, polystyrene mas known in England. Cognizance nas taken of the valuable properties of this plastic, but methods of producing styrene economically and with a sufficiently high degree of purity to achieve the necessary transparency and durability were not perfected until 1937, when the Dow Chemical company and the Bakelite corporation started the manufacture of styrene resins in clear transparent form

Polystyrene plastics are characterized by unusual properties outstanding among which are their low power factor and water absorption, high chemical resistance and physical strength at lon temperatures. These properties combine to make polystyrene exceptionally well suited to radio frequency insulation, parts of refrigeration equipment, and caps and closures for bottles containing fairly strong acids. Polystyrene is also used for transparent dials and indirect lighting of amperage, oil, temperature. fuel, mileage and other indicators in aeroplanes and automobiles.

Acrylic Resins.—The acrylic resins, with their crystal clarity. edge-lighted beauty, and inherent sparkle and brilliance, became perhaps the most popular of plastics. Dr. Otto Rohm, a German. is credited with having initiated the fundamental research on the synthesis and polymerization of this material in 1901. The development and research which resulted in its widespread use mas done by Imperial Chemical Industries Ltd., in England. The two United States suppliers were Rohm and Haas and du Pont. They were first offered for sale in 1931 as materials for coatings and laminated glass binders under the trade names Acryloid and Plexigum. In 1936 methyl methacrylate resin was introduced in transparent sheet form by Rohm and Haas company as Plexiglas, and du Pont offered both the sheet and the moulding powder under the trade name Lucite in 1937. Rohm and Haas moulding powder, originally called Crystalite, became available in 1938. The company now refers to both their sheet material and moulding powder as Plexiglas.

The optical qualities of these plastics are principal considerations in the manufacture of surgical instruments, spectacle lenses, camera lenses, edge-lighted advertising signs, and reflectors for highway illumination, as well as radio and automobile dials, etc. The material is practically impervious to moisture, and that factor, combined nith its lightness, toughness, dimensional stability and colourability make it an ideal material for lifelike, realistic dentures. Because of strength, weather resistance and clarity, acrylics are used extensively in aircraft as landing light covers, gun turrets, cockpit enclosures, windows and aindshields.

Cellulose Acetate **Butyrate and** Ethyl Cellulose.—One of the most serious drawbacks of the cellulose acetate plastics is their poor resistance to moisture and weathering. The determined effort on the part of researchers to overcome this disadvantage led to the development of cellulose acetate butyrate, in which the cotton linters of the base are treated with butyric acid in addition to the acetic acid and acetic anhydride used for the regular cellulose acetate. The Hercules Ponder company introduced cellulose acetate butyrate in 1932 as Hercose for use in protective coatings and followed it in 1937 with Hercose Acetate Propionate made in collaboration with Tennessee-Eastman company. The latter company brought out a cellulose acetate butyrate moulding composition in 1938 which they called Tenite II. Such applications as automobile headlights, fender guides and outdoor furniture (in place of reed materials) profit from the toughness, weathering qualities and fine colours available in this material, which is also used as a base for aeroplane "dope" to replace the more hazardous and dangerously flammable cellulose nitrate.

Ethyl cellulose was the first cellulose ether made commercially in the United States, having been introduced by Hercules Ponder in 1935 and by Dow Chemical in 1937. A second cellulose ether. methyl cellulose, was made available by Dow Chemical in 1939 under the trade name Methocel. Both came into general use for moulding purposes. Ethyl cellulose has low flammability, high dielectric properties. good acid and alkali resistance, resistance to moisture and humidity, and excellent insulation Chief uses have been for protective coatings, adhesives, paper and fabric coatings and for wire insulation. The ethyl cellulose lacquers were remarkably successful, displaying unusual toughness and flexibility under widely varying temperature conditions.

These same cellulose derivatives have properties uhich make them auitable for use in the production of less rigid plastics. a fact which had special significance during the acute scarcity of natural rubber in World War II. Cellulose derivatives such as ethyl cellulose may be compounded with chemical arid oil plasticizers to yield compositions which have many of the qualities that have made rubber applicable to a wide variety of uses. These compositions can be made tough and pliable, flexible and thermoplastic, although they must be handled differently from rubber in the manufacturing process. Some of the cellulose derivative., can be fabricated into products with qualities equal or even superior to rubber compositions, although their resilience and stretching properties are limited as compared with rubber. They can, however, be made to show only minor deformations when subjected to stress at room temperatures, and their water resistance is comparable to that of compounded rubber. These compositions have good pliability at low temperatures, good chemical resistance, and they may even be made oil-, gasoline-, or flame-proof with proper addition of modifiers or plasticizers.

Lignin.—In the 1930s, men began to search patiently for a means to utilize waste wood and sawdust as a possible component of a moulding composition. Wood contains approximately 25% lignin, a resin which forms the natural bond for wood cellulose fibres. It is possible to soften this resin to separate the wood fibres. In 1937 the Masonite company succeeded in developing a lignin plastic which they called Benaloid. This material was manufactured in sheet form about 4 by 12 ft. for laminating. The sheets may be drilled, turned, sawed, tapped and nailed, and are superior to natural woods both by virtue of their uniformity, and the fact that they are almost entirely unaffected by moisture and immersion in water. Both thermoplastic and thermosetting lignin moulding compositions were made available in 1939 by the Marathon Chemical company.

Experiments demonstrated that lignin can be added to phenolics to make a highly satisfactory moulding compound for such items as closures and a whole variety of industrial parts.

Similar experiments were conducted with the use of lignin as an extender for urea formaldehyde and thermoplastic materials.

Other Resins and Plastics.—An outstanding commercial use of synthetic resins is as a protective coating material; the automotive industry has used enormous quantities of the alkyd resins for this purpose. Originally cellulose nitrate lacquers were used for coating. After the alkyd resins were made available by General Electric in 1926 and subsequently by American Cyanamid, du Pont, and Resinous Products and Chemicals company, they were mixed with the cellulose nitrate lacquers for better adhesion, and to lessen the porous qualities of the cellulose nitrate lacquers. Later developments, however, led to use of the all-resin lacquers which, although they require a longer drying period, produce a fine lustrous surface, excellent adhesion, a durable finish and first-rate insulating qualities.

The coumarone indene resins have their source in the light coal-tar oils, and are polymerized by the addition of sulphuric acid to form resins. Work was begun on this development as far back as 1890, but manufacture was not started in the United States until 1919, when the Barrett company began its commercial presentation under the name of Cumar. This type of resin became one of the most important and widely used in the market. Its brittleness and low softening point prevented use as a binder for moulding compounds, but it was used extensively as a modifier of the properties of other resins and as a plasticizer with various organic binding materials, particularly to soften rubber during milling operations. In the automotive industry, the coumarone indene resins are used as a softening material for rubber in tire compounds, and in combination with rubberlike resins in hose, gasket and similar parts. They are also used for composition floor tiling and other industrial applications.

Another resin which expanded rapidly in use is melamine, which became commercially available in the U.S. in 1939. Only a few years before, it had been considered a rare chemical, available in minute quantities at $40 a pound. The cost was rapidly lowered with increased production and melamine became the base of a large group of plastic products. In combination with formaldehyde, it demonstrates arc-resisting properties, and it may be combined with alkali fillers such as asbestos to produce heat-resistant materials with unusually high arc resistance, or with alkali-curing resins for the production of laminated parts. Melamine resins may also be combined with cotton or rag fillers for the production of impact-resistant moulding materials, the chief characteristics of which are high flexural strength, very low water absorption and general inertness. In solution this material may be used to impregnate paper, canvas, asbestos cloth and paper, glass cloth and wooden veneers for laminating purposes.

Alpha cellulose-filled melamine moulding material was adopted for tableware by U.S. airlines because of its resistance to boiling water, fruit juices and similar agents. It was also used as a button material by the U.S. army because of its durability and wide range of colours. Mineral-filled melamine moulding compounds fulfilled important functions in World War II because of their high dielectric strength; they were used in ignition systems of aircraft, tanks, tractors, etc.

A new material produced during World War II under the name of C R 39, with its chemical composition a closely guarded secret, mas described as a colourless liquid of low viscosity, containing only carbon, hydrogen and oxygen. Reputed to be 40 times harder than other clear plastics, notably the acrylics, it is stable at ordinary temperatures, but upon heating in the presence of a catalyst such as benzoyle peroxide, passes through an induction period, then gradually increases in viscosity and finally jells. Upon application of further heating, the jell hardens and finally becomes a strong, hard, insoluble, infusible, crystal clear solid plastic.

Resin Bonds for **Plywood.**—A great improvement in plywood techniques took place during World War II. The use of resin-bonded plywood for aircraft, small boat construction, pontoons, housing developments and other large-scale industrial enterprises became entirely practical not only as a materials-saving expedient, but as a means for increasing the strength and efficiency of such constructions with no corresponding increase in time or labour costs.

Wood is one of the oldest structural materials known to man, and its use in aeroplane construction had begun in World War I, at which time its excellent strength-weight ratio was established. However, the best adhesives then' available were albumen and casein, which had only limited uses because of their inability to combat the effects of moisture, fungus and mould growth. It was not until the early 1930s that developments in Europe demonstrated the fact that the phenol formaldehyde resins are endowed with the properties necessary to overcome the limitations of the earlier adhesives. They are waterproof, boilproof, heatproof and highly resistant to fungus and mould attack. By 1935 phenolic resins became commercially available and the value of plywood as a prime structural material for the aircraft industry, as well as for others, was on its way to becoming a reality.

The relatively high cost of the phenolic resins limited their use to high-cost fields where durability and service requirements transcended price considerations. The need for a resin that could be used in outlets where standards were less severe, and where the cost factor could be controlled, led to the development of the urea formaldehyde resins in 1937. Although this latter type of adhesive does not quite achieve the bonding strength of the phenolic resins, it is far superior to the animal-vegetable glues formerly used in such products as radios and furniture.

Keeping pace with the perfection of the phenolic and urea resins were the fabricating developments in the construction of plywood. One of the most notable of these developments was the rubber-bag moulding process used extensively in the manufacture of large aircraft parts. A wood mould is constructed with the exact contours and specifications of the part to be fabricated—fuselage, wing, pilot seat, etc. The wood veneers are then wrapped around the wooden die or form, and between each layer a resin solution is sprayed or brushed onto the wood plies. Ribs or other reinforced parts may be made integral parts of the moulded structure by placing them into slots in the wooden form before covering it with the veneers. The part is then placed into a rubber bag or composition membrane which is deflated by a vacuum pump so that the veneers are held rigidly in place against the wood mould. The rubber bag with its contents is then placed into an autoclave, where the heat converts the resin into an infusible state, thus fixing the veneers permanently into the desired shape. The steam pressure within the tank assures uniform application of heat and pressure over the surface of the rubber bag, and when the resin-bonded structure is removed from the wood mould after the curing treatment in the autoclave, the moulded parts are ready for assembly with only a limited amount of finishing necessary. This process made possible the speedy construction of completely formed fuselages, wing sections and other large aircraft parts.

MOULDING PROCESSES

Any basic definition of a plastic establishes one incontrovertible fact—that a plastic must be capable of being moulded. Upon the success of the moulding process and upon the efficiency of the essential equipment for the process is predicated the successful development of plastics.

The basic principle for the operation of the hydraulic press is believed to have been conceived as far back as 1653, but the adaptation of the principle to a practical machine was not achieved until about 1795. Not until approximately 1839, with Goodyear's discovery of the vulcanization of rubber, did the hydraulic press begin to be an industrial reality. At that time the simplest hand-type of hydraulic press, constructed on the rod principle, was developed for the manufacture of rubber products, and it was subsequently used for moulding the early thermoplastics, pyroxylin and shellac. This type of press was used for nearly 70 years without any startling changes, and in fact was still employed in the 1940s for some types of moulding operations in which only limited quantity is required and the mould is sufficiently light to warrant manual handling.

With the advent of the phenolic thermosetting resins, impetus was given to the improvement of the compression moulding press in a manner calculated to increase the output from a given mould. Semi-automatic presses were then developed in which moulds were mounted on platens, thus providing for mechanical opening and closing. Pins were also incorporated in the design which made possible automatic ejection of pieces. Later improvements brought about automatic regulations of the degree of pressure, as well as of the timing of the pressing operation, and such semi-automatic presses became standard equipment for compression moulding.

The modification of the semi-automatic moulding press was introduced in 1918 in order to facilitate the handling of moulds with metal inserts. This was achieved by the development of a movable upper platen which presents the top die in a vertical, accessible position and which makes the placing of inserts a relatively simple and efficient operation.

Fully automatic compression moulding presses were later developed to perform all the operations of routine moulding of thermosetting plastics, including measuring the charge of moulding powder, preheating it, loading it into cavities, closing and opening the mould, ejecting finished pieces and repeating the cycle indefinitely. These presses succeeded in reducing the human element and margin of error to a minimum.

Injection moulding was a still later development in plastic production. Originally conceived in 1865 as a die-casting machine for forcing molten metal into a die by mechanical or hydraulic means, the method did not make much progress until 1872, when the Hyatt brothers were granted a patent for a machine to extrude celluloid. The design of the heating cylinder of this machine embodied many of the principles incorporated into subsequent models, and although the Hyatts had to abandon its use for the purpose intended, it left its mark on injection moulding equipment. Later developments in the manufacture of injection moulding presses took place in Germany and were adapted for U.S. models. The first such units to be introduced into the U.S. market had an injection capacity of only ½ to 1½ oz. per cycle, and were suitable for moulding small articles like buttons, combs and costume jewellery. To meet the demands of U.S. moulders for machines of increased capacity, sturdier construction and more efficient design, domestic manufacturers improved the presses until they attained a capacity of 36 oz. By 1935 there were about 75 injection moulding presses in the United States, mostly importations from Germany. By Dec. 1939, the number had increased to 574, and by 1943 to an estimated 1,300.

Transfer Moulding.—Thermosetting resins remain plastic at high temperatures for a relatively short interval before the resin hardens to an infusible mass. Therefore the heating chamber must be loaded with a quantity of compound sufficient for each cycle, and the maximum plasticizing heat must be restricted only to this amount.

This moulding of thermosetting resins by their injection in a plastic state into a hot mould is called transfer moulding. The press is similar to that of injection moulding of thermoplastics except that the mould itself is kept hot constantly to effect the transformation of the resin to the cured or hardened state.

The special advantage of this process is that erosion of dies, breakage of small pins and damage to inserts can be avoided. Because the material flows into the mould cavity as a liquid, no large stress is built up to break the mould or displace fragile inserts; glass and fine metal parts can be used without danger of distortion or breakage. Higher and more uniform density can be produced, and separation of the resin from the filler is minimized. Small holes and deep holes which are impractical in compression moulding are easily accomplished by the transfer process. For impact materials which produce a heavy flash in compression moulding, and for decorative pieces, the process is particularly well adapted. Greater strength, more uniform density, freedom from gas pockets and extremely close tolerances are possible.

Extrusion.—The process of continuous extrusion was known and used for many years in the rubber industry and in connection with pyroxylin fabrication before it was adapted for thermoplastics. The extrusion process is a technique of continuous production analogous to squeezing toothpaste out of a tube to form a strip or ribbon unit. The plastic materials in powder, granular or cube form, are forced through a die to produce a strip of material that takes the shape of the die opening. The extrusion machine is a fairly simple and inexpensive mechanism. The plastic material is fed into a heated cylinder and is extruded through nozzles to produce rods and tubing of various shapes and sizes. Continuous canvas or rubber belts are frequently used to move the strip along as it emerges from the die, and harden it by cooling. Sometimes the belt is shaped to fit the extruded form, thus reducing possible distortion to a minimum.

PRODUCTION IN THE UNITED STATES

Total production of synthetic resins and plastics in the U.S. during 1941 was approximately 438,000,000 lb., or 219,000 tons—almost half the estimated world production in that year. Complete figures of production in the United States were not revealed after that country entered World War II, but it was known that cellulose ester plastics production for the first six months of 1942 showed an increase of approximately 25% over the same period in 1941. Cellulose nitrate sheets, rods and tubes were produced at the rate of 8,515,000 lb. for the first half of 1942—substantially the same as for the like period in the preceding year. Cellulose acetate sheets, rods and tubes produced remained almost constant for the first half of 1942, but later suffered because of restrictions on some of the plasticizers.

Cellulose ester moulding powders showed an increase of over 30% up to July 1942, an increase which was purely due to wider use of cellulose acetate butyrate moulding powder. There were approximately 21,000,000 lb. of cellulosic moulding powder sold in six months of 1942 as compared to approximately 31,000 lb. in all of 1941.

USE OF PLASTICS IN WORLD WAR II

Practically all plastic materials were directed into essential war uses in the United States during World War II. Their inherent physical properties, such as lightness, strength, insulation (both heat and electrical), resistance to acids and alkalis, weathering, ease of mouldability and fabrication made them excellent material for military uses. Such materials must be so stable that they will withstand extremes of temperature (–40 to 160° F.) and rapid humidity changes without distortion. Close tolerances and absolute uniformity must be maintained in moulding because there is very small margin for error in any war application.

Phenolic formaldehyde plastics were perhaps the most widely used during World War II, because of their light weight, stability under rapid temperature changes, good insulating qualities, imperviousness to weathering and high impact resistance. In planes, phenolic materials were fabricated into pulleys, fairleads, for control cables to every part of the structure, cabin air controls, propellers and propeller parts, aileron control quadrants, illuminated dials and name plates for night flying. These same materiais were incorporated into warships—in elevators, gun turrets, gun light switches, radios, pumps, junction boxes, etc.

The need for moulding materials of exceptional mechanical strength to replace strategic metals greatly stimulated the use and further development of compounds known as high or medium impact phenolics. Plastic of this type successfully passed the test for 37-mm. dummy-fuses, and for the 60- and 81-mm. mortar shell fuse. In the Browning machine gun it replaced the black walnut used for grip handles. Booster tubes for demolition bombs were made of phenolics. Even the traditional duck of army tents was treated with phenolic formaldehyde resins, to increase the life of the material, improve its water impermeability and protect the fire-resistant finish against weathering or deterioration in storage. Melamine resins were used for buttons and as the basis of a treatment for paper pulp, for such uses as clothing, army tents, sandbags, etc.

World War II saw a vast increase in the manufacture of acrylic plastics, as well as the expansion of the facilities for fabricating aircraft parts. The aircraft industry used a large percentage of the sheet production, turning out more planes per month and using a larger area of acrylics per plane. Another development was an acrylic power turret which could be revolved mechanically. Blackout lights on army trucks and jeeps were made from acrylics. Tank sight windows were cut from sheet acrylics. Navy PT boats were equipped with acrylic machine-gun housings, as well as acrylic windows. Dials and gauges were protected from the effects of salt water by moulded or fabricated acrylic covers.

The vinyl resins became vital as rubber substitutes. The Baruch report on the U.S. rubber situation after Pearl Harbor pointed out that vinyls saved the equivalent of 22,000 tons of crude rubber per year.

Wartime applications for polyvinyl compounds were numerous. Polyvinyl butyral, long used only as the plastic sandwich for laminated safety glass in automobiles, coated the fabric from which lightweight army raincoats were made for soldiers ($1\frac{3}{4}$ lb. of crude rubber were saved for each coat). Polyvinyl alcohol was moulded into heat-resisting tubing and gaskets for trucks. Polyvinyl acetate was used instead of rubber latex in mid-soles for shoes. Polyvinyl butyral was also used in bags for transporting drinking water, hospital sheeting for military and civilian use, life belts for the navy and merchant marine, food bags and waterproof, oil-resistant suits for seamen. In extruded form, polyvinyl butyral replaced rubber in tubing, in clamps to prevent vibration of fuel lines in aircraft and in a host of other military applications.

Cellulosic materials were extensively employed in gas mask parts, including lenses, knobs, starter buttons, blackout lenses and protective surfaces for maps and documents. Cellulose acetate sheeting found a large war use in windows for trainer aeroplanes and gliders, and for windshields for motorcycles. Fluorescent cellulose acetate sheeting was used for lighting fixtures in war equipment, where visible lighting could not be used. The butyrate and the high acetic acid content cellulosic plastics were used for applications requiring improved water resistance and dimensional stability. Among such uses were gas mask lenses, hoze nozzles, pistol grips, flashlight cases, first-aid kits, stirrup pump parts and shaving brush handles.

Polystyrene was employed in enormous quantities during the war. In 1942 productive capacity for the manufacturing of monomeric styrene for polymerization into the plastic was a fortuitous circumstance, since this product became available for the manufacturing of the Buna-S type of rubber, which was applied to battery boxes, radio insulations, coaxial cable insulation, resin modifiers for wire coating, etc.

Like other plastics, ethyl cellulose was placed under strict allocation by the War Production board because of its adaptation to military uses, including coating for braided ignition cable, fire and waterproofing dyes, artificial leather, etc. In sheeting form it mas made into transparent face shields for gas masks, goggles and envelopes for shop prints. Ethyl rubber, made of ethyi celiuiose combined with an oii plasticizer, proved to be flexible and elastic and showed better resistance to abrasion, ozones and gasoline than natural rubber, but less resilience, elongation or resistance to permanent deformation. It was used instead of natural rubber for gun covers, electrical or junction tape, water tubing to replace brass, raincoats, hospital sheeting, gloves, footwear, etc.

Plastic plywood also became increasingly important as a major structural material for war use, in lightweight training planes, assault boats, floating ramps, pontoons and for the famous PT motor torpedo boats. Pilot seats of plastic plywood were an important development.

After their introduction in 1940, the vinylidene chloride resins (Saran) aroused considerable interest because of their unusual properties—water, chemical and solvent resistance combined with toughness, durability and appearance. It found its way into such varied products as piping for use in plumbing fixtures, to replace brass and copper in defense housing, for electric fixtures and installations.

The laboratories of the plastics industry by 1943 had established as many as 5,000 different formulations of plastics, each with characteristics of its own, mostly for wartime uses. (See also SYNTHETIC FIBRES.)

PLATA, RIO DE LA or **RIVER PLATE,** a funnel-shaped estuary, on the east side of South America. extending west-northwest from the sea about 170 miles. The discovery of the South sea by Balboa, then governor of Castilla del Oro, of which Darien formed a part, created a lively desire to learn something of its coastline, and the year following (in 1514), the Spanish monarch concluded a navigation contract with Juan Diaz de Solis, then Piloto Mayor, to search for a strait connecting the Atlantic with the newly found ocean. De Solis set sail from the port of Lepe on Oct. 8, 151j, reached the Bay of Rio de Janeiro on Jan. 1, 1516, and continuing southward to lat. 3j° entered the great estuary now known as the Plata, which, for a short period of time, was called the de Solis and the Mar Dulce. Ascending it to the vicinity of the island of Martin Garcia. near the mouth of the Paraná river, de Solis was ambushed and killed early in 1516 by Guarani Indians. In 1520 Magellan explored the Rio de la Plata, and discovered and navigated the straits which bear his name. In 1526 Cabot ascended the Mar Dulce, discovered the Paraná river and reached a point on the Paraquay near the site of the present city of Asunción. Here he obtained by barter from Guarani Indians silver ornaments. The receipt of these silver baubles caused the name of Rio de la Plata to be applied to the third greatest river of the western continent.

The extreme breadth of the river at its mouth is 138 miles. It narrows quickly to 57m. at Montevideo, and to 25m. at its head, where it receives the Paraná and Uruguay rivers. Its northern or Uruguayan shore is somewhat elevated and rocky, while the southern or Buenos Airean one is very low. The whole estuary is very shallow, and in no place above Montevideo exceeds 36ft. in depth at low water. The bottom generally consists of sand covered with from 10 to 20ft. of water. A dredged channel of about 22ft. in depth leads from the port of Buenos Aires 20m. east to deep water. Winds and tides considerably affect the depth of the channel. The Plata is simply the estuarine receptacle of two mighty streams, the Uruguay and Paranb which drain the Plata basin. This has an area of 1,198,000sq.m., or over two and one-half times that of the Pacific slope of the Andes, and comprises the most fertile, healthiest and best part of Brazil, a large portion of the Argentine republic, the whole of Paraguay and south-eastern Bolivia, and most of Uruguay.

The Uruguay and **Affluents.**—The Uruguay river has a length of about 1,000 miles. Many small streams from the western slope of the Brazilian Serra do Mar unite, in about 27" 45' S., to form this river, which then flows W.N.W., serving as the boundary between the States of Santa Catharina and Rio Grande do Sul, as far as 52° W., near which it receives a considerable tributary from the north, called the Pepiri-guazú. Between 27° 58′ and 33° 34' S. three important tributaries join it from the east—the Ipui-guazli, the Ibicui and the Negro.

The Pepiri-guazú in its lower course is about 250ft. wide, but higher up it narrows to about 30ft., and runs with great violence between high wooded banks. It is navigable for canoes for about 70m. above its mouth, as far as its first fall. The Rio Negro has a delta of several large islands at its confluence with the Uruguay. Its head-waters are in the southern part of Rio Grande do Sul, but the main river belongs entirely to the State of Uruguay. Its lower reaches are navigable for craft of moderate draught.

From its source in the coast range of Brazil the Uruguay runs through open, hilly country, and then enters a forest belt of high lands. At the river Pepiri-guazú it turns suddenly to the south-west, and continues this course to its junction with the Paraná and Plata. Near Fray Bentos, 61m. before reaching the Plata, it forms a great lake, about 56m. long and from 4 to 6m. wide. At Punta Gorda, where it debouches into the Plata, it is about 1m. wide, but is 90ft. deep. From the Pepiri-guazú junction its banks are high and covered with forest as far down as 27° 30' S., where the river is 2,300ft. wide and from 10 to 40ft. deep. The Uruguay is much obstructed by rocky barriers. Four miles below its confluence with the Pepiri-guazú it has a cataract, about 8m. long, with a total fall of 26ft. at low water. The river near the Pepiri-guazú is 1,550ft. wide, but about $1\frac{1}{2}$m. before reaching the cataract its width is reduced to 600ft. Along the cataract it is closed in between high precipitous walls of black rock only 70ft. apart. Above Punta Gorda, 212m., is the Salto Grande, which has a length of 15m. of rapids, the greatest single fall being 12ft., and the difference of level for the entire length of the reefs 25ft. Nine miles below the Salto Grande is the Salto Chico, which bars navigation during six months of the year, but in flood-time may be passed in craft drawing 5ft. of water. The Uruguay can be navigated at all seasons by vessels of $4\frac{1}{2}$ft. draught as far up as the Salto Chico, and of 14ft. up to Paysandú for a greater part of the year. Fray Bentos may be reached all the year round by any vessel that can ascend the Parana. Above the navigable lower river there is launch and canoe navigation for many hundreds of miles upon the main artery and its branches, between the rapids which are met with from time to time. The Uruguay has its annual floods, due to the rains in its upper basin. They begin at the end of July and continue to November, attaining their maximum during September and October. Except in floods, it is a clear-water stream, and even at its highest level carries comparatively little silt.

The **Paraná** and Its **Affluents.**—The Paraná (the "Mother of the Sea" in Guarani) drains a vast area of southern Brazil. It is formed by the union of the Rio Grande and Paranáhyba, and is about 1,600m. long from its source in Goyaz to its junction with the Paraguay, and thence 600 more to the Plata estuary. Its average width for the latter length is from 1 lo 3m. Its Rio Grande branch descends from the slope of the Serra da Mantiqueira, in the region where the orographic system of Brazil culminates near the peak of Itatiaia-assu, almost in sight of Rio de Janeiro. It is about 680m. long, but only navigable in the stretches between the many reefs, falls and rapids which interrupt its regular flow.

Besides these rivers, the Paranb has many long and powerful affluents from the Brazilian States of São Paulo and Paraná. Most of them, although obstructed by rapids, are navigable for launches and canoes. Among the eastern tributaries are the Tiété, the Paraná-panema, formerly known as the Anemby, and the Iguazu. The Paraná-panema is about 600m. long, and rises in an offshoot of the Serra Paranápicaba which overlooks the Atlantic ocean. It is navigable for only 30m. above its mouth.

The Iguazú, also called the Rio Grande de Curutiba, has its sources on the slopes of the Serra do Mar of Brazil, and flows nearly west, through thick forests, along the line of 26" South. Its navigation is difficult even for small craft, as it is full of reefs, rapids and cataracts. Sixteen miles above its mouth is the magnificent Salto del Iguazú, sometimes called the Victoria Fall, round which canoes have to be transported 37m. before quiet water is again reached. The width of the falls, measured along their crest or edge, is $2\frac{1}{2}$m.; part of the river takes two leaps of about 100ft. each, but a portion of it plunges down the whole depth in unbroken mass. Its mouth is about 800ft. wide, and the depth in mid-river 40ft.

The Paraná has unobstructed navigation for about 400m. between the Falls of Urubuponga and the Falls of Guayra, in 24" 3' S., where it forms a lake $4\frac{1}{2}$m. long and $2\frac{1}{2}$m. wide, preparatory to breaching the Serra de Mbaracayú, which there disputes its right of way. It has torn a deep gorge through the mountains for a length of about 2m., where it is divided into several channels, filled with rapids and cataracts. It finally gathers its waters into a single volume, to plunge with frightful velocity through a long cañon only about 200ft. wide. From these so-called falls of Guayra or "Sete Quedas," as far as its confluence with the Paraguay river, the Paraná has carved a narrow bed through an immense cap of red sandstone, along which it sometimes flows with great rapidity, occasionally being interrupted by dangerous narrows and rapids, where the banks in some places close in to a width of 450 to 600ft., although the average is from 1,200 to 1,600 feet. At the south-east angle of Paraguay the Paraná is turned westwards; but before escaping from its great sandstone bed it is obstructed by several reefs, notably at the rapids of Apipé, which are the last before it joins the placid Paraguay, 130m. farther on.

The Paraguay.—The river Paraguay, the main affluent of the Paranb, rises in Matto Grosso, in the vicinity of the town of Diamantino, about 14° 24' South. It flows south-westwards, as far as Villa Maria, along the foot of the high plateau which divides it from the Cuyabá river to the east, and then, turning southwards, soon reaches the morass expansion of Xarayes, which it traverses for about 100m. A few miles below Villa Maria it receives an affluent from the north-west, the Jaurá, which has its source nearly in contact with the head-waters of the Guaporé branch of the river Madeira. From the junction of the São Lourenço (or Cuyabá) with the river Paraguay, the latter, now a great stream, moves sluggishly southwards, spreading its waters, in the rainy season, for hundreds of miles to the right and left, as far south as 20°, turning vast swamps into great lakes—in fact, temporarily restoring the region, for thousands of square miles, to its ancient lacustrine condition.

On the west side of the upper Paraguay, between about 17° 30' and 19° S., are several large, shallow *lagunas* or lakes which receive the drainage of the southern slopes of the Chiquitos sierras, but represent mainly the south-west overflow of the vast morass of Xarayas. The principal of these lakes, naming them from north to south, are the Uberaba, the Gaiba, Mandioré and the "Bahia" de Caceres. The Uberaba is the largest. It is in great part surrounded by high ground and hills, but its southern coast is swampy and flooded during the rainy season. The west shore is historic. Here, in 1543, the conquistador, Martinez de Irala, founded the "Puerto de los Reyes," with the idea that it might become the port for Peru; and from Lake Gaiba several expeditions, in Spanish colonial days, penetrated 500m. across the Chaco to the frontier of the empire of the Incas. At the Puerto de los Reyes Bolivia laid out a town in Dec. 1900, in the forlorn hope that the "Port" may serve as an outlet for that commercially suffocated country, there being no other equally good accessible point for Bolivia on the Paraguay river.

South of the São Lourenqo, the important rivers entering the Paraguay from the east are the Taquary, which rises in the Serra Cayapó, on the southern extension of the Matto Grosso tableland; the Mondego, with many branches, draining a great area of extreme southern Matto Grosso, and the Apb, which forms the boundary between Paraguay and Brazilian Matto Grosso.

The **Pilcomayo.**—The Pilcomayo rises among the Bolivian Andes north of Potosi and north-west of Sucre, races down the mountains to their base, crosses the Chaco plains, and pours into the river Paraguay near Asunción. It does not receive any branch of importance until it reaches about 21° S., where it is joined from the south-west by the river Pelaya, upon which Tupiza, the most southerly city of Bolivia, is situated. Just below the junction is the fall of Guarapetendi, 23ft. high. From this point to the mouth of the Pilcomayo the distance in a straight line is 480m., although by the curves of the river, which is extremely tortuous, it is about double that distance. According to Storm, who quotes Captain Baldrich, the river bifurcates at 21° 51′ S., but again becomes a single stream at 23° 43′, the right channel being the greater in volume. It is probable that between 23" and 24" S. it throws three great arms to the river Paraguay, the upper portions of which have yet to be explored, but the lower parts have been examined for 100 to 200m. up from the Paraguay. From 180 to zoom. above its mouth the Pilcomayo filters through a vast swamp about 100m. in diameter, through which there is no principal channel. This swamp, or perhaps shallow lagoon, is probably partly drained by the river Confuso, which reaches the Paraguay between the Pilcomayo and Macá. A northern branch of the Pilcomayo, the Fontana, the junction being at 24° 56′ S., is probably also a drainage outlet of the same great swamp.

For the first 100m. below the Fall of Guarapetendi the Pilcomayo is from 600 to 1,000ft. wide, but it so distributes its waters through its many bifurcations, and loses so much from infiltration and in swamps, and by evaporation from the numerous lagoons it forms on either side of its course, that its channel is greatly contracted before it reaches the Paraguay. From Sucre to the Andean margin of the Chaco, a distance of about 350m. by the river, the fall is at least 8,000ft.—a sufficient indication that its upper course is useless for purposes of navigation. Its lower course is of little value for commercial purposes.

The **Bermejo.**—The Bermejo river flows parallel to the Pilcomayo, and enters the Paraguay a few miles above the junction of this with the Paranb. Its numerous sources are on the eastern frontage of the inland Andes, between the Bolivian town of Tarija and the Argentine city of Jujuy. In 23" 50′ S. the Bermejo receives its main affluent, the San Francisco, from the south-west. The latter has its source in about 22° 30′ S., and, under the name of Rio Grande, runs directly southwards, in a deep mountain valley, as far as Jujuy. It then turns eastwards for 50m., and is joined by the Lavayen from the south-west. These two streams form the San Francisco, which, from their junction, runs north-eastwards to the Bermejo. From its junction with the latter stream the Bermejo flows south-eastwards to the Paraguay with an average width in its main channel of about 650ft., although narrowing at times to 160 and even 100. In its course, however, it bifurcates and ramifies into many channels, forming enormous islands, and frequently leaves old beds for new ones.

Since the exploration of the Bermejo by Patiño in 1721, it has often been examined from its sources to its mouth, with a view to ascertaining its navigability. Like the Pilcomayo, the Bermejo is of little use owing to swift currents, shoals, quicksands, snags and fallen trees.

The **Salado.**—The Salado, about 250m. south-west of and approximately parallel to the Bermejo, is the only great tributary which the Paranb receives from the west below its confluence with the Paraguay. Its extreme head-waters, the Santa Maria and Calchaqui, which unite near the town of San Carlos and form the river Guichipas, drain a much broken Andean region lying between 24° and 26° 30′ S. in the Argentine province of Salta. Having received the Arias, the Guáchipas runs north-eastwards about 50m., and then it changes its name to the Juramento, which is retained until the river reaches the Chaco plains at the base of the foot-hills of the Andes. Here it becomes the Salado. It joins the Paraná near Sante FC in 31° 39' S. and 60° 41′ West. Explorers of the Salado, inclusive of Captain Page in 1855, claim that its lower half is navigable, but the many efforts which have been made to utilize it as a commercial route have all resulted in failure.

The Pilcomayo, the Bermejo and the Salado erode quantities of the Pampean material, dissolve it into silt and pour it into the Paraguay and Paranb rivers. The engineer, Pelleschi, estimates that "the soil annually subtracted from the territory of the Chaco by the Bermejo alone equals 6,400,000 cubic yards."

Lower Course of the Paran&.——From 31° 30' south to the Plata estuary the western bank of the Paraná is a precipitous bluff of reddish clay, varying from 25 to 75ft. above mean river level. It is being gradually undermined, and tumbles into the water in great blocks, adding to the immense volume of silt which the river carries. The Paranb is lowest in December; it rises in January, February and March, reaching its greatest height in March. It is steady in April, May and June, but falls and rises irregularly during the next three months. The difference between low and high river is generally about 12ft., depending upon the varying quantity of rains in Brazil and the melting of the Andean snows. Below its junction with the Paraguay the Paraná has an average current of 2½m. an hour, and the river varies in width from 1 to 3m., at low water; but in floods it seems almost a continuous lake, broadening to 10 and 30m. and burying many of its numerous islands and marginal swamps under a vast sheet of water, and obliterating its many parallel lateral channels and connecting canals.

Islands of Parank.—In the middle Paraná, from the mouth of the Iguazú to the mouth of the Paraguay river, there are many islands, some of them large, rocky and high above the river. From Paraguay to the city of Rosario, islands are numerous, many of them of great area; and again below Rosario they soon increase in number and size until the Plata estuary is reached. In flood-time the upper portion of the trees being out of water, they have the appearance of floating forests. Then the river often makes wild work with its banks, and builds up or sweeps away entire islands, leaving deep channels instead. The lower delta of the Paraná does not share in these phenomena; its islands and main channels appear more fixed. This probably is due to the less elevation attained by the waters in flood-time, and the numerous branches which distribute them into the Plata estuary. This must have extended, in a very recent geological period, inland from its present head to at least 32° S.; but the enormous quantity of silt which the Paraná receives from its Paraguay affluent, and from the tributaries which reach it from the Andes, has filled this length of about 220m. with these muddy islands, which rest upon a sandy bed of great depth.

Paraná Delta.—The frontage of the Paraná delta is 40m. across, almost in a straight line from north to south. Through this the river finds its way to the Plata by 11 outlets, large and small, the two principal ones being the Paraná-Guazú and the Paraná de las Palmas. The Paraná is navigable to the São Lourenqo river by craft drawing 3ft. of water, and to within a few miles of Asunción, the capital of Paraguay, by vessels drawing 9ft. The city of Paraná may always be reached with a draught of 12 and Rosario with 1jft. of water.

The commercial development of the Plata basin promises to become gigantic. The Andes on the west, the interior of South America on the north, great rivers, and the Brazilian mountains on the east of the Plata basin are obstacles which compel the rich and varied products of at least 1,500,000sq.m. of fertile country to seek access to the ocean by a single avenue—the Plata estuary. (G. E. C.)

During the 20 years ending in 1928 many of the ports, cities and towns located on the Plata-Parani-Paraguay river system have made marked progress. Millions of dollars have been spent in extending and improving shipping facilities by Montevideo, La Plata. Buenos Aires, Rosario—all of them ports of call for ocean-going steamships. Many of the smaller ports like Santa Fé, Paraná, Corrientes, Posadas and Asunción, have also improved their facilities, and have increased their exports of grain, hides, meat, quebracho wood and extract, maté and lumber.

Improved Communications.—The completion, in 1916, of a 37m. railway around the Falls of Guayra, on the Alto Paranb river, opened a new river and rail gateway to the heart of Brazil, the principal outward shipments being yerba-maté and dried beef. A new hotel at Iguazú River falls and a motor-car service from Puerto Aguirre to the falls, 10m. distant, provide modern accommodation, and, aided by better steamboat service on the Alto Paraná have brought more tourists to the cataracts. The Rondon, the Roosevelt (1913–14) and other expeditions of recent years; the colonization schemes of European and American companies in Paraguay and Bolivia; the completion of a Brazilian railway from São Paulo nearly to the Paraguay; petroleum investigations in eastern Bolivia; larger areas planted with cotton in Argentina and Paraguay have combined to arouse wider interest in the vast region watered by the Plata river system. On the Uruguay river the cities of Mercedes, Paysandú and Salto have new water systems, improved streets and extended sanitation. A packing plant at Fray Bentos has increased operations there. The Argentine Navigation company, the Lloyd Brazileiro and local steamboat lines operate La Plata services to Corumbb, Brazil, 1,800m. from the Atlantic. Ocean-going vessels ascend as far as Rosario and Santa FC 200m. and 300m. above Buenos Aires. Throughout the Plata region the gradual introduction of modern agricultural implements has increased output, and, consequently, river traffic.

PLATAEA or **PLATAEAE,** an ancient Greek city of Boeotia, situated close under Mt. Cithaeron, near the passes leading from Peloponnesus and Attica to Thebes, and separated from the latter city's territory by the River Asopus. Though one of the smallest Boeotian towns, it stubbornly resisted the centralizing policy of Thebes. In 519 B.C. it invoked Sparta's help against its powerful neighbour, but was referred by king Cleomenes to Athens (for the date, *see* Grote's *History of Greece,* ed. 1907, p. 82, note 4). The Athenians secured Plataea's independence, and thus secured its enduring friendship. In 490 the Plataeans sent their full levy to the assistance of the Athenians at Marathon, and during the invasion of Xerxes they joined eagerly in the national defense. At Artemisium they volunteered to man several Athenian ships, and subsequently abandoned their town to be burnt by Xerxes. In 479 they fought against the Persians under Mardonius in the decisive battle which bears the name of the city. (For an account of the battle *see* GRAECO-PERSIAN WARS.) Their great victory was celebrated by annual sacrifices and a Festival of Liberation (*Eleutheria*) in every fourth year at Plataea, whose territory moreover was declared inviolate.

In spite of this guarantee Plataea was attacked by Thebes at the beginning of the Peloponnesian War (431) and formally besieged by the Peloponnesians (429–27). The garrison after capitulating was put to death, and the city razed by the Thebans. The remaining Plataeans received a qualified franchise in Athens, and in 421 were settled on the territory of Scione. Expelled by Lysander in 404 they returned to Athens, until in 387 Sparta restored them in their native town as a check upon Thebes. The city was again destroyed by Thebes in 373, and the inhabitants once more became citizens of Athens. Plataea was rebuilt by Philip and Alexander of Macedon, and during the rest of antiquity enjoyed a safe but obscure existence. It continued to flourish in Byzantine and Frankish times. The walls of the town, which at various periods occupied different portions of the triangular ledge on which it stood, remain partly visible. Recent excavations have discovered the Heraeum; but the temple of Athena the Warlike, built from the Persian spoils and adorned by the most famous artists, has not been identified.

PLATE, the common name for the electrode from which the current flows through the vacuous space in a radio vacuum tube.

PLATEAU, JOSEPH ANTOINE FERDINAND (1801–1883), Belgian physicist, was born at Brussels on Oct. 14, 1801, and died on Sept. 15, 1883 at Ghent, where he had been professor of physics from 1835. The more original investigations of Plateau refer chiefly to physiological optics and molecular forces. We owe to him the "stroboscopic" method of studying the motion of a vibrating body, by looking at it through equidistant radial slits in a revolving disk. In 1843 Plateau became permanently blind. He published an analytical catalogue of memoirs from the earliest times to the end of the 18th century on his favourite theme of subjective visual phenomena. This blind man's investigations on molecular forces, embracing hundreds of novel experiments whose results he saw only with others' eyes, are described in his great work *Statique expérimentale et théorique des liquides soumis aux seules forces moléculaires* (2 vols., 1873).

PLATEN-HALLERMUND, AUGUST, GRAF VON (1796–1835), German poet and dramatist, was born on Oct. 24, 1796, at Ansbach, and entered the Bavarian life guards in 1814. He took part in the short campaign in France of 1815; he then obtained a long leave of absence, and after a tour in Switzerland and the Bavarian Alps, entered the University of Wurzburg in 1818 as a student of philosophy and philology. In 1819 he removed to Erlangen, where he sat at the feet of F. W. J. von Schelling. As a result of his Oriental studies he published a little volume of poems—*Ghaselen* (1821), each consisting of from ten to twenty verses, in which he imitates the style of Ruckert; *Lyrische Blätter* (1821); *Spiegel der Hafis* (1822); *Vermischte Schriften* (1822); and *Neue Ghaselen* (1823).

Though Platen was at first influenced by the school of Romanticism, and particularly by Spanish models, yet the plays written during his university life at Erlangen. *Der gläserne Pantoffel, Der Schatz des Rhampsinit, Berengar, Treue um Treue, Der Turm mit sieben Pforten,* show a clearness of plot and expression foreign to the Romantic style. His antagonism to Romanticism became more and more pronounced, and he attacked its extravagances in the witty "Aristophanic" comedies *Die verhängnisvolle Gabel* (1826) and *Der romantische Oedipus* (1828). In 1826 he visited Italy, which he henceforth made his home, living at Florence, Rome and Naples. *Der romantische Oedipus* earned for him the bitter enmity of Karl Immermann and Heinrich Heine, but he retained many staunch admirers, who delighted in the purity of the subject matter of his productions and their beauty of form and diction. In Naples were written his last drama *Die Liga von Cambrai* (1833) and the delightful epic fairy-tale *Die Abbassiderz* (1830; 1834), besides numerous lyrical poems, odes and ballads. He died at Syracuse on Dec. j, 1835. Platen's odes and sonnets, to which must be added his *Polenlieder* (1831), expressing his sympathy for the Poles in their rising against the rule of the Tsar, rank among the best classical poems of modern times.

Platen's *Gesammelte Werke* were first published in one volume in 1839, and have been frequently reprinted; a convenient edition is that edited by K. Goedeke in Cotta's *Bibliothek der Weltiteratur* (4 vols., 1882). His *Tagebuch* (1796–1825), was published in its entirety by G. von Laubmann and L. von Scheffler (2 vols., 1896–1900). *See* P. Besson, *Platen, étude biographique et littéraire* (1894); A. Fries, *Platen-Forschungen* (1903); E. Petzet, *Platens Verhältnis zur Romantik in sein italien Zeit* (1911); R. Schlosser, *August Graf von Platen. Ein Bild seines geistigen Entwicklungsganges und seines dichterischen Schaffens* (Munich, 1910–13).

PLATERESQUE, the earliest of the styles of Spanish Renaissance, so called, either because the Renaissance found its first popular Spanish expression in silverware (*platero*, silversmith), or because its rich and delicate ornament resembled silversmith work. It is characterized by the application to forms structurally simple, of extremely rich ornament, distantly based on Italian Renaissance forms, using pilasters, entablatures, carved rectangular panels, shallow niches, much heraldic ornament and rich pierced, scrolled cresting. Its courtyards, usually with two or more openings on the upper floor, above a single opening below, are famous for their decorated columns, sometimes simulating balusters, their bracketed capitals and their graceful delicacy Owing to Moorish influence, there is a common tendency to carry the decoration around the door over the full height of the wall above. Decorative ironwork, as in the church *rejerías* (*q.v.*), or open metal screens, was highly developed. The style embraces, generally, the first half of the 16th century, but its decorative ideals influenced not only the classic period which followed, but the Baroque as well. Characteristic examples are the hospital of Santa Cruz, Toledo, by de Egaz (1504–16), the college at Alcalá de Henares, by Gumiel (1500–17), the university and Irish college at Salamanca, the Casa de las Conchas at Salamanca and the Infantada at Guadalajara. (See RENAISSANCE ARCHITECTURE.)

(T. F. H.)

PLATERSPIEL, BLATERPFEIFE, a mediaeval simplified bagpipe, consisting of an insufflation tube, a bladder and a chaunter; the double reed in its socket at the top of the chaunter being concealed within the bladder. In the platerspiel we recognize the early mediaeval chorus (*q.v.*) a word which in mediaeval Latin was frequently used also for the bagpipe, while in its later forms it was practically identical with the cromorne (*q.v.*).

PLATINUM, a very heavy steel-grey metal of great usefulness in the chemical and mechanical arts.

Platinum was probably known in the impure state from very early times, but because of its physical properties and especially its high melting point it was impossible to work it by any of the arts then known and it therefore remained as an unnamed substance. (Symbol Pt, atomic number 78, atomic weight 195·23.) It was probably the metal alluded to in the early part of the 16th century by Scaliger, who refers to a metal incapable of being fused obtained from the mines in Mexico and Darien. About the middle of the 18th century it was introduced into Europe in small quantities and attracted the notice of various chemists. Scheffer, in a paper read before the Stockholm Academy entitled "On white gold or the seventh metal, termed in Spanish platina del Pinto" (1752), showed that it was insoluble in nitric acid but soluble in aqua regia, was precipitated from its solutions by mercury, and was infusible at the highest temperature of the furnace. He also dealt with some of its alloys and discovered that it was fusible when mixed with arsenic. Platinum was melted by Macquer and Baumé in 1758 in the focus of a powerful burning glass. Count von Sickingen in 1772 prepared the metal in the form of foil and wire and showed that it was soluble in nitric acid when alloyed with a large quantity of silver. For the later history of platinum, its occurrence and separation from the other metals, see PLATINUM METALS and RUTHENIUM, RHODIUM, PALLADIUM, OSMIUM and IRIDIUM.

Platinum in the massive state is a greyish-white metal having a specific gravity of 21·4 and is exceedingly malleable and ductile. It melts at about 1,755° C and volatilizes readily in the electric furnace. Its latent heat of fusion is 27.18 calories It is a bad conductor of heat and electricity. When pure it is a soft metal and on this account is not suitable for some purposes, but on alloying it with iridium in small amounts the hardness is greatly increased. It is capable of being welded at a temperature near its melting point, but for easier working at a lower temperature gold is used as a solder in repairing damaged crucibles and other articles. It alloys easily with all the other metals of its own group, likewise with gold, silver and lead, but is scarcely acted upon by metallic mercury. It has been obtained in the crystalline condition by distillation in the electric furnace or by heating the fluoride to a red heat (Moissan). Spongy platinum is readily produced by ignition of the double chloride $(NH_4)_2PtCl_6$; it possesses a much greater surface area than the massive metal and hence is more active when employed in catalysis. Platinum black is best prepared by warming a solution of any of the chlorides or double chlorides of platinum in caustic alkali with alcohol or some similar reducing agent, or by dissolving the lead in nitric acid from a not very rich lead–platinum alloy. It has an enormous surface area and hence is the most usual form in which platinum is employed in catalytic reactions. The platinum black, for convenience in handling and also to minimize loss, is usually deposited upon some suitable material such as asbestos or barium sulphate. Colloidal platinum can be obtained in solution by passing an electric arc between platinum terminals under pure water.

Uses.—Platinum is used in the laboratory in the form of dishes, crucibles and weights, although a small amount of iridium is generally added to increase its hardness and hence its durability. Platinum vessels, however, should never be used for heating caustic alkalis, as they undergo corrosion producing platinates, and no metal of low melting-point should ever be heated in them. At one time platinum vessels were almost exclusively used in concentrating sulphuric acid (*q.v.*) made by the chamber process; this use has been abandoned as sulphuric acid made by the contact process is already concentrated, and the chamber acid is now concentrated in cheaper vessels.

Platinum is the best catalyst for the manufacture of sulphuric acid by the contact process; at a temperature below a red heat it is capable of causing the reaction $2SO_2+O_2=2SO_3$ to be nearly completed. The resulting SO, is dissolved in water till an acid of the required strength is obtained (see SULPHURIC ACID). Its use for this purpose has been partly given up, as some cheaper catalysts such as the oxides of iron and chromium, although less efficient, have been found more economical. In this process platinum is always used as platinum black. The material to be platinized (asbestos, pumice, brick, barium sulphate, etc.) is dipped in a dilute solution of platinum chloride, dried and ignited, an enormous catalytic surface of platinum black being thus produced. Another large and rapidly extending use for platinum is in the catalytic production of nitric acid from ammonia by oxidation. A mixture of ammonia gas and air (or oxygen) in the right proportion is passed in a very rapid stream over a network of heated platinum gauze. Either ammonium nitrate or nitric acid can be produced according to the proportions of oxygen and ammonia in the reaction mixture. The reaction is exothermic, and by adjusting the rate of flow of the mixed gases the reaction temperature can be kept constant.

Platinum or, better, iridium-platinum alloy is the most suitable anode material for electrolysis of all kinds. It remains unattacked under practically all conditions, but owing to the initial expense, some form of carbon, especially Acheson graphite, is now generally used for this purpose. Two methods of measuring high temperatures depend upon the use of platinum; the first is the platinum resistance thermometer, which depends upon the change of resistance of a platinum coil with temperature when a constant current is passing through it; the second is the use of a platinum and rhodium–platinum thermocouple. By careful calibration either of these instruments is capable of giving a very exact measurement of high temperatures. As platinum is not oxidized by air at the temperature of the electric spark, it is very suitable in electro-technics for contact-points of magnetos and induction coils and the armatures of electric beils; it can also be used when caused to glow by the passage of an electric current as a heating-element; for some of these uses it has now been displaced by cheaper materials, one of the best being a chromium–nickel alloy known as nichrome.

Platinum is extensively used for some surgical instruments such as needles for hypodermic syringes, for the metal can be sterilized even in the flame of a match; it is also used in the incandescent state as an electric cautery. Unfortunately it cannot be hardened sufficiently to make a good cutting edge. In dentistry platinum was formerly used extensively for making dental plates, etc., as an alloy of 2 parts of silver to one of platinum possesses the same coefficient of expansion as the hard porcelain-like material of which artificial teeth are composed. Owing to the rise in the price of platinum, gold or gold alloys have now almost entirely displaced it for this purpose. The use of platinum in jewellery is considerable; during the World War palladium replaced it to a large extent and now an alloy called white gold, which consists chiefly of gold alloyed with a small quantity of either palladium or platinum, is largely displacing it. Another use for platinum is the production of photographic prints by the platinotype process. These prints are of great beauty owing to the variety of tones that can be thus produced, and have the advantage over silver prints of being absolutely permanent.

Platinum Compounds. — Platinum does not combine directly with oxygen at any temperature, although in the molten state it absorbs several times its volume of this gas, which, however, is released when the metal cools. Four oxides of platinum are obtainable by indirect methods, viz., PtO, Pt_3O_4, PtO_2 and PtO_3. Of these, PtO and PtO_2 are important as they are the bases of the platinous and platinic salts. *Platinous oxide,* PtO, is obtained by gentle ignition of the corresponding hydrate, $PtO,2H_2O$, which is obtainable by precipitating either PtCl, or K_2PtCl_4 with caustic alkali. It is a black powder, soluble in acids when freshly prepared. *Platinic oxide,* PtO_2, is known in the hydrated form $Pt(OH)_4$, but only a portion of the combined water can be removed before deeper decomposition begins to take place. The hydroxide is obtained by adding excess of caustic soda to a boiling solution of PtCl,, which gives a yellow solution of sodium platinate, and then precipitating the cold solution with acetic acid. It is a white or yellowish solid soluble both in dilute acids and in alkalis when freshly prepared, but after losing water on heating it becomes black and insoluble. The peroxide, PtO_3, is obtainable by electrolyzing an alkaline solution of $Pt(OH)_4$ at 0° C. It is a red-brown unstable solid which readily parts with some of its oxygen at ordinary temperatures.

Two well-defined chlorides of platinum are known — platinous chloride, PtCl,, and platinic chloride, PtCl,. *Platinous chloride* is formed by heating chloroplatinic acid to 300° C or evaporating a solution of the same substance with absolute alcohol to dryness several times. It is a greenish or sometimes brownish substance insoluble in water but soluble in hydrochloric acid or alkali chloride solutions, with which it forms double chlorides of the form M_2PtCl_4; these are the alkali salts (platinochlorides) of chloroplatinous acid, H_2PtCl_4. This acid, which is known only in solution, can be obtained also from either its barium or silver salt by exact precipitation by means of sulphuric or hydrochloric acid respectively. The best known salt of the acid is the potassium compound, which is easily produced by reducing a boiling solution of potassium chloroplatinate with sulphur dioxide. It crystallizes in dark red prisms easily soluble in water, and in the case of certain unfortunate persons, traces of it act as a violent irritant to the mucous membrane of the eyes and nose. Platinous chloride combines with various unsaturated substances to form double compounds; it combines directly with carbonic oxide at 250° C to form three compounds, $PtCl_2,CO$; $(PtCl_2)_2,3CO$; and $PtCl_2,2CO$; with phosgene to form $PtCl_2,2COCl_2$; with ethylene to produce $PtCl_2,2C_2H_4$; and with phosphorus trichloride to form compounds $PtCl_2,PCl_3$ and $PtCl_2,2PCl_3$.

Platinic chloride, $PtCl_4$, is formed by the action of chlorine on platinum at a temperature below 500°. If platinum is dissolved in aqua regia or in hydrochloric acid in a stream of chlorine and the solution is evaporated with hydrochloric acid till free from nitric acid, reddish-brown crystals of chloroplatinic (platinichloric) acid, $H_2PtCl_6,6H_2O$, are produced: these if ignited in a stream of hydrogen chloride gas at 165° give a residue of $PtCl_4$ as a reddish-brown, very hygroscopic, crystalline mass. The pure chloride, however, is rarely met with, and the platinic chloride of commerce is the compound $H_2PtCl_6,2H_2O$ formed by heating the hexa-hydrated compound to 100° C. Chloroplatinic (platinichloric) acid is a weak acid, it reddens litmus paper and decomposes metallic carbonates producing the corresponding platinichlorides. It forms potassium and ammonium compounds which are nearly insoluble in water and quite insoluble in a mixture of alcohol and ether; the corresponding sodium compound is soluble in this mixture, and this circumstance affords the best method of separating potassium from sodium quantitatively. Chloroplatinic (platinichloric) acid forms compounds with organic bases which are usually difficultly soluble in water.

Platinum is not attacked by fluorine at a low temperature, and advantage of this was taken by Moissan when he first isolated that element and by Moissan and Dewar when they first liquefied this gas. At higher temperature (500°–600° C) Moissan obtained two fluorides, PtF_2 and PtF_4. Platinum does not readily form stable salts with oxy-acids. A sulphate $Pt(SO_4)_2$ is said to have been produced by dissolving platinic hydroxide in sulphuric acid but no nitrate of platinum is known. A series of salts known as platino-nitrites having the general formula $M_2Pt(NO_2)_4$ is well known, and another series, the platino-oxalates of the composition $M_2Pt(C_2O_4)_2$ has also been recorded. Two sulphides of platinum, PtS and PtS_2, are definitely known, and the existence of various intermediate ones has been announced from time to time. PtS and PtS_2 are produced by acting upon solutions of corresponding platinum compounds with sulphuretted hydrogen. Both sulphides are black powders; PtS_2 must be dried without access of air as it readily undergoes oxidation.

Platinous cyanide, $Pt(CN)_2$, is best produced by precipitating a solution of potassium platinochloride, K_2PtCl_4, with mercuric cyanide. It is of importance as it combines with cyanides of the alkali and alkaline-earth metals to produce a series of salts known as platinocyanides which are remarkable for their wonderful colours and for their use in radiography. They are derived from platinocyanic acid, $H_2Pt(CN)_4$, which can be prepared by decomposing the mercury or copper salt with sulphuretted hydrogen. The acid crystallizes from water in deliquescent prisms but is better crystallized from an ether–alcohol mixture. Potassium platinocyanide, $K_2Pt(CN)_4,3H_2O$, is easily produced by dissolving spongy platinum in a solution of potassium cyanide, preferably in the presence of air, or by the interaction of a solution of platinous chloride with excess of potassium cyanide; in the latter method recrystallization is necessary to remove the potassium chloride simultaneously produced. It crystallizes in rhombic prisms which are yellow by transmitted light but have a blue metallic lustre by reflected light. The magnesium salt, $MgPt(CN)_4,7H_2O$, crystallizes in beautiful red tetragonal prisms with metallic moss-green reflex. Its solution in water is colourless. Barium platinocyanide, $BaPt(CN)_4,4H_2O$, is the compound used for X-ray screens. It occurs in citron-yellow monoclinic prisms with a green reflex.

Platinum salts combine with ammonia in various proportions to form two series of bases, platinous and platinic ammines (see AMMINES). In the platinous series there are two compounds having the formula $PtCl_2,2NH_3$; they are probably cis- and trans-isomerides. A polymeride having the formula $(Pt,4NH_3)$ $PtCl_4$ has long been known as the "green salt of Magnus," and is made by the action of ammonia upon platinous chloride. These compounds, although of great interest theoretically, are of little practical value. A complete account of these interesting compounds may be found in Gmelin-Kraut's *Handbuch.* (F. E. *M.)*

See L. Duparc and M. N. Tikhonovich, ***Le Platine et les*** *gftes platanifères de l'Oural et du Monde* (1920); C. Janin, *World's Outlook for Platinum* (1928).

PLATINUM METALS. Although generally found in nature in the metallic condition, native platinum is never chemically pure. With it in varying proportions five other metals are generally associated, and to this group of six elements the name "platinum metals" has been given. The six metals in the order of their atomic numbers and weights are as follows:—

Metal	*Symbol*	*Atomic No.*	*Atomic Wt.*	*Metal*	*Symbol*	*Atomic No.*	*Atomic Wt.*
Ruthenium	Ru	44	101·7	Osmium	Os	76	190 8
Rhodium	Rh	45	102·91	Iridium	Ir	77	193·1
Palladium	Pd	46	106·7	Platinum	Pt	78	195 23

Although certain properties are common to the whole group, yet very great chemical and physical differences are found between the various members. It will be noticed that the atomic numbers of the first three and second three members are consecutive and that a common difference of 32 separates them. This common difference in atomic number corresponds to similarity in chemical properties between members differing by this constant number; at the same time similarities, more especially physical, are noticed amongst the members of each group.

One property common to the whole of the platinum metals is the high temperature of their melting points. The most easily fusible of them, palladium, only assumes the liquid condition at about 1,550° C; platinum comes next with a melting point of about 1,750° C and the other metals fuse at temperatures intermediate between these and the melting point of osmium, which is about 2,700° C. Another property common to this group of metals is the valuable one of resisting chemical action and especially oxidation (the particular cases of ruthenium and osmium as regards oxidation will be dealt with when those metals are considered in detail).

Another property common to all members of the group is their great catalytic action, that is, the power of bringing about chemical action between other substances without themselves undergoing any alteration. In small chemical operations platinum and palladium are extensively used, but for large-scale or commercial working these metals, on account of their high cost, are not suitable unless the wastage is very small or negligible. Thus platinum and palladium are most efficient catalysts in the hydrogenation of oils and fats for the production of edible glycerides (*q.v.*); they are, however, seldom used for this purpose since the inevitable wastage would cause the process to be too costly. Metallic nickel or certain of its compounds are used instead, with the result that the operation has to be carried out at a considerably higher temperature, resulting in the destruction of some of the important vitamins which would have survived had palladium been used instead of nickel.

As regards density or specific gravity, the platinum metals resolve themselves naturally into two groups: the three members of lowest atomic weight have specific gravities of 11–12, *i.e.*, somewhat higher than, but not far removed from, that of silver, 10–11; the three higher members, however, are much denser and their specific gravities range from 21·4 for platinum to 22.5 for osmium which is the heaviest massive substance known under terrestrial conditions. As the specific gravity of platinum is near to that of gold, 19·4, an alloy of platinum with some base metal is easily prepared possessing the same density as gold.

Being bad conductors of electricity, platinum and its allied metals in the form of wire easily become incandescent when an electric current is passed through them. Incandescent lamps with very luminous filaments for electric lighting could be made without any danger of fusing of these metals. The first practical success was attained with filaments of metallic osmium, which was found to glow more vigorously and thus give better illumination than the other platinum metals. This fact is perpetuated in the name "Osram" which is still a trade-mark of certain lamp manufacturers, although the use of osmium for this purpose has long been discontinued. Although the platinum filaments for lamps was soon displaced by tantalum and tungsten, yet for a considerable time platinum entered into their construction, as some material had to be used, which could be fused into the glass without cracking, to carry the necessary leading-in wires. The only suitable substance then known was platinum, which has a coefficient of expansion almost the same as that of glass, and for a considerable time this was the only available material. This wasteful use of platinum has now been obviated by the production of alloys of much cheaper material having the same coefficient of expansion as ordinary glass.

Occurrence.—The platinum metals appear to be widely distributed in nature, although generally in very small quantities. Localities in which they occur are Brazil, Colombia, Peru, Russia, Australia, Borneo, Tasmania, California and South Africa. Alluvial deposits have hitherto been the usual sources, but platiniferous reefs have now been found in the Transvaal and Natal. Alluvial platinum was reported in 1927 from Sierra Leone over an area of 40sq. miles. The first definite recognition of crude platinum as a separate metal occurs in the 18th century, when chemists obtained samples of platinum ore from Carthagena.

In 1803 and 1804 four new metals were obtained from platinum. Osmium and iridium were discovered and isolated by Smithson Tennant and palladium and rhodium by W. H. Wollaston. The remaining platinum metal, ruthenium, was not discovered till 1828 when Osann succeeded in isolating it from the platiniferous ore of the Ural mountains, a deposit discovered in 1819. The platinum ores obtained from various localities differ greatly in composition. Platinum is generally found as the chief metal and the other metals of the group occur in relatively small and variable quantities. Occasionally, however, and especially in Australia and South Africa, small nuggets or grains of osmiridium are found, and recently considerable amounts have been found in Tasmania which is now its chief source. This mineral consists chiefly of the metals osmium and iridium, and also usually of a certain amount of ruthenium, the other platinum metals occurring to a small extent only. In addition to the six platinum metals, platinum ores contain other elements, the most common being gold, copper, silver, iron, chromium and nickel.

Separation.—The methods in general use for the separation of the six platinum metals are here outlined, detailed accounts of their purification being shown under the headings of the several metals. A platinum ore which has been freed from base metals and other impurities is treated with aqua regia (*q.v.*); osmium, most of the iridium and a small amount of ruthenium remain undissolved. The solution, containing platinum, palladium, rhodium and small amounts of ruthenium and iridium, is evaporated to dryness, when the metals are obtained as chlorides. These chlorides are then heated to about 150° C whereby the chlorides of palladium and iridium are partly decomposed giving lower chlorides. The residual mass is dissolved in very dilute hydrochloric acid, and ammonium chloride is added to precipitate most of the platinum and iridium as double chlorides, the other metals remaining in solution. This solution is then treated with metallic iron (technically termed "footing"), which throws all the metals completely out of solution; this precipitate, like all others similarly obtained, is technically called "foots." The precipitate after thorough washing is again dissolved in aqua regia, the solution is concentrated and again treated with ammonium chloride to remove further amounts of platinum and iridium and then treated with ammonium hydrate, when nearly all the palladium is thrown out as a difficultly soluble ammine, $Pd(NH_3)_2Cl_2$. The solution now containing rhodium and ruthenium is evaporated to dryness and strongly ignited, leaving the metals themselves. These are fused with potassium bisulphate, when the rhodium forms a soluble double sulphate leaving the ruthenium unattacked.

The foregoing residues containing osmium, iridium and some ruthenium are heated in a tube in a stream of air or preferably oxygen. Osmium and ruthenium form volatile oxides which are deposited in the cold parts of the tube. The residue, iridium with some ruthenium and small amounts of other platinum metals, is purified by suitable methods. A method of treating crude platinum ores, particularly useful in concentrating the platiniferous portion, is to heat the ores with metallic lead or to make a mixture of the ores with galena, scrap iron, glass and borax, the last two materials serving as a flux. The platinum metals, except most of the osmiridium, are dissolved in the lead which is removed by ordinary cupellation, the platinum metals remaining ready for subsequent treatment. In modern reef-mining, the platiniferous ores are concentrated after grinding by methods of oil flotation.

Another method of opening up platinum ores is to treat a heated mixture of the substance and common salt with chlorine. All the platinum metals are attacked by this process giving double chlorides of the metal with sodium. As these double chlorides differ in stability, variations of the temperature of treatment give different products. Even if the double chloride is decomposed at or below the temperature of formation, the metal resulting from this decomposition remains in a finely divided condition and subsequent treatment is facilitated, and at the same time some of the stable double chlorides, especially that of iridium, are soluble in water and are easy to treat subsequently. It is obvious that with ores of different compositions some of the foregoing methods are more suitable than others in particular cases. Furthermore, all firms engaged in the refining of these metals have their own special secret methods. (F. E. M.)

BIBLIOGRAPHY.—E. A. Smith, *Platinum Metals* (1925); A. D. Lumb, *The Platinum Metals* (1920).

PLATO (c. 428 B.C.–*c.* 348 B.C.), Greek philosopher, son of Ariston and Perictione, was born in the year 428–427 B.C. and died in 348–347 at the age of over 80. His family was, on both sides, one of the most distinguished of Athens. Ariston is said to have traced his descent through Codrus to the god Poseidon; on the mother's side, the family, that was related to Solon, goes back to Dropides, archon of the year 644 B.C. Perictione apparently married as her second husband her uncle Pyrilampes (Parm, 126 C) a prominent supporter of Pericles, and Plato was probably chiefly brought up in his house: Critias and Charmides, leading men among the extremists of the reactionary Terror of 404, were respectively cousin and brother of Perictione; both were old friends of Socrates, and through them Plato must have known the philosopher from boyhood.

His own early ambitions as he tells us in the seventh Epistle (324 *b.*–326 b.) were political. The reactionaries urged him to enter public life under their auspices—at the age of 24—but he wisely held back till their policy should declare itself. He was soon repelled by their violences, particularly by their attempt to implicate Socrates in the illegal execution of their victim Leon. He hoped better things from the restored democracy, but its condemnation of Socrates finally convinced him that there was no place for a man of conscience in active politics. Hermodorus, an immediate disciple, is the authority for the statement that, on the execution of Socrates in 399 B.C., Plato and other Socratic men took temporary refuge with Eucleides at Megara. The later Lives represent the next few years as spent in extensive travels in Greece, Egypt, Italy. Plato's own statement is only that he visited Italy and Sicily at the age of 40 and was disgusted by the gross sensuality of life there, but found a kindred spirit in Dion, brother-in-law of Dionysius I. of Syracuse.

The Academy.—About or soon after 387, Plato founded the Academy as an institute for the systematic pursuit of philosophical and scientific research. He presided over the society for the rest of his life, making it the recognized authority alike in mathematics and in jurisprudence. From the allusions of Aristotle we gather that Plato lectured without manuscript, and we know that "problems" were propounded for solution by the joint researches of students. On the political side there are traces of tension between the Academy and the rival school of Isocrates.

The one outstanding event in Plato's later life is his intervention in Syracusan politics. On the death of Dionysius I. in 367, Dion conceived the idea of bringing Plato to Syracuse as tutor to his successor, whose education had been neglected. Plato himself was not sanguine of results, but as both Dion and the philosopher-statesman Archytas of Tarentum thought the prospect promising, he felt bound in honour to risk the adventure. The project was by training Dionysius II. in severe science to fit him for the position of a constitutional king who might hold Carthaginian encroachment in Sicily at bay. The scheme was crushed by his natural jealousy of the stronger Dion, whom he drove into virtual banishment. Plato paid a second and longer visit to Syracuse in the year 361–360, in the hope of still effecting an accommodation, but failed, not without some personal danger. When Dion captured Syracuse by a coup-de-main in 357, Plato wrote him a short letter of congratulation and warning against his own lack of tact and graciousness. After the murder of Dion in 354 the philosopher drew up the important seventh and eighth Epistles, reviewing and justifying the policy of Dion and himself and making proposals, unsuccessfully, for a conciliation of Sicilian parties.

The prejudice which led students in the 19th century to discredit the Epistles, in spite of the favourable opinion of scholars such as Bentley, Cobet, Grote, Blass, E. Meyer, worked havoc with their accounts of Plato's life. It is safe to say that at present the authenticity of the two letters of chief biographical importance, VII. and VIII., is established. I. and perhaps XII. are admittedly unauthentic; on the rest opinion is divided. It seems to be inclining (rightly, as the present writer thinks), in favour of acceptance. The best recent account of the events in Sicily is in E. Meyer, *Geschichte des Altertums*, vol. 5.

To us Plato naturally is important primarily as the greatest of philosophical writers, but to himself the foundation and organization of the Academy must have appeared his chief "work." In the seventh Epistle he utters on his own account the same comparatively unfavourable verdict on written works, in contrast with the contact of living minds, as a vehicle of "philosophy," which he ascribes to Socrates in the Phaedrus (Ep. VII. 341 *b.–e.*, 344 c.). It can hardly be doubted that he regarded his dialogues as intended in the main to interest an educated outside world in the more serious and arduous labours of his "school."

All the most important mathematical work of the 4th century was done by friends or pupils of Plato. Theaetetus, the founder of solid geometry, was a member of the Academy, as were also the first students of the conic sections. Eudoxus of Cnidus, the author of the doctrine of proportion expounded in Euclid's Elements, inventor of the method of finding the areas and volumes of curvilinear figures by exhaustion, and propounder of the astronomical scheme of concentric spheres adopted and altered by Aristotle, removed his school from Cyzicus to Athens for the purpose of cooperation with Plato. Archytas, the inventor of mechanical science, was a friend and correspondent. The Academy is thus the connecting link between the mathematics of the 5th century Pythagoreans and those of the geometers and arithmeticians of Alexandria.

Science.—Nor were other sciences neglected. Speusippus, Plato's nephew and successor, was a voluminous writer on natural history; Aristotle's biological works have been shown to belong largely to the early period in his career immediately after Plato's death, before the breach between the younger philosopher and the Academy. The comic poets found matter for mirth in the attention of the school to botanical classification. The Academy was particularly active in jurisprudence and practical legislation. "Plato sent Aristonymus to the Arcadians, Phormion to Elis, Menedemus to Pyrrha. Eudoxus and Aristotle wrote laws for Cnidus and Stageirus.

"Alexander asked Xenocrates for advice about kingship; the man who was sent to Alexander by the Asiatic Greeks and did most to incite him to his war on the barbarians was Delius of Ephesus, an associate of Plato." (Plutarch, against Colotes, 1126 *c.–d.*) The creation of the Academy as a permanent society for the prosecution of both exact and humane sciences was, in fact, the first establishment of a University.

Socrates.—The most important formative influence to which Plato's mind was exposed in youth and early manhood was that of Socrates. But it does not appear that Plato, whose first ambitions were political, belonged to the innermost circle of the old man's intimates, or regarded himself as a "disciple." In *Ep.* VII. he is careful to speak of Socrates not as a "master" but as an older "friend" (*ἑταῖρος*) for whose character he had a profound respect, and has recorded his own absence (through indisposition) from the death-scene of the Phaedo. It would seem that his own vocation to philosophy only dawned on him afterwards, as he reflected on the moral to be learned from the treatment of Socrates by the democratic leaders. Aristotle incidentally ascribes to him an early familiarity with the Heracleitean Cratylus, a younger man than Socrates and apparently an admirer of the philosopher. This may be only Aristotle's Inference from the existence of the diaiogue

Cratylus. It is more important to remember Plato's connection with Pyrilampes and Critias. Pyrilampes was a Periclean politician, and Critias was known as a democrat until his moral balance was upset by the collapse of the Periclean system in 404. Early upbringing in a family of Periclean politics having connection with Solon may explain why Plato's own estimate of democracy in the *Politicus* and *Laws* is much less unfavourable than that which he ascribes to Socrates in the *Gorgias* and *Republic.*

Beyond this, we can say only that Plato in early life must have been exposed to the same influences as his contemporaries. His early experiences covered the disastrous years of the Deceleian War, the shattering of the Athenian Empire and the fierce civil strife of reactionaries and democrats in the year of anarchy 404–403. He was too young to have known anything by experience of the imperial democracy of Pericles and Cleon, or of the full tide of the "sophistic" movement. It is not from memory that he depicts Protagoras or even Alcibiades, as they were in their great days.

The Works. — The canon and text of Plato appears to have been fixed by two scholars, Dercylides and Thrasylus, either shortly before or shortly after the Christian era. Thrasylus is uncertainly identified with a grammarian of the name who flourished in the reign of Augustus and was "heard" by Tiberius. By reckoning the *Epistles* as one item, the list was made to consist of 36 works, arranged in nine "tetralogies," or groups of four. (Aristophanes of Byzantium had already attempted an arrangement in "trilogies," or groups of three, which, however, he did not carry through.)

Textual **Problems.**—No genuine work of Plato has been lost, but there is a general agreement of modern scholars to reject a number of small items from the text. Their verdict may be said to have gone definitely against the following, *Alcibiades I., Alcibiades II.* (suspected by some even in ancient times), *Theages, Erastae, Clitophon, Hipparchus, Minos.* Most or all of these are probably early Academic work, and possibly not all later in date than Plato's death. Most, though not all, contemporary scholars also regard the *Epinomis*—in the present writer's opinion wrongly—as an appendix to the *Laws* added *de suo* by the mathematician Philippus of Opus, who is recorded by Diogenes Laertius (III. 37) to have transcribed the work for circulation. The *Greater Hippias* and *Menexenus* are still regarded as doubtful by some, though Aristotle used both, and expressly quotes the latter, in a way which seems to prove that he regarded them as Platonic. (The wild negative criticism of German scholars of the middle of the 19th century, which received its death-blow in 1867 from L. Campbell's proof of the genuineness of *Sophistes* and *Politicus,* is now universally recognized to have been an aberration.) Plato's will, preserved by Diogenes (III. 41–43), is pretty certainly authentic. Some of the 32 epigrams ascribed to him in the *Anthology,* may conceivably be genuine.[1]

Order **of Dialogues.**—Plato's literary career extended over the greater part of a long life. The *Apology* must have been written while the memory of Socrates' appearance before his judges was still fresh; the *Laws* is confessedly the work of an old man with a long experience of life behind him, and the state of its text fully bears out the tradition, preserved by Proclus, that its aged author never lived to give it final revision. Some half a century or more must have elapsed between Plato's last and his earliest composition.

This of itself would prove that Schleiermacher, with whom modern critical study of Plato begins, went astray in assuming that Plato started his career with a ready-made complete "system" to be disclosed. We must expect to find in his writings evidence of the development of his mind. But if we are to read the development aright we must have some trustworthy way of determining the order of the dialogues. Plato himself has only given us the scantiest indications of the order He has linked the *Sophistes* and *Politicus* externally with the *Theaetetus* as professed continuations of the conversation reported in that dialogue; he has also, as most students recognize, linked up the *Timaeus* in the same way with the *Republic.* Aristotle adds one other piece of information, that the *Laws* were written after the *Republic.* Further investigation of the problem opens in 1867 with L. Campbell's edition of the *Sophistes* and *Politicus,* and the work thus begun was continued by others, notably W. Dittenberger, C. Ritter and W. Lutoslawski.

By consideration of numerous independent stylistic criteria (for which *see* the works named at the end of this article), it has been definitely established that the dialogues *Sophistes, Politicus, Philebus, Timaeus* (with its fragmentary sequel *Critias), Laws,* form a distinct linguistic group, which must belong to the later years of Plato's life, as we might have presumed from the consideration that Socrates, the central figure of other dialogues, becomes, in those of this group (with a solitary exception for the *Philebus,* the one member of the group which is wholly preoccupied with ethics), a secondary personage, and disappears altogether from the *Laws.* The whole group must therefore be later than the *Sophistes,* which professes to be a sequel to the *Theaetetus.* Now the *Theaetetus* can be dated with some accuracy, since it commemorates the recent death of the eminent mathematician after whom it is named from disease and injury contracted in a campaign before Corinth, which, as elaborately proved by Eva Sachs (*de Theaeteto Atheniensi*, Berlin, 1914), must be that of 369 B.C. The dialogue may thus be safely ascribed to 368–367, the eve of Plato's departure for Syracuse, and the marked change of style visible in the *Sophistes* is best explained by the supposition that there was a break in Plato's literary activity during the years 367–360 when he was specially occupied with Sicilian affairs. So much may be regarded as fairly certain.

The Earlier Dialogues. — It is not so easy to reach definite conclusions about the order of composition of the more numerous earlier group of dialogues. It is generally recognized, on linguistic and other grounds, that the series ends with the *Theaetetus* and the closely related *Parmenides.* Attempts have been made by C. Ritter, Lutoslawski and others, to determine the internal order of the group on linguistic evidence, but there are obvious reasons for doubting whether the methods which have been successful in establishing the distinction between the two great groups of earlier and later dialogues can be applied with the same confidence to works belonging to the same general period of their author's life and composed probably at no great distance of time from one another.

In point of fact, there is not complete agreement between the arrangements proposed by different "stylometrists," and their advocates have usually eked out the strictly philological argument by more or less dubious assumptions about the development of Plato's thought, though it is very questionable whether any real development can be traced before the *Theaetetus* and *Parmenides.*[2] Perhaps all that can be said with certainty is that the great outstanding dialogues, *Symposium, Phaedo, Republic* (and the writer of this article would be inclined to add *Protagoras),* in which Plato's dramatic power is at its highest, mark the culmination of this first period of literary activity. The comparative decline of dramatic power, accompanied by compensating maturity of critical acumen is the most striking contrast between the dialogues of the second and those of the first period.[3] A good account of the work done by the "stylometrists" will be found in H. Raeder, *Platons philosophische Entwickelung* (1905).

The **Socrates of** the Dialogues. — The great initial difficulty which besets the modern student of Platonic philosophy is that created by the dramatic form of Plato's writings. Since Plato

[1]The most dubious are also the best known. That on Agathon (imitated by Shelley, "Kissing Helena") and that on Alexis and Phaedrus are condemned by the occurrence of the names Agathon and Phaedrus. They are obviously suggested by the parts played by the tragic poet Agathon and Phaedrus of Myrrhinus in the *Symposium* and *Phaedrus.* The author has forgotten that both were grown men in Plato's childhood. This suggests suspicion of all the "amatory" verses. The syntax of the first of the epigrams on Aster is also singular.

[2]*See* in particular the important study of P. Shorey, The *Unity of Plato's Thought* (1903).

[3]In *Ep.* VII. *326a* Plato seems to refer to Rep. VI. 499 *b.-c.* as already written before his first visit to Sicily in 387. It has been argued that the *Symposium* must be later than 385 since Aristophanes, who died in that year, is introduced into the dialogue. But it is not clear that Plato made it an absolute rule never to introduce living speakers. It is hard *e.g.,* to believe that Eucleides must have died while the *Theaetetus* was being written

never introduces himself into his own dialogues, he is not formally committed to anything which is taught in them. The speakers who are formally bound by the utterances of the dialogues are their protagonists, Socrates, Parmenides, the Pythagorean Timaeus, and all these are real historical persons. The question thus arises, with what right do we assume that Plato means us to accept as his own the doctrines put into the mouths of these characters? Is his purpose dogmatic and didactic, or may it be that it is mainly dramatic? Are we more at liberty to hold Plato responsible for what is said by his *dramatis* personae than we should be to treat a poet like Browning in the same fashion?

It is tempting to evade this formidable issue in one of two ways. One is that of Grote, who held that Plato allows himself freely to develop in a dialogue any view which interests him for the moment, without pledging himself to its truth or considering its compatibility with other positions assumed elsewhere in his writings. Thus, according to this theory, Plato can make Socrates advocate hedonistic utilitarianism in the Protagoras, or denounce it in the Gorgias, can assert the so-called "ideal theory" through the mouth of Socrates in the Phaedo, or refute it in the character of Parmenides in the dialogue of that name, with equal gusto and without pledging himself in either case. His championships are purely dramatic, or, at most, reflect his passing mood at the moment of composition.

The more common assumption of the 19th century was that scme of Plato's characters, notably Socrates and Timaeus, are "mouthpieces" through whom he inculcates tenets of his own, without concern for dramatic or historical propriety. Thus it was, and often still is, held that the most famous philosophical doctrines of the Phaedo and *Republic,* the "ideal theory," the doctrine of "recollection" and of the tripartite soul, were actually originated by Plato after the death of Socrates, to whom these speculations were entirely unknown, and consciously fathered on the older philosopher by a mystification too glaring to deceive any one seriously. Careful study of the dialogues should satisfy us that neither of these two extreme views is tenable.

The Thought of the Earlier and Later Dialogues.—There is undeniably a real difference between the thought of the dialogues which are later than the Theaetetus and those which are earlier, and this difference will have to be accounted for. But there are no serious discrepancies of doctrine between the individual dialogues of the same period.[1]

Now Plato seems to announce his own personal conviction of certain doctrines of the second group of dialogues by a striking dramatic device. In the Sophistes and Politicus the leading part is taken by an Eleatic and in the Laws by an Athenian who are the only anonymous, indeed almost certainly the only imaginary, personages in the whole of Plato's writings.[2] It can hardly be doubted that the reason why these two characters have been left anonymous is precisely that the writer may be free to use them as "mouth-pieces" for his own teaching. Plato thus takes on himself the responsibility for the logic and epistemology of the Sophistes and Politicus and the ethics and educational and political theory of the Politicus and Laws in a specially marked way, and by doing so compels us to face the question how far he means the utterances of Socrates in his earlier dialogues to be taken as expressions of a philosophy of his own.

"Forms."—It may be regarded as an established result of the inquiries of Dr. Henry Jackson and others that there is a definite philosophical doctrine running through the earlier dialogues which has as its main ieatures the theory of "Forms" (the "ideal" theory), the theory that knowledge is "recollection," and the theory of the "tripartite soul." In the dialogues of the second period these tenets, as we have learned to know them from the earlier dialogues, appear only in the mouth of Timaeus, a 5th century Pythagorean older than Socrates, and the most important of them all, the theory of "Forms" is actually made the object of what looks like a refutation in the Parmenides.

The problem is to find an explanation of this puzzling fact. Are we, with Dr. Jackson[3] and others to distinguish two philosophies, both originated by Plato after the death of Socrates, an earlier and a later? Or are we to suppose that in the main the object of the first group of Plato's dialogues is to preserve the memory of Socrates and that the philosophy expounded is in the main what it professes to be, the thought of Socrates, coloured, no doubt, unconsciously but not consciously distorted, in its passage through the mind of Plato? On the second view we should have to say that, strictly speaking, Plato had no distinctive Platonic philosophy until a late period in his life, much as we can say that, though Kant was all through his life a prolific writer on philosophy, there was no distinctive Kantian philosophy before the Critique of *Pure* Reason. Most Platonic scholars are still unwilling to accept this interpretation of the facts, though there are weighty considerations which plead strongly for it.

Socrates and Plato.—It is significant that the only dialogue not earlier than the Theaetetus in which Socrátes takes a leading part is the Philebus, the one member of the second group which deals exclusively with those ethical problems on which the thought of the historical Socrates had been specially concentrated. This is most naturally explained by supposing that Plato, from regard to fact, was unwilling to make Socrates the exponent of doctrines which he knew to be his own property, though it is hard to understand his misgivings if he had already for years been employing him in that very capacity.[4] (If, as is most probable, *Ep.* II. is authentic, the question would be definitely settled by the sentence of the latter [314 c.] "there is not, and never will be, a work of Plato; the works which now go by that name belong to Socrates embellished and rejuvenated.")

It is notable, too, that Aristotle apparently knew nothing of an earlier and a later version of Platonism. He attributes a definite doctrine to Plato which is quite unlike anything to be found in the first great group of dialogues, and seems to be known to him from oral communications in the Academy, though something like it can, by looking hard, be read between the lines in the *Philebus.* It was also the view of Neo-Platonic scholars like Proclus that the "ideal theory" expounded in the great earlier dialogues really originated with Socrates and that something of the same kind was also held by contemporary Pythagoreans in Italy (Proclus in *Parmenidem* ed. Stallbaum 562, 610), and the fact that Proclus does not find it necessary to argue the point seems to show that this had been the standing tradition of the Academy. Similarly Galen, in the early 3rd century of our era, has preserved the definite statement of the learned Stoic Poseidonius that the doctrine of the "tripartite soul," often said in modern times to be another invention of Plato's, is as old as Pythagoras (Galen de *placit. Hipp.* et Plat. 425, 478).

Moreover, as Burnet has argued, it is very hard to believe that any writer would introduce a far-reaching novel speculation of his own to the world in the curious fashion which Plato is supposed to have adopted in the Phaedo, where Socrates is made to describe the "ideal theory" as something quite familiar which he has for years constantly canvassed with his intimates (nearly all, if not all, of whom, were certainly living when the Phaedo was circulated). It is not necessary here to determine the historical question. We may be content to turn to the Platonic dialogues, carefully distinguishing the successors of the Theaetetus from its predecessors, and attempt a summary of their contents. The general doctrine of the first period will be described without any more or less arbitrary attempt to say how much of it may be actually "Socratic." We may then consider how far this doctrine is modi-

[1]As there would be betweeh the Protagoras and the Gorgias or Phaedo if the Protagoras really said that the pleasure is the good. What it actually says is only that "the many," "most men," hold this view (353 *d.–e.*), and ought not therefore to regard the doctrine that "goodness is knowledge" as paradoxical, since on their own theory, virtue will amount to right computation of pleasures and pains.

[2]Except the two minor personages of the Laws, a Spartan and a Cretan, who have really nothing to do except to say "Yes." "Yo," in the appropriate places.

[3]*Journal* of Philology X.–XII.

[4]It might be said that if the principal doctrines of the Platonic Socrates were known by Plato to be his cwn peculiar property, he might feel a difficulty about putting a new and more critical philosophy into the mouth of the speaker who had been used as the exponent of his "earlier" teaching. Rut this would not wholly explain why Socrates might not have been made to teach the logic of the *Sophistes.*

fied in later dialogues, or in the version of Platonism presupposed by Aristotle's criticisms.

No attempt will be made here to describe the personality or temperament of Plato which is, in fact, as elusive as that of Shakespeare and for the same reason. He is often credited with a strongly "mystical" and "erotic" temperament. He does ascribe such a temperament to Socrates, but it is puerile to treat his picture of Socrates as evidence about himself, though the mistake is constantly committed.

It should therefore be noted that the "mysticism" is confined to dialogues of the first period, in which Socrates is its exponent, and that the "erotic" language in which Plato's Socrates speaks of his devotion to his young friends was also used by the Socrates of Aeschines to describe his relations with Alcibiades (Fr. 4, Krauss). There is no evidence that Plato personally ever fired the imagination of gifted boys as Socrates did. Apart from the Epistles, the most valuable light we possess on Plato's personality is afforded by Aristotle's description of him as a man "whom it is blasphemy in the base even to praise" (ὅν οὐδ' αἰνεῖν τοῖσι κακοῖσι θέμις).

THE EARLIER DIALOGUES

In the Republic, the greatest of all the dialogues which precede the Theaetetus, there may be said to be three main strands of argument deftly combined into a consummate artistic whole, the ethical and political, the aesthetic and "mystical," and the metaphysical. Other major dialogues belonging to this period give special prominence to some one of these three lines of thought; the Phaedo to the metaphysical theme, the Protagoras and *Gorgias* to the ethical and political, the *Symposium* and Phaedrus to the aesthetic and "mystical," though in none does Plato make an artificially rigid separation of any one of the great ideal interests of human life from the rest.

The shorter dialogues deal with more special problems, usually of an ethical character, and mostly conform to a common type. A problem in moral science, often that of the right definition of a "virtue," is propounded, a number of tentative solutions are considered and are all found to be vitiated by difficulties which we cannot dispel; we are thus left, at the end of the conversation, aware of our discreditable ignorance of the very things it is most imperative for man to know. We have formally "learned" nothing, but have been made alive to the worthlessness of what we had hitherto been content to take for knowledge and the need of seeking further enlightenment.

The effect of these "dialogues of search" is thus to put us in tune with the spirit of Socrates, who had said that the one respect in which he was wiser than other men was just his keen realization of his own ignorance of the most important matters. We learn the meaning of his ruling principle that the supreme business of life is to "tend" the soul (to "make it as good as possible") and his conviction that "goodness of soul" means first and foremost, knowledge of good and evil. The three dialogues directly concerned with the trial of Socrates have manifestly a further purpose. They are intended to explain to a puzzled public why Socrates thought it stuff of the conscience neither to withdraw from danger before trial, nor to make a conciliatory defence, nor, finally, to avail himself of the opportunity of flight after conviction. Even well-wishers like Xenophon, as we know, were puzzled by what had seemed his wilfully defiant attitude; it was therefore a debt of honour to his memory to put the matter in the true light. In the remarks which follow, we will consider these shorter dialogues in an order adopted simply for purposes of convenience.

Hippias I. and II.—In these dialogues Socrates has as "respondent" the well-known polymath Hippias of Elis, whose self-complacency is sharply satirized. In the *Hippias Maior* the question propounded is "What is the fine" (καλόν)? "Fine" is a predicate by which we are constantly expressing both aesthetic and moral approval; do we really know what we mean by it? We discover that we do not, though incidentally we also learn that "fine" or "beautiful" is certainly not a synonym for either "useful" or "pleasant." *Hippias* Minor deals directly with the famous Socratic paradox that "wrong-doing is involuntary." It is commonly held that it is much worse to tell a wilful untruth than to blunder into an unintentional false statement. Yet the analogy of the arts and professions seems to show that the man who errs intentionally, if there is such a person, is a better man than he who errs unintentionally. (The suggested thought, of course, is that there "is no such person." The man who knows what is good will always aim at this and at nothing else,—the familiar doctrine of Socrates.)

Ion, Menexenus.— Both these are "occasional" works. Socrates had said that he found the poets, who as a class are commonly reckoned "wise," quite unable to explain to him how they came to say their best things, or what they meant by them. (*Apol.* 22 *a.–c.*) The *Ion* develops this thought into the theory that neither the poet, nor his interpreter the "rhapsode," produces his effects "by science," *i.e.*, as a result of conscious "artistry"; the effect in both cases is due to a non-rational "inspiration," or, as we now say, "native genius." (The importance of this is that it rules out appeal to the poets as specially competent authorities on the conduct of life.)

The *Menexenus*, which professes to repeat a "funeral oration" learned from the famous Aspasia, is apparently meant as a satire on "patriotic" distortion of history. Apparently the "discourses" satirized are those of Pericles in Thucydides, Lysias (Lysias II.) and Isocrates (the Panegyricus). The singular anachronism by which Socrates (and Aspasia) are represented as commenting on the events of the Corinthian War down to the year 387 must be intentional, whatever its object.

Charmides, Laches, **Lysis.**—These are typical "dialogues of search." The question of the Charmides, which contains a particularly delightful picture of the way of Socrates with a promising lad, is what is meant by sophrosyne, the virtue which is shown alike in graceful and easy command of one's appetites and passions, in dutiful behaviour to parents, elders, official "superiors," in balance and sanity amid the ups and downs of fortune. We seem to be in a fair way to identify this virtue with "knowledge of self"—the self-knowledge Socrates had valued so highly—when we are confronted with an ambiguity. "Self-knowledge" might be taken to mean a knowledge which has knowledge itself for its object, in fact for "epistemology." But it is hard to be sure that there is any such science as "the knowledge of knowledge," and harder still to see how such knowledge could be directive of conduct.

In the Laches we are concerned with valour, the soldier's virtue. Here again we are on the point of defining the virtue as knowledge of what is and what is not really to be dreaded. But this is tantamount to saying the true knowledge of evil and good, and the resultant definition, "valour is knowledge of good" would identify valour with the whole "goodness of man." That is, the definition is only possible if we can meet the popular objections to the Socratic thesis of the "unity of virtue."

The *Lysis* examines in the same tentative way, friendship, the relation in which self-forgetting devotion most conspicuously displays itself. The crux of the problem is that after many false starts, we seem to have reached a promising result in the view that each friend is really "a part of" the other in "soul or temper or body," and yet it is hard to reconcile this position with the facts which seem to show that "unlikeness" is a potent source of attraction. Aristotle has taken up and discussed the issues raised in the dialogue in his own treatment of the same subject (E.*N.* VIII.–IX.).

Cratylus.—The question here, one much agitated in the age of Socrates, is whether names are significant by "nature" or "convention." Is there some special appropriateness of the sounds of names to the objects called by them, or is there no bond between the thing and its name but that of the "usage of the community"? The absurdity of attempts to get metaphysics out of etymologies is humorously exposed by showing that the method can be used at pleasure to prove either that the "giver of names" agreed with Heracleitus that motion is the sole reality or that he held, with Parmeaides, that motion is an illusion. Yet there are real analogies between "vocal gestures" and the things signified by them, which are pointed out with a good deal of insight. The main purpose of Plato, however, is to dwell on the point that language is an instrument of thought; the test of its rightness is not mere "social usage," but its capacity to express true thought accurately.

Euthydemus.—The dialogue is, in large part, broad satire on "eristics" who misapply the logic of Zeno for the purpose of entangling anyone who commits himself to any assertion in fallacies due to the ambiguity of language. (Aristotle has drawn freely upon it in his own essay on Fallacies, the de *Sophisticis* Elenchis.) Its more serious purpose is to contrast this futile contradiction-mongering with the "protreptic" of Socrates. The lad Clinias is simply bewildered by the questions of the two professors of "eristic"; those of Socrates have the purpose of convincing him that the happiness we all desire is not guaranteed by the possession of the things the world accounts good, but depends on our making the right use of them. If we would attain happiness we must "tend" our "souls," and that means that we must acquire the "royal" science which ensures that we shall make the right use of all the gifts of mind, body and fortune, in other words, the knowledge of true and absolute good.

Gorgias.—The Gorgias is a much greater, as well as a much longer work than any of those we have considered, and has always been a prime favourite with serious moralists. Beginning ostensibly as an enquiry into the nature and worth of "rhetoric," the art of advocacy professed by Gorgias, it develops into a plea of sustained eloquence and logical power for absolute right, as against expediency, as the sovereign rule of life private and public, and ends with an imaginative picture, on Orphic lines, of the eternal destinies of the righteous and the unrighteous soul. Literature has no more impressive presentation of the claim of conscience to unqualified obedience and the impossibility of divorcing the politically from the morally right.

Gorgias holds that "rhetoric" is an "art," the application of knowledge to practice, and the queen of all "arts," since it gives its possessor the abject of man's highest ambition, power to enforce his will on society. The statesman, who is the man of men, is just a consummate advocate speaking from a brief. If he is clever enough he will, though a layman, carry the day with an audience of laymen, even against the expert specialist. To his audience he will seem, though he is not, the superior of the real expert. Socrates declares. that "rhetoric" is not an "art," a matter of native principles, but a mere "empiric knack" (τριβή) of humoring the prejudices and pleasing the tastes of an audience. It is a subspecies of κολακεία, "parasitism."

There are two genuine "arts" conducive to the health of the body, those of the trainer and the physician; each has its parasitic counterfeit, the one in the profession of the "beautifier," the other in that of the confectioner. So there are two "arts" conducive to "health of soul," those of the legislator, who lays down the rule of morally sane life, and of the judge, who corrects moral disorders. The "sophist" counterfeits the first, as the "rhetorician" the second, by taking the "pleasant" instead of the "good" as his standard The "rhetorician" is thus not the wise physician of the body politic but its "toady" (κόλαξ). This severe judgment is disputed by Polus, the ardent admirer of Gorgias, on the ground that the successful "rhetorician" is virtually the autocrat of the community; every man's life and property are at his mercy.

To be such an autocrat is the summit of human happiness; even if, like Archelaus of Macedonia, the aspirant only reaches the position by a series of shocking crimes, he is the most enviable of mankind, because he is above law and can do "whatever he likes." Socrates denies this. The autocrat always does "as he pleases," and for that reason never does "what he wishes"; like all mankind, he wishes for true happiness or good, but no act which is immoral ("unjust") ever leads to happiness. To suffer a wrong is an evil, but to inflict one is much worse. And if a man has committed a wrong, it is much worse for him to go unpunished than to be cured of his moral malady by the sharp but wholesome medicine of punishment. If "rhetoric" is of real service to men, it should be most of all serviceable to an offender. If he knew his own interest, he would employ all his powers of persuasion to move the authorities to inflict the penalties for which the state of his soul calls. Polus is unable to meet this reasoning, because he had at least conceded to current morality that it is more disgraceful, though not more evil to inflict wrong than to suffer it.

This is denied by Callicles of Acharnae, an otherwise unknown politician, who proceeds recklessly to develop the doctrine of the "will to power." It may be a convention of the herd that unscrupulous aggression is discreditable and wrong, but "nature's convention" (the νόμος τῆς φύσεως, a phrase which appears here for the first time in literature) is that the strong are justified in using their strength as they please, while the weak "go to the wall." Callicles and Socrates thus appear as champions of two contrasted moralities of private and public life. Callicles stands for self-assertion in ethics and aggressive "Imperialism" in politics. Socrates opposes both. In his judgment the creators of the imperialistic Athenian democracy were no true statesmen, because they were content to give Athens a navy and a commerce without creating a morally sound national character. They may have been capable "domestic servants" of the democracy for whose tastes they catered; they were not its physicians. The one true statesman of the past was the "just" Aristeides; in the present, Socrates himself is the one man who shows a statesman-like mind, though it is perfectly true that he might at any moment have to pay with his life for refusing to call that good which pleases the public fancy. It is not true, as Callicles supposes it to be, that the secret of happiness is to have strong and vehement passions and be able to gratify them to the full. That would be a condition like that of the fabled sinners who are punished in Hades by being set to spend eternity in filling leaking pitchers. The truly happy life is that of "measure" in which the gratification of desire is strictly regulated by regard for justice and *sophrosyne.* If we may believe the Orphic doctrine of judgment to come, the votary of "passion" and injustice has a heavy reckoning to await hereafter.

Meno.—The *Meno* is nominally concerned with the question what virtue is and whether it can be taught, but it is further interesting for two reasons. It states clearly the doctrine, which we have not met so far, that knowledge is "recollection"; it also introduces as a character the democratic politician, Anytus, the main author of the prosecution of Socrates. It seems plain that Plato wishes to indicate his opinion that it was Socrates' severe criticism of the great figures of the history of Athenian democracy which led to the prosecution.

Can virtue be taught or learned (as must be the case, if the professional sophists can really do what they profess)? That depends on what virtue is. We are on the way to define it as "ability to secure good things by honest means," when we reflect that honesty itself is a "good thing," and the definition consequently is circular. This reminds us of the current dilemma that all such inquiries are futile because it is idle to inquire into what you already know, useless to inquire into what you do not know (since you could not recognize the unknown, even if you found it). This difficulty would vanish if it were true that the soul is immortal and has long ago learned all truth, so that it needs now only to be "reminded" by sense-experiences of truths it once knew and has forgotten. This (Orphic) doctrine seems to be supported by the experience that a lad who has never studied geometry can be brought to recognize mathematical truths by merely showing him a diagram and asking him appropriate questions about it. He produces the right answer "out of himself." (The point thus is the presence of an a *priori* element in mathematical truth)

In any case, we may say that if "virtue" is knowledge, it can be taught; if it is not knowledge, it cannot. But is it knowledge? If it is, one would suppose that there must be professional teachers of it. But Anytus assures us vehemently that the sophists, who claim to be such professionals, are mischievous impostors, and we can be sure that the ordinary decent citizen cannot "teach virtue," as Anytus maintains, since the "best men" of the democracy, Themistocles and the rest, have been unable to teach it to their own sons. Perhaps, then, we must say that the "best men" of Athens have no genuine knowledge of good; their successes have been due not to knowledge, but to mere "correct opinions." Still, for practical purposes a correct opinion will serve as well as knowledge. The trouble is that you cannot depend on its permanency unless you fasten it down by thinking out the reason why of it (αἰτίας λογισμῷ). Then it becomes knowledge. If a man should arise who could actually teach statesmanship to others, he would be one who really *knew* what good is; the virtue of such a scientific statesman would he to that of other men as substance is to shadow.

Protagoras. — This finely dramatic dialogue gives us the completest presentation to be found in Plato of the main principles of the Socratic morality, and is the direct source of Aristotle's statements about the teaching of Socrates in the *Nicomachean* Ethics.

Socrates meets, in the house of Callias, the eminent sophist Protagoras, who is very attractively drawn and represented as a great admirer of the younger man's ability. Protagoras explains that his profession is the "teaching of goodness," and that by "goodness" he means the art of making a success of one's own life, that of one's household and that of one's "city." (Thus he teaches "the conduct of life, private and public," and has done so for years with success.) Socrates urges that there are two considerations which make it look doubtful whether this art can be taught. The Athenians have a high reputation for intelligence, but it is notorious that the Ecclesia requires no evidence of expert knowledge in a speaker who discusses the niorality of a proposed course of action.

Also the eminent democratic statesmen have never taught their own "goodness" to their sons. Public opinion and the practice of the eminent few alike suggest that the "conduct of life" is not teachable. Protagoras, to be sure, thinks that the absence of special teachers only proves that every citizen of a civilized city can, in his degree, act as teacher, exactly as he can teach his children his native language or his trade. Goodness depends on δίκη and αἰδώς; the sense of right and conscience, and the whole of life in a civilised society, is a process of education in these. His exposition at once raises the problem of the unity of virtue. Are the various commonly recognized "virtues" really different, so that a man may be strong in one but weak in another? Protagoras is at first inclined to say that they are, but on reconsideration is ready to identify all of them but one with wisdom or sound judgment.

An exception must be made for courage, a virtue which is popularly regarded as having something conspicuously non-rational about it. The dialogue culminates in an argument by which Socrates attempts to show that there is no need to make this exception. The general public, the party which insists so much on the non-rational character of courage, would be ready to accept the identification of the good and the pleasant, and to grant that the goodness of courage means that by facing pain and danger one escapes worse pain or danger. On their own theory, then, courage, and the rest of virtue, can be reduced to prudent computation of pleasures and pains. The humour of the situation is that Socrates and Protagoras have thus changed places. Socrates, who had raised a difficulty about the teachability of virtue, is left satisfied that virtue must be knowledge; Protagoras, who claimed to be able to teach it, ends by declaring that, whatever virtue may be, it cannot be knowledge. It is important to observe that the dialogue does not teach Hedonism. The equation good=pleasant is advanced 'only as one which would be accepted by "the mass of men," and should forbid them to find a paradox in the identification of virtue with knowledge; it is expressly repudiated by Protagoras as unworthy of a man of high character.

All that Socrates asserts is that virtue is knowledge and wrong-doing consequently involuntary. There is no disagreement in moral principle between the *Protagoras* and the *Phaedo* or *Gorgias.* If the "mass of men" are ready to accept the Hedonist formula, that is because they are votaries of the body-loving life (βίος φιλοσώματος); this is why we are told in the *Phaedo* that "popular" virtue is illusory. The true explanation of Socrates' doubts is that though he holds that true virtue, being knowledge, is teachable, he does not believe that what Protagoras is trying to teach is true virtue. "Success" depends on personal "tact" and "tact" cannot be learned from an instructor.

Euthyphro, Apology, **Crito.**—The main purpose of these three works, which deal with the bearing of Socrates before, during and after his trial, is to obviate possible serious misunderstandings of the Master's position and motives; the theme of all three may be said to be the true meaning and importance of "care" or "tendance" of the soul.

The problem of the *Euthyphro* is what is religion (τὸ ὅσιον). The respondent Euthyphron is certainly meant to be a kind of Orphic sectary, not, as has been fancied, a representative of ordinary Athenian belief and practice. Socrates had associated with such men and was known to hold unusual beliefs about the soul; hence it was important to make it plain that he was something different from a fanatic. The dialogue, interesting also from its well-developed logical terminology, enables Socrates to repudiate immoral mythology and to reject the conception of "religious duty" as fulfilment of purely arbitrary commands. Its central thought, which, however, is not formally asserted as a conclusion, is that the "service" (θεραπεία) of God which is religion means co-operation with God and under God in the production of a "noble work" (πάγκαλον ἔργον), the nature of which is not further defined, though it is sufficiently clear that the "work" meant is the "tendance of the soul."

Consideration of the *Apology* and *Crito* in detail belongs rather to the study of Socrates (*q.v.*) than to that of Plato. Of the *Apology* we must be content to say here that the real defence of Socrates is contained in the pages which explain that the mainspring of his life has been his conviction that he has a mission from God to spend his life in "philosophy," the endeavour to "make his own soul as good as possible," and to incite mankind to do the same; to this mission it is his duty to be strictly faithful, even if faithfulness means condemnation as a traitor by the democracy. The *Apology* thus depicts Socrates as carrying out in his own practice the ethical programme of the *Gorgias.* The actual accusation is treated with contempt and satirical humour. *(See* article SOCRATES.)

The point of the *Crito,* though simple, is often missed. Was Socrates wantonly throwing away a valuable life by refusing to escape from prison? Why did he make this refusal? Because, though the conviction was materially iniquitous, it was the verdict of a legitimate court, which could not be disregarded without real disloyalty. Socrates has been wronged not by the law, but by politicians who have abused the law. If he disregarded the conviction, he would be directly doing a wrong against the whole social system.

Foundation **of** Plato's Doctrine — In the works so far considered we have the foundation of a moral and political doctrine based on Socratic principles, from which Plato never departed. The main underlying thought is that the great concern of man, a concern not limited to this earthly life, is the development of a rational moral personality (the "tendance of the soul"). Our felicity depends wholly on our success in this task (to use Butler's language, on "our conduct," not on "our condition"). And this success, again, depends on rational insight into the true scale of good. Men do not miss felicity because they do not desire it; on the contrary no man ever really desires anything else. The reason why men forfeit felicity is that they mistake apparent good for real, the conditionally for the absolutely good. If a man ever knew with assurance what absolute good is, he would in practice never pursue anything else. It is in this sense that "all virtue is knowledge" and that "all wrong-doing is involuntary" (*i.e.,* consists in the pursuit of what is falsely supposed to be good).

"Popular morality" is confused in theory and unreliable in practice because it does not rest on any assured insight into absolute good; "philosophic morality," just because it does rest on such certain insight, is a morality of absolute and unconditional obedience to conscience, such as Socrates had shown. Since the task of the statesman is simply the task of "tending the soul" extended to the "national" soul as its object, the "philosophical" moralist is also the only true statesman. True statesmanship means the promotion of national character as the one thing which matters, and is therefore simply the application, on the grand scale, of the principles of absolute morality; what falls short of this is opportunism masquerading as statesmanship.

These convictions clearly imply a far-reaching metaphysic as their foundation and justification. The principles of this metaphysic, though they are frequently hinted at in passages of dialogues alrrady reviewed, are put before us more explicitly in those we have now to consider; in connection with them we shall also observe an explicit theory of knowledge and scientific method.

Phaedo.—The Phaedo is often treated as though its object were to provide a demonstration of the immortality of the soul. It does not really profess to do this. The object is to justify faith in immortality as a rational faith by showing that it follows naturally from a fundamental metaphysical doctrine (the "ideal theory" or "doctrine of Forms"), which seems to afford a rational clue to the structure of the universe, though it is expressly said at the end of the whole discussion that this doctrine itself still requires further examination. At the same time, it is made fully clear that the writer accepts this metaphysical doctrine, with the reservation just mentioned, and is passionately sincere in the faith in "personal immortality" which he brings into connection with it. To be strictly accurate, indeed, we ought to say that the faith to be defended goes beyond belief in "immortality." What is being maintained is the "divinity" of the soul; its survival of death is a consequence of this inherent divinity.[1]

The argument is briefly as follows. A true philosopher may naturally look forward to death without dismay. For death is the separation of soul from body, and the philosopher's whole life has been spent in trying to liberate the soul from dependence on her body. In life, the body is always interfering with the soul's activity. Its appetites and passion interrupt our pursuit of wisdom and goodness; its infirmities are perpetually hindering our thinking. Even in our scientific work, we only attain exact and certain truth in proportion as we detach ourselves from reliance on sense-perception and learn to depend on pure thinking.

Death, then, only completes a liberation which the philosopher has been "rehearsing" all through life—if, that is, the soul continues to exist after death, as there are reasons for thinking. For:

I. There is a belief that the soul has a succession of many lives, and that when it is born into this world, it has come back from another. And there are two considerations to be urged on behalf of this belief. (a) The processes of nature in general are cyclical. The hot becomes cold, the cold hot; the waking go to sleep, the sleeping wake. It is reasonable to suppose that this applies to the case of dying and coming to life, so that the dead return to life, just as the living die. If this were not so, if the process of dying were not reversible, life would ultimately vanish from the universe. And (b) we may appeal to the doctrine that what we call "learning" is really "recollection," "being reminded" of something. This certainly seems to be the case, for in all our science we are perpetually being "put in mind of" precise ideal standards, mathematical or moral. We reason about exact quality, absolute justice and the like. Sense or experience never presents us with such perfect equality or justice; it only suggests them or "reminds us of them." We must therefore have become acquainted with them before we were confined to our bodies, and therefore must have existed before our birth. Now *(a)* and (b) together would prove what we want to prove, the soul's survival of death, though our "dread of the dark" makes us demand a more convincing argument.

II. We may consider the antithesis between the divine and eternal and the temporal and mutable, which runs through the universe. The body is certainly temporal and mutable. The soul is relatively immutable, like the fixed ideal standards or norms which she contemplates in her scientific thinking. Her thought is concerned with eternal objects and she herself has the likeness of that which she contemplates. If, then, some constituents of the body are nearly indestructible how much more should one expect the divine element in us, the soul, to resist destruction, as the traditions about re-birth assert that it does.

There are two grave "scientific" difficulties still to face. It may be argued: *(a)* that the soul is an "epiphenomenon," the "tune" (ἁρμονία) given out by the body, and if so, its superior "divinity" will not protect it from vanishing when the instrument which makes the music is broken; (b) that though the soul actually makes its own body, and perhaps can make a long succession of bodies, it cannot do so without "expending energy"; a time will come when it can no longer make a fresh body, and then it will itself disappear. We must not be driven into misology, antipathy to science, by this apparent clash between science and a faith to which we are attached.

The answer to (a) is that there are good souls and bad ones, and the good soul is "more in tune" than the bad one. But that which can be more or less "in tune" is clearly not itself a "tune." And if the soul were the "tune" resulting from the functioning of the body, its character at any moment would be a resultant of the condition of the body. How then could we have the experience, characteristic of the moral life, of the conflict between the soul with its aspirations and the body with its carnalities? The answer to (b) can only be given as part of a whole theory of the causes of "coming into being and passing out of being." Socrates had been led, early in life, to frame a tentative theory of the matter in consequence of his dissatisfaction with the chaotic state of physical speculation, and in particular with the failure of Anaxagoras to make any satisfactory use of his apparently teleological principle that "mind is the cause of all order and structure." He fell back on the method of "hypothesis."

What distinguishes this method from all others is that it begins by making an undemonstrated "postulate" (ὑπόθεσις). It then proceeds from this point to consider the truth or falsehood of the consequences which follow logically, from the initial postulate; the question of the truth of the postulate is, for the present, left unasked. Socrates' own fundamental unproved postulate has always been that usually, but loosely, called the "theory of Ideas." The postulate is that there really is a single determinate and immutable something (εἶδος, ἰδέα) answering to every significant "general term," and apprehended only by pure thought. The sensible things of which we predicate general terms temporarily "partake in" or "communicate with" the Idea or Form (ἰδέα, εἶδος). When we say that a thing becomes *e.g.,* beautiful, what we mean is that the Form (ἰδέα) "beauty" begins to be "present to" that thing, the thing begins to "partake of" the Form. When we say that a thing ceases to be beautiful, we mean that this relation of "presence," "participation," "communication" (παρουσία, μέθεξις, κοινωνία) is dissolved. This is the true account of the cause of "coming into and passing out of being," and if we accept it, we may proceed to our final argument for immortality.

III. There are Forms which are mutually incompatible, such as warmth and cold. Heat is never cool, and cold is never warm. But there are also certain sensible things of which it is an essential character to "partake of" a given Form. Such things will never admit an incompatible Form. Thus it is an essential character of snow to "partake of" cold. It will never, therefore, "partake of" the Form "heat." Similarly it is an essential character of a soul to be alive, to "partake of" the Form "life." It refuses to "partake of" the Form "death." At the approach of death, the soul must either retire or be annihilated (the metaphors are military). What we have said of its divinity forbids us to think that it is annihilated; we must therefore assume that it "retires" to some other region. The proof of immortality is thus hypothetical; it is shown to be involved as a consequence by the doctrine of Forms. This doctrine has been stated as a fundamental unproved postulate and it is admitted that it demands fuller consideration.

But our enquiry has at least satisfied us that the hope of immor-

[1]Plato's belief in immortality ought never to have been disputed. It is re-affirmed in the most unqualified way in the seventh *Epistle* (335*a–b*) and his very latest work, the Laws (904*c*–905*d*), though the particular arguments of the *Phaedo* do not re-appear there. Aristotle, too, in his early days as a member of the Academy, had taught the doctrine in his *Eudemus* (*Fragmenta,* ed. Rose 37–48). This consideration is really decisive. The characteristic argument of the Law, from the "self-moving" nature of the soul had already been used in the *Phaedrus* (245*c*). *Timaeus* 41*a*, where the final appeal is to the goodness of the Creator, formally applies not to men but to the stars.

tality Is a reasonable one. (To distrust it would be to call the foundation of our whole philosophy into question.) The discourse ends with an imaginative cosmological myth depicting the future of the just and the unjust respectively.

In this statement of the theory of Forms (ἰδέαι, εἴδη) we may note the following points: (1) The doctrine is a piece of "realist" metaphysics. It is assumed that a universally predicated "general term" denotes or stands for an individual reality, apprehensible by thought, though not by sense. (2) There are a plurality of such Forms, standing in various logical relations with one another; whether they constitute a system with a definite structure the *Phaedo* does not tell us. (3) They are at once the objects known in all genuine science and the formal causes of all the temporal processes of the sensible world. (4) The sensible things which have the same names as Forms are said to owe their character to their "participation" (μέθεξις) of the Forms, or, equivalently, to the "presence" (παρουσία) or "communication" of the Forms to them. The precise character of this relation of "participation" is admitted to need further explanation. So far as the language of the *Phaedo* goes, a sensible thing would seem to be thought of as a temporary "complex" or meeting-place of universal characters and as nothing more.

Symposium, **Phaedrus.**—It is by no means clear that these two dialogues are closely connected in point of date, but they may be considered together as both presenting the Forms in a special light, as objects of mystical contemplation and excitant of mystical emotion.

The argument of the *Symposium* cannot be reproduced here as a whole. The immediate object of the dialogue, which professes to record the discourses made in eulogy of Eros by a group of eminent speakers at a banquet in honour of the tragic poet Agathon, in the year 416–5, is to find the highest manifestation of the "Love" which controls the world in the mystic aspiration after union with the eternal and super-cosmic Beauty, to depict Socrates as the type of the aspirant who has reached the goal of "union," and to set in sharp opposition to him the figure of Alcibiades, who has sold his spiritual birthright for the pleasures and ambitions of the world. The centre of philosophical interest lies in the discourse of Socrates, which he professes to have learned a quarter of a century ago from the priestess Diotima of Mantineia.[1]

The main argument may be summarized thus. Eros, *desirous* love, in all its forms, is a reaching out of the soul to a good to which it aspires but has it not yet in possession. The desirous soul is not yet in fruition of good. It is on the way to fruition, just as the "philosopher" is not yet in possession of wisdom but is reaching out after it.

The object which awakens this desirous love in all its forms is Beauty, and Beauty is eternal. In its crudest form, love for a beautiful person is really a passion to beget offspring by that person and so to attain, by the perpetuation of one's stock, the *succedaneum* for immortality which is all the body can achieve. A more spiritual form of the same craving for eternity is the aspiration to win immortal fame by combining with a kindred soul to give birth to sound institutions and rules of life. Still more spiritual is the endeavour, in association with chosen minds, to enrich philosophy and science with "noble discourses and thoughts."

But the goal still lies far ahead. When a man has followed the pilgrimage so far, he "suddenly descries" a Supreme Beauty which is the cause and source of all the beauties he has discerned so far. The true achievement of immortality is finally effected only by union with this. The philosopher's path thus culminates in a supreme "beatific vision." It is clear that the object of this vision, the "Beauty sole and eternal" of the dialogue, means what the *Republic* calls "the Good" or "Form of Good," which by its presence actually causes the goodness of everything else to which the name of good can be given. The Forms are thus thought of as a hierarchy with a supreme Form at their head, though no attempt is made at a rational theory of the way in which the supreme Form unites the rest into the system.

The immediate subject of the *Phaedrus* is the principles of "rhetoric" or, as we should say, prose composition. The *Gorgias* had told us that "rhetoric" as commonly practised is not a matter of rational principles at all, but a mere empirical trick of adapting one's tone to the prejudices of an audience. The *Phaedrus* aims at showing how a really scientific "rhetoric" might be built on the double foundation of logical method and scientific study of human passions. Plato contrives, however, by making a real or supposed "erotic" composition of Lysias the starting-point of his criticisms, to unite with this topic a discussion of the psychology of "love," and this, as in the *Symposium*, leads him to speak of the Forms as the objects of transcendental emotion. The soul is immortal, because it has within itself a native source of spontaneous movement.[2] In its disembodied state it shared the life of the gods and could enjoy the direct contemplation of "unbodied" reality, that is, of the Forms. It has suffered an antenatal fall into an embodied condition in which it is blind to everything which does not come in at the avenues of sense.

Now our senses only suggest few and faint images of such Forms as Justice and Temperance, but they can suggest Beauty in a much more impressive and startling way. To "fall in love" is to come under the influence of such sudden and arresting suggestions of Beauty; the "unreason" and "madness" of the lover mean that he is being awakened to realities which other men ignore. The "wings" of his soul are beginning to grow again, and his experience, rightly used, will be the first step in the soul's return to its high estate. This section of the *Phaedrus* is the *locus classicus* in Plato for the Forms as objects of mystical contemplation.

Republic.—The philosophy pre-supposed in all these dialogues receives its fullest exposition in the *Republic*. Here the immediate problem is strictly ethical. What is Justice (τὸ δίκαιον, δικαιοσύνη)? Can it be shown that Justice is always a boon, injustice a curse, to its possessor, apart from all consideration of consequences in this life or another? That is, is there a rational principle at the root of moral distinctions, and does the principle carry with itself its own intrinsic and indefeasible authority?

Plato's answer is that there is such a principle; each of us, in virtue of his special endowments and aptitudes, has a specific "work" or "vocation"; there is some special contribution which he, and no other, can make most effectively to the life of a rational society. Morality, "Justice," is to discharge that vocation to the height and with a single mind (τὰ αὑτοῦ πράττειν καὶ μὴ πολυπραγμονεῖν). To live thus is to be in spiritual health; to live otherwise is to be spiritually diseased. The obligation is thus intrinsic and absolute. This position has to be made good against the incoherencies of a morality of uncriticized traditional maxims, as well as against the "immoralism" of advanced thought (represented by Thrasymachus in Bk. I., expounded more intelligently by Glaucon in Bk. II.).

This leads us to consider what would be the general type of life in a society where the principle of Justice had power as well as manifest authority, and how it might acquire that power. Hence the need for a sketch (II., III.) of the institutions of the reformed society, and particularly of its moral and religious education. We have next to satisfy ourselves that the principles which regulate the public life of the morally healthy society are also recognizably the principles of the great virtues of private life. For this purpose, we need a psychology of voluntary action which is provided (Bk. IV.) by the doctrine of the "tripartite soul." This is not, indeed, a scientific psychology, but proves adequate to describe the moral life of the ordinary good citizen of such a society as we have conceived. The foundation of all this moral excellence

[1]It is important to remember that Socrates professes to be repeating a lesson he had learned at about the age of *30*. This explains at once the words of *Symposium 210a*, where Diotima expresses uncertainty about Socrates' achievement of the complete "vision." He has his life yet to live; what it will be is not revealed. That the words have gravely been interpreted as a claim on Plato's part to have transcended his Master's limitations is only one example of the perversity with which he has been misunderstood.

[2]This is the argument for immortality to which Plato trusts in the *Laws*. It is not specially mentioned in the *Phaedo*, but this can hardly mean that Plato had not yet discovered it, since it is, in fact, taken from Alcmaeon of Crotona, a medical man of the beginning of the fifth century.

is thus laid in absolute loyalty to a sound moral tradition enforced by education. To ensure that the tradition shall be thoroughly sound, we must stipulate that the authorities who create it do not themselves depend on tradition for their convictions about good and evil; they must not "opine," but know, by personal insight. The statesmen at the head of the community must be "philosophers" as well as kings (Bk. VI.).

But the vision of "the Good" will only dawn on them if they have been prepared for it by an intellectual discipline in hard thinking which leads them through the curriculum of the exact sciences to the critical study of the metaphysical principles involved in science (Bk. VII.). The central books of the *Republic* thus present us with an outline of metaphysics and a philosophy of the sciences. We now turn back to consider the various stages of degeneration through which national and personal character pass when the true moral ideal is allowed to fall more and more completely out of view. As we pass them in review, we are increasingly confirmed in our conviction that, in respect of happiness, the life of regard for right is immeasurably superior to that of sating one's cupidities or gratifying one's personal ambitions (VIII.–IX.), and this conclusion is finally clinched (X.) by re-affirmation of the immortality of the soul. Since the soul is immortal, the issue which hangs upon our choice to live well or ill is one of infinite moment (X.).

The ethical scheme of the *Republic*, like that of the *Gorgias* and *Phaedo*, is dominated by the conception of the "three lives," ascribed by credible tradition to Pythagoras. The "lives" are those of the philosopher, the "man of action" (φιλότιμος), the votary of enjoyment (φιλήδονος, φιλοσώματος, φιλοχρήματος). The end of the first is wisdom, of the second, distinction, of the third, the gratifications of "appetite." Distinction is a worthier end in life than mere satisfaction of appetite; the supremely worthy end is wisdom. In a well-lived life, then, the attainment of wisdom will be the paramount end, and ambition and appetite will only be allowed such gratification as is compatible with loyalty to the pursuit of that paramount end. The psychological foundation of this doctrine is the theory of the "tripartite" soul, expounded fully in *Rep*. IV. Analysis of familiar experience reveals three "elements" (μόρια, εἴδη) or "active principles" within us, (1) considered rational judgment of good (τὸ λογιστικόν); (2) a multitude of clamant appetites for particular gratifications, which may be in violent conflict with our own considered judgment of good (76 ἐπιθυμητικόν); (3) a factor of "spirit," higher "ideal emotion," which manifests itself as "resentment" against both the infringement of our just rights by others and the rebellion of our own appetites against our judgment (τὸ θυμοειδές).

The same distinctions reappear in the structure of society. A society naturally falls into three divisions, the statesmen, who direct the public life, the genera1 civilian population, who carry on the business of providing for material needs, and the executive force (army and police), whose function is, in a rightly ordered society, to give effect to the counsels of the statesmen by repressing attacks from without and rebellion from within.

These three "orders" are thus respectively, the judgment, the "appetitive" and "spirited" elements in the national soul. On this basis, we can proceed to work out an ethical and political theory. In ethics we can define the great leading types of "goodness," the quadrilateral, later known as the four "cardinal" virtues. *Wisdom* is the "excellence" of the "thinking part," clear and assured knowledge of the good; *courage,* the fighting man's virtue, is the "excellence" of the "spirited" part, unswerving loyalty, unshaken by pain, by danger, by the seductions of pleasure, to the rule of life laid down by judgment; *temperance,* the special excellence of the "appetitive" part, is the contented acquiescence of the non-rational elements in the soul in the plan of life prescribed by judgment; *justice* is just the state in which each of the elements is vigorously executing its own function and confining itself within the limits of that function. In the rightly ordered society, the national wisdom has the statesmen as its organ, the national courage the executive force; the national temperance is shown in the loyal contentment of each class in the community with its prescribed place and its duties.

Such a society is a true aristocracy, or rule of the best; "timocracy" the military state, in the better sense of that phrase, arises when the mere "man of action," only competent to fill the part of a good soldier, takes the place which rightly belongs to the thinker as directing statesman; "oligarchy" (*i.e.,* the dominance of "merchant princes," plutocracy), is a further deviation from the ideal, which arises when political power is bestowed on property as such. A still worse system is democracy, in which no attempt is made to connect political power with any special qualifications. Worst of all is tyranny, exercise of irresponsible power by the positively disqualified. the man of "criminal" will. The psychological scheme on which this construction is based is not given by Plato as a piece of strict science. We are carefully warned that exact truth is not to be reached by such an analysis of *prima facie* facts of social life (435 d.), and reminded later on that this apparent triplicity of the soul may prove to be only a temporary consequence of its conjunction with the body (611 *b.*).[1] The "tripartite" psychology, it is meant, enables us to give an account of the moral life, as it actually appears in a good citizen, which will fairly describe the facts. It is good popular psychology, useful for the moralist, but it is no more.

Hence it is improbable that the analysis originated with Plato himself. More probably it was, as the Stoic Poseidonius asserted, a piece of earlier Pythagorean doctrine, as is also suggested by the constant recurrence, throughout the section of the *Republic* in which the analysis is offered, of analogies from the specially Pythagorean science of Harmonics, and by the fact that the same doctrine is taught by the Pythagorean speaker in the *Timaeus.* Plato has, however, worked the theory into his ethics so completely that through him it has actually become a part of the psychology of Thomism, where it has to be squared, not quite satisfactorily, with the radically divergent psychological scheme of Aristotle.

In point of fact, the tripartite *schema* proves inadequate in the *Republic* itself when we advance in Bk. VI. to the consideration of the moral life of the "philosopher-king," whose "virtue" is founded on a personal *knowledge* of good. A higher level of moral goodness is demanded of him than of other citizens even of the ideal Utopia; his courage, for example, is declared to be no mere loyalty to right opinions inculcated by early education, but a high serenity arising from the knowledge of the relative insignificance of a brief individual life in the great universe which lies open to his contemplation. This has an important bearing on the teaching of the *Republic* about the unity of virtue.

In the ideal State itself, virtue does not appear as a complete unity. The leading types of moral excellence receive their several definitions. It is recognized that a special demand may be made on a particular section of the society in respect of a particular virtue of which it is, so to say, the public organ, as the fighting force is of the valour of the whole society. This is because, even in the ideal state, the moral convictions of citizens, other than the men of superlative intelligence and character who become "kings," are not supposed to arise from personal insight. They rest on opinions implanted by education, and are thus taken on trust. The good civilian or soldier, after all, is not living by a knowiedge which is his own. But the rulers, by whose knowledge the rest of the community lives, must not, of course, themselves take their convictions on trust. They must know with a personal knowledge. The foundation of their virtue must be *insight* into a system of absolute values embodied in the very structure of the universe. In virtue of this deeper foundation the virtues in them are, so to say, transubstantiated and can no longer be distinguished from one another. They will fuse in knowledge of the good, as, in the Christian saints, they are fused in knowledge and love of God. It is in this form that the Socratic doctrine, "all virtue is one thing, knowledge" reappears in the *Republic* as the foundation of a society in which mankind has at last '(escaped from its wretchedness," because knowledge rules.

In the *Republic,* as in the *Phaedo,* the Forms (ἰδέαι, εἴδη) ap-

[1]Timaeus is expressly made to teach that the θυμοειδές and ἐπιθυμητικό are a "mortal element" (θνητόν εἶδος) added to the immortal soul to fit it for its habitation in the body (*Tim.* 69c.).

pear in the double character of objects of all genuine science and formal causes of the world of events and processes. It is expressly denied that there can be knowledge, in the proper sense of the word, of the temporal and mutable. In the scheme laid down for the intellectual training of the philosophic rulers, ten years, from the age of 20 to that of 30, are assigned for systematic study of the exact sciences in the order: arithmetic, plane geometry, solid geometry, astronomy and harmonics. Special stress is laid on the points that the object of these studies is not practical applications but the familiarizing of the mind with relations between terms. which can only be apprehended by thought, and that diagrams and models are to be treated merely as incidental aids to imagination. Five years are then further to be given to the still severer study which Plato calls "dialectic," a study which avails itself of no sensible aids to imagination. It proceeds "by means of Forms, through Forms, to Forms" *(511 b.)*. It is, in fact, what we should call a critical metaphysic of the sciences. It examines the ὑποθέσεις or unproved postulates, of the various sciences, and its object is to "destroy" their character as unproved ultimate postulates (τὰς ὑποθέσεις ἀναιροῦσα 533 *c)* by discovering some still more ultimate really self-evident principle (an ἀνυπόθετον, 511 *b)* from which they follow as consequences.

There can be no doubt that this most ultimate principle which is more than a "postulate" means the Good or Form of Good (ἰδέα τἀγαθοῦ) which is said to be the source at once of the reality and the knowability of all that is real and knowable, though it is itself neither knowledge nor being, but transcendent of both (509 *b.)*. On the methodological side the *Republic* thus completes the teaching of the *Phaedo* by providing the answer to the question then left open, when a "postulate" (ὑπόθεσις) may be regarded as finally established. It may be so regarded when it is seen to follow itself from the Good, which is the principle at once of existence and of value.

Socrates is made to confess *(506 d-e)* that he can give no positive account of this supreme metaphysical principle; he can only indicate its nature by an analogy. It is to the whole system of Forms what the sun is to the system of visible things, the source at once of their existence and of the light by which they are apprehended. The Good is thus thought of, to use scholastic terminology, as a transcendent reality which can be apprehended but never fully comprehended. The comparison with the sun and the free employment of the metaphor of "vision" indicate that the thought of the *Republic* is here the same as that of the *Symposium;* the Good is no other than the supreme Beauty which was there said to dawn suddenly upon the pilgrim of "Love" as he draws near to the goal of the journey. R. L. Nettleship rightly says that it holds the place taken in later philosophies by God, when God is thought of as the "Light of the world." But it would be deforming Plato's thought to call the Good of the *Republic* "God." The *Republic* is permeated by religious faith, but Theism as a principle of metaphysical explanation only makes its appearance in Plato's latest dialogues, and there as the solution of a problem which can hardly be said to have been adequately faced in the dialogues so far considered.

How the Good gives systematic structure to the plurality of Forms, the *Republic* does not tell us.

Development of the Doctrine of Forms.—So far we have been presented with a body of thought which has remained recognizably the same without serious modification throughout its various expositions. When we come to the two works which there is reason to regard as directly preluding to the dialogues of Plato's old age, the *Parmenides* and *Theaetetus,* we are struck by a remarkable difference of tone. With Plato, as with Kant, the "middle years" of life were clearly a period of fruitful critical reconstruction. There is an obvious motive for each reconstruction suggested by the *Phaedo* and *Republic* themselves.

The theory there expounded does not allow enough reality to the sensible world. It is quite false to say that even the *Phaedo* teaches an "absolute dualism" of two disconnected worlds, a realm of genuine being which never "appears" and a realm of sensible appearances which are merely unreal. What is true is that both *Phaedo* and *Republic* leave us with an unsolved problem. They tell us that a sensible thing is a complex or meeting-place of a plurality of Forms. What else, or what more, it is they do not tell us. And yet it is clear that a "thing" is not simply a bundle of "universal predicates."

Or, to put the point rather differently, according to the *Phaedo* a thing becomes for a while beautiful because Beauty "becomes present to it." But why does Beauty become present to this particular thing at just this particular moment? Clearly the relation between a "thing" and a Form which has been called "participation" needs further elucidation. Again the simple epistemological formula that knowledge is confined to Forms and their relations, while we can only have shifting "opinions" about temporal facts does less than justice to our scientific knowledge of the natural world; "truths of fact" have not yet come by their rights. Finally, if the Forms constitute a rationally ordered system, there must be definite principles of inter-relation between Forms themselves as well as between Forms and sensible things and these principles demand investigation. (If the Good is what the *Republic* saps it is, not only will things "participate" in Forms; Forms also will "participate" in it.) Here are internal motives for active re-examination of the whole system.

It is clear that there was also an external motive. *Parmenides, Theaetetus, Sophistes,* all reveal a special interest in the Eleatic philosophy, and the first and third show an anxiety on Plato's part to maintain that, in spite of important divergences, he, and not the professed Eleatics, is the true spiritual heir of the great Parmenides. This is easily explained when we remember that Plato was personally a friend of the chief representative of Eleaticism among the Socratic circle, Eucleides of Megara, while Polyxenus of Megara, an associate of Eucleides, was a hostile critic of the doctrine of "participation."[1] The doctrine of Eucleides, like that of Parmenides was that "sensible appearances" are illusions with no reality at all. Against criticism from this quarter, it would be necessary for Plato to show that the *Phaedo* itself does not allow too much reality to the sensible; the attempt to prove this point would inevitably show that it had conceded too little. Continued reflection on the same problem of the worth of propositions about sensible fact leads straight to the discussion of the meaning of the *copula,* and the significance of denial, which is the subject of the *Sophistes.*

Parmenides.—Formally the dialogue conducts to an *impasse.* In its first half the youthful Socrates expounds the doctrine of the "participation" of things in Forms to the Eleatic philosophers, Parmenides and Zeno, as the solution of the problem of the One and the Many. Parmenides raises what appear to be insoluble objections to the conception of "participation," though he admits that "dialectic" would be impossible if the existence of Forms were denied; he hints that the helplessness of Socrates under his criticism arises from insufficient training in logic.

In the second and longer half, Parmenides gives an example of the logical training he recommends. He takes for examination his own thesis, "the One is," and constructs an elaborate set of antinomies after the fashion of Zeno, apparently proving that whether this thesis be affirmed or denied, in either case we are compelled either to affirm simultaneously or to deny simultaneously a series of contradictory predicates, alike of the "One" and of the "Many." The conclusion is patently ironical, and we are left to divine the author's purpose, if we can.

The objections to "participation," which is formulated precisely as in the *Phaedo,* are directed not against the existence of Forms, but against the possibility that sensible things should "participate" in them. From the point of view of this criticism Socrates' error is that he attributes some sort of secondary reality to the sensible, The main arguments are two: *(1)* the doctrine does not really reconcile unity with plurality, since it leads to a *regressus in indefinitum.* It says that the many things which have a common predicate "participate of" or "imitate" a single Form. But the Form itself also admits of the common predicate, and there must therefore be a second Form, "participated" or "imitated" alike by the sensible things and the first Form, and so on endlessly. We could not escape by the suggestion that the Form exists only "in our

[1]Alexander Aphrodis. on Aristot. *Met.* 990 b. 17.

minds," since that would mean that a Form is a thought, and it would follow that "things" are made of thoughts. But if so, either everything thinks, or there are thoughts which do not think, and both alternatives are absurd; (2) it is a still graver difficulty that if there are two realms, a realm of Forms and a realm of sensible things, the relations between Forms must belong to the realm of Forms, those between sensible things to the realm of things. We ourselves belong to the second, and therefore all our knowledge belongs to it too; we know nothing of the true realities, the Forms: if anyone knows them, it is God, but God's knowledge, being knowledge of realities, will not extend to *our* world, the sensible. The purpose of the objections is thus to suggest that the "manifold of sense" has not even a derivative reality; it is mere illusion.

This is precisely the position of the Eleatics and their Megarian continuators. The inference is that Plato is reproducing Megarian criticisms of the doctrine ascribed by himself to Socrates, an inference confirmed by the notice preserved by Alexander of Aphrodisias (on *Met.* ggo b 15) of the "third man" argument of the Megarian Polyxenus against "participation." Plato does not indicate his own opinion of the cogency of the reasoning, which is, in fact, fallacious, as was properly pointed out by Proclus.[1]

The purpose of the antinomies which follow has been very differently understood. In the present writer's opinion, they are deliberate parody, the object being to show that the methods of the Megarian logicians are even more damaging to their own fundamental metaphysical tenet than they are to the doctrine of "participation." Megarian logic is a double-edged weapon, and Plato, if he chooses, can apply it even more dexterously than its inventors.

Theaetetus.—Except for a magnificent interlude in praise of the contemplative life, the dialogue is a straightforward discussion of the question how knowledge should be defined. It naturally ends negatively. None of the proposed definitions will stand examination (the reason is that we are really trying to define truth and truth is an ultimate). But the incidental results of the discussion are of the first importance. We learn *(a)* that knowledge cannot be identified with sensation nor with any formless "simple apprehension"; (b) that pure relativism is as impossible in epistemology as in metaphysics. We have the beginning of a doctrine of the "categories" which is further developed in the *Sophistes.*

The increasing value which Plato is coming to put upon "natural knowledge" is marked by the use of the word δόξα, which in earlier dialogues had commonly meant mere uncertain "opinion" as contrasted with knowledge, in the new sense of "judgment" which it retains in Plato's subsequent work. The most striking negative feature of the *Theaetetus* is that it discusses knowledge at length without making any reference to the Forms and the mythology of "recollection." It remains to this day the best of introductions to the "problem of knowledge."

The main argument may be very briefly summarized thus: I. It seems plausible at first to say that knowledge (ἐπιστήμη) *is* sensation (αἴσθησις). This sounds very much like the proposition of Protagoras, "what seems to me is so to me; what seems to you is so to you." We might base such a thorough-going doctrine of the relativity of all knowledge on a still more ultimate metaphysical theory, if we said—it is implied that Protagoras himself said nothing of the kind—that, within us and without us, the only reality is motion. "Organ" and "environment" are both motions; when these motions impinge on one another, they give rise to the twin-product, felt sensation–sensible quality.

Both the sensation and the quality "sensed" will therefore be affected by any difference in the pair of slower "motions" which cause them (the "organ" and its "environment"), and each percipient, therefore, is confined to his strictly private world, which exists only "for" him. There is no "common" perceived world, and therefore no standard of truth or reality other than the individual percipient. A teacher does not aim, any more than a physician, at convincing his pupil of the "falsity" of his judgments, but at giving him "useful" or healthy convictions in place of harmful or diseased convictions.

[1]For a detailed discussion of it, *see A. E.* Taylor, *Parmenides, Zeno and Socrates* (Transactions of Aristotelian Society, N. S. xvi. 234 ff.)

The full discussicn of such a theory would demand a thorough study both of the Heracleitean philosophy, which says that there is nothing but motion, and the Eleatic philosophy which says that motion is an illusion. But for our immediate purpose, a more summary argument is sufficient. It is certain that even the relativists, who hold that each man is the one infallible "measure" of his *present* perceptions, do not hold that he is the only and inerrant measure of his *future* sensations. *A* physician can often judge better than his patient whether the patient is going to have, *e.g.*, the sensations of an ague. A man's own opinion whether a certain course will be expedient or good for him is often far from being the soundest. We must distinguish carefully between what the mind perceives "through bodily organs"—the data of sense—and the things she apprehends "by herself" (αὐτὴ 61' αὑτῆς) without "organs." These latter include number, sameness, difference, likeness, unlikeness, being, good, bad, right, wrong, *i.e.*, the great universal "categories" of fact and value. These are apprehended not by sense, but by thinking, and as they are the formal element in all knowledge, knowledge must be found not in our sensations, but in "the judgment (συλλογισμός) of the mind upon" them.

II. Is knowledge, then, "true judgment"? The statement implies that we know what we mean by "false" judgment, error. But is this the case? Error must not be confused with mere false recognition, misinterpretation of present sensation, since there are purely intellectual errors, and we find ourselves unable to explain the nature of this kind of error. And, in fact, it is clear that persuasive rhetoric may produce in the hearer judgments which are true, but have no claim to be called knowledge. III. Finally, is knowledge "true judgment accompanied by discourse (μετὰ λόγου), true judgment for which we can give grounds"? This would distinguish knowledge from "simple apprehension," and would harmonize with the theory of those who hold that knowledge is always of complexes, never of their simple constituents. But this doctrine has difficulties of its own, and, in any case, if we say that knowledge is true judgment + "discourse," the "discourse" meant must be a statement of the logical *differentia* of the object of which I have knowledge. The proposed definition therefore amounts to saying that knowledge is true judgment about an object + *knowledge* of the *differentia* of that object, and so is circular.

LATER DIALOGUES

Sophistes and Politicus.——Formally these two important dialogues are closely connected. They are made to appear as a sequel to the *Theaetetus*, and a further connection is afforded between them by the fact that both are ostensibly concerned with a problem of definition, which is treated by the characteristic Platonic method of repeatedly subdividing a *genus* until we obtain the *definiendum* as a sub-species. The real purpose of the *Sophistes* is logical or metaphysical; it aims at explaining the true nature of negative predication and so disposing of the Eleatic thesis that the temporal and sensible realm, containing, as it does, a negative moment, must be mere unreal illusion. The object of the *Politicus* is to consider the respective merits of two contrasted forms of government, "personal rule" and "constitutionalism," and to recommend the second, particularly in the form of "limited monarchy," as most suitable to the actual condition of mankind. The *Sophistes* lays the foundations of all subsequent logic, the *Politicus* those of all "constitutionalism."

A more temporary purpose in both dialogues is to illustrate the value of careful classification as a basis for scientific definition. In both dialogues Socrates is almost silent; his place as chief speaker is taken by an unnamed and very unorthodox Eleatic, who seems to be a purely fictitious character. Plato is, in fact, claiming that he, and not the formal logicians of Megara, is the continuator of Parmenides, much as Aristotle in his polemic against Xenocrates claims to be the true successor of Plato.

In the *Sophistes* the main discussion is led up to through a definition of the "sophist" as an "illusionist," a person who, by abuse of logic, produces the illusion, or false appearance, that nature and human life are alike riddled by insoluble contradictions. (This shows that the persons aimed at under the name "sophist" are the

Megarian controversialists who make an illegitimate use of the dialectic of Zeno and Socrates.) Now the "sophist" himself would retort that this definition is senseless, for there can be no such thing as a false statement or a false impression. For the false means "what is not," and "what is not" is nothing at all, and can neither be uttered nor thought. To refute him we need to correct the fundamental thesis of so venerable a thinker as Parmenides.

We must either admit that there can be no false statements, or we must be prepared to maintain that "what is not, in some sense also is," and "what is, in some sense is not" (*i.e.,* we must explain what is the meaning of a significant negative proposition). In our theory of "being" we have to meet at once Parmenides and two different types of pluralist opponents of Parmenides, (a) the corporealists who say that the real, "what is," is just visible and tangible body, and (b) certain "friends of Forms" who maintain that the real is a multitude of incorporeal Forms, denying that sense-perception gives us any apprehension of it. The corporealist is sufficiently refuted by the consideration that he himself cannot deny the reality of "force" (δύναμις) and that force is not a body. The incorporealist "friends of Forms" cannot be met in this way. They regard force, or activity itself as belonging to the unreal realm of "becoming." We meet them by urging that knowing is itself an activity and that we cannot deny intelligence and knowledge to the supreme reality. This means that it has a "soul" and is alive. But if life is real, movement and repose from movement must be real too.[1]

This leaves us free to attack the Parmenidean Monism itself. That is refuted by drawing the distinction between absolute and relative "non-being." A significant denial, *A* is not B, does not mean that *A* is nothing, but that *A* is other than B. Every one of the great categorical features of reality is other than every other, and the true business of "dialectic" is to study the various possible combinations of these universal "categories." The dialogue mentions five of them, being, identity, difference, motion and rest. It is not said that this is a complete list of "categories," though it was treated as such by the Neo-Platonists.

The important result is thus that we have learned to think of Forms themselves as an inter-related system, with relations of compatibility and incompatibility among themselves. Negation is a moment in the system of intelligible reality, and therefore its presence in the sensible realm does not stamp that realm as illusion. This is the ontological position which interests Plato; the recognition of the function of the logical copula is a consequence.

The Politicus has as its main result the conclusion that government by the personal direction of a benevolent "dictator" is not suitable to the conditions of human life, where the direction is necessarily that of a fallible man, not of a god. In an actual human society, the surrogate for personal direction by a god is the impersonal supremacy of inviolable law. Where there is such a recognized sovereign law, monarchy is the most satisfactory type of constitution, democracy the least satisfactory, but where there is no "fundamental law," this situation is inverted. A "sovereign" democracy is preferable to an irresponsible autocrat. The dialogue is rich in thoughts which have passed into the substance of Aristotle's ethics and politics. Aristotle took directly from it the conception of "politics" as the "architectonic" practical science to which all others are subordinate; the formula of the "right mean" comes from it together with the Philebus.

Philebus.—The subject of the dialogue is a strictly ethical one, and this, no doubt, explains why it is the only dialogue after the *Theaetetus* in which Socrates is the principal speaker. The issue propounded is the question whether the "good" is pleasurable feeling or whether it is thought, the exercise of intelligence.

Comparison with the notices of Aristotle in the *Nicomachean* Ethics shows that this was the subject of a sharp division in the Academy, the Hedonist party being led by the mathematician and astronomer Eudoxus, the anti-Hedonists by Speusippus. Under the guidance of Socrates the question is narrowed down to a consideration of the good for *man* in particular, and a mediating conclusion is reached. The best life for man contains both elements, but intelligence is the "predominant partner."

All forms of knowledge find a place in it, but only those pleasures which are compatible with wisdom and virtue, *i.e.,* those which are "unmixed," not preceded by a sense of want or craving, and those of the "mixed" pleasures, the satisfactions of appetite, which are innocent and moderate. The Philebus contains Plato's ripest moral psychology; it is the immediate source of the famous "doctrine of the Mean."

Philosophically the most important feature of the dialogue is a classification adopted with a view to determining the formal character of the two claimants to recognition as the good. All components of the actual belong to one of four classes, (1) the infinite or unbounded (ἄπειρον), (2) the limit (πέρας), (3) the mixture or combination of (1) and (2), (4) the cause of the mixture. ([1] and [2] are just the two fundamental "opposites" of Pythagoreanism.) All the good things of life belong to (3), that is, they are produced by the introduction of definite "limit" or "ratio" into an indeterminate "continuum." (This is precisely the doctrine of the "Mean.") The establishment of such a "ratio" is a *γένεσις εἰς οὐσίαν,* a process resulting in a stable "being," and it is indicated that the cause or agent in such a process is always intelligence, human or divine.

There has been much discussion of the question in which of these "classes" the Forms should be placed. The only tenable alternatives would be to put them into the class of "limit" or into that of the "mixture" (a view suggested both by the teaching of the Sophistes and by Aristotle's express statement that Plato distinguished two constituents within the Form and advocated ably by Dr. H. Jackson). The truth seems to be that the particular classification in the *Philebus* is devised for a special purpose, and that it is not intended to apply to anything but the things and processes of the sensible realm. In that case, though there is a close correspondence between what the *Philebus* teaches about "stable being" in the sensible realm and what, as we know from Aristotle, Plato taught about the Forms, it will be a mistake to look for any actual exposition of the metaphysic of the Forms in the *Philebus.*

Timaeus.—The Timaeus is an exposition of cosmology, physics and biology put into the mouth of the astronomer Timaeus of Locri. Though Plato avoids expressly describing the speaker as a Pythagorean, his doctrine is revealed by attentive analysis as an attempt to combine the mathematics and astronomy of the Pythagorean~with the biology of Empedocles, the real founder of Sicilian medicine. The discussion is introduced by the famous narrative of the gallantry of the prehistoric Athenians who defeated the kings of the imaginary Atlantis in their ambitious attempt to become masters of the world. The story was to have been told more in detail in the unfinished Critias.

Timaeus opens his discussion by drawing a sharp distinction between eternal being and temporal becoming, and insisting on the point that it is only of the former that we can have exact and final knowledge. All accounts of the temporal can be only tentative and liable to repeated revision. Cosmology, then, at best, is not exact science. The visible world, being mutable and temporal, is a copy of a model which is eternal, and the copy is the work of God. The reason why there is a copy at all is the unceasingly active and generous goodness of God. (In the sequel Timaeus speaks of the Forms which God had before Him as His model in much the same language as the Phaedo, except that he uses the Pythagorean word "imitation," not "participation," to describe the relation of sensible things to Forms.)

The world, then, had a beginning. (The Academic tradition from the first was that this is not to be understood literally; Aristotle

[1]It is still a much agitated question who are the "logical atomists" described in the Sophistes as the "friends of Forms." The view that they are adherents of the philosophy of the Phaedo and Republic is deservedly dead. They are still often supposed to be Megarians, but this seems inconsistent with the way in which they are carefully distinguished from the followers of Parmenides as belonging to "the other side" at 245 *e.* Proclus (in Parm. 562 St.) says positively, as though it were the only view known to him, that they are Italian Pythagoreans, and this is probably correct, since the Eleatic of the dialogue refers to them as persons with whom he is "familiar." It is important to remark that the identification of "being" with "force" is given merely as a consequence which would follow from, and contradict, the corporealist "hypothesis." The implication of the passage is rather that the identification is false than that it is true.

insists on taking it literally.) Cod first formedits soul out of three constituents, Identity, Difference, Being. Its body was made later from the four Empedoclean "elements." The world-soul was placed in the circles of the sidereal Equator and Ecliptic, the latter being split into seven lesser circles, those of the planets, and the two were animated with movements in opposite senses. Subsequently were formed the various subordinate gods and the souls of human beings, that is the "immortal" and rational element in the human soul, which come straight from the hands of God Himself. The formation of the human body and of the two lower "mortal" components of the human soul was effected through the intermediacy of the "created gods" (*i.e.,* the stars). The most important question of detail arising from this part of the dialogue is that debated between Boeckh and Grote. Does Timaeus ascribe a motion to the earth? The restoration of the correct text at 40*c*[1], proves definitely that he does, but it is not a diurnal revolution, as Grote supposed; it must be rectilinear displacement of unknown period. The contact is made between Pythagorean geometry and the Empedoclean biology which will be needed for the physiology and medicine of the dialogue by a mathematical construction of the "elements."

Starting with two primitive triangles, the isosceles right-angled, and the right-angled scalene in which the hypotenuse is double the shortest side, Timaeus constructs four of the regular solids, cube, tetrahedron, octahedron, icosahedron, and these are assumed to be the shapes of the corpuscles of earth, fire, air, water. These four in their turn are the immediate constituents of all organic and inorganic compounds.

The important features of the dialogue are not the particular tentative scientific hypotheses but its leading methodological principles. We should note the introduction of God as the intelligent efficient cause of all order and structure in the world of "becoming," which preludes to the natural theology of the *Laws,* and the emphatic recognition of the essentially tentative, and therefore progressive, character of natural science. It is also noticeable that though Plato's scientific ideal is a mathematical corpuscular physics—his influence in creating this ideal has been much more important than that of the ancient Atomists—he constructs his physical world without "matter" as a metaphysical "substrate." The place of matter is taken in his analysis, as Aristotle complained, by *χώρα,* space, as in the *Principia* of Descartes, a point of view to which physical speculation seems to be returning. He analyses the "passage of Nature" into three factors: *ὄν* ("being": a Form), *χώρα* (space), *γένεσις* (happening), much as Whitehead analyses it into "objects," "events" and the "ingredience of object into event."

It is a fundamental point that the presence of *χώρα* as a factor makes it necessary to recognise over and above "God" or "mind" a subordinate element of *ἀνάγκη,* "necessity" in events. Since necessity is also called the "errant" cause, *πλανωμένη αἰτία* (with an allusion to the name of the "planets" or "tramp-stars") the word clearly does not mean "conformity to law." It is rather a name for the fact that there is always in the actual an irreducible remainder of "brute" datum, "conjunctions" in Hume's phrase, which we cannot rationalize completely into intelligible "connections." Thus *ἀνάγκη* is not a rebel or evil principle in the constitution of things; its function is everywhere to be instrumental to the intelligent and beneficent purpose of "mind" or God. There are many facts which we have to be content to accept simply as facts without seeing their "reason why." We do not know and may never know, why it is "best" that they should be as they are—*e.g.,* why "it is best" that we should live on a moving earth—but we may be sure that, since it is the fact. it is in some way best that it should be so. This seems to be what is meant by the statement that God or "mind" (*νοῦς*) persuades *ἀνάγκη.* It is the expression of a rational faith in Providence and the supremacy of the moral order. The details of the cosmology, physiology and psycho-physics of the dialogue are of great importance for the history of science, but metaphysically of secondary interest.

Laws and Epinomis.—The Laws, Plato's longest, is also his most intensely practical work, and contains his ripest utterances on ethics, education and jurisprudence, as well as his one entirely non-mythical exposition of theology. The immediate object is to meet a practical need by providing a model of constitution-making and legislation for members of the Academy who may be called on to assist as advisers in the actual founding or re-founding of cities.

Plato's attempt to do work of this kind himself, at Syracuse, had borne no immediate fruit, but had given the Academy a recognized standing as a school of scientific politics and jurisprudence. The work of constitution-making and legislation was going on in many quarters at the end of his life, and his experience might be made fruitful in sage counsels to younger men. The practical character of the subject explains some novelties in the outward form of the work. As the dialogue is assumed to be dealing with the actual present, Socrates has disappeared and his place is taken by an unnamed Athenian who is, to all intents, Plato himself.

The scene is laid in Crete; the imagined situation is that the Cretans are about to found a settlement on the site of a long deserted city. The chief Commissioner for the project is walking out to inspect the proposed site with a Spartan friend, when they fall in with the Athenian, and being favourably impressed by his conversation invite him to join them as an "expert adviser."

The problem thus differs from that of the Republic; the question is not the construction of an ideal Utopia, but the framing of a constitution and code which might be successfully adopted by a society of average Greeks in the middle of the fourth century. Hence the demands made on average human nature, though exacting, are not pitched too high; the communion of the *Republic* is dropped. And for the same reason it is assumed all through that the regulations are carefully adapted to the particular economic and geographical conditions, though it is said that these conditions will not really suit any actual Cretan locality. If so, we must suppose that Plato, under a transparent disguise, is contemplating the actual conditions in quarters from which the Academy was more likely to receive appeals for help.

The special purpose of the work also explains why purely speculative philosophy and science are excluded from its purview. The metaphysical interest is introduced only so far as to provide a basis for a moral theology; the one matter of first-rate scientific importance touched on is the diurnal motion of the earth, and this is only hinted in connection with the practical problem of the construction of the Calendar. In compensation, the Laws is exceptionally rich in political and juristic wisdom, and appears, indirectly, through its influence on the law of the Hellenistic age, to have left its mark on the great system of Roman jurisprudence.

It is impossible to do more than to call attention to a few of the striking features of this great work. The ethical ideal is still that familiar from earlier dialogues. It is interesting that the demand is expressly made that all "unnatural" vices shall be completely suppressed, and that the rule of sexual life is to be monogamous marriage with strict chastity, outside the limits of marriage, for both sexes. In politics, Plato declares himself definitely in favour of a "mixed" constitution; a good government demands a balance between two principles, *ἐλευθερία,* "popular control," and *μοναρχία,* "personal authority." Persia is an illustration of the mischief of unqualified autocracy, Athens of the evils which come from elimination of the "authoritarian" principle, and considerable care is taken in the suggested system of magis-

[1]The words used of the earth *ἰλλομένην τὴν περὶ τὸν διὰ παντὸς πόλον τεταμένον* admit of only one rendering "going up and down on the path about the axis of the universe." Timaeus thinks of the earth as placed about the axis of the whole universe and being displaced to North and South by a sliding movement along this axis. Aristotle was then exactly right in saying that Timaeus teaches that the earth "is at the centre" and moves there *(de Coelo* 293 *b*30) and distinguishing this view carefully from that which he ascribes to the Pythagoreans, "that the earth revolves as a planet about the centre." It is this second view which is implied in the language of *Laws* 822*a* and *Epinomis* 987*b* and expressly attributed to Plato "in his later years" by Theophrastus ap. Plutarch *Quaest. Plat.* 1006*c.* There is no reason to suppose that Plato ever himself held the curious view he has ascribed to his fifth century Pythagorean. He has his own reasons for insisting as strongly as he does on the provisional character of all the science of the dialogue.

tracies to secure both genuine "popular representation" and the proper regard for personal qualifications. The basis of society is to be agriculture, not commerce; the citizens are to be "peasant proprietors'—communism is regretfully abandoned as impracticable in a society of ordinary human beings. But the patrimony of each household is to be strictly inalienable, and differences in "personal" property are to be kept within strict bounds by what amounts to a super-tax of 100% on incomes beyond the statutory limits. Education, as in the *Republic,* is regarded as the most important of all the functions of government; it is placed under the control of a minister who is the "premier." As far as possible, the distinction between the sexes is, as in the Republic, to be treated as irrelevant to the educational programme.

The most striking features of the scheme are the careful attention paid to the problems of the physical training of children in their earliest infancy, and the right utilization of the child's instinct for play, and the demand. made now for the first time, that in adolescence, the young shall be taught in institutions where expert instruction in all the various subjects is co-ordinated. It is from this proposal that the "grammar school," or secondary school, has taken its origin. Though we hear no more of "philosopher-kings" the demand is still made that the members of the "Nocturnal Council." the supreme Council of the State, which is always in permanent session, and exercises a general control over administration, shall be thoroughly trained, not only in the exact sciences, but in the supreme science, which "sees the One in the Many and the Many in the One;" that is, they are to be "dialecticians."

The work is full of suggestions for the practical application of science, such, for example, as that of the necessity of strictly standardizing all weights and measures, or that of basing the Calendar on a solar year (of 365 days). The object of the apparently arbitrary selection of the number of patrimonies and the scheme of sub-division of the whole society into smaller groups appears to be the practical one of making it easy to determine exactly what quotum each subdivision may justly be called on to contribute to the revenue or the defences.

At least two fundamental improvements are made on the Attic jurisprudence which Plato has adopted as the foundation of his own code. One great blot on the Heliastic system is removed by the regulations which ensure that trials for serious offences shall take place before a court which contains highly qualified magistrates, and shall proceed with due deliberation, and that there shall be provision for appeals from the primary tribunal to a "Court of Cassation." It is even more important, perhaps, that Laws IX. by drawing a clear distinction between βλάβη, detriment, and ἀδικία, infringement of rights, lays the foundation for the discrimination between civil and criminal actions at law.

An incidental passage in the Laws (822 a-h) and another in the *Epinomis* (987*b*) definitely show that Theophrastus was right in crediting Plato with belief in the earth's motion. In the Laws it is said that the real orbit of each planet is a single closed curve, in the *Epinomis* the view that the "circle of the stars" communicates its motion to those of the planets is called that of men "who know but little of the subject." The allusion is to the famous theory of the celestial motions put forward by Plato's friend and associate, the great mathematician Eudoxus.

According to this, the first great "geocentric" theory in scientific astronomy, the movements of each planet can be analyzed into a combination of circular revolutions, the unmoved earth being taken as the common centre of all. What Plato asserts is that each planet has only one "proper" revolution, the remaining revolutions are apparent, not real. The implication is that these apparent revolutions of the planet must be real motions of the earth from which we make our observations. The earth is thus a planet, though not a satellite of the sun. The language of the *Epinomis*—which may bc safely regarded as at least true to Plato's thought—definitely makes the sun, itself, one of the planets. We have, therefore, to think of the earth as also a planet revolving with the rest round an unseen centre. We may infer from the words of Theophrastus that Plato, like some of the Pythagoreans, held that there is a luminary, the "central fire," at this centre. The period of the earth's revolution would certainly be taken to be the natural day, so that the motion ascribed to the earth is equivalent to the diurnal rotation, though from Plato's point of view, it is not a rotation on an axis, but a revolution round a centre. It follows that the alternation of day and night is no longer accounted for by a rotation of the "heaven of the fixed stars." This "outermost circle" is still credited in the *Epinomis* with a revolution in the sense E. to W., but its period is not specified. We need not suppose either that Plato could have specified the period or that he used it to explain any special appearances.[1]

What is to Plato's credit is that he has the insight to see that, with all its attractions, the scheme of Eudoxus starts from a wrong pre-supposition, a stationary earth.

In Laws X. Plato, for a practical purpose, creates natural theology. There are three false beliefs which are fatal to moral character, atheism, denial of the moral government of the world, the belief that divine judgment can be bought off by offerings. Plato holds that he can disprove them all. The refutation of atheism turns on the identification of the soul with the "movement which can move itseif," already used in the *Phaedrus.* All motion is either communicated from without or self-initiated, and the ultimate source of all communicated motion must be self-initiated motion. The only thing which can move itself is a soul. It follows that all motion throughout the universe is ultimately initiated by souls. It is then inferred from the regular character of the great cosmic motions and their systematic unity, that the souls which originate them form a hierarchy with a "best soul," God, at their head. Disorderly and irregular motions are equally due to souls, but to bad and disordered souls, and since there are disorderly motions, it is inferred that the "best soul" cannot be the only soul.

There is no suggestion that there is a "worst soul," a "devil" or "evil world-soul"; all that is said is that there *must* be one soul which is not the best, and may be more. This is Plato's way of excluding Pantheism, as incompatible with the reality of evil. The argument thus establishes at once the immortality of the soul and the existence of God. The other two heresies can now be disposed of. It is inconsistent with the goodness of the best soul to be indifferent to our conduct, and still more so to be venal. The moral government of the world is, in fact, assured by the establishment of the single principle that every soul gravitates into the society of its likes, and consequently "does and has done to it what it befits such a soul to do and have done to it." Plato thus becomes definitely the originator of the view, that there are certain theological truths which can be strictly demonstrated by reason.

It is these demonstrable truths which are subsequently named by Varro "natural" or "philosophical" theology in contradistinction to the "poetical theology." the myths related by the poets, and the "civil theology," the ritual cultus instituted by politicians. From Varro the distinction of three theologies passed to St. Augustine, and thus in the end became the foundation of the scholastic distinction between natural theology, those truths about God which can be ascertained independently of any specific revelation, and revealed theology, the further truths which are only made accessible by the Christian revelation. Since Plato's object in demonstrating his three propositions is an ethical one, he goes on to enact that the maintenance of any of them shall be a grave crime to be visited by the State with penalties ranging from a minimum of five years' solitary confinement, and with death on a second conviction. Plato is thus the inventor, so far as European society is concerned, of the proposal to make an official creed for the State and to treat dissent from it as criminal, an innovation foreign to the spirit of the Hellenic cities, in which religion was a matter not of beliefs but of cultures. Plato's last word, then, on the problem how the sensible comes to "partake" of Form is that it does so through the agency of divine goodness and wisdom. God moulds the sensible upon the pattern of the' intelligible. The obvious question, how God, who is a "soul"

[1]It has nothing to do with "precession of the equinoxes," being in the wrong sense for that purpose.

not a Form, is related to "the Good" which is the supreme Form never receives discussion or solution. To answer it was to be the main business of Plotinus.

PLATONISM AFTER PLATO

Aristotle's Account of Platonism. — Since Plato refused to write any formal exposition of his own metaphysic, our knowledge of its final shape has to be derived from the statements of Aristotle, which are confirmed by scanty remains of the earliest Platonists preserved in the Neo-Platonist commentaries on Aristotle. These statements can, unfortunately, only be interpreted conjecturally. According to Aristotle (Metaphysics, *A* 987, *b* 18–25) Plato's doctrine of Forms was, in its general character, not very different from Pythagoreanism, the Forms being actually called Numbers. The two points on which Aristotle regards Plato as disagreeing with the Pythagoreans are, that (1) whereas the Pythagoreans said that numbers have as their constituents, the unlimited (ἄπειρον) and the limit (πέρας), Plato taught that the forms have as constituents "the One" and the "great and small"; (2) the Pythagoreans had said that things are numbers, but Plato intercalated between his Forms (or Numbers) and sensible things an intermediate class of "mathematicals." It is curious, that in connection with the former difference Aristotle dwells mainly on the substitution of the "duality of the great-and-small" for the "unlimited," not on the much more significant point that the "One," which the Pythagoreans regarded as the simplest complex of unlimited and limit, is treated by Plato as itself the element of limit. He further adds that the "great-and-small" is, in his own technical terminology, the "matter," the One, the formal constituent, in a Number.

If we could be sure how much of the polemic against Number-Forms in *Metaphysics* M-N is aimed directly at Plato, we might add considerably to this bald statement of his doctrine, but unluckily it is certain that much of the polemic is concerned with the teaching of Speusippus and Xenocrates. It is not safe, therefore, to ascribe to Plato statements other than those with which Aristotle explicitly credits him. We have then to interpret, if we can, two main statements: (1) the statement that the Forms are Numbers; (2) the statement that the constituents of a Number are the "great-and-small" and "the One."

Light is thrown on the first statement if we recall the corpuscular physics of the Tirnaeus and the "mixture" of the *Philebus.* In the *Timaeus,* in particular, the behaviour of bodies is explained by the geometrical structure of their corpuscles, and the corpuscles themselves, are analysed into complexes built up out of two types of elementary triangle, which are the simplest "elements" of the narrative of Timaeus. Now a triangle, being determined in everything but "absolute magnitude" by the numbers which express the ratio of its sides, may be regarded as a triplet of numbers.[1] If we remember then, that the triangles determine the character of bodies, and are, themselves, determined by numbers, we may see why the ultimate Forms on which the character of Nature depends should be said to be Numbers, and also what is meant by the "mathematicals" intermediate between the Forms and sensible things. According to Aristotle, these "mathematicals" differ from Forms because they are many, whereas the Form is one, from sensible things in being unchanging. This is exactly how the geometer's figure differs at once from the type it embodies and from a visible thing. There is, for example, only one type of triangle whose sides have the ratios 3:4:5, but there may be as many "pure" instances of the type as there are triplets of numbers exhibiting these ratios; and again, the geometrical triangles which are such "pure" instances of the type, unlike sensible three-sided figures, embody the type exactly and unchangingly. A mathematical physicist may thus readily be led to what seems to be Plato's view that the relations of numbers are the key to the whole mystery of nature, as is actually said in the *Epinomis* (ggoe).

We can now, perhaps, see the motive for the further departure from Pythagoreanism. It is clear that the Pythagorean parallelism between geometry and arithmetic rested upon the thought that the "point" is to spatial magnitude what the number 1 is to number. Numbers were thought of as collections of units, and volumes, as, in like fashion, collections of points; that is, the point was conceived as a minimum volume. As the criticisms of Zeno showed, this conception was fatal to the specially Pythagorean science of geometry itself, since it makes it impossible to assert the continuity of spatial magnitude. (This, no doubt, is why Plato, as Aristotle tells us, rejected the notion of a point as a fiction.)

There is also a difficulty about the notion of a number as a "collection of units," which must have been forced on Plato's attention by the interest in "irrationals" which is shown by repeated allusions in the dialogues, as well as by the later anecdotes which represent him as busied with the problem of "doubling the cube" or finding "two mean proportionals" "'Irrational" square and cube roots cannot possibly be reached by any process of forming "collections of units," and yet it is a problem in mathematics to determine them, and their determination is required for physics (*Epin.* 990*c*–991b).

This is sufficient to explain why it is necessary to regard the numbers which are the physicist's determinants as themselves determinations of a continuum (a "great and small"), by a "limit" and why, at the same time "the One" can no longer be regarded as a "blend" of "unlimited" and "limit" but must be, itself, the factor of "limit." (If it were "the first result" of the blending, it would re-appear in all the further "blends"; all numbers would be "collections of one" and there would be no place for the "irrationals.") There is no doubt that Plato's thought proceeded on these general lines. Aristotle tells us that he said that numbers are not really "addible"(οὐ συμβλητοὺς εἶναι robs ἀριθμοὺς πρὸς ἀλλήλους, Met M 1083 a 34), that is that the integer-series is not really made by successive additions of 1[2], and the *Epinomis* (*loc. cit.*) is emphatic on the point that contrary to the accepted opinion, "surds" are just as much numbers as integers. The underlying thought is that numbers are to be thought of as generated in a way which will permit the inclusion of rationals and irrationals in the same series. In point of fact there are logical difficulties which make it impossible to solve the problem precisely on these lines. It is true that mathematics requires a sound logical theory of irrational numbers, and again, that an integer is not a "collection of units"; it is not true that rational integers and "real numbers" form a single series.

The Platonic number-theory was inspired by thoughts which have since borne fruit abundantly, but it was itself premature. We learn partly from Aristotle, partly from notices preserved by his commentators, that in the derivation of the integer-series, even numbers were supposed to be generated by the "dyad" which "doubles" whatever it "lays hold of," odd numbers in some way by "the One" which "limits" (ὁρίζει) or "equalises" (ἰσάζει), but the interpretation of these statements is, at best, conjectural. In the statement about the "dyad" there seems to be some confusion between the number 2 and the "indeterminate dyad," another name for the continuum also called the "great-and-small," and it is not clear whether this confusion was inherent in the theory itself, or has been caused by Aristotle's misapprehension.

Nor, again, is it at all certain exactly what is meant by the operation of "equalising" ascribed to the One." It would be improper here to propound conjectures which our space will not allow us to discuss.

The Academy After **Plato.**—Though Plato's Academy produced only one later philosopher of the first order, it continued to exist as a corporate body down to the year 529 A.D. when the Emperor Justinian, in his zeal for Christian orthodoxy, closed the

[1]Thus the two fundamental triangles of Timaeus may be called the triplets $(1,1,\sqrt{2})$ $(1,\sqrt{3},2)$ respectively.

[2]2, for example, does not "contain" two 1's, 2 is not "1 and another 1"; it is "the integer after 1."

[3]A full collection and examination of all the available evidence is given by L. Robin in his *Théorie platonicienne des Idées et des Nombres d'après Aristote* (1908), and an admirable exposition of the significance of the problem of the irrational for Plato's philosophy by G. Milhaud in *Les philosophes-géomètres de la Grèce, Platon et ses prédécesseurs* (1900). For a recent conjectural interpretation *see* A. E. Taylor's essay, "Forms and Numbers," in Mind, N.S. 140, 141.

schools of Athens and appropriated their emoluments. Plato's greatest scholar, Aristotle, finally went his own way and organised a school of his own in the Lyceum, claiming that he was preserving the essential spirit of Platonism, while rejecting the difficult doctrine of the Forms; the place of official head of the society was filled first by Speusippus, Plato's nephew (347–339 B.C.), then by Xenocrates (339–314 B.C.). Under Arcesilaus (276–241 B.C.) the Academy began its long-continued polemic against the sensationalist dogmatism of the Stoics, which accounts both for the tradition of later antiquity which dates the rise of a "New" (some said "Middle") and purely sceptical "Academy" from Arcesilaus, and for the eighteenth-century associations of the phrase "academic philosophy."

In the first century B.C. the most interesting episode in the history of the school is the quarrel between its President, Philo of Larissa and his scholar Antiochus of Ascalon, of which Cicero's *Academica* is the literary record. Antiochus, who had embraced Stoic tenets, alleged that Plato had really held views indistinguishable from those of Zeno of Cittium, and that Arcesilaus had corrupted the doctrine of the Academy in a sceptical sense. Philo denied this. The gradual *rapprochement* between Stoicism and the Academy is illustrated from the other side by the work of Stoic scholars like Panaetius of Rhodes, and Poseidonius of Apamea, who commented on Platonic dialogues and modified the doctrines of their school in a Platonic sense.

The history of the Academy after Philo is very obscure, but early in our era we meet with a popular literary Platonism of which the writings of Plutarch are the best example. This popular Platonism insists on the value of religion, in opposition to Epicureanism, and on the freedom of the will and the reality of human initiative, in opposition to the Stoic determinism; a further characteristic feature, wholly incompatible with the genuine doctrine of Plato, is the notion that matter is inherently evil and the source of moral evil.

Genuine Platonism was revived in the third century A.D. at Rome, and independently of the Academy, by Plotinus. His Neo-Platonism (*q.v.*) represents a real effort to do justice to the whole thought of Plato, but there are two sides of it which inevitably, in the changed conditions, fell into the background, the mathematical physics and the politics. The third century A.D. had no understanding for the first, and the Roman Empire under a succession of military chiefs no place for the second. The doctrine of Plotinus is Platonism seen through the personal temperament of a saintly mystic, and with the *Symposium* and the teaching of the *Republic* about the "Form of Good" always in the foreground. Plotinus lived in an atmosphere too pure for sectarian polemic, but in the hands of his successors, Neo-Platonism was developed in conscious opposition to Christianity. Porphyry, his disciple and biographer, was the most formidable of the anti-Christian controversialists; in the next century, "Platonists" were among the allies and counsellors of the Emperor Julian in his ill-advised attempts to invent an Hellenic counterpart to Christianity.

Early in the fifth century, Neo-Platonism flourished for a short time in Alexandria (which disgraced itself by the murder of Hypatia in 415) and captured the Athenian Academy itself, where its last great representative was the acute Proclus (A.D. 410–485). The latest members of the School, under Justinian, occupied themselves chiefly with learned commentaries on Aristotle, of which, those of Simplicius are the most valuable. The doctrine of the school itself ends in Damascius with complete agnosticism.

Influence on Christian Thought.— Traces of Plato are probably to be detected in the Alexandrian *Wisdom of Solomon;* the thought of the Alexandrian Jewish philosopher and theologian Philo, at the beginning of our era, is at least as much Platonic as Stoic. There are, perhaps, no certain marks of Platonic influence in the New Testament[1], but the earliest apologists (Justin, Athenagoras) appealed to the witness of Plato against the puerilities and indecencies of mythology. In the third century Clement of Alexandria, and after him, Origen, made Platonism the metaphysical foundation of what was intended to be a definitely Christian philosophy. The Church could not, in the end, conciliate Platonist eschatology with the dogmas of the resurrection of the flesh and the final judgment, but in a less extreme form the Platonizing tendency was continued in the next century by the Cappadocians, notably St. Gregory Nyssen, and passed from them to St. Ambrose of Milan. The main source of the Platonism which dominated the philosophy of western Christian divines through the earlier Middle Ages, were, however, Augustine, the greatest thinker among the Western Fathers, who had been profoundly influenced by Plotinus, read in a Latin version, before his conversion to Christianity, and Boethius, whose wholly Platonist vindication of the ways of Providence in his *Consolatione Philosophiae* was the favourite "serious" book of the Middle Ages.

[1]We may perhaps detect it in John i. 18 if the true text is "the only begotten God (μονογενὴς θεός) which is in the bosom of the Father" This may be an echo of the phrase used in the *Timaeus* (92*d*) about the visible world "A God apprehensible to sense one and only begotten" (μονογενὴς ὤν). But it *is* not safe to assert it.

A further powerful influence was exerted by the writings of the so-called Dionysius the Areopagite, which laid down the main lines of mediaeval mystical theology and angelology. These works are, in fact, an imperfectly Christianized version of the speculations of Proclus, and cannot date before the very end of the fifth century A.D. at the earliest, but they enjoyed an immense authority based on their attribution to an immediate convert of St. Paul.

After their translation into Latin in the ninth century by Johannes Scotus Erigena, their vogue in the West was as great as in the East. Apart from this theological influence, Plato dominated the thought of the earlier Renaissance which dates from the time of Charlemagne in another way. Since the West possessed the philosophical writings of Cicero, with the Neo-Platonic comment of Macrobius on the *Sontnium Scipionis,* as well as the Latin translation of the first two-thirds of the *Timaeus* by Chalcidius, with his commentary on the text, and versions, also, at least of the *Phaedo* and *Meno,* whereas nothing was known of the works of Aristotle except Latin versions of some of the logical treatises, the Middle Age, between Charlemagne and the beginning of the 13th century, when the recovery of Aristotle's physics and metaphysics from Moors, Persians and Jews began, was much better informed about Plato than about Aristotle; in particular in the various "encyclopaedias" of this period, it is the *Timaeus* which forms the regular background.

The thirteenth century saw a change. Aristotle came to displace Plato as "the philosopher," partly in consequence of the immediately perceived value of his strictly scientific works as a storehouse of well-digested natural facts, partly from the brilliant success of the enterprise carried through by St. Thomas Aquinas, the reconstruction of philosophical theology on an Aristotelian basis. Plato is, however, by no means supplanted in the Thomist system; the impress of Augustine on Western thought has been far too deep for that. Augustine's "exemplarism," that is, the doctrine of Forms in the version, ultimately derived from Philo of Alexandria, which makes the Forms "creative thoughts" of God, is an integral part of the Thomist metaphysics, though it is now denied that the exemplars are themselves cognizable by the human intellect, which has to collect *its* "forms," as best it can, from the data of sense.

Directly or through Augustine, the influence of Plato, not only on strictly philosophic thought but on popular ethics and religion, has repeatedly come to the front in ages of general spiritual requickening, and shows no signs of being on the wane.

Two "revivals" in particular are famous. The first is that of the 16th century, marked by the Latin translation of Marsilio Ficino and the foundation of Lorenzo dei Medici's fantastic Florentine Academy. What was revived then was not so much the spirit of Plato as that of the least sober of the Neo-Platonists; the influence of the revival was felt more in literature than in philosophy or morals, but in literature its importance may be measured by the mere mention of such names as Michelangelo, Sidney, Spenser.

In the 17th century, Plato, seen chiefly through the medium of Plotinus, supplied the inspiration of a group of noble thinkers who were vindicating a more inward morality and religion against the unspiritual secularism and erastianism of Hobbes, the so-called "Cambridge Platonists," Whichcote, Henry More, Cudworth, John Smith. At the present moment the writings of A. N. Whitehead contain an attempt to work out a philosophy of the sciences which confessedly connects itself with the ideas of the Timaeus.

Bekker's edition of the text (1816–23), and the prefaces and prolegomena to the volumes of the editions of Schanz, Burnet, the *Collection des Universités de France* (1920), also pp. xciv. ff. of the introduction to Waddell's edition of *Parmenides*, Jowett and Campbell's *Republic*, vol. ii. The important *Codex* Clarkianus (B) of the Bodleian Library has been reproduced in facsimile with a preface by T. W. Allen (1898–1899). *See* also ARISTOTLE, NEOPLATONISM, SOCRATES. (A. E. TA.)

PLATO, Athenian comic poet of the Old Comedy, flourished between 428–389 B.C. According to Suïdas, he was the author of 30 comedies. Some of these deal with political matters. Such were the *Cleophon* and *Hyperbolus*, directed against the well-known demagogues. His later plays are satires handled in a burlesque spirit. Such were the *Sophistae*, akin to the *Clouds* of Aristophanes; the *Cinesias*, an attack on a contemporary poet and the *Festivals*.

See T. Kock, *Comicorum atticorunt fragmenta*, i. (1880); A. Meineke, *Poetarum comicorum ggrecorum fragmenta* (1855).

PLATON, LEVSHIN (1737–1812), Russian divine, was born at Chashnikovo near Moscow, and educated in the academy of that city. In 1763 the empress Catherine II. invited him to instruct her son Paul in theology, and he became one of the court chaplains. Three years afterwards Platon was appointed archimandrite of the monastery of the Trinity (Troitskaya Lavra) near Moscow, in 1770 archbishop of Tver, and in 1787 archbishop of Moscow and metropolitan. He died in 1812, one of his last acts having been to write an encouraging letter to the emperor Alexander I. in view of the French invasion. Platon was a brilliant and learned man, and the author of *A Short History of the Russian Church*.

PLATONIC LOVE, a term commonly applied to an affectionate relation between a man and a woman into which the sexual element does not enter. The term in English goes back as far as Sir William Davenant's *Platonic Lovers* (1636). It is derived from the conception, in Plato's *Symposium*, of the love of the idea of good which lies at the root of all virtue and truth.

PLATOON, a sub-division of a company of infantry. In the 17th century it was, in some cases, the infantry tactical unit and was commanded by a captain. At the beginning of the 18th century the term referred to a small body of musketeers of about 40 or 50 men arranged in a square to strengthen the angle of the battalion when formed in hollow square. About the middle of the 18th century a battalion was generally organized into 16 platoons, of about 24 men each, plus two or four platoons of grenadiers. In the 19th century, the term has been applied solely to a squad of recruits under training. "Platoon fire" was the systematic and regulated fire of platoon volleys. Hence a "platoon" sometimes meant a volley. The term was retained for a type of manual exercise. As a sub-division of an infantry company it was re-introduced into the British service in 1913 and is now the name of the sub-division of a company in most modern armies (*see* COMPANY). In the U.S. cavalry a troop is divided into four platoons.

PLATOON SCHOOL, a work-study-play school organization found in the educational system of the United States. It was originated by William Wirt who started the first school of this type in Bluffton, Ind, in 1902. When he became superintendent of schools of Gary, Ind., in 1907, he organized all the schools of that city on the work-study-play plan. By 1917, 25

American cities had schools so organized, and by 1928, there were 153 cities in 38 States which had over 850 platoon schools.

We begin with the theory that modern cities are extremely bad for children since they deprive them of the healthful work and play which are as essential elements in a child's education as study. The platoon school returns to children opportunities for work and play by providing schools containing not only classrooms but well-equipped shops, science rooms, drawing and music studios, cooking rooms, auditoriums, playgrounds and gymnasiums. The traditional public school is operated on a "peak. load" plan of operation, *i.e.,* on the principle of reserving a school sear. for the exclusive use of one child during the entire year. When the children leave these seats to go to shops or playgrounds the seats remain vacant. Under such a plan there are seldom enough seats, playgrounds or shops to accommodate all the children in a city at one time.

Under the platoon plan, on the contrary, all facilities in the school—classrooms, auditoriums, gymnasiums, shops and laboratories—are in use every hour of the day. The school is divided into two parts, each having the same number of classes and each containing aii the eight or nine grades. While one of the schools is in classrooms, the other is in special activities, auditorium, playgrounds and gymnasiums. This means that only half the usual number of classrooms is needed. Since the cost of a classroom (1928) is approximately $12,000, this means that in a go-class school only 15 classrooms are needed, instead of 30, with the result that 15 times $12,000 is released for all other activities in the school. Under this "balanced load," the special facilities add nothing to the cost of the school. According to tests, the children in platoon schools rank as high as the children in non-platoon schools in tests of accuracy; in comprehension and reasoning tests they rank higher.

PLATT, CHARLES ADAMS (1861–1933), American architect, was born in New York city on Oct. 16, 1861 and educated in the National academy of design, and in Paris under Boulanger and Lefebre. At first he intended to become a painter and etcher, but the outcome of a visit to Italy was a book, *Italian Gardens* (1892). This explained his adoption of architecture, and his work showed the marked influence of Italian form. He designed many private houses and gardens in addition to public buildings, among the latter being the Maxwell memorial library, Rockville (Conn.) (1917); the Freer Gallery of Art, Washington (D C.) (1918); the library, Connecticut college for women, New London (1922); the agricultural building, University of Illinois, Urbana (Ill.) (1923); and the Lowell memorial fountain, New York city.

See *Monograph of the Work of Charles A. Platt,* with an introduction by Royal Cortissoz (1913).

PLATTE, a river system of Colorado, Wyoming and Nebraska, tributary to the Missouri river, which it enters immediately north of Plattsmouth, Nebraska, 18 m. below Omaha, in about 41° 3′ N latitude. Including the North Platte it is about 900 m. long from its headwaters, with a drainage basin for the entire system of 90,000 square miles. The tributaries of the main stream all flow in from the north; the most important being the Loup, and the Elkhorn. The main stream west of Kearney, as well as the North and the South Platte, are extensively used for irrigation.

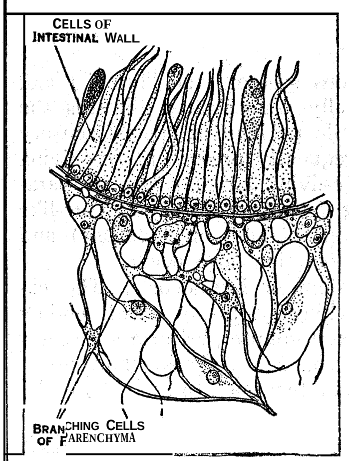
See R P. Teele, "Water Rights in Interstate Streams," U.S. Dept. of Agric. *Bulletin No. 157* (1905) and J. C. Stevens, *Surface Water Supply of Nebraska* (1909).

PLATTEVILLE, a city of Grant county, Wisconsin, U.S.A., 20 mi. from the southwest corner of the state; on federal highway 151 and served by the Chicago and North Western and the Chicago, Milwaukee, St. Paul and Pacific railways. Pop. (1930) 4 047; in 1940, 4,762. It is in a zinc and lead mining region, and is the seat of a state teachers college. The city was settled about 1827 and incornorated in 1880.

PLATTSBURG, a city of northern New York, U.S.A., on the west shore of Lake Champlain, is on federal highway 9 and is served by the Delaware and Hudson railway and lake steamers. Pop. (1930) 13,349 (90% native white); 1940 federal census 16,351. Plattsburg is surrounded by beautiful scenery: the broad, island-studded lake in front, with the Green mountains beyond, and on the southern horizon the distant Adirondacks. South of the city, at Piattsburg barracks (an army post established in 1815), 29,000 reserve officers were trained during the war of 1914–18, and since 1920 it has been one of the citizens' military training camps, with an enrolment of 3,000 to 4,000 every summer. Cliff Haven (2 mi. S.) is the seat of the Catholic Summer School of America, which has an attendance of about 3,000. Plattsburg is a centre for summer touring and winter sports. Its manufactures (chiefly lumber and various kinds of paper) were valued at $7,698,292 in 1937. Plattsburg was founded by Zephaniah Platt (1740–1807), who brought a colony from Long Island. It was incorporated as a village in 1795 and as a city in 1902. The opening naval engagement of the Revolution (a victory for the British) tonk place at Valcour island, j mi. S E. of Plattsburg, on Oct. 11, 1776. In the War of 1812 Plattsburg was the headquarters of the American army on the northern frontier. On Sept. ' ' the village was besieged by land, and or, Sept. 11, the Commodore Thomas Macdonough defeated the invading fleet.

PLATTSMOUTH, a city of eastern Nebraska, U.S.A., on the Missouri river, at the mouth of the Platte, 21 mi. below Omaha; the county seat of Cass county. It is on federal highways 73 and 75, and is served by the Burlington Route and the Missouri Pacific railway. The pop. was 3,793 in 1930; 4,268 in 1940. The city ships grain and cattle, and has large railroad shops. flour mills, broom factories and other manufacturing plants. Plattsmouth is one of the oldest settlements of the state. A trading post licensed by the U.S. government was opened there in 1853; a town was platted in 1854; and the city was incorporated in 1855.

PLATYHELMINTHES or **PLATODARIA,** a phylum of invertebrate animals, containing soft-bodied creatures which are bilaterally symmetrical and usually somewhat flattened in shape, and in which there is no true "coelom" or perivisceral cavity and no true (metameric) segmentation. The animals contained in this group (flatworms) are the simplest and probably the most primitive of those in which the tissues and organs of the body are developed from three, instead of two, original embryonic layers.



AFTER KERBERT, IN "ARCHIV FUR MIKROSKOPISCHEN ANATOMIE" (FRIEDRICH COHEN)

FIG. 1.—SECTIONAL PORTION THROUGH THE BODY OF A TREMATODE (PARAGONIMUS), SHOWING STRUCTURE OF TISSUES

The external covering of the body is typically an epidermis provided with vibratile cilia These serve partly for locomotion and partly for creating a respiratory current In the adults of certain parasitic groups, the epidermis is replaced by a smooth or spiny cuticle Pigment is commonly present beneath the epidermis in free-living forms, but is usually absent in those which are parasitic. The spaces between the internal organs are for the most part filled up with a kind of loose connective tissue called the parenchyma. The coelom is represented, perhaps, by the cavities of the gonads and of the excretory organs. The musculature of the body is mainly peripheral, consisting of layers of transverse, longitudinal and sometimes also oblique muscle-fibres running through the outer, or "cortical," portion of the parenchyma. These muscles render the body capable of extreme elongation and contraction, and often of surprising variability in shape.

Anterior and posterior ends of the body can usually be distinguished, the animals having a definite direction of locomotion, accompanied by a greater degree of specialization of, the anterior extremity. Dorsal and ventral surfaces are also generally distinguishable, the latter being that on which the animal creeps, and on which the oral and genital apertures are commonly situated. In the parasitic flatworms special clinging organs are generally developed, in the form of muscular suckers, often supplemented by chitinoid hooks or spines.

An alimentary canal may or may not be differentiated. When present, it may either be a simple sac-like organ or may be variously branched. With very few exceptions, its only aper-

FIG. 2.— EXCRETORYSYSTEM OF A PLATYHELMINTH
Below, diagram of a portion of the excretory system showing branching ducts ending in flame cells. Above, a single flame cell more highly magnified

ture is the mouth, which may be situated subterminally, near the anterior end, or much further back, sometimes even behind the middle of the body. The mouth may be surrounded by an oral sucker, or developed into a protrusible and highly muscular pharynx.

The main ganglia of the nervous system (the "brain") and the chief sense-organs are generally concentrated towards the anterior end. In addition to tactile papillae or special sensory cilia, "eye-spots" or ocelli are frequently present in free-living forms, and sometimes in the free-living larval stages of parasitic forms. In certain free-living flatworms statocysts (sac-like organs containing minute calcareous nodules or statoliths) and ciliated pits, probably sensory in function, also occur.

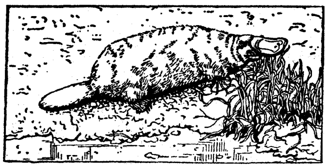
There is no blood-vascular system or haemocoele. The excretory organs consist of a branching system of canals ending internally in "flame-cells." These are minute pyriform structures containing cilia which keep up a constant flickering movement. The main collecting vessels of the system open to the exterior by one, two or many pores.

The Platyhelminthes are, with rare exceptions, hermaphroditic animals, each individual being potentially both male and female. The reproductive system is usually very complex. The male organs consist essentially of one or more (often very numerous) testes, whose ducts are usually connected with a protrusible intromittent organ (penis or cirrus). The essential organs of the female apparatus are an ovary (sometimes multiple ovaries) and a tubular duct communicating with the exterior. The arrangement of the parts of the female system is subject to great variation in different groups. Sometimes the same duct functions in turn as a vagina or fertilization canal, as a uterus or reservoir for fertilized eggs, and as an oviduct by which the eggs reach the exterior. In some cases (most Cestodes) the only communication with the exterior is a vagina, which is connected internally with an oviduct leading from the ovary to a sac-like uterus; but does not serve for the expulsion of eggs. In such forms the eggs are either shed only by the dehiscence of the wall of the uterus and of the body-wall, or by a special (temporary or permanent) birth-pore. In almost all flatworms there is a yolk-gland or vitellarium (often multiple vitellaria), producing yolk-cells which form nutritive material for the developing embryos. The vitellarium, in the most primitive forms, appears to be developed as a sterile portion of the ovary. There is also usually a "shell-gland," possibly concerned in the secretion of the outer covering of the eggs. The ducts of these glands open into the oviduct or into a specialized portion of it called the ootype. The external apertures of the male and female ducts are sometimes separate, but frequently both ducts open into a common "genital atrium," which is often muscular.

The Platyhelminthes are extremely widely distributed, free-living forms occurring in almost every kind of environment—in shallow or deep water, both fresh and marine, and on land—while parasitic forms occur on or in animals of almost every class. The free-living forms usually feed actively on small animals or plants. The parasitic forms show various degrees of modification in habits, some being external parasites and feeding on mucus or other matter derived from the skin of their hosts, while others are internal parasites and feed on partly digested food or on body-fluids. Among the latter class some are without special digestive organs and can only feed by the absorption of liquid nourishment.

The phylum is usually considered to include three main divisions or classes: (1) Turbellaria (including Temnocephalidea), the majority of which are free-living, but some parasitic. This group is probably nearest to the primitive ancestral form. (2) Trematoda (flukes), all of which are wholly or partly parasitic either upon or within other animals. (3) Cestoda (tapeworms), all of which are wholly endoparasitic. See NEMERTINEA, TAPEWORMS, TREMATODES, TURBELLARIA. (H. A. B.)

PLATYPUS, a remarkable Australian aquatic mammal belonging to the primitive sub-class Monotremata (*q.v.*). The duck-billed platypus (*Ornithorhynchus* anatinus), the only species,' is oviparous; two eggs, $\frac{3}{4}$in. long and $\frac{1}{2}$in. wide, each enclosed in a strong, flexible, white shell, are produced at a time. The animal shows many primitive features; there are no true teats in the female, the milk glands being probably modified sweat glands; the body temperature is relatively low. The platypus inhabits the streams and rivers of south-east Australia and Tasmania. About 20in. long, it is clad in short, dense fur of a deep brown above, paler below. There are no teeth in the adult, their purpose being served by horny prominences, two on each side of each jaw, giving the muzzle a very beak-like appearance. In the cheek are capacious pouches. The limbs are short and strong, each with five claw-bearing toes. In the fore-feet, the web extends far beyond the ends of the claws, but it can be folded back on the palm when the animal comes out on to the land. On the heel of the male is a movable horny spur, perforated by a canal which communicates with a poison-gland. The platypus forms deep burrows in the banks, in which it sleeps and brings up its young, the entrance being under water. The food consists of aquatic insects, Crustacea and worms. The animal is nocturnal.



PLATYPUS (ORNITHORHYNCHUS ANATINUS), AN EGG-LAYING MAMMAL

See H. Burrell, *The Platypus* (1927).

PLATYRRHINE APE, the name applied, in contradistinction to Catarrhine [*q.v.*], to the New World monkeys, on account of the broad septum between the nostrils. See PRIMATES.

PLAUEN, a town of Germany, in the Land of Saxony. Pop. (1939) 110,342. Plauen, probably founded by the Slavs, is first mentioned in 1122. It passed under the authority of Bohemia in 1327 and came to Saxony in 1466, remaining united with the electorate after 1569. The manufacture of white goods was introduced by Swabian, or Swiss, immigrants about 1570.

It was formerly the capital of Vogtland, or Voigtland, a territory governed by the imperial vogt, or bailiff, and this name clings to the district, The fine Gothic church of St. John, with twin spires, was restored in 1886. The town hall dates from about 1550; and the old castle, Hradschin, is now a law court. Plauen manufactures embroidered white goods and makes lace. It manufactures much of the machinery used in the town and it has a trade in coal, yarn and cattle.

PLAUTUS, TITUS MACCIUS (originally, perhaps, MACCUS; cf. *Asin,* Prol. 11), the great comic dramatist of ancient Rome, was born at Sarsina in Umbria according to the testimony of Festus, who calls him Umber Sarsinas, and Jerome. The date of his death was 184 B.C. (Cicero, *Brutus,* XV. 60). The date of his birth depends upon an inference based on the statement of Cicero (De *senectute,* xiv. 50) that he was an old man, when he wrote his *Truculentus* and Pseudolus. The latter play was produced in 191 B.C.; hence we get 254–251 B.C. as the approximate date of his birth. The only record that we possess as to his life is that contained in Aulus Gellius iii. 3, 14 (based on Varro), the historical character of which is doubted by Leo (*Plautinische Forschungen*, ch. ii.). The chief fact that emerges is that he left his native Umbrian home and settled as a peregrinus at Rome, where, after earning some money and losing it again, he took to writing plays.

The Plays.—His literary activity may well have begun somewhat late in life; for it must have taken him a long time and much hard study to acquire the mastery of Latin and Greek which his dramas attest. The main body of his extant works belongs, so far as can be ascertained from the scanty evidence which we have, to the last 20 years of his life; 206–204 B.C. is the approximate date of the Miles *Gloriosus;* cj. line 211 seq., quoi *bini custodes* . . . occubant (present tense), which alludes to the imprisonment of Naevius. Of the extant plays the Cistellaria and the Stichus must be associated with the Miles as comparatively early works; for the former was clearly produced before the conclusion of the Second Punic War, see 1. 201 *seq.;* and the Stichus is proved by its didascalia to have been produced in 200 B.C. The Pseudolus and the Truculentus fall within the last seven years of his life; and the *Trinummus* is later than 194 B.C.; cf. 1. 990 *novi* aediles.

The dates of the other extant plays are uncertain. An interesting attempt to place them in chronological order according to the proportion in them of scenes written in lyrical metres and set to music (cantica) has recently been made by W. B. Sedgwick (Classical Review, xxxix., 1925, p. 55 seq.). It is at any rate not improbable that the poet gave greater scope to his musical innovation (see below) as his command over language and metres developed and the success of his experiment became assured. The titles of the other extant plays are (in alphabetical order) Amphitruo, Asinaria, *Aulularia,* Bacchides (later than the Epidicus, see 1. 214), *Captivi, Casina, Curculio, Epidicus, Menaechmi,* Mercator (later than the Rudens according to F. Marx and E. Fränkel, but regarded as one of the earliest plays by P. J. Enk in Mnemosyne, liii., F. A. Wright in Broadway Translations, and W. Beare in Classical Review xlii., 1928, pp. 106 and 214 *seq.*), *Mostellaria,* Persa, Poenulus, Rudens (probably first acted 192 B.C.) *Vidularia* (existing only in a fragmentary condition in the codex Ambrosianus). Some of these may possibly be earlier than 204 B.C.; and it seems a *priori* likely that the 35 other Plautine plays known to us only by their titles and a few fragmentary quotations were not all written within the last 20 years of the poet's life.

Indebtedness and Originality.—The plays of Plautus are based on Greek originals of the New Comedy, of which one complete specimen is extant. But Plautus was not a mere translator. This was shown by K. M. Westaway (The Original Element *in Plautus,* 1917), and has been recently demonstrated in detail by E. Fränkel (*Plautinisches im* Plautus, 1922), who calls attention to certain mannerisms as evidence of unmistakable Plautine additions to the Greek texts, and also points out the originality of the Roman in the introduction of a musical element into his plays (see below). On the other hand, there are passages in which he does not hesitate to take over from his originals, allusions which can hardly have been intelligible to a Roman audience, *e.g.,* the reference to Stratonicus, a musician of the time of Alexander the Great (*Rudens,* 932); and in the delineation of character we have no reason to suppose that he improved on his models (cf. Aul. Gell. ii. 23). Even the bulk of the prologues may be of Greek origin, though certain passages in them must have been added by Plautus, and other passages (e.g., *Casina* 5–20) are post-Plautine. And where Plautus varies his plot on lines of his own by amalgamating the plots of two distinct Greek comedies (*e.g.,* in the Miles and the Poenulus) the result is generally not happy; the romanization of the plays by way of allusions to towns in Italy, to the streets, gates and markets of Rome, to Roman magistrates and their duties, to Roman laws and the business of Roman law courts, banks, comitia and senate, etc., involves the poet in all the difficulties of attempting to blend two different civilizations. The inconsistency of his attitude is shown by his use, side by side, of the contemptuous expressions *barbarus* (applied to the Romans) and pergraecari (applied to the Greeks). In some passages the poet seems to take delight in casting dramatic illusion to the winds (e.g., *Pseudolus,* 720; *Poenulus,* 550).

But as an adapter for the Roman stage Plautus is nothing less than masterly. His command of Latin is such that his plays read like original works, and it may be at least said that some of his characters stand uui su vividly from his canvas that they have ever since served as representatives of certain types of humanity, *e.g.,* Euclio in the *Aulularia,* the model of Molière's miser. Alliteration, assonance, plays upon words and happy coinages of new terms, give his plays a charm of their own. "To read Plautus is to be once for all disabused of the impression that Latin is a dry and uninteresting language" (Skutsch, in Die Cultur der *Gegenwart,* 1905). It is a mistake to regard the Latin of Plautus as "vulgar" Latin. It is essentially a literary idiom, based upon the language of intercourse of the Roman society of the day (cf. Cic. De *oratore,* iii. 12, 45).

The Characters in his plays are the stock characters of the New Comedy, and they remind us also of the standing figures of the Fabulae Atellanae (Maccus, Bucco, Dossennus, etc.). We may miss the finer insight into human nature and the delicate touch in character-drawing which Terence presents to us in his reproductions of Menander, but there is wonderful life and vigour, and considerable variety in the Plautine embodiments of these different types. Their language is often coarse; and there is some deliberate obscenity in it, but not so much as has been discovered by Gurlitt and introduced into his German translation (1920–22). And the careful reader will take note of occasional touches of serious thought (no doubt derived from the Greek originals), as in the enumeration of the ten deadly political sins (Persa, 555 seq.) and allusions to ethical philosophy (Pseud. 972 *seq.; Stich,* 124; Trin. 305 seq., 320 seq., 363 seq., 447; Rud. 767, 1235–1248, etc.). The *Captivi* is the story of the heroic self-sacrifice of a slave. The *Amphitruo* is a mythological burlesque. But most of his plays depend for their main interest in intrigue, such as the Pseudolus, Bacchides, Mostellaria. In the Menaechmi and as a subordinate incident in the Amphitruo we have a comedy of errors.

Metres.—In the metrical structure of his plays Plautus introduced an important innovation. The New Comedy of Greece had confined itself for the most part to the metres of dialogue: Plautus took the bold step of transposing whole scenes into metres suitable for singing to the accompaniment of the flute (cantica); and to other scenes he gave a quasi-operatic character by the use of recitative. But the cantica are not mere inserts or accessories, like the songs introduced in the Shakespearean drama; they form integral parts of the action, which would often be unintelligible without them (see Fränkel [*op. cit.*] whose theory is a development of that of Leo in Die *plautinischen Cantica und* die *hellenistische* Lyrik, 1897). The metres employed were, of course, not invented by Plautus; they are of Greek origin and are common to Roman tragedy and Roman comedy; but Plautus gave them a new development and a wider scope. Further light is thrown upon the immediate source of these Plautine metres by J. H. O. Immisch (*Zur* Frage der *plaut. Cantica,* in Berichte der Heidelb. Akad., 1923). The Plautine metres are wonderfully varied, and the textual critic does well not to attempt to limit the possibilities of original metrical combinations and developments in the Roman comedian.

Reputation.—Plautus was a general favourite in the days of republican Rome. Cicero, though he found fault with the iambics of the Latin comedians generally as abiecti "slovenly" (Orator lv. 184), admired Plautus as elegans, *urbanus, ingeniosus, facetus* (*De. offic.* i.,29,104). To the fastidious critics of the Augustan age, such as Horace, he seemed rude (*cf. Ars Poetica*, 270–274), just as Addison declared Spenser to be no longer fitted to please "a cultivated age." In another passage (Epist. ii. 1 170–176) Horace accuses him of clumsiness in the construction of his plays and the drawing of his characters, and indifference to everything except immediate success; *gestit enim nummum in loculos demittere,* post *hoc securus cadat an* recto stet *fabula talo.* That there are many inconsistencies and signs of carelessness in his work has been proved in detail by Langen. But that he found many admirers, even in the Augustan age, Horace himself bears witness (ibid. 1. 58), where he says that Plautus was regarded as a second Epicharmus: Plautus ad exemplar *Siculi* properare *Epicharmi;* cf. Varro's statement (in Priscian ix. 32), *deinde* ad *Siculos se applicavit.* It is possible that Plautus may have been working on the lines of the old comedy in the tell-tale names which he is so fond of inventing for his characters such as Polymachaeroplagides (*Pseud.* 988), Pyrgopolinices (Mil. 56), Thesaurochrysonicochrysides (*Capt.* 285)—names which stand in remarkable contrast to the more commonplace Greek names employed by Terence.

In the middle ages Plautus was little regarded, and 12 of his plays (*Bacchides—Truculentus*) disappeared from view until they were discovered (in the ms. called D) by Nicholas of Treves in the year 1429. But after the revival of learning Plautus was reinstated, and took rank as one of the great dramatists of antiquity; cf. Shakespeare, Hamlet, II., ii., 420, where Polonius says "The best actors in the world . . . Seneca cannot be too heavy nor Plautus too light."

Influence on Modern Literatures.—A comprehensive view of the widespread influence of Plautus on modern literatures is given by Reinhardstoettner, *Spätere* Bearbeitungen *plautinischer Lustspiele* (1886). Many adaptations for the Italian stage were produced between the years 1486 and 1550, the earliest (the *Menaechmi*) under the direction of Ercole I., duke of Ferrara. From Italy the practice spread to France, Spain, England and other countries.

Of English plays the interlude called Jack Juggler (between 1547 and 1553) was based on the *Amphitruo,* and the lost play called the *Historie* of Error (acted in 1577) was probably based on the *Menaechmi;* Nicholas Udall's Ralph *Royster Doyster,* the first English comedy (acted before 1551, first printed 1566), is founded on Miles *Gloriosus;* Shakespeare's Comedy of Errors (about 1591) is an adaptation of the *Menaechmi;* and his Falstaff may be regarded as an idealized reproduction or development of the braggart soldier of Plautus and Terence—a type of character which reappears in other forms not only in English literature (*e.g.,* in Shakespeare's Parolles and Ben Jonson's Captain Bobadil) but also in most of the literatures of modern Europe. Shakespeare's *Taming* of the Shrew has been influenced in several respects (including the names *Tranio* and Grumio) by the *Mostellaria.* Ben Jonson produced a skilful amalgamation of the *Aulularia* and the *Captivi* in his early play The Case is Altered (written before 1599). Thomas Heywood adapted the *Amphitruo* in his Silver *Age* (1613), the *Rudens* in his *Captives* (licensed 1624), and the Mostellaria in his *English* Traveller (1633). Dryden's *Amphitryon* or the *two Sosias* (1690) is based partly on the *Amphitruo,* partly on Molikre's adaptation thereof; Fielding's Miser (acted 1732) on Molikre's *L'Avare* rather than on the *Aulularia,* and his *Intriguing Chambermaid* (acted 1733) on Regnard's Le *Retour imprévu* rather than on the Mostellaria.

Bibliography.—Standard Texts and Editions with Notes: Texts by Goetz and Schoell (*editio* minor, 1893–1907), by Leo (1895–96), by Lindsay (1904–05). With notes: *Captivi,* by Lindsay (1900), by Brix (6th ed., 1910); *Menaechmi,* by Brix (5th ed., 1912); *Miles* by Lorenz (2nd ed., 1886), by Brix (3rd ed., 1901); *Mostellaria* by Lorenz (2nd ed., 1883), by Sonnenschein (2nd ed., 1907); *Pseudolus* by Lorenz (1876); Rudens by Sonnenschein (1891, ed. min., 1901); *Trinummus* by Brix (5th ed., 1907); other plays in Macmillans Classical Series and the Pitt Press Series. Lexicon: Gonzalez Lodge's *Lexicon Plautinum* (nearing completion and indispensable). Syntax: Lindsay, *Syntax of Plautus* (1907): Metre and Prosody: Lindsay, *Early Latin Verse* (1922); Vollmer, *Römische* Metrik (1923); and Ueber die sogenannte *Iambenkürzung* (1924); Sonnenschein In What *is* Rhythm? (1925, ch. vi.). E. Frankel's *Iktus und Akzent im lateinischen Sprechvers* (1928) is an attempt to show that in the dialogue metres, as distinct from the metres set to music, the verse-stress (ictus *metricus*) nearly always coincides with a genuine speech-accent, or at any rate corresponds to some modification of accentuation or intonation. Translations: English prose by P. Nixon in the Loeb Series (1916–24; 2 vols. still to come); English verse by Wright and Rogers in *Broadway Translations*—select plays (1923).

PLAY: see Drama.

PLAYA (a Spanish word meaning "shore"), the name applied in America to a level plain formed of the deposits of a river which has no outlet to the sea or a lake. If at seasons of high water a river floods any area and temporarily converts it into a lake, which subsequently dries up in hot weather, the tract thus left dry is called a playa. The barren Black Rock desert in north-western Nevada, about 100m. in length by 15 in breadth, is typical.

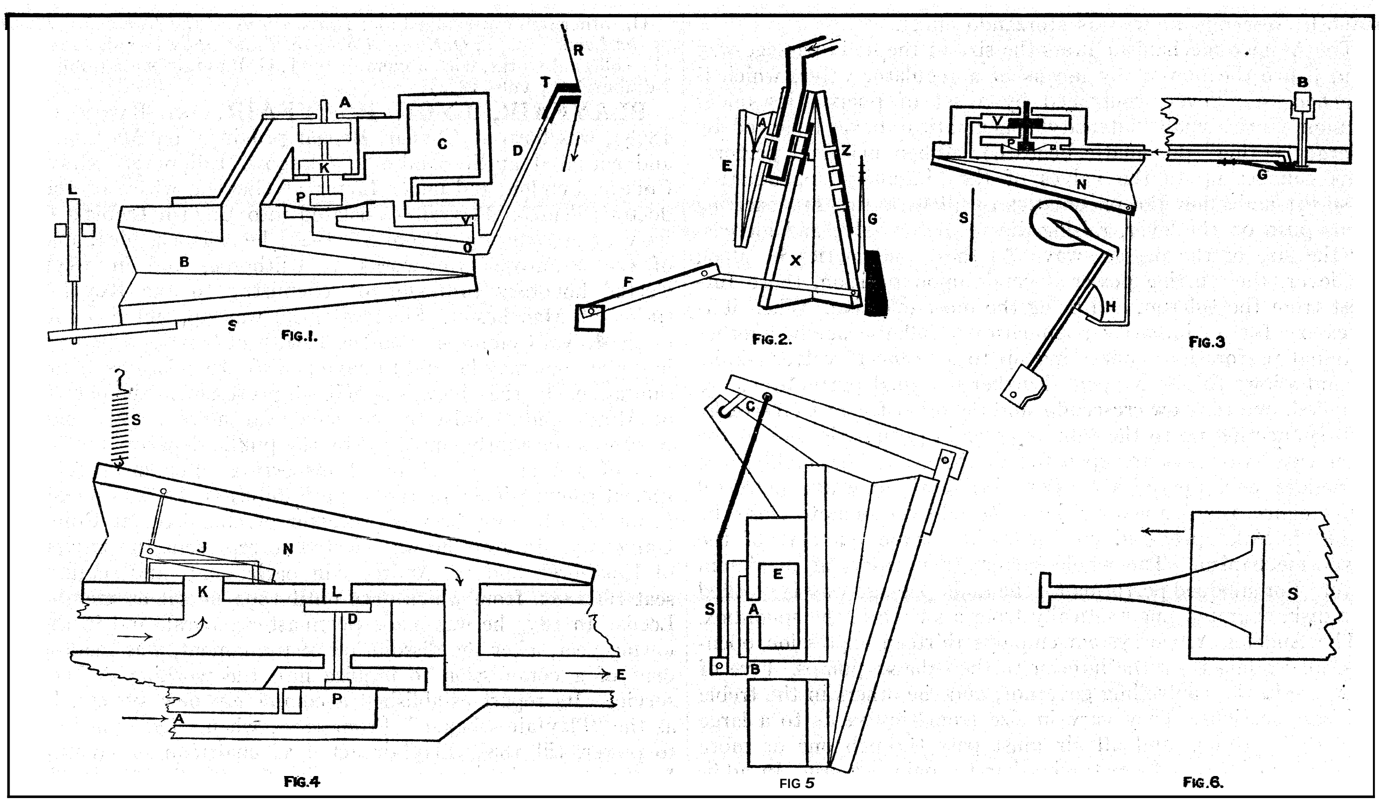
PLAYER-PIANO, a piano equipped with a mechanical device for automatically playing written music or for reproducing the playing of a pianist. All types of player-piano mechanism are operated by utilizing the difference between external and internal air pressures. In fig. 1, the tracker-bar, T, with its 88 holes, is represented as being closed by the paper roll, R, which lies closely against it. Some of the air has been extracted from the duct, D, and from the chamber, C, by means of an air-exhaust to which they are connected. There is a very tiny vent, V, which allows air from the tracker duct to leak into the chamber. A disk, K, closes the chamber from the outer air, being held down because the air in C, is at a lower pressure than normal. The pneumatic, B, is full of air at normal atmospheric pressure and is open to the external air by means of the port, A.

Should a hole in the paper come into line with any hole in the tracker-bar, the external air rushes into the duct and lifts the pouch, P, which is simply a circular piece of soft kid about $\frac{3}{4}$in. in diameter, and bigger than K. Hence it lifts K, connecting the pneumatic with the partial vacuum, C, and disconnecting it from the external air by closing the port A. The air in B spreads to C and, the external pressure on the surface, S, being greater than the reduced pressure inside, the pneumatic collapses suddenly, the movable leaf rising and lifting with it the pilot, L, which operates the piano action.

The pneumatic remains collapsed until paper again blocks the hole in the tracker-bar. The air in D then leaks through into C and can no longer hold up the pouch, which falls back into position and allows K to close the chamber C again, at the same time opening the pneumatic to the external air at A. The external and internal pressure on S now being the same, the pneumatic re-inflates and allows the pilot to drop back into position.

In the days of heavy and clumsy valves it was difficult to provide the necessary power to lift them rapidly without hard pedalling and consequent loud tone. To overcome this defect the more expensive player action was provided with an additional (or primary) valve of light construction, easily lifted by the inrush of air when a hole was opened on the tracker-bar. Its lifting admitted air to the other and heavier valve, through the port O, operating the striking pneumatic as previously described. Both single and double valve systems are still in use.

The interior of the player action is maintained in a steady state of reduced pressure by forcing the pedal, F, to open the exhaust, X (fig. 2). This allows all the interior air to spread itself into X past L, a flat strip of well-tanned leather, lying over holes. A fan spring, G (about 12lb. in strength), then closes the exhaust, expelling the air via another flap valve, Z. A strong spring, A, is always trying to open the equalizer, E, but is prevented from so doing when the external air pressure is much greater than the reduced pressure inside. When, however, there is not much difference between the external and internal pressures the spring can open and in so doing allows air to spread into it from the interior. The effect is to reduce the internal pressure



MECHANISM OF THE PLAYER-PIANO. THE FIGURES AND LETTERS ARE EXPLAINED IN THE TEXT

once more to such an extent that the equalizer begins to collapse. Its constant to-and-fro motion enables a steady amount of reduced pressure to be maintained in the interior channels, despite unsteady working of the pedals.

Controls.—The simplest method of operating the "soft" and "sustaining" pedals is to connect the ordinary mechanism of the piano, by suitable levers, to finger controls in front of the keyboard. Many manufacturers prefer to control the distance from the hammers from the strings as shown in fig. 3. A button, B, opens a gate, G, when pressed down. This admits air to a pouch, P, which lifts the valve lying above it, and puts the pneumatic, N, into communication with a partial vacuum, V, thus collapsing it andwcausing it to lift the hammer rail, H, which softens the tone by giving the hammerhead less distance to travel towards the string, S.

A similar device withdraws all the dampers from the strings. This being a heavier task than shifting the hammers, a larger pneumatic has to be employed, and two valves instead of one. Music rolls are provided with an additional hole at the left-hand edge, which works the lifting of the dampers, if desired.

Change of power, in addition to the means above described, is provided by varying the strength of the blow given to the hammer. Fig. 4 sho s how the normal amount of reduced air is altered by interposing a pneumatic, N, between the main exhaust, E. and the small playing pneumatics. Pressing a button (as in fig. 3), air is allowed to enter at A, the pressure from which lifts the pouch, P, and with it the valve, D. This closes the large hole, L, and leaves only the aperture, K, over which lies a knife-cutter valve, J, so called because it closes like the blade of a pen-knife. The spring, S, is of such strength that it governs the amount of air passing through to the bellows, hard pumping closing N and therefore closing the aperture K and preventing loud playing.

A slight alteration of fig. 4 would give a fair representation of the automatic Accenting Device, which is worked from marginal perforations in the music roll. The valve disk, D, is moved to the other side of the hole, L, keeping it normally closed and softening the tone until a marginal perforation allows air to rush towards P. The pouch lifts the valve, opens L and accents the note.

The pedals also provide sufficient power to work the spool which draws the music roll over the tracker-bar. Five pneumatics of the type shown in fig. 5 are fixed at equal angular distances upon a crank-shaft, C, each one collapsing in turn and so driving the shaft round steadily. Collapse is effected when the hollow slide, S, is covering both of the ports A and B, for the pneumatic is then in direct communication with the main exhaust, through E. As the crank-shaft is thus moved round, the slide is raised, and no longer covers both ports. External air is admitted to the pneumatic, and the collapse of one of its neighbours provides the power to lower its slide and again get into communication with the main exhaust.

All communication between motor and exhaust is by way of a governor pneumatic; powerful pedalling tends to collapse it, but directly this happens a knife-valve partly closes the passage-way (as in fig. 4), and thus prevents the motor from "racing." Variation in tempo is secured by deliberately altering the size of the passage-way within an enclosure known as the Tempo Box. The shape of the slot is usually as shown in fig. 6, over which passes a slide, S. When half the area of the slot is covered, the speed of the motor is half its maximum, and so on, the slide being worked mechanically from the control board.

The holes in the paper roll being so close together, it is essential that they should track correctly, despite the effects of wear and weather. Correct tracking is controlled in ways which vary in detail, but usually depends upon the action of two pneumatics, kept under exhaust. Holes in the tracker-bar are so placed as to be uncovered when (and only when) the roll goes to one side, letting air into one of the pneumatics and causing it to open slightly, taking with it either tracker-bar or spool.

Reproducing Pianos.—The "reproducing" instruments are in a separate class, designed to reproduce faithfully all the shades of tempo and expression made by well-known pianists. All control is rightly withdrawn from the operator when using the specially cut rolls, but the same instrument may be used for ordinary rolls by putting the reproducing mechanism out of action. Additions to the normal player mechanism are mostly for the purpose of controlling more completely the comparative loudness or softness of individual notes. To do this effectively it is necessary to have as many grades of power as possible, to include smooth crescendo as well as sforzando effects.

The Ampico mechanism alters the size of the main passage-way (and hence the power) by means of a regulator valve, which is attached to a lever, controlled by a set of pneumatics under vacuum (three small "intensity" pneumatics above, balanced by a large "spring" pneumatic beneath). When marginal perforations connect up to the valves of the "intensity" pneumatics, these lift and allow the pneumatics to fill with air, thus exerting an up-push on the lever, raising the regulator valve and increasing the size of the passage-way. As these pneumatics lie along the lever, their lifting power depends upon position, those furthest from the fulcrum end being the most effective. When it is necessary for an intensity pneumatic to collapse again, another marginal perforation, connecting up to a "cancel" valve, admits air and allows this to happen. Further marginal perforations are provided, one for slow crescendo, and the other for fast crescendo, each connecting up to the same crescendo pneumatic, but in the latter case two ways are open for the air to escape, making the pneumatic collapse quickly. For "brilliant" or extra powerful performance, the Ampico can be switched over so as to close the slight "in-leak" provided on one of the three pumpers of the power mechanism. The whole system then works at maximum power. For subdued performance the main passage-way is blocked by a disk, operated pneumatically from a switch in the spool-box.

The Angelus Artrio system employs thirteen expression openings, all leading from the interior to the exhaust pumps. Five of these are in the controlling governor, and the others in the treble and bass sections. They vary in size from tiny vents to a large "melody" opening, and all air must pass through one or more openings on its way from tracker-bar to main exhaust. In addition, there is an "in-leak" as on the Ampico, but the Angelus system works it from the tracker-bar. When a perforation appears against the second hole from the left-hand side, the "in-leak" is closed and an increase of power results.

The Duo-Art (Aeolian Company) is essentially a theme and accompaniment expression arrangement, the former being at a higher dynamic power than the other. Each has a knife-valve control of the passage-way, operated by a set of four pneumatics, varying in their amount of possible collapse. In this way sixteen variants of power are obtained There is also an "in-leak," automatically closed by another knife-valve so as to get maximum power when the passage-may is already nearly full open.

The Welte-Mignon is worked by suction fan instead of the usual pumpers. Its expression unit consists of a governor bellows, held open by a coiled spring This controls the position of a conical valve in the passage-way, and is itself automatically responsive to the amount of work being done at any moment within the pneumatic system. The expression pneumatic, which also works the same conical valve, is operated from the tracker-bar, and can act slowly or quickly according to the perforations in operation. (S. A. H.)

Bibliography.—S. Grew, *The Art of the Player-Piano* (1922), *The Book of the Player-Pianist* (1925); D. M. Wilson, *The Player-Piano: its Construction, how to play (1923).*

Value of **the** Player-piano.— The player-piano in its modem perfected form enjoys the whole-hearted support of musicians. In schools it has proved invaluable, while in musical colleges and academies it is utilized as a means of familiarising students with the interpretations of the greatest performers.

PLAYFAIR, JOHN (1748–1819), Scottish mathematician, was born at Benvie, Forfarshire, where his father was parish minister, on March 10, 1748. He was educated at home until the age of 14, when he entered the University of St. Andrews. He was ordained, and succeeded his father in the parish of Benvie, but continued his scientific studies. In 1785 he succeeded Dugald Stewart in the chair of mathematics at Edinburgh, which he exchanged in 1805 for that of natural philosophy. In 1795 he published his *Elements of Geometry,* which later passed through many editions. He enunciated the axiom now known by his name, viz., that two intersecting straight lines cannot both be parallel to the same straight line. He was elected F.R.S. in 1807. He died in Edinburgh on July 20, 1819.

His other publications include: *Illustrations of the Huttonian Theory of the Earth* (1802); *Outlines of Natural Philosophy* (2 vols., 1812–16). His collected works, with a memoir by J. G. Playfair, were published at Edinburgh (4 vols. 1822).

PLAYFAIR, LYON PLAYFAIR, 1st Baron (1818–1898), was born at Chunar, Bengal province, on May 21, 1818, and educated at St. Andrews, Glasgow, Edinburgh, University College, London, and under Liebig at Giessen, where he took his doctor's degree. Playfair translated into English Liebig's *Chemistry of Agriculture.* From 1841–42, he was chemical manager of the Primrose print-works at Clitheroe, and in 1843 was elected honorary professor of chemistry to the Royal Institution of Manchester. Soon after he was appointed a member of the Royal Commission on the Health of Towns, a body whose investigations may be said to have laid the foundations of modern sanitation. In 1845 he was appointed professor in the new School of Mines, and chemist to the geological survey, and thenceforward was constantly employed by the public departments in matters of sanitary and chemical inspection. For his services as special commissioner of the 1851 Exhibition, he was made C.B. From 1856 to 1869 he was professor of chemistry at Edinburgh University. In 1868 he was elected to represent the universities of Edinburgh and St. Andrews in parliament, and retained his seat till 1885, from which date until 1892 he sat as member for Leeds. In 1873 he was made postmaster-general, and in the following year, after the dissolution of parliament, was made president of a commission to inquire into the working of the civil service. Its report established a completely new system, known as the "Playfair scheme." From 1880, when Gladstone returned to power, till 1883, Playfair acted as chairman of committees. In 1892 he received a peerage, and in 1895 the G C.B. He died in London, on May 29, 1898, and was buried at St. Andrews. He published a volume, *Subjects of Social Welfare.*

A memoir by Sir Wemyss Reid was published in 1899.

PLAYFAIR, SIR NIGEL (1874–1934), actor and theatrical manager, was born in London on July 1, 1874. Educated at Harrow and at University college, Oxford, he acted with the Oxford University Dramatic Society. For some time he practised as a barrister. On July 30, 1902, he made his first appearance as a professional actor at the Garrick theatre, London, in "A Pair of Knickerbockers." He was chiefly associated with the Lyric theatre, Hammersmith, London, the management of which he assumed in 1919. Among his most famous productions at this theatre were John Drinkwater's *Abraham Lincoln* (1919) and the revival of Gay's *Beggar's Opera* (1920) which ran for over three years. He published *The Story of the Lyric Theatre, Hammersmith* (1925), and other works. He was knighted in 1928.

PLAYFORD, JOHN (1623–*c.* 1686), English musical publisher, was born at Norwich. From 1653 he was clerk to the Temple church, and from his shop in the Inner Temple issued most of the English music of his day. Of his own compositions the chief are numerous psalm tunes, the popular *Introduction to the Skill of Musick* (1654, 19 ed. 1730) and *The Dancing Master* (1650), a collection of airs for the violin used for country dances which constitute an invaluable treasury of English national tunes.

See F. Kidson, *British Music Publishers.*

PLAY IN ANIMALS. Play is illustrated by kittens with their ball, puppies and their sham-hunt, lambs and their races, monkeys and their "follow-my-leader." There are often sham-fights among birds which seem to be entirely playful, besides exhibitions of flying powers that have no direct usefulness. For it is one of the criteria of play that it is not directly useful. Play is not work, though it may be as strenuous and may lead to exhaustion; it is not mere exercise, though, perhaps, it exercises best; it has no deliberate (or, in animals, perceived) end, for the sake of which it is played, yet it may be almost indispensable if the animal is to attain to the full use of its powers. Play is not necessarily social, for many a kitten plays alone; and it is not necessarily competitive, though rivalry may give it zest. Its key-note is its anticipation of modes of activity characteristic of adult life.

Play is well illustrated by many young carnivores, such as cats, dogs, foxes, otters and bears; by many young ungulates, such as

Lambs, kids, caives and foais; by most monkeys, and by less familiar cases like young squirrels and water-shrews. Yet it cannot be said to be a general feature in the youthful life of mammals. It is not common among birds; it is only hinted at in reptiles, amphibians and fishes; and it is at most incipient among backboneless animals. This raises the question why a playing period should be interpolated in the life-history of only a small minority. There must be some particular biological advantage in play, yet one which only certain types have been able to secure.

Uses **of** Play.—The poet Schiller suggested that animal play is an expression of overflowing energy. But while this theory has its grain of truth, it is far too simple. Thus there are many young animals with abundant vigour that never play; and it is well known that a thoroughly tired animal, such as a dog, may turn in a moment from fatigue to play, as children often do. Moreover, half the problem is that different types of mammals play in characteristic or specific ways.

Schiller's theory of play was re-expressed by Herbert Spencer with the important additional suggestion that imitation accounts for the particular form that the playing takes. The physiological condition of play is superfluous energy, but imitation defines the channel of expression. Young creatures mimic in play what they see their seniors doing in earnest. Here again there is some truth, and corroboration may be found in the imitativeness of certain forms of playing in children. But Spencer's theory will not cover the facts. Thus an isolated young animal, such as a kitten, will play, and will play true to type, provided that an appropriate liberating stimulus, apart from imitation, is supplied at an appropriate time. But if a kitten reaches a certain age—usually about two or three months—without having had any experience of mice, it will not afterwards show any "mousing instinct," nor any capacity for playing with a mouse.

A third idea has some relevance, namely the close correlation between pleasant emotions and bodily movements. It is a familiar fact of experience, elaborately studied by the physiologists and psychologists, that pleasant feelings reverberate in various parts of the body, such as the heart, lungs, larynx, food-canal and bladder. The correlation of emotional excitement and activity of the suprarenal bodies is well known. But to the internal movements there may be added movements of the body as a whole, and these will be naturally specific for different types. The child dances with joy; the otter cub gambols exuberantly. This simple movement-play may be a useful safety-valve, but it is also a natural expression of overflowing *joie-de-vivre.*

To Karl Groos we owe the illuminating suggestion that play is important as an irresponsible apprenticeship to the subsequent business of life. It is the young form of work, and this accounts for its specificity. The young carnivore has its sham hunt, the young ungulate its amateurish race, neither involving serious responsibilities. Under the shelter of parental or communal care the playing animal educates powers essential in after-life, and is afforded opportunities without the serious consequences involved whenever the struggle for existence sets in keenly. As Groos puts it, animals do not play because they are young; they continue young in order that they may play. No doubt non-playing young animals also educate their capacities, but the point is that the interpolation of the play-period is an additional advantage which some plastic and well-endowed creatures have been able to secure for themselves. It is interesting that most of the mammals man has succeeded in domesticating are playing mammals.

Another aspect of the play-period is that it affords opportunity for testing new variations before the struggle for existence sieve becomes too fine in the mesh. Play affords elbow-room for new departures. and its value is particularly clear when the adult life is very varied, like an otter's, demanding plasticity and resourcefulness. Here there is a marked contrast between games, which are restricted to mankind, and play, which children share with young animals. For the game has its rules and demands self-subordination, whereas play is spontaneous and allows of idiosyncrasies and experimentation. From the biological point of view it is clear that human games cannot fulfil all the functions of play.

According to Groos there is no general "instinct to play"; it is enough to suppose that each type of playing animal has its inborn or instinctive system or pattern of predispositions towards particular types of adult activity, and that the young are peculiarly sensitive to liberating stimuli. Play implies not only susceptibility, but precocity and plasticity. It secures a certain freedom for initiative before habituation sets in. And this, as has been said, is of especial value when the adult life demands considerable versatility. In such cases, the animals that play best are also likely to work best.

Types **of** Play.—If play is anticipatory of future work, the different kinds of play will correspond to the chief activities of adult life. (a) Many forms of play are of the nature of experiments in locomotion, as in aimless racing, rival jumping, riotous gambolling and feats of climbing or of flying. Here one pictures the behaviour of lambs, kids, calves, young antelopes, young chamois, foals, young squirrels and young monkeys. (b) On another line is sham-hunting, in which the young animal chases some moving object irrespective of all utility. A leaf blown by the wind or a ball of grass will pull the trigger as effectively as a small animal, The mother sometimes aids and abets, and here play may coalesce with education *(see* ANIMALS, EXPERIMENTS *OK).* The kitten's play with the mouse, often absurdly misinterpreted as "delight in torture," is paralleled in many other young carnivores. It is justified in the present by the repetition of pleasurable excitement, and in the future by the increased dexterity it develops. When the mouse-play is exhibited by cats of mature years, and apart from their education of their kittens, it is probably a relapse into youthful play, illustrated less poignantly in some other adults. (c) **A** third form of play is the sham-fight, familiar in puppies. It has been described among lions, tigers, hyenas, wolves, foxes, bears and other carnivores; among lambs, kids, calves, foals, antelopes and other ungulates. It is also common among birds. Care must be taken to keep the sham-fight distinct from the combats of rival males, the first hints of which may begin early, as in bull-calves. And even apart from sex, it is not always easy to distinguish the sham-fight from serious combativeness. In his description of the behaviour of two young gluttons, Brehm says that nothing could be more playful, they were hardly at a rest for a minute, but every now and then the note of earnest was struck. Very curious, considering the level at which they occur, are the so-called sham-fights which several good observers have described among ants. There is energetic wrestling and the like, but no discharge of poison or actual wounding. *(d)* Perhaps one may recognize another type which may be called playful experiment, when animals test things, often pulling them to pieces; or test themselves, often performing interesting but useless feats; or test their neighbours, discovering how they will respond to sundry provocations. The difficulty is to distinguish these playful experiments from the ways in which many well-endowed young animals feel their way about in their environment. But Hamerton describes how his young goats would spend hours in jumping in and out of a basket, or would try to upset the artist by getting under his seat, or would tease the big dog to the limit of his endurance.

Along this line the subtlest forms of play are found in apes, where experimenting may go far, and sometimes become sheer mischief. Chimpanzees often show what looks like delight in being a cause, and an entirely useless activity may be repeated over and over again. Thus a chimpanzee will entice a hen with bread, and pull the reward away at the last minute, repeating the trick many times with evident gusto. Or it will attract a hen close to the cage and then give her a sudden poke with a stick when she is preoccupied with her food. This seems almost like a joke.

Of interest are those cases where playing or something like playing is continued long after youth is past. This is familiar in domestic dogs, but is also exhibited in natural conditions, for instance by the otter. This extension of play may be sometimes associated with the mother's habit of playing with successive litters of young ones year after year. But this interpretation does not apply to all cases, for instance to the communal playing of full-grown penguins on the sea-ice. Thus Murray Levick has described the diving play in which the succession of birds may be so rapid "as to have the appearance of a lot of shot poured out of a bottle into the water." A favourite activity was to board an ice-floe till it would hold no more, and get carried by the tide to the lower end of the rookery, where every bird would suddenly jump off and swim back against the stream to catch a fresh floe and get another ride down. An adult snake-bird (*Anhinga*) has been seen playing catch with twigs, an activity obviously correlated with its dexterity of head and neck in catching fish. Many birds have flight games; the "shooting" and tumbling of rooks and herons, and the turning upside-down of ravens may be specially mentioned. It seems impossible to restrict the idea of play to youth.

But in general play is a mode of behaviour characterizing the youthful period of certain well-endowed animals, a precocious exhibition of activities more or less anticipatory of those characterizing adult life, but not in themselves of direct utility. Its biological significance is partly as a safety-valve for overflowing energy, partly as an early expression of imitativeness, partly as a correlate of pleasant feelings, but mainly as an irresponsible apprenticeship to adult activities and an opportunity for testing new departures, especially in habit.

***Restrictions of* Play.**—Since these characteristics of typical play are tolerably well-defined, it is undesirable that the concept should be blurred by a vague and loose application of the term. The following restrictions may be suggested: (1) The term play should not be used for the idle movements of animals, such as insects and fishes, unless there is evidence that these are serving as an apprenticeship. Gregarious swimming on the part of cuttle-fishes and fishes, gregarious flying on the part of insects and birds, may have no utility, and yet hardly deserve the name of play.

(2) It is undoubtedly difficult to draw the line, but it seems useful to try to exclude from typical play all activities bound up with sex-display or courtship. For while these resemble play in being artistic and spontaneous expressions of individuality, they have an immediate outcome: they serve to arouse sex interest and sex desire, whereas typical play never has any immediate reward. If it seem impossible to draw a line between play and display, it might conduce to clearness if the word, sex, were used as a prefix. Thus' one might use some phrase such as courting dance for many of the extraordinary displays that birds make at the breeding season (see BIRD, *Reproductive* Habits; COURTSHIP OF ANIMALS). W. H. Hudson portrays the dance of the cock-of-the-rock (*Rupicola*) of tropical South America: "A mossy level spot of earth surrounded by bushes is selected for a dancing-place, and kept well-cleared of sticks and stones; round this area the birds assemble, when a cock-bird, with vivid orange-scarlet crest and plumage, steps into it and, with spreading wings and tail, begins a series of movements as if dancing a minuet; finally, carried away with excitement, he leaps and gyrates in the most astonishing manner, until, becoming exhausted, he retires and another bird takes his place." This strikes a note quite different from that sounded in the races of lambs and kids, wild foals and asses, or "tag" and "follow my leader" among monkeys.

(3) It is part of the essence of play that it is not directly useful, but has a prospective value in educating efficiency. But not a few animals with abundant spare energy and initiative are known to indulge in occasional adventures which, though they can hardly be called other than playful, have no prospective meaning. Some of the experiments of apes, to which we have already referred, may illustrate this kind of behaviour, and should perhaps be called tricks rather than play. True play is characteristic of a species and is neither occasional nor individual. A naturalist relates that on one occasion, when botanizing on the Alps, his dog ceased to follow him on the graduated path, and was seen to choose a more direct slope of hard snow. There he lay down on his back, folded his legs and slid down like a toboggan. At the foot he looked up at his astonished master and wagged his tail! No conclusion can be based on single instances, however well documented, but we cite this case as an instance of probable misinterpretation. The observer supposed that the dog had thought out a short cut—an unnecessarily generous view; others have called it a piece of play. But the probability is that it was a casual adventure, such as may be reasonably put to the credit of many a well-endowed animal. Similar instances are known at much lower levels of intelligence. The ecological concept of animal play is most useful when employed in the strictest sense, as already defined. (See ANIMAL BEHAVIOUR; PSYCHOLOGY, COMPARATIVE; SEXUAL SELECTION.)

PLEADING: see PRACTICE AND PROCEDURE.

PLEASANTVILLE, a city of Atlantic county, New Jersey, U.S.A., 5 mi. W.N.W. of Atlantic City; served by the Pennsylvania and the Reading railways. Pop. (1930) 11,580; (1940) 11,050.

PLEASURE: see FEELING, PSYCHOLOGY OF; HEDONISM; ETHICS.

PLEBISCITE, a term borrowed from the French for a vote of all the electors in a country or given area taken on some specific question. The most familiar example of the use of the plebiscite in French history was in 1852, when the coup *d'état* of 1851 was confirmed and the title of emperor was given to Napolean III. Its essential characteristic, as distinguished from the referendum (*q.v.*), is this:—A plebiscitary vote decides a specific question, ad *hoc* and pro *hac* vice. It is not, as in the case of the referendum, a normal method or procedure of voting applied on a general system to certain classes of legislation. It is sometimes used in England to decide questions of municipal rates or other local questions, and extensively in the Dominions and the United States on certain local or State questions. In Europe its use has been almost wholly political and national.

In that sense it is a method of ascertaining the general desire of the inhabitants of a given territory or area. As a means of settling the destination of populations and territories, this method was first used in the French Revolution to defend the wholesale annexations of territory made by the conquering French Republic, and subsequently by Napoleon I. It was revived by Napoleon III. and applied (successfully for him) in the case of Nice and Savoy, and (successfully for Victor Emmanuel) in the duchies of north Italy during the years 1859–60.

The Peace Conference of 1919 proposed the taking of 17 plebiscites to settle difficult national questions of which eight were actually held. Of these the Turkish plebiscite in Transcaucasia was a farce. Others, which decided the fate of Allenstein Marienwerder, of the Burgenland, of Klagenfurt, the economic destiny of Luxembourg, the attribution of the northern and southern zones of Slesvig, and the partition of Upper Silesia had substantial and important results, which are noted elsewhere under the individual articles, The Versailles Treaty provided for a plebiscite of the Saar district in 1935 to decide the future of the region.

Temperley, ed., *A History of the Peace Conference of Paris* (1920); references in Subject Index to vol. vi., 703; *Plebiscites* in Historical Section of Foreign Office Peace Handbooks; Sarah Wambaugh, *A Monograph on Plebiscites*, Carnegie Endowment for International Peace (1920); Sarah Wambaugh, *La Pratique des Plébiscites*, Recueil des Cours de l'Academie de Droit International; F. Llewellyn Jones, *Plebiscites*, Grotius Society Transactions (1927).

PLEBS, the "multitude," or unprivileged class in the early Roman state (from the root *pleo*, seen in Latin *plenus*, fill; cf. Gr. πλῆθος). For the origin and history of this order see PATRICIANS. Its disqualifications were originally based on descent, but after the political equalization of the two orders these ceased.

PLECOPTERA (Gr. πλέκος plaited, and πτερόν, a wing) is that order of insects which comprises the stone-flies: by some authorities they are termed Perlaria from *Perla*, the principal genus. Stone-flies are dull coloured insects, either black, brown or grey, or in some species green. They are poor fliers and do not wander far from water where their early stages are passed. Their habitation is the margins of streams and lakes, especially in hilly or rocky districts and they are usually found resting on stones, palings or tree-trunks, or crawling about over stones or plants: the green forms frequent bushes or other herbage and are difficult to detect. Fewer than 500 species are known and these are classified into seven families: about 30 species inhabit the British Isles and a considerably larger number is found in the United States. The richest fauna is found in the southern hemisphere and the earliest forms are confined to the Australian region and Chile.

Stone-flies are soft-bodied insects with long thread-like antennae: the wings are membranous, folded flat over the back in repose and the hind pair is usually the largest with a plicated posterior lobe. The mouth-parts are weak and of the biting type, the tarsi are three-jointed and the body is generally terminated by long, many-jointed tail-feelers. These insects derive their name from the fact that their nymphs are often common beneath stones in the beds of streams. The females discharge their eggs in masses into the water: metamorphosis is incomplete and the nymphs only occur in clear, unfouled streams or lakes, not in stagnant water. Some are carnivorous, while others feed upon organic particles of various kinds. In form they resemble the perfect insects very closely except for the absence of wings: they are provided with lateral tufts of abdominal tracheal gills or with a terminal group of these organs around the anus. When fully grown the nymph crawls out of the water and the imago emerges. A few Plecoptera in the fossil condition are met with in the Upper Jurassic rocks of Europe, and in the Lower Permian of Kansas.

The nymphs serve as food for certain fishes, such as trout, and are in that respect valuable. The species Taeniopteryx *pacifica,* has been recorded as damaging the buds of fruit trees in Washington State.

Further information on these insects will be found in works on aquatic insects (see INSECTS), while for the British species see papers by K. J. Morton in Trans. *Entomological Soc.* London (1894, 1896). The North American species are dealt with by J. G. Needham and C. P. Claassen, The Plecoptera or Stone-Flies of North America (1925), and for the general classification of the order see R. J. Tillyard, Canadian *Entom.* (vol. liii., 1921). (A. D. I.)

PLECTRUM, a small contrivance, made of metal, wood or some other suitable material, and used as a substitute for the finger in plucking the strings of musical instruments. In ancient times the strings of the lyre were sometimes so plucked, while later the lute was similarly played, as are the mandolin and zither to-day; the same term being applied also to the quills and bristles of the harpsichord and spinet.

PLEDGE or **PAWN,** in law, a "bailment of goods by a debtor to his creditor to be kept till the debt is discharged" (Jones on Bailments). The term is also used to denote the property which constitutes the security. Pledge is the *pignus* of Roman law from which most of the modern law on the subject is derived. It differs from hypothecation and from the more usual kind of mortgage in being confined to personal property, and also in that the pledge is in the possession of the pledgee. A mortgage of personal property, in the majority of instances, takes the name and form of a bill of sale (*q.v.*). In the case of a pledge, it is held that a special property passes to the pledgee, sufficient to enable him to maintain an action against a wrongdoer, but the general property, *i.e.,* the property subject to the pledge, remains in the pledgor. As the pledge is for the benefit of both parties, the pledgee is bound to exercise only ordinary care over the pledge. He must, however, insure against loss by fire (35/36 Vict. ch. 93, s.36). The pledgee has the right of selling the pledge if the pledgor makes default in payment at the stipulated time.

The law of Scotland as to pledge generally agrees with that of England, as does also that of the United States. The main difference is that in Scotland and in Louisiana a pledge cannot be sold unless with judicial authority. Chattel mortgages, which differ from pledges in that the owner retains possession of the article, are uniformly required to be recorded in order to be valid against third parties, but except for a few States and aside from the Factors acts, a pledge, for the validity of which possession must be transferred to the pledgee, will be enforcible against third parties without being recorded. (See also FACTORS and PAWNBROKING.)

PLEHVE, VIATSCHESLAF KONSTANTINOVICH (1846–1904), Russian statesman, was born of Lithuanian stock in 1846. He was educated at Warsaw and at the university of St. Petersburg (Leningrad) before he entered the department of justice, in which he rose rapidly to be assistant solicitor-general in Warsaw, then solicitor-general in St. Petersburg, and in 1881 director of the state police. As assistant to the minister of the interior he attracted the attention of Alexander III. by the skill he showed in investigating the circumstances of the assassination of Alexander II. He received the title of secretary of state in 1894, became a member of the council of the empire, and in 1902 succeeded Sipiaguine as minister of the interior. Plehve carried out the "russification" of the alien provinces within the Russian Empire, and earned bitter hatred in Poland, in Lithuania and especially in Finland. He despoiled the Armenian Church, and oppressed the Armenians of the Caucasus. He certainly did nothing to discourage pogroms against the Jews, and he was credited with being accessory to the Kishinev massacres. His logical mind and determined support of the autocratic principle gained the tsar's entire confidence. He opposed commercial development on ordinary European lines on the ground that it involved the existence both of a dangerous proletariat and of a prosperous middle class equally inimical to autocracy. He was a determined and successful opponent of Witte's policy. An attempt was made on his life early in 1904, and he was assassinated on July 28 of the same year by a bomb thrown under his carriage as he was on his way to Peterhof to make his report to the tsar; the assassin, Sasonov, was a member of the socialist revolutionary party.

PLEIAD, in Greek literature, the name given (by analogy from PLEIADES) by the Alexandrian critics to seven tragic poets who flourished during the reign of Ptolemy Philadelphus (285–247 B.C.). In French literature, in addition to the Pleiad of Charlemagne, there were two famous groups of the kind. The first, during the reign of Henri III. (1574–89), the chief member of which was Pierre de Ronsard, sought to improve the French language and literature by enthusiastic imitation of the classics; the second, under Louis XIII. (1610–43), consisted of authors who excelled in the composition of Latin verse.

PLEIADES, the constellation so called is in mythology the seven daughters of Atlas and Pleïone, and sisters of the Hyades. Owing to their grief at the death of their sisters or at the sufferings of their father, they were changed into stars. In another account, the Pleiades and their mother met the amorous hunter Orion (*q.v.*) in Boeotia; for five years he pursued them through the woods, until Zeus translated them all—Pleïone and her daughters, Orion and his dog—to the sky. This is one of the few myths really astronomical in origin, for it is based on the relative positions of the constellations in the sky. The names of the sisters are Alcyone, Asterope, Electra, Kelaine, Maia, Merope, and Taygete (Hesiod fr. 275 Rzach); one is always dim or invisible, because she is Electra mourning for Troy, or Merope, who is ashamed of having wedded a mortal, Sisyphus. All the Pleiades became the ancestresses of divine or heroic families. The spring rising and early winter setting of the Pleiades (Lat. *Vergiliae*) are important dates to the farmer.

See H. J. Rose, Handbook of Greek Mythology (1928).

The stars are situated in the constellation Taurus. They are supposed to be referred to in the Old Testament (Job ix. 9, xxxviii. 31). The brightest star is Alcyone (3rd magnitude); Pleïone and Atlas are also of the 3rd magnitude. This group is physically connected, being distinguished from the background stars by community of proper motion. Photographs show a faint nebulosity filling the whole region; there is little doubt that this is rarefied matter made luminous by stimulation of the radiation of the hot stars comprised in it. The distance of the Pleiades is estimated at 100 parsecs (300 light-years), but is not very certainly known. Alcyone and the other bright stars are of the hottest type of spectrum (Type B), and give out several hundred times as much light as the sun.

PLEISTOCENE (Gr. *πλεῖστον*, most, and *καινός*, recent), in geology the epoch which succeeded the Pliocene. The Pliocene is now usually considered the last of the Tertiary period and hence the Pleistocene forms the lower subdivision of the Quaternary era. The period saw the arrival of the great Ice age (see GLACIAL

PERIOD) and the Pleistocene and Glacial period are sometimes used as if synonymous. The general geology of the period is considered under QUATERNARY.

PLEKHANOV, GEORGY VALENTINOVITCH (N. BELTMAN) (1857–1918), the founder and for many years the chief exponent of Russian philosophic Marxism, was born on Nov. 26, 1857, in the province of Tambov, of an old noble family. His father wished him to enter the army, but while a student he joined the Narodnist (populist) revolutionary movement. In 1876 he led the first great popular demonstration at St. Petersburg (Leningrad) in the Kazansky square. When the majority section of the Narodnists adopted terrorist methods in 1879, Plekhanov seceded, and with Deutsch, Axelrod, Vera Sassulitch and Ignatov, formed the Marxist "Liberation of Labour" group in Geneva (1883). He spent 40 years in exile, chiefly at Geneva, from which town he became the intellectual leader of the Russian Social-Democratic movement, in particular playing a large part in Lenin's early mental development. In the '90s and the early years of the 20th century the two men were closely associated. In Dec. 1900 was founded the S.D. journal Iskra (The Spark) of which Plekhanov was joint editor with Lenin, Martov, and others. In the first split of the Russian S.D. Party in 1903 Plekhanov was largely on the side of the Bolsheviks, holding views closely akin to those of Lenin.

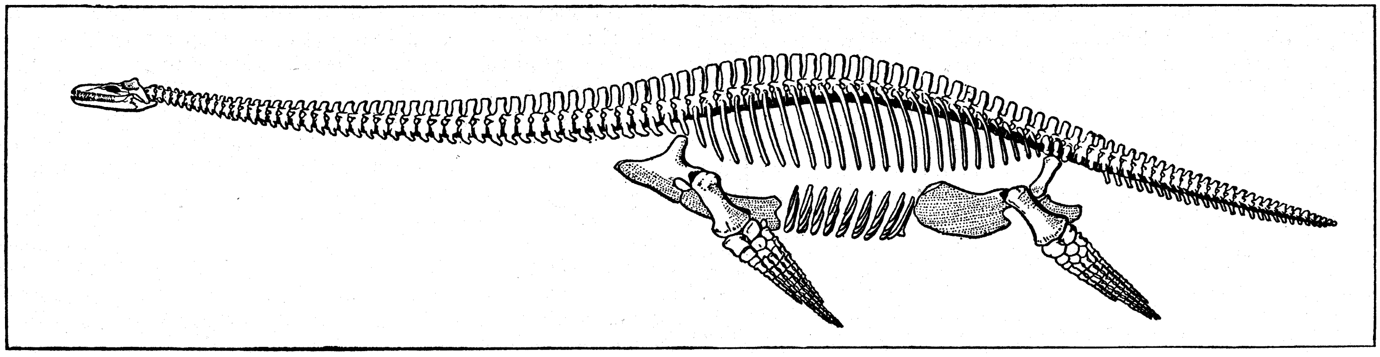
After the resignation of the Mensheviks from editorship of the Zskra Plekhanov and Lenin were joint editors, but some months later differences arose between them on the question of collaboration with the Mensheviks, and Lenin resigned. Thenceforth for several years Plekhanov worked with the Menshevik section of the party, but after 1907, while remaining a Menshevik, he took up an attitude on many issues, particularly on the question of participation in the State Duma and also on illegal activities, in agreement with that of the Bolsheviks. At the end of 1910 he again co-operated with the latter in contributing to the Bolshevik *Zviezda* (The Star) but the alliance did not last long, and when the war broke out in 1914 Plekhanov was foremost in advocacy of the principle of "revolutionary defence" of the country against the Bolshevik policy of working for the defeat of the Government. After the March revolution he returned to Russia and was invited to join the Provisional Government. He refused, but actively supported the Government against the Bolsheviks, and remained an opponent of the Bolshevik revolution until his death in Finland on May 30, 1918.

Plekhanov had an enormous influence on the development of the Socialist movement in Russia. The Moscow Marx-Engels Institute has published a complete edition of his works in 26 volumes. His biggest work is available in German: *Beiträge zur* Geschichfe des *Materialismus*.

PLENER, ERNST, FREIHERR VON (1841–1923), Austrian politician, was born on Oct. 18, 1841, at Cheb in Bohemia, the son of the Austrian statesman Ignaz von Plener (1810–1908). From 1888 onwards he was the acknowledged head of the German Liberals in their struggles against the Slav-Conservative majority in the Chamber. Consequently he represented Germanism on the nationalities question, but was not averse to concessions compatible with the maintenance throughout the whole monarchy of the position due to the German Austrians. He sought to compromise the quarrel between Germans and Czechs, and the so-called "points" of 1890, a summary of the bases for a German-Czech understanding, were essentially his work. In the Windischgratz Coalition Ministry (1893–5), Plener took over the portfolio of Finance. Soon after his retirement from the Finance Ministry, Plener was appointed president of the Supreme Audit Department (Oberster *Rechnungshof*). He entered the Upper House in 1900, and died on May 1, 1923.

Plener wrote a series of economic and political works, among others *Die englische Fabriksgesetzgebung* (1871); *Englische Baugenossenschaften* (1873). He published *Erinnerungen,* 3 vol. (1911–21).

PLESIOSAURUS, technically the name of a genus of extinct reptiles of the group Sauropterygia; it is commonly used to apply to all the later members of that group. The typical plesiosaurs are completely adapted for a marine existence in the open sea.



FROM THE "CATALOGUE OF MARINE REPTILES OF THE OXFORD CLAY"

SKELETON OF MURAENOSAURUS, A LONG NECKED PLESIOSAUR. FROM THE OXFORD CLAY OF PETERBOROUGH, ENGLAND

They first appear in the Rhaetic and are last seen in the Upper Cretaceous. A typical plesiosaur has a small head with a large mouth and slender pointed teeth adapted to the catching of fish. The neck is long, often four times as long as the head. The body is relatively short, as is the tail. All four limbs are converted into paddles, no external trace of the fingers being visible.

From these forms two main evolutionary lines appeared. In one, the animals adopted the habit of living on large prey which they captured by their superior speed; in this line the head grew bigger and the neck shorter until it became no longer than the head. The body is comparatively long, the tail little more than the pointed hinder extremity of the body. The paddles become very large indeed, the hinder pair being bigger than the front ones. The largest members of this group are the plesiosaurs from the European Jurassic. In them the skull may be'nearly 6 ft. in length and an individual tooth a foot long. In an animal whose head was just under 5 ft. in length the whole creature had a length of some 16 ft., and the hind paddles were about 5 ft. long.

The other line consists of animals which fed on small quick-moving prey which they seem to have captured by sudden lateral movements of the head and neck. Its most recent member, *Elasmosaurus,* is found in the Upper Cretaceous of Kansas, England, Queensland and New Zealand. In it the head is about 18 in. in length, the neck with as many as 76 vertebrae may reach a length of 19 ft., and the total length of the animal about 30 ft. The paddles of such an animal were about 3 ft. in length. Some plesiosaurs had the interesting habit of eating pebbles which were kept in the stomach to assist in grinding up food. Although the majority of plesiosaurs were marine, some few are always found in estuaries or freshwater deposits. See REPTILES.

(D. M. S. W.)

PLEURISY or **PLEURITIS.** A medical term for inflammation and the effects of inflammation affecting the pleura (see COELOM AND SEROUS MEMBRANES). Pleurisy may be induced mechanically, *e.g.,* by a blow, but more commonly is the result of microbial infection whether conveyed directly by the blood (as in scarlatina) or extending to the serous membranes from an inflammatory focus in the lung or adjacent part.

The condition may be acute or chronic. In acute pleurisy the normal glistening appearance of the serous membrane is lost, it becomes injected with blood, roughened from the deposition of fibrin from the serum that exudes from the dilated and inflamed blood vessels and so long as the two surfaces are in contact occasions much pain from friction during respiration. The amount of serum poured out into the pleural cavity and the amount of fibrin formed vary within wide limits. The fluid may accumulate to such an extent that there is bulging outwards of the intercostal spaces and the lung is rendered airless and compressed at the back of the pleural cavity close to the vertebral column. The fibrin may form a thick white felty layer over the entire lung.

The subsequent history of a pleurisy varies. If the effusion of fluid causes respiratory or cardiac distress surgical removal (thoracentesis) of a portion of the fluid is necessary; lymphatic and venous drainage are effective in removing the remainder. There may then be complete recovery, the compressed lung resuming its function if it has not been left compressed too long. In other cases fibrous adhesions, formed by the same process as that which leads to scar tissue (see PATHOLOGY) bind the two layers of the pleura together over a greater or less extent of their surface. The condition is then one of chronic pleurisy and recrudescences of inflammation with local pain and effusion of fluid may occur. If the pleurisy arise by extension from a pulmonary, diaphragmatic, costal or pericardial focus of disease its character is determined by that of the primary focus. If tuberculous, tuberculous nodules are found in the thickened material covering and replacing the normal serous membrane; if malignant disease the nodules are cancerous and the fluid often contains many red blood cells; while if the primary focus be that form of pneumonia which is caused by the pneumococcus and is characterized by the local output of numerous leucocytes, the pleurisy will be similar and frequently purulent (see EMPYEMA).

The symptoms and signs of pleurisy present difficulty. Where the patient complains of a sharp pain in the side especially on drawing a deep breath, the normal resonant note on percussion of the chest is replaced by a dead, dull note, the breath sounds are barely audible and the ear applied to the chest detects a rubbing sound, a diagnosis of pleurisy is easy. But the relative infrequency of these phenomena and the very great frequency with which pleural adhesions, often of wide extent, are found in the post-mortem room without the slightest indication that the patient during life complained of symptoms such as the appearances would seem to suggest, indicate that pleurisy is often symptomless. The inference is that pleurisy is very common, but comparatively rarely calls for medical or surgical treatment.

Treatment. — In many cases strapping of the affected side to limit movement is sufficient; where effusion becomes purulent and thoracentesis will be insufficient, a wide opening into the pleural cavity with removal of portions of one or more ribs to provide drainage becomes necessary. (W. S. L.-B.)

PLEURONECTIDAE, the family of fishes to which the name "flat-fish" is popularly applied. It includes the sole, flounder, turbot and plaice (*qq.v.*). (See FISHES.)

PLEURO-PNEUMONIA or **LUNG-PLAGUE,** a contagious disease peculiar to the bovine species generally affecting the lungs and pleura, producing a particular form of lobar or lobular pleuro-pneumonia, and, in the majority of cases, transmitted by the living diseased animal, or, exceptionally, by mediate contagion. Cattle and closely allied species are susceptible; other animals and man are immune. Inoculation of healthy cattle with the fluid from the diseased lungs produces, after a certain interval, characteristic changes at the seat of inoculation, and though the inoculated animal does not develop the lung lesions always observed in natural infection, yet there is a local anatomical similarity or identity. In 1888 Arloing, of Lyons, described various bacilli obtained from the lesions of lung-plague. The cause is now held to be a polymorphic micro-organism capable of passing through ordinary bacterial filters. With a high magnification, coccal-like bodies, vibrios, short spirilla, branching and asteroid bodies, also mycelioid moulds may be seen. Fine mucin coverings are always present and for the latter reason the name Asterococcus mycoides was formulated by Borrel.

The earliest notices of this disease testify that it first prevailed in Central Europe, and in the 18th century it was present in certain parts of Southern Germany, Switzerland and France, and had also appeared in upper Italy. In 1769 it was definitely described as prevailing in Franche-Comté by the name of "murie." From that date down to 1789 it appears to have remained more or less limited to the Swiss mountains, the Jura, Dauphiné and Vosges, Piedmont and upper Silesia; it showed itself in Champagne and Bourbonnais about the time of the Revolution, when its spread was greatly accelerated by the wars that followed. In the 19th century its diffusion was accurately determined. It invaded Prussia in 1802, and soon spread over north Germany. It was first described as existing in Russia in 1824; it reached Belgium in 1827, Holland in 1833, the United Kingdom in 1841, Sweden in 1847, Denmark in 1848, Finland in 1850, South Africa in 1854, the United States — Brooklyn in 1843, New Jersey in 1847, Brooklyn again in 1850, and Boston in 1850; it was also carried to Melbourne in 1858, and to New South Wales in 1860; New Zealand and Tasmania in 1864; and also into Asia Minor. During the 20th century it has occurred in Asia, Africa, Australia, South America, Russia, Germany, France and Spain.

It has now been eradicated, or the incidence very much reduced, in most countries by compulsory slaughter and veterinary police measures. Great Britain has been free since 1898.

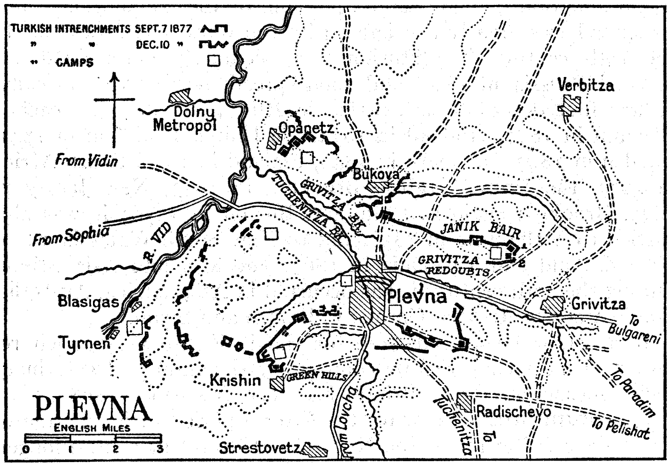
Symptoms and Treatment. — After a period of incubation of 12–16 days (after inhalation Nocard and Roux) or a little longer, loss of appetite and fever are apparent, accompanied by a dry, painful cough, which later becomes more frequent and moister. Pulse and respiration are accelerated with the customary signs of acute pulmonary disease. Generally the disease persists for some weeks before death supervenes, or apparent recovery ensues, with a later recrudescence of symptoms. High temperature with death in a few days is less common. Recovered cases should be regarded with suspicion.

Willems of Hasselt (Belgium) 1852 introduced protective inoculation, employing lymph obtained from a diseased lung; since that date the protective value has been proved in the field. Not entirely free of danger, the method appears to confer a temporary immunity. The inoculation is made in the extremity of the tail. In France, Nocard and Roux have used as a vaccine, an eight days' old culture of the virus in Martin's broth. Injected in the same manner, the method has given good results. An anti-serum, capable of conferring a passive immunity, has also been prepared. The disease is scheduled in Great Britain under the Diseases of Animals Act. (A. R. S.)

PLEVNA (Bulgarian Pleven), a city in Bulgaria; on the Tutchinitza, and Sofia-Varna railway (opened in 1899). Pop. (1934) 31,520. A branch line, 25 m. long, connects Plevna with Samovit on the Danube, where a port has been formed. After the events of 1877, it was almost entirely forsaken by the Turks, and most of the mosques have gone to ruin; but, peopled now mainly by Bulgarians, it has quite recovered its prosperity, and has a large commerce in cattle and wine (see Russo-TURKISH WARS).

Plevna, a small and unknown town without fortifications, became celebrated as the scene of Osman Pasha's exploits. He left Widin on July 13 with a column consisting of some 12,000 men and 54 guns. Hearing that he was too late to relieve Nikopol, he pushed on to Plevna, where there was a small garrison and on July 19 he took up a position on the bare hills to the north and east. He was none too soon. General Schilder-Schuldner, commanding the 5th division of the IX. corps, which had just captured Nikopol, had been ordered to occupy Plevna, and his guns were already in action. On July 20, having made no preliminary reconnaissance, the Russian commander advanced his infantry in four separate columns. On the north flank they pressed into Bukova, and also succeeded in driving back the Turkish right wing; but in both cases Turkish counter-attacks pressed back the Russians, with the result that by noon they were in full retreat, having lost 2,800 men out of a total of 8,000. The Turks lost 2,000. Osman at once drew up plans for the fortification of the position and the troops were employed night and day constructing redoubts and entrenchments. In order to secure his line of communications, he occupied Lovcha (Lovatz). The Plevna garrison had now been reinforced to 20,000. Trenches were 4 ft. deep and the redoubts had a command of 10 to 16 ft., with parapets about 14 ft. thick. There were in some cases two lines of trench to the front, thus giving three tiers of fire.

Second Battle **of Plevna.**—In accordance with orders from the Russian headquarters at Tirnova, a fresh attack was made by



MAP OF PLEVNA SHOWING TURKISH ENTRENCHMENTS DURING THE FIVE-MONTHS DEFENCE OF THE TOWN BY OSMAN PASHA AGAINST THE RUSSIANS IN 1877

Kriidener on July 30. He had been reinforced and his force numbered nearly 40,000 with 176 guns. After a preliminary cannonade the infantry advanced at 3 P.M., as before in widely spread columns. The columns attacking from the north and north-east were repulsed with heavy loss. Shakovskoi temporarily occupied two redoubts, but a counter-stroke by the Turkish reserves forced him back. The Russians retreated, their losses amounting to 7,300, while the Turkish losses exceeded 2,000. The victory was decisive, but Osman again failed to pursue. His troops were elated by success, the moral of the enemy severely shaken, the undefended Russian bridge over the Danube was within 40 m. of him, but he lost his opportunity, and contented himself with strengthening his defensive works. It is said that he was tied down to Plevna by orders from Constantinople.

The Russians now concentrated all their available forces against Plevna and called in the aid of the Rumanians. By the end of August they had assembled a force of 74,000 infantry, 10,000 cavalry and 440 guns. On August 30 Osman moved out of Plevna, and on the 31st attacked the Russians about Pelishat. He returned to Plevna the same evening. The Turks lost 1,300 and the Russians 1,000 men. The Russians determined to occupy Lovcha, and so cut Osman's communications before again attacking Plevna. After three days' fighting this was accomplished by Skobelev, acting under Imeretinski, with a force of 20,000 men, on September 3. Osman moved out to the relief of the garrison that day with a strong column, but, finding he was too late, returned to Plevna on the 6th. The survivors from Lovcha were re-formed into 3 battalions, including which Osman had been reinforced to a strength of over 30,000, with 72 guns.

Third Battle of **Plevna.**—The Russians moved to their preliminary positions on the night of September 6–7. Their plan was to attack the north-east, south-east and south fronts simultaneously. An artillery bombardment began at 6 A.M. on September 7, and was carried on till 3 P.M. on the 11th, when the infantry advanced. The Rumanians took one Grivitza redoubt; Skobelev occupied two redoubts on the south front, but the centre attack on the Radischevo front failed. On the 12th the Turks recaptured the southern redoubts, the Rumanians remained in possession of the Grivitza redoubt, but the Russian losses already amounted to 18,000 and they withdrew, and entrenched themselves on a line Verbitza-Radischevo. with cavalry on either flank to the Vid. The Turkish losses totalled 5,000, of which only a few hundred were caused by the artillery fire of the first few days. There was no question of pursuit. The Russians were greatly superior in numbers and the Turks were completely exhausted.

Investment and Fall of **Plevna.**—This was the last open-force attack on Osman's lines. General Todleben, the defender of Sevastopol, was now entrusted with the conduct of the siege, and he determined to complete the investment, which was accomplished by October 24, Osman's request to retire from Plevna having been refused by Constantinople. Supplies eventually gave out and a sortie on the night of Dec. 9–10 failed, with the result that he and his army capitulated.

Plevna is a striking example of the futility of the purely passive defence, which is doomed to failure however tenaciously carried out. Osman Pasha repelled three Russian attacks and practically held the whole Russian army. It remained for the other Turkish forces in the field to take the offensive and by a vigorous counter-stroke to reap the fruits of his successes. Victories which are not followed up are useless. (J. H. V. C.)

Langlois, *Lessons of Two Recent Wars* (Eng. trans., War Office, 1910); Th. von Trotha, *Kampf um Plewnu* (Berlin, 1878); Vacaresco (Ger. trans.), *Rumaniens Antheil am Kriege, 1877–1878* (Leipzig, 1888).

PLEYEL, IGNAZ JOSEPH (1757–1831), Austrian musician, was born at Ruppersthal, near Vienna, on June 1, 1757, the 24th son of a poor village schoolmaster. He studied the pianoforte under Van Hal (known in England as Vanhall), and in 1772 learned composition from Haydn, who became his dearest friend. He was appointed temporary *maître* de *chapelle* at Strasbourg in 1783, receiving a permanent appointment to the office in 1789. In 1791 he paid a successful visit to London. He narrowly escaped the guillotine on returning to Strasbourg, and was only saved by the existence of a cantata which he had written, and in which the inspiration could fairly be claimed to be on the side of liberty; so that he was permitted to remain until 1795, when he migrated to Paris. Here he opened a large music shop, published the first complete edition of Haydn's quartets, and founded, in 1807, the pianoforte manufactory which still bears his name. The latter years of his life were spent in agricultural pursuits. He died on Nov. 14, 1831, in Paris.

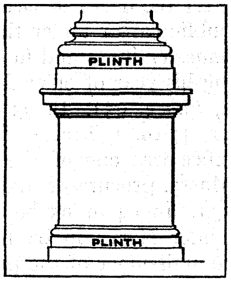
PLIEKSANS, JAN (1865–1929), Latvian poet and dramatist, was born on Sept. 12, 1865, at Tadenava in the district of Illulrst, Courland. He adopted the pen name of József Rainis. He was educated at the Riga gymnasium, and from 1884 to 1888 studied law at St. Petersburg (Leningrad). He then practised as a barrister at Mitau, Courland. From 1891 to 1895 he edited in Riga a democratic Latvian paper, Dienas *Lapa* (Daily Paper). He was arrested by the Russian Government on political grounds and remained in exile, first at Pskov and then at Viatka, until 1903. He may be considered the chief exponent of democracy in Latvian poetry. He translated plays from Shakespeare, Goethe and Schiller. His principal historical tragedies are Uguns *un* nakts (Fire and night), *Put vejini* (Blow *breeze*) and Daugava (The Dvina). The *Sons* of *Jacob* has been translated into English, and was produced on May 22, 1925, at the New Scala theatre, London, by the International Theatre Society. For several years he was director of the Latvian National Theatre, and in 1920 became member of the Latvian Saeima (parliament).

PLIMER, ANDREW (c. 1763–1837), English miniature painter, was the son of a clock-maker at Wellington. With his brother Nathaniel (1757–*c.* 1822) he joined a party of gipsies and wandered about with them, eventually reaching London, where in 1781 he was engaged by Mrs. Cosway as studio boy. Cosway sent him to a friend to learn drawing, and then received him into his own studio. In 1785 he set up lor himself in Great Maddox Street. He exhibited many times in the Royal Academy, resided ior a while in Exeter and travelled a good deal through England. He died at Brighton in 1837 and was buried at Hove His miniatures are of great brilliance and are in considerable demand among collectors. They are to he distinguished by the peculiar wiry-treatment of the hair and by the large full expressive eyes which Plimer invariably gave to his female sitters, eyes resembling those of his own wife and daughters. *See* G. C. Williamson, *Andrew and Nathaniel Plimer* (1903). (G. C. W.)

PLIMSOLL, SAMUEL (1824–1898), British politician and social reformer, was born at Bristol on Feb. 10, 1824. His efforts for reform were directed more especially against "coffinships" — unseaworthy and overloaded vessels, often heavily insured, in which unscrupulous owners risked the lives of their crews. Plimsoll entered parliament as Liberal member for Derby in 1868, and failing to pass a bill dealing with the subject, he published a work entitled *Our Seamen* (1872), which made a great impression throughout the country. On Plimsoll's motion in 1873, a royal commission was appointed, and in 1875 a government bill was introduced, which Plimsoll, though regarding it as inadequate, resolved to accept. On July 22, when Disraeli, announced that the bill would be dropped, Plimsoll lost his self-control, applied the term "villains" to members of the house, and shook his fist in the Speaker's face.

Eventually Piimsoli apologised, but the country shared his view that the bill had been stifled by the pressure of the shipowners, and the popular agitation forced the government to pass a bill, which in the following year was amended into the Merchant Shipping Act. This gave stringent powers of inspection to the Board of Trade. The mark that indicates the limit to which a ship may be loaded is generally known as Plimsoll's mark. Plimsoll was re-elected for Derby at the general election of 1880, but gave up his seat to Sir W. Harcourt, in the belief that the latter, as home secretary, could advance the sailors' interests more effectively than any private member. Later on Plimsoll was estranged from the Liberal leaders by what he regarded as their breach of faith in neglecting the question of shipping reform. He became president of the Sailors' and Firemen's Union, and raised a further agitation about the horrors of the cattle-ships. Later he visited the United States with the object, in which he did good service, of securing the adoption of a less bitter tone towards England in the historical textbooks used in American schools. He died at Folkestone on June 3, 1898.

PLINTH, in architecture, the lowest member of a classic base, also any rectangular block on which a statue or vase is placed. In a pedestal or podium the plinth is the lowest member, and usually consists of a projecting, continuous block above which are the base mouldings. *(See* ORDER.)



PLINY THE ELDER (GAIUS PLINIUS SECUNDUS) (*c.* A.D. 23–79), Roman polymath, was born at Novum Comum (Como), in Transpadane Gaul, on which ground he claims Catullus, a native of Verona in the same region, as a fellow countryman *(N.H. praef.* I., *Catullum conterraneum meum*). The date of his birth is fixed as A D. 23 or 24 (Plin. *Epp. III.* 5,7). He must have come to Rome at an early age (N.H. *XXXVII.* 81). He practised for some time as an advocate (Plin. *Epp. 111.* 5, 7, *aliquamdiu causas actitasse).* He saw military service in various parts of the world, Germany, Spain, Gaul. Under Vespasian, with whom he was on the most intimate terms (Plin. *Epp. III.,* 5, 9), he served as *procurator* in Gallia Narbonensis (A.D. 70) and Hispania Tarraconensis (A.D. 73). At some time — the date is not known—he was in Africa (N.H. *VII.* 36. *"I* myself saw in Africa," etc., *cf. XVII.,* 41, *XXV.* 123). Frnally Vespasian appointed him praefect of the Roman fleet at Misenum, in Campania, which Augustus had made one of the principal Roman naval stations (Sueton. *Aug.* 49). He was stationed at Misenum when on Aug. 24, A.D. 79 there occurred the great eruption of Vesuvius which overwhelmed Herculaneum and Pompeii and incidentally cost Pliny his life. The circumstances are vividly told in a letter of the younger Pliny to the historian Tacitus (Plin. *Epp.* VZ. 16). Surveying the eruption from a ship, Pliny took refuge with his friend Pompeianus at Stabiae (Castellamare) on the southern shore of the Bay of Naples. There, in order to allay the fears of his friends, he dined, as his nephew says "cheerfully, or what was equally splendid, with a pretence of cheerfulness," and then retired to rest. In the middle of the night, when stones and ashes were already falling about the house and the house itself was rocking alarmingly, he was roused by his friends and the party determined to seek safety in the open, binding pillows about their heads as a protection against falling debris. "Now it was day elsewhere," to use his nephew's words, "but there night darker and denser than any night, alleviated a little by numerous torches and lights of various sorts. It was decided to go out upon the shore and see at close quarters whether the sea now offered any prospect of safety; it still continued wild and adverse. There Pliny lay down upon a cast-off linen cloth, and once and again he asked for cold water, which he drank. Then flames and a smell of sulphur announcing the approach of flames, caused the others to take to flight and roused him. Supported by two slaves he got upon his feet, but immediately collapsed, his breathing, I gather, being obstructed by'the thickening vapour which closed up his throat — naturally weak and narrow and frequently inflamed. When day returned — the third (in English reckoning the second, *i.e.,* Aug. 26) after the last day (Aug. 24) that he had seen—his body was found intact and uninjured, covered as he had been dressed. The appearance of the body suggested one sleeping rather than dead."

A list of Pliny's writings is given in a letter by his nephew, (Plin. *Epp. 111.* 5) as follows: 1. *De iaculatione equestri* (On throwing the javelin from horse-back), "written while he was serving as commander of a cavalry regiment with equal ability and care." 2. *De vita Pomponi Secundi duo* (Life of Pomponius Secundus, in 2 books), "the discharge, as it were, of a debt due to the memory of a friend who had entertained a singular affection for him." This Pomponius, who is described by Tacitus *(Ann.* V. 8) as a man "of refined character and conspicuous ability" was a tragic poet who had also a military career of some distinction, cf. Plin. *N.H. XIV,* 56. 3. *Bellorum Germaniae viginti* (German Wars, in 20 books), "in which he brought together all the wars waged between us and Germany. He began the work while he was serving in Germany, being admonished by a dream. The ghost of Drusus Nero (stepson of Augustus who died in Germany in 9 B.C.) who, having carried his conquest of Germany to the widest extent, died there, stood by him as he slept and commended to him his memory and entreated him to vindicate him from the injustice of oblivion." This work is cited by Tacitus, *Ann. 1.* 69; Sueton. *Calig.* 8 and *Vita Plinii,* and was probably used by Tacitus in his *Germania.* 4. *Studiosi tres* (The Student, in 3 books) "in which he instructs and perfects the orator from the cradle up" *(cf.* Aul. Gell. *IX.* 16. *Plinius Secundus . . . libros reliquit quos studiosorum inscripsit,* Quintil *III.* 1.21). 5. *Dubii sermonis octo* (Dubious Language, in 8 books) "written in the last years of the reign of Nero when slavery had rendered dangerous every study of a free and elevated character," *cf.* Plin. *N.H.* praef. 22. Fragments of the treatise were edited by Beck, Leipzig 1894. 6. *A fine Aufidi Bassi triginta unus* (Continuation of the History of Aufidius Bassus, in 31 books). The History of Bassus seems to have ended with the reign of Claudius (cf. Quintil *X.* 1. 103, Tac. *Dial* 23, Seneca Epp. 30), and Pliny continued the story down to his own times. *Cf. N.H.* praef. 20. 7. *Historiae Naturalis* 37 (Natural History in 37 books). This work alone is extant (for fragments of Pliny's lost works cf. *Historicorum Romanorum Reliquiae,* coll. *H.* Peter, 2,109 ff.).

Pliny, the Younger, has given a description of the uncle's studious habits. He would call upon the Emperor Vespasian before daybreak and then after performing his official duties, return home and devote what time remained to study. After a light luncheon, if it were summer and he had leisure, he would lie in the sun while a book was read, annotated and extracts made: he never read a book without making extracts, holding that no book was so bad as not to contain something good. Next he had a cold bath, a snack, and a short siesta, after which, "as if it were another day," he studied till dinner-time. During dinner a book was read and notes made. He rose from the dinner table in summer before night-fall, in winter within the first hour of night. Thus at Rome; but in vacations no time was exempt from study, save bath-time, nay, even then, he had something read to him or he dictated something, while he dressed. When traveliing he was accompanied by a shorthand writer armed with book and notebook and in winter provided with gloves. To procure time for study he generally drove even in Rome and his nephew tells how he was once reproved by him for wasting valuable time in walking. When he died he bequeathed to his nephew 160 volumes of annotated selections (electorurn *commentarios*) "written on both sides and in the minutest hand," for which, when he was procurator in Spain (A.D. 73) and when the number of volumes was rather less, he had declined an offer from Largius Licinus of 400,000 sesterces.

The Natural History, which was dedicated to Titus, son of Vespasian and his successor as emperor, and of which the first ten books were probably published in A.D. 77, is, as we have seen, in 37 books. Bk. I. has a general preface and contains a table of contents of the other books, to each being appended a list of the authors consulted, the order of enumeration corresponding to the order in which they are utilised. These lists contain the names of 146 Latin and 327 foreign authors. Bk. II. is devoted to a mathematico-physical description of the world and deals with the heavenly bodies—sun, moon, planets, fixed stars; various meteorological phenomena; the succession of the seasons, the earth's shape and surface phenomena; seas, rivers, springs, and the like. The subject matter of this book affords Pliny an opportunity, of which he readily avails himself, to expound his own philosophic creed, which is a modified Stoicism. His view of nature is pantheistic (N.H. II. 1). Bks. III.–VI. are devoted to geography and ethnography. This is unscientific and uncritical but extremely valuable from the incidental facts which it presents. There is an interesting mention of a map of Armenia (N.H. VI. 40).

Books VII.–XI. are occupied with zoology and are the most generally interesting section. The seventh book deals with man and is occupied less with the normal than with the marvellous and portentous, which the scientific creed of the author and his belief in the infinite power of *ingeniosa* natura enabled him to accept or at least not forthwith to reject. Thus we have tales such as would have charmed the ear of Desdemona—of men whose feet were turned the wrong way, of the Mouthless Men (*Astomi*) who subsisted upon the mere fragrance of flower and fruit, of the Umbrella-foots (*Sciapodae*) who used their extensive feet by way of parasol to protect them from the sun; monstrous births; precocity or exceptional development of physical strength or speed, of sight or hearing, of mental powers; of men who were unconscionably long of dying. Incidently (c. 55) he declares his disbelief in immortality. The eighth book treats of terrestrial animals other than man. Here again, amid much that is interesting in detail, there is an unfortunate absence of scientific arrangement and an excessive proneness to accept the marvellous of which he was so unconscious that he expresses surprise at the credulity of the Greeks (N.H. VIII. c. 22 *mirum* est quo procedat Graeca credulitas). Hence side by side with sound science, mostly taken from Aristotle and, so far as concerns Africa, from Iuba, we have a host of imaginary animals—winged horses, unicorns, and the like monstrosities. Book IX. deals with aquatic animals and scientifically is the soundest of all the zoological books, which is no doubt due to the fact that his information is mainly derived from the History of *Animals* of Aristotle, who treats of aquatic animals with unusual fullness. The marvellous in this book is chiefly represented by his belief in Nereids and Tritons and the usual stories of the human sympathies of the dolphin. The tenth book treats of birds, commencing, according to Pliny's practice of beginning with the largest, with the ostrich. Such classifications as he makes of birds is of an empirical kind and based on very superficial observations. The first part of the eleventh book is occupied with insects—the bee being treated with some fullness—and the latter part with what may be called comparative anatomy. Books XII.–XIX. deal, generally speaking, with botany, including forestry and agriculture, the subject of Book XVIII., which is one of the most interesting in this section. Books XX.–XXVII. treat of medical botany or the medicines derived from plants. Books XXVIII.–XXXII. deal with other than botanical *materia medica, i.e.,* of medicines derived from the bodies of man and other land animals (XXXII.). The remaining books are occupied with what may be described roughly as mineralogy, *i.e.,* with metals and metallic products, the precious metals, gold and silver, being discussed in bk. XXXIII., bronze and bronze statuary in bk. XXXIV., painting in bk. XXXV., stone as used in building and sculpture in bk. XXXVI., gems and precious stones in bk. XXXVII.

The style of the *Natural* History gives an impression at once of affectation and of slovenliness which may in some degree be attributable to the condition of the text. On the Natural History was based the Collectanea *rerum memorabilium* of Julius Colinus (3rd cent. A.D.) and on Bks. XX.–XXXII. the *Medicina Plinii,* a compilation of the 4th century.

PLINY THE YOUNGER (GAIUS PLINIUS CAECILIUS SECUNDUS) (A.D. 61 or 62–*c.* 113), Latin prose author, was born at Novum Comum (Como) in Cisalpine Gaul. The second son of L. Caecilius Cilo and Plinia, sister of the elder Pliny, he bore the name P. Caecilius Secundus until the death of his uncle (A.D. 79), who by his will made him his adopted son, when he assumed the name C. Plinius Caecilius Secundus. He was then in his 18th year (*Epp.* VI. 20. 5). Educated in rhetoric under Quintilian (*Epp.* II. 14. 9, VI. 6. 3), he made his debut as an advocate at the age of 18 (*Epp.* V. 8. 8).

Pliny was fortunate in having as guardian—doubtless under his father's will (*Epp.* II. 1. 8)—L. Verginius Rufus (A.D. 14–97), who had three times declined to become emperor (in Nero's lifetime, Dio 63. 25, after Nero's death, Plut. Galb. 10. Dio 64. 4, after the death of Otho, Plut. *Oth.* 18). He thus commenced his public career under the most favourable auspices. He became a quaestor in 89 and in 91 a tribune of the plebs, withdrawing during his year of office from practice at the bar (*Epp.* i. 23, vii. 16. 2, Paneg. 95). In 93 he became praetor (*Epp.* 111. 11. 2; VII. 11. 4; 16. 2, Tac. Agric. 6, 45; Juv. x. 36) and during his year of office was one of the counsel for the impeachment of Baebius Massa, procurator of Hispania Baetica (*Epp.* III. 4, VI. 29, VII. 33). In 94 or 95 he was appointed *praefectus* aerarii militaris. Under Nerva in 98 he became praefectus aerarii *Saturni* (*i.e.,* commissioner of the public treasury in the temple of Saturn). In September 100 he became consul, holding office for two months. His oration of thanks to Trajan for his nomination (*Epp.* III. 13. 1; 18. 1) is what is called in the mss. *Panegyricus* Traiano dictus. After acting as counsel for the defence of two ex-governors of Bithynia—Iulius Bassus and Varenus Rufus—he was himself appointed by Trajan, circ. 111 A.D., governor of that province. Whether he died in that office is not known, but the probable date of his death is 113, since in the Comum inscription Trajan is mentioned without the titles, conferred in 114, of *Optimus* and *Parthicus.* The inscription referred to was inscribed on a marble slab in the wall of the baths (thermae) presented by Pliny to Comum and commemorated that and other benefactions, including a library. The stone was removed to Milan and broken into six pieces. Four of these were built into a tomb in the church of St. Ambrose, and from the only one of these now known Mommsen, with the aid of other records, restored the inscription.

The extant works of Pliny are the Panegyric on *Trajan* already referred to (cf. *Epp.* III. 18), which is of some historical importance, the Letters in nine books, and a tenth book comprising his Correspondence *with Trajan.* Mommsen (*Zur Lebensgeschichte des jüngeren* Plinius, in Hermes 3, 1868), suggests as dates: Bk. I., A.D. 97; II., early in 100; III., 101 or 102; IV., early in 105; V., 106; VI., 106 or 107; VII., 107; VIII., 109; IX., perhaps at same time as VIII.; and *Correspondence with Trajan,* 111–113. Merrill has modified Mommsen's theory by the suggestion that the *Letters* were published in groups: I.–II. in 97 or 98, III.–VI. in 106, VII.–IX. in 108 or 109.

The interest attaching to letters selected and edited for publication, like those of Pliny, is wholly different from that of such a frank and unguarded correspondence as the letters of Cicero. There is in Pliny always a suggestion of pose, of self-consciousness and self-complacency. But the *Letters* are admirable examples of polished and pointed Latinity, while the range of subject and the quality of the persons to whom some of them are addressed render them of singular interest and attraction. As an example of his manner may be taken the letter (I. 21) which he writes on hearing of the death of the poet Martial, who had some time before retired from Rome to his native Bilbilis: "I hear that Valerius Martialis has gone, and I am sorry. He was a man able, acute, and keen: one in whose writing there was wit and pungency, yet not less candour. When he was leaving Rome I provided hi; travelling expenses, a tribute to friendship, a tribute also to the lines which he wrote about me. It was an old custom to reward with honours or money those who had written the praises of individuals or of cities: in our times, like other fair and excellent things, this also among the first has become obsolete: for since we ceased to do things worthy of praise, praise itself we account foolishness. You ask what are the lines for which I showed my gratitude? I would have referred you to the book itself [Martial, X., 19], were it not that I remember certain of them. He addresses the Muse, bids her seek my house on the Esquiline, approach it reverently:

> But beware nor in season unpropitious,
> Tipsy reveller, knock upon the door of
> Him who dedicates all his days to Pallas,
> While he cons for the hearing of the Hundred
> What posterity and the after ages
> May compare to the writings of Arpinum:
> Safer go when the lamps of eve are lighted:
> Thine the hour when the ruddy wine is flowing,
> On locks perfume-bedewed the roses glowing—
> Then stern Catos themselves might read my verses.

Did not he who wrote thus of me deserve that I should both speed him then, as I did, in friendliest fashion, and mourn him now, which I do, as a dear friend departed? For he gave me the best that he had to give and would have given me more had be been able. Yet what greater gift can be given to any man than glory and praise and immortality? But his writings will not be immortal? Perhaps not: but he wrote them as if they would be." Other letters of special interest are VI. 16, one of several addressed to the historian Tacitus which gives a vivid account of the death of the elder Pliny (*q.v.* for citations from the letter) through the eruption of Vesuvius; VI. zo, also to Tacitus, narrating the experiences of Pliny and his mother; those (I. 18, III. 8, V. 10, IX. 34) written to Suetonius, the biographer of the twelve Caesars; II. 17 which gives a description of Pliny's Laurentine villa; VII. 27 which recounts a couple of ghost stories.

The *Correspondence with Trajan* which consists, apart from the first 15 letters, wholly of letters written during Pliny's governorship of Bithynia, contains much that is of value regarding provincial administration under the empire. But the interest of the modern reader centres chiefly in the two letters (96 and 97) relating to the Christians. In the first Pliny writes to the emperor:

> Sire, It is my custom to refer to you all matters about which I am doubtful: for who is better able to direct my hesitation or instruct my ignorance? At trials of Christians I have never been present and I am therefore ignorant of the usual and the limits of punishment or in regard to the matter I have had also no little difficulty as to whether some distinction of age should be made, or if persons of the most tender age stand on the same footing as the more adult; whether the penitent is to be pardoned or if a person who has once been a Christian shall have no benefit of ceasing to be one. Whether the mere name of Christian, apart from crime, is punishable, or only crime coupled with the name. Meanwhile in the case of those reported to me as Christians I have followed this procedure. I asked themselves whether they were Christians. If they admitted it, I put the question a second time and a third, with threats of punishment. If they persisted in their confession, I ordered them to be led to execution; for I had no doubt that whatever the nature of that which they confessed, in any case their pertinacity and inflexible obstinacy deserved to be punished. There were others of a similar delusion whom, as they were Roman citizens, I noted for remission to Rome.
>
> Presently the mere handling of the matter produced the usual result of spreading the crime, and more varieties occurred. There was published an anonymous pamphlet containing many names. Those who denied that they were Christians or ever had been, when, after me, they invoked the gods and worshipped with incense and wine your statue which I had ordered to be brought for that purpose along with the images of the gods, and, further, reviled Christ—things which it is said that no real Christian will do under any compulsion—I considered should be dismissed. Others who were named by the informer admitted that they were Christians and presently denied it, admitting indeed that they had been, but saying that they had ceased to be, some several years before, some even twenty. All these likewise did homage to your statue and to the images of the gods and reviled Christ. They affirmed moreover that the sum of their crime or error was that they had been wont to meet together on a fixed day before daybreak and to repeat among themselves in turn a hymn to Christ as to a god and to bind themselves by an oath (*sacramentum*), not for some wickedness but not to commit theft, not to commit robbery, not to commit adultcry, not to break their word, not to deny a deposit when demanded; these things duly done, it had been their custom to disperse and to meet again to take food—of an ordinary and harmless kind. Even this they had ceased to do after my edict by which, in accordance with your instructions, I had forbidden the existence of societies *(hetaeriae)*. For these reasons I deemed it all the more necessary to find out the truth by the examination—even with torture--of two maids who were called deaconesses (ministrae=διακόνοι). I found nothing but a perverse and extravagant superstition.
>
> I have therefore adjourned the inquiry and have had recourse to consulting you. For the matter seemed to me one deserving a consultation, especially in view of the number of those imperilled. For many persons of every age, of every rank, of both sexes even, are daily involved and will be, since not in the cities only, but in villages and country districts as well, has spread the contagion of that superstition—which it seems possible to check and correct. At any rate it is certain that temples which were already almost deserted have begun to be frequented; the customary religious rites, long intermitted, are being restored; and fodder for sacrificial victims—for which hitherto it was rare to find a purchaser—now finds a market. Whence it is easy to infer what a mass of men might be reformed, if penitence were recognized.

The reply of the emperor briefly approves of the procedure adopted by Pliny:

> No formula capable of universal application can be laid down. The Christians are not to be sought out; if reported and convicted, they are to be punished, with this reservation that any person who denies that he is a Christian and confirms his testimony by overt act, that is, by worshipping our gods, however suspect he may have been in the past, shall obtain pardon by penitence. Anonymous publications ought to have no place in a criminal charge. It is a thing of the worst example and unworthy of our age *(et pessimi exempli nec nostri saeculi est)*.

The full discussion of the questions raised by the correspondence on the matter of the Christians belongs to the province of Church history, but no one can fail to be interested in the account which Pliny gives of the practice of the early Christians: the meeting on a fixed day before day-break (if the "fixed day" means Sunday, the early hour points to a desire for secrecy perhaps rather than to the rest of the day being occupied with other avocations); the singing or reciting of a hymn or psalm of an antiphonal character (*rf.* O.T. Psalm lxxxvii. 7); the recital of the ten commandments; the love feast (ἀγάπη) with its innocuous elements; the existence of women office-bearers or deaconesses.

When a person selects for publication from his private letters, or when he writes a private letter with an eye to its eventual publication, he is necessarily confronted by a dilemma. The self-revelation, the candour of motive, the frankness of prejudice or predilection, which are not merely appropriate to the private letters but are its chief charm, are incompatible with the reserve which is proper to a public document, and while suppression and excision inevitably produce an air of unreality, unreserved publication is almost certain to expose the writer to a charge of priggishness or self-conceit. Those who care to attack Pliny on this ground will find a store of arrows ready-winged for their satire in his letters, even without mistranslating or misunderstanding his words (e.g., "*Maxime* imitabilis" used quite innocently of Tacitus in VII. 20). It is a kinder and more pleasing occupation to recognize the amiability and culture of the character which the Letters everywhere reveal, and, what at least no competent judge will seek to controvert, the many admirable qualities — conciseness combined with lucidity, precision united with the picturesque — of the style in which they are written.

It need only be added that though Pliny on occasion courted the Muses (*Epp.* IV. 27, Ego interdurn versibus *ludo,* cf. Mart. X. 19, Non *Musis* vacat aut suis vacaret) and wrote a Greek tragedy at the age of fourteen (Epp. VII. 4), the specimens of his verses which he quotes (Epp. VII. 4 and 9) do not suggest that his talent lay in that direction.

PLIOCENE (Gr. πλεῖον, more, and καινός, recent), in geology, the name given by Sir Charles Lyell to the system of strata lying between the Miocene and the Pleistocene. The name refers to the increasing number of living species amongst the fossils of this, the highest division of the Tertiary. The Pliocene is now considered the upper of the two subdivisions of the Neogene or Newer Tertiary period.

Conditions During the Pliocene. — During this period the great land masses were approaching the configuration which they exhibit at the present day and the marine Pliocene deposits are limited to comparatively few areas. In Europe the marine regression which closed the Oligocene was succeeded by a new, but feeble, marine transgression in the Pliocene, which was closed by a final regression before the opening of the Quaternary. Reference should be made to the article on Miocene for the extent of the seas at the opening of the period. The North sea of the Pliocene period covered parts of East Anglia, northern Belgium and Holland, and in the earliest part of the period is believed to have occupied the Thames valley. Bays from the Atlantic covered parts of south-western England and north-western France, and the valley of the Guadalquivir. From the western Mediterranean a bay extended up the Rhone valley as far as the present position of Lyons. Early in the period the sea covered considerable areas of Italy and Sicily, but these lands had assumed approximately their present form by the close of the period. The eastern Mediterranean remained cut off from the west, and the Black sea and Aralo-Caspian sea began to assume their present form. Generally, however, all over the world the majority of Pliocene formations are non-marine, and hence local in their distribution. In many areas the Alpine earth movements did not cease until the close of the period, and not only are the Pliocene deposits represented by vast accumulations of coarse sediment — such as the Siwalik series (Mio-Pliocene) of northern India and the Irrawaddian sands (Mio-Pliocene) of Burma — but these sediments have themselves been severely folded. The formation of some of the great rifts, such as those of East Africa, is attributed to the Pliocene period; volcanic outbursts of the central plateau of France, Etna and the Italian volcanoes, and the East Indian volcanoes probably commenced in this period. In North America marine Pliocene is found fringing the coasts of California and continental deposits are widespread. The oncoming of a glacial era is evidenced by the lowering of temperature during the period. In Britain the earlier Pliocene seems to have been warmer than at present, but the percentage of arctic or northern species amongst marine fossils increases as the period advanced.

Life of the Period. — Sir Charles Lyell defined the Pliocene strata as those which contained from 36 to 95% of living marine mollusca. Although this rule is no longer strictly applicable, the Pliocene marine organisms are very like their living representatives, and there is often practically no specific difference. Thus most of the existing genera of mollusca have Pliocene representatives. It is notable, too, that there is often a closer resemblance between Pliocene faunas and the faunas existing in the neighbouring seas or rivers than there is between Pliocene faunas in widely separated regions.

The mammals of the British Pliocene include *Machaerodus* (the sabre-toothed tiger), hyenas, dogs, fox, wolf, glutton, marten, bears (*Ursus* arvernensis, the grizzly bear and the cave bear), seals, whales, dolphins, bisons, musk ox, gazelle, the red deer and many others now extinct, the roebuck, pigs and wild boar, hippopotamus, hipparion and horse (Equus *caballus* and E. stenonis), several species of rhinoceros, tapir, hyrax, elephants (Elephas meridionalis, and E. *antiquus*), several mastodons, squirrel, beaver, hare, mice, voles, etc. The mastodon disappeared from Europe before the close of the period, but lived longer in America. Although no generally accepted direct ancestor of man sufficiently advanced to be called human has yet been found in the Pliocene, there are several manlike forms which represent offshoots from the main human tree. Amongst these the most famous are Pithecanthropus *erectus,* found by E. Dubois in Java, and *Eoanthropus dawsoni,* found by C. Dawson at Piltdown in Sussex. Monkeys such as Macacus and Semnopithecus occur in the Pliocene of Europe as well as in the Upper Siwalik of India. During the Pliocene the mammals of North America were able to migrate into South America, and a few of the southern forms travelled northwards.

Pliocene Stratigraphy. — The following stages have been distinguished in the Mediterranean Pliocene: —

	Marine Facies	Continental Facies
2	Upper — Calabrian	Villafranchian
1	Lower {Astian facies Plaisancian facies	Lower Pliocene

The Pontian, sometimes included as Lower Pliocene, has been considered under Miocene.

The Lower Pliocene of the Mediterranean basin differs from the Miocene in the disappearance of numerous species and the appearance of many new ones. One finds most of the molluscs now living in the Mediterranean as well as others now only found in the marine waters of the west African coasts.

The Upper Pliocene of the Mediterranean basin has a fauna almost identical with that of the Mediterranean of to-day, but includes a few northern forms such as *Cyprina* islandica, now living in the cold seas of the north of Europe, and hence it is believed that the temperature of the Mediterranean sea in late Pliocene times was much lower than it is to-day. This marine type of Upper Pliocene, well developed in Italy, is known as Calabrian or Sicilian. More often the Upper Pliocene is represented by continental formations known as the Villafranchian (from Villafranca d'Asti in Piedmont). The clearest classification of the continental types of Pliocene is by means of the mammalian remains:—

Upper Pliocene or Villafranchian — marked by appearance of true elephants (E. meridionalis), and true horses (E. *stenonis*), and true oxen (*Bovus* etruscus), and by the last mastodons (M. arvernensis). Another mammal is Rhinoceros etruscus. The mastodons are absent from the higher Villafranchian, which is sometimes, therefore, known as Saint-Prestian. Famous localities include Villafranca d'Asti, Val d'Arno and St. Prest near Chartres.

Lower Pliocene — with Mastodon *arvernensis,* M. *borsoni,* Rhinoceros leptorhinus and large antelopes. Famous localities include Montpellier and Bresse.

The Pliocene rocks of Britain now occupy principally a small area in Norfolk, Suffolk, and part of Essex. Small outlying patches in Cornwall (St. Erth and St. Agnes) and elsewhere in the west of England supply evidence that the Pliocene sea was responsible for the planation of much of the present surface of the peninsula of Devon and Cornwall. Small patches of ferruginous sands and gravels on the North downs of Kent and Surrey, on the chalk hills north of London and on the South downs of Sussex have also been shown to be of Pliocene age. In early Pliocene times a large bay of the North sea occupied what is now the

London basin; the shore lines of this bay have been traced. as well as the plane of marine denudation for which it is responsible. Later in the period the sea retreated and covered only parts of East Anglia whilst a great spread of fluvio-marine gravels was deposited in the London basin at an elevation of, roughly, 400 ft. above present sea-level. Still later in the period the sea left even East Anglia, and the highest Pliocene there were probably laid down in a distributary of the Rhine-Thames system. The Pliocene of East Anglia has been classified as follows:—

9 Cromerian	Cromer forest bed series (freshwater and estuarine)
8 Weybournian	Weybourne crag (marine)
7 Chillesfordian	Chillesford clay and sand (estuarine)
6 Icenian	Norwich crag (marine and estuarine)
5 Butleyan 4 Newbournian 3 Waltonian	Red crag (marine)
2 Gedgravian	Coralline crag (marine)
1 Lenhamian or Diestian	Lenham beds (marine)

The Pliocene deposits of Belgium and Holland are closely related to those of Britain but are much thicker and more extensive. The sea retreated northwards as it did in England. In Germany the retreat of the Oligocene sea left vast lakes in which swamp forests gave rise to lignites.

In Brittany and Normandy there are patches of marine sands comparable with those of Cornwall; in Central France no marine beds are found, but many interesting and in some cases highly fossiliferous deposits occur in volcanic rocks.

In North America the marine Pliocene—marls, clays and limestones—are well developed in Florida and can be traced into the Carolinas and Virginia; they have been classed as the Lafayette group (with lignites), the Florida group, and the Calooshatchis stage. On the Pacific coast the marine beds have attained great thicknesses, notably in the Merced series of San Francisco. In the San Luis Obispo region the non-marine Paso Robles beds, said to be 1,000 ft. thick, belong to this period. Other local formations of marine origin in California are those of San Diego and Wild Cat. In the Rocky mountains are large lacustrine formations of considerable thickness, and certain conglomerates in Wyoming and Bishop mountain are assigned to this age.

(L. D. S.)

PLOCK or **PLOTSK,** a town of Poland in the province of Warsaw, on the Vistula, 67 mi. by the Vistula W.N.W. of Warsaw. Pop. (1931), 32,777 It has a cathedral, dating from the 12th century, but restored in 1903, which contains tombs of Polish dukes and of Kings Wladyslaw and Boleslaw (of the 11th and 12th centuries). There is considerable navigation at this point on the Vistula. German troops took Plock soon after the start of World War II in 1939.

PLOËRMEL, a town of western France in the department of Morbihan, 36 mi. N.N.E. of Vannes by rail. Pop. (1936) 3,384. Ploermel (*Plo Armel,* people of Armel) owes its name to Armel, a hermit who lived in the district in the 6th century. The Renaissance church of St. Armel (16th century) is remarkable for the delicate carving of the north façade and for fine stained glass. It also possesses effigies of John II. and John III., dukes of Brittany, brought from their tomb in an ancient Carmelite monastery founded in 1273 and destroyed by the Protestants in 1592 and again at the Revolution. The lower ecclesiastical seminary has a room in nhich the Estates of Brittany held several meetings.

PLOEȘTI, the capital of the department of Prahova. Rumania; at the southern entrance of a valley among the Carpathian foothills, through which flows the river Prahova; and at the junction of railways to Buzau, Bucharest and the Transylvanian system. Pop. (1939) 77,376. As the name Ploești (*pluviena,* rainy) implies, the climate is moist. The surrounding hills are rich in petroleum, salt and lignite. Ploești is the greatest centre of the Rumanian oil industry, and as such was severely bombed by British, Americans and Russians in World War II. There are cardboard factories, roperies, tanneries and oil mills. Ploești possesses schools of commerce and of arts and crafts, several banks, and many churches, including the Orthodox church of St. Mary, built in 1640 by Matthew Bassarab.

PLOMBIÈRES-LES-BAINS, a town of eastern France, in the department of Vosges, on a branch line of the Eastern railway, 17 mi. S. of Epinal by road. Pop. (1936) 1,581. The town stands at a height of 1,410 ft. in the picturesque valley of the Augrogne and is a tourist centre, famous for its mineral springs, containing sodium sulphate and silicic acid, varying from 66° to 166° F. The waters have been used since Roman times.

PLOTINUS (A.D. 204 or 205–270) was a native of Egypt, but it is not known from what race he sprang. As a young man he studied philosophy at Alexandria, and at last found a congenial teacher in Ammonius Saccas, under whom he worked till he was 39. Then he accompanied the expedition of the emperor Gordian against Persia, hoping to have an opportunity of studying the wisdom of the East. Gordian was assassinated in Mesopotamia and Plotinus escaped to Antioch with difficulty. In 244 he went to Rome, where he lived for the rest of his life. There he opened a school and gathered round him an enthusiastic band of disciples. For many years the instruction was purely oral, and Plotinus took but little pains to perpetuate his teachings. We owe the preservation of it mainly to his pupil Porphyry, who edited his scattered lectures and tried to reduce them to order. The philosopher died after a long illness at the age of 66. His biographer Porphyry described him as a man of saintly character and very attractive personality. In him philosophy and personal religion were closely connected; the apex of the dialectical pyramid was also the beatific vision in which the mystical life culminates. He made no enemies and was loved and reverenced by all who knew him. The later members of the school spoke of him as "the most divine Plotinus."

The importance of Plotinus in the history of thought can hardly be exaggerated. Among the philosophers of mysticism he holds an undisputed pre-eminence, since no other writer unites in the same measure metaphysical genius with intimate personal experience. On the theoretical side he draws mainly from Plato, but on Plato as interpreted by a long series of scholars, and buttressed by Aristotle and (to a less extent) by the Stoa. The rival schools of Greek philosophy were in fact beginning to coalesce into a theocentric system, at once universal and individual, of religious discipline. Plotinus gave an impetus to this fusion; for the victory of his philosophy was so rapid and overwhelming that it absorbed the other schools, and when Neoplatonism captured the Platonic Academy at Athens, the seat of the official Diadochus, it reigned almost without a rival until Justinian closed the Athenian schools in 529.

Neoplatonism remained attached to the classical tradition, and Porphyry wrote against Christianity. But even Augustine recognized that the differences between Platonists and Christians were slight, and the Church gradually absorbed Neoplatonism almost entire. The Christian Platonists of Alexandria led the way; then came Augustine himself, the Cappadocian fathers, and the Pseudo-Dionysius, a disciple of Proclus, whose writings, popularly ascribed to St. Paul's Athenian convert, introduced the whole scheme of Plntinian mysticism into the Church. It is no paradox to say with Eucken that the pagan Plotinus has left a deeper mark upon Christian thought than any other single man. In reading the Enneads we can realize the truth of Troeltsch's famous dictum, that the Catholic Church does not belong to the middle ages, but is rather the last creative effort of classical antiquity, which may be said to have died in giving birth to it. Troeltsch adds that in a new synthesis of Neoplatonism and Christianity lies "the only possible solution of the religious problem at the present day," and "does not doubt that this synthesis will once more be dominant in modern thought." Such a judgment, from the foremost thinker of his day in Germany, is enough to show that the philosophy of Plotinus, so far from being extinct, is still a factor in modern civilization. As Eunapius said, "the altars of Plotinus are still warm."

His Philosophy. — Whatever English equivalents we choose for the Plotinian technical terms must be misleading. The "Matter" of Plotinus is immaterial, being the all-but nothing which remains when we have deprived an object of contemplation of the form and meaning which make it a possible object of contemplation. "Soul" is often nearer "life," the word usually translated "intelligence" is much nearer to "Spirit"; "God" is not the deity of personal theism, and the Absolute is "beyond existence." It is mainly mistranslation of technical terms that has caused many to ascribe metaphysical dualism to Plotinus, for which there is no ground whatever. There are no hard and fast dividing lines in this philosophy, but a graduated hierarchy of existence and value, in every grade of which the soul finds affinities.

The soul is a stranger among the things of sense, into which it has "come down." From the desire of Soul to create after the pattern of Spirit, "the whole world which we know arose and took its shapes." The universal soul is the creator and providence of the visible world, which is in it, rather than the soul being in the world. "There is nothing between soul and spirit except that spirit imparts and soul receives. But even the Matter of Spirit is beautiful and of spiritual form." "There is nothing Yonder that is not also Here." Plotinus therefore blames the half-Christian Gnostics, who despise the visible world and are blind to its beauties. Souls cannot be divided quantitatively; "all souls are one." In the spiritual world there is distinction without separation; individuality is preserved, but all spirits are transparent to each other. Even on earth there is a "faint sympathy" which connects all beings together, a pale reflection of the complete unity in plurality which prevails Yonder. The character of the soul depends on the sphere in which it voluntarily moves. If it chooses to live among the shadows of the true, it forfeits its birthright, and is "lost," so far as a divine being can be lost. There is a higher soul which never consents to sin, and remains in the eternal world. (Here the school was to differ. Later Neoplatonists asked, "If the will sins, how can the soul be impeccable?")

The soul neither comes into existence nor perishes; "nothing that possesses real being can ever perish." But souls that have lived unrighteously will be punished by being reincarnated in the bodies of lower animals; the soul will also be chastened by its daemcn or guardian angel. It is not quite clear whether every soul must at last find deliverance from its chains. The world Yonder is the heaven of Neoplatonism. It is the realm of spiritual existence, in which the ultimate and eternal values — Truth, Goodness and Beauty — are fully realized and fully operative. It consists in the unity of *Nous, Noësis* and *Noëta*, in which the whole nature of the Absolute is manifested. It is essentially a kingdom of values, but of values which are fully realized. It is eternal, not as existing through an infinite series of moments, but as belonging to the divine life, of which indestructibility is an attribute. The world reflects in its everlastingness the eternity of its archetype. There is no change or progress Yonder, since the perfect cannot receive augmentation; but there is unceasing life and movement, which on the lower side is manifested in perpetual creativeness. The lower orders of being proceed from the higher in a constant stream, though the higher loses nothing in the process of creation. The lower is immanent in the higher, not the higher in the lower. Nothing that takes place in time can affect the essential nature of eternity.

The duality in unity of the spiritual world points to an absolute unity behind it. This unity, though the necessary culmination of the dialectic, is beyond knowledge and existence, and is revealed to experience only in the mystical trance. The "soul become spirit" cannot rest even in this state of blessedness; it is impelled by its inner nature to aspire still further, "always attaining and always striving upward." Plotinus is convinced that in the mystical state we have actually an experience of formless intuition. This is, it is needless to say, the testimony of all the mystics, of every age, country and creed. The mystical ascent seems to those who pass through it to be a progressive stripping off of everything that is alien to the purest nature of the soul, which cannot enter into the Holy of Holies while any trace of earthliness still clings to it. Hence the constant reiteration of such symbols as nakedness, nothingness and darkness. Plotinus in the well-known sentence with which the *Enneads* as arranged by Porphyry end, defines it as "a flight of the alone to the Alone." He gives us several eloquent descriptions of the mystical trance, drawn evidently from intimate personal experience; but like other mystics he knows that it is impossible to utter the ineffable, and repeats cautions like "The vision is for him who will see it"; "he who has seen it knows what I say."

It is part of the fundamental sanity of Plotinus that he always speaks of the vision of the One as an exceedingly rare experience. It is the consummation of a life-long quest of the highest, to be earned only by intense contemplation and unceasing self-discipline. He says nothing of supernatural favours granted for their encouragement to young aspirants. Nor are there any traces of those attempts to force the pace which in many mystics produce the terrible reactions which are described as the dark night of the soul. This sense of dereliction, which fills so large a place in the records of the mysticism of the cloister, may have some connection with a deeper sense of guilt and sinfulness than the Neoplatonists ever felt; but it is partly the effect of nervous overstrain and of severe mortification of the body, which Platonism has never encouraged. Plotinus, as we have seen, lived the active and sociable life of a professor among his pupils; his habits were austerely simple, but neither he nor his disciples tortured themselves like Heinrich Suso and many other Catholic saints. The combination of healthy asceticism with humanism is the hall-mark of Platonists in all times.

The ethical scheme of Plotinus falls, like everything else in his philosophy, under three heads — purification, enlightenment and unification. The "political virtues," which include all the conduct expected of a good citizen. are the preliminary but indispensable prelude to the course. It was not to be expected that any writer in the 3rd century of our era should show much interest in what we call social questions, which occupied the attention of Plato and Aristotle. The special task of philosophy in that distracted age was to isolate religion in its purity, detaching it from all that was local and temporal, and bringing to light its innermost essence. To have done this is an achievement of permanent value, and we must not blame Plotinus for his apparent indifference to the misfortunes which were threatening his country. But, like all the ancients, he does not sufficiently emphasize our need of our fellow-men to develop the best in human nature. The bravest of the Greeks could never renounce the hope of making himself invulnerable.

Neoplatonism culminates in Plotinus. Of his successors, Proclus alone was a thinker of the first rank, and in Proclus the system is intellectualized and scholasticized. The later history of this type of religious thought and practice is mainly within Christianity. As a philosophy, it was restated with acumen by Scotus, Erigena and Meister Eckhart; but many of the post-Kantians are deeply indebted to Plotinus, and Troeltsch is probably right in thinking that even in the future Christian philosophy must continue to be largely Plotinian. The Church carried off this Hymettian honey to its hive just at the time when the intellectual formulation of the victorious creed was taking its permanent shape.

(W. R. I.)

Bibliography.—The *Enneads* of Plotinus were first made known in the Latin translation of Marsilio Ficino (Florence, 1492) which was reprinted at Basle in 1580, with the Greek text of Petrus Perna. Later editions by Creuzer and Moser ("Didot" series, 1855), A. Kirchhoff (1856), H. F. Müller (1878–80), R. Volkmann (1883–84). There is an English translation of selected portions by Thomas Taylor, re-edited in Bohn's *Philosophical Library* (1895, with introduction and bibliography by G. R. S. Mead). Translation of the whole (except *Ennead* vi., not yet published (in 1928) by S. Maclienna.

On Plotinus generally *see* article in Suidas; Eunapius, *Vitae sophistarum;* and above all the *Vita Plotini* by his pupil Porphyry. Among modern works, *see* the treatises on the school of Alexandria by J. F. Simon. I. (1845), and R. Vacherot (1846); A. Richter, *Ueber Leben und Geistesentwicklung des Plotin* (Halle, 1864–67); T. Whittaker, *The Neoplatonists* (1901); A. Drews, *Plotin und der Untergang der antiken Weltanschauung* (1907); E. Caird, *Evolution of Theology in*

the Greek Philosophers (1904), ii. 210–157; W. R. Inge, The *Philosophy of Plotinus* (2 vols., 1918; 3rd ed. revised, 1928); F. Heinemann, *Plotin* (1921). A detailed account of Plotinus's philosophical system and an estimate of its importance will be found in the article NEO-PLATONISM, the works above referred to, and the histories of philosophy. For his list of categories, see CATEGORIES; also LOGOS; MYSTICISM; MAGIC.

PLOUGH, PLOW: see CULTIVATING MACHINERY.

PLOVER, the name given to an indefinite group of birds which, with the snipes and sandpipers, form the group *Limicolae* or "waders," although the plovers themselves rarely enter water. Perhaps the best entitled to the name are the golden plover (*Charadrius pluvialis*) and the grey plover (*Squatarola helvetica*). The latter is the larger and lacks the hind toe; otherwise the two forms are very similar. The grey plover breeds in the far north of America, Asia, and Europe, migrating south in the winter, when it reaches the Cape, Australia, and Ceylon. The golden plover is more local but ranges from Iceland to Siberia, including the British Isles, as a breeding species. It also migrates south in winter. Both forms are exceedingly wary. In America occur two further golden plovers, breeding in the far north, where, in Alaska, their ranges are scarcely 100 miles apart. But whereas the eastern form winters in Patagonia, which it reaches via Labrador, Newfoundland, and the Antilles, returning by way of Panama, the Pacific bird winters in the Low Archipelago (*see* Coward's *Migration of* Birds). Plovers are gregarious but monogamous birds, partial to mud-flats and marshes and eating worms and small arthropods and molluscs. The legs are long, the bill shorter than in most waders.

The ringed plovers include the shore-haunting British bird of that name; killdeer (*q.v.*); zick-zack (*Hoplopterus spinosus*), celebrated for its connection with the crocodile, from the mouth of which it picks leeches and other parasites, besides, from its wariness, acting as a sentinel to the reptile. The coursers, *Cursorius* and allied genera, to which the last belongs, are mainly desert forms from Africa and India. Other allies of the plovers are the stone curlews (*see* CURLEW), lapwings (*q.v.*), oyster-catchers (*q.v.*), turnstones (*q.v.*), and avocets (*q.v.*). (For "plovers' eggs" see LAPWING.)

PLUCKER, JULIUS (1801–1868), German mathematician and physicist, was born at Elberfeld on June 16, 1801. After studying at the universities of Bonn, Heidelberg and Berlin he went in 1823 to Paris, where he came under the influence of the great school of French geometers, whose founder, Gaspard Monge, had only recently died. In 1825 he was received as *Privatdozent* at Bonn, and after three years he was made professor extraordinary. He then held the following posts: professor of mathematics at Friedrich Wilhelm's Gymnasium, Berlin (1833–34), professor of mathematics at Halle (1834–36), professor of mathematics (1836–47) and finally professor of physics at Bonn. He died on May 22, 1868.

From his lectures at Bonn sprang his first great work, *Analytisch-geometrische Entwickelungen* (vol. i., 1828; vol. ii., 1831), in which he introduced the abridged notation which has since characterized modern analytical geometry. (*See* ANALYTIC GEOMETRY.) He applied this notation to the straight line, circle and conic sections, and he used it in his theory of cubic curves. Also he established the great principle of duality. Plucker discovered the six equations known as "Pliicker's equations" connecting the numbers of singularities in algebraical curves. (*See* CURVE.) Plucker communicated his formula? in the first place to *Crelle's Journal* (1834), vol. xii.. and gave a further extension and complete account of his theory in his Theorie der algebraischen *Curven* (1839). In his *System* der *analytischen* Geometrie (1835) he introduced the use of linear functions in place of the ordinary co-ordinates; he also made the fullest use of the principles of collineation and reciprocity. He discussed curves of the third order and gave a complete enumeration of them, including two hundred and nineteen species. In 1846 Pliicker published his *System* der *Geometrie* des *Raumes* in *neuer* analytischer *Behandlungsweise,* but this contains merely a more systematic and polished rendering of his earlier results.

After his appointment as professor of physics at Bonn, Plucker began a series of researches in physics. His first physical memoir, published in *Poggendorffs Annalen* (1847), deals with the behaviour of crystals in a magnetic field. Then followed a long series of researches, mostly published in the same journal, on the properties of magnetic and diamagnetic bodies, establishing results which are now part and parcel of our magnetic knowledge. This was followed by researches on the discharge tube; he investigated the deflection of the discharge by a magnet and the behaviour of the negative glow in a magnetic field. Plucker, first by himself and afterwards in conjunction with Hittorf, made many important discoveries in the spectroscopy of gases. He anticipated Bunsen and Kirchhoff in announcing that the lines of the spectrum were characteristic of the chemical substance which emitted them, and in indicating the value of this discovery in chemical analysis. According to Hittorf he was the first who saw the three lines of the hydrogen spectrum, which a few months after his death were recognized in the spectrum of the solar protuberances, and thus solved one of the mysteries of modern astronomy. Induced by his mathematical friends in England, Plucker in 1865 returned to "line geometry." His first memoir on the subject was published in the *Philosophical* Transactions of the Royal Society of London in 1865. Plücker himself worked out the theory of complexes of the first and second order, introducing in his investigation of the latter the famous complex surfaces of which he caused those models to be constructed which are now so well known to the student of the higher mathematics. He left an uncompleted work on the subject which was so far advanced that his pupil and assistant Felix Klein was able to complete and publish it. (*See* LINE GEOMETRY)

See R. F. A. Clebsch's obituary notice (*Abh.* d. kon. *Ges.* d. *Wiss. z. Göttingen,* 1871, vol. xvi.), to which is appended an appreciation of Plucker's physical researches by Hittorf, and a list of Plucker's works by F. Klein. See also C. I. Gerhardt, *Geschichte* der *Mathematik in Deutschland,* p. 282, and Pliicker's life by A. Dronke (Bonn, 1871).

PLUM, the English name both for certain kinds of tree and also generally for their fruit. The plum tree belongs to the genus *Prunus,* family Rosaceae. Cultivated plums are supposed to have originated from one or other of the species P. *domestica* (wild plum) or P. *insititia* (bullace). The young shoots of P. *domestica* are glabrous, and the fruit oblong; in P. insititia the young shoots are pubescent, and the fruit more or less globose. A third species, the common sloe or blackthorn, P. *spinosa,* has stout spines; its flowers expand before the leaves; and its fruit is very rough to the taste, in which particulars it differs from the two preceding. These distinctions, however, are not maintained with much constancy. P. domestica is a native of Anatolia and the Caucasus, and is considered to be the only species naturalized in Europe. P. insititia is wild in southern Europe, in Armenia, and along the shores of the Caspian. In the Swiss lake-dwellings stones of the *P.* insititia as well as of P. spinosa have been found, but not those of P. *domestica.* Nevertheless, the Romans cultivated large numbers of plums. The cultivated forms are extremely numerous. some of the groups, such as the greengages, the damsons and the egg plums being very distinct, and sometimes reproducing themselves from seed. The colour of the fruit varies from green to deep purple, the size from that of a small cherry to that of a hen's egg; the form is oblong acute or obtuse at both ends, or globular; the stones or kernels vary in like manner; and the flavour. season of ripening and duration are all subject to variation. From its hardihood the plum is one of the most valuable fruit trees, as it is not particular as to soil, and the crop is not readily destroyed by spring frosts. Prunes and French plums are merely plums dried in the sun. Their preparation is carried on on a large scale in Yugoslavia, as well as in Spain, Portugal and southern France.

Plums are propagated chiefly by budding on stocks of the mussel, Brussels, St. Julien and pear plums. The damson, winesour and other varieties, planted as standards, are generally increased by suckers. For planting against walls, trees which have been trained for two years in the nursery are preferred, but maiden trees can be very successfully introduced, and by liberal treatment may be speedily got to a fruiting state. Any good well-drained loamy soil is suitable for plums, that of medium quality as to lightness being decidedly preferable. Walls with an east or west aspect are generally allowed to them. The horizontal mode of training and the fan or half-fan forms are commonly followed; where there is sufficient height probably the fan system is the best. The shoots should be laid in nearly or quite at full length. The fruit is produced on small spurs on branches at least two years old, and the same spurs continue fruitful for several years. Stacdard plum trees should be planted 25 ft. apart each way, and dwarfs 15 or 20 feet. The latter are now largely grown for market purposes, being more easily supported when carrying heavy crops, fruiting earlier, and the fruit being gathered more easily from the dwarf bush than from standard trees.

PLUM (PRUNUS DOMESTICA), SHOWING (A) LONGITUDINAL SECTION THROUGH FLOWER, (B) TWIG WITH BLOSSOM, (C) FRUITS (DRUPES)

Diseases.—The plum is subject to several diseases of fungal origin. A widespread disease known as pocket-plums or bladder-plums is due to an ascomycetous fungus, *Exoascus pruni,* the mycelium of which lives parasitically in the tissues of the host plant, passes into the ovary of the flower and causes the characteristic malformation of the fruit which becomes a deformed, sometimes curved or flattened, wrinkled dry structure, with a hollow occupying the place of the stone. Plum-leaf blister is caused by *Polystigma rubrum,* a pyrenomycetous fungus which forms thick fleshy reddish patches on the leaves. The reproductive spores are formed in embedded flesh-shaped receptacles (perithecia) and scattered after the leaves have fallen. The spots are not often so numerous as to do much harm to the leaves, but where the disease is serious diseased leaves should be' collected and burned. Sloes and bird-cherries should be removed from the neighbourhood of plum-trees, as the various disease-producing insects and fungi live also on these species.

Of recent years the most troublesome disease has been that of Silver leaf due to *Stereum purpureum.* The fungus, one of the Basidiomycetes (*see* FUNGI), enters through a wound and through the mycelium remains in the stem. The leaves become affected and turn a curious ashen colour, something of the appearance of lead. The valuable Victoria plum is particularly attacked. The disease is a notifiable one in Great Britain. (X.)

Cultivation in the United States.—In European countries, varieties of three, or at most four, species of plums are under cultivation, but in North America representatives of at least 12 quite distinct species are commonly cultivated, 2,000 forms of which have been named and described. It is hardly too much to say that of all drupe fruits plums furnish the greatest diversity. Species and varieties give a great range of colours, forms, kinds, sizes, flavours, aromas and textures. The plants are quite as diverse in America as the fruits; some plums are true trees with stout trunks and sturdy branches, while others are slender shrubs; some species have thin, delicate leaves; others, coarse, heavy foliage; in some the plums are large and attractive, in others, small and unattractive with a disagreeable odour.

In geographical distribution in North America, wild and cultivated plums cover almost the whole temperate zone, the several species and varieties being adapted to a great diversity of soils and climates. In Europe nearly all of the varieties of plums belong to the species *Prunus domestica.* This species does not hold the same relative position in America that it does in Europe for the reason that it does not possess in a high degree the power of adaptation to trans-Atlantic environment. The feature of environment most uncongenial to European plums in America is the climate. The plums thrive best in an equable climate like that of Eastern Europe and Western America, and do not endure such extremes of heat and cold, wet and dry, as are found in America east of the Rocky Mountains.

The temperate zone in North America, however, is a natural orchard of wild species of plums, scarcely any part of the United States lacking in one or more species of this fruit growing in the wild. At least ten of these wild species have been more or less domesticated with orchard representatives of several species commonly grown.

The plum is comparatively easy to suit in the matter of soils, and orchard exposure. The chief requisite for the genus in general seems to be a good drainage. Given this condition, some sort of plum can be grown in almost any soil in the United States not wholly prohibitive to plant growth. In western America several plums are commonly grown for the making of prunes. Any plum that can be cured, without removing the pit, into a firm, long-keeping product is a prune. The growth of the prune industry on the Pacific coast is one of the most remarkable industrial developments of American agriculture. The first commercial orchard of prunes was planted in California about 1870. In 1930, the output per annum was valued by the producers at over $1,500,000.

About 1,500 varieties of plums have been described in horticultural literature in America. Of these perhaps 1,000 are of the common European domestic type; perhaps 100 are damson plums; and 400 sorts may be distributed among the 10 or 12 species of wild native plums now under domestication. In addition to the European and native species, an Asiatic plum, *Prunus salicina,* has been introduced from Japan, of which there are probably zoo sorts, if hybrids with native species be included.

The leading varieties of plums cultivated at the present time are in order of ripening:—

Beauty, a splendid large, very early Japanese plum, yellow. juicy flesh; Abundance, a large, juicy, sweet, Japanese plum; Burbank, a productive, red, early Japanese plum, home or local markets: Formosa. Japanese plum recommended for productiveness and large fruits; Santa Rosa, new Japanese plum, tree and fruit characters surpass Abundance and Burbank; American Mirabelle. larger than the European Mirabelle, splendid for dessert and culinary purposes; Grand Duke, very large, dark purple, long oval in shape, low quality; Hall, good, dark purple, large, well flavoured, desirable for roadside stands or city markets; Stanley, prune shape, large, dark blue, freestone. excellent quality; Imperial Epineuse, purplish red, prune shape, excellent in quality; Reine Claude, yellow, roundish oval, good in quality, late, desirable for canning; Italian Prune, purplish black, freestone, excellent quality for dessert or canning; French damson, the largest and best of the damsons, excellent for preserves; Albion, purplish black, large, flesh golden yellow, clingstone, good, very late.

BIBLIOGRAPHY.—L. H Bailey, *Standard Cyclopedia of Horticulture* (1914–27); U. P. Hedrick. Plums *of New York* (1911). (U. P. H.)

PLUMBAGO, a name frequently applied to graphite (*q.v.*).

PLUMBING, properly working in lead (Lat. *plumbum),* now a term embracing all work not only in lead, but also in tin, zinc, copper and other metals, connected with the installation, fitting, repairing, soldering, etc., of pipes for water, gas, drainage, on cisterns, roofs and the like in any building.

Water Supply.—Where there is no public water supply, an important part of plumbing is to bring water for domestic and other purposes from streams and wells, to buildings for distribution to various fittings and sanitary appliances.

In the case of streams giving an abundant supply, the general appliance to use is the hydraulic ram. This works automatically by raising a portion of the water flowing through it to a high level cistern, from which fittings are supplied by gravitation. The ram is fitted in a frost proof house and provided with a supply or drive pipe, delivery and waste pipes. Excess water which forms the motive power may usually be conveyed through the waste pipe to the stream at a lower level. Particular features in this work are strength and permanent soundness, because of the shock and strain due to pulsation of the ram, while entry of air would have detrimental effect. Pipes used in this work are lead, iron or copper.

Water is extracted from wells by pumps of different types. Suction pumps deliver water at their own height, while lift pumps deliver to greater heights than that at which they are placed. As pumps arc dependent for their working upon atmospheric pressure, it is not wise to fix them more than 28 ft. above the water level in the well, consequently, in deep wells, they must be fixed actually in the weil. Lead, iron or copper pipes are used for this work. Suction and delivery pipes should be at least half the diameter of the pump barrel; airtightness is essential, and in the case of long pipes or high lifts adequate air vessels must be inserted to overcome the inertia of water and keep it in motion between the strokes of the pump. Again lead, iron or copper pipes may be used, due regard being paid to the character of the water and its action on metals.

Where there is a public supply, a separate communication pipe is laid to each building, the size being dependent upon the size of the building and whether fire hydrants, etc., are fitted. This pipe should be, at least, 2 ft. 6 in. below ground as a protection from frost, and a stop cock, with draw-off, should be placed in an accessible position, immediately within the premises. Branches are often taken from the communication pipe for drinking water, but its main purpose is to supply the house storage cisterns. Here the supply is controlled by a ball valve which automatically cuts off the supply when the cistern is filled.

House cisterns should be placed in clean, accessible positions, be fitted with a cover and overflow pipe and stand over a metal tray, also provided with an overflow pipe, to protect the structure in case of fracture and leakage.

Distribution pipes of lead, iron or copper are led from the cistern to supply various fittings throughout the building; these should be protected from damage and frost and well fixed to prevent sagging with consequent trouble from air-locks.

The character of the water has an important bearing upon the selection of metals for use in connection with water supply. Soft waters, especially from moorland sources, often dissolve lead, which should therefore not be used for the storage or conveyance in these cases. These waters also cause excessive rusting with iron, with offence to the aesthetic senses, owing to discolouration, and damage to linen when used for laundry purposes. Here copper has manifest advantages.

With hard waters, mineral salts are deposited, causing obstruction in vessels and pipes. Hardness may be removed by the introduction of water softening apparatus in the main supply pipe or by the physical action of "etherium" activators in cisterns.

Rain water is conducted from roofs by gutters and pipes. In towns it is usually run to waste, while in country houses it is collected in underground tanks, filtered, pumped and used for laundry or carriage washing purposes.

Fire hydrants are connected to cast or wrought iron pipes, in which the water is under constant pressure, their disposition being such that operators may have easy escape. Pipe sizes for this work should be carefully calculated to ensure an adequate supply at all points.

Drinking fountains are usually connected to the main water supply, while unfiltered water may be used for ornamental fountains.

Drains.—With ever increasing heavy traffic, drains are best constructed of heavy cast iron. jointed with metallic lead. The use of this material is facilitated by the number of fittings of varying angles now obtainable. In large buildings drains are often fixed on walls or suspended from ceilings in basements, especially where basement floors are below sewer levels. Such drains must be properly sealed at all openings and traps. This procedure necessitates extra provision of ventilating pipes to protect the water seals of traps and to remove gases. Access covers are made air-tight with greased felt washers.

Soil pipes may be in lead or iron. Lead is preferable because of its internal smoothness, adaptability, freedom from corrosion, and permanent soundness when jointed with wiped soldered joints, especially when in concealed positions inside buildings. Lead should not be used for the waste of slop sinks where hot water is used. Cast iron pipes are used where strength is required.

Waste pipes may be in lead, iron or copper. When lead is used for main waste pipes through which heated discharges pass it must have expansion joints to obviate fracture, it must be well supported to prevent sagging. Wrought iron and copper pipes are largely supplanting lead for waste pipes because of their greater strength, whereby they maintain their alignment between fixings Special maiieabie iron fittings are used with wrought iron wastes to maintain internal bore without recesses for lodgement.

Both soil and waste pipes require adequate ventilation to preserve the water seals of traps.

Sanitary Fittings.—All fittings such as baths, bidets, lavatories, slop sinks and water closets should be fixed on impervious floors. The craze for open haths is disappearing. When covered, these fitments should be entirely enclosed so that there is no possibility of undesirable articles being placed underneath. The essential points of sanitary fittings are absence of corners where filth may collect, adequate water supply, quick discharge arrangements, proper trapping and ventilation to preserve the water seals of traps.

In large houses different types of sinks are used for various purposes, such as the reception of slops, preparation of vegetables and food, washing up, etc.

Bath rooms *en* suite with bedrooms are becoming common, and wash basins with running water are frequently fixed in bedrooms. These often necessitate concealed piping systems, which work should only be entrusted to skilled plumbers who have proved their ability as craftsmen and their knowledge of sanitary principles.

Roof Work.—An outstanding feature of plumbing is lead work on roofs. Although lead is not so largely used for covering large flat roof surfaces as formerly, it is in evidence upon practically all roofs in the form of gutters, flashings, etc., for making watertight joints between slated or tiled roofs and brick walls, chimneys, etc., in addition to covering dormer windows, stone cornices, domes, turrets and other ornamental features. The great malleability of lead and comparative ease with which skilled plumbers can boss it into intricate shapes renders it invaluable for this purpose.

For some years there has been a revival in the use of cast lead rain-water pipes, heads, cornices, etc., because of its undoubted superiority and lasting qualities.

Milled sheet lead is more generally used for roof work, although for the very best work, as on cathedrals, and the like, cast sheet lead is still largely used.

An entirely new feature of plumbing is the covering of steel columns and constructional work with ornamental cast lead, both for preservation of the metal structure and to give artistic appearance.

Hot Water.—The increasing number of baths and wash-basins has added much work under the category of plumbing in the arrangement and fixing of domestic hot water apparatus. This consists of the fixing of boilers and storage vessels with circulating pipes between the same, and adequate draw off pipes. Especial points to be considered are the sizing of pipes and vessels to ensure adequate heating of the water, while at the same time providing sufficient supplies; effective insulation to conserve heat; and general arrangement of pipes to ensure the withdrawal of all heated water, upon the opening of taps, before cold water can find exit. One of the greatest faults in this direction is the possibility of drawing cold water from taps while heated water is bottled up in the apparatus. While gravity circulations are more general, accelerating pumps are often installed to ensure adequate circulation and supplies.

Insulation consists of covering pipes and vessels with some porous material to provide a layer of stagnant air around them and so obviate the withdrawal of heat by conduction.

Other Points.—Pipes for conveyance of gas to lighting points, cooking and warming stoves and water heating apparatus are usually of wrought iron or steel with fittings of similar material or malleable iron. Screwed joints being used, the threads are smeared with a lead and oil compound. These pipes must be well fixed to prevent damage. They are usually concealed.

For beer engines, pumps and spirit pipes, block tin pipes are used, joints being of the cupped variety known as blown joints. The solder used contains bismuth to lower its melting point so that a surface alloy is formed at a temperature below the melting point of the pipes. Pewter, an alloy of lead and tin, is used for washing bowls, trays, etc.

Plumbing work in connection with cold storage, etc., consists of bending and fixing wrought iron tubes and connections.

Chemical Plumbing consists of the erection and jointing of large chambers of heavy sheet or plate lead; the manufacture and fixing of large pipes for conveyance of acids and gases; covering of earthenware cocks; iron fans and lining vessels constructed of other metals with lead. In this work lead is used because of its great immunity from destruction by the action of acids; consequently all joints are made by lead burning or the fusing together of edges with the addition of extra lead to strengthen the seams and joints from a filling rod.

Plumbing work on ships is similar in many respects to that ashore. Fresh water is carried on liners in tanks in the ship's bottom, from which it is pumped to the upper decks for filtration, aeration, and storage for delivery by gravitation to various points about the ship. Waste water, soil, etc., from fittings above the water-line is carried in pipes to openings in the ship's side immediately above the water-line, and there discharged into the sea through storm valves. Waste matter from decks and fittings below the water-line is carried to bilge tanks in the ship's bottom, from which such is pumped for delivery overboard. Wrought iron pipes are largely used on ships and the process of welding branches to them, as well as flanges for connections by the oxy-acetylene flame, is largely followed. Plumbing work on ships is of a heavy character. Special fittings such as water closets arranged so that they may be securely bolted to the decks, are used.

Materials. — The following is a short description of materials used in plumbing with methods of jointing.

Sheet lead may be either cast or milled. Cast sheet lead is lead poured over a prepared sand-bed and struck off to a required thickness. With milled sheet lead, sheet copper, zinc and iron, the metals are passed backwards and forwards between huge rollers until they assume a required thickness, consequently these latter are more dense.

All sheet metals used for roof coverings are joined by rolls, laps, welts, etc., which, while providing fixings allow for movements of the metals under the influence of varying temperatures. Soldering, brazing and rigid fixings are not resorted to unless unavoidable.

For internal work, lead is jointed by soldering with wiped joints. Copper is brazed and iron is welded.

Lead pipes are squirted from a machine under great pressure while the metal is in a plastic condition. These are joined by wiped soldered joints, which process consists of pouring or splashing heated solder on to prepared ends, manipulating them until the pipe is sufficiently heated to permit a surface alloy to form, and then the solder is wiped with a cloth.

Lead burning consists of applying an intense flame, produced by mixing coal-gas and oxygen, oxygen and acetylene or other combinations of gases to prepared edges and fusing them together with local heat; extra lead is added from a filling rod.

Cast iron pipes are made by pouring molten metal into a vertical mould with the socket end downwards, or into a horizontal water-cooled mould, which revolves rapidly, thereby spinning the metal to shape with increased density. These pipes are jointed by filling the sockets with yarn and metallic lead tightly staved home with special tools.

Wrought iron and steel pipes are made from strip metal bent to form a tube and welded by either butting or lapping the edges. Lap-welded tubes are the best. These pipes are usually made in three strengths, designated gas, water and steam, and are jointed by threading the ends and screwing together with prepared fittings.

Fittings used with wrought iron and steel tubes are either made from strip metal bent to shape and welded, or of malleable iron, which is cast iron rendered less brittle by extended annealing.

Iron pipes are protected from corrosion by galvanizing, which consists of coating the metal with zinc; painting; subjecting them to the action of superheated steam which forms a protective coating of magnetic oxide on the surface or by dipping them while hot into a bath containing a mixture of coal tar, pitch, resin and linseed oil, the latter process being known as Dr. Angus Smith's method.

Copper tubes are made by drawing extrusions from cast billets over mandrils, with huge machinery. When of stout substance, these tubes are joined by screwed and socketed joints. Owing to the great strength and excellent physical properties of this metal, it has been found that tubes of thin substance or light gauges are extraordinarily strong, although not of sufficient thickness to cut a thread into their walls. The comparatively recent introduction of compression joints, whereby soundness is assured by simply compressing the ends of tubes in gun-metal joints, has rapidly brought these tubes into prominence for use in connection with hot and cold water supplies and other features of plumbing, thus facilitating installations *de luxe* at comparative costs.

Welding operations in plumbing are usually carried out by use of the oxy-acetylene flame (*q.v.*). (W. Sco.)

PLUM CURCULIO, a North American curculionid beetle, or weevil (*Conotrachelus nenuphar*). This insect is confined to North America east of the Rocky mountains. It ranges as far north as Manitoba and Quebec, and as far south as Victoria, Texas, and northern Florida. In this territory it is a serious enemy to stonefruits and also attacks the apple and other pomaceous fruits. It is especially injurious to all varieties of plums, and to peaches and cherries. Its original food was probably the fruit of native *Crataegus*.

The adult 'curculio is small (about ¼ in. long), dark brown in colour, with whitish markings on the thorax and the hinder part of the wing-covers. It lays its eggs in holes next to a crescent-shaped cut made in the skin by the beetle's beak. The function of the crescent-shaped cut is to kill the spot in the fruit containing the egg, so that the latter will not be crushed by the rapidly growing fruit. The larvae penetrate the flesh of the fruit, and a number of them may occur in the same plum or peach. On reaching full growth, the larva leaves the fruit and enters the soil, forming a cell in which it transforms successively to the pupa and adult. It rests in the pupal stage for two or three weeks. The resulting beetles feed upon the fruit and foliage until the approach of cold weather, when they enter hibernating quarters in protected places such as under trash in the orchards or in near-by woods. In its more northern range the insect has but one generation annually. In the far south some individuals develop a second generation.

The plum curculio is a great enemy to orchards. It was estimated in 1938 that the annual loss through its work in the United States was about $10,000,000. It has several natural enemies among the hymenopterous and dipterous parasites, and it is destroyed by a few species of predatory insects. The fruit attacked by it often falls to the ground, and under such conditions poultry destroy many of the pests.

Fruit growers rely chiefly on spraying with lead arsenate for the control of the plum curculio. The foliage of the peach is particularly susceptible to injury by arsenicals, although most of this can be overcome by the addition of lime or of zinc sulphate and lime.

The sprays on peach are usually combined with a self-boiled lime sulphur or one of the so-called wettable sulphurs to control various diseases, especially brown rot, which often gains entrance into the fruit at points injured by the curculio.

In areas in which a second brood of the curculio develops and where the insect becomes especially abundant, spraying is supplemented by a number of other practices, including the jarring of the trees and the capturing of the beetles on sheets placed underneath, the picking up and destruction of infested wormy drop peaches, and cultivation during the period when the insect is transforming in the ground and when it is readily injured by any disturbance of the soil.

Detailed information on the control of the insect may be obtained from State Agricultural Experiment Stations or from the U.S. Department of Agriculture. (L. O. H.)

PLUMER, HERBERT CHARLES ONSLOW PLUMER, 1ST VISCOUNT, of Messines, cr. 1929 (1857–1932), British field-marshal, was born on March 13, 1857, and entered the army in 1876. He served on the Red Sea littoral in 1884, and in 1896 commanded a mounted regiment in the Matabele Campaign. Before the outbreak of the South African War (1899) he raised the Rhodesian field force, which he commanded during the early months of the contest. He was promoted major-general on the conclusion of hostilities.

In May 1915 Sir Herbert Plumer was selected to lead the II. Army on the Western Front. His army was not very actively engaged during the remainder of 1915, nor yet in 1916, but on June 7, 1917, Plumer gained a signal victory at Messines, *(See* YPRES, BATTLES OF.) In November he took charge of the British troops sent to the basin of the Po after the Italian defeat at Caporetto, and in the following March was recalled to Flanders to resume the leadership of the II. Army just before the great German offensive started. In the general advance in August, his army took part in the operations for the recovery of Belgian Flanders. At the peace he received a peerage, promotion to field-marshal and a grant of £30,000. He subsequently commanded the British forces on the Rhine for a short time. From 1919 to 1925 he was governor of Malta, and from 1925 to 1928 high commissioner for Palestine. He died July 16, 1932.

PLUMPTRE, EDWARD HAYES (1821–1891), English divine and scholar, was born in London on Aug. 6, 1821. A scholar of University college, Oxford, and a fellow of Brasenose, he was ordained in 1847, and became professor of pastoral theology at King's college, London. in 1863 he was given a prebendal stall at St. Paul's, and from 1869 to 1874 he was a member of the committee appointed by Convocation to revise the authorized version of the Old Testament. He was Boyle lecturer in 1866–67 ("Christ and Christendom"), and Grinfield lecturer on the Septuagint at Oxford 1872–74. After successively holding the livings of Pluckley and Brickley in Kent, he was installed in 1881 as dean of Wells. He died on Feb. 1, 1891.

Plumptre translated the plays of Sophocles (1865) and Aeschylus (1868), and the *Divina commedia* of Dante (1886). In verse his main achievements were *Lazarus* (1864), and *Master and Scholar (1866).* Among his many theological works may be mentioned *An Exposition of the Epistles to the Seven Churches of Asia* (1877), *The Spirits in Prison* (1884), "The Book of Proverbs" (which he annotated in the Speaker's *Commentary),* the "Synoptic Gospels, Acts, and II. Corinthians," in Bishop Ellicott's *New Testament Commentary,* and *Life of Bishop* ***Ken*** *(1888).*

PLUNKET, OLIVER (1629–1681), Irish Roman Catholic divine, was born at Loughcrew, Co. Meath. He was appointed archbishop of Armagh and primate of Ireland in July 1669 and in November he was consecrated at Ghent, reaching Ireland in March 1670. The measures following on the Test Act bore hardly upon him, and in Dec. 1678 he was imprisoned in Dublin Castle for six weeks. Accused of a share in the Irish branch of the "Popish Plot," he was brought to London, and in June 1681 arraigned in the King's Bench, charged with conspiring to bring a French army to Carlingford. He made a good defence, but on the most absurd of evidence the jury convicted him of treason, and on July 1, he was hanged, drawn and quartered at Tyburn.

PLUNKET, WILLIAM CONYNGHAM PLUNKET, 1ST BARON (1764–1854), Irish lawyer, orator and statesman, was born in the county of Fermanagh in July 1764, the son of a Presbyterian minister, and studied at Trinity college, Dublin. Having entered Lincoln's Inn in 1784, Plunket was called to the Irish bar in 1787. He gradually obtained a considerable practice in equity and was made a king's counsel in 1797.

In 1798 he entered the Irish parliament as member for Charlemont. He was an anti-Jacobin Whig of the school of Burke, and a fervent Irish patriot. But he was a sincere admirer of the constitutional government of England as established in 1688; he even justified the ascendancy it had given to the Established Church, although he thought that the time had arrived for extending toleration to Roman Catholics and dissenters. To transfer it to Ireland as thus modified, and under an independent legislature, was the only reform he sought for his country; he opposed the union because he thought in incompatible with this object.

When Plunket entered the Irish parliament, the Irish Whig party was almost extinct, and Pitt was feeling his way to accomplish the union. In this he was seconded ably by Lord Castlereagh, by the panic caused by a wild insurrection, and by the secession of Grattan from politics. When, however, the measure was brought forward, among the ablest and fiercest of its adversaries was Plunket, whose powers as a great orator were now universally recognized. His speeches raised him immediately to the front rank of his party; and when Grattan re-entered the moribund senate he took his seat next to Plunket, thus significantly recognizing the place the latter had attained.

After the union Plunket returned to the practice of his profession, and became at once a leader of the equity bar. In 1803 he was selected as one of the Crown lawyers to prosecute Emmet. For his speech on this occasion he was exposed to much obloquy, and more especially to the abuse of Cobbett, against whom he brought a successful action for damages. In 1803, in Pitt's second administration, he became solicitor-general, and in 1805 attorney-general for Ireland; and he continued in office when Lord Grenville came into power in 1806. Plunket held a seat in the Imperial parliament during this period, and there made several able speeches in favour of Catholic emancipation, and of continuing the war with France; but when the Grenville cabinet was dissolved he returned once more to professional life.

In 1812 he re-entered parliament as member for Trinity college, and identified himself with the Grenville or anti-Gallican Whigs. He was soon acknowledged as one of the first orators, if not the first, of the House of Commons. In 1822 Plunket was once more attorney-general for Ireland, with Lord Wellesley as lord-lieutenant. One of his first official acts was to prosecute for the "bottle riot," an attempt on his part to put down the Orange faction in Ireland. He strenuously opposed the Catholic Association, which about this time, under the guidance of O'Connell, began its agitation. In 1825 he made a powerful speech against it; thus the curious spectacle was seen of the ablest champion of an oppressed church doing all in his power to check its efforts to emancipate itself. In 1827 Plunket was made master of the rolls in England; but, owing to the professional jealousy of the bar, who regarded an Irishman as an intruder, he resigned in a few days. Soon afterwards he became chief justice of the common pleas in Ireland, and was then created a peer of the United Kingdom. In 1830 he was appointed lord chancellor of Ireland, and held the office, with an interval of a few months only, until 1841, when he finally retired from public life. He died on Jan. 4, 1854, and was succeeded by his eldest son, Thomas Spen Plunket (1792–1866), bishop of Tuam, as and baron. *See* the *Life of the First Lord Plunket* (1869), by his grandson, David Robert Plunket.

PLUNKETT, SIR HORACE (CURZON) (1854-1932), K.C.V.O. (1903), son of the 13th Baron Dunsany, was born on Oct. 24, 1854, and educated at Eton and Oxford. After engaging in cattle ranching for ten years, his interest in agriculture led him to devote himself to the promotion of agricultural co-operation, and in 1894 he founded the Irish Agricultural Organization Society. As a member of parliament from 1892 to 1900, he strongly advocated the cause of agriculture, and in 1899 he was appointed vice-president of the department of agriculture and technical instruction for Ireland. Two years later he became commissioner of the Congested Districts Board in Ireland. He was elected F.R.S. in 1902, and in 1919 endowed a trust, known by his name, for the development of agriculture. He presided over the Irish Convention of 1917–18, and was a Senator (1922–23) of the Irish Free State. He died March 26, 1932.

His works include, *Ireland in the New Century* (1904); *The Rural Life Problem of U.S.* (1910); *Some Tendencies of Modern Medicine* (1913); and *A Better Way* (1914).

PLURALISM. The term describes certain schools of philosophical thought. It is, indeed, distinctive of one of the two groups into which metaphysical theories may be divided by what is perhaps the profoundest of the many differences apparent between the various directions taken by the speculations of eminent philosophers. In short, every philosophical system is either singularistic or pluralistic; that is, it takes for its starting point, and for the guiding principle which directs its development, the idea of the essential unity of reality; or, on the other hand, it regards as fundamental the characters of diversity and plurality which are everywhere in evidence in the realms open to observation.

Nevertheless, the term "pluralism" is by no means definite in meaning. On the contrary it is ambiguous and capable philosophically of a number or different meanings, each of which, however, refers to some peculiarly radical distinction in philosophic thought. But, as so frequently happens in such cases, the word has tended more and more to become restricted in meaning to one particular type of theory. This is perhaps an example of the survival of the fittest, for it is probable that what is nowadays generally meant by "pluralism" is capable of giving a better account of itself and of putting up a stronger defence than any of the other kinds of theory which may be included within the scope of the term as literally interpreted

QUALITATIVE PLURALISM

In the first place the term "pluralism" may have a *qualitative* meaning. One of the oldest problems of philosophy is that which concerns itself with the question whether the ultimate fundamental stuff, which is the ground of reality, is a single substance or includes a number of substances with differing attributes. Theories founded on the supposition that there are many ultimate substances, or at any rate more than one, are "pluralistic" in the qualitative sense of the term.

As a matter of fact only one theory of this type has ever been seriously propounded and effectively defended. This is the theory of "dualism," which holds that there are two kinds of fundamental substance. The two substances of dualism are commonly termed "mind" and "matter." and the distinctive attributes assigned to them are not merely different but are strictly incomparable with one another. The essential property of "mind" is thought; that of "matter" is extension. Dualism, which probably approximates more nearly than any other metaphysic to the practical, if unformulated, belief of the ordinary man who does not concern himself with philosophical analysis, recurs at intervals, in one form or another, throughout the history of speculative thought. But the clearest statement and the most able defence of it are to be found in the writings of Descartes (1596–1650), with whom modern philosophy is generally regarded as beginning. Descartes starts from the existence of the self. The fact of consciousness is, he holds, quite undeniable. He then proceeds to deduce the existence of God from the presence in our minds of an idea of God which embraces attributes so exalted as to make it inconceivable that the idea could have originated in anything so limited as the human mind. Accordingly its presence can only, he thinks, be explained by an external cause, namely, God himself. From this it is an easy step to the existence of matter. For God, being perfect, would not falsify our clearest perceptions; and among these is the perception of matter. Moreover, the attribute of matter which is most distinctly apparent to us is its extension, or occupancy of space, and this must accordingly be regarded as the essentially distinctive property of material substance.

We need not stop to consider in detail the defects of this argument which Descartes elaborated with remarkable thoroughness and ingenuity. It is sufficient to point out that the essential feature of his analysis, namely, the division of reality into mind and matter, was at fault. Matter as he conceived it, so far from being a substance and therefore concrete in the most complete sense, was altogether abstract. The same is true, though to a lesser extent, of his conception of mind. In fact the dualistic division of the universe into mind and matter, though it starts, as all philosophical theories must start, from the elements given in immediate experience, proceeds by abstracting some of these elements and elevating them to the position of concrete entities in their own right. This process, useful and indeed necessary for the purposes of such bodies of knowledge as the special sciences, is too artificial to yield anything of metaphysical value. Metaphysics, to achieve its end, must keep in constant touch with the concrete, that is, with experience. But a process of reasoning like that adopted by Descartes inevitably tends further and further away from the concrete to the abstract. The practical consequences of this for dualism are seen in its inability to attack with any success such problems as those concerned with the relation of body and mind, the nature of the external world, and the question as to how knowledge is possible at all.

Dualism is the only form of qualitative pluralism which has ever been seriously developed. (But it should perhaps be pointed out that the cosmology of Empedocles [490–430 B.C.], with its four elements, earth, air, fire, water, together with the qualitative atomism of his follower Anaxagoras, who regarded the universe as made up of a countless number of qualitatively simple elements, are really forms of qualitative pluralism.) It is true that some of the doctrines of theosophy and allied systems appear to tend to a pluralism of more than two kinds of substance, but these doctrines are essentially speculative and have never been developed in a form sufficiently definite, nor defended by arguments sufficiently logical, to affect at all seriously the development of philosophical thought. We may therefore conclude this brief survey of qualitative pluralism and pass on to consider quantitative pluralism.

QUANTITATIVE PLURALISM

. Quantitative pluralism includes all those theories which hold reality to be made up of a number of relatively independent substantial entities, each of which exists, at any rate to some extent, in its own right. Quantitative pluralism is thus sharply contrasted with those forms of singularism or absolutism which regard reality as ultimately consisting of a single individual being, of which the many and diverse elements which seem to exist in the world are no more than mere appearances, qualities, or modes, having no real existence in themselves. This contrast has sometimes been expressed by saying that whereas, according to pluralism, the multitude of entities which appear to find a place in the universe have a "substantival" existence, according to singularism their existence is merely "adjectival" as attributes or aspects of the one real being.

We may classify types of quantitative pluralism according to their doctrine regarding the substance composing the real entities which they postulate. This substance may be material, spiritual (or mental), or it may be neutral in the sense that its essential character is unknown, or, if known in part, cannot be placed definitely in any particular category.

Neutral Pluralism.—The first kind of neutral pluralism, where the nature of the ultimate substance of which individual entities are composed is taken as unknown, though not altogether untenable, is philosophically barren and need not detain us. Its best known exponent is Herbart, who contended that reality is ultimately made up of a number of independent entities, of the inner nature of which we could know nothing, although they were the ground of all the facts of which knowledge was possible. Herbart's theory did not seriously affect the course of metaphysical speculation. It was largely a reaction against the philosophy of Hegel (1770–1831).

The second kind of neutral pluralism, in which the nature of the ultimate reals is regarded as known, at least in part, but as not definitely classifiable, has been developed only in comparative!~recent years. William James (1842–1910), foremost and most original of American philosophers, seems to have been the first to have given it clear expression, though he was probably influenced to some extent by the speculations of the German physicist Ernst Mach. James based his belief on what he himself described as a "radical empiricism." He held essentially that the world of which we have knowledge is made up of a number of fundamental elements which may be taken as arranged in different types of patterns or sequences. If the elements are set out in one way we get the kind of structures or series which make up the contents of what we call "minds." Another method of selecting the elements will give the type of arrangements which constitute those entities which we know as material objects or physical events. Yet the elements of a pluralistic universe of this kind are not to be regarded as themselves essentially mental or material—they are of "neutral" stuff. Incidentally James was the first thinker to give the term "pluralism" currency among English-speaking philosophers, though in Germany we find it even as early as Wolff, the disciple of the great Leibniz (1646), to whom we shall refer later.

More recently still, a neutral pluralism which in some respects exhibits a strong family likeness to that of William James has been developed in England by Bertrand Russell, who describes his own theory by the name "logical atomism." Russell's procedure consists essentially of an exceptionally detailed analysis of the material open to immediate observation, especially the particulars given in sensation and in imagery, followed by an attempt to build up from this material alone constructions corresponding to the fundamental concepts characteristic of physics and of philosophy, or to such among these concepts as analysis may show to be valid within their limits. Russell has applied his method to the analysis both of "mind" and of "matter." Current developments in the theories of some of the American neo-realists seem also to be moving along rather similar lines.

There can be no doubt that a neutral pluralism of the type we have outlined is in many respects an extremely powerful theory. Not only does it establish a metaphysical position which calls for serious consideration, but it introduces into the philosophical world an analytic technique the value of which it would be difficult to overestimate. It is not possible to undertake a detailed criticism here; but it is probable that the chief objections to current expositions of the theory are to be found in the fact that they dispose of some of the traditionally pressing questions of metaphysics with arguments which may be regarded as unduly facile, to say the least; while many will feel that most of the really ultimate problems are left untouched. No doubt the supporters would retort that these problems are insoluble, and no more time should be wasted on them.

Material Pluralism.— There remain for consideration material pluralism and spiritual pluralism. For the material pluralist the world consists, in the last analysis, entirely of particles or bodies, the properties of which are among those commonly associated with the concept of matter, in particular mass (or, perhaps, electric charge); position and (perhaps) extension in space; and position and (perhaps) extension in time.

The earliest philosophers to give coherent expression to a theory of this kind were the Greeks, Leucippus and Democritus (about 460–350 B.C.). We owe to Leucippus the first clear statement of philosophic materialism, namely, the reduction of all reality to the primary qualities of matter. The denial of qualitative differences between the elements was combined with an atomic theory of matter which was conceived as split up into an infinite number of minute reproductions of itself, these "atoms" being invisible to the eye, eternal and unchangeable, and differing from one another only in shape and size. The scientific development of this point of view by Democritus was an outstanding philosophical achievement which marked a definite stage in the progress of the speculative thought of antiquity.

Although material pluralism, or atomistic materialism, suffered long periods of eclipse during the middle ages and the Renaissance, it has been revived at intervals and was finally given complete and powerful expression as a result of the great advances made during the last century in physical and biological science. Twentieth century materialism is chiefly associated with the name of Herbert Spencer (1820–1903), who developed an extremely comprehensive system based on three current doctrines which were just then achieving remarkable triumphs in the respective realms of chemistry, physics and biology. These doctrines were the atomic theory, the principles governing the distribution and conservation of energy, and the Darwinian theory of evolution by natural selection. In a swift and temporarily overwhelming advance, philosophic materialism reached its zenith. But its success was a transient one. Before the end of the century it was already beginning to stagger under the powerful blows of its opponents, and during the years that have since elapsed it has ceased to be regarded as a tenable metaphysical theory. It can probably be safely stated that it will never again be revived unless it be in so changed a form as to be unrecognizable. Briefly, its downfall may be said to be due to three inherent defects. In the first place the concepts and principles on which it is based are merely descriptive in character, that is, they do no more than give an account of what actually occurs, or is presumed to occur, in the world, and do not even begin to provide any kind of genuine explanation of reality. Not only this, but secondly, modern analysis has shown that most of the conceptions of conventional materialism, so far from corresponding to anything really concrete, are most probably no more than abstractions from, or constructions made up of, the content perceived by minds in sense-experience or perception. Thirdly, materialism has never yet been able to give an account of the origin of mind which could possibly be accepted as a satisfying one, while its consequent attempts to dismiss mind as unreal or at most real but ineffective, have been extremely facile and altogether unconvincing.

Spiritual Pluralism.— There remains spiritual pluralism, and it is to this type of theory that the name "pluralism" is most commonly understood to apply at the present time. It is the belief that the world consists ultimately of an indefinite number of beings, essentially spiritual in character. Its origin can be traced back, albeit in a vague form, even to the obscure hylozoism of the ancients, who regarded all nature as alive and informed with a countless number of animate beings, to whose activities all her manifestations were due. But at this epoch the distinction between the physical and ihe mental had not begun to emerge clearly, and only when this occurred was it possible for the development of spiritual pluralism to take place.

But it was not till the coming of Leibniz (1646) that spiritual pluralism at last received definite and coherent statement, together with logical development. Leibniz started from a conception of mind directly opposed to that which had been given currency by Locke and the English empiricists. The latter regarded the mind as a passive receiver of impressions from objects external to it. But Leibniz realized that it is the essence of mind to be active. In his famous work, the *Monadology,* he elaborated the theory that reality consists of an infinite number of individual forces or agents, psychic in nature, which he termed "monads." These individual minds or spirits exhibited every degree of mental development and complexity, from that of beings even higher than man (the "angels") right down to that of psychic entities of so low an order that Leibniz described their being as a *mens momentanea* or mere flash of conscious awareness. In this hierarchy of mind a complete continuity from one level of development to another was postulated.

Leibniz conceived each monad as reflecting within itself the rest of the universe from its own particular "standpoint." The perceptions of each monad were partly conditioned by its particular level of development, and constituted the appearance to it of all the other monads. But Leibniz met with great difficulty at this point. He had conceived the monads as absolutely independent reals with no ground of connection between them. But how could the appearance of beings other than itself arise in such an isolated entity as a monad, which, being "windowless" (as Leibniz put it), was impervious to external influence? Leibniz tried to solve this difficulty by his doctrine of "Pre-established Harmony," which involved the introduction of the idea of God into his system. According to this doctrine the development of the universe is the working out of a plan conceived by God when he created the monads. Each monad contains the principle of its own development, but the course of that development is so arranged that, at any instant, the unfolding order of phenomena within each monad is an accurate representation of the rest of the universe at that instant. This may be illustrated by the analogy of a number of clocks set going by the watchmaker so as always to keep time with one another, though actually there is no connection between them.

The spiritual pluralism of Leibniz, though it continued to exert a dominant influence in Germany until the time of Kant (1724–1804), did not find much vogue among English-speaking philosophers until comparatively recent times. During the last years of the 19th and the early years of the present century, however, it was adopted and developed, in the reaction against crude materialism, by one or two influential thinkers, including Howison in America and the late James Ward in England. Though his system is founded on that of Leibniz, Ward introduced very considerable modifications, exposing the weaknesses of the original theory and endeavouring to eliminate them. He pointed out that pluralism has to explain away three difficulties. Two of these are concerned with what he calls respectively "the upper limit" and "the lower limit" of pluralism. If we are to make reality at all intelligible we must, with Leibniz, postulate continuous development of the monads. But from what did this development originate and how was it set going? We can trace it downwards to ever lower levels, but we cannot find within it the principle and the explanation of its own origin. On the other hand, whither is it tending? A mere plurality of independently developing beings cannot contain any indication of a satisfying explanation which shall harmonize, and give point to, the manifold separate developments. Thirdly, there is the old difficulty, encountered by Leibniz, as to the impossibility of interaction between the monads if these are really independent individuals.

Ward comes to the conclusion that a thoroughgoing pluralism is untenable. It must be supplemented by a principle of unity which, while it does not destroy the conception of the monads as real individuals having a "substantival" and not a merely "adjectival" existence, at the same time enables us to get rid of the difficulties raised by a pure pluralism. Ward finds his unifying principle in a theistic theory, conceiving God as a supreme being transcending the world of the many and yet immanent in it. On the one hand God, as creator, originates monadic development; on the other, He stands as the supreme unity to a harmonious co-existence with whom that development is for ever more nearly approaching. Moreover, as immanent in the world, He mediates the interaction between the monads.

It is impossible to enlarge here upon the metaphysical theory thus outlined. It must suffice to point out that it has many important possibilities and merits serious consideration. Moreover, it is a healthy corrective to the cruder forms of materialism, for while the latter are ultimately based on conceptions which can be shown to represent pure abstractions, spiritual pluralism starts from a fact of which each of us is certain from his own immediate experience, namely, the concrete existence of such a thing as an individual "mind," or better, perhaps, "spirit."

A form of spiritual pluralism is being developed in America by the Personal Idealists; while in England Wildon Carr has propounded an interesting monadism with especial reference to the philosophical importance of Einstein's principle of relativity and its apparent implication of the reality and profound significance of the existence of individual observing minds.

(C. A. R.)

PLURALITY, a term applied particularly to the holding of two or more offices by the same person (called then a *pluralist).* In ecclesiastical law, plurality, or the holding of more than one benefice or preferment, was always discountenanced, and is now prohibited in England by the Pluralities Act, 1838, as amended by the Pluralities Act, 1850, and the Pluralities Acts Amendment Act 1885. By the latter act a provision was made that two benefices might be held together, by dispensation of the archbishop on the recommendation of the bishop, if the churches be within four miles of each other, and if the annual value of one does not exceed £200. *(See* BENEFICE.)

In the United States, the term is used in election law to denote the number of votes which a candidate has received for a public office in excess of the number received by any one of two or more other candidates.

PLURALITY OF CAUSES, in logic, is the view that one and the same kind of effect can be produced in different cases by different causes. This is quite distinct from the question whether the cause of an effectis as a rule a complex or multiplicity of several or many constituent or contributory factors or conditions. Assuming the complexity of each cause, there still remains the further question whether any one of several separate causes can produce the same kind of effect as another. In other words can one cause ever act vicariously for another? (Hence the alternative, and less ambiguous name, "vicarious causes.") J. S. Mill is the best known advocate of the doctrine of plurality of causes. Examples taken from daily experience seem to support the view. Many different causes can produce death for example. For most practical purposes the doctrine holds good. The whole system of substitutes, in peace and in war, is based on it. But for practical purposes many effects are sufficiently similar, although they are really very different when closely scrutinised. The *total* state called death is very different according as one cause or another led to it. The holding of coroner's inquests is based on the assumption that a close examination of the state of a dead body can help to determine the precise cause of death in each case. Similarly with all cases in which details matter. The total effect produced by one kind of cause is never precisely the same as that produced by any other. So that strictly speaking the doctrine of plurality of causes is not true. But where the interest is centred in broad kinds of effect, and differences of detail do not matter much, there the doctrine holds good for all practical purposes.

See J. S. Mill, *System of Logic* (1875 etc.); J. Venn, *Empirical Logic* (1889); J. Welton, *Manual of Logic* (1896).

PLUSH. Plush fabrics are characterized by a fur-like or velvet pile surface somewhat typical of the short hairy pelts of certain animals as, for example, the seal and otter. A plush pile surface is developed in woven fabrics by causing a series of tufts of pile to project more or less vertically from a foundation texture. The tufts of pile virtually consist of short lengths of warp threads usually of silk, artificial silk or mohair yarn interwoven with the foundation fabric in such a manner that the tufts of pile are looped under the picks of weft by which they are securely retained in the fabric.

PLUTARCH (Gr. Πλούταρχος) (*c.* A.D. 46–120), Greek biographer and miscellaneous writer, was born at Chaeronea in Boeotia. After having been trained in philosophy at Athens he travelled and stayed some time at Rome, where he lectured on philosophy and undertook the education of Hadrian. (There seems no authority for this statement earlier than the middle ages.) Trajan bestowed consular rank upon him, and Hadrian appointed him procurator of Greece. He died in his native town, where he was archon and priest of the Pythian Apollo. In the *Consolation to his Wife* on the loss of his young daughter, he tells us (§ 2) that they had brought up four sons besides, one of whom was called by the name of Plutarch's brother, Lamprias. We learn incidentally from this treatise (§ 10) that the writer had been initiated in the secret mysteries of Dionysus, which held that the soul was imperishable. He seems to have been an independent thinker rather than an adherent of any particular school of philosophy. His vast acquaintance with the literature of his time is everywhere apparent.

The celebrity of Plutarch, or at least his popularity, is mainly founded on his 46 *Parallel Lives.* He is thought to have written this work in his later years after his return to Chaeronea. His knowledge of Latin and of Roman history he must have partly derived from some years' residence in Rome and other parts of Italy *(Demosth.* § 2), though he says he was too much engaged in lecturing (doubtless in Greek, on philosophy) to turn his attention much to Roman literature during that period.

Plutarch's design in writing the *Parallel Lives—for* this is the title which he gives them in dedicating *Theseus* and *Romulus* to Sosius Senecio—appears to have been the publication, in successive books, of authentic biographies in pairs, taking together a Greek and a Roman. In the introduction to the *Theseus* he speaks of having already issued his *Lycurgus* and *Numa,* viewing them, no doubt, as bearing a resemblance to each other in their legislative character. Theseus and Romulus are compared as the legendary founders of States. In the opening sentence of the life of Alexander he says that "*in this book* he has written the lives of Alexander and Caesar" (Julius), and in his *Demosthenes,* where he again (§ 1) mentions his friend Sosius, he calls the life of this orator and Cicero the fifth book. (It is quite evident that the original order of the books has been altered in the series of *Lives* as we now have them.) It may, therefore, fairly be inferred that Plutarch's original idea was simply to set a Greek warrior, statesman, orator or legislator side by side with some noted Roman celebrated for the same qualities, or working under similar conditions. Nearly all the lives are in pairs; but the series concluded with single biographies of Artaxerxes, Aratus (of Sicyon), Galba and Otho. In the life of Aratus, not Sosius Senecio, but one Polycrates, is addressed.

The *Lives* are works of great learning and research, long lists of authorities are given, and they must for this very reason, as well as from their considerable length, have taken many years in compilation. It is true that many of the lives, especially of Romans, do not show such an extent of research. But Plutarch must have had access to a great store of books, and his diligence as an historian cannot be questioned, if his accuracy is in some points impeached. From the historian's point of view the weakness of the biographies is that their interest is primarily ethical. The author's sympathy with Doric characters and institutions is very evident; he delights to record the exploits, the maxims and virtues of Spartan kings and generals. This feeling is the key to his apparently unfair and virulent attack on Herodotus, who, as an Ionian, seemed to him to have exaggerated the prowess and the foresight of the Athenian leaders.

The voluminous and varied writings of Plutarch exclusive of the *Lives* are known under the common term *Opera moralia.* These consist of above 60 essays, some of them long and many of them rather difficult, some too of very doubtful genuineness. Their literary value is greatly enhanced by the large number of citations from lost Greek poems, especially verses of the dramatists, among whom Euripides holds by far the first place. The principal treatises in the *Opera moralia* are the following: —

On the Education of Children; How a Young Man Ought to Hear Poetry, on the moral aspect of Homer and the tragedians, with quotations *On the Right Way of Hearing* (Περὶ τοῦ ἀκόυειν) is another educational essay. Among the moral essays may be included: *How a Flatterer may be Distinguished front a Friend, How One May be Conscious of Progress in Goodness,* addressed to Sosius Senecio, consul under Nerva and Trajan; three short essays, *On Having many Friends, On Chance* and *On Virtue and Vice,* mainly valuable for quotations from poets otherwise lost; *Advice to the Married, On the Late Vengeance of the Deity, On the Genius of Socrates, On Superstition, On Exile,* a fine essay plentifully illustrated with quotations; *The Amorous Man,* and the *Gryllus,* an entertaining dialogue proving the moral superiority of many animals over man. The speakers are Circe, Odysseus, and a pig; the pig wins.

Another group includes some physical treatises such as *Precepts about Health,* which do not often coincide with modern ideas; *On the Face of the Moon's Disk,* which throws light on ancient astronomical theory; *Whether Land or Water Animals are the Cleverer; Whether Water or Fire is the More Useful; On Primary Cold; Questiones Naturales* and *On Flesh Eating.* The historical treatises include: *On the Fortune of the Romans,* two essays on the career of Alexander, *Whether the Athenians were More Renowned for War or for Wisdom,* and the famous *De Malignitate Herodoti,* charging Herodotus with unfair treatment of the non-Ionic States. There are also a purely metaphysical work, the *Platonic Questions,* and two political treatises, *Should a Man Engage in Politics when No Longer Young?* and *Political Precepts.* There are also two *Consolations,* one to Apollonius for his son, and one to his own wife for their daughter. There remains a group of his most valuable and interesting works, on archaeological questions generally, and especially religious history. These include *On Isis and Osiris, On the Cessation of Oracles, On the Pythian Responses* (an appendix to the last), and *On the* E *at Delphi,* of the exclusively ritual discussions; and t o miscellaneous works, which contain a vast collection of information and discussions on points of almost every kind, the *Symposiaca* (9 books), and the *Quaestiones Romanae* and *Graecae,* which is of considerable importance to classical archaeology. There is also the collection of *Short Sayings,* divided into (1) of kings and commanders, (2) of Spartans, and (3) of Spartan women. Doubt is thrown on the validity of The *Banquet of the Seven Wise Men, On Fate; Parallels; On Accepted Opinions and the Lives of the Ten Orators.*

BIBLIOGRAPHY.—Editio princeps, by H. Stephanus (1572); other complete editions by J. J. Reiske (1774–82), J. G. Hutten (1791–1804), T. Dohner and F. Dubner (1846–55). Of the *Lives,* there are editions by A. Coray (1809–14), C. Sintenis (1839–46; ed. min., 1874–81), and of many separate lives by Siefert-Blass, Sintenis-Fuhr, Holden, Hardy and others; Loeb ed., with trans. (11 vols. 1914–26). There are many English translations, of which the most popular is that by John and William Langhorne; also the old French version by Jacques Amyot (1559) from which Sir Thomas North's (1579) was made, newly edited by G. Wyndham (1895); many of the Roman lives have been translated, with notes, by George Long. The *Moralia* has been edited by D. Wyttenbach (1795–1830), and G. N. Bernardakes (1888–96) Loeb ed, with trans. (1927–). The old English translation by Philemon Holland (1603) has been revised by C. W. King and A. R. Shilleto in Bohn's *Classical Library* (1882–88), and a later translation by various hands (London, 1684–94), edited by W. W. Goodwin with introduction by R. W. Emerson, has been republished at Cambridge, Massachusetts (1874–78). Mention may also be made of P. Holland's *Roman Questions,* edited with introductory dissertations by F. B. Jevons (1892); *Roman Problems,* with essay on "Roman Worship and Belief," by G. C. Allen (1904); H. J. Rose, *The Roman Questions of Plutarch* (Text and Commentary, 1924); *De la Musique,* edit. H. Weil and Th. Reinach (1900); J. Oakesmith, *The Religion of Plutarch as expounded in his Ethics* (1902); Archbishop Trench, *A Popular Introduction to Plutarch* (1873); O. Gréard, *De la Morale de Plutarque* (1866); R. Volkmann, *Leben, Schrif n und Philosophie des Plutarch* (1869); R. Hirzel, *Plutarch* (1912). The earlier literature of Plutarch is very extensive, for which W. Engelmann, *Scriptores graeci* (1881), may be consulted.

PLUTARCH, of Athens (350?–430), Greek philosopher, head of the Neoplatonist school at Athens, was the son of Nestorius. His main principle was that the study of Aristotle must precede that of Plato, and that the student should be shown the fundamental points of agreement between them. With this object he wrote a commentary on the *De anima* which was the most important contribution to Aristotelian literature since the time of Alexander of Aphrodisias. This critical spirit reached its greatest height in Proclus, the ablest exponent of this latter-day syncretism. Plutarch was versed in all the theurgic traditions of the school, and believed in the possibility of attaining to communion with the Deity by the medium of the theurgic rites. Unlike the Alexandrists and the early Renaissance writers, he maintained that the soul which is bound up in the body by the ties of imagination and sensation does not perish with the corporeal media of sensation. He interposed between sensation and thought the faculty of Imagination, which is the activity of the soul under the stimulus of unceasing sensation, and provides the raw material for Reason. Reason is present in children as an inoperative potentiality; in its pure activity, it is the transcendental or pure intelligence of God.

See Marinus, *Vita Procli,* 6, 12; Zeller's *History of Greek Philosophy.*

PLUTO, a euphemistic name for the Greek god of the lower world (Gr. Πλούτων), properly Hades, Aïdes or Aïdoneus, "the Unseen." He was the son of Cronus and Rhea, and brother of Zeus and Poseidon. Having deposed Cronus, the brothers cast lots for the kingdoms of the heaven, the sea, and the infernal regions. The last, "the house of Hades," sometimes loosely called Hades, fell to Pluto. Here he ruled with his wife, Persephone, over the other powers below and over the dead. He is stern and pitiless, deaf to prayer or flattery, and sacrifice to him is of no avail; only the music of Orpheus prevailed upon him to restore his wife Eurydice. His helmet, given him by the Cyclopes after their release from Tartarus, rendered him invisible (like the Tarn —or Nebelkappe of German mythology). Being feared, he is usually alluded to by euphemistic epithets: Polydectes (the receiver of many), Clymenus (the Illustrious), Eubulus (the giver of good counsel). But, perhaps by contamination with a god of the fertility of the earth, he is also Pluto, the "giver of wealth" (a name that first occurs in the Attic poets of the fifth century), and at most of the centres of his cult he was so worshipped; At Elis alone he was Hades, the god of the dead. The plants sacred to him were the cypress and narcissus; black victims were sacrificed to him, as to all underworld powers. In art he was represented like Zeus and Poseidon, but sterner; his attributes are a sceptre and Cerberus; he carries the key of the world below and is frequently in company with Persephone.

PLUTO is the outennost known member of the planetary system, ninth in order of distance from the sun. It was discovered by C. W. Tombaugh of the Lowell Observatory on January 23, 1930 by examination of photographic plates of the region of the sky near the star δ Geminorum. The discovery was the result of a systematic search, both theoretical and observational, instituted by the late Percival Lowell because of his belief that the motion of Uranus gave evidence of the existence of a trans-Neptunian planet. It is believed among those most conversant with this field of astronomy, however, that the finding of Pluto was a happy accident of the search and that the discordance between theoretical and observed motion of Uranus is evidence of inaccuracy of the older observations and incompleteness of theory for that planet rather than of gravitational attraction by the newly-discovered one.

Pluto moves around the sun in an ellipse with major axis 79 astronomical units in length and minor axis three per cent shorter, passing within less than 30 units of the sun at perihelion (as in 1989 for instance) and receding to an aphelion distance of almost 50 units during the century and a quarter following. The orbital plane is inclined about 17 degrees to the plane of the ecliptic and is so oriented in space that the apparent path of the planet on the celestial sphere intersects the ecliptic near δ Geminorum and near π Sagittarii. The planet was near its northward crossing (or ascending node) when discovered and requires 248 years to make one complete circuit of its path. It should be noticed that it is only this inclination of the orbit of the outer planet which prevents the orbits of Neptune and Pluto intersecting in space.

Pluto appears of the fifteenth magnitude on the astronomical scale, that is of the brilliance of an ordinary candle four hundred miles from the observer; it is half as bright photographically and must therefore have a surface of slightly yellowish cast. The evidence so far adduced suggests a diameter about one-half and a mass about one-tenth that of the earth. Solar radiation provides illumination on Pluto about equal to that produced by a 75-watt mazda lamp at a distance of one yard, but furnishes so little heat that the surface temperature is probably below $-200°$ Centigrade.

PLUTO MONKEY, a guenon, *Cercopithecus leucampyx,* nearly allied to the mona monkey, which takes its name from the black fur of the under-parts, passing into blackish gray on the head and back. The violet-coloured face is fringed by large bushy whiskers and surmounted by a white band above the brows. The species extends from the Congo to Nyasaland.

PLUTUS, properly, the abundant increase of the earth; child of Demeter (*q.v.*) and Iasion; in art, usually shown as a child. alone or in company with Tyche, Eirene, Athena, or some other goddess. In popular thought, allegories and comedy, he was represented as Wealth. He was said to be blind.

PLYMOUTH, a city and county borough and seaport of Devonshire, England, 231 mi. W.S.W. of London. Pop. (est. 1938) 211,800. Area 14.9 sq.mi.

Plymouth, the Suton of Domesday, was afterward divided into the town of Sutton Prior, the hamlet of Sutton Valletort and the tithing of Sutton Ralph. The market, established about 1253, became in 1311 town property. In 1292 the town first returned members to parliament. In the 14th century it was often used for armies to and from France and it suffered from French attacks. In 1412 the inhabitants petitioned for a charter, which was granted Nov. 12, 1439, the town being the first in England to be incorporated by act of parliament. In the discovery of the new world it played an important part. Sir John Hawkins was port admiral and (in 1571) M.P. From Plymouth in 1577 Drake set out on his voyage round the world; in 1581 he became mayor and represented the borough in parliament during 1592–1593. Sir Humphrey Gilbert (M.P. 1571) sailed on his second colonizing expedition to America in 1583 from the port. Plymouth supplied seven ships against the Armada, and it was in the sound that the English fleet awaited the Spaniards. A stone on a quay at the Barbican records the fact that this was the last port touched by the Pilgrim Fathers on their voyage to America. During the Civil War the tonn withstood all efforts by the Royalists to take it, and it early declared for William of Orange. Plymouth was created a city in 1928 and the title of lord mayor was granted in 1935. Four years later its area was extended by almost 4,000 ac.

It lies at the head of Plymouth sound. stretching westward from the river Plym toward the mouth of the Tamar, from which it is separated by the township of East Stonehouse and the borough of Devonport, both of which were included in Plymouth in 1914. The water frontage of the "Three Towns" consists of Plymouth sound, with its inlets. The Cattewater and Hamoaze are flanked on the east and west respectively by high ground, on which are built forts. On the western side of the entrance to Cattewater is the Citadel, founded in the reign of Henry VIII and rebuilt by Charles II. It is a specimen of 17th century military architecture, an irregular bastioned pentagon in trace and during World War II was used as army headquarters and barracks. The adjacent Hoe extends along the northern edge of the sound. To the north is seen the town of Plymouth. In the sound is Drake's (formerly St. Nicholas's) island. The city suffered air raids during World War II, and much of it was destroyed. More than 50,000 houses had been damaged before the close of 1941 and among noteworthy buildings the Guildhall (which contained a contemporary portrait of Sir Francis Drake), the law courts, the municipal buildings, the G.P.O., the old Guildhall, the library and the city hospital were wiped out, along with the main shopping centres of both Plymouth and Devonport. Among churches, St. Andrews, a Perpendicular building of 1480–1520 restored in 1874, was destroyed, only the walls and clock tower remaining.

Plymouth is the seat of a Roman Catholic bishopric founded in 1851, the cathedral, in Wyndham street, being completed in 1858. The building is in the Early English style, and adjoining are the bishop's house and the convent of Notre Dame.

The "Port of Plymouth" in 1311 embraced Plympton, Modbury and Newton Ferrers, and received a customs grant from Richard II. In 143j sixty-five cargoes mere imported, and in the reign of Elizabeth it rose to be the foremost port in England. The 18th century saw a great development of trade with Virginia and the West Indies, and this resulted in the establishment of a sugar-refining industry that was maintained into the 20th century.

In 1749 the "town's water" was carried to the Barbican to supply shipping. The port of Plymouth as at present constituted embraces the waters of the Plymouth sound and the Hamoaze. The chief water area within the limits of the port is the sound with its inlets, the Cattewater, Sutton Pool, Mill Bay, Stonehouse Pool and the Hamoaze. The sound itself covers an area of 4,500 ac. and is sheltered from the southwest gales by a breakwater a mile long with a lighthouse at its eastern end. It was constructed in 1841. Cattewater, Sutton Pool and Mill Bay constitute the three mercantile harbours of Cattewater harbour, Sutton harbour and the Great Western docks, while Hamoaze was set aside for H.M navy. Cattewater harbour has an area of 260 ac. and 8,000 ft. of quayage space. Sutton harbour entered from Cattewater has a quayage space of 4,500 ft. Great Western docks at Mill Bay has an outer basin of 35 ac., an inner one of 13.

Steamers sail regularly from Plymouth for Australia, New Zealand, the Cape and North America. The port has productive fisheries. It has also a considerable export and import trade. As a naval station it is second only to Portsmouth. The city is served by the G.W. and S. railways.

The industries of Plymouth include soapmaking, manufacture of chemicals, artificial manure and paper staining. There is some electrical engineering, and a clothing factory. Plymouth has returned three members to parliament, from the Drake, Devonport and Sutton divisions, since 1918. Lady Astor, the first woman elected to the House of Commons, was returned in 1919.

PLYMOUTH, a town of Massachusetts, U.S.A., 37 mi. S.E. of Boston, on Plymouth bay; a port of entry and the county seat of Plymouth county. It is served by the New York, New Haven and Hartford railroad and in summer by buses from Boston. Pop. (1930) 13,042 and in 1940 it was 13,100. Visitors to the number of many thousands are brought annually by the historic interest of the town and its attractions as a summer resort. The modern town has important manufacturing industries (notably the largest cordage works in the world, with its own steamers bringing cargoes of sisal fibre from Yucatan). Plymouth has two large woollen mills. Other important industries are cranberry culture, herring fisheries and the propagation of clams. Lobster fishing is also an important industry.

Plymouth was the landing-place of the Pilgrims and the first permanent settlement by Europeans in New England. Plymouth Rock, the granite boulder on which the Pilgrims stepped from the shallop of the "Mayflower" on Dec. 21, 1620, was placed in 1920 on the spot it originally occupied, under a protecting portico of granite, presented by the Society of Colonial Dames, and this part of the water front has been made a part of the State park system. Rising behind the Rock is Cole's Hill, where during their terrible first winter in America the Pilgrims buried half their number, levelling the graves and sowing them with grain in the spring to conceal their losses from the Indians. Burial Hill (the site of the first fort and of a watch-tower) contains the graves of William Bradford and others of the original Pilgrims, though the oldest stone is dated 1681. In the Registry building are the original records of Plymouth Colony, the will of Myies Standish, the original patent of Jan. 23, 1630, and many other interesting historical docunients. Pilgrim hall, a large stone building erected in 1824, houses a rich collection of relics of the Pilgrims and of early colonial times. The oldest house still standing (the Crowe house) was built in 1664, and many others antedate the Revolution. In the northern part of the town is the National Monument to the Forefathers (of Maine granite), designed by Hammatt Billings, which was dedicated on Aug. 1, 1889, 30 years after the cornerstone was laid. Plymouth dates its founding from the landing of the Pilgrims. It was never incorporated as a town, but in 1633 the general court of the Colony recognized it as such by ordering that "the chiefe government be tyed to the towne of Plymouth." It remained the seat of government until 1692, when Plymouth Colony was united to Massachusetts Bay.

PLYMOUTH, a borough of Luzerne county, Pennsylvania, U S.A., on the west bank of the Susquehanna river, opposite Wilkes-Barre. It is on federal highway 11 and is served by the Lackawanna railway. Pop. (1920) 16,500 (24% foreign-born white, over half from Poland and Lithuania); 1940 federal census 15,507. Plymouth is in the midst of the anthracite fields, and is surrounded by the beautiful scenery of the Wyoming valley. The mining, preparation and handling of anthracite provide the principal occupations, but there are silk mills and various other factories, with an output in 1937 amounting to $618.625. Plymouth was settled in 1769 under the auspices of the Susquehanna Company of Connecticut, by colonists from Plymouth, Litchfield county, Conn., and other places in New England, and became a centre of the conflict known as the Pennamite-Yankee War. *(See* WYOMING VALLEY.) The first coal shipped from the anthracite region was sent from Plymouth in 1808 by Abijah and John Smith. The borough was incorporated in 1866.

PLYMOUTH BRETHREN, a community of Christians who received the name in 1830 when the Rev. J. N. Darby (1800–1882) induced many of the inhabitants of Plymouth, England, to associate themselves with him for the promulgation of his opinions. Although small Christian communities existed in Ireland and elsewhere calling themselves *Brethren,* and holding similar views, the accession to their ranks of Darby so increased their numbers and influence that he is usually called the founder of Plymouthism. Darby had been a curate in Wicklow 1825–1827, when he felt himself constrained to leave the Anglican communion; going to Dublin, he became associated with several devout people who met statedly for public worship, and called themselves "Brethren." Among these were A. N. Groves and J. G. Bellett, who deserve to rank among the founders of the movement. In 1830 Darby at Plymouth won over many people to his way of thinking, among them the well-known Biblical scholar Samuel Prideaux Tregelles. During the next eight years progress was rapid, and communities were founded in many of the principal towns in England.

In 1838 Darby went to reside in French Switzerland, and made many disciples. French Switzerland has always remained the stronghold of Plymouthism on the Continent, and far his followers there Darby wrote two of his most important tracts, Le *Ministère considéré dans sa nature* and *De la Présence et de l'action du S. Esprit dans l'église.* The revolution in the canton Vaud, brought about by Jesuit intrigue in 1845, brought persecution to the Brethren in the canton and in other parts of French Switzerland and Darby's life was in great jeopardy.

He returned to England, and his reappearance was followed by divisions among the Brethren at home. These divisions began at Plymouth. Benjamin Wills Newton, head of the community there, who had been a fellow of Exeter College, Oxford, was accused of departing from the testimony of the Brethren by reintroducing the spirit of clericalism. Unable to detach the congregation from the teacher, Darby began a rival assembly. The majority of the Brethren out of Plymouth supported Darby, but a minority remained with Newton. The separation became wider in 1847 on the discovery of supposed heretical teaching by Newton. In 1848 another division took place. The Bethesda congregation at Bristol, where George Muller was the most influential member, received into communion several of Newton's followers and justified their action. Out of this came the separation into Neutral Brethren, led by Muller, and Exclusive Brethren or Darbyites, who refused to hold communion with the followers of Newton or Muller. The Exclusives, who were the more numerous, suffered further divisions. An Irish clergyman named Samuel O'Malley Cluff had adopted views similar to those of Pearsall Smith, who preached a doctrine of sanctification called "Death to Nature" as an antidote to the supposed prevalent Laodiceanism, and when these were repudiated seceded with his followers. The most important division among the Exclusives came to a crisis in 1881, when William Kelly and Darby became the recognized leaders of two sections who separated on a point of discipline. This was followed (1885) by the disruption of the strict Darbyite section, two communions being formed out of it upon points of doctrine.

The theological views of the Brethren differ considerably from those held by evangelical Protestants (for a list of divergences, see Teulon *History and Doctrines of the Plymouth Brethren).* They make the baptism of infants an open question and celebrate the Lord's Supper weekly. Their distinctive doctrines are ecclesiastical. They hold that all official ministry, whether on Episcopalian, Presbyterian or Congregationalist theories, is a denial of the spiritual priesthood of all believers, and sets aside the Holy Spirit's guidance. The movement, if it has had small results in the formation of a sect, has at least set churches to consider how they might make their machinery more elastic. The movement spread to the United States where, in 1915, there were 10,566 communicants.

PLYMPTON ST. MARY and **PLYMPTON ST. MAURICE** or **ERLE,** two small adjacent towns in Devon, England, 5 mi. E.N.E. of Plymouth, on the Great Western railway. Pop. (1931), Plympton St. Mary, 5,077, Plympton St. Maurice, 1.075. The earthworks on which in the 12th century Richard de Redvers reared his Norman castle at Plympton St. Maurice were probably of British origin; traces of the castle remain. A Saxon document dated 904 records a grant by Edward the Elder to Asser, bishop of Sherborne, of twelve manors in exchange for the monastery of "Plymentun." Plympton St. Mary has a Decorated and Perpendicular church, with a lofty tower of the later period. Near it are remains of the former Augustinian priory of Plympton, founded by William Warelwast, bishop of Exeter (1107–36). They include an Early English refectory with Norman undercroft, the kitchen and other fragments; but there are no remains of the great priory church. There are several old houses in the town, together with a guildhall dated 1696, and a grammar school founded in 1658, of which Sir Joshua Reynolds's father was master.

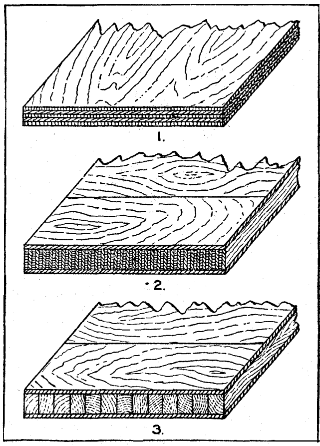
PLYNLYMON (*Plynlimmon, Pumplumon, Pumlumon, Penlumon:* pump means fire: *lumon*, chimney flag or beacon; *pen*, head), a mountain of Wales 2,463 ft. high, about 10 m. from Machynlleth and Llanidloes. It is composed of Bala (Ordovician) grits and stands out above the high plateau of Central Wales. There are three summits with a carnedd (stone-pile, probably a military or other landmark, rather than the legendary barrow or tomb) on each. Plynlymon is the source of the Rheidol, the Llyfnant and the Clywedog, the Wye and the Severn.

The morasses of Plynlymon saw many a struggle, notably the war between Owen Cyfeiliog (*fl. c.* goo), prince of Powys, and Hywel ab Cadogan. Here also Owen Glendower unfurled the banner of Welsh independence; from here, in 1401, he harassed the country, sacking Montgomery, burning Welshpool, and destroying Abbey Cwm Hir. Aberystwyth obtains its water from a reservoir on the mountain slopes. There are slate quarries, also old lead and copper mines in the district. The district west, north and east of Plynlymon is a very wild and lonely moorland, with very few roads. Around the sharp northern and western edges of the moorland are deep-cut ravines with waterfalls.

PLYWOOD. Board made of several plies or veneers (*q.v.*) of wood, glued together with the object of obtaining comparatively large sheets free from some of the natural defects and limitations of timber. Rotary cut (peeled) or sliced veneers are used, if necessary joined edgewise, to form each ply, and thus large sheets with an unbroken surface are obtained; the plies are sorted as to their appearance, and the inferior (knotty, shaky or sappy) material is generally utilized for the interior of the board (core), leaving the best plies for the outer surfaces (face and back).

The natural tendency of wood to shrink, swell and warp is effectively neutralized, and the comparatively low tensile strength of wood along its grain is greatly improved upon, by carefully cross-graining the plies. In the result, a large flat board of wood is produced, practically unaffected by climatic influences, and possessing considerably higher shearing, braking and bending properties than ordinary wood of similar thickness.

The plies are glued (cemented) together under considerable pressure, different adhesives being used, dependent upon whether or not the gluing process is aided by heat, and also varying according to the kind of timber used. The veneers are wet when produced from the log and may be glued together either in their wet state or after a pre-drying process. Plywood is, therefore, grouped into two classes, wet and dry produce. The drying of veneers before being cemented and pressed into a board prevents their shrinkage during the pressing process and, therefore, helps to make a better plywood board. If the veneers be glued wet the drying process is combined with the glueing operation in the press, and this often produces face checks (cracks) on the surfaces of the finished board.



PLYWOOD CONSTRUCTION
(1) Ordinary plywood, (2) laminated plywood, (3) batten board

In the construction of plywood the following different types are known:

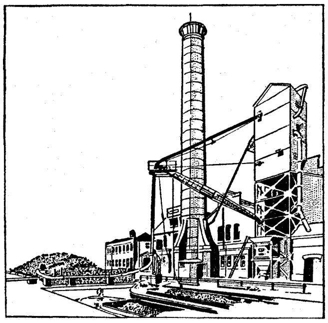
The outside plies of the laminated type and of battenboards may be occasionally superimposed on so-called crossbandings (veneers lying crosswise to the outer plies) to ensure still greater rigidity of the boards.

Utilization.— Plywood is used wherever a material is required to cover large unbroken spaces with a light but strong and rigid sheeting, *e.g.*, in cabinet-making (for panels, bed-ends, sides of wardrobes, tabletops, etc.); *building* (for doors, wall panelling, ceilings, flooring, etc.); coach-building (for coach panels, motor bodies, railway carriage roofs and walls, vans, baby carriages, etc.); *shipbuilding* (for bulkheads, etc.); boxmaking (for tea chests, rubber chests, cases, etc.); engineering (for aeroplane fuselages, hydroplane hulls, bed plates, etc.); etc.

Although there is evidence that the principle of "plying" thin strips of wood into panels to ensure permanent flatness was known and practised in very early days of civilization and was continued by the cabinet-maker and builder all over the world, mechanical production of plywood originated comparatively recently, *i.e.*, in the eighteen-eighties, when the first factories specializing in the production of plywood were erected in Russia. The industry has since spread to all parts of the world wherever large timber resources are available and where widespread employment of the material makes local manufacture profitable.

Wainwright, Modern Plywood (1927); Bulletins of the Forest Products Laboratory, U.S. Department of Commerce; B. C. Boulton, The Manufacture and Use of Plywood and *Glue* (1920); The Timber Trades Journal (London; wkly.).
(A MOR.)

PNEUMATIC CONVEYING is the utilization of the conveying power of air in motion. It will be realized that conveyance of material through a pipe-line, either by suction or blast, is ideal; since there are no mechanical parts in the path of the material there cannot be any contamination by lubrication. Another advantage is the greater flexibility of pneumatic plant; every part of the hold of a vessel, for instance, can be reached by flexible tubes for the purpose of unloading a grain cargo, whereas a more complex mechanical plant is rigidly fettered to straight lines.



BY COURTESY OF MESSRS. HENRY SIMON, MANCHESTER
PNEUMATIC COAL-HANDLING PLANT AT BRIMSDOWN POWER STATION

The *modus operandi* of a pneumatic plant is extremely simple and is as follows:—Into a grain cargo in a vessel, for instance, a hosepipe is lowered, the nozzle at the end of which admits a mixture of air and grain. The other end of the pipeline enters tangentially into the upper part of a cylindrical receiver from which the air is exhausted, while the grain is withdrawn from the cone-shaped lower end by an air-trap, without, however, admitting air into the receiver. When comparing pneumatic with mechanical handling devices the former have but one drawback, viz.: the greater consumption of driving power for handling a given quantity. This, however, is more than compensated for by the greater flexibility and the hygienic value of the system. The first grain handling installation on the Duckham system was known as "Mark Lane No. 1," and was built, under the personal supervision of the inventor, by the East Ferry Road Engineering Co., during the closing years of the 19th century. This was one of the most epoch-making revelations of all systems of handling. The plant is mounted on a pontoon and sucks the grain through a nozzle and pipeline from the ship's hold to an elevated receiver, whence it runs by gravity to a given point, via an air trap; an exhauster furnishes a partial vacuum by pipes connected with the said receiver.

As has been shown, the material in a pneumatic plant floats, so to speak, in a current of air, from which it is separated by its specific gravity when the air expands in the receiver. The heavier the material to be handled the greater must be the speed of travel of the air in the conveying pipes in order to ensure the floating of the material in and with the air. If the air speed is too slow the tendency will be for the material to separate from the air and thus block the pipes, especially such portions as are horizontally disposed, or nearly so. Obviously, therefore, installations for such heavy materials as coal and ash require more powerful pumps. Similar installations in which, however, draught is induced by "steam jets" are successfully employed for handling ash from boilers.

Owing to the advantages accruing from the use of pneumatic handling plants new avenues for their employment are being constantly opened. Such varied materials as grain, small coal, chemicals, ashes, potatoes, and even red-hot rivets and artillery shells are now successfully handled by pneumatic means. An offshoot of this system is the pneumatic tube, which is largely employed in postal and telegraph offices, as well as in great variety in business offices and stores. (*G.* F. Z.)

PNEUMATIC DISPATCH, a system of transporting written dispatches through long tubes of small diameter by means of compressed or rarefied air. It was introduced in 1853 by J. Latimer Clark between the Central and Stock Exchange stations of the Electric and International Telegraph company in London, the stations being connected by a tube 1½in. in diameter and 220yd. long, the messages, enclosed in a tight fitting carrier, being drawn through it by the production of a partial vacuum at one end. The system was improved in 1858 by C. F. Varley, who used compressed air to return the carriers in the other direction. By this means it was possible to develop two-way working on single tubes between a central station, equipped with air-compressing plant, and outlying offices

Pneumatic dispatch tubes are in extensive use in many countries for both telegraphic and postal matter.

Radial System: This system of pneumatic dispatch was developed by R. S. Culley and R. Sabine in connection with the British post office for the transmission of telegrams between local collection and delivery offices and the central telegraph office; it became generally more economical, under normal conditions of traffic and distance, to transmit these messages by tube rather than wire so dispensing with the employment of skilled telegraphists.

Since that time the system has been greatly extended both in London and the large provincial towns until in London alone the street tubes laid measure over 57m., varying in length from 100yd. to nearly 4,000yd. These tubes are either single tubes working in both directions or, where the traffic warrants it, separate "up" and "down" tubes are installed. In a few cases intermediate offices are connected to the tubes, but this practice is not desirable as delay in transmission is caused and direct tubes are installed wherever possible.

A further development is the laying of pressure worked trunk tubes from the central telegraph office to an outlying centre, messages being transmitted between this centre, where a pumping plant is also installed, by radial tubes to offices in the vicinity.

House Tubes and Street Tubes.—Short tubes known as house tubes are in use in a large number of offices and telephone exchanges for carrying messages from the public counter or one room to another. These tubes, which are generally 1½in. in diameter, are made of brass and are operated by hand-worked pumps where the distance is short and the traffic inconsiderable, or by means of small electrically driven centrifugal fans or other form of blower. The pressure or vacuum required is only a few inches as shown by water gauge and the blowers are either run continuously or switched on as required.

Street tubes used by the post office are generally 2¼in. in diameter, but 3in. and 1½in. tubes are also used. These tubes when laid in the street are in all cases made of lead and are protected by cast-iron pipes. Where they are run in buildings or subways brass tubing is used. They are operated by electrically driven compressors.

Carriers.—The carriers, in which the messages are inserted for dispatch, are made of gutta-percha covered with felt, the front of the carrier being provided with a buffer or head formed by several layers of felt fitting the tube closely, the messages being held in place by means of an elastic band. The 3in. carriers hold 50, the 2¼in. carriers 20 and the 1½in. carriers five ordinary forms. The carrier used on house tube systems are generally made of fibre the messages being retained by a clip.

Working.—The air for working the street tubes is supplied by electrically driven compressors, the standard pressure and vacuum used being 10lb. and 6½lb. per sq.in. respectively, which values give approximately the same speed.

The time of transit of a carrier through a tube at the ordinary pressures in use is given approximately by the empirical formula:—

$t=\cdot 00872\sqrt{\frac{l^3}{Pd}}$ where l=length of tube in yards,

d=diam. in inches, P=effective air pressure in pounds per sq. inch,

t=transit time in seconds.

For vacuum working the formula is:—

$t=\frac{\cdot 00825}{1\cdot \quad \cdot \quad -P_1}\sqrt{\frac{l^3}{d}}$ where P_1=effective vacuum in lb. per sq. inch.

The horse-power required to propel the carrier is approximately

for pressure $\text{H.P.}=(\cdot 574+\cdot 0011P)\sqrt{\frac{P^3d^5}{l}}$

for vacuum $\text{H.P.}=(5\cdot 187-1\cdot 214\sqrt{15\cdot 5-P_1})\,P_1\sqrt{\frac{d^5}{l}}$

For a given transit time the horse-power required is less in the case of vacuum than in the case of pressure working, owing to the lesser density of the air column moved: thus, for example, the transit time under 10lb. pressure is the same as with a vacuum of 6½lb., but the horse-power required is as 1·83 to 1. A 2¼in. tube 1m. long worked at 10lb. per sq.in. pressure will have a transit time of 2¼min. and will theoretically require 3·35 h.p. to work it. Actually owing to various losses 25% more power must be allowed for the compressor. When working at the same pressure the transit time for a 2¼in. tube is 16% more than that for a corresponding length of 3in. tube, but the power required is 50% less and it is therefore advisable to use the smallest tube compatible with the traffic.

Dispatching and Receiving Apparatus.—On house tube systems, where only low pressures and vacuum are required, simple forms of terminals consisting of cast-iron bodies with flap-doors are used, the doors being opened to insert a carrier, and through which carriers are automatically ejected, the door closing behind them. Dispatching funnels are also used at the open end of tubes.

On the street tubes, however, a more complicated type of apparatus, called a double slide switch, is used at the central office. This consists of two vertical sections of tube secured into top and bottom plates and provided with a handle by which it is rocked between two fixed horizontal plates forming a frame, three holes being provided in each plate, the air supply pipe and dispatch tube being connected to the centre holes and funnels for inserting or removing the carriers to the other holes. The carrier on arriving is received in one of the vertical sections and on the rocker being moved to its second position the carrier drops out through the funnel provided. The second tubular section is now ready to receive a carrier, which is discharged when the rocker is returned to its first position. The process is reversed for dispatching purposes, and where the tube is used for two-way working one position is reserved for sending and one for receiving. The supply of air, and whether under pressure or vacuum for sending or receiving purposes, is controlled by a three-way valve mounted under the switch.

A form of flap terminal, the door being restrained by a spring in view of the higher pressures used, is installed at the outlying offices in place of the receiver originally used and the carrier is automatically ejected.

On tubes where the carrier reaches a high velocity, a by-pass is provided near the terminal by means of which the air pressure behind the carrier is released after it has passed this point so as to reduce the velocity of egress. This terminal is also used for the dispatch of carriers to the central office, the supply of air to the tube being changed from vacuum to pressure at the latter point in response to a bell signal. When used for dispatching the by-pass is cut off by a remote control valve. Carriers may be diverted from one tube to another by means of a moving section of tube directly or remotely controlled.

A further development is the provision of an automatic rotat-

ing pneumatic tube switch by which carriers can be transferred between street and house tubes for both sending and receiving purposes, the terminals used being of the flap type.

Circuit *System.—Another system of working is the circuit system, in which stations are arranged in circular or loop lines round which the carriers travel in one direction only, both pressure and vacuum being used. This system is in use in Paris and other Continental cities. In Messrs. Siemens' system a continuous flow of air is maintained in the tube, the carriers being dispatched or removed through a form of rocking switch so designed that the movement of carriers in other parts of the system is not interfered with. More usually carriers, or trains of carriers, are dispatched at intervals, the air supply being cut off when not required. Long tubes may be sectionalized, means being provided at the various stations by which air is only supplied to the working section.*

In America, under the Batcheller system, tubes 8in. *in diameter are used for postal purposes in New York, Brooklyn, Chicago, Philadelphia, Boston and St. Louis; tubes* 6in. *and* 10in. *in diameter are also used. These tubes are essentially cast-iron pipes, carefully bored and equipped with suitable apparatus for introducing and receiving the carriers. The carriers for the* 8in. *tubes consist of cylindrical steel shells about 7in. in diameter and* 21in. *long (inside dimensions) with suitable end covers. They are fitted with lubricated soft bearing or packing rings. The working capacity of these tubes may be taken as* 8lb. *per container and six containers per minute, or* 2,880lb. *of postal matter per hour in each direction, the average speed being about* 25 *to* 30m. *per hour.*

The dispatching apparatus is similar to that in the Siemens' system, consisting of two sections of tube supported in a rocking frame so arranged that either section may be brought into line with the main tube, in which a current of air is constantly flowing. One of these sections maintains the continuity of the tube while the other section is loaded. The switch is then swung over by means of a pneumatically operated piston to insert the carrier in the tube. A by-pass is provided to maintain the flow of air in the tube during the operation. As soon as the carrier leaves the switch it trips a lever and the switch automatically returns to the loading position. A time lock is used to prevent carriers being dispatched too frequently. The carrier is received by an air cushion formed by closing the end of the tube with a sluice gate, a by-pass being provided before this point to allow the air to flow away.

In addition to their use for postal and telegraphic purposes pneumatic dispatch tubes are used for internal communication in offices, hotels, etc., also in shops for the transport of money and bills between the counters and the cashiers' desk. Pneumatic tubes are also used for the unloading and transport of grain and other commodities in bulk between warehouses and ships, trains, etc.

BIBLIOGRAPHY.—*The system as developed for use in the British post office by Messrs. Culley and Sabine is described in a* paper *in Min. Proc. Inst. Civil Eng., vol. xliii. The same volume contains a description of the Paris system and of experiments thereon by M. Bontemps, and also a discussion of the theory of pneumatic transmission by Prof. W.* C. *Unwin. Reference should also be made to a paper by C. Siemens (Min. Proc.* Inst. *Civ. Eng. vol. xxxiii.),* describing *the Siemens' circuit system; to Les Télégraphes, by M. A. L.* Ternant *(1881); to* the *report to Congress of the American joint commission on pneumatic tube mail service, March* 1919; *General Post Office engineering department's Technical Instruction* No. *X (Pneumatic Tubes); a short paper by J.* McGregor *on the automatic system in the post office (P.O. Elec. Eng. Journal, vol. xix., part 1), and to Kempe's Engineer's Year Book.* (J. McG.)

PNEUMATIC GUN. *Air as a propellant commended itself to some early designers of guns on account of its comparatively gentle action which proved advantageous with the primitive high explosive shells of the time. In 1883 Mefford of Ohio utilized an air pressure of* 500lb. *per* sq.in. *in a 2-in. gun, and succeeded in propelling a projectile* 2,100yds. *The arrangement was of the simplest form—a hose with an ordinary cock by which the air was admitted into the gun behind the projectile. The question was then taken up by Capt. E. L. Zalinski* (1849–1909) of *the United States Artillery, who in 1888 reduced the so-called "dynamite gun" to a more practical shape and obtained excellent firing results.*

The only record of the practical employment of a dynamite gun afloat was the case of the U.S. gunboat "Vesuvius," which carried three of the weapons in the bows. The guns were fixed at a constant angle of elevation, and the range regulated by an air valve, training being given by the helm. The "Vesuvius" was employed during the Spanish-American War of 1898, when on several nights in succession she approached the defences of Santiago under cover of darkness and discharged three projectiles. Fire delivered under such conditions could not be sufficiently accurate to injure coast defences; but the shells burst well, and made large craters. A small dynamite gun on a field-carriage was used in the land operations above Santiago in the same war.

PNEUMATIC POWER TRANSMISSION. *Every wind that blows is an instance of the pneumatic transmission of power, and every windmill or sail that catches the breeze is a demonstration of it. The modern or technical use of the term, however, is confined to the compression of air at one point and its* transmis*sion to another point where it is used in motors to do work. The first recorded instance of this being done was by* Denis Papin *(b.* 1647*), who compressed air with power derived from a water-wheel and transmitted it through tubes to a distance. About* 1800 *George Medhurst* (1759–1827) *took out patents in England for compressing air. He compressed and transmitted air which worked motors, and he built a pneumatic automobile. William Mann in 1829 took out a patent in England for a compound air compressor. In his application he states: "The condensing pumps used in compressing I make of different capacities, according to the densities of the fluid to be compressed, those used to compress the higher densities being proportionately smaller than those previously used to compress it to the first or lower densities," etc. This is a very exact description of the best methods of compressing air to-day, omitting the very important inter-cooling. Baron Van* Rathen *in 1849 proposed to compress air in stages and to use inter-coolers between each stage to get 7jo lb. pressure for use in locomotives. For the next 40 years inventors tried without success all manner of devices for cooling air during compression by water, either injected into the cylinder or circulated around it, and finally, with few exceptions, settled down to direct compression with no cooling worthy of mention. Only in the last ten years of the* 19th *century were the fundamental principles of economical air compression put into general practice, though all of them are contained in the patent of William Mann and the suggestion of Van* Rathen.

The first successful application of compressed air to the transmission of power, as we know it, was at the Mont Cenis tunnel in 1861. The form of compressor used was a system of water rams—*several of them in succession—in which water was the piston, compressing the air upwards in the cylinder and forcing it out. Although the air came in contact with the water, it was not cooled, except slightly at the surface of the water and around the walls of the cylinders. The compressors were situated near the tunnel, and the compressed air was transmitted through pipes to drilling machines working at the faces in the tunnel. Rotary drills were tried first, but were soon replaced by percussion drills adapted from drawings in the U.S. Patent Office, copied by a French and Italian commission from the patent of J. W. Fowle of Philadelphia. H. S. Drinker (Tunneling, Explosive Compounds and Rock Drills, New York, 1893) states positively that the first percussion drill ever made to work successfully was patented by J. J Couch of Philadelphia in 1849. Shortly afterwards Fowle patented his drills, in which the direct stroke and self-rotating principle was used as we use it now. The first successful drill in the Hoosac tunnel was patented in 1866 by W. Brooks, S. F. Gates and C. Burleigh, but after a few months was replaced by one made by Burleigh, who had bought* Fowle's *patent and improved it. Burleigh made a compressor, cooling the air during compression by an injected spray of water in the cylinders. The successful work in the Mont Cenis and Hoosac tunnels with the percussion drilling machines caused the use of compressed air to spread rapidly, and it was soon found there were many other purposes for which it could be employed with advantage.*

Application of Pneumatic Power.—The larger tunnels and metal mines were naturally the earliest to adopt pneumatic transmission, often using it for pumping and hoisting as well as drilling. In Paris and Nantes, in Berne and in Birmingham (England), street tramways have been operated by pneumatic power, the transmission in these, however, being in tanks rather than pipes. Tanks on the cars are filled at the central loading stations with air at very high pressure, which is used in driving the motors, enough being taken to enable the car to make a trip and return to the loading station. Several attempts in pneumatic street traction were made in America, but failed owing to financial troubles and the successful introduction of electric traction. It is used very successfully, however, both in Europe and in America, in underground mine haulage, being especially adapted to coal mines, where electricity would be dangerous from its sparks. The copper smelting works at Anaconda, Mont., uses 12 large pneumatic locomotives for charging the furnaces, removing slag, etc. Many stone quarries have a central plant for compressing air, which is transmitted through pipes extending to all working points. and operates derricks, hoists, drills, stone cutters, etc., by means of motors. Every considerable ironworks, railroad shop or foundry has its pneumatic transmission plant. Also in the erection of the larger steel bridges or buildings a pneumatic transmission system is part of the contractor's outfit, and many railways have a portable compressing plant on a car ready to be moved to any point as needed.

Dr. Julius G. Pohle, of Arizona, patented in 1886, and introduced extensively, the use of compressed air for lifting water directly, by admitting it into the water column. His plan is largely adopted in artesian wells that do not flow, or do not flow as much as desired, and is so arranged that the air supply has a back pressure of water equal to at least half the lift. If it is desired to lift the water 30 ft. the air is admitted to the water column at least 30 ft. below the standing water surface. The air admitted being so much lighter than the water it displaces, the column 60 ft. high becomes lighter than the column 30 ft. high and is constantly released and flows out at the top. The efficiency of this method is only 20 to 40%, depending on the lift, but its adaptation to artesian wells renders it valuable in many localities.

A remarkable pneumatic transmission system was installed in 1890 by Priestly in Snake River desert, Idaho. On the north side of the river is a cliff, nearly perpendicular, about 300 ft. high. One hundred and ninety feet above the river, for a considerable distance along the cliff, streams of water gush out from between the bottom of the great lava bed and the hardened clay of the old lake bottom. Priestly, without knowledge of Pohle's system, built a pipe line down the bluff and trained the water into it in such a way that it carried a very considerable quantity of air in the form of bubbles along with it down the pipe, compressing it on the way. The air was collected at the bottom in a covered reservoir, and taken up the cliff again to the lower part of an inverted siphon pipe, one side of which reached down from the water-supply about 60 ft. and the other side reached up and over the bluff. Allowing the water to fill both sides of the pipe to the level of the water-supply, he admitted his compressed air at about 7j lb. pressure into the long side of the pipe near the bottom, and soon had water flowing upwards over the cliff and irrigating a large tract of rich lava land. He had made a power, a transmission and a motor plant without a moving part. A similar compressor was installed near Montreal, Canada, in 1896; another at Ainsworth, British Columbia, in 1898; and another at Norwich, Conn., in 1902. These are called hydraulic air compressors and show an efficiency of about 70%. They are particularly adapted to positions with a large flow of water with a slight fall or head.

Theory **of** Pneumatic Power Transmission.—The actual transmission of power by air from the compressor to the motor is simple and effective. The air admits of a velocity of 1j to 20 ft. per second through pipes, with very slight loss by friction, and consequently there is no necessity for an expensive pipe system in proportion to the power transmitted. It is found in practice that, allowing a velocity as given above, there is no noticeable difference in pressure between the compressor and the motor several miles away. Light butt-welded tubing is largely used for piping, and if properly put in there is very slight loss from leakage, which, moreover, can be easily detected and stopped. In practice, a sponge with soap-suds passed around a joint furnishes a detective agency, the escaping air blowing soap bubbles. In good practice there need not be more than 1% loss through leakage and 1% possibly through friction.

Air develops heat on compression and is cooled by expansion, and it expands with heat and contracts with cold. For the purpose of illustration suppose a cylinder 10 ft. long containing 10 cu.ft. of air at 60° F, with a frictionless piston at one end. If this piston be moved $7\frac{1}{2}$ ft. into the cylinder, so that the air is compressed to one-quarter of its volume, and none of the heat developed by compression be allowed to escape, the air will be under a pressure of 90 lb. per square inch and at a temperature of 460° F. If this air be cooled down to 60° F the pressure will be reduced to 45 lb. per square inch, showing that the heat produced in the air itself during compression. gives it an additional expansive force of 45 lb. per square inch. The average force or pressure in compressing this air without loss of heat is 21 lb. per square inch, whereas if all the heat developed during compression had been removed as rapidly as developed the average pressure on the piston would have been only 11 lb. per square inch, showing that the heat developed in the air during compression, when not removed as fast as developed, caused in this case an extra force of 10 lb. per square inch to be used on the piston. If this heated air could be transmitted and used without any loss of heat the extra force used in compressing it could be utilized; but in practice this is impossible, as the heat is lost in transmission. If the piston holding the $2\frac{1}{2}$ cu.ft. of air at 45 lb. per square inch and at 60° F were released, the air expanding without receiving any heat would move it back within 35 ft. of the end only, and the temperature of the air would be lowered 170° F, or to 110° F below zero. If the air were then warmed to 60° F again it would move the piston the remaining 35 ft. to its starting point.

It is seen that the ideal air-compressing machine is one which will take all the heat from the air as rapidly as it is developed during compression. Such "isothermal compression" is never reached in practice, the best work yet done lacking 10% of it. It follows that the most inefficient compressing machine is one which takes away no heat during compression—that is, works by "adiabatic compression," which in practice has been much more nearly approached than the ideal. It also follows that the ideal motor for using compressed air is one which will supply heat to the air as required when it is expanding. Such "isothermal" expansion is often attained, and sometimes exceeded in practice by supplying heat artificially. Finally, the most inefficient motor for using compressed air is one which supplies no heat to the air during its expansion, or works by adiabatic expansion, which was long very closely approached by most air motors. In practice isothermal compression is approached by compressing the air slightly, then cooling it, compressing it slightly again and again cooling it until the desired compression is completed. This is called compression in stages or compound compression. Isothermal expansion is approximately accomplished by allowing the air to do part of its work (as expanding slightly in a cylinder) and then warming it, then allowing it to do a little more and then warming it again, and so continuing until expansion is complete. It will be seen that the air is carefully cooled during compression to prevent the heat it develops from working against compression, and even more carefully heated during expansion to prevent loss from cold developed during expansion. More stages of compression of course give a higher efficiency, but the cost of machinery and friction losses have to be considered. The reheating of air is often a disadvantage, especially in mining, where there are great objections to having any kind of combustion underground; but where reheating is possible, as W. C. Unwin says, "for the amount of heat supplied the economy realized in the weight of air used is surprising. The reason for this is, the heat supplied to the air is used nearly five times as efficiently as an equal amount of heat employed in generating steam." Practically there is a hot-air engine, using a medium much more effective than common air, in addition to a compressed-air engine, making the efficiency of the whole system extremely high. (*See* also PNEUMATIC TOOLS.)

(A. DE W. F.)

PNEUMATICS, the branch of physical science concerned with the properties of gases and vapours (Gr. πνεῦμα, wind, air).

PNEUMATIC SUCTION CLEANING AND CONVEYING: *see* VACUUM CLEANER.

PNEUMATIC TOOLS comprise various classes of hand tools which are operated by compressed air power. They are divided in two general classes according to the principle of operation (1) percussion, (2) reciprocating motor-driven. Under percussion tools are grouped rivetting, chipping and sand rammers, pneumatic diggers, rock drills, paving breakers, etc.; each using a piston or plunger for striking a blow. Reciprocating motor-driven tools employ a reciprocating piston air motor to drive a spindle from which power can be used for drilling, grinding, etc. The tools under this classification include pneumatic drills, grinders, motors, hoists, etc. Pneumatic tools usually operate best when supplied with compressed air at 90 lb. gauge pressure.

The principal uses of pneumatic tools occur on those classes of work where it is not possible or not advisable to take the work to a machine. A pneumatic tool, being a self-contained power unit, can be taken to the work and various operations performed rapidly, with a minimum of manual labour. Pneumatically operated tools are suited for a wide variety of uses because of their availability, the adaptability of compressed air power, the absence of danger and because they embody within small confines a great range of power and action. Other advantages are rugged construction, simplicity, and easy operation.

Pneumatic Hammers are made in a variety of sizes and types, and the name for each is governed largely by the work to be performed. This group covers chipping, rivetting, scaling and caulking hammers, diggers, paving breakers, rock drills and the like implements. (*See* BLASTING.) Each class of work requires a hammer of a particular size, weight, speed and strength of blow. In the operation of most rivetting hammers air enters the hammer at the air inlet in the handle, the amount of air being controlled by the throttle valve which is actuated by a trigger. After passing the throttle valve the air is conducted through the passage in the handle to the valve chamber containing the operating valve and valve box. The valve is moved back and forth in the valve box by the action of the air pressure on its differential areas. As the valve moves forward it admits air back of the piston, throwing it forward against the rivet set, which forms the rivet head. The piston, after striking a blow, is returned for another stroke by air admitted to the front of the cylinder, which is covered by the piston in this position. Hammers for chipping, caulking and scaling are very similar in construction to the rivetting hammer. The chipping hammer is used to clean foundry castings, for caulking the seams of boilers and tanks, pipe joints, etc., saving two-thirds the time required by hand work.

Sand Rammers have a long barrel containing a piston having a projecting rod at one end, to which the tamping butt is attached. In action the piston moves rapidly up and down in the barrel lifting the tamping butt from the sand and returning it with considerable impact against the material to be rammed. The ramming of certain classes of moulds in foundry work, a long and arduous task when done by hand, is rapidly accomplished by means of the pneumatic sand rammer. Machine-rammed moulds are harder and more uniform than those rammed by hand, resulting in better castings. Floor rammers are used for working on large moulds on the floor, and the bench rammer on small bench moulds. These tools strike up to 800 blows per minute. The force and number of blows are regulated by the operator with a throttle. The sand rammer is also used to tamp the back-fill in trenches in city streets, where it is desired to pack the sand solidly and by this means avoid the subsequent settling.

Pneumatic Drills. — Portable pneumatic drills are divided into four general types: the reversible drill, the non-reversible drill, the woodborer and the close-quarter drill. The several types are also given certain other minor divisions according to the use to which they are put, such as boring, reaming, tapping, flue rolling and stud-setting. The larger sizes of pneumatic drills use a four-cylinder V-type air motor, with one crank throw provided for each pair of cylinders in the same cross plane. The power from the crank-shaft is transmitted to the drilling spindle by gears arranged to give the spindle speed desired. A feed screw with a feed handle is used to feed the drill up to the work. A main valve, of rotary type, controls the supply of air to each of the four cylinders, the air supply reaching this main valve through a throttle handle. At the upper end of the main valve is located a centrifugal speed governor which limits the speed of the drill motor after it has passed the point of maximum horsepower.

Another small class of pneumatic drills employ a three-cylinder radial air motor, the three cylinders being in one plane with one crank provided for all three cylinders. The power from the crank is transmitted through a spindle and gears to the point where the drill chuck is attached. The main spindle also serves as a valve controlling the air to the three cylinders, greatly simplifying the construction of the tool. These tools are used for light drilling in metal, in the automobile assembly plants for running up nuts, and for running in screws. They are equipped with either feed screw, spade handle or breast plate. The close-quarter type of pneumatic drill uses a two-cylinder, double-acting motor to give a flat and compact construction. The power is transmitted from the crank-shaft to the spindle by a train of gears. A feed screw is located at the end of the spindle and can be turned by means of the ratchet handle. This type of drill is used for drilling, reaming and tapping in cramped spaces where the usual drill cannot be employed.

Pneumatic Grinders. — The pneumatic grinder is similar in general construction to the air drill except that a higher speed motor, operating at 3,000 to 6,000 r.p.m. is used. The motor is directly connected to a spindle upon which is mounted the grinding wheel. These tools are used in all kinds of service where a portable grinding tool, buffer or polisher is needed and are widely used in foundries and machine shops, monumental stone shops and automobile body plants.

Pneumatic Diggers. — Pneumatic diggers, of the same operating principle as a rivetter, are made in two styles. A short-handle type is used in tunnel work or in close quarters and an extension-handle type for trench or shaft. Pneumatic diggers are a recent development for work where it is desired to replace the hand pick. The tools are used for loosening up clay, hard ground, etc. The pneumatic digger consists of a hammer having a piston which strikes against a blade or scoop. The blows of the piston drive the blade into the ground, prying it loose. One man with such a tool is the equal of six men using ordinary hand picks.

Rock Drills.- he removal of solid rock in excavation for foundations, trenches, highways, in mining and many other projects calls for the use of a vast number of compressed-air rock drills. These tools are made in a wide variety of sizes for all classes of work, depending on the size and depth of the hole to be drilled, the hardness of the rock and other factors. In the "Jackhammer" type of rock drill, compressed air enters to a throttle valve in the handle and then passes to a flapper type of plate valve, which controls the movement of the piston. On the forward or downward movement of the piston it strikes against the shank of the drill steel, and imparts a cutting action to the points of the steel. On the back stroke of the piston it slides over a fluted rifle-bar which turns the piston and causes it to turn the drill steel. Rotation of the drill steel is desired in order that the cutting edges on the end of the drill steel may be put in a new position with regard to the rock being drilled. A ratchet mechanism ensures rotation in one direction. To blow out the cuttings and dust from the hole in the rock, air is passed down through the rifle-bar and piston and through the drill steel to the cutting face.

These tools make it possible to drill holes in rock for inserting the explosives which blast out rock. One rock drill bores 100 to 150 ft. of hole in rock in an eight-hour day, while the best a man can do using a hand hammer and steel is not more than 8 to 10 ft. a day. Rock drilling requires the use of pointed drill steels which must be resharpencd as the cutting edges become worn and dulled by the rock. This is done by compressed-air-operated drill steel sharpening machines in which after the drill steel is heated and inserted quickly shapes and sharpens the steel by means of dies many times faster than is possible by hand methods.

Paving **Breakers.**—The paving breaker is a tool somewhat similar in construction to the rock drill and is used in demolition work such as breaking up pavement, tearing out concrete walls, foundstions, etc. This tool uses a pointed chisel or steel, but it is not rotated. The absence of the rotation mechanism simplifies the general construction of the paving breaker. Paving breakers are extensively used by public utilities for making openings in the pavement prior to installing or repairing sewer pipes and connections. They are usually operated from a portable air compressor, mounted on a motor truck, which can be quickly taken to the place where the work is to be done. One man operating one tool is able to break out more pavement in a given time than 12 to 15 men using hand sledges and steels.

Air Motor Hoists.—These are made in a range of sizes to handle loads from 500 lb. up to 20,000 pounds. This style of hoist is equipped with a high-powered air motor of the four-cylinder type which is geared to a hoisting drum. A feature of these hoists is the automatic brake which acts to hold the load at any point after the air pressure is shut off. When the motor is operating, air passes to the brake through a connecting tube releasing it. When the air is shut off at the throttle, the brake is automatically applied. These air hoists are widely used in industrial plants for handling material too heavy to be easily lifted by one man. In machine shops they lift and place heavy parts on lathes, milling machines and planers. (See MECHANICAL HANDLING.)

Air hoists are particularly suited for foundry work because the operation is not affected by dust, dirt or fumes, and they are not damaged by overloading. Another type is the portable hoist, which can be mounted wherever convenient; *i.e.*, to a post or timber. It is used for pulling cars, skidding timbers, pulling a scraper on back-fill work, and dozens of other applications.

Tools for Railroad Track Work.—Special pneumatic tools have been developed for a number of applications in railroad track construction and maintenance. There are pneumatic tie tampers for tamping ballast under ties, pneumatic spike pullers, spike drivers, rail drills, pneumatic wrenches, rail bonding drills and others. Tamping ballast with pneumatic tampers is much easier than swinging a pick or tamping with a hand bar. The air tampers strike a uniform blow all day long and produce a uniform track. In removing old rail, the old spikes must be pulled. A compressed-air-operated spike puller draws 10 to 15 spikes per minute. One such machine does as much work as eight to ten men using hand claw bars. The pneumatic wrench removes the nuts or runs up nuts on the joint bolts much faster than is possible with a hand wrench. The air-operated spike driver puts down the spikes in a fraction of the time required by a hand hammer. A pneumatic rail drill bores a $\frac{7}{8}$ in. hole through the web of a rail in from 25 to 30 seconds. Small holes for signal wires are drilled with pneumatic rail bonding drills at the rate of 60 per hour. (R. A. Lu.)

PNEUMATOLYSIS (nū-măt-ŏl'ĭ-sĭs), in petrology, discharge of vapours from igneous magmas and effects produced by them on rock masses (so called from Gr. πνεῦμα, vapour, and λύειν, to set free). In volcanic eruptions the gases given off by molten lavas are powerful agencies. The slaggy clots of lava thrown out from the crater are so full of gas that when they cool they resemble spongy pieces of bread. The lava-streams as they flow down the slopes of the volcano are covered with white steam clouds, while over the orifice of the crater hangs a canopy of vapour which is often darkened by fine particles of ash.

Cause of Volcanic Explosions.—Most authors ascribe volcanic explosions to the liberation of steam from the magma which held it in solution, and the enormous expansive powers which free water vapour possesses at very high temperatures. Of these gases the principal are water and carbonic acid; but by analysis of the discharges from the smaller fumaroles, for the active crater is generally too hot to be approached during an eruption, it has been ascertained that hydrogen, nitrogen, hydrochloric acid, boron, fluorine, sulphuretted hydrogen and sulphurous acid are all emitted by volcanoes. A recent lava flow has been likened to a great fumarole pouring out volatile substances at every crack in its slaggy crust. Many minerals are deposited in these fissures, and among the substances produced in this way are ammonium chloride, ferric chloride and oxide, copper oxide (tenorite and cuprite) and sulphur; by reacting on the minerals of the rock many zeolites and other secondary products are formed. These processes have been described as "juvenile" or "post-eruptive," and it is believed that the amygdales which occupy the cavities of many porous lavas are not due really to weathering by surface waters percolating in from above, but to the action of the steam and other gases set free as the lava crystallizes. The zeolites are the principal group of minerals which originate in this way together with chlorite, chalcedony and calcite. The larger cavities (or geodes) are often lined with beautiful crystal groups of natrolite, scolecite, thomsonite, stilbite, and other minerals of this order.

Solfataric Activity.—The active gases were evidently in solution in the magma as it rose to the surface. Geologists now believe they are of subterranean origin like the lava itself, and an essential or original component of the magma. Long after a lava has cooled down and become rigid the vapours continue to ooze out through its fissures, and around many volcanoes which are believed to be extinct there are orifices discharging gas in great quantities. This state of activity is said to be "solfataric," and a good example of it is the volcano called the Solfatara near Naples. The numerous "soufrières" of the West Indies are further instances. The prevalent gas is steam with sulphuretted hydrogen and carbonic acid. White crusts of alum, various sulphates, and sulphides such as pyrites, also carbonates of soda and other bases, are formed by the action of the acid vapours on the volcanic rocks. The final manifestation of volcanic activity in a solfataric region may be the discharge of heated waters, which have ascended from the deep-seated magma far below the surface, and make their appearance as groups of hot springs; these springs persist long after the volcanoes which give rise to them have become extinct.

Rôle of Hot Waters.—It is now believed by a large number of geologists and mining engineers that these ascending hot waters are of paramount importance in the genesis of some of the most important types of ore deposits. Analyses have proved that the igneous rocks often contain distinct though very small quantities of the heavy metals; it is also established beyond doubt that veins of gold, silver, lead, tin and mercury most commonly occur in the vicinity of intrusive igneous masses. At Steamboat, Nev., hot springs, probably of magmatic origin, are forming deposits of cinnabar; at Cripple Creek, Colo., and in many other places gold-bearing veins occur in and around intrusive plugs of igneous rock. Tin ores in all parts of the world are found in association with tourmaline granites, and in all cases the veins bear evidence of having been filled from below by hot waters set free during the cooling of the igneous intrusions. Volcanic rocks are consequently the parent sources of many valuable mineral deposits, and the agency by which they were brought into their present situations is the volatile products discharged as the magma crystallized. The process was no doubt a long one and it is most probable that both steam and water took part in it. In what condition the metallic ores are dissolved and by what reactions they are precipitated depends on many factors only partly understood. The tin ores are so often associated with minerals containing boron and fluorine that it is quite probable that they were combined with these elements in some way, but they were deposited in nearly all cases as oxides. Other gaseous substances, such as sulphuretted hydrogen, carbonic acid and hydrochloric acid, probably have an important part in dissolving certain metals; and the alkaline carbonates, sulphides and chlorides have been shown by experiment to act also as solvents. In these ore deposits not only the heavy metals are found, but often a much larger quantity of minerals such as calcite, barytes, fluorspar, quartz and tourmaline which serve as a matrix or gangue, and have been deposited by the same agencies, and often at the same time as the valuable minerals.

Alteration of Minerals.—In their passage upwards and outwards through the rocks of the earth's crust, these gases and liquids not only deposit minerals in the fissures along which they ascend, but attack the surrounding rocks and alter them; the granite or other plutonic mass from which the vapours are derived is specially liable to transformation, probably because it is at a high temperature, not having yet completely cooled down. Around the tin-bearing veins in granite there is extensive replacement of felspar and biotite by quartz, tourmaline and white micas (the last-named often rich in lithia). In this way certain types of altered granite are produced, such as greisen (*q.v.*) and schorl rock (see SCHORL). In the slates adjacent to the tin veins tourmalinization also goes on, converting them into schorl-schists. The alteration of felspar into kaolin or china clay is also a pneumatolytic process, and is often found along with tin veins or other types of mineral deposit; probably both fluorine and carbonic acid operated in this instance along with water. Equally common and important is the silicification of rocks near mineral veins which carry gold, copper, lead and other metals. Granites and felsites may be converted into hard cherty masses of silica; limestones undergo this transformation very readily; at the same time they are regarded as rocks very favourable to the deposition of ores—probably the great frequency with which they undergo silicification and other types of metasomatic replacement is one of the main causes of the abundance of valuable deposits in them. The process known as "propylitization," which has extensively affected the andesites of the Hungarian goldfields, is believed to be also a consequence of the action of pneumatolytic gases. The andesites change to dull, soft, greenish masses, and their original minerals are to a large extent replaced by quartz, epidote, chlorite, sericite and kaolin. Around granites intrusive into serpentine and other rocks containing much magnesia, there is often extensive "steatization," or the deposit of talc and steatite in place of the original minerals of the rock. Some of the apatite veins of Canada and Norway accompany basic rocks of the gabbro group; it has been argued that the apatite (which contains phosphorus and chlorine) was laid down by vapours or solutions containing those gases, which may play a similar part in the basic rocks to that taken by fluorine and boron in the pneumatolytic veins around granites. In the country rock around the veins scapolite (*q.v.*), a lime alumina silicate, containing chlorine, often is substituted for lime-felspar.

These extensive changes attending the formation of mineral veins are by no means common phenomena, but in many plutonic masses pneumatolytic action has contributed to the formation of pegmatites (*q.v.*). (J. S. F.)

PNEUMONIA, a term used for inflammation of the lung substance. The disease has long been divided into three varieties: (1) Acute Croupous or Lobar pneumonia; (2) Catarrhal or Broncho-pneumonia; (3) Interstitial or Chronic pneumonia.

1. Acute Lobar Pneumonia (Pneumonic Fever) is now classed as an acute infective disease of the lung, characterized by fever and toxaemia, running a definite course and being the direct result of a specific micro-organism or micro-organisms. The micrococcus lanceolatus (pneumococcus, or diplococcus pneumoniae) of Fränkel and Weichselbaum is present in a large number of cases in the bronchial secretions, the affected lung and the blood. This organism is also present in many other infective processes which may complicate or terminate lobar pneumonia, such as pericarditis, endocarditis, peritonitis and empyema. The bacillus pneumoniae of Friedlander is also present in a proportion of cases, but is probably not the cause of true lobar pneumonia. Lobar pneumonia is an acute endemic disease of temperate climates, though epidemic forms have been described. It has a distinct seasonal incidence, being most frequent in the winter and spring. Osler strongly supported the view that it is an infectious disease, quoting the outbreaks reported by W. L. Rodman of Frankfort, Kentucky, where in a prison of 735 inhabitants there were 118 cases in one year; but direct contagion does not seem to be well proved, and it is undoubted that the pneumococcus is present in the fauces of numbers of healthy persons and seems to require a lowered power of resistante or other favouring condition for the production of an attack.

Lobar Pneumonia begins with an acute inflammatory process in the alveoli. The changes which take place in the lung are chiefly three: (1) Congestion, or engorgement, the air cells still contain air. (2) Red *Hepatization,* so called from its resemblance to liver tissue. In this stage the congested blood-vessels pour into the air spaces of the affected part an exudation which speedily coagulates, causing the lung to become airless and solid. In this condition the lung substance sinks in water. (3) Grey *Hepatization.* In this stage the lung still retains its liver-like consistence, but its colour is now grey, not unlike the appearance of grey granite. This is due partly to anaemia from pressure of the solidified exudation on the pulmonary capillaries, partly to local accumulation of enormous numbers of white blood corpuscles. The fibrin of the solid exudation is now liquefied by a process of autolysis or peptonization by unorganized ferments and the entangled cells undergo fatty degeneration ("resolution"). Absorption of this liquefied material is carried out by the lymphatics and veins and in most cases the lung soon recovers its normal function apparently uninjured. The absorbed exudate is mainly excreted by the kidneys, excess of nitrogen being found in the urine during this period. When resolution does not take place, death may occur from extension of the disease and subsequent toxaemia, heart failure, the formation of abscess or, more rarely, gangrene of the lung or from some complication. Usually pneumonia affects one lower lobe but it may extend to the whole lung or even to parts of both lungs (double pneumonia). In some cases, and particularly in children, the apex of the lung alone is affected. The prognosis of lobar pneumonia depends to a great extent on the previous history of the patient, especially in respect of alcohol; a chronic alcoholic patient with apical or double pneumonia rarely recovers. The death rate of acute lobar pneumonia in the chief London hospitals is 20%.

Symptoms.—The attack is usually ushered in by a rigor (or in children a convulsion), and rise of temperature to 102° F or more. Pulse and respiration are quickened but disproportionately so that the normal ratio (3 or 4:1) is replaced by 2:1 or even 1:1. The extraordinary muscles of respiration come into play and rhythmic dilatation of the alae nasi is very characteristic. Pain in the side is felt, especially should any amount of pleurisy be present, as is often the case. Cough is an early symptom. It is at first frequent and hacking, and is accompanied with a little tough colourless expectoration which soon, however, becomes more copious and of a rusty red colour, either tenacious or frothy and liquid. The patient during the greater part of the disease lies on the back or on the affected side. The urine is scanty, sometimes albuminous, and its chlorides are diminished. In favourable cases, however severe, there generally occurs after six or eight days a distinct crisis, marked by a rapid fall of the temperature accompanied with perspiration and a copious discharge of lithates in the urine. Although no material change is as yet noticed in the physical signs, the patient breathes more easily, sleep returns, and convalescence advances rapidly in the majority of instances.

The complications of acute pneumonia are pleurisy, empyema, pericarditis and endocarditis, while meningitis is responsible for a large percentage of the fatal cases. The pneumococcus has been found in the exudate in all these cases. Secondary pneumonias chiefly follow the specific fevers, as diphtheria, enteric fever, measles and influenza. Bacteriologically a number of different organisms have been found, together with the specific microbe of the primary disease; the striking features of primary lobar pneumonia are often masked in these types.

Treatment.—This is partly general, partly by means of vaccines and serums. Many trials have been made with antipneumococcic serum, but it has not been shown to have a very marked effect in cutting short the disease. The polyvalent serum of Romer has given the best results. Much more favourable results have been obtained from the use of a vaccine. The vaccine producing the best results is autogenous, *i.e.*, prepared from the patient's own strain of pneumococcus but in order to save time a "stock" mixture of known pneumococcus strains is employed, at least for a first injection. The value of vaccine treatment seems to depend upon recognition of the particular "type" of pneumococcus causing the disease.

2. **Broncho-Pneumonia** (Catarrhal or Lobular Pneumonia or Capillary Bronchitis). The term "broncho-pneumonia" is here used to denote a widespread catarrhal inflammation of the smaller bronchi which spreads in places to the alveoli and produces consolidation. All forms of broncho-pneumonia depend on the invasion of the lung by micro-organisms. No one organism has however been constantly found which can be said to be specific, as in lobar pneumonia; the influenza bacillus, micrococcus catarrhalis, pneumococcus, Friedlander's bacillus and various staphylococci have been found and often the infection is mixed. Broncho-pneumonia may occur as an acute primary affection in children, but more usually is a secondary extension of the bronchitis found in infectious fevers, measles, diphtheria, whooping cough, scarlet fever and typhoid fever. In these it forms a frequent and often a fatal complication especially in early childhood. In adults it may follow influenza or complicate chronic Bright's disease or various other. disorders. Broncho-pneumonia also may follow operations on the mouth or trachea, or the inhalation of foreign bodies into the traches.

The lung shows numerous prominent dark red patches in contact with depressed areas of collapsed and airless lung. Under the microscope the air vesicles and finer bronchi are blocked with epithelial cells and leucocytes, but there is no fibrinous exudation as in croupous pneumonia. In favourable cases resolution takes place by fatty degeneration, liquefaction, and absorption of the cells, but in weakly children the foci are liable to be infected by B. tuberculosis and the subsequent changes are those of tuberculosis. Broncho-pneumonia is a serious disease; the death-rate in children under five has been estimated at 30 to 50%.

The treatment is mainly symptomatic. In children, should the secretion accumulate in the bronchial tubes an emetic is useful. Inhalations relieve the cough, and circulatory stimulants such as strychnine are valuable, together with belladonna and oxygen.

3. Chronic Interstitial Pneumonia (Cirrhosis of the Lung) is a fibrosis chiefly around the walls of the bronchi and vessels, and in the intervesicular septa, which proceeds to such an extent as to invade and obliterate the air cells. The lung becomes shrunken, dense in texture and solid, any unaffected portions being emphysematous; the bronchi are dilated (see BRONCHIECTASIS), the pleura thickened, and the lung substance often deeply pigmented, especially in miners, who are apt to suffer from this disease. This condition is present to some degree in almost all chronic diseases of the lungs and bronchi, but it is specially apt to arise in persons folloxving dusty occupations such as those of colliers, flax-dressers, stonemasons, millers, etc., to which the term pneumonokoniosis is now applied (including anthracosis, siderosis,chalicosis and "grinder's rot"). (See MINERS' PHTHISIS.)

The malady is usually of long duration, many cases remaining for years in a stationary condition and even undergoing temporary improvement in mild weather, but the tendency is on the whole downward.

PNEUMOTHORAX. The lungs are elastic organs kept extended by their indirect attachment to the walls of the bony thorax. This is effected through the intervention of the pleura (see COELOM AND SEROUS MEMBRANES), the surfaces of which are held in contact by atmospheric pressure, and glide over one another during respiration. If gas or air gain entry to the pleural cavity, the lung on account of its elasticity tends to collapse and empty itself of air. This is the condition known as Pneumothorax, and according to the means of its production is spcken of as Spontaneous or Artificial.

Spontaneous **Pneumothorax.**—This is generally due to the rupture of an air-containing lung into the pleural sac, commonly caused by softening of a tuberculous nodule. According to the size and nature of the rupture the pneumothorax is formed gradually, with slow development of symptoms, or suddenly with immediate and urgent distress. A rapid and complete collapse of one lung, accompanied, as commonly happens, by encroachment of the chest contents on the other lung, leads to severe breathlessness. Where, however, the collapsed organ was extensively diseased its loss may be less urgently felt and occasionally its collapse may be actually beneficial. It was largely the benefit arising from certain of these cases that directed attention to the idea of inducing collapse artificially. In most cases of spontaneous pneumothorax the pleura becomes inflamed, and fluid, whether thin or purulent, transforms the condition into a hydro- or pyo-pneumothorax.

Artificial **Pneumothorax.**—Otherwise known as pneumothorax treatment, or as collapse-therapy, artificial pneumothorax was first urged on theoreticai grounds in 1821 by an Irishman, James Carson of Liverpool. His views were supported by clinical observations on Spontaneous Pneumothorax (Houghton, 1832; Stokes, 1837), but not till 50 years later did Potain (1884) put air into a spontaneous pneumothorax, and Cayley (1885) treat a case of haemoptysis by this method. The treatment on its modem lines may be said to originate with Forlanini, who reported his first cases in 1894–5.

The aim of this treatment is the collapse of a diseased lung, where disease does not respond to other measures, and the other lung is sufficiently sound. Its main field has been pulmonary tuberculosis, but it has also been used in lung abscess and bronchiectasis, in the diagnosis of obscure lung conditions, especially turnours, and to assist the surgeon in certain chest operations. The gases used are commonly air, nitrogen or oxygen, according to the requirements of the case.

The gas is delivered from a "gas bottle" connected with a "pressure bottle" containing fluid, and enters the chest through a special needle attached to a water manometer to control the pressure. It is introduced in small quantities at first and collapse brought about slowly. As it collapses the lung squeezes out the diseased secretions it contains, and these are brought up as sputum. In a favourable case the sputum then ceases, the temperature becomes normal and the patient regains his lost health. Gas is introduced every few weeks, and treatment is carried on till disease is judged to be healed. The lung is then allowed to expand and does so to a varying extent. The main impediment to pneumothorax treatment is the occurrence, in a large proportion of cases, of adhesions between the surfaces of the pleura. The main source of failure during its course is the development of fresh disease in the functioning lung. The success of pneumothorax treatment in severe tuberculous disease has been very notable, at least 50% being improved, arrested or cured.

(C. RI.)

PNOM-PENH, a town of French Indo-China, capital, since 1886, of the protectorate of Cambodia and seat of the resident-superior. Pop. (1936) 103,000, consisting of Cambodians, Annamese, Chinese, Malays, Indians and some Europeans. It is situated on the Mekong about 173 m. from its mouth at the point where it divides into two arms and is joined by the Tonlé-Sap river. Its position makes it the market for the products of Cambodia, Laos, Upper Burma and part of Siam (dried fish, rice, cotton, indigo, cardamoms, etc.). The administrative opening of the Mekong to maritime navigation in 1908 has contributed a great deal to its development. The palace of the king of Cambodia occupies a large space in the Cambodian quarter. The town gets its name from the Pnôm, a hill surmounted by an ancient pagoda.

PO (anc. *Padus*, Gr. Πάδος), a river of northern Italy, and the dominating factor in its geography. It is the longest river in Italy (310 m. direct, 417 m. including its many windings), and the area of its basin, which includes portions of Switzerland, is estimated at 26,798 sq.m. For its course and principal tributaries, *see* ITALY.

The lower valley of the Po was at an early period occupied by people of the Palaeolithic and Neolithic stages of civilization, who built houses on piles along the swampy borders of the streams. The river regulation works originated in pre-Roman times. The reclaiming and protecting of the riparian lands went on rapidly under the Romans, and in several places the rectangular divisions of the ground are still remarkably distinct. *(See* ESTE.) During the barbarian invasions much of the protective system decayed but the later middle ages saw the works resumed, so that the present arrangement existed in the main by the close of the 15th century.

The Ligurian name of the Po was Bodincus or Bodencus, *i.e.,* the bottomless. The name Padus was taken from the Celts or the Veneti. Thus we find Bodincomagus as a town name (Industria) on the upper course, and Padua, as a name of one of the mouths of the river. The name Ἠριδανός (Eridanus) of Greek poetry was identified with it at a comparatively late period.

See A. Beltramelei, *Da Comacchio* ad *Argentn* (Bergamo, 1905); *A.* Cappellini, *Il Polesine* (Rovigo, 1925).

POBÊDONOSTSEV, CONSTANTINE PETROVICH (1827–1907), Russian jurist, state official, and writer on philosophical and literary subjects. Born in Moscow in 1827, he studied at the School of Law in St. Petersburg, and entered the public service as an official in one of the Moscow departments of the senate. From 1860 to 1865 he was professor of Russian civil law in Moscow University, and instructed the sons of Alexander II. in the theory of law and administration. In 1868 he became a senator in St. Petersburg, in 1872 a member of the council of the empire, and in 1880 chief procurator of the Holy Synod. He was an uncompromising reactionary.

In the early years of the reign of Alexander II. (1855–1881), Pobêdonostsev maintained, though keeping aloof from the Slavophils, that Occidental institutions were radically bad in themselves and totally inapplicable to Russia. Parliamentary methods of administration, modern judicial organization and procedure, trial by jury, freedom of the press, secular education—these were among the principal objects of his aversion. He subjected all of them to a severe analysis in his *Reflections of a Russian Statesman* (English by R. C. Long, London, 1898). To these dangerous products of Occidental rationalism he opposed the autocratic power, and the traditional veneration for the ritual of the national Church. He therefore persecuted the dissenters, Stundists, Doukhobors and others, and insisted on severe measures of repression in education and in the press. In the sphere of practical politics he exercised considerable influence by inspiring and encouraging the Russification policy of Alexander III. (1881–1894). After the death of Alexander III. he lost much of his influence. Pobêdonostsev retired in 1905, and died on March 23, 1907.

For an account of Pobêdonostsev's policy of repression *see* B. Pares, *A History of Russia.*

POCAHONTAS (1595–1617), daughter of the Indian chief, Powhatan, is the heroine of one of the best-known traditions connected with the beginnings of American history. The story is that Capt. John Smith, as head of a band of soldiers in search of food and exploring the Chickahominy river, was waylaid by Indians and taken prisoner by their chief, Powhatan. Smith had been forced to kneel down while his head was laid on a stone preparatory to having his brains crushed out with heavy clubs, when Pocahontas, a young daughter of the chief, sprang forward, seized his head in her arms, and saved his life. She is supposed to have come again to his aid a year later by revealing a plot made against Smith by her father. All this is said to have happened in connection with the expedition under Capt. Bartholoinew Gosnold and others, who landed in Chesapeake Bay in 1607, explored the James river, and formed a settlement. Owing to the fact, however, that no mention of this experience is made in the minute personal narrative covering this period, written by Capt. Smith at the time of the supposed occurrence and published immediately thereafter, nor in the recollections of his comrades who usually gave him full credit for any of his exploits, doubts have arisen as to the authenticity of the tale. The first story concerning Pocahontas appears in the *Generall Historie,* first published in 1624, after she had been made much of in England as the attractive daughter of an emperor and the first convert of her tribe to Christianity, and it is to be feared that the temptation to bring her on the stage as heroine in a new character in connection with Smith, ever the hero of his own chronicles, was more than he or the publishers of the *Generall Historie* could withstand. Among the many prominent Virginia families who trace their ancestry to the son of Pocahontas and her husband, John Rolfe, are the Bollings (Mrs. Edith Bolling Galt married President Woodrow Wilson in 1915), the Guys, the Robertsons, the Elbridges, and the John Randolphs. (See *Lincoln Library of Facts* and *American Antiquarian Society Trans.,* vol. iv., p. 40.)

POCATELLO, a city of southeastern Idaho, U.S.A., on the Portneuf river, at an altitude of 4.460 ft., 170 mi. S. by W. of Yellowstone National park; the county seat of Bannock county and the second city of the state in size. It is on federal highways 30N and 91 and the Union Pacific railway system; and has a municipal airport and station for the air-mail service. Pop. (1940) 18,133—82% native white—16,471 in 1930 by the federal census. Beyond the Snake river (15 mi. distant) to the north and west stretches the Snake river lava plain of 20.000 sq mi. American Falls (1940 pop. 1,439), 23 m i W. of Pocatello, is the centre of a great hydro-electric power and irrigation project. Pocatello has extensive railroad shops, large wholesale houses and a variety of manufacturing establishments (including cheese factories with a norld-wide market) with an output valued in 1940 at $8,000.-000. It is the seat of the southern branch of the state university. which duplicates the first two years of the curriculum offered at Moscow. Seven miles north is the Ft. Hall Indian Reservation. and within its limits is the site of old Ft. Hall. built in 1834 at the intersection of the Missouri-Oregon and the Utah-Canada trails. The early history of this region, when the overland stage made its way through the Portneuf valley, was full of episodes with Indians and highwaymen. At Massacre Rocks, 38 m. S.W. of Pocatello, an emigrant train was annihilated by Indians in Aug. 1862. The city is built on 2,000 ac. sold by the Indians to the United States. It began as a tent colony in 1882, when the railroad was completed to this point, and was incorporated in 1892. Its growth was due at first to the railroad shops, and later to the irrigation projects which turned much of the surrounding desert into productive agricultural lands.

POCHARD, a diving duck, *Nyroca ferina,* the female of which is sometimes called the dunbird. In the male in full plumage the head is coppery-red, the breast black, and the back and flanks a dull white, closely barred with fine undulating black lines. The tail coverts and quill feathers are black and the lower surface dull white. The female is duller. The pochard breeds throughout the northern hemisphere, migrating to the coast in winter and retiring southward. The American subspecies is larger. A second American species is the much bigger canvas-back duck (*q.v.*). Both species are excellent table birds when they frequent fresh water, the canvas-back being pre-eminent.

Allied to the pochards are the scaup duck (N. *marila*), the tufted duck and the eiders.

POCKET-GOPHER, the name of a group of (chiefly North) American rat-like rodents, characterized by large cheek-pouches, the openings of which are external to the mouth; while their inner surface is lined with fur. The second and third front-claws are greatly enlarged, and all the claws are furnished at the base with bristles. The eyes are small, and the external ears rudimentary.

Pocket-gophers, which typify a family, the *Geomyidae,* spend the whole of their time underground, their powerful claws being adapted for digging, while the bristles on the toes prevent the earth from passing between them. The upper incisor teeth are employed to loosen the ground, like a fork; and the little rodents are able to move both backwards and forwards in their runs. The cheek-pouches are employed in carrying food, which consists of roots. The common pocket-gopher, *Geomys bursarius,* of the Mississippi Valley measures about 8 in. in length, with a tail of between 2 and 3 in.; its colour being rufous brown and greyish beneath. A well-known representative of the second genus is the Canadian *Thomomys talpoides,* which is considerably smaller than the former. *(See* RODENTIA.)

POCKET-MOUSE, the name of a number of small jerboa-like, chiefly North American rodents belonging to the family *Heteromyidae,* and including the genera *Dipodomys, Microdipodops, Perognathus,* and *Heteromys.* The typical pocket-mouse P. *fasciatus* is *a* native of Montana, Dakota and Wyoming. The Pocket-Mice (*Perognathus*) and Kangaroo Rats (*Dipodomys*) are fairly closely allied genera, the latter looking very like jerboas, with long hind-feet and plumed tails. *Heteromys* contains a number of Spiny Pocket-Mice, in which the hair is spiny and the colour of the coat usually black; the majority of the species of this genus are from Central America and Mexico.

POCOCKE, EDWARD (1604–1691), English Orientalist and biblical scholar, the son of a Berkshire clergyman, was educated at the free school of Thame in Oxfordshire and at Corpus Christi college, Oxford of which he became a fellow in 1628. He discovered in a Bodleian ms. the missing Syraic versions of the four New Testament epistles (2 Peter, 2 and 3 John, Jude) which were not in the old Syriac canon, and were not contained in European editions of the Peshito. His edition of these was published at Leyden in 1630, when Pococke sailed for Aleppo as chaplain to the English factory. At Aleppo he studied Arabic, and collected many valuable mss. Laud founded an Arabic chair at Oxford, and invited Pococke to fill it. He began to lecture on Aug. 10, 1636; but next summer sailed again for Constantinople, and remained there for about three years. When he returned to England Laud was in the Tower, but had placed the Arabic chair on a permanent footing. Pococke's rare scholarship and personal qualities won him influential friends among the opposite party, and through the good offices of John Selden and John Owen he was advanced in 1648 to the chair of Hebrew, though as he could not take the engagement of 1649 he lost the emoluments of the post soon after, and did not recover them till the Restoration. During the Commonwealth attempts were made to deprive him of his living of Childrey. In 1649 he published the *Specimen historiae arabum,* a short account of the origin and manners of the Arabs, taken from Barhebraeus (Abulfaragius), with notes from a vast number of *MS.* sources which are still valuable. This was followed in 1655 by the *Porta Mosis,* extracts from the Arabic commentary of Maimonides on the Mishna, with translation and learned notes; and in 1656 by the annals of *Eutychius* in Arabic and Latin.

After the Restoration Pococke's political and pecuniary troubles were removed, but the reception of his *magnum opus*—a complete edition of the Arabic history of Barhebraeus *(Greg. Abulfaragii historia compendiosa dynastiarum*), which he dedicated to the king in 1663—showed that the new order of things was not very favourable to profound scholarship. After this his most important works were a *Lexicon heptaglotton* (1669) and English commentaries on Micah (1677), Malachi (1677), Hosea (1685) and Joel (1691), which are still worth reading.

See a curious account of his life and writings by L. Twells prefixed to *Theological Works of Dr. Pococke* (2 vols., 1740).

PODĚBRAD, GEORGE OF (1420–1471), king of Bohemia, was the son of Victoria of Kunstat and Poděbrad, a Bohemian nobleman, who was one of the leaders of the "Orphans" or modern Taborites during the Hussite wars. George became early prominent as leader of the National, or Calixtine party in Bohemia, becoming its chief at the death of Ptacek of Pirkstein. In 1448, during the minority of Ladislas Posthumus, having raised a force of 9,000 men in north-east Bohemia, where the National cause was strongest and where his own ancestral castle was situated, he marched on Prague and took it, afterwards defeating the Romanist or Austrian party led by Ulrich von Rosenberg. In 1451 the emperor Frederick III., Ladislas' guardian, entrusted Poděbrad with the administration of Bohemia. In the same year a diet assembled at Prague also conferred on Podilbrad the regency. The struggle of the Bohemians against Rome continued uninterruptedly. and Poděbrad's position became very difficult when Ladislas, who was crowned in 1453, expressed his sympathies for the Roman Church, though recognizing the compacts and ancient privileges of Bohemia. In 1457 King Ladislas died suddenly. Public opinion from an early period accused Podilbrad of having poisoned him; but the suggestion is undoubtedly a calumny. On Feb. 27, 1458, the estates of Bohemia unanimously chose Poděbrad as king, even the adherents of the Austrian party voting for him. A year later, Pius II. (Aeneas Sylvius) became pope, and his incessant hostility proved a serious obstacle to Poděbrad's rule.

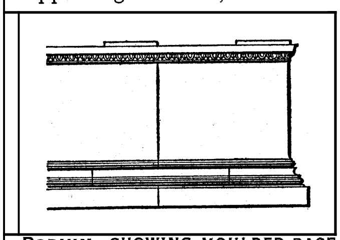
Though refusing to let the compacts be abolished, as Pius demanded, Poděbrad placated him by punishing the most advanced enemies of the papacy, including the newly-founded community of the Bohemian brethren; but his endeavours to establish peace with Rome proved ineffectual, although the death of Pius II. prevented him from carrying out his planned crusade against Bohemia. Despite the prosperity enjoyed by Bohemia under Poděbrad's rule, the malcontent nobles of the Romanist party, meeting on Nov. 28, 1465, at Zelena Hora, formed a confederacy against him which was supported by the Roman see. On Dec. 23, 1466, Paul II., the successor of Pius II., excommunicated Poděbrad and pronounced his deposition as king of Bohemia, forbidding all Romanists to continue in his allegiance. The emperor Frederick III., and King Matthias of Hungary, Poděbrad's former ally, joined the insurgents. Matthias conquered a large part of Moravia, and was crowned king of Bohemia at Briinn on May 3, 1469. On March 22, 1471, Poděbrad's death ended the war. He was the only native king of Bohemia, and the only one not a Roman Catholic.

See H. Markgraf, *Über das Verhältniss des Königs Georg von Poděbrad zu Papst Pius 11.* (1867); Jordan, *Das Königthum Georgs von Poděbrad* (1861); A. Bachmann, *Ein Jahr böhmischer Geschichte* (1876), and *Urkunden . . . zur oesterreichischen Geschichte . . . im Zeitalter George von Poděbrad* (1879); E. W. Kanter. *Die Emordung König Ladislaus* (1906); Novotry, *Über den Tod König Ladislaws Postumus* (1906). *See* also BOHEMIA.

PODGORICA (pronounced *Podgoritsa*), the commercial capital of Montenegro, Yugoslavia, occupied by Italy in 1941. Pop. (1931) 10,651. The town lies in a fertile plain on the Moracha, here spanned by a fine old Turkish bridge, while a tributary separates the Turkish town lying within the ruined ramparts, and inhabited by Albanians, from the new Montenegrin quarter built in 1878. The latter contains a state agricultural college, a gymnasium, a bank, a prison, a large tobacco factory and one of the few sawmills in the country.

PODIATRIST: *see* CHIROPODIST.

PODIUM, in architecture, a continuous pedestal, a low wall supporting columns, or the lowest portion of the wall of a building when given a separate architectural treatment. Sometimes the basement (*q.v.*) story of a classic building may be treated as a podium. The podium is usually designed with a moulded base and plinth (*q.v.*) at the bottom, a central plane surface known as a die or dado, and a projecting cornice or cap. The majority of Etruscan and Roman temples were raised on podiums and the entrance steps ascended between wing walls which were the continuations of the podium at the sides.



PODIUM; SHOWING MOULDED BASE, PLANE SURFACE OR DADO, AND CORNICE

PODMOKLY (Ger. Bodenbach), a town on the Elbe in N.W. Bohemia. Situated on the main Prague-Dresden-Berlin railway, it is an important junction, custom-house and passport control with a transit trade, in part supplied by its varied industries, which include textiles, porcelain, chemicals and foodstuffs. Pop. 22,648. The town was occupied in 1938 by Germany.

PODMORE, FRANK (1856–1910), English psychologist, was born at Elstree, Herts., on Feb. 5, 1856, and educated at Haileybury and at Pembroke college, Oxford. He became interested in psychical research, and was closely associated with Edmund Gurney and F. W. H. Myers in the telepathic and psychical investigations described in their joint publication Phantasms of the Living (1886). He was found drowned near Malvern on Aug. 15, 1910.

His publications include Apparitions and Thought *Transference* (1894); Studies in Psychical Research (1897); *Modern* Spiritualism (1902).

PODOCARPACEAE: see GYMNOSPERMS.

PODOLIA, a former government of European Russia now in the Ukrainian S.S.R. (See UKRAINE.)

PODOLSK, a town of Russia in the province of Moscow, in 5j° 27' N., 37° 28' E., 26 m. S. of Moscow, on the railway and on the Pakhra river, crossed by a suspension and a railway bridge. Pop (1939) 72,422. The town manufactures cement, lime, silicates and silk goods and has a railway repair shop. Until 1781 it was a dependency of the Danilov monastery of Moscow. Near it is an unkept park on the banks of the Pakhra, on the former estate of Count Tolstoi, and a museum, once a house of Prince Golitzin.

PODOPHYLLPN, a drug obtained from the rhizome of the American mandrake or May apple (*q.v.*). As met with in commerce, the rhizome occurs in cylindrical pieces 2 or 3 in. long and about ¼ in. in diameter, of a chocolate or purplish-brown colour, smooth, and slightly enlarged where the juncture of the leafy stem is indicated by a circular scar on the upper and a few broken rootlets on the under side. The odour is heavy and disagreeable, and the taste acrid and bitter.

Podophyllin is a resinous powder obtained by precipitating an alcoholic tincture of the rhizome by means of water acidulated with hydrochloric acid. The powder is soluble in alcohol and strong solutions of alkalis. There are at least two resins in the powder (which is known officially as *Podophylli resina*), one being soluble and the other insoluble in ether. Each contains an active substance, which can be obtained in crystalline form, and is known as podophyllotoxin. It is soluble in alcohol, ether, chloroform and boiling water. The properties of podophyllin resin vary with the reaction of the tissue with which it is in contact; where this is acid the drug is inert, the picro-podophyllin being precipitated. The resin does not affect the unbroken skin, but may be absorbed from a raw surface, and will then cause purging. When taken internally it is both a secretory and an excretory cholagogue. It is largely used in patent medicines, usually as an auxiliary to aloes. The best method of prescribing podophyllin is in pill form. In toxic doses podophyllin causes intense enteritis which may end in death. (See MAY APPLE.)

PODBSTEMONACEAE, a remarkable family of dicotyledonous plants, living only on rocks in rushing streams. The seeds are shed on the rocks during the dry season, germinating when the rocks become submerged in the rainy season. The vegetative parts consist mainly of a flattened green thallus, usually derived from adventitious roots. There are 40 genera and about 175 species, nearly all tropical, a single representative, *Podostemon Ceratophyllum* (river-weed), occurring in North America, found in shallow streams from Maine to Minnesota and southward to Georgia and Alabama. For a treatment of the genera, see A. Engler, "Podostemonaceae." Engler and Prantl, *Natürlichen Pflanzenfamilien,* ed. 2, 18a:3–68, fig. 1–61 (1930).

POE, EDGAR ALLAN (1809–1849), American poet and critic, cultivated the literature of mystery, and is himself, to a great extent, a mystery. His work owes much to the drift of romanticism (of which he is a late heir) towards the occult and the satanic. It owes much also to his own feverish dreams, to which he applied a strange power of logic and a rare faculty of shaping plausible fabrics out of impalpable materials. With an air of objectivity and spontaneity, his productions are closely dependent on his own idiosyncrasy and an elaborate technique.

He was born in Boston, Mass, Jan. 19, 1809, and was three years old when his mother, a young English actress, the widow of an American player, died at Richmond, Va., in 1811. The well-to-do childless Mrs. Allan, who adopted him, gave him motherly care and affection — reluctantly seconded by her husband. Edgar received a good education, first in England, then in a private school at Richmond, whence he went, in 1826, to the University of Virginia. Differences arose between him and his foster-father. Prevented from returning to college after the end of the first year, the youth ran away to Boston, where he enlisted in the Army. For three years he was a soldier (1827–31)—the last three months in the capacity of a cadet at West Point.

BY COURTESY OF THE ACADEMY OF ARTS AND SCIENCES
POE'S COTTAGE AT FORDHAM, NEW YORK CITY (RESTORED)

His inclination led him towards writing. In spite of untoward circumstances and uncongenial surroundings, he wrote poetry, which he managed to have published in Boston (Tamerlane, 1827), in Baltimore (*Al* Aaraaf, 1829) and in New York (Poems, 1831). Poe settled as a man of letters at Baltimore in 1832, and struggled with poverty, at times with actual want, upheld by his pride and his set resolution to achieve work that would count in America and in the world. He had neither family nor friends. Disappointments in love and social slights threw a sombre cloud over his disposition. He was afflicted with a strange susceptibility to the effects of liquor, combined with an attraction towards it which he did not always resist successfully.

Jt was this defect (or hereditary flaw) that, in a large measure, made it impossible for him to remain literary editor, in Richmond, Philadelphia or New York, of magazines which he had raised to prosperity; that, later, discouraged J. R. Lowell from taking him as contributor to The Pioneer; that disqualified him for a clerkship in a Government office at Washington. He made worthy efforts to abstain from stimulants after he had married Virginia Clemm (1836), but relapsed when his child-wife fell dangerously ill, in 1841, with scant hope of recovery. After the death of Virginia, in 1847, his morbid condition grew worse and seems to have assumed the form of a lesion of the brain with temporary crises of delirious fever. "I became insane," he wrote, "with intervals of horrible sanity." His last years were marked by fits of platonic erotomania, the objects of which were successively or at the same time women of letters, such as Mrs. Osgood, Mrs. Shew (Maria Louise), Mrs. Whitman (Helen), Mrs. Lewis (Stella), and new or old friends, like Annie and Mrs. Shelton. He died after letting himself be entrapped into drinking too much liquor at Baltimore, in 1849.

For 40 years he had fought, against terrible odds, to keep his genius clear and accomplish the work of a creative artist. While continuing to write verse, he began composing prose tales in 1832, and started a career of literary critic in 1835 which he was to carry on steadily in various magazines till the end. His keen and sound judgment as appraiser of contemporary literature, his idealism and musical gift as a poet, his weirdness and dramatic power as a story teller, though hardly appreciated in his lifetime, have secured him to-day a prominent place among universally known men of letters. The complex and elusive nature of his productions can best be understood when one tries to seize the relations of his personality to the working of his mind.

The outstanding fact in Poe's character is a strange duality. We find this trait in his temper, in his mind, in his art. The wide divergence of contemporary judgments on the man seems to point to the coexistence in him of two persons. With those he loved and who saw him in repose, he was gentle, affectionate, obliging and devoted. Others, who were the butt of his sharp criticism or who happened to meet him in moments of excitement, found him irritable, arrogant, self-centred, sombre, rebellious, and went so far as to accuse him of lack of principle and conscience. Was it, in the latter case, a double of the man rising from harrowing nightmares, or from the haggard inner vision of dark crimes, or from appalling graveyard hallucinations, that ominously loomed through the gentler Poe's unstable being?

If we consider the mind of Poe, the duality is still more striking. On one side he was an idealist and a visionary. His yearning for the ideal was both of the heart and of the imagination. His sensitiveness to the beauty, purity and lovingness of woman, associated with the contemplation of her amid the sweetest objects of nature or in the glory of ethereal radiance, inspired him with his most touching lyrics ("To Helen," "The Sleeper," "Eulalie," "To One in Paradise"), and with the full-toned prose hymns to beauty and love in "Ligeia" and "Eleonora." His imagination carried him away from the earth and the material world into the angels' dwelling-place ("Israfel"), into fairyland or dreamland, or into the empyrean, where souls dwell in immortality, where Monos and Una, Eiros and Charmion, Oinos and Agathos hold discourses on the secrets of life and death, and whither the prophet of "Eureka" takes his flight to meditate on ultimate causes.

This Pythian mood was especially characteristic of the later years of his life. More generally, either in his verse ("Valley of Unrest," "Lenore," "The Raven," "For Annie," "Ulalume") or in his prose-tales, his familiar mode of evasion from the universe of common experience was through converse with death-in-life or life-in-death, and through haunting thoughts, impulses, or fears that seem to belong to an eerie world of horrible dreams, lurking in his abnormal subliminal consciousness. From these materials he drew the startling effects of his "tales of death" ("House of Usher," "Red Death," "Valdemar," "Premature Burial," "Oval Portrait," "Shadow"), of his "tales of wickedness and crime" ("Berenice," "Black Cat," "William Wilson," "Imp of the Perverse," "Cask of Amontillado," "Tell-Tale Heart"), of his "tales of survival after dissolution" ("Ligeia," "Morella," "Metzengerstein"), and of his "tales of fatality" ("Assignation," "Man of the Crowd"). Even when he does not hurl his characters into the clutch of fearful, mysterious or supernal forces or on to the untrodden paths of the beyond, he uses the anguish of imminent death as the means of causing the nerves to quiver and the flesh to creep ("Pit and the Pendulum"), and his very grotesque inventions deal with corpses and decay in an uncanny play with the aftermath of death.

On the other side, Poe is conspicuous for a close observation of minute details, which characterizes the realist or the painter of *trompe-l'oeil* landscapes or familiar scenes. He resorts to this gift of precise, Defoe-like apprehension in the long narratives and in many of the descriptions that introduce the tales or constitute their setting. Closely connected with this accurate scanning of actual or imagined things, is his power of ratiocination. He prided himself on his faultless logic and he carefully handled this real accomplishment so as to impress the public with his possessing still more of it than he had. Hence the would-be feats of thought-reading, problem-unravelling and cryptography which he attributed to his Legrand and his Dupin. This suggested to him the "analytical tales," which introduced into literature the detective story, and his "tales of pseudo-science."

The same duality is evinced in his art. He was capable of writing angelic or weird poetry with a supreme sense of rhythm and word-appeal, or prose of sumptuous beauty and suggestiveness, with the apparent abandon of compelling inspiration; and he would write down a problem of morbid psychology or the outlines of an unrelenting plot in a hard and dry style, with the clear-cut directness of algebraic reasoning. He was capable of throwing massively into a poem or a prose-tale the most impressive unity of effect, as if urged by a flashing vision or an irresistible creative impulse; and he would dissect in cold blood that seemingly unanalysable whole and show by precept and rule that it was the result of the most deliberate and artificial technique. In Poe's masterpieces, the double contents of his temper, of his mind and of his art are fused into a oneness of tone, structure and movement, the more effective, perhaps, as it is compounded of various elements that give depth and intensity to the total sheen or dismal glow.

Poe's genius was first recognized abroad. None did more to persuade the world, and, in the long run, America, of Poe's greatness than Baudelaire and Mallarmé. The one was a romanticist and the other a symbolist; they hailed Poe as the wizard of letters who had had intimation of immortal truths and the divine faculty of calling up an other-worldly thrill. Even if the present and the future generations are less likely to tremble in awe at Poe's would-be revelations of Elysian or Tartarian lore, they will concur with his "discoverers" in admiring his fecund and startling invention, his exact dosage of artifice and spontaneity, and his supreme artistry.

Poe's works have been edited by J. A. Harrison (1903, containing biography and letters), and by E. C. Stedman and G. E. Woodberry (1914, with a memoir, biography and criticism).

POELZIG, HAMS (1869–), German architect, was born in Berlin, April 30, 1869. He studied architecture at the technical high school in Berlin (1888–93); in 1900 he was appointed a lecturer in the Breslau academy of arts, of which he was subsequently director (1903–16). He was architect to the city of Dresden (1916–20) and also professor at the technical high school there. In 1920 he started an advanced studio for applied arts at the academy of arts in Berlin. He was professor of the architectural section of the Technische *Hochschule* in Berlin 1924–35. Poelzig was also a member of the academies of arts at Dresden and Berlin and president of the Deutscher Werkbund. Among his buildings, which display remarkable versatility, may be mentioned the dam in the Klingenberg valley; the Centenary exhibition in Berlin (gardens and buildings); reconstruction of the Grosses *Schauspielhaus,* Berlin; the water tower at Posen; the "Kapitol" cinema, Berlin; Keksfabrik, Hanover; the remarkable interior of Reinhardt's theatre; a chemical factory at Luban with an effective rhythmical arrangement of windows; an office-building at Breslau, almost completely glass-walled; and flat-roofed dwelling-houses partially in ferro-concrete exhibited at Die Wohnung, Stuttgart, 1927; he was also associated with Prof. Tessenow in a new housing scheme near Berlin.

POERIO, AEESSANDRO (1802–1848), Italian poet and patriot, was descended from an old Calabrian family, his father, Baron Giuseppe Poerio, being a distinguished Neapolitan lawyer. In 1815 he and his brother Carlo accompanied their father, who had been identified with Murat's cause, into exile, and settled at Florence. In 1818 they were allowed to return to Naples. Alessandro fought as a voiunteer, under Guglielmo Pepe (*q.v.*), against the Austrians in 1821, but when the latter reoccupied Naples and the king abolished the constitution, the family was sgain exiled and settled at Gratz. Alessandro studied in Germany, and at Weimar he became the friend of Goethe. In 1835 the Poerios returned to Naples. In 1848 Alessandro accompanied Pepe as a volunteer to fight the Austrians in northern Italy, and on the recall of the Neapolitan contingent he followed Pepe to Venice. He was severely wounded in the fighting round Mestre, and died on Nov. 3, 1848. His poetry "reveals the idealism of a tender and delicate mind"; but he could also sound the clarion note of patriotism, as in his stirring poem *Il Risorgimento.*

His brother Carlo (1803–67), after returning to Naples, practised as an advocate, and from 1837 to 1848 was frequently arrested and imprisoned. Under the short lived constitution of 1848 he was minister of education. He resigned office in April and took his seat in parliament, where he led the constitutional opposition. After the Austrian victory Poerio was arrested (July 19, 1849) tried, and condemned to 19 years in irons. Chained in pairs, he and other political prisoners were confined in one small room in the bagno of Nisida, near the lazaretto. The exposure (1851) of the horrors of the Neapolitan dungeons by Gladstone, who emphasized especially the case of Poerio, awakened the indignation of Europe, but he was not released till 1858. He and other exiles were then placed on board a ship bound for the United States, but the son of Settembrini, another of the exiles, who was on board in disguise, compelled the crew to land them at Cork, whence Poerio made his way to London. In the following year he returned to Italy, and in 1860 he was elected deputy to the parliament of Turin, of which he was chosen vice-president in 1861. He died at Florence on April 28, 1867.

Gladstone, *Two Letters to the Earl of Aberdeen* (1851); *Carlo Poerio and the Neapolitan Police* (1858); Vannucci, *I Martiri della libertà italiana,* vol. iii. (Milan, 1880); Imbriani, *Alessandro Poerio a Venezia* (Naples, 1884); Del Giudice, *I Fratelli Poerio* (Turin, 1899); Countess Martinengo Cesaresco, *Italian Characters* (1901).

POET LAUREATE. The laurel (Lat. *laurea*) was sacred to Apollo, and as such was used to form a crown or wreath of honour for poets and heroes. The word "laureate" or "laureated" thus came in English to signify eminent, or associated with glory, literary or military. "Laureate letters" in old times meant the despatches announcing a victory; and the epithet was given, even officially (*e.g.,* to John Skelton) by universities, to distinguished poets. The term "poet laureate" was ultimately restricted to the office of the poet attached to the royal household, first held by Ben Jonson, for whom the position was, in its essentials, created by James I. in 1617. (Jonson's appointment does not seem to have been formally made as poet-laureate, but his position was equivalent to that). The office was really a development of the practice of earlier times, when minstrels and versifiers were part of the retinue of the king; it is recorded that Richard Coeur de Lion had a *versificator regis* (Gulielmus Peregrinus), and Henry III. had a versificator (Master Henry); in the 15th century John Kay, also a "versifier," described himself as Edward IV.'s "humble poet laureate." Moreover, the Crown had shown its patronage in various ways; Chaucer had been given a pension and a perquisite of wine by Edward III., and Spenser a pension by Queen Elizabeth. Sir William Davenant succeeded Jonson in 1638, and the title of poet laureate was conferred by letters patent on Dryden in 1670, two years after Davenant's death, coupled with a pension of £300 and a butt of Canary wine. This was the beginning of the official laureateship. The successors of Dryden were T. Shadwell (who originated annual birthday and new year odes), Nahum Tate, Nicholas Rowe, Laurence Eusden, Colley Cibber, William Whitehead, Thomas Warton, H. J. Pye, Southey, Wordsworth. Tennyson, Alfred Austin, Robert Bridges (appointed 1913) and John Masefield (appointed 1930).

The poet lau eate, being a court official, was considered responsible for producing formal and appropriate verses on birthdays and state occasions. Wordsworth stipulated before accepting the honour, that no formal effusions from him should be considered a necessity; but Tennyson was generally happy in his numerous poems of this class. The emoluments of the post have varied. To Pye an allowance of £27 was made instead of the Canary wine. Tennyson drew £72 a year, and £27 in lieu of the "butt of sack."

See Walter Hamilton, *Poets Laureate of England* (1879), and E. K. Broadus, *The Laureateshap* (1921).

POETRY. In modern criticism the word poetry (*i.e.* the art of the poet, Gr. *ποιητής*, maker, from *ποιεῖν*, to make) is used sometimes to denote any expression (artistic or other) of imaginative feeling, sometimes to designate a precise literary art, which ranks as one of the fine arts. As an expression of imaginative feeling, as the movement of an energy, as one of those great primal human forces which go to the development of the race poetry in the wide sense has played as important a part as science. In some literatures (such as that of England) poetic energy, and in others (such as that of Rome) poetic art is the dominant quality. It is the same with individual writers. In classical literature Pindar may perhaps be taken as a type of the poets of energy; Virgil of the poets of art. With all his wealth of poetic art Pindar's mastery over symmetrical methods never taught him to "sow with the hand," as Corinna declared, while his poetic energy always impelled him to "sow with the whole sack."

In some writers, and these the very greatest—in Homer, Aeschylus, Sophocles, Dante, Shakespeare, Milton, and perhaps Goethe—poetic energy and poetic art are seen in something like equipoise. It is of poetry as an art, however, that we have mainly to speak here; and all that we have to say upon poetry as an energy is that the critic who, like Aristotle, takes this wide view of poetry—the critic, who, like him, recognizes the importance of poetry in its relations to man's other expression of spiritual force, claims a place in point of true critical sagacity above that of a critic, who, like Plato, fails to recognize that importance.

With regard to poetry as an art, most of the great poems of the world are dealt with elsewhere in this work, either in connection with the names of the writers or with the various literatures to which they belong; consequently, these remarks must be confined to general principles. Under VERSE the detailed questions of prosody are considered: here we are concerned with the essential principles which underlie the meaning of poetry as such.

All that can be attempted is to inquire:

(1) What is poetry?

(2) What varieties of poetic art are the outcome of the two great kinds of poetic impulse, dramatic imagination, and lyric or egoistic imagination?

Definition of Poetry.—Definitions are for the most part alike unsatisfactory and treacherous; but definitions of poetry are proverbially so. Yet some definition must be here attempted; and, using the phrase "absolute poetry" as the musical critics use the phrase "absolute music," we may, perhaps, without too great presumption submit the following:

Absolute poetry is the concrete and artistic expression of the human mind in emotional and rhythmical language.

This, at least, will be granted, that no literary expression can, properly speaking, be called poetry that is not in a certain deep sense emotional, whatever may be its subject-matter, concrete in its method and its diction, rhythmical in movement, and artistic in form.

That the expression of all real poetry must be concrete in method and diction is obvious, and yet this dictum would exclude from the definition much of what is called didactic poetry. With abstractions the poet has nothing to do, save to take them and turn them into concretions; for, as artist, he is simply the man who by instinct embodies in concrete forms that "universal idea" which Gravina speaks of—that which is essential and elemental in nature and in man; as poetic artist he is simply the man who by instinct chooses for his concrete forms metrical language.

As an example of the absence of concrete form in verse take the following lines from George Eliot's *Spanish Gipsy:*

"Speech is but broken light upon the depth
Of the unspoken; even your loved words
Float in the larger meaning of your voice
As something dimmer."

Without discussing the question of blank verse cadence and the weakness of a line where the main accent falls upon a positive hiatus, "of the unspoken," we would point out that this powerful passage shows the spirit of poetry without its concrete form. The abstract method is substituted for the concrete. Such an abstract phrase as "the unspoken" belongs entirely to prose.

That poetry must be metrical or even rhythmical in movement, however, is what some have denied. Here we touch at once the very root of the subject. Aristotle seems to have assumed that the indispensable basis of poetry is invention; and perhaps the first critic who tacitly revolted against the dictum that substance. and not form, is the indispensable basis of poetry was Dionysius of Halicarnassus, whose treatise upon the arrangement of words is really a very fine piece of literary criticism.

By the poets themselves metre was for long considered to be the one indispensable requisite of a poem, though, as regards criticism, even in the time of the appearance of the *Waverley Novels,* the *Quarterly Review* would sometimes speak of them as "poems"; and perhaps even later the same might be said of romances so concrete in method and diction, and so full of poetic energy, as *Wuthering Heights* and *Jane Eyre,* where we get absolutely all that Aristotle requires for a poem. However, at all events this at least may be said, that the division between poetical critics is not now between Aristotelians and others; it is of a different kind altogether. While one group of critics may still perhaps say with Dryden that "a poet is a maker, as the name signifies" and that "he who cannot make (that is, invent) has his name for nothing," another group contends that it is not the invention but the artistic treatment, the form, which determines whether an imaginative writer is a poet or a writer of prose—contends, in short, that emotion is the basis of all true poetic expression, whatever be the subject-matter, that thoughts must be expressed in an emotional manner before they can be brought into poetry, and that this emotive expression demands even yet something else, viz., style and form.

Although many critics are now agreed that "L'art est une forme," that without metre and without form there can be no poetry, there are few who would contend that poetry can exist by virtue of any one of these alone, or even by virtue of all these combined. Quite independent of verbal melody, though mostly accompanying it, and quite independent of "composition" there is an atmosphere floating around the poet through which he sees everything, an atmosphere which stamps his utterances as poetry. This atmosphere is what we call poetic *imagination.*

In order to produce poetry the soul must for the time being have reached that state of exaltation, that state of freedom from self-consciousness, depicted in ihe lines.—

"I started once, or seemed to start, in pain
Resolved on noble things, and strove to speak
As when a great thought strikes along the brain
And flushes all the cheek."

Whatsoever may be the poet's "knowledge of his art" into this mood he must always pass before he can write a truly poetic line. For, notwithstanding all that may be said upon poetry as a fine art, it is in the deepest sense of the word an '(inspiration." No man can write a line of genuine poetry without having been "born again" (or as the true rendering of the text says, "born from above"); and then the mastery over those highest reaches of form which are beyond the ken of the mere versifier comes to him as a result of the change.

It might almost be said, indeed, that Sincerity and Conscience, the two angels that bring to the poet the wonders of the poetic dream, bring him also the deepest, truest delight of form. It might almost be said that by aid of sincerity and conscience the poet is enabled to see more clearly than other men the eternal limits of his own art—to see with Sophocles that nothing, not even poetry itself, is of any worth to man, invested as he is by the whole army of evil, unless it is in the deepest and highest sense good, unless it comes linking us all together by closer bonds of sympathy and pity, strengthening us to fight the foes with whom Fate and even Nature, the mother who bore us, sometimes seem in league—to see with Milton that the high quality of man's soul which in English is expressed by the word virtue is greater than even the great poem he prized, greater than all the rhythms of all the tongues that have been spoken since Babel—and to see with Shakespeare and with Shelley that the high passion which in English is called love is lovelier than all art, lovelier than all the marble Mercuries that "await the chisel of the sculptor" in all the marble hills.

Varieties **of** Poetic Art.—We have now reached the inquiry: What varieties of poetic art are the outcome of the two kinds of poetic impulse, dramatic imagination and lyric or egoistic imagination? Allowing for all the potency of external influences, we shall not be wrong in saying that of poetic imagination there are two distinct kinds—(I) the kind of poetic imagination seen at its highest in Aeschylus, Sophocles, Shakespeare, and Homer, and (2) the kind of poetic imagination seen at its highest in Pindar, Dante, and Milton, or else in Sappho, Heine, and Shelley. The former, being in its highest dramatic exercise unconditioned by the personal or lyrical impulse of the poet, might perhaps be called absolzrte dramatic vision; the latter, being more or less conditioned by the personal or lyrical impulse of the poet, might be called *relative* dramatic vision. It seems impossible to classify poets, or to classify the different varieties of poetry, without drawing some such distinction as this, whatever words of definition we may choose to adopt.

For the achievement of all pure lyric poetry such as the ode, the song, the elegy, the idyll, the sonnet, the stornello, it is evident that the imaginative force we have called relative vision will suffice. And if we consider the matter thoroughly, in many other forms of poetic art—forms which at first sight might seem to require absolute vision—we shall find nothing but relative vision at work.

Even in Dante, and even in Milton and Virgil, it might be difficult to trace the working of any other than relative vision. And as to the entire body of Asiatic poets, it might perhaps be found (even in view of the Indian drama) that relative vision suffices to do all their work. Indeed the temper which produces true drama is, it might almost be said, a growth of the Western mind. For, unless it be Semitic, as seen in the dramatic narratives of the Bible, or Chinese, as seen in that remarkable prose story The *Two Fair Cousins* translated by Rémusat, absolute vision seems to have but small place in the literatures of Asia. The wonderfulness of the world and the romantic possibilities of fate or circumstance, or chance—not the wonderfulness of the character to whom these possibilities befall—are ever present to the mind of the Asiatic poet. It was left for the poets of Europe to show that, given the interesting character, given the Achilles, the Odysseus, the Helen, the Priam, any adventure happening to such a character becomes interesting.

What then is this absolute vision, this true dramatic imagination which can hardly be found in Asia—which even in Europe cannot be found except in rare cases? Between relative and absolute vision the difference seems to be this, that the former only enables the poet, even in its very highest exercise, to make his own individuality, or else humanity as represented by his own individuality, live in the imagined situation; the latter enables him in its highest exercise to make special individual characters other than the poet's own life in the imagined situation.

"That which exists in nature," says Hegel, "is a something purely individual and particular. Art, on the contrary, is essentially destined to manifest the general." And no doubt this is true as regards the plastic arts, and true also as regards literary art, save in the very highest reaches of pure drama and pure lyric, when it seems to become art no longer—when it seems to become the very voice of Nature herself. The cry of Priam when he puts to his lips the hand that slew his son is not merely the cry of a bereaved and aged parent; it is the cry of the individual king of Troy, and expresses above everything else that most naïve, pathetic, and winsome character. Put the words into the mouth of the irascible and passionate Lear and they would be entirely out of keeping.

Lyric, Epic, *and* Dramatic Singers.—It may be said then that, while the poet of relative vision, even in its very highest exercise, can only, when depicting the external world, deal with the general, the poet of absolute vision can compete with Nature herself and deal with both general and particular. If this is really so, we may perhaps find a basis for a classification of poetry and of poets. That all poets must be singers has already been maintained. But singers seem to be divisible into three classes: first the pure lyrists, each of whom can with his one voice sing only one tune; secondly the epic poets, save Homer, the bulk of the narrative poets, and the quasi-dramatists, each of whom can with his one voice sing several tunes; and thirdly the true dramatists, who, having like the nightingale of Gongra many tongues, can sing all tunes.

It is to the first-named of these classes that most poets belong With regard to the second class there are not of course many poets left for it; the first absorbs so many. But, when we come to consider that among those who, with each his one voice. can sing many tunes are Pindar, Firdausi, Jami, Virgil, Dante, Milton, Spenser, Goethe, Byron, Coleridge, Shelley, Keats, Schiller. Victor Hugo, the second class is so various that no generalization save such a broad one as ours could embrace its members. And now we come to class three, and must pause. The third class is necessarily very small. In it can only be placed such names as Shakespeare, Aeschylus, Sophocles, Homer, and (hardly) Chaucer.

These three kinds of poets represent three totally different kinds of poetic activity.

With regard to the first, the pure lyrists, the impulse is mere egoism. Many of them have less of even relative vision at its highest than the mass of mankind. They are often too much engaged with the emotions within to have any deep sympathy with the life around them. Of every poet of this class it may be said that his mind to him "a kingdom is" and that the smaller the poet the bigger to him is that kingdom. To make use of a homely image—like the chaffinch whose eyes have been pricked by the bird-fancier, the pure lyrist is sometimes a warbler because he is blind. Still, he feels that the Muse loves him exceedingly. She takes away his eyesight, but she gives him sweet song. And his song is very sweet, very sad, and very beautiful; but it is all about the world within his own soul—its sorrows, joys, fears, and aspirations.

With regard to the second class the impulse here is no doubt a kind of egoism too; yet the poets of this class are all of a different temper from the pure lyrists. They have a wide imagination; but it is still relative, still egoistic. They have splendid eyes, but eyes that never get beyond seeing general, universal humanity (typified by themselves) in the imagined situation. Not even to these is it given to break through that law of centrality by which every "me" feels itself to be the central "me"—the only "me" of the universe, round which all other spurious "me's" revolve. This "me" of theirs they can transmute into many shapes, but they cannot create other "me's"—nay, for egoism, some of them scarcely would, perhaps, if they could.

The third class, the true dramatists, whose impulse is the simple yearning to create akin to that which made "the great Vishnu yearn to create a world," are, "of imagination all compact" — much so that when at work "the divinity" which Iamblichus speaks of "seizes for the time the soul and, guides it as he will."

The distinction between the pure lyrists and the other two classes of poets is obvious enough. But the distinction between the quasi-dramatists and the pure dramatists requires a word of explanation before we proceed to touch upon the various kinds of poetry that spring from the exercise of relative and absolute vision. Sometimes, to be sure, the vision of the true dramatists—the greatest dramatists—will suddenly become narrowed and obscured, as in that part of the *Oedipus Tyrannus* where Sophocles makes Oedipus ignorant of what every one in Thebes must have known, the murder of Laius. And again, finely as Sophocles has conceived the character of Electra, he makes her, in her dispute with Chrysothemis, give expression to sentiments that, in another play of his own, come far more appropriately from the lofty character of Antigone in a parallel dispute with Ismene. And, on the other hand, examples of relative vision in its furthest reaches can be found in abundance everywhere, especially in Virgil, Dante, Calderon, and Milton.

In Coleridge's "Ancient Mariner" we find an immense amount of relative vision of so high a kind that at first it seems absolute vision. When the ancient mariner, in his narrative to the wedding guest, reaches the slaying of the albatross, he stops, he can proceed no farther, and the wedding guest exclaims:—

> "God save thee, Ancient Mariner,
> From the fiends that plague thee thus!
> Why look'st thou so?" "With my cross-bow
> I shot the albatross."

But there are instances of relative vision—especially in the great master of absolute vision, Shakespeare—which are higher still—so high indeed that not to relegate them to absolute vision seems at first sight pedantic. Such an example is the famous speech of Lady Macbeth in the second act, where she says:—

> "Had he not resembled
> My father as he slept, I had done't."

Marvellously subtle as is this speech it will be found, if analysed, that it expresses the general human soul rather than any one special human soul. Indeed, Leigh Hunt records the case of a bargeman who, charged with robbing a sleeping traveller in his barge, used in his confession almost identical words—"Had he not looked like my father as he slept, I should have killed as well as robbed him." Again, the thousand-and-one cases (to be found in every literature) where a character, overwhelmed by some sudden surprise or terror, asks whether the action going on is that of a dream or of real life, must all, on severe analysis, be classed under relative rather than under absolute vision—even such a fine speech, for instance, as that where Pericles, on discovering Marina, exclaims:—

> "This is the rarest dream that e'er dull sleep
> Did mock sad fools withal"—

even here, we say, the humanity rendered is general and not particular, the vision at work is relative and not absolute. The poet, as representing the whole human race, throwing himself into the imagined situation gives us what general humanity would have thought, felt, said, or done in that situation, not what one particular individual and he alone would have thought, felt, said, or done.

Now what we have called absolute vision operates in a very different way. So vividly is the poet's mere creative instinct at work that the *ego* sinks into passivity—becomes insensitive to all impressions other than those dictated by the vision—by the "divinity" which has "seized the soul." Shakespeare is full of examples. Take the scene in the first act of *Hamlet*, where Hamlet hears for the first time, from Horatio, that his father's ghost haunts the castle. Having by short sharp questions elicited the salient facts attending the apparition, Hamlet says, "I would I had been there." To this Horatio makes the very commonplace reply, "It would have much amazed you." Note the marvellously dramatic reply of Hamlet—"Very like, very like! Stayed it long?" Suppose that this dialogue had been attempted by any other poet than a true dramatist, or by a true dramatist in any other mood than his very highest, Hamlet, on hearing Horatio's commonplace remarks upon phenomena which to Hamlet were more subversive of the very order of the universe than if a dozen stars had fallen from their courses, would have burst out with: "Amazed me!" and then would have followed an eloquent declamation about the "amazing" nature of the phenomena and their effect upon him. But so entirely has the poet become Hamlet, so completely has "the divinity seized his soul," that ail language seems equally weak for expressing the turbulence within the soul of the character, and Hamlet exclaims in a sort of meditative irony, "Very like, very like!" It is exactly this one man Hamlet, and no other man, who in this situation would have so expressed himself.

While all other forms of poetic art can be vitalized by relative vision, there are two forms (and these the greatest) in which absolute vision is demanded, viz., the drama, and in a lesser degree the Greek epic, especially the *Iliad.* This will be seen more plainly perhaps if we now vary our definitions and call relative vision *egoistic imagination;* absolute vision *dramatic imagination.*

The nature of this absolute vision or true dramatic imagination is easily seen if we compare the dramatic work of writers without absolute vision, such as Calderon, Goethe, Ben Jonson, Fletcher, and others, with the dramatic work of Aeschylus and of Shakespeare. While of the former group it may be said that each poet skilfully works his imagination, of Aeschylus and Shakespeare it must be said that each in his highest dramatic mood does not work, but is worked by his imagination. Note, for instance, how the character of Clytaemnestra grows and glows under the hand of Aeschylus. The poet of the *Odyssey* had distinctly said that Aegisthus, her paramour, had struck the blow, but the dramatist having imagined the greatest tragic female in all poetry, finds it impossible to let a man like Aegisthus assist such a woman in a homicide so daring and so momentous. And when in that terrible speech of hers she justifies her crime (ostensibly to the outer world, but really to her own conscience'), the way in which, by sheer magnetism of irresistible personality, she draws our sympathy to herself and her crime is unrivalled out of Shakespeare and not surpassed even there.

Epic and **Drama Compared.**—Much has been said as to the scope of these. If in epic the poet has the power to take the imagination of his audience away from the dramatic centre arid show what is going on at the other end of the great web of the world, he can do the same thing in drama by the chorus, and also by the introduction into the dramatic circle of messengers and others from the outside world. But as regards epic poetry, is it right that we should hear. as we sometimes do hear, the voice of the poet himself as chorus bidding us contrast the present picture with other pictures afar off, in order to enforce its teaching and illustrate its pathos? This is a favourite method with modern poets and a still more favourite one with prose narrators. Does it not give an air of self-consciousness to poetry? Does it not disturb the intensity of the poetic vision? Yet it has the sanction of Homer; and who shall dare to challenge the methods of the great father of epic? An instance occurs in *Iliad* v. 158, where, in the midst of all the stress of fight, the poet leaves the dramatic action to tell us what became of the inheritance of Phaenops, after his two sons had been slain by Diomedes. Another instance occurs in iii. 243–244, where the poet, after Helen's pathetic mention of her brothers, comments on the cause of their absence, "criticizes life" in the approved modern way, generalizes upon the impotence of human intelligence—the impotence even of human love—to pierce the darkness in which the web of human fate is woven. Thus she spoke (the poet tells us); but the life-giving earth already possessed them, there in Lacedaemon, in their dear native land:—

> ὥς φάτο· robs 6' ἤδη κάτεχεν φυσίζοος αἶα
> ἐν Λακεδαίμονι αὖθι, φίλῃ ἐν πατρίδι γαίῃ.

This, of course, is "beautiful exceedingly," but, inasmuch as the imagination at work is egoistic or lyrical, not dramatic; inasmuch as the vision is relative, not absolute, it does not represent that epic strength which we call specially "Homeric."

The deepest of all the distinctions between dramatic and epic methods has relation, however, to the nature of the dialogue. Aristotle failed to point it out, and this is remarkable until we remember that his work is but a fragment of a great system of criticism. In epic poetry, and in all poetry that narrates, whether the poet be Homer, Chaucer, Thomas the Rhymer, Gottfried von Strassburg, or Turoldus, the action, of course, is moved partly by aid of narrative and partly by aid of dialogue, but in drama the dialogue has a quality of suggestiveness and subtle inference which we do not expect to find in any other poetic form save perhaps that of the purely dramatic ballad. In ancient drama this quality of suggestiveness and subtle inference is seen not only in the dialogue but in the choral odes. The third ode of the *Agamemnon* is an extreme case in point, where by a kind of double *entendre* the relations of Clytaemnestra and Aegisthus are darkly alluded to under the cover of allusions to Paris and Helen. Of this dramatic subtlety Sophocles is perhaps the greatest master; and certain critics have been led to speak as though irony were the heart-thought of Sophoclean drama. But the suggestiveness of Sophocles is pathetic (as Professor Lewis Campbell well pointed out), not ironical. This is one reason why drama more than epic seems to satisfy the mere intellect of the reader, though this may be counterbalanced by the hardness of mechanical structure which sometimes disturbs the reader's imagination in tragedy.

The Lyric *Imagination.*—But we must now give undivided attention to pure egoistic or lyric imagination. This, as has been said, is sufficient to vitalize all forms of poetic art save drama and the Greek epic. It would be impossible to discuss adequately here the Hebrew poets, who have produced a lyric so different in kind from all other lyrics as to stand in a class by itself. As it is equal in importance to the Great Drama of Shakespeare, Aeschylus, and Sophocles, we may perhaps be allowed to call it the "Great Lyric." The Great Lyric must be religious—it must, it would seem, be an outpouring of the soul, not towards man, but towards God, like that of the God-intoxicated prophets and psalmists of Scripture. Even the lyric fire of Pindar owes much to the fact that he had a childlike belief in the myths to which so many of his contemporaries had begun to give a languid assent. But there is nothing in Pindar, or indeed elsewhere in Greek poetry, like the rapturous song, combining unconscious power with unconscious grace, which we have called the Great Lyric. It might perhaps be said indeed that the Great Lyric is purely Hebrew. But, although we could hardly expect to find it among those whose language, complex of syntax and alive with self-conscious inflexions, bespeaks the scientific knowingness of the Western mind, to call the temper of the Great Lyric broadly "Asiatic" would be rash. It seems to belong as a birthright to those descendants of Shem, who, yearning always to look straight into the face of God and live, could (when the Great Lyric was sung) see not much else.

Though two of the artistic elements of the Great Lyric, unconsciousness and power, are no doubt plentiful enough in India, the element of grace is lacking for the most part. The Vedic hymns are both nebulous and unemotional, as compared with Semitic hymns. And as to the Persians, they, it would seem, have the grace always, the power often, but the unconsciousness almost never. This is inevitable if we consider for a moment the chief characteristic of the Persian imagination—an imagination whose wings are not so much "bright with beauty" as heavy with it—heavy as the wings of a golden pheasant—steeped in beauty like the "tiger-moth's deep damasked wings." Now beauty of this kind does not go to the making of the Great Lyric.

Then there comes that poetry which, being ethnologically Semitic, might be supposed to exhibit something at least of the Hebrew temper—the Arabian. But, whatever may be said of the oldest Arabic poetry, with its deep sense of fate and pain, it would seem that nothing can be more unlike than the Hebrew temper and the Arabian temper as seen in later poets. It is not with Hebrew but with Persian poetry that Arabian poetry can be usefully compared. If the wings of the Persian imagination are heavy with beauty, those of the later Arabian imagination are bright with beauty—brilliant as an Eastern butterfly, quick and agile as a dragon-fly or a humming-bird. To the eye of the Persian poet the hues of the earth are (as Firdausi says of the garden of Afrasiab) "like the tapestry of the kings of Ormuz, the air is perfumed with musk, and the waters of the brooks are the essence of roses." And to the later Arabian no less than to the Persian the earth is beautiful; but it is the clear and sparkling beauty of the earth, as she "wakes up to life, greeting the Sabaean morning"; we feel the light more than the colour. But it is neither the Persian's instinct for beauty nor the Arabian's quenchless wit and exhaustless animal spirits that go to the making of the Great Lyric; far from it. In a word, the Great Lyric, as we have said, cannot be assigned to the Asiatic temper generally any more than it can be assigned to the European temper.

The Ode.—In the poetry of Europe, if we cannot say of Pindar, devout as he is, that he produced the Great Lyric, what can we say of any other European poet? The truth is that, like the Great Drama, so straight and so warm does it seem to come from the heart of man in its highest moods that we scarcely feel it to be literature at all. Passing, however, from this supreme expression of lyrical imagination, we come to the artistic code. Whatever may have been said to the contrary, enthusiasm is, in the nature of things, the very basis of the ode; for the ode is a mono-drama, the actor in which is the poet himself; and, as Marmontel has well pointed out, if the actor in the mono-drama is not affected by the sentiments he expresses, the ode must be cold and lifeless. But, although the ode is a natural poetic method of the poet considered as a prophet—although it is the voice of poetry as a fine frenzy—it must not be supposed that there is anything lawless in its structure. "Pindar," says the Italian critic, Gravina, "launches his verses upon the bosom of the sea; he spreads out all his sails; he confronts the tempest and the rocks; the waves arise and are ready to engulf him; already he has disappeared from the spectator's view; when suddenly he springs up in the midst of the waters and reaches happily the shore." Now it is this Pindaric discursiveness, this Pindaric unrestraint as to the matter, which has led poets to attempt to imitate him by adopting an unrestraint as to form. Although no two odes of Pindar exhibit the same metrical structure (the Aeolian and Lydian rhythms being mingled with the Doric in different proportions), yet each ode is in itself obedient, severely obedient, to structural law. This we feel; but what the law is exactly no metricist has perhaps ever yet been able to explain.

It was a strange misconception that led people for centuries to use the word "Pindaric" and irregular as synonymous terms; whereas the very essence of the odes of Pindar (of the few, alas! which survive to us) is their regularity. There is no more difficult form of poetry than this, and for this reason: when in any poetical composition the metres are varied, there must be a reason for such freedom, and that reason is properly subjective—the varying form must embody and express the varying emotions of the singer. But when these metrical variations are governed by no subjective law at all, but by arbitrary rules, supposed to be evolved from the practice of Pindar, then that very variety which should aid the poet in expressing his emotion crystallizes it and makes the ode the most frigid of all compositions. Great as Pindar undoubtedly is, it is deeply to be regretted that no other poet survives to represent the triumphal ode of Greece—the digressions of his subject matter are so wide, and his volubility is so great.

The great difficulty of the English ode is that of preventing the apparent spontaneity of the impulse from being marred by the apparent artifice of the form; for, assuredly, no writer subsequent to Coleridge and to Keats would dream of writing an ode on the cold Horatian principles adopted by Warton, and even by Collins, in his beautiful "Ode to Evening."

Fervour being absolutely essential, we think, to a great English ode, fluidity of metrical movement can never be dispensed with. The more billowy the metrical waves the better suited are they to render the emotions expressed by the ode, as the reader will see by referring to Coleridge's "Ode to France" (the finest ode in the English language according to Shelley), and giving special attention to the first stanza—to the way in which the first metrical wave, after it has gently fallen at the end of the first quatrain, leaps up again on the double rhymes (which are expressly introduced for this effect), and goes bounding on, billow after billow, to the end of the stanza. Not that this fine ode is quite free from the great vice of the English ode, rhetoric. If we except Spenser, and in one instance Collins, it can hardly be said that any English writer before Shelley and Keats produced odes independent of rhetoric and supported by pure poetry alone. But fervid as are Shelley's "Ode to the West Wind" and Keats's odes "To a Nightingale" and "On a Grecian Urn" they are entirely free from rhetorical flavour. Notwithstanding that in the "Ode on a Grecian Urn" the first stanza does not match in rhyme arrangement with the others, while the second stanza of the "Ode to a Nightingale" varies from the rest by running on four rhyme-sounds instead of five, vexing the ear at first by disappointed expectation, these two odes are, after Coleridge's "France," the finest regular odes perhaps in the English language.

The main other varieties of lyrical poetry, such as the idyll, the satire, the ballad, the sonnet, etc., are treated in separate articles.

(T. W.-D.; X.)

MODERN DEVELOPMENTS IN BRITISH POETRY

This note purports only to deal with the principal developments of British verse in the 20th century. The difficulty, however, is to decide when that century began. We cannot, unhappily, for this purpose permit the composers of almanacs to settle the question. Something more subtle than arithmetic is at work. What we have actually to do is to isolate the moment at which Victorianism was definitely spent and something new was born. From that point of view an attempt will be made to show that the new period was precipitated not earlier than 1910 with the Georgians. Till then we are still in the spacious days of great Victoria.

The '90s were, of course, essentially Victorian, in the sense that every blind reaction is an integral part of that from which it reacts. The Rhymers' club was not that new way of saying "yes" which alone is the mark of a new movement. It was merely spirited contradiction, or even what we should now call a rather blatant exhibition of an inferiority-complex. When Arthur Symons, for example, wrote his defence of the prostitute, with cock-robin self-consciousness, he was not so much shocking the suburbs as Lord Tennyson. When Ernest Dowson fainted prettily with Pierrot, or invited Cynara to share his exquisite self-depreciation, he was not in fact languid or corrupt. He was protesting against the heartiness of Dickens and the incorruptibility of King Arthur. In that way a queer self-condemned poetry of artifice arose, which had its roots neither in life nor in the refusal of life, but in the rejection of the poet laureate. That, however amusing or lively, is not a broad enough basis for a new period of literature.

Poetry of the '90s.—Two objections may fairly be raised to this interpretation of the '90s. On the one hand the names of Robert Bridges, Thomas Hardy and Rudyard Kipling will be advanced as proving that at that time there was a volume of virile and important verse being written which was influenced neither by liking nor distaste for Victorianism. On the other hand, it will be pointed out that W. B. Yeats and A. E. Housman—two of the most considerable poets of our time—had both fully established themselves in the '90s. Having regard to the profound influence of *A Shropshire Lad* an objector might go so far as to claim that the 20th century began not in 1906 but ten years earlier in 1896.

Yet these objections, though serious, are not valid. In every period there are distinguished writers who do not influence, and are not influenced by their contemporaries in their sphere of creation. That is essentially true, though for different reasons, of Bridges, Hardy and Kipling. Robert Bridges in such a poem, for example, as "I have loved flowers" permanently enriched the English treasury. But it has that curiously withdrawn quality, that affinity to the grave unswerving mould of the classic, which distinguishes all his work. Both in his simplicity here, and his metrical experiments and complexities elsewhere, Bridges is neither Victorian nor post-Victorian. He contributes, but he neither borrows nor influences. So, too, with Hardy. That reluctant expression, that constant effect of breaking a chisel on obdurate stone, may be admired: it can never be imitated, and it is doubtful whether any one would seek to imitate it. Standards that apply to no other poet, and to no other poetry, have been applied to Hardy, and by those standards he has by some been adjudged triumphantly successful. But he has no disciples as he had no master. To some his poetry may stand out like Stonehenge in a great plain, and in these it will inspire awe and perhaps worship. But it will remain as rugged, as isolated, and to many as unmanageable as those great monoliths. Kipling again, though incomparably the most popular poet of his time, is not, and could not be, a poet's poet. In so far as he was a brilliant and sometimes vicious pamphleteer, he was bound to suffer the fate of all politicians. As the author of *Barrack Room Ballads* he created not so much a new school of verse as a new army, just as in his poems of empire he joined hands with Cecil Rhodes and Joseph Chamberlain, and turned his back on Parnassus. When he consented to be a poet, as in such a perfect lyric as the Valour and Innocence poem in *Rewards and Fairies*, he did not affect his fellow poets because they had been frightened away by the outcries of the imperial buccina. The small body of his real verse will be winnowed out by Time from the great quantity of chaff, but its effect will not be felt till the separation is complete.

W. B. Yeats did start, or was an important part of, a new and fertile period. But it was an Irish and not an English period. It is indeed one of the curiosities of literature (and races) that the Celtic revival so little influenced poetry in the sister-island. Yeats, "A. E." and James Stephens affected the English hardly at all. It is, however, true that for Ireland the 20th century began in the '90s and what a century! Yeats and the Abbey Theatre, rather than all the politicians who spoke and died for Erin, were the fathers of the Revolution. Poets in Ireland always, more than elsewhere, have been recognized as

"the movers and shakers Of the world for ever."

Yeats wrote the first draft of the Constitution of the Free State in "The Lake-isle of Innisfree."

The answer to the objectors, therefore, remains. The typical poets of the '90s did not look forward eagerly, but backward contemptuously. They were not creating; they were for the most part sneering. The more considerable names either like Yeats belonged to Irish literature, or like the other three belonged to themselves only, or with Kipling to himself and certain echoes overseas. But there is still A. E. Housman. In his case it is certain that he did profoundly influence his fellow-writers, but it is more open to question whether it was not rather with the last enchantment of the old than with the first of the new age. Perhaps Housman is no more than Robert Louis Stevenson signalling in vain from his Pacific island to the future. Because, though this has not been generally accepted, if at all, it is Stevenson in verse that was the most potent influence in the early part of the 20th century, and that influence was exerted in part at least through Housman, a disciple so unconscious of his master that he would certainly repudiate him. Yet the two are in essence the same—poets of comment, and not of participation. They have each a small neat explanation of the events they so competently, and sometimes so endearingly, describe. The older man is the more human, the younger the better poet. But Housman carried on the Stevenson note of deliberate interpretation with feeling introduced from without. Housman attracted, and deserved to attract, general attention, but when his *Last Poems* was published three or four years ago, it became clear that he belonged to the world of Stevenson and not to ours. His lads found the brook of the 20th century too broad for leaping. They do not lie on the further side, but they stand there a little wistful and dim against a background of-end-of-the-century self-consciousness. They belong to the horizon whose margin fades behind us "for ever and for ever as we move."

Predecessors of the New Age.—Of the writers who carry over from the '90s to the first decade of the 20th century (for purposes of the almanac) none can be saluted even as the St. John the Baptist of the New World. Three at least deserve mention as writers of importance, though each must be denied the title of the forerunner—John Davidson, "Michael Field" and Stephen Phillips. Of these Davidson in his baffled fury, his fundamental inability to clinch with his hated antagonist because he never recognized him, is nearest to being the prophet. He did not hate Victoria, or the Victorians. He did not hate the gently anaemic Rhymers. But what inspired his fits of temper, that sometimes rose almost into a genuine poetry of hate? Life, of course, but it is doubtful whether he ever knew exactly what in life it was that bit him. Had it ever declared itself then Davidson might have set the trumpet of the herald to his mouth. As it was the instrument was something of a broken reed. "Michael Field," was the name chosen by those two remarkable women, Katherine Bradley and Edith Cooper, aunt and niece, who composed their poems together. For all their lovely cadence the verses never could have been more than a museum-piece in a living world of letters. Though there is in bulk a surprising quantity of their work, and though much of it will endure, yet even while it was, written it had the air of a gracious antique. It was a little as though those delicate fingers had discovered a lost art, and were. like Count Caloveglia in *South Wind,* moulding a Faun with the enigmatic ecstasy of some disciple of Praxiteles. Their best poems had an old and final ring.

Stephen Phillips is a very different case, and much more difficult to assess. In his poetic youth the fixed stars of poetry were crowded by the critics to give place to this new and larger luminary. Within less than a quarter of a century he passed "unwept, unhonoured and unsung." So much so that recently when a posthumous play of his was published the writer who had undertaken the preface used it to indicate his author's remarkable shortcomings. The truth about Stephen Phillips's rise and fall has not been told yet, and certainly the present estimate of his work is unfair to the writer who rediscovered the blank verse line. The rhetoric of *Herod* will disappear. It was inspired rather by Beerbohm Tree than the tetrarch. But "Marpessa" will quietly and in due course climb to its modest place among the quieter candles of the night. For the purpose of this essay, however, Stephen Phillips is important because of the disappointment he provoked. It was believed that the great tradition of English verse that Swinburne had for all his exotic beauty failed to renew, had returned. The blank verse line is the most English and at its best the most decisive of metres. In Stephen Phillips it was hoped that it had resumed its old immortal mastery in a new prevailing way. Stephen Phillips had some of the manner, but none of the substance to restore the accent of the heroes. He had a genuine singing impulse, and hands fit for a flute with two stops. He was asked to play the organ in the Albert Hall. Me should have been strong enough to refuse, but the blame attaches not a little to all the noisy pack of fawning critics who bayed him on to his doom. Whoever's the fault, at least he left no mark on his successors.

They were pressing on. At the very moment when the world was beginning to doubt its new idol, and in their doubt of him renewing their despair in poetry in general, the New Age was beginning in Oxford with a swarthy malcontent called Flecker, at Cambridge with a group which Rupert Brooke led by unquestioned right, and outside Cambridge, but still in the polite world. with a certain Walter Ramal (Walter de la Mare), and a much less certain John Masefield, and outside the world altogether with W. H. Davies, who was not so much a man on the tramp as a bird on the wing. But before all these gathering rivulets converged into the broad flood of Georgianism that forced its way ever widening into the threshhold of the War and, beyond it, strained and parcelled into the swamps of death, there were still the names of Herbert Trench, Sturge Moore, Henry Newbolt and Laurence Binyon, each with his individual claim and contribution. While roaring and laughing by their side, like two huge children in H. G. Wells's *Food of the Gods,* Hilaire Belloc and G. K. Chesterton shouted to each other across the world, and "when all church bells were silent, their caps and bells were heard."

It is perhaps not necessary to attempt to range the first three in this list. Herbert Trench was a far from negligible poet, but he wrote in the grand manner at a time when events were conducting themselves in a manner at once small and obscene. His verse was too much a stranger to the times in which he lived ever to be at home there. He speaks, therefore, always a little like a foreigner. Sturge Moore, also a poet of distinction, perhaps influenced his generation of writers more by his personality than his work, interesting and diverse as it is. He has to his credit not merely a brilliant anthology of "Michael Field," but a solid body of mature and constructive criticism. Henry Newbolt, who is at times unfairly bracketed with Alfred Noyes as a poet of "patriotism," has suffered by succeeding with his worst work. "Drake's Drum" had (and continues to have) almost a music-hall success. The result is that Newbolt has quite unfairly been classified as a minor Kipling—another partisan of the white man's beneficent destiny to take up his dividends. But that is wholly unjust to a poet with a clear perception of realities, and an almost humble readiness to adapt his manner to his subject. He came a little too early to belong to the new movement. If there had been no new movement his name would have stood very high. Nor need we re-classify Hilaire Belloc and G. K. Chesterton. They refused to be treated as grown-up poets. They were Trinculo, Falstaff, or Father Christmas in *The Christmas Carol*, and they deceived the world into believing them to be mere wassaillers. They nlmost deceived themselves, but not quite. Both, when they hated, wrote poetic satire unequalled since Pope, and Chesterton, at least, when he loved had a star hidden up his sleeve. In vain he assured his audience to the contrary. Why, his very words are on fire!

But Belloc and Chesterton stood outside the main stream of development, watching it as though two players in a football match should stand among the spectators applauding heartily. In the circumstances it is difficult to accuse them of desertion: it is better to take them for what they are—and to be thankful. We may turn from them to the players, who are thinking and who thought of nothing but the game.

Georgian Poetry.—The name "Georgian poetry" was coined in the first anthology of contemporary poets published in 1911 under the editorship of Edward Marsh, to whom, and to Harold Monro the publisher of this and the subsequent volumes, modern British poetry owes much. But the name is misleading, and has constantly misled critics. It has been assumed that it represented a single school of writers with the same aim and the same method, much as were exhibited in the case of painting by the Pre-Raphaelites. This is in fact a quite false view. The contributors to the Georgian volume—and to Georgian poetry—represented at least five divergent streams, their only link being a common passion for verse, and a common response to something in the age which was evoking it. Those who believe that the name is more than convenient shorthand may be asked to explain what community of aim and method are represented by de la Mare, Masefield, Hodgson, Drinkwater, Rupert Brooke, Flecker, Harold Monro, D. H. Lawrence and W. H. Davies, to name only nine of the leading figures in the revival. Can the dark Arabian musician mute his strings while Saul Kane is smashing a beer-bottle with a hammer? Would the Song of Honour be audible among the mild country sounds of the Cotswolds? How would the young men "into cleanness leaping" endure the doubtfully delicious neighbourhood of "Yasmin," and what would happen in Harold Monro's week-end cottage if two of D. H. Lawrence's lovers set about breaking up the eloquent crockery in the course of their noisily stark embraces? And would W. H. Davies's nightingales sing through it all like choir boys when the organ's loud? The wealth and the strength of the period consists in its amazing diversity. It was the great achievement of Edward Marsh and Harold Monro to find a common meeting place for all these vigorous tendencies, but they had the wisdom to make no attempt to assimilate them.

It is difficult, if not impossible, to explain why one period rather than another should be rich in poetry. It is, for example, maintained that great verse generally coincides with some great national excitement, either of victory or defeat. Men sing, this view would maintain, best when they are most disturbed, and poetry, like trade, follows the battle-flag. This theory could easily be destroyed by instances both from England and France, and there is another theory which better explains the periods of fertility that supervene, as did the Georgian, on a long period of barrenness. It may perhaps be stated that poetry goes in long cycles for two reasons. First because it is the most intensive form of art: it is a divine shorthand, and can summarize in a page what may require a volume in prose. Poetry therefore is liable quickly to absorb its material. In the second place, though mankind never wants much poetry, it always demands a little. Poetry is in a sense the ultimate luxury of the human mind: it is a luxury that no men want all the time, few men want much of the time, but that all men must have some time. So great a need and so vast a desire do in the long run precipitate their object, and thus after silence song is born.

The Georgian period may have owed something to the stormy days in which it was generated. Imperialism had seen itself in the mirror of the Boer War and found that it looked uncommonly like a skeleton. Industrialism which for a century had been an affair of capital was with urgent creaks and groans becoming a problem of labour. Victorian comfort was changing into the lurid extravagance of Edwardianism. The oil-engine was challenging the printing-press for the control of the soul of man.

Here were conditions which called for examination, explanation, defence and condemnation, and if the prose-writers—Wells, Bennett, Galsworthy and Shaw—were at work, how and why should the poets be still? They weren't. But poetry is a subtler thing than prose. It is less like a photograph than a picture, less like a picture than a face seen by a lightning flash and remembered in a dream. Therefore it is not surprising that this grossly confused age should express itself supremely in a poet of sheer and airy music like Walter de la Mare, or in so consciously exquisite a craftsman as Flecker. These two with Masefield, Davies and Brooke stand out as the leading names of the period.

It is not our business to range as much as to record. The world was in fact brought to the realization of the re-birth of poetry not by Brooke, nor by the first Georgian anthology, nor by the publication of Flecker's *Bridge of Fire*, nor even by the establishment of the Poetry Bookshop in 1912. It was not to the marvel of *The Listeners* that the gates swung open, but to the huge hammer-blows of *The Everlasting Mercy* published in the *English Review*. The effect of that poem was almost comparable to the excitement induced by the appearance of *Don Juan*. Poetry with Masefield had once again ceased to be a matter for poets and coteries: it had become the possession of the people.

By that one blow Masefield flung the door of public interest wide, and the rest of the waiting poets flooded through it with a shout. The period is so rich that in the first place there must be a catalogue of names like the Homeric catalogue of the ships—Lascelles Abercrombie, Gordon Bottomley, Rupert Brooke, W. H. Davies, John Drinkwater. F. S. Flint, John Freeman, Ralph Hodgson, W. W. Gibson, Gerald Gould, D. H. Lawrence, Walter de la Mare, Harold Monro, John Masefield, Thomas Goult, Charlotte Mew, Edward Shanks, Fredegond Shove, J. C. Squire, Anna Wickham, and of the Irish, W. B. Yeats, "A.E.," James Stephens, Padraic Colum, Francis Ledwidge, Seumas O'Sullivan and Dr. Douglas Hyde. And when it is recalled that all belong to the pre-War period, it is reasonable to suggest that Victorianism was dead, that a new and fertile period had begun. It is difficult to classify material so various, or in respect of work so recent to identify the prevailing influence, particularly as these influences are still working themselves out. Certain of these poets, it was clear from the outset, whatever their individual merits, would not be likely to found a school. Lascelles Abercrombie and Gordon Bottomley, for example, both engaged in revising the blank verse line and, if possible, in re-establishing the poetic drama, were necessarily monks of verse. With such preoccupations they would be bound to stand outside the main stream. Both added notably to the intensification of poetic language, and Bottomley in *Gruach* wrote a play in verse which in time will be recognized as a permanent part of British dramatic effort. But they were not likely to impinge on the work of their fellows. D. H. Lawrence, if a poet at all, was one so savagely individual, so arrogantly physical, that he must have abashed even his admirers. He reached the extreme of remorseless resignation to the senses. He might be endured: he could not be copied. Charlotte Mew, Fredegond Shove and Anna Wickham of the women all had their own self-centred emotions. In each case their output was limited to the attar of their spiritual nature. No other poets of their period reached such continuous intensity of expression, but its very merit made it fatiguing. They are all three poets whose poems should be lived with like a great picture rather than caught suddenly like the colour of a flower. Finally, of those not likely to fit into a scheme or to herald a new world those two distinguished poets Gerald Gould and Ralph Hodgson should be mentioned. Both were poets of discontent with their age. Gerald Gould carried into action what Ralph Hodgson immortally expressed in such a poem as "The Gipsy Girl." But each had his own secret. Gould was on a pilgrimage: he was not sure whither, nor could he guide others. But he must seek. Ralph Hodgson of all his age saw loveliness most directly and strongly. He recorded it, and was struck dumb by the very completeness of his utterance.

These were then all poets who belonged to no school. But of the rest it might have been expected that de la Mare, Flecker or Masefield might each have set a fashion, though in fact it was Brooke who with Drinkwater and Harold Monro created that general attitude to which Freeman, Squire, Shanks and later Martin Armstrong, F. W. Harvey and Edmund Blunden attached themselves—the attitude to which the generic term "Georgian" has tended to be specifically applied. Of these in time Squire assumed the leadership, and he will be entitled to special memory if not as the founder at least as the saviour of a school of poetry.

De la Mare founded no school, though his rhythms have effected a profound revolution in the structure of English verse. No poet writing for the next 50 years will or can be unaffected by those fairy declensions, those elfin ascents. De la Mare need not fear mortality. His accent is now a part of English verse. He will continue to have imitators of his manner, but he is too incorrigibly delicate in substance to prevail upon the mind of other poets. Flecker perhaps failed of influence because of his long illness and untimely death. A poet cannot found a correspondence school, and Flecker, except for the earliest years of his output—the Oxford and Cambridge years—was first an exile in the East, and then a dying man in a Swiss sanatorium. It is, even so, surprising that "The Old Ships" should drag no lesser ships in their shining wake, or that no later pilgrims should have set out on "The

Golden Journey to Samarkand."

Effects of the War.—It is a question whether Masefield might not have created a school, if his violence had not been outpointed by the War. Strength and beauty, ranging hand in hand, were an intoxicating sight for all men. but most of all for poets. And it might have been supposed at least that Masefield would restore the narrative poem to its proper place in English poetry. He has not, and it is more than likely that the War, which encouraged pastoral poetry, the verse of retreat from uproar, may have equally turned men's minds from poetry, like Masefield's, of conflict and tumult.

However that may be, it is true that when war had with its usual foul impartiality murdered good and evil alike, it was to Brooke and the poets of release that the world for a moment turned. Brooke burst into fame with his War sonnets consecrated by his death in that Greek island. He became for the moment the expression of the youth of the world, gladly offering itself to wholesale assassination. But behind that momentary magnificence were the more enduring meadows of Grantchester. In these the wracked world might find peace. In these—or by the trees, whose whisper Freeman overheard, in the long wholesome stretches of Drinkwater's Cotswolds, by the harsher northern uplands of Wilfrid Gibson, in Harold Monro's most endearing consolation of the country cottage, or with the birds and the moon of Squire. This was a corporate offer to the world, and it was eagerly accepted.

For the moment. Because it was the habit of the War to make and break its idols almost simultaneously. Hardly had the new recruits flocked to the banner, hardly had Edward Shanks and Martin Armstrong added their conspiracy of release, when the poets of hatred burst upon the world like an angry shell. Robert Graves, Robert Nichols, Wilfred Owen, Siegfried Sassoon one after another blasted the romantic assumption that war was the consecration of youth by fire. In the teeth of a world staggering under its weight of stupid ugliness, these poets flung the single word "Murderers." The other poetry grew for the moment strangely dim and pale. Men were listening to this new and abominable accusation—and even the fields, the birds and the moon could not distract them from it.

The name of Edward Thomas should be mentioned in this connection. Thomas was a much older man than the other poets here mentioned, and had written much before the War. But the War in some way released his response, and his reputation—growing and deserved—is wholly post-War. Because of the circumstances in which he wrote Thomas was entirely a poet for posterity. He could do nothing to arrest the doom of silence which the exhaustion of the War was suddenly to impose. Relentlessly this poison-gas of despair advanced till a period that had seemed to be most fertile since the Elizabethan, ended choking in the fog of the spirit that denies. By the end of the decade which had seen its origin Georgian poetry was spent, and the war poetry with it. Because it seemed that the poets, who had exposed its horrors and cursed its originators, were content to forget, or at least to live back into peace. Wilfred Owen was quiet for ever, Robert Nichols turned to prose and play writing, Siegfried Sassoon at long intervals reminded the world of his genius. Only Robert Graves remained to write new forms of verse in the desperate hope of escaping from the memories he had permanently established in traditional shapes

After the War.—And thereupon the silence smashed in 1910 began slowly to settle again. The Georgian period is over, and the war-period is over. There have been two later revolts, one known as "the Imagist" headed by F. S. Flint, with Transatlantic sanction, another led by Edith, Osbert and Sacheverell Sitwell. The first revolt like the poetry against which it protested has apparently ended. Flint, Richard Aldington and the Americans "H. D." and Ezra Pound, have contributed some ravishing melodies in free verse. They seem now to be replaced by verse not so much of freedom but in dissolution. They cannot compete and they are wisely content to let the beauty they hare made speak for itself. The Sitwell family on the other hand, and in a world of denial, affirm that with a slight shifting of the vision, a little readjustment of values, living beauty can still be restored. At a time when verse was in active danger of dying of suffocation, they breathed new life into it. Their work at least is not dead.

For the rest of the most recent work there should be mentioned Edmund Blunden and Humbert Wolfe. Blunden, though associated with the Georgian school, has lived at first hand with his fields and his farms. To read him is not like paying a visit to the country but like living there. Humbert Wolfe attempted both satire and verse that is accused of a facile romanticism. His *Requiem* was in some quarters regarded as making an advance on his earlier work; but with him, as with the Sitwells, for the moment we must be content with saying that he continued the attack.

Two things have still to be said. Among the greatest of the names in contemporary poetry are the Irish poets, who have only been mentioned, but not discussed. That was for the reason given above, that Yeats created the new Irish poetry and had far less effect on purely English verse than Housman. But the body of English literature is one and indivisible, and though it is possible in the light of the strong impulse given by Yeats to see Irish verse of the century separately, it must at least be mentioned here. All of it, as it was bound to be, is informed by a passionate consciousness of Ireland. But if the matchless rhythms of Yeats turned back to legend for consolation and hope, if "A. E." plunged into a mysticism as profound as Blake's, though, unlike Blake's, regulated by a sweet humanity, James Stephens was already looking forward. He has found truth through laughter, the laughter of a thrush. He has probably more than the other two influenced the latest developments of Irish verse. Padraic Colum and Seumas O'Sullivan are not of the same order as these, though both are poets of distinction. Colum has the quiet dignity of the inspired peasant, while O'Sullivan writes in the immediate shadow of Yeats. There remain Francis Ledwidge, who died young after an early lyric promise of almost torturing loveliness, and Bertram Higgins and Austin Clarke who are going steadily forward in the paths laid down by Yeats and his peers.

(H. Wo.; X.)

United States; Modern Developments.— Modern American poetry, characteristic of the 20th century, attempted a complete fusion of romanticism and realism; Carl Sandburg defined it as a "synthesis of hyacinths and biscuits." It was experimental and, to a large extent, anti-traditional. It sought to find fresh subject matter and unexploited material as opposed to "literary" conventions; it placed its emphasis on the local scene instead of on foreign or mythical regions; it cultivated a native idiom rather than the customary poetic diction. As early as the middle of the 19th century Walt Whitman had invited the Muse to migrate from Greece and Ionia, to "cross out those immensely overpaid accounts, that matter of Troy and Achilles' wrath, and Aeneas', Odysseus' wanderings," and turn from retrospections, recording proofs of the past, to the American continent—

For know a better, fresher, busier sphere, a wide, untried domain awaits, demands you.

Whitman and Emily Dickinson prepared the way for the changes which followed. The pioneer vitalism of the former proclaimed a new force and unity through affirmation of the democratic spirit; the puritan mysticism of the latter achieved another kind of vigour which encouraged the use of daring metaphors and audacious turns of phrase. It took time to establish the new forces. The first edition of Whitman's *Leaves of Grass* was published in 1855 and Whitman prefaced a "deathbed edition" in 1891; Emily Dickinson's first posthumous volume was published in 1890, but no attempt at a biography of Emily Dickinson was written until 1924 and volumes of further unpublished poems kept appearing as late as 1935.

What has been called "the new era in American poetry" manifested itself suddenly in 1913. Edsin Markham's "The Man With the Hoe" had already struck the social conscience, but there was little to rouse the aesthetic consciousness. A number of small magazines devoted themselves exclusively to poetry; controversy was in the air; every month another new name was a signal for dispute which augmented the poetic "renaissance." *General William Booth Enters Into Heaven* (1913) by Vachel Lindsay (1879–

1931) and *The Congo* (1914) brought excitement and a curiously syncopated music into verse; Lindsay's *Collected Poems* (1923) gave America its wide-swinging jazz in terms of literature. A missionary and evangelist at heart, Lindsay combined revivalism and ragtime; he preached the Gospel of Beauty through a saxophone.

Robert Frost's *A Boy's Will* appeared in England in 1913, but it was *North of Boston* (1914) which fully revealed Frost's union of playfulness with profundity and his gift for suggestive understatement. A restrained but distinctive tone of voice rose from all his subsequent work, six volumes of which were assembled in *Collected Poems* (1939), and showed him to be a farmer by circumstance, a philosopher by instinct, and a teacher by experience. Though his backgrounds were those of New England, his half-whimsical, half-sombre lyrics and monologues gave regionalism a universal amplitude and traditionalism a new direction.

The year 1914 marked the rise of free verse and the Imagist movement, a movement which recalled the program of the French Symbolists and which was divided between poetry and propaganda. Amy Lowell (1874–1925) was its militant champion; her own craftsmanship, at its best in *Selected Poems* (1928), preoccupied itself with enamelled images, vivid surfaces, and the swiftly changing contours of the external world.

John Gould Fletcher, another Imagist, intensified motion with emotion; his XXIV *Elegies* (1935) are a far cry from the unrelated "colour symphonies" of *Goblins and Pagodas* (1916). "H. D.," who, with Ezra Pound, was one of the first Imagists, revealed a cumulative tensity beneath the stripped technique of her *Collected Poems* (1925). Edgar Lee Masters' *Spoon River Anthology* (1916) explored the limbo between prose and verse in a set of sociological epitaphs; its disillusioned gossip and documentation of the "small town" gave rise to a school of satire and self-criticism, of which Sinclair Lewis's *Main Street* (1920) was a prose counterpart.

The ranging impulses and far-flung creative energies extended throughout the country and into the mid-twenties. Edwin Arlington Robinson had been writing for years (his concise *Children of the Night* appeared as early as 1897), but *The Man Against the Sky* (1916) was the first of his characteristically astringent works to draw an audience which reached great numbers with *Tristram* (1927); his voluminous *Collected Poems* (1937) appeared two years after his death. Carl Sandburg first blended folk-stuff and fantasy, slang and mysticism in *Chicago Poems* (1916); his *The People, Yes* (1936) added national significance to the peculiar fusion. Edna St. Vincent Millay's remarkable *Renascence* (1917) was succeeded by ten volumes which displayed her virtuosity and which, at the best, engagingly combined the voice of a precocious, eager child and the mind of an experienced, disillusioned woman. Her later work evoked varying degrees of enthusiasm; several critics deprecated the "destructive rôle of unofficial feminine laureate" which Miss Millay seemed called upon to assume in such collections as *Conversation at Midnight* (1937) and *Huntsman, What Quarry?* (1939). Sara Teasdale (1884–1933) became something of a vogue with *Rivers to the Sea* (1915), but the graver music of her *Dark of the Moon* (1926) was almost unnoticed. Elinor Wylie (1885–1928) strengthened the notes sounded by the contemporary singers; her lyrics and sonnets grew from the adroitness of *Nets to Catch the Wind* (1921) to the exaltation of the posthumously published *Angels and Earthly Creatures* (1929).

The strain of lyrical poetry was swelled by Léonie Adams, Louise Bogan, Genevieve Taggard, Jean Starr Untermeyer, and Dorothy Parker, whose wry flippancies were collected in *Not So Deep as a Well* (1936). A still more subtle music was registered in Conrad Aiken's *Selected Poems* (1929); in (or in spite of) the typographical oddities of E. E. Cummings; and in the modern ballads of William Rose Benét and Stephen Vincent Benét, whose *John Brown's Body* (1928) was panoramic in scope and epic in effect. Efforts to sound the "realistic" implications of the American scene were made by Kenneth Fearing, Muriel Rukeyser, and the pioneering William Carlos Williams, whose *Complete Collected Poems 1906–1938* were applauded alike by radicals and conservatives. Robinson Jeffers unleashed a violent. and often uncontrolled, power in a series of volumes from *Roan Stallion* (1926) to *Such Counsels You Gave to Me* (1938). Archibald MacLeish shaped words into surprisingly suspended cadences in *Poems 1924–1933,* fitted them into a new type of poetic drama in *Panic* (1935), put them to work on the radio and on the sound-track in *Land of the Free* and *Air Raid* (1938).

A definite and seemingly determined attempt to join traditional metaphysical poetry with indigenous accents was expressed by a group calling itself "The Fugitives"; its leading exponents were John Crowe Ransom, Allen Tate, Donald Davidson, and Robert Penn Warren. Their verse was alternately teasing and tortuous; the very richness of their allusive material made it difficult. Equally fascinating to the student and equally forbidding to the average reader were the abstract elegances of Wallace Stevens, the verbal legerdemain of Hart Crane, the crowded imagery of Horace Gregory, and the erudite intricacies of tno celebrated cxpatriatcs: Ezra Pound and T. S. Eliot. Eliot's work was the most considerable; it ranged from the baffled frustration of *Prufrock and Other Poems* (1917) through the drought and disintegration of *The Waste Land* (1922) to the desperate faith of Eliot's later religious plays and essays. Finally there were the prodigies, notably Nathalia Crane, whose *The Janitor's Boy* (1924) was published when its author was not quite eleven; George Dillon, who won prizes in his teens and whose *Boy in the Wind* (1927) was published in his twenty-first year; and Merrill Moore, a psychiatrist, uho wrote many of his poems in shorthand, and whose third volume, starkly entitled M (1938), contained 1,000 autobiographical sonnets. (L. UN.)

POEY Y ALOY, FELIPE (1799–1891), Cuban naturalist, was born in Havana on May 26, 1799. He received his degree in law at the University of Madrid (1820) but abandoned practice to devote himself to natural history. He returned to Cuba and formed a collection which he carried back to Paris. Here he remained until 1833, publishing many articles and his *Centurie de Lepidopferes de L'ile de Cuba* (1832). He became professor of zoology and comparative anatomy in the University of Havana in 1842 and in 1863 was appointed to the chair of botany, mineralogy and geology. From 1873 until his death at Havana on Jan. 28, 1891, he was professor of philosophy and belles lettres. His magnum opus is the *Catdlogo rozonado de los peces cubanos,* an atlas of ten volumes with over 1,000 of his own drawings, and describing about 800 tropical fish, about half of which he first made known to science.

POGGENDORFF, JOHANN CHRISTIAN (1796–1877), German physicist, was born in Hamburg on Dec. 29, 1796. He became an apothecary's assistant and later went to Berlin, where he entered the university in 1820. In 1823 he was appointed meteorological observer to the Academy of Sciences. Poggendorff founded in 1824 the *Annalen der Physik und Chemie,* which became the foremost scientific journal in Europe. He was its editor for 50 years. His Biographisch-literarisches *Handworterbuch zur Geschichte der exacten Wissenschaften* (2 vols. 1863) contains notices of the lives and labours of mathematicians, astronomers, physicists and chemists, of all peoples and all ages. This publication was continued by other hands, after his death, in later volumes, which appeared in 1898, 1904, and 1924–25. He devoted his energies to the editorship of the *Annalen,* and to the pursuit of his scientific researches. He died at Berlin on Jan. 24, 1877.

POGGIO (1380–1459). Gian Francesco Poggio Bracciolini, Italian scholar of the Renaissance, was born in 1380 at Terranuova, a village in the territory of Florence. He studied Latin under John of Ravenna, and Greek under Manuel Chrysoloras. His distinguished abilities and his dexterity as a copyist of mss. brought him into early notice with the chief scholars of Florence. Coluccio Salutati and Niccolo de' Niccoli befriended him, and in the year 1402 or 1403 he was received into the service of the Roman curia. His functions were those of a secretary; and, though he profited by benefices conferred on him in lieu of salary, he remained a layman to the end of his life. It is noticeable that, while he held his office in the curia through that momentous period of 50 years which witnessed the Councils of Constance and of Basle, and the final restoration of the papacy under Nicholas V., his sympathies were never attracted to ecclesiastical affairs. Nothing marks the secular attitude of the Italians at an epoch which decided the future course of both Renaissance and Reformation more strongly than the mundane proclivities of this apostolic secretary, heart and soul devoted to the resuscitation of classical studies amid conflicts of popes and antipopes, cardinals and councils, in all of which he bore an official part. Thus, when his duties called him to Constance in 1414, he employed his leisure in exploring the libraries of Swiss and Swabian convents. The treasures he brought to light at Reichenau, Weingarten, and above all St. Gall, restored many lost masterpieces of Latin literature, and supplied students with the texts of authors whose works had hitherto been accessible only in mutilated copies. In one of his epistles he describes how he recovered Quintilian, part of Valerius Flaccus, and the commentaries of Asconius Pedianus at St. Gall.

Manuscripts of Lucretius, Columella, Silius Italicus, Manilius and Vitruvius were unearthed, copied by his hand, and communicated to the learned. Wherever Poggio went he carried on the same industry of research. At Langres he discovered Cicero's *Oration* *for Caecina*, at Monte Cassino a ms. of Frontinus. He also could boast of having recovered Ammianus Marcellinus, Nonius Marcellus, Probus, Flavius Caper and Eutyches. If a codex could not be obtained by fair means, he was ready to use fraud, as when he bribed a monk to abstract a Livy and an Ammianus from the convent library of Hersfield.

Poggio embraced the whole sphere of contemporary studies, and distinguished himself as an orator, a writer of rhetorical treatises, a panegyrist of the dead, a violent impugner of the living, a translator from the Greek, an epistolographer and grave historian and a facetious compiler of *fabliaux* in Latin. Of his moral essays it may suffice to notice the dissertations *On Nobility, On Vicissitudes of Fortune, On the Misery of Human Life, On the Infelicity of Princes* and *On Marriage in Old Age*. These compositions belonged to a species which, since Petrarch set the fashion, were very popular among Italian scholars. They have lost their value, except for the few matters of fact which are embedded in a mass of commonplace meditation, and for occadonal brilliant illustrations.

Poggio's *History of Florence,* written in avowed imitation of Livy's manner, requires scparatc mention, since it exemplifies by its defects the weakness of that merely stylistic treatment which deprived so much of Bruni's, Carlo Aretino's and Bembo's work of historical weight. A somewhat different criticism must be passed on the *Facetiae,* a collection of humorous and indecent tales expressed in such Latinity as Poggio could command. This book is chiefly remarkable for its unsparing satires on the monastic orders and the secular clergy.

Among his contemporaries Poggio passed for one of the most formidable polemical or gladiatorial rhetoricians; and a considerable section of his extant works are invectives. One of these, the *Dialogue against Hypocrites,* was aimed in a spirit of vindictive hatred at the vices of ecclesiastics; another, written at the request of Nicholas V., covered the anti-pope Felix with scurrilous abuse. But his most famous compositions in this kind are the personal invectives which he discharged against Filelfo and Valla. All the resources of a copious and unclean Latin vocabulary were employed to degrade the objects of his satire; and every crime of which humanity is capable was ascribed to them without discrimination. In Filelfo and Valla Poggio found his match; and Italy was amused for years with the spectacle of their indecent combats. About the year 1452 Poggio finally retired to Florence, where he was admitted to the burghership, and on the death of Carlo Aretino in 1453 was appointed chancellor and historiographer to the republic. He had already built himself a villa in Valdarno, which he adorned with a collection of antique sculpture, coins and inscriptions. In 1435 he had married a girl of 18 named Vaggia, of the famous Buondelmonte blood. His declining days were spent in the discharge of his honourable Florentine office and in the composition of his history. He died in 1459, and was buried in the church of Santa Croce. A statue by Donatello and a picture by Antonio del Pollajuolo remained to commemorate a citizen who chiefly for his services lo humanistic literature deserved the notice of posterity.

Poggio's works were printed at Basle in 1538, "ex aedibus Henrici Petri." Dr. Shepherd's *Life of Poggio Bracciolini* (1802) is a good authority on his biography. For his position in the history of the revival, *see* Voigt, *Wiederbelebung des classischen Alterthums* (3rd ed., *1893)* and Symonds, *Renaissance in Italy* (1875–86). (J. A. S.; X.)

POGLIZZA (Serbo-Croatian, Poljica), a tract of mountainous land in Dalmatia, Austria; formerly the seat of an independent republic. The territories of Poglizza lay chiefly within the south-easterly curve made by the river Cetina before it enters the Adriatic at Almissa (Omiš). They also comprised the fastnesses of the Mossor range (4,500 ft.) and the fertile strip of coast from Almissa to Stobrez, 10 m. W.NW. The population of Poglizza numbered 6,566 in 1806. In the following year, however, the republic incurred the enmity of Napoleon by rendering aid to the Russians and Montenegrins in Dalmatia: and it was invaded by French troops, who plundered its villages, massacred its inhabitants, and finally deprived it of independence.

See the *Annuario Dalmatico* for 188; (published at Zara); and A. Fortis, *Travels into Dalmatia* (1778).

POINCARÉ, JULES HENRI (1854–1912), French mathematician, was born at Nancy, on April 29, 1854. He studied at the École Polytechnique, devoting himself to scientific mining, and took his degree in 1879. He was lecturer at Caen and then was transferred to the University of Paris in 1881, lecturing first on physical mechanics, then on mathematical physics, and ultimately on astronomical mechanics.

Poincaré's work falls into three main divisions: his work in pure mathematics, in astronomy and in physics. Most important is his work in pure analytical mathematics; he took the main points of an existing theory, simplified it and then developed it beyond all recognition. In this way he opened up new fields for the mathematician and gave new material to the mathematical physicist. In pure analytical mathematics a good deal of his work is on the theory of functions. He developed automorphic functions and his work on the "Fuchsian" functions he applied to the non-Euclidean geometry of Lobatchevski; he also wrote a number of papers on Abelian functions. Poincaré's work on differential equations is also important; here he extended the work of Cauchy; he dealt with linear differential equations on the lines of Riemann and Fuchs and he wrote a number of papers on the differential equations which occur in physics. In astronomy he dealt chiefly with the theory of orbits; he began with an idea due to Hill and investigated the general problem of three bodies. In addition to his purely mathematical and scientific work he also wrote on philosophy. He died in Paris on July 17, 1912.

His works include *Cours de Physique mathe'matique,* 10 vol. (1889, etc.); *Leçons de la me'canique ce'leste* (1905, etc.); *Théorie de Maxwell et les oscillations hertziennes* (1907); *La théorie du potentiel newtonien* (1899); *Science d'hypothèse* (1903); *La valeur de la science* (1904); *Science et méthode* (1908).

POINCARE, RAYMOND (1860–1934), French statesman, was born at Bar-le-duc on Aug. 20, 1860, the son of Nicolas Poincaré, a distinguished civil servant and meteorologist. Educated at the university of Paris, Raymond was called to the Paris bar, and was for some time law editor of the *T'01taire.* He had served for over a year in the department of agriculture when in 1887 he was elected deputy for the Meuse. He made a great reputation in the chamber as an economist, and sat on the budget commissions of 1890–91 and 1892. He was minister of education, fine arts and religion in the first cabinet (April–Nov. 1893) of Charles Dupuy, and minister of finance in the second and third (May 1894–Jan. 1895). In the succeeding Ribot cabinet Poincaré became minister of public instruction. Although he was excluded from the Radical cabinet which followed, the revised scheme of death duties proposed by the new ministry was based upon his proposals of the previous year. He became vice-president of the Chamber in the autumn of 1895, and in spite of the bitter hostility of the Radicals retained his position in 1896–97.

In March 1906 Poincaré became minister of finance in the Sarrien Government, but he gave up his portfolio to Caillaux in October of the same year, when Sarrien was succeeded by Clemenceau as prime minister. During the next five years, though he still continued to exercise a powerful influence in the senate, Poincaré devoted himself mainly to his legal career. In 1909 he was elected a member of the French Academy. In Jan. 1912, Caillaux, who had been prime minister since the beginning of the previous year, resigned, whereupon Poincaré formed a government in which he himself held the portfolio of foreign affairs.

Poincaré's cabinet constituted an *entente nationale,* and his first aim was to pursue a more definite foreign policy. In home affairs the problem which presented the greatest difficulties was that of electoral reform. Poincaré induced the chamber to pass a proportional representation bill. But above all diplomatic affairs claimed his constant attention; for during the negotiations with Germany which took place in consequence of the dispatch of a gun-boat by that country to Agadir, certain incidents had occurred during the Caillaux administration which had produced a feeling of disquietude in regard to foreign policy. Poincaré therefore sought to re-establish a continuity of policy; and though he maintained courteous relations with Germany his main endeavour was to prove that France would remain faithful to both friends and allies. The ratification by the senate of the Franco-German Treaty of Nov. 4, 1911, was followed by France's definite establishment in Morocco.

Almost immediately after the establishment of the Poincaré Government, an incident had occurred which temporarily obscured the friendly relations between France and Italy. The Italians, who at that moment were at war with the Turks, seized two French mail-steamers, the "Carthage" and the "Manouba," which were on their way to Tunis, on Jan. 16 and 18, 1912. But Poincaré, by his calmness and resolution, succeeded in re-establishing amicable relations between the two countries. By the end of October Italian sovereignty in Libya was recognised, and by a mutual declaration of the two Governments, full liberty of action was granted to France in Morocco and to Italy in Libya. When in the autumn of 1912 the Balkan War broke out, Poincaré made every effort possible to prevent the conflagration from spreading. Nevertheless the succession of European crises, combined with the ever-increasing menace from Germany and Austria-Hungary, rendered it necessary to take precautions; and Poincaré induced parliament to vote a programme of naval construction; through the strengthening of Franco-British relations it became possible to concentrate the whole of the French fleet in the Mediterranean.

On Jan. 17, 1913, Poincaré was elected president of the republic in place of Fallières. In power, he endeavoured to cement the friendships and strengthen the alliances of France. (See FRANCE, HISTORY.) At a later stage, his enemies at home and abroad criticised him severely for this policy; yet it is hardly reasonable because a man is sufficiently far-seeing to apprehend a storm and make preparations for it, to accuse him of wishing to hasten it. He claimed that he did his utmost to avert war, holding that the way to prevent the conflict was for those powers against whom the menace was directed to present a powerful and united front, thus making it imprudent to attempt any act of aggression.

In July 1914 Poincaré went to Russia on a visit which had been planned for some time past. He was on his way home, having arranged to visit the three Scandinavian capitals, when the news of the Austrian ultimatum to Serbia reached him. After a short stay in Stockholm he returned hastily to Paris; and in a letter to King George V. he pleaded for a clear declaration that the entente *cordiale*, if necessary, would prove its strength on the battlefield, pointing out that such a statement would have a restraining effect on the policy of Vienna and Berlin. Throughout the World War he continued to perform his duty with the same energy and discretion as before; though sometimes he visited the front, he never placed any obstacle whatever in the way either of the Government or of the army. In Nov. 1917 he gave proof of his vision and disregard of self by placing in power Clemenceau, who, though undoubtedly the man of the moment, was one with whom he had little sympathy. During the critical months of 1918, Poincaré revealed an inflexible resolution and a supreme confidence in the ultimate victory.

During the peace negotiations divergence of views again became apparent between Poincaré and Clemenceau. On more than one occasion the president found it necessary to write to the prime minister pointing out the errors which, from his paint of view, were being committed. His counsels, however, were not followed, and at the beginning of 1920, after having completed seven years as president, he left the Elysée and was shortly after re-elected senator for the department of the Meuse. In Jan. 1922, the Briand cabinet having resigned, Poincaré once more became prime minister and minister for foreign affairs. He made it his chief aim to insist on the fulfilment by Germany of her obligations in regard to reparations. During the first year of his new government he failed to arrive at any agreement on this subject with the British cabinet, whose views differed so widely from his own. The Inter-Allied Conference in London in Aug. and Dec. 1922 produced no result. A further conference took place in Paris on Jan. 2 and j, 1923. But Poincaré rejected the proposals drawn up by Eonar Law.

At this moment, the Reparations Commission, with Britain dissenting, having declared that Germany had failed to fulfil her obligations in regard to the delivery of coal and coke, Poincaré, in agreement with Belgium, undertook the occupation of the Ruhr (*q.v.*). At first this measure involved merely a method of control, but gradually, owing to the passive resistance of the Germans, it became necessary to exploit the railways and to some extent also the mines by means of Franco-British supervision. But by autumn the passive resistance had ceased, and Poincaré awaited the German proposals which never came. He then accepted the American suggestion that a group of experts should be given the task of finding the solution of the reparation problem; this resulted in the adoption of the Dawes Plan. But Poincaré had made up his mind not to withdraw from the Ruhr until he was satisfied that this plan was being carried out.

During the first three months of 1924 Poincaré had to face a financial crisis due to the state of the exchange. Not without difficulty he induced parliament to vote new taxes and succeeded in saving the situation. But from now onwards he had to withstand strenuous opposition from the parties of the Left consisting of the Radicals and Socialists. The policy of these groups met with a marked success at the general elections of May 11, 1924, and resulted in a majority for the Left which now formed a coalition under the name of the Cartel des Gauches. Immediately the results were announced, Poincaré stated that he would retire on the day when the new Chamber was to assemble, which took place on June 1, 1924.

Thenceforward he took his place in the senate, intervening only rarely in political debates. But he was to come into power once more. When, in the middle of the summer of 1926, the financial crisis, which successive cabinets since 1924 had been unable to check, became more and more serious, public opinion saw in him the only man capable of meeting the situation. After the fall of the Briand-Caillaux cabinet, which only lasted a few weeks, and of the Herriot cabinet, which only existed a few hours, Poincaré, in the last days of July, formed a ministry which included both moderate Republicans and Radical-Socialists, and had as its object the stabilization of French finances by means of a policy of national union. Public opinion was immediately reassured. At the beginning of August the ministry caused the national assembly, meeting at Versailles, to pass, as articles embodied in the constitution, and therefore not at the mercy of political changes, regulations for the establishment of an automatic sinking-fund, to which would be attributed funds which could not be touched (death duties, revenues from the tobacco monopoly, etc.).

In three months he succeeded in raising the value of the franc from 264 francs to the pound sterling, to 124. This rate was achieved in Dec. 1926, and thenceforward the value of the franc did not fluctuate. For a year and a half Poincaré, who had restored a strict financial equilibrium, maintained this stabilization of the currency de *facto*. The general election of April 1928 having returned a majority which approved of his policy, a law was voted in June by the new assembly, and by the senate, establishing the stabilization de *iure*. It was one of the most successful operations of this nature in history. Withdrawal of the Radical-Socialist support from his government, engineered by Caillaux, caused his resignation on Nov. 7, 1928, but he formed a new ministry on Nov. 12. He resigned because of illness, on July 27, 1929. Poincaré undertook the publication of an important work in 10 volumes, entitled *Au* service de la France; *neuf années de souvenirs*, the plan of which is to describe the sequence of events from 1911 to 1920 and the rôle which he himself played in them. Four of these volumes appeared in 1926, 1927 and 1928 under the titles of *Le lendemain d'Agadir*, Les Balkans en feu, *L'Europe sous les armes*, and *L'Union sacrée*. He died Oct. 15, 1934.

See H. Girard, *Raymond Poincaré* (1913); E. Charton, *L'Angleterre et M. Poincaré* (1923); S. Huddleston, *Poincaré* (1924); Sir George Arthur, ed., *Memoirs of Raymond Poincaré* (1929). (P. B.)

POINSETTIA, a popular greenhouse winter-flowering shrub of the family Euphorbiaceae. The *Euphorbia pulcherrima* of gardens, a native of Mexico and Central America, with its scarlet bracts, stands high among decorative plants. The white-bracted sort, var. *alba*, is not so effective, but the double-flowered, var. *plenissima*, in which the inflorescence is branched, is as brilliant as the type, and keeps long in flower.

They are propagated by cuttings in spring. When taken off with a heel. cuttings strike freely in brisk heat. They require good turfy loam, with an addition of one-sixth of leaf-mould and a little sand, and should be kept in a heat of from 65° to 70° at night, with a rise of 10° by day. About August they may be inured to a heat of 50° at night, and should be placed out of doors for a month under a south wall in the full sun. This treatment matures and prepares them for flowering. In autumn they must be removed to a house where the temperature is 50° at night, and by the end of September some of them may be put in the greenhouse, where they will come into flower, the remainder being placed under heat later for succession.

POINSOT, LOUIS (1777–1859), French mathematician, was born at Paris on Jan. 3, 1777. In 1794 he became a scholar at the École Polytechnique, which he left in 1796 to act as a civil engineer. In 1804 he was appointed professor of mathematics at the Lycée, in 1809 professor of analysis and mechanics, and in 1816 examiner at the École Polytechnique. On the death of J. L. Lagrange, in 1813, Poinsot was elected to his place in the Académie des Sciences; he was chosen a member of the senate formed in 1852. He died at Paris on Dec. 5, 1859.

Poinsot's earliest work was his *Élémens de statique* (1803; 9th edition, 1848), in which he introduces the idea of statical couples and investigates their properties. In his *Théorie nouvelle de la rotation des corps* (1834) he treats the motion of a rigid body geometrically.

See J. L. F. Bertrand, *Discours aux funérailles de Poinsot* (1860).

PQINT, in finance, the unit used to estimate or quote the changes in market price of securities, commodities, or exchange. In the security market a point is 1% or $1 per share of stock or $10 per bond. Variations in securities are quoted as low as $\frac{1}{8}$ of a point, $12\frac{1}{2}$ cents on stock and $1.25 on bonds. In commodities such as cotton, coffee, and sugar the point is $\frac{1}{100}$ of a cent per pound, and no fractional points are quoted. Thus in cotton a decline or advance of $\frac{1}{4}$ cent a pound would be 25 points or $1.25 per bale. A point in exchange is $\frac{1}{100}$ of a cent. Thus an advance in sterling from 4.8625 to 4.8635 would be a ten-point rise. In the English market stock is quoted at so much per £100 and the loss of a point would not necessarily mean the loss of 1%. If, for example, £100 worth of stock were quoted at "£87, dropped one point," this would be equivalent to £86. On the other hand, £100 stock quoted at "£237, gained one point," would indicate that the closing price was £238.

POINT PLEASANT, a town and the county seat of Mason county, W. Va., U.S.A., on the Ohio river, at the mouth of the Kanamha river, and about midway between Pittsburg and Cincinnati. Pop. (1940) 3.538. It is on federal highway 35 and is served directly by the Baltimore and Ohio railway, and by the New York Central railway. The Kanawha river is navigable (by the use of locks and dams) for 90 mi. above the town, and Point Pleasant is a reshipping point for Kanawha coal.

The permanent settlement of the town dates from 1785. In 1794 the village of Point Pleasant was planned; it was incorporated as a town in 1833. A granite monument (86 ft. high) commemorating the battle was unveiled on Oct. 10, 1909.

See J. T. McAllister's article, "The Battle of Point Pleasant," in the *Virginia Magazine of History and Biography* (1901–02), vol. x., and Virgil A. Lewis, *History of the Battle of Point Pleasant* (Charleston, W. Va., 1909).

POINT SETS. A point set is a collection of points selected from a given space. The study of the properties of point sets constitutes that branch of mathematics known as point sets, or the theory of sets of points. Generally speaking, the properties of a point set may be classified under two heads, (1) topological and (2) metric. For a description of the former see ANALYSIS SITUS. A brief introduction to the metric properties of point sets is given below.

The Problem of Measure.—In order to approach the subject by as simple an example as possible, let us confine ourselves to the case where the given space is an ordinary straight line, L. If P and Q are distinct points of L, then the point set consisting of P and Q together with all points between them is called an interval and is denoted by $[P,Q]$. Let us imagine that we have a common foot-rule which can be applied to L in order to measure lengths. Then given an interval $[P,Q]$ we can measure its length, and say that it is a certain number of feet. Of a single point we would say, in accordance with the ordinary geometry notion, that its length is zero. If we are given two intervals which have no point in common, it is not natural to speak of the length of the set of points which they represent, the word "length" being usually applied only to connected pieces. In this case we shall use the word "measure," and say that the measure of this point set is the sum of the lengths of the two intervals.

However, when we speak of a point set on L, this does not necessarily imply that we are thinking of an interval, a single point, or a set of intervals; we sometimes mean to indicate a set of points which contains no connected portion, *i.e.,* which contains no interval. One might be tempted to say that since a point has length zero, the "measure" of such a set would be the sum of the lengths of its individual points, *i.e.,* the sum of a set of zeros, and hence zero. Such a hasty decision would not lead to very fruitful results, however, for the following reason. If we determine upon a "measure" for two point sets, A and B, which have no points in common, the sum of their measures should naturally be the measure of the point set which is made up by them taken together. Thus, above, we have stated that the measure of a set consisting of two intervals with no common point is the sum of the lengths of those intervals. Now any interval $[P,Q]$ can easily be shown to be the sum of two sets A and B each of which fails to contain any interval, and if we arbitrarily call the measure of both A and B zero, the sum of their measures would be zero, which is not the length of $[P,Q]$, no matter how small the length of $[P,Q]$. In other words, we want a measure of a set of points which will correspond to the ordinary idea of length.

We have now introduced what is known, in the theory of sets of points, as the problem of measure. There have been several methods devised for finding a measure of an arbitrary set of points. We shall describe, briefly, the theory of Lebesgue measure, which is the foundation of the Lebesgue theory of integration.

Lebesgue Measure.—A set, A, is said to be covered by a collection, G, of intervals, when every point of A is in some interval of G. If the set of intervals G is denumerable, then we shall say that it is a covering of A. (A set is called denumerable if its elements can be "tagged" with positive integers in such a way that no two elements of the set are "tagged" with the same integer.) If the sum of the lengths of the intervals of G exists, let us call this the sum-length of the covering. Now of all possible coverings of A consider the corresponding sum-lengths, and let N be the largest number which is not greater than any of these sum-lengths. Then N is called the exterior measure of A and is denoted by m_eA. Suppose, now, that $[P,Q]$ is some interval, whose length we shall denote by d, such that all points of A are within $[P,Q]$. Let B be the set of all points of $[P,Q]$ that do not belong to A, and let m_eB denote the exterior measure of B, found just as m_eA was found. If it happens that $m_eA+m_eB=d$, then m_eA is accepted as the measure of A, and is what is known as the Lebesgue measure of A. Of course we have at the same time that m_eB is the Lebesgue measure of B, and in accordance with our ideas of length we have required that the sum of the two measures give the length of $[P,Q]$. To be sure, the Lebesgue measure of a set of points may not exist, but it does exist for all ordinary point sets. Indeed it is not at all easy to give an example of a set of points which has no Lebesgue measure, and all of those examples which have been given make use of certain methods which are held to be unacceptable by many mathematicians.

For the measure of a set of points in a plane, areas are employed. Thus, the measure of the set of all points in a square is the area of the square. And to get the measure of a general plane point set M, a covering of M is made by means of squares. In three dimensions cubes are employed, and we deal with sum-volumes.

The introduction of the notion of measure has led to an enriching of the content of general analysis that could hardly have been realized otherwise. And the effect has been felt not only in mathematics itself, but in the closely allied fields of mechanics and dynamics.

POISON. There is no official legal definition of the meaning of the word "poison" though from the phraseology of the sections in the various laws relating to poisoning it may readily be inferred what is understood by the term "poison" in its legal aspects.

The legal sections relating to criminal poisoning contain the expressions "poison or other destructive thing," "poison or other destructive or noxious thing," "to inflict upon such person grievous bodily harm," "any chloroform, laudanum or other stupefying or overpowering drug, matter or thing."

These phrases all occur in the sections where the crime for wilful intent in "unlawfully administering" is regarded as felony. In the section dealing with intent to injure, aggrieve or annoy any person the expression "poison or other destructive or noxious thing" is used and the offence is regarded as misdemeanour.

In the section dealing with criminal abortion the term "poison or other noxious thing" is used, and the unlawful administration of such with intent to procure a miscarriage is regarded as felony.

The term "noxious thing" has been held to include all substances causing symptoms which might be dangerous to life, or symptoms giving rise to pain, serious discomfort or incapacity. In the case of abortion it includes all substances which might under the circumstances in which they were administered reasonably give rise to any risk of abortion.

The sale of "poisons" to the public is carefully controlled by law, and the danger to human life from the indiscriminate sale of poisons by unqualified persons is thereby reduced.

With certain exceptions only duly qualified and registered pharmacists and medical practitioners are permitted to sell poisons.

Definition.—A convenient and comprehensive definition of the word "poison" is "A substance which by its direct action on the mucous membrane, tissues, or skin, or affer absorption into the circulatory system can, in the way in which it is administered, injuriously affect health or destroy life." This definition includes such substances as powdered glass, metallic filings, etc., which would act mechanically as irritants if swallowed. It also includes substances which are ordinarily of a harmless nature but by nature of the excessive quantity, or of their physical condition or manner of administration may act injuriously on the body, for example, water at the boiling temperature or milk given intramuscularly or intravenously would be included.

The commonly understood definition of a poison would be a substance which if taken internally in small doses is capable of acting deleteriously on the body or of destroying life.

Poisoning may be accidental, suicidal or homicidal. By far the commonest type of poisoning is that due to accidental causes. In spite of the precautions taken by the State in the sale of poisons much too little care is taken by the public in the safeguarding of poisons in their possession, and these are commonly taken in mistake for other substances of a harmless nature, or often an overdose is taken from pure carelessness.

Thus, oxalic acid crystals when purchased in a paper packet may be transferred to a bottle or jar which is unlabelled and then taken in mistake for Epsom salts which they closely resemble.

Similarly tablets of corrosive sublimate have been taken in mistake for tablets of a harmless nature such as Blaud's pills. It cannot be too strongly insisted upon that it is the duty of every individual possessing a substance of poisonous nature to take the utmost care that this is correctly labelled and kept safely guarded under lock and key; by this means accidental poisoning would be largely prevented.

ACTION OF POISONS

Poisons may have a local action or a general systemic action after absorption into the circulatary system, or they may act in both ways. Almost all poisons have a general systemic action. Some poisons such as "corrosives" destroy the mucous membrane or tissues with which they come in contact and cause serious or dangerous injury thereby. Irritant poisons set up a local inflammatory reaction in the mucous membrane of the alimentary tract.

Apart from these local effects, the common result of the absorption of a poison is the harmful effect produced by the poison on the important organs of the body, for example, the liver, kidneys, heart and nervous system are almost certain to be adversely affected. A poison after absorption attacks all the organs of the body to a more or less extent and it is a mistake to regard poisons as being exclusively selective in their action though some poisons appear to direct the brunt of their attack on a particular system.

Among the conditions affecting the action of a poison may be mentioned the following:

1. The Amount Taken.—Usually the quantity of a poison taken bears a relation to the effects produced; exception to this rule are substances in the case of which owing to the quantity taken vomiting occurs so that most of the poison is expelled; oxalic acid and tartar emetic are examples.

The term "fatal dose" when applied to a poison means the smallest amount which is known to have caused death in an adult. Frequently larger doses may be taken without death resulting, but much depends on other factors than quantity, and also as to whether adequate treatment has been adopted.

2. Mabit.—A tolerance to some poisons occurs after their repeated use, and in some cases doses far greater than a normal "fatal dose" may be tolerated without serious symptoms developing; examples of such drugs are morphine, opium, cocaine and alcohol. In the case of some of these poisons their repeated use leads to the development of the "drug habit" with all its pernicious symptoms and effects.

3. Idiosyncrasy.—Some persons are exceedingly intolerant of certain drugs which in moderate doses may cause in them dangerous or even fatal symptoms; examples are salicylates and aceto-salicylic acid which in some persons have a severe cardio-depressant action.

4. Age.—Usually children are much more susceptible to the effects of a poison than adults. The dosage of drugs in the case of children has been fixed by a pharmacological rule, but exceptions to this are morphine, opium and its preparations which are much more toxic than the rule would indicate; on the other hand children tolerate belladonna preparations better than adults. Aged persons withstand poisons badly.

5. The State of Health.—In disease, usually drugs are much more toxic and this is especially so where the excretory organs are diseased. For example, in nephritis medicinal doses of such drugs as morphine, salvarsan, hyoscine, etc., often cause dangerous symptoms, likewise in cirrhosis of the liver there is a greatly increased susceptibility to such drugs. In conditions of gastritis or enteritis irritant drugs like arsenic are especially toxic.

On the other hand in some conditions associated with delirium or pain large doses of sedative drugs produce little effect provided that the excretory organs are healthy.

6. Condition and Mode of Administration.—If a poison is taken by the mouth in solution it acts much more powerfully than if in an insoluble form, for example, an insoluble preparation of arsenic may produce little poisonous effect even in large doses; similarly strychnine given in hard pills has a much delayed action.

The state of the stomach as regards the presence of food has a marked influence on the effect of a poison; for example, if the stomach is empty the effect will be rapid, particularly so when the poison is in a soluble form; on the other hand if the stomach is full considerable delay may occur in the action of the poison as is well shown in acute arsenical poisoning.

Poisons administered subcutaneously or intravenously act more powerfully than by the mouth.

When a poison is inhaled in the form of spray, vapour or gas its absorption from the respiratory tract is rapid and the effect great. Poisons may be absorbed by the skin or mucous membrane of the vagina or rectum with fatal result.

DIAGNOSIS AND TREATMENT OF POISONING

Evidence of Poisoning.— It must be remembered that the symptoms of poisoning may be closely simulated by the symptoms of natural disease and the greatest care must be taken before a diagnosis of "poisoning" is arrived at. For example, the symptoms of acute arsenical poisoning closely resemble those of cholera or acute bacterial food poisoning. The only certain differentiation is the finding of arsenic in the excreta or of the bacteriological evidence of a cholera or food poisoning infection.

The evidences of poisoning are — (I) The symptoms are usually sudden in onset and they occur after the taking of food or drink or after exposure to poisonous gases or vapours. (2) If several persons are similarly exposed all are affected more or less with similar symptoms. An exception may occur in the case of bacterial food poisoning (so called ptomaine poisoning) where certain persons may be immune, or some be specially susceptible. (3) The analysis which should always be carried out in suspected cases may reveal the presence of the poison in the vomit and urine and faeces and possibly also in some articles of food or medicine.

Post-mortem Evidence.—If death occurs a post-mortem examination should only be made following instructions from the coroner. The post-mortem signs found should be consistent with those occurring from poisoning by the suspected poison. The analysis of the viscera should yield results consistent with that of poisoning by the suspected poison having regard to the circumstances attaching to the date of administration and death.

Treatment.— The mode of treatment to be adopted varies according to the nature of the poison.

The first *measure* to be adopted *without* delay, is the removal of the unabsorbed poison. If the case is seen within six hours of the taking of the poison by mouth the stomach should be emptied and *washed* out as soon as possible. Emetics are a poor substitute for the emptying and washing out of the stomach by means of the funnel and stomach tube, but they may be employed if the more effective treatment is impossible. Safe emetics are mustard and water, salt and water, ammonium carbonate (30 grains) in a tumblerful of water, or apomorphine **gr.** $\frac{1}{10}$ hypodermically.

The only contra-indication to the emptying and washing out of the stomach by means of the stomach tube and funnel are where poisoning occurs from the corrosive mineral acids or alkalies. In such cases there might be danger of perforation. After the stomach has been emptied and washed out suitable antidotes should be given, such as chalk and lime water to neutralize oxalic acid and the mineral acids, lime water for carbolic acid. Atropine may be given hypoderniically in the case of morphine poisoning. Where morphia and cocaine are taken the stomach should be washed out with diluted permanganate of potash solution.

Elimination by the bowel is facilitated by colon washes with warm normal saline solution and by free bowel evacuations. The symptoms of poisoning are subdued by the administration of appropriate remedies, thus, pain may be relieved by hypodermic injection of morphine, and the convulsions from strychnine by chloroform inhalation.

CHARACTERISTICS OF DIFFERENT POISONS

Classification.— Poisons may be classified in many different ways, *e.g.,* according to their chemical composition, to their action on the body. to their physical characters, etc.

The following is a convenient and simple classification.

1. Corrosive Poisons are those which destroy by direct action the tissues with which they come in contact. They are the mineral acids such as sulphuric, hydrochloric, nitric acids, etc; the caustic alkalies such as caustic soda, caustic potash, ammonia, etc.; carbolic acid; metallic poisons such as corrosive sublimate, zinc chloride, silver nitrate. These latter will be considered under irritant poisoning. It should be remembered that corrosive poisons in diluted condition lose their corrosive effect and become irritants.

2. *Irritant* Poisons.—These poisons by their direct action on the mucous membrane set up inflammation. Examples are:— oxalic acid and its soluble salts; arsenic compounds, antimony compounds; most of the metallic poisons in solution; phosphorus, bromine, iodine, boracic acid, etc.

3. Systemic Poisons which act on the nervous system or other important organs such as the heart, liver, lungs or kidneys without having any special irritant or corrosive effect. This group includes the majority of poisonous substances such as the vegetable poisons or their alkaloids, hydrocyanic acid, its salts, chloral, chloroform, alcohol, ether, hypnotic drugs such as veronal, sulphonal, etc. Also liver poisons such as those causing toxic jaundice, tetrachlorethane, trinitrotoluene, picric acid, etc., and renal poisons such as cantharides, turpentine, etc.

4. Gaseous Poisons such as chlorine, carbon-monoxide and coal gas, carbon-dioxide, etc.

5. Poisonous Foods such as mushrooms, shell fish and food contaminated with dangerous pathogenic bacteria.

CORROSIVE POISONS

Symptoms.—These produce severe symptoms immediately they are taken—"a burning pain" in the mouth, throat and oesophagus and pain referred from the stomach and intestines. Vomiting occurs quickly and the vomit contains blood which may be altered in colour by the action of the poison; often also shreds of destroyed mucosa are present, Collapse occurs early, and perforation is common when, should the patient survive, signs of general peritonitis develop.

An examination of the patient will show signs of the corrosive action of the poison on the mouth and throat, and marked tenderness will be present on palpation over the stomach and intestine. Corrosive poisons if swallowed in poisonous quantity are usually fatal within 24 hours unless immediate treatment with a suitable antidote is adopted.

Should the patient survive the immediate effects of the poison, serious after effects result owing to the damage done to the alimentary tract and in the case of volatile corrosives often serious pulmonary complications ensue. Post-mortem examination shows evidence of the destructive action of the poison on the mucous membrane of the mouth, throat, oesophagus and stomach, there being often extensive haemorrhage in the underlying tissues.

Among examples of corrosive poisons may be named:

The Corrosive Mineral Acids.—These include: *Sulphuric* Acid commonly known as oil of vitriol; this is used in various industries and in all chemical laboratories. It is a most powerful corrosive in the concentrated form, whether taken internally, or applied externally as in cases of "vitriol throwing." One drachm has caused death in an adult, and half that quantity in a child.

Hydrochloric Acid is known also as muriatic acid or spirits of salts. It is used largely for industrial and chemical purposes and is a common article of domestic use. It is readily obtainable and is very commonly used for suicidal purposes. It is a most dangerous corrosive and one drachm has caused death in an adult.

Nitric Acid is known as "aqua fortis" and is used for industrial and chemical purposes. It is a most dangerous corrosive and produces characteristic yellow staining of the tissues with which the strong acid comes in contact. The vapour of the acid, if inhaled into the lungs, often produces an acute fatal form of pneumonia which is a common cause of death in nitric acid poisoning. Two drachms of the acid have caused death.

Other mineral acids such as *Hydrofluoric, Phosphoric* and *Sulphurous* acids in concentrated form produce similar effects.

Treatment.--The treatment of poisoning by corrosive mineral acids consists in giving as soon as possible harmless alkaline remedies such as magnesia powder, lime water, sodium bi-carbonate or chalk. These should be given freely, and plenty of egg albumen (white of egg) should also be given since this tends to neutralise the acid by forming a protein combination, and also it has a soothing effect on the damaged mucosa.

The stomach should not be washed out for fear of perforation Pain is relieved by the free use of morphine hypodermically and after the swallowed acid has been neutralised food should be withheld by the mouth and normal saline given as freely as can be retained per rectum.

The Caustic Alkalies.—Among these may be named the following: Caustic potash or potassium hydrate or potash lye is a powerful corrosive, and potassium carbonate known as salt of tartar has a similar but less powerful effect. Both are used industrially. Forty grains of caustic potash have caused death.

Caustic Soda or Sodium Hydrate, or Soda lye is a powerful corrosive and quite as dangerous as caustic potash. It is commonly used industrially.

Ammonia, liquid ammonia or spirits of hartshorn, is used largely for domestic and industrial purposes. It is also used in the form of smelling salts when mixed with carbonate of ammonia. It is a powerful corrosive poison and in addition the vapour has a very injurious effect on the lung giving rise to bronchopneumonia which takes on a septic type. One drachm of the strong solution has caused death.

As regards treatment in respect of the foregoing, harmless acid drinks such as diluted vinegar or lemon juice or citric or tartaric acid should be given freely. Pain should be relieved by the free use of morphine hypodermically and nourishment should not be given by the mouth but rectal feeding adopted.

Carbolic Acid or phenol is commonly used as a disinfectant for domestic and surgical purposes. Allied preparations such as creasote, cresol, etc., have a similar poisonous effect. Lysol is a combination of cresol with soap and is similar in action to phenol.

Carbolic acid and the allied substances have a powerful corrosive action causing necrosis of the tissues with which they come in contact, the superficial part of which has a whitish appearance, the deeper parts being dark red owing to resulting haeinorrhage into them Carbolic acid is one of the poisons most frequently used by suicides, and owing to its common use for domestic purposes accidental poisoning by it often occurs.

The symptoms caused by carbolic acid are those of corrosive poisoning but owing to its local anaesthetic action vomiting may he absent, and pain may be less marked. If death does not result from shock, the profound effect of the poison on the nervous system causes paralysis of the respiratory and cardiac centres, with rapid feeble pulse, and stertorous breathing, coma develops in severe cases and is usually followed by death.

One drachm of carbolic acid taken by the mouth has caused death in 12 hours. Death has resulted from the absorption of phenol by the skin, and from rectal injections of the drug in solution. Usually death occurs in from 3 to 4 hours after the taking of a large dose.

With respect to treatment, the stomach should be washed out by means of a soft stomach tube with diluted saccharated lime water, or fresh lime water; by this means the phenol is converted into calcium phenate which is not poisonous.

IRRITANT POISONS

The more important irritant poisons will be considered under this heading (vide list above) but it must be remembered that many of the general poisons, *e.g.*, savin, cantharides, etc., have an irritant action on the stomach and intestines in addition to their special action on important organs and nerve centres.

Oxalic Acid occurs in colourless crystals resembling Epsom salts; it is very soluble in water. Salts of Sorrel or Salts of *Lemon* is the quadrioxalate of potash; it is a white powder very soluble in water. Both of these substances are commonly used for domestic purposes, *e.g.*, for cleaning straw hats, removing ink stains, cleaning brasses, etc. They are frequently the cause of accidental and of suicidal poisoning.

As regards symptoms, when swallowed in solution the typical symptoms of irritant poisoning are set up, but in addition the poison when absorbed into the system has a profound depressing action on the heart and nervous system. Thus an acrid burning taste is experienced and pain occurs which is referred from the throat, oesophagus, stomach and later possibly the intestines. Vomiting is common, the vomit being very acid, and giving the tests for oxalic acid. It often contains blood. Unless immediate treatment is adopted collapse speedily occurs, the patient being cold, pale and faint with a rapid feeble pulse and at this stage death from syncope may occur. In some cases nervous symptoms such as tinglings and numbness, muscular spasms, convulsions, delirium and coma occur, but these symptoms are uncommon. Owing to the rapid absorption of the poison death is likely to occur rapidly, *e.g.*, within an hour, but it may be delayed.

As respects treatment, fresh lime water, or better the saccharated lime water which is 15 times as strong, should be given in large quantities and it should be mixed with calcium carbonate in the form of chalk or whiting. Since oxalic acid has only slight corrosive action the stomach should be washed out immediately if no antidote is at hand. It is best to give the antidote freely if immediately available and after a few minutes to wash out the stomach thoroughly with a soft stomach tube and funnel, and then finally introduce a pint of lime water made into a thin cream with an ounce of chalk, leaving this mixture in the stomach.

Arsenic.—This is the most important of the irritant poisons and owing to the tasteless property of many of its compounds and preparations it is the commonest poison used for homicidal purposes.

The most important and commonest compound is arsenious anhydride or white arsenic. It occurs in the form of a white powder or in lumps of a white porcelain-like appearance. The powdered form resembles powdered sugar or flour and when mixed with food is almost tasteless. It is sparingly soluble in cold water. When mixed with alkaline substances white arsenic becomes freely soluble.

Commercial preparations containing white arsenic mixed with alkalies such as sodium hydrate or carbonate are weed killers, sheep dip and wood preservatives which may contain from 20% to 40% of white arsenic. Copper arsenite (Scheele's Green), lead arsenate and other arsenical preparations are used as insecticides for the spraying of fruit trees. Kat poisons may contain arsenic as the active ingredient. Wallpapers which formerly often contained green pigment (Scheele's Green) or the yellow sulphides of arsenic are now coloured with arsenic-free pigments, arsenic being prohibited from use. White arsenic, if sold except for medicinal purposes, must be coloured with soot or indigo

Arsenic in Food.—Accidental contamination of food with arsenic has occurred in the past. Thus in 1900 a beer poisoning epidemic occurred as the result of the use of commercial glucose which contained arsenic in the preparation of beer. (See ADULTERATION.)

Acute Arsenical Poisoning.—When arsenic is taken by the mouth in poisonous quantities symptoms of acute gastro-intestinal irritation such as vomiting, diarrhoea and abdominal pain occur within a few hours and death may result within a few days. Two grains of arsenic have caused death though larger quantities have been taken without fatal result. In acute arsenical poisoning the heart, kidneys and other organs are seriously affected so that the poison has a systemic action in addition to its irritant properties to the stomach and intestines.

Chronic *Arsenical* Poisoning occurs when small quantities of arsenic are absorbed over long periods. The gastro-intestinal symptoms may be slight. but other symptoms such as skin rashes and pigmentation, conjunctivitis, become manifest.

In suspected arsenical poisoning the diagnosis can be made certain by analysis of the vomit, urine and faeces in acute cases. In chronic cases additional information may be obtained by analysis of the hair and nails.

Antimony is an irritant poison like arsenic. Tartar emetic or potassium antimony tartrate is one of the most commonly used compounds. It has on several occasions been used for homicidal purposes owing to the possibility of its being administered without detection by taste or smell.

Metallic Poisons if taken by the mouth give rise to irritant poisoning. Examples are:—

Lead.—The common salts of lead will in large doses cause gastro-intestinal irritation. Acute poisoning by lead is rare Chronic lead poisoning is caused by the continued absorption of small quantities of lead and is a dangerous condition owing to the causation of disease of the kidneys, blood vessels, heart and nervous system. Lead-tetra-ethyl is a very poisonous organic compound of lead. It has been recently used commercially as a constituent of ethyl petrol, which is claimed to be superior in some respects to ordinary petrol as a fuel for motor engines. In Great Britain the possible dangers from its use have led to a special Government enquiry.

Copper.—The sulphate of copper (blue vitriol) and other copper compounds are irritant poisons. The use of copper salts as a colouring matter of foodstuffs such as preserved green vegetables is reprehensible, and has often led to legal action.

Zinc Salts are irritant poisons. The sulphate of zinc (white vitriol) occurs in crystals like Epsom salts for which it has been taken in mistake. Zinc chloride has a corrosive as well as an irritant action.

Barium Salts.—Except the quite insoluble sulphate these are irritant poisons and may also act on the nervous system.

Chromates especially potassium bichromate are powerful irritant poisons.

Phosphorus.—The yellow variety is intensely poisonous and used to be used iargeiy in the manufacture of matches. Owing to its dangerous properties its use for this purpose has been abandoned. Yellow phosphorus is used as a constituent of some rat poisons. The substance, in addition to being a gastro-intestinal irritant, is a deadly poison to the liver and kidneys.

Mercury.—Acute mercurial poisoning usually arises from the taking of mercuric chloride (corrosive sublimate) or from the biniodide of mercury, both of which are extensively used as disinfectants for medical purposes. The immediate symptoms are those of acute gastro-intestinal irritation (vomiting, abdominal pain and diarrhoea) but they are generally followed by suppression of urine and symptoms of acute ulcerative colitis which latter symptoms are commonly fatal. Chronic Mercurial Poisoning is characterised by inflammation of the mouth and gums.

SYSTEMIC POISONS

The systemic poisons include the following:—

Prussic or *Hydrocyanic* Acid.—Hydrocyanic acid is one of the best known poisons, and a very deadly one. In the pure state it is said to kill with lightning-like rapidity. It is met with in commerce only in a dilute state. In Great Britain two kinds of acid are commonly sold—the pharmacopoeia1 acid, containing 2% of anhydrous prussic acid, and Scheele's acid, containing 4 to 5%. Less than a teaspoonful of the 2% acid has caused death.

Given in fatal doses, the symptoms of prussic acid poisoning set in with great rapidity; and, in consequence of the readiness with which the poison is absorbed from the stomach and diffused through the circulation, the onset of symptoms is reckoned by seconds rather than by minutes. Occasionally the victim may be able to perform a few voluntary actions before alarming symptoms are developed. There is first a very brief stage of difficult breathing, and slow action of the heart, with a tendency for the organ to stop in the state of dilatation. With widely dilated pupils of the eye the patient is then seized with violent irregular convulsive movements. The rhythm of the respiratory movements is disturbed, and the countenance becomes of a bluish cast. The patient now sinks to the ground with complete loss of muscular power; and the third or asphyxia1 stage is reached, in which there are slow gasping respirations, loss of pulse, and paralysis of motion. Death is frequently preceded by spasms.

The lightning-like character of the illness, and the speedy death of the patient, coupled with the peculiar odour of the acid in the breath and atmosphere around the body, seldom leave any doubt as to the nature of the case.

The treatment consists in inhalation of fumes of strong ammonia, drinks of warm and cold water alternately, friction of the limbs, and artificial respiration. The subcutaneous injection of atropine, which acts as a cardiac stimulant, may prove serviceable.

Other soluble cyanides, more especially cyanide of potassium, a salt largely used in photography and in the arts, are equally poisonous with hydrocyanic acid.

Strychnine and *Strychnine-yielding* Plants.—The alkaloids strychnine and brucine, as well as the plants in which they are found, all act in the same manner, being highly poisonous and causing death after spasms of a severe character. Many vermin-killers contain strychnine as their active ingredient.

Strychnine, and all substances containing that alkaloid, produce their effects within a very few minutes—usually within ten or fifteen minutes. The patient complains of stiffness about the neck, and his aspect exhibits terror. There is an impression of impending calamity or death. Very speedily the head is jerked back, the limbs extended, the back arched (opisthotonos) so that the body may rest on the head and heels only. In a few moments these symptoms pass off, and there is complete relaxation of the spasm. The spasmodic condition speedily returns, and is brought about by the slightest touch or movement of the patient. Accessions and remissions of the tetanic state ensue rapidly till the patient succumbs, usually within half an hour of the administration of the poison.

The best treatment is to put the patient under the influence of chloroform and wash out the stomach, a full dose of chloral and bromide being afterwards introduced into the stomach.

Opium.—In consequence of the extent to which opium, its preparations, and its active alkaloid morphia are used for the relief of pain, poisoning by opium is of frequent occurrence. It is largely used by suicides; and children, being very susceptible to its influence, frequently die from misadventure after administration of an overdose of the drug. The ordinary preparations of opium are the drug itself, which is the inspissated juice of the oriental poppy, and the tincture, commonly known as laudanum. Opium contains a variety of more or less active principles, the chief of which is the alkaloid morphia, which is present in good opium to the extent of about 10% in combination with meconir acid, which is physiologically inactive.

Heroin is an artificial derivative of morphine (diacetyl morphine hydrochloride) and is more toxic than morphine. It has been largely used medicinally. It is a dangerous drug of addiction (see DRUG ADDICTION).

Belladonna.—The belladonna or deadly nightshade, atropa belladonna, contains an alkaloid, atropine, which is largely used by oculists to procure dilatation of the pupils of the eye. The brown or black berries of the plant have been eaten by children, who are attracted by their cherry-like appearance. Belladonna produces dilatation of the pupils, rapid pulse, hot dry flushed skin, with an eruption not unlike that of scarlatina, soreness of the throat, with difficulty of swallowing, intense thirst and delirium.

The treatment consists in evacuation of the poison by means of the stomach-pump, and the hypodermic injection of morphia as a counter-poison. Stramonium, hyoscyamus (henbane), hyoscyamine, hyoscine and scopolamine all produce symptoms similar to atropine poisoning, the narcotic effects being more marked.

Aconite Poisoning.—The ordinary aconite, wolfsbane or monkshood (*Aconitum Napellus*), and an alkaloid extracted from it, aconitine, are perhaps the most deadly of known poisons. One-sixteenth of a grain of aconitine, its active alkaloid, has proved fatal to a man. All the preparations of aconite produce a peculiar burning, tingling and numbness of the parts to which they are applied. When given in large doses they produce violent vomiting, as a rule, more or less paralysis of motion and sensation, and great depression of the heart, usually ending in death from syncope. Intelligence remains unaffected till almost the last.

The treatment consists in the hypodermic injection of digitalin, which is a counter-poison in its action upon the heart. The root of aconite has been eaten in mistake for that of horse-radish.

Cocaine Poisoning.—Cocaine is the active alkaloid of coca leaves. The hydrochloride salt is the commonly used preparation. It is a powerful deliriant narcotic poison. If taken by the mouth or given hypodermically or otherwise absorbed it may cause delirium and coma. Sometimes convulsions and sudden death occur. It acts on the heart and may cause fatal syncope. Cocaine is a dangerous drug of addiction (see DRUG ADDICTION).

Organic *Compounds* Used as Hypnotics.—These if taken in excessive doses act as poisons, and the symptom which attracts attention is the deep coma produced.

Examples are:—chloral, veronal and its derivatives, medinal, proponal, luminal, also sulphonal, trional and tetronal. Any hypnotic drug if taken in excessive quantity will act as a coma-producing poison. (See BARBITURIC ACID and SULPHONAL.)

GASEOUS POISONS

These include the following:

Carbon Monoxide Poisoning.—This occurs from coal gas, water gas or exposure to the suffocating fumes from fires. smoky grates, stoves or lamps; also from the fumes from geysers.

The diagnosis may be made at once by the clinical symptoms of drowsiness, collapse and coma and the cherry-red colour of the face and mucous membranes. The examination of the blood will make the diagnosis certain, since the presence of carbon monoxide haemoglobin may readily be detected by the spectroscope.

The treatment consists in giving oxygen freely and employing artificial respiration if necessary. Strychnine and digitalin should be given hypodermically, also brandy by the mouth, and warm saline either subcutaneously or by the bowel may be given. For heart failure pituitary extract may be given hypodermically.

Carbon Dioxide Poisoning, or *Carbonic* Acid Poisoning.—This occurs in coal mines from choke-damp or after-damp. Cellars of houses, wells, brewers' vats, lime-kilns, etc., frequently contain large quantities of carbonic acid gas.

The treatment consists in fresh air, rest, oxygen, artificial respiration if necessary, and the employment of warmth and stimulants.

Sulphuretted Hydrogen *Poisoning.*—This occurs from contamination of the air with sewer gas, and from the gases evolved when iron slag becomes moistened with water. The gas is frequently produced in various chemical processes.

The treatment consists in giving the patient plenty of fresh air. Oxygen and stimulant treatment must be used.

Chlorine.—This, even in minute proportion in the air, acts as a powerful irritant to the lungs, and causes an acute bronchial catarrh and pulmonary congestion, which may be followed by bronchopneumonia and other serious complications. Intense cyanosis and dyspnoea occur quickly, and severe spasm of the glottis occurs often associated with some oedema.

POISONOUS FOODS

Poisonous fungi, for the characters of which the reader is referred to special works on toxicology, are sometimes eaten in mistake for mushrooms. They cause a severe gastroenteritis and at the same time are powerful general poisons having a profound action on the nervous system and liver.

Food Poisoning (*q.v.*) generally results from the contamination of food with pathogenic bacteria allied to the typhoid and colon group of bacilli. "Food poisoning" is often erroneously called "ptomaine poisoning." The symptoms are those of acute gastroenteritis and may clear up quickly or terminate fatally. In some cases a prolonged illness with pyrexia like that of typhoid results. The symptoms of "food poisoning" usually come on within 3 days and most often within **24** hours of the taking of food. In some cases the symptoms are so acute as to resemble cholera.

The treatment and general management of these cases is on the same lines as that of acute gastroenteritis.

It must be remembered that "food poisoning" is a notifiable disease in some districts, and in all cases where death occurs the coroner should be informed. (W. H. WI.)

POISON IVY, the name commonly applied to several, mostly white-fruited, trifoliate species of woody vines or shrubs of the genus *Toxicodendron* (family Anacardiaceae), native to North America. The forms with bushy habit and lobed leaflets are often called "poison oak," especially in the western United States. The common poison ivy (*Toxicodendron radicans*), the most widespread species, abundant in eastern North America and less common westward, is a variable species with a bushy or climbing habit, leaves with three leaflets which may be smooth and glossy or hairy, entire, toothed or lobed. Many of these not too constant variations have been designated as separate species or varieties. The more common of these forms with their ranges are: *T. quercifolium*, with deeply lobed leaflets, Maryland to Texas; T. radicans rydbergi, with thicker leaves, Great Plains to Rocky mountains; and T. diversilobum, with leaflets mostly scalloped on the margin, Pacific coast. The poison sumac (*T. vernix*), native in swamps from Quebec to Minnesota and south to Texas and Florida, is a tall bush or small tree with pinnately-compound leaves with 7 to 13 entire leaflets and drooping, axillary clusters of persisting white fruits. All species of Toxicodendron are poisonous to touch, producing in many persons a severe inflammation of the skin or dermatitis. Sumacs with red fruits are nonpoisonous. The toxic principle, urushiol, is produced in the resinous juice of the resin ducts of the leaves, flowers, fruits and bark of stems and roots but not in the pollen grains. Being almost nonvolatile, the urushiol may be carried from the plant on clothing, shoes, tools, soil, by animals, by smoke from burning plants, to persons who never go near the poison ivy plants. Poisoning may occur if clothing is worn a year after contact with poison ivy.

FIG. 2.—A LEAF OF POISON SUMAC (TOXICODENDRON VERNIX)

The remedies and preventive treatments used against poisoning from contact with species of Toxicodendron are legion. With the exception of the following, none should be used without the advice of a physician. Either before exposure, or immediately after it is discovered that contact has been made with the plant, wash the exposed parts of the body thoroughly with water and an alkaline laundry soap. Lather the parts well and let the lather dry on. Repeat this treatment every 3 or 4 hours, leaving the dry lather on between applications. Avoid oily soaps or washing with alcohol to prevent spreading the toxic material.

(W. C. M.)

POISONOUS PLANTS. It is not practicable to divide the members of the vegetable kingdom into poisonous and nonpoisonous plants. Most of the quarter million known species of plants are harmless; only a relatively few are poisonous under ordinary conditions; others are poisonous only under special conditions. I'oisonous plants under natural conditions contain or produce physiologically active substances in quantities sufficient to cause death or a disease condition when eaten, or sometimes when touched, by man or animals.

FIG. 1.—WHITE SNAKEROOT (EUPATORIUM RUGOSUM). A, PLANT SHOWING GENERAL HABIT: B, HEAD OF FLOWERS; C, FLOWER: D. SEED (ACHENE) WITH PAPPUS ATTACHED

In general the toxic properties of poisonous plants are due to the presence, in some or all parts of the plant, of one or more organic compounds such as alkaloids, glucosides, resinoids and organic acids. Alkaloids are responsible for the toxic properties in certain members of the families Liliaceae, Amaryllidaceae, Papaveraceae, Ranunculaceae. Leguminosae and Solanaceae. Among the glucosides that yield toxic substances upon hydrolysis are those produced in wild cherries (*Prunus* sp.), flax (*Linum* sp.), purple cockle (*Agrostemma githago*), foxglove (Digitalis purpurea), and various members of the mustard family, Cruciferae. Resinoids containing toxic substances occur in poisonous members of the heath family, *Ericaceae*, water hemlock (Cicuta maculata), and milkweeds (*Asclepias* sp.).

Not all parts of a poisonous plant are equally toxic. In some the toxic principle is mostly concentrated in the seed, *e.g.,* purple cockle (*Agrostemma* githago); in others the root is the most toxic part, *e.g.,* water hemlock (*Cicuta* maculata). Some plants are toxic only in certain stages of development. The cocklebur (*Xanthium* orientale) is very poisonous in the seedling stage and harmless in later stages of growth. Other plants are poisonous when eaten green but are harmless after they are thoroughly dried and the toxic principle is dissipated. Some plants, *e.g.,* certain locoweeds (Astragalus sp.), vary greatly in their toxicity, depending upon the type of soil on which they grow.

Most cases of poisoning from eating toxic plants occur in animals; comparatively few occur in man. Some plants, such as water hemlock (*Cicuta* maculata), poison hemlock (*Conium maculatum*) and locoweeds (Astragalus sp.), produce characteristic symptoms in animals poisoned by eating them. Many poisonous plants, although belonging to widely unrelated plant families, may produce identical symptoms because their toxic principle is the same; *e.g.,* species of wild cherries (Prunus sp.), sorghum (Holcus sp.) and arrowgrass (Triglockin *maritima*) all produce the same symptoms because the toxic principle in them is prussic acid, which under certain conditions is released by the hydrolysis of glucosides produced in them. Another example of a disease caused by widely different plants is trembles, caused by white snakeroot (*Eupatorium* rugosum) in the eastern United States and by the rayless goldenrod (*Aplopappus heterophyllus*) from western Texas to Arizona and adjacent Mexico. In these plants the toxic principle is tremetol, which, being soluble in the fat of milk, may be transmitted from diseased cows through the milk to humans, causing the disease known as milk sickness. Some plants, *e.g.,* scouring rushes (*Equisetum* spp.) and iocoweeds (Astragalus spp.) may produce different types of diseases, acute or chronic, depending upon whether an animal eats a large quantity of the plants at one time or small quantities repeatedly for a considerable time.

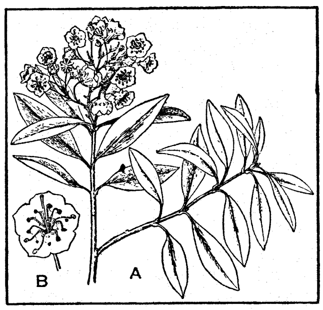
Among cultivated plants the following poisonous species, originating mostly in the old world, are common and widely grown in the temperate regions: castor bean (*Ricinus communis*), daphne (*Daphne* nzezereum), foxglove (Digitalis purpurea), lily-of-the-valley (Convallaria *majalis*), meadow saffron (*Colchicum* autumnale), monkshood (*Aconitum* napellus), larkspur (*Delphinium* spp.), narcissus (Narcissus poeticus), oleander (*Nerium* oleander).

Plants Poisonous by Contact. — Most cases of contact poisoning by plants occur in man; animals are rarely poisoned by contact alone. In man certain plants produce a skin poisoning or dermatitis consisting of minor or temporary irritation or a painful inflammation with vesicles or blisters lasting for days or weeks. depending upon the susceptibility of the individual or the severity of the infection. The toxic principle in these plants is often most concentrated in a resinous or milky juice. Among the species uhich cause many cases of dermatitis may be mentioned the following:

Cashew family.—Poison ivy and poison oak (Toxicodendron radicans) and related forms, common in North America; poison sumac (Toxicodendron *vernix*), eastern North America; poison wood (*Metopium* toxiferum), of southeastern United States and West Indies; Japanese lacquertree (Toxicodendron *verniciflunm*), eastern Asia; cashew (*Anacardium* occidentale), widespread in tropical regions.

Spurge family.—Manchineel tree (*Hippomane mancinella*), common in the West Indies and Central America; sandbox tree (Hura *crepitans*), native to Central American lowlands; spurges (Euphorbia spp.), many species, especially some native to Africa and Asia, very toxic; snow-on-the-mountain (Euphorbia *marginata*), an annual native to western North America, widely introduced as an ornamental. A few species of primrose, notably *Primula* obconica, a favourite house plant, several kinds of lady-slipper (*Cypripedium reginae* and C. *parviflorum*), native to eastern North America, the garden parsnip (Pastinaca sativa), often escaped as a weed, and several species of milkweed (*Asclepias*), are responsible for dermatitis in many susceptible persons.

Photodynamic Plants.—Several plants appear to contain substances that sensitize domestic animals to light. If animals with white fur or unpigmented skin eat these plants and are subsequently exposed to strong sunlight they may develop a disease with characteristic symptoms that may result in death. Animals that are not exposed to sunlight subsequent to eating these plants do not develop any symptoms. Some of the widely distributed photosensitizing plants are buckwheat (*Fagopyrum* esculentum), St. Johnswort (*Hypericum perforatum* and H. *crispum*), bur clover (Medicago denticulata) and puncture vine (*Tribulus terrestris*).



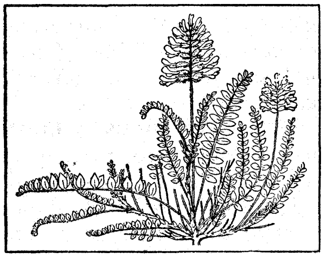
COURTESY, NEW YORK COLLEGE OF AGRICULTURE AT CORNELL UNIVERSITY

FIG. 2.—MOUNTAIN LAUREL (KALMIA LATIFOLIA). A, FLOWERING BRANCH; B, FLOWER

Seleniferous **Plants.**—Several species of plants when growing on certain soils from Cretaceous or Eocene shales take up enough selenium compounds to make them toxic. In several regions in western North America, cattle and horses have been poisoned by eating such seleniferous plants, resulting in alkali disease and blind staggers. Selenium absorbed from seleniferous shales by these plants upon their decomposition is returned to the soil and becomes available and may be taken up by other native plants or by crop plants that are unable to absorb inorganic selenium. By such action crops like wheat may become poisonous. The locoweeds (*Astragalus bisulcatus,* A. pectinatzis, *A. racemo-*

sus), wild aster (*Aster commutatus* and *A. xylorrhiza*), princes plume (*Stanleya bipinnata* and *S. pinnata*), are examples of seleniferous plants of western North America.

Principal Stock-poisoning Plants.—Several forms of bracken or brake-fern (*Pteridium*) occurring in widely distributed places throughout temperate regions from Eurasia to Australia and North America, when eaten fresh or in hay over a prolonged period, are the cause of poisoning of cattle and horses. Horsetail (*Equisetum arvense*) of Eurasia and North America causes an acute or chronic disease, equisetosis. Arrowgrass (*Triglochin maritima*) of Eurasia, North Africa and North America produces prussic acid which poisons cattle and sheep. Darnel (*Lolium temulentum*), native to Europe and introduced in North America, contains a poison in its grains. Death camas (*Zygadenus venenosus*) and related species, all native to North America, contain toxic alkaloids and cause considerable losses among sheep and cattle grazing on ranges in the spring. False hellebore (*Veratrum viride*), widespread in North America, and the European V. *album* contain toxic alkaloids.



FROM "POISONOUS PLANTS OF U.S." BY W. C. MUENSCHER, THE MACMILLAN CO.

FIG. 3.—WOOLLY LOCOWEED (ASTRAGALUS MOLLISSIMUS)

Fly poison (*Amianthemum muscaetoxicum*) causes losses among cattle and sheep in the eastern United States. Lily-of-the-valley (*Convallaria majalis*), native to Europe and the eastern United States, widely cultivated as an ornamental, contains toxic alkaloids. Star-of-Bethlehem (*Ornithogalum umbellatum*), native to Europe and naturalized in North America, and other species of *Ornithogalum* native to South Africa cause poisoning of cattle and sheep. Meadow saffron (*Colchicum autunrnale*), native to Europe and widely introduced in North America, contains toxic alkaloids. Lechuguilla (*Agave lechegzcilla*), native to southwestern United States and Mexico, contains a photosensitizing agent and causes poisoning, chiefly of sheep and goats.

Pokeweed (*Phytolacca americana*), native to eastern North America, contains a toxic alkaloid chiefly in the root. Purple cockle (*Agrostemma githago*), native of Eurasia and widely naturalized in most regions where winter wheat is grown, contains a toxic glucoside in its seeds. Monkshood (*Aconitzcm napellus*), a native of Europe, and *A. columbianum*, native of the mountain ranges of western North America, both contain toxic alkaloids. Larkspurs (*Delphinium* spp.) contain toxic alkaloids: several species native to western North America cause heavy losses when grazed by cattle.

Hellebore (*Helleborus niger* and *H. viridis*), native to Europe and introduced in North America, contain toxic glucosides. Opium poppy (*Papaver somniferum*), of Asiatic origin and widely introduced in warmer parts of the world, contains several alkaloids. Dutchmans-breeches (*Dicentra cucullaria*) and squirrel corn (D. *canadensis*), native to eastern North America, contain toxic alkaloids and cause blind staggers in cattle and sheep. Wild cherry (*Prunus serotina*), a common native tree in eastern North America, chokecherry (*P. demissa*) of western North America, the cherry laurel (*P. laurocerasus*) of Europe and other species contain a glucoside that may yield prussic acid upon hydrolysis. When the leaves of these plants are eaten by cattle or sheep, death may result quickly.

Several European and North American species of lupines (*Lupinus* sp.) contain toxic alkaloids. In western North America losses among cattle and sheep grazing on lupine seed pods may be large. A number of species of locoweeds (*Astragalus* sp. and *Oxytropis* sp.) native to North America in the region from the great plains westward to the Rocky mountains are poisonous and when eaten cause loco disease in cattle and horses. The plants appear to be "habit forming," and animals may develop a habit of seeking out locoweeds in preference to other vegetation. The disease may be acute from eating large amounts at one time, or chronic from eating small amounts over a long period. Some, but not all, locoweeds owe their toxic properties to selenium compounds absorbed from the soil.

Precatory bean (*Abrus praecatorius*), a native shrub of India, is widely introduced in subtropical regions.

Its seeds contain a toxic substance, abrin, and may poison cattle and sheep. In India immunity has been developed in animals by feeding them very small amounts of the abrin and gradually increasing the dose. Black locust (*Robinia pseudo-acacia*), a native tree of eastern North America and widely introduced in Europe, contains a toxic substance in its bark. Horses are sometimes fatally poisoned by eating the bark. Puncture vine (*Tribulus terrestris*), a more or less cosmopolitan weed in the warmer parts of the world, contains a photosensitizing agent and causes a disease, tribulosis, when eaten by animals.

China-tree (*Melia azedarach*), a native tree of India widely introduced in many warm regions of the world, including the southern United States, contains a narcotic poison, especially in its fruits. Many species of spurges (*Euphorbia* sp.) native to Africa, Europe and America contain toxic substances in their latex. These plants are not only poisonous when eaten but many of them arc poisonous to touch. Coyotillo (*Karwinskia humboldtiana*), a shrub native to Mexico and the southwestern United States causes a paralytic disease, "limberleg," when the leaves are grazed by cattle. St. Johnswort (*Hypericum perforatum*), native to Europe but widely naturalized in North America, Australia, and North Africa, contains a photosensitizing agent. This species and also *H. crispum* cause a disease osteoporosis or bighead, in cattle and sheep.

Water hemlock (*Cicuta virosa*), native to Europe, and *C. maculata* and *C. douglasi*, native to wet lands in eastern and western North America, contain a resinous substance, cicutoxin, especially in their roots. Only a small piece of root may kill a cow. Poison hemlock (*Conium maculatum*) and iool's parsley (*Aethusa cynapium*), both native to Europe and naturalized in North America, contain alkaloids in their roots and seeds. Mountain laurel (*Kalmia latifolia*) and sheep laurel (K. *angustifolia*), two native evergreen shrubs of eastern North America, frequently cause death of cattle and sheep when they eat the leaves. Indian hemp (*Apocynum cannabinum*) and dogbane (*A. androsaemifoliunz*), native North American herbs, produce a resinous material with toxic substances responsible for poisoning cattle and horses. Oleander (*Nerium oleander*) native to Asia but widely introduced in the warmer parts of the world, contains toxic glucosides. Various domestic animals have been poisoned by eating the leaves.

Whorled milkweeds (*Asclepias galioides, A. mezicana*) and related species native to western North America, have caused death of sheep and cattle grazing on the tops. Black nightshade (*Solanum nigrum*) and European bittersweet (*S. dulcanzara*) contain the alkaloidal glucoside solanine in the leaves and berries. Thorn apple (*Datura stramonium*) and related species, native to warmer parts of the world but now widespread, contain toxic alkaloids. Belladonna (*Atropa belladonna*) and henbane (*Hyoscyamus niger*), European species introduced into North America, are poisonous and are also grown as medicinal plants for their powerful alkaloids. Foxglove (*Digitalis purpurea*), native to Europe and naturalized in western North America, contains several glucosides, mostly in the leaves. Animals, and rarely people, are poisoned by eating the leaves. White snakeroot (*Eupatorium rugosum*), native to eastern North America, causes the disease trembles in cows and milk sickness in people. Cockleburs (*Xanthium* sp.), widespread in warmer parts of the world, are poisonous in the seedling stages. Ragworts (*Senecio jacobaea* and other species) cause a disease of the liver in cattle and horses in North America, South Africa, parts of Europe and New Zealand.

POISSY, a town of N. France, in the department of Seine-et-Oise, 17 mi. W.N.W. of Paris, on the railway from Paris to Rouen. Pop. (1936) 12.502. Poissy was the ancient *Pinciacum*. The ancient church, dating from the 12th century, and restored under Viollet le Duc, affords one of the earliest and best examples of transition from the Romanesque to the Pointed style. There are metalworks and construction of railway cars; printing and manufacture of footwear and furniture are carried on.

POISSY, COLLOQUY OF, a conference held in 1561 with the object of effecting a reconciliation between the Catholics and Protestants of France. The conference was opened on the 9th of September in the refectory of the convent of Poissy, the king himself being present. At the end of a month their difficult labours seemed on the point of success when the assemblage of prelates refused assent, and the conference broke up.

See H. Küpffel, *Le Colloque de Poissy* (Paris, *1868*); E. Lacheinmann in Herzog-Hauck, *Realencyklopädie f. protest. Theologie* (3rd ed., 1904), xv. 497.

POITIERS (pwă-tyā), a town of W. France, formerly capital of Poitou, and now the chief town of the department of Vienne, 61 mi. S.S.W. of Tours on the railway to Bordeaux. Pop. (1936), 41,384. Called *Limonum* at the time of the Roman Conquest, Poitiers afterwards took the name of its Gallic founders, the Pictones or Pictavi. Christianity was introduced in the 3rd century, and the first bishop of Poitiers, from 350 to 367, was St. Hilarius. Fifty years later the city had fallen into the hands of the Arian Visigoths, and became one of the principal residences of their kings. Alaric II. was defeated by Clovis at Vouillé, not far from Poitiers, in 507, and the town became a part of the Frankish dominion. This was the first occasion on which the peoples of northern and southern Gaul met in conflict near the town which was to see the so often join battle. By his victory in 732 over the Mohammedans at Moussais-la-Bataille in this region, Charles Martel proved the saviour of Christendom. Eleanor of Guienne frequently resided in the city and in 1199 entrusted it with communal rights. After the battle of Poitiers in 1356 (see below), Poitou was recognized as an English possession by the treaty of Brétigny (1360); but by 1373 it was recovered by Bertrand Du Guesclin.

Between the north-west of the plateau central and the Gâtine, both heights of old rock, lies the relatively low land called the Seuil du Poitou, giving a historic connection between the Paris basin and the basin of the Garonne. In this lowland streams have dissected valleys in the Jurassic rocks, and Poitiers stands on a promontory above the junction of the Boivre and the Clain (a tributary of the Loire by the Vienne); its situation has given it a peculiar importance in military and political history. The town is picturesque; and its streets are interesting for their remains of ancient architecture, especially of the Romanesque period, and the memories of great historical events. Till 1857 Poitiers contained the ruins of a Roman amphitheatre more extensive than that of Nîmes; remains of Roman baths, constructed in the 1st and demolished in the 3rd century, were laid bare in 1877; and in 1879 a burial-place and the tombs of a number of Christian martyrs were discovered on the heights to the south-east, the names of some of the Christians being preserved in paintings and inscriptions. Not far from these tombs is a huge dolmen (the "Pierre Levée"), 22 ft. long, 16 ft. broad and 6 or 7 ft. high, around which used to be held the great fair of St. Luke.

The cathedral of St. Peter, begun in 1162 by Henry II. of England and Eleanor of Guienne on the ruins of a Roman basilica, and completed by 1379, is in the Romanesque and Early Gothic styles. It consists of three naves almost equal in height and width, all of which decrease towards the west. The fine windows of the choir and the transepts preserve their stained glass of the 12th and 13th centuries. The choir stalls (1235–57) are among the oldest in France. The church of St. Jean near the cathedral is the most ancient Christian monument in the country. Built as a baptistery in the first half of the 4th century, it was enlarged in the 7th century, since when it has suffered little structural alteration.

The church of St. Radegonde, a great resort of pilgrims, commemorates the consort of Clotaire (d. 587), and preserves in its crypt the tomb of Radegonde, who founded at Poitiers the abbey of the Holy Cross, and two others reputed to be those of St. Agnès and St. Disciola. The choir and tower above the entrance are of the 11th century, while the nave (late 12th century) is in the Angevin style Notre-Dame la Grande (late 11th century) represents a much older collegiate church and has a richly sculptured Romanesque facade. The church of Moutierneuf (*Monasterium Novum*) was begun in 1077 by William VI., duke of Aquitaine and count of Poitiers, who is buried within its walls; and the choir (13th century modified by the erection of a "lantern") was solemnly consecrated by Urban II. in 1096. Restorations have been effected in the 19th century. The beautiful 11th century tower of St. Porchaire was restored in the 19th century.

Poitiers is the seat of a bishop, a prefect, a court of appeal and a court of assizes, and centre of an educational division (*académie*), and has tribunals of first instance and of commerce. It has a university with faculties of law, science and letters, a preparatory school of medicine and pharmacy and a school of theology. There are artillery practice-grounds and an airfield. Trade is in farm produce, wine, wool, honey, goose-quills and leather. The industries include the preparation of goose- and swan-skins, printing, and the manufacture of hosiery, brushes, oil, paint and candles.

Counts of Poitiem.—In the time of Charlemagne the countship of Poitiers, then part of the kingdom of Aquitaine, was represented by a certain Abbon. Renoul (Ranulph), created count of Poitiers by Louis the Pious in 839, was the ancestor of a family distinguished in the 9th and 10th centuries for its attachment to the Carolingian dynasty. One of his successors, Ebles the Bastard (d. 935), took the title of duke of Aquitaine; and his descendants retained the hereditary name of William. In accordance with the dying wishes of William X his daughter Eleanor was married in 1137 to Louis, the son of Louis VI of France. Sole heiress, she brought her husband Poitou, Saintonge, Aunis, a part of Touraine and Berry, Marche, Angoumois, Périgord, Auvergne, Limousin, Bordelais, Agénois and Gascony. After a divorce in 1152, Eleanor married the count of Anjou, Henry Plantagenet, who became king of England as Henry II. The west of France thus passed into the hands of England. Philip Augustus reconquered Poitou in 1204. When Charles VII ascended the throne he united the countship of Poitiers to the crown. During World War II, the town was occupied by the Germans in June 1940, and the demarcation line ran through the vicinity.

Battle of **Poitiers.**—This battle, fought on Sept. 19, 1356, between the armies of King John of France and of Edward the "Black Prince," was the second of the three great English victories of the Hundred Years' War. From Bordeaux the Black Prince had led an army of his father's Guienne vassals, with which was a force of English archers and men-at-arms, into central France and had amassed an enormous booty. King John, hitherto engaged against the army of John of Gaunt, duke of Lancaster, in Normandy, hurried south to intercept the raiding army and to bar its homeward road. After an unexpected encounter with the French rear, the Black Prince, by forced marching, was able to slip past the French, but reaching Maupertuis, 7m. S.E. of Poitiers, with the king's army in chase, he found himself compelled to choose between fighting and abandoning his spoil. He chose the former course, in spite of the enemy's great superiority in numbers (perhaps 16,000 to 6,500), and in order to give his trains time to draw off took up a defensive position on Sept. 18 with a slight hollow in front and a wood behind, between the Poitiers-Bordeaux main road and the River Maussion.[1] John, instead of manoeuvring to outflank the English, allowed the Cardinal Talleyrand de Périgord to attempt to negotiate a peace. This proving vain, the French army attacked without any attempt at manoeuvre or reconnaissance, and on a front so narrow that the advantage of superior numbers was forfeited. Moreover, King John ordered all but the leading line to dismount and to attack on foot (tactics suggested by the success on the *defensive* of the dismounted English men-at-arms at Crécy and the Scots at Bannockburn), and thus condemned the best part of his army to a fatiguing advance on foot across difficult country in full armour.

The French crossbow-men, who might have crushed the relatively few English archers present, were mingled with the mounted men in first line, but, as the latter charged, their advance masked the fire of the cross-bowmen in the first few seconds, besides leaving the others, dismounted, lines far in rear. Thus the first attack on the Black Prince's line, which was greatly strengthened by trees and hedges in front of it, was promptly brought to a standstill by the arrows of the archers lining a hedge which overlooked

[1]The view adopted is that of Oman, *Art of War in the Middle Ages.*, p. 631.

the hollow in front; and the earl of Oxford hastily drawing out a body of archers beyond the defenders' left, into the marshy valley of the Maussion, completed their rout by firing up the hollow into their flank. But it was not so easy to deal with the second line of dismounted men-at-arms, led by the dauphin, which was the next to arrive on the French side. The hedge indeed was held, and the assailants, unable to advance beyond the hollow, gave way, but to achieve this the prince had to use all but 400 of his men. Had the third body of the French advanced with equal spirit the battle would probably have ended there and then, but the duke of Orléans, who commanded it, was so demoralized by the retirement of the dauphin's division that he led his whole force off the field without striking a blow.

Thereupon the king himself advanced furiously with the fourth and last line, and as it came on, the situation of the English seemed so desperate that the prince was advised to retreat. But his determined courage was unshaken; seeing that this was the last attack he put his reserve into line, and rallying around this nucleus all men who could still fight, he prepared not only to repulse but to counter-attack the French. He despatched 60 men-at-arms and 100 archers under the Captal de Buch to ride round the flank of the enemy and to appear in their rear at the crisis of the fight. Though a mediaeval knight, he knew as well as Napoleon at Arcole that when the moral force of both sides has passed its culminating point even a materially insignificant threat serves to turn the balance. And so it fell out. When both lines were fighting hand-to-hand, the 60 horsemen of the Captal de Buch appeared in rear of the French. The front ranks fought on, but the rearmost Frenchmen melted away rapidly, and at last only a group of the bravest, with Ring John and his son Philip, a boy of 14, in their midst, mere left. This band continued their hopeless resistance for a time, but in the end they were killed or captured to a man. The rest of the French army, totally dispersed, was pursued by the victors until nightfall. Two thousand five hundred of the French, 2,000 of them knights and men-at-arms, were killed, including the Constable, one of the marshals, the standard-bearer and six other great lords. The prisoners included the king and his son Philip, the other marshal and 25 great lords, and 1,933 knights and men-at-arms as well as 500 others. The Black Prince then resumed his march to Bordeaux, making no effort to exploit his military ascendancy. And in this he was justified, for he had now in his hands a political key which could yield him all the possible profits of victory, without their military cost.

POITOU, one of the old provinces of France, also one of the great military governments of the kingdom, bounded on the N. by Brittany, Anjou and Touraine; on the S. by Angoumois and Aunis; on the E. by Touraine. Berri and Marche; and on the W. by the ocean. It was divided into Lower Poitou, which corresponded to the modern department of La Vendée, and Upper Poitou, now split into the departments of Deux-Sèvres and Vienne. The principal town in Upper Poitou was Poitiers the capital. Poitou (Poictou, Pictavia) takes its name from the Pictones or Pictavi, a Gallic nation mentioned by Caesar, Strabo and Ptolemy, and described by Strabo as separated from the Namnetes on the north by the Loire. It formed part of the territory known as Aquitaine (*q.v.*).

For the history *see* the *Mémoires* of the Société des Antiquaires de l'Ouest (1835 *sqq.*) and the documents published by the *Archives historiques du Poitou* (1872 *sqq.*); also L. Rédet, *Dictionnaire topographique de la Vienne* (1881).

POKEBERRY or **POKEWEED,** the popular name (from the American-Indian *pocan,* applied to any plant yielding a red or yellow dye) of Phytolacca decandra, a strong-smelling perennial herb, a native of North America, with ovate-lanceolate sharp-pointed leaves, racemes of small greenish-white flowers and flattish berries nearly $ in. in diameter, which contain a crimson juice. The young asparagus-like shoots are sometimes used as a pot-herb, but the roots are poisonous. The plant is often cultivated in Europe, and has become naturalized in the Mediterranean region.

POKER, a game of cards, for any number of players from two to eight. each for himself. The usual pack is 52 cards, to which the joker is sometimes added, or the pack may be "stripped" by deleting the 2s, 3s and 4s. When eight play, a pack with 11's and 12's is sometimes used. The suits have no rank, but the cards rank from the ace, king, queen, down to the deuce. Players are provided with chips of various colours and values; white being the lowest, then red, blue and yellow.

This game is evidently an adaptation of the Persian game of Âs nbs, as it was originally played with only 20 cards, dealt to four players, and went to the United States by way of New Orleans. Owing to its resemblance to the French game of "poque," and the German game of "pochen," the French colonists called it poque, and this spelling was mispronounced by the English-speaking players as po-que, easily converted into po-ker.

"Full-deck poker," with 52 cards, was not played until about 1830, but was still "straight poker" or "bluff," there being no draw to improve the hands until the early '60s, during the American Civil War. About this time straights were introduced, but they ranked below triplets, beating two pairs. This led to the straight flush in the early '70s, and shortly afterward the jack pot was introduced, so as to force cautious players to come in and bet, whether they had strong hands or not. This rendered useless much of the "scientific" playing of the old school.

A card is dealt face up to each player and the first one dealt a jack takes his choice of seats and deals the first hand. Sometimes, instead of the player dealt the first jack, the one dealt the highest card takes the deal and seat, the others in order after him to the left. At the end of each hour seats may be redistributed in the same way. If a newcomer enters, cards are dealt round, and he takes his seat to the left of the holder of the first jack.

There are two standard games: draw poker and stud poker. In draw poker the "age" (player on the dealer's left) puts up a white chip "blind," which may be "straddled" by the player on his left by putting up two chips, but this is seldom done. In "all jacks," no one can draw cards until someone has "opened" by declaring he has a hand as good as a pair of jacks. In this game everyone antes the same amount and there is no straddle. The man on the dealer's left is "under the gun."

Before play begins two things must be agreed upon: a betting limit, which is the amount by which any previous bet may be increased, and the value of the blind; of the ante in jack pots. As soon as the blind or the antes have been put up the cards are dealt.

Any player may shuffle the pack, the dealer last. The player to the right of the dealer cuts and the cards are distributed one at a time from left to right until each has five. It is a misdeal if a card is found faced in the pack, or more than five are given to more than one player; but a card faced in dealing must be taken. The players then examine their hands. Those wishing to draw cards in the regular game make the ante good by putting in twice as much as the blind or straddle, with the privilege of increasing it any amount within the betting limit. Each player to the left must then "call" this amount, raise it or throw up his hand. In jack pots, each player in turn to the left of the dealer examines his hand, and if he has a pair of jacks or better, he may "open," if he wishes to do so, by betting any amount within the limit. This opening is not compulsory, the man under the gun frequently passing with nothing but jacks, owing to the disadvantage of his position.

Those who wish to draw cards against the opener may call or raise his bet without any restrictions on what they may hold, even if they passed before the pot was opened. Those who do not draw cards should not abandon their hands until they have seen that the opener has the necessary qualification. This is to protect their interest in the pot, as the opener is required always to place his discard under the chips in the pool, whether he is splitting his openers or not. Modern poker, as played in the United States, is almost all jack pots.

The betting before the draw being settled, those still in the pool draw to improve their hands. beginning with the player on the dealer's left. A player may "stand pat" or take any number from one to five, discarding an equal number face down on the table before he is helped. Any card faced in dealing for the draw cannot be replaced until all the others are helped. The cards dealt, the player to the left of the age (or in jack pots the opener) makes the first bet or passes out. Each player to the left must then either call, raise or drop out. This continues until no one will call the last bet, or until two or more have bet an equal amount. If no one antes against the age, the next deal is a jack pot. If no one opens *a* jack pot, all put up another ante and the deal passes.

If the last raise is not called, the player takes the pool without showing his hand, unless he has opened a jack pot, when he must show his opening qualification. False openers forfeit all they have put into the pool. If drawn to, they must ante for all the others for the next deal; but if any have come in against the false openers, they stay and play for the pool. When two or more hands are shown for the pool, they decide it by the rank of the hands shown, a straight flush being the best possible hand, and no-pair the lowest. The following table shows the number of each class of hand that it is possible to hold, and the odds against any individual player's holding it before the draw, in his five cards:

Table of Poker Hands

Number	Class	Odds against
40	Straight flush	64,973 to 1
624	Four-of-a-kind	4,164 to 1
3,744	Full hand	693 to 1
5,108	Flush	508 to 1
10,200	Straight	254 to 1
54,912	Three-of-a-kind	46 to 1
123,552	Two pairs	20 to 1
1,098,240	One pair	$1\frac{1}{4}$ to 1
1,302,540	No pair	Even

A straight flush is any sequence of five cards in the same suit. A royal flush is ace, king, queen, jack and ten. Four-of-a-kind is any four of the same denomination and an odd card. A full hand is three of one kind and a pair. A flush is any five cards of the same suit. A straight is five cards in sequence of different suits. Two pairs are two each of different denominations, the rank of the hand being decided by the higher pair. One pair outranks a lower pair. If the pairs are equal, the next higher card decides the tie. In flushes, the rank of the various cards decides. If the hands are still tied in any case, they divide the pool. Any hand of more or less than five cards is foul.

In addition to the standard hands, there are four that are frequently played in the South in the United States, but which have been ranked by guess-work instead of the calculated odds against them, and therefore incorrectly. These are:—

Skip straight, such as 2, 4, 6, 8, 10, played to beat two pairs; but should rank between a straight and a flush, as the odds are 423 to 1 against it. A tiger, seven high and deuce low, without a pair, sequence or flush; sometimes called big or little dog, and played to beat a straight or lose to a flush, but should beat a flush and lose to a full hand; 636 to 1 against it. Round-the-corner straight, the ace connecting the deuce and king; played to beat the smallest possible straight, which would be 5 high, as A, 2, 3, 4, 5, is not ace high, but ace low. This should rank between a full hand and four-of-a-kind, as the odds are 848 to 1 against it. A blaze, any five picture cards, such as two kings, two queens and a jack; played to beat two pairs and lose to triplets, but should rank just below four-of-a-kind; 3,008 to 1 against it.

The chances of improving any of the regulation hands by drawing to them are as follows: Drawing to one pair, the odds against getting four-of-a-kind are 359 to 1; against a full hand, 97 to 1; against triplets, 8 to 1; against two pairs, 5 to 1; against any improvement, 24 to 1. Holding up a "kicker" such as an ace, drawing two cards only, it is 4 to 1 against any improvement.

Drawing to two pairs, it is 11 to 1 against filling the hand by getting the third to either pair. Discarding the smaller pair, the chances are practically the same as drawing to one pair. Drawing to straights: If open at both ends, it is 5 to 1 against filling; if an interior, 11 to 1 against filling. Drawing to triplets: Drawing two cards, it is $22\frac{1}{2}$ to 1 against getting four-of-a-kind; $14\frac{1}{2}$ to 1 against getting a pair; and $8\frac{1}{2}$ to 1 against either improvement. If you draw one card only, to mask the hand, it is 46 to 1 against your getting four-of-a-kind; 15 to 1 against matching the odd card; and 11 to 1 against either improvement, as compared to $8\frac{1}{2}$ to 1 if you draw two cards. Drawing to flushes: Drawing to four cards, it is 43 to 1 against filling; drawing to three cards, 23 to 1 against; drawing to two cards, 96 to 1 against. Players often take these chances with two or three high cards of the same unit.

While a flush is easier to fill than a straight, it is harder to get the four-card flush to draw to in the first place. There are about 500 ways to get a four-card straight; only 112 ways to get a four-card flush.

Drawing four cards to an ace it is 4 to 1 against getting the pair; 12 to 1 against aces up or better. Drawing three cards to an ace and king, it is 3 to 1 against making a pair of either. The chances for a flush, if they are of the same suit, have been given.

In drawing against openers in jack pots, one pair is as good as another; a psir of tens is no better than deuces, as either must improve enough to beat jacks. No one is obliged to open a jack pot, even with the qualification, and the man under the gun seldom opens on just jacks.

If two or more players have bet equal amounts, each is assumed to hare called the other, and both hands must be shown to the board, it being against the rules for one to throw in and say, "that's good." This is to prevent collusion.

Stud Poker.—This is the standard game to-day. One card is dealt face down to each player and then one to each face up. The one having the highest card showing, next to the left of the dealer, makes the first bet or throws up his cards, all having seen what they have "in the hole." Each player in turn then sees this bet, raises it or passes out. Another card is then dealt to each of the survivors, and the best hand showing bets first. This is continued until four cards are face up, and one still face down. The final bets made, the "hole" cards are exposed, the hands in the call are shown and the best hand wins.

High Low Stud.—In order to keep as many in the betting as long as possible, the highest hand shown in the call divides the pool with the lowest hand.

Peek Poker.—This is a variety of stud in which seven cards are dealt to each player, two face down, and two are discarded just before the show-down.

Straights and flushes are seldom played in any form of stud.

Deuces Wild.—This is a variation for any form of poker, in which the four deuces may be called anything, regardless of whether or not the player himself holds the actual duplicate of the card named. Four hearts to the ace and the deuce of any suit may be called an ace-ace high flush. In cases of ties natural cards beat wild ones; thus three kings and a deuce will beat three deuces and a king.

Wild Widow.—One card is dealt face up in the centre of the table, and all cards of that denomination are "wild."

Joker Poker.—This is sometimes called Mistigris. The joker is added to the pack and is "wild." When added to deuces wild there is an unbeatable hand, all wild cards. Five of a kind is not uncommon in playing wild, and beats a straight flush.

Stripped Pack Poker.—In order to upset the calculations of the experts, the 2s, 3s and 4s are sometimes deleted.

Table Stakes.—In this game each player puts a certain amount on the table in front of him, which cannot be changed after he has looked at his hand. He can "call a sight" for his pile if any player or players bet more.

Whisky Poker.—An extra hand is dealt face down, and each player in turn may take it in exchange for his own, leaving his cards on the table face up. Any following player may then exchange one card or take them all. If no one takes the widow while face down the dealer turns it face up, and the players draw or exchange. This continues until some player "knocks," without drawing, and after each of the others has had a draw, the hands are shown for the pool, to which each has equally contributed. See *Webster's* Poker Book (1925). (R. F. F.)

POKOMAM, a group of Indians speaking a Maya dialect who live in southern Guatemala. Their territory runs from the upper part of the Motaqua river to the border of Salvador. They inhabit to-day the departments of Chimaltenango (in part), Guatemala, Amatitlán and Jalapa in Guatemala, and at the time of the conquest they extended to Chalchuapa in Salvador. The principal towns where this tongue is spoken are San Martin Jilotepeque, Mixco, Petapa, Jalapa, Jilotepeque and Asuncion Mita. They number about 50,000, of whom over half speak their native tongue. The ancient capital of the Pokomam was the fortress of Mixco situated on a steep hill in the valley of Xilotepeque.

POLA, a seaport of Italy, the capital of the province of Pola, in the district of Venezia Giulia, 86 mi. S. of Trieste by rail. Pop. (1936) 34,090 (town), 42,259 (commune). It was the principal naval harbour and arsenal of the Austro-Hungarian monarchy until 1918, and is situated near the southern extremity of the peninsula of Istria. It lies at the head of the Bay of Pola, and possesses a safe and commodious harbour almost completely landlocked. An extensive system of fortifications, constructed on the hills which enclose the harbour, defends its entrance, while it also possesses a good roadstead in the large channel of Fasana.

The modern town of Pola lies round the base of a hill formerly crowned by the Roman capitol, and now by a castle of the 17th century. Besides the castle the chief buildings are the cathedral, burnt down in 1923 and reconstructed on the lines of a 6th cent. Ravenna basilica; the new garrison church, completed in 1898 in the basilica style, with a marble façade; and the Franciscan church dating from the 14th century. To the south-west, along the coast, extends the marine arsenal, which has now been dismantled; the large barracks are equally deserted. The chief interest of Pola centres in its fine Roman remains. The most extensive of these is the amphitheatre built in A.D. 198–211, in honour of the emperors Septimius Severus and Caracalla, which is 79 ft. high, 400 ft. long and 320 ft. wide, and could accommodate about 23,000 spectators. It is remarkable as the only Roman amphitheatre of which the outer walls have been kept intact. The history of Pola begins with its capture by the Romans in 178 B.C. It was destroyed by Augustus on account of its espousal of the cause of Pompey, but was rebuilt under the name of Pietas Iulia, and was mainly important as a harbour. Later it became the capital of the margraves of Istria, and was captured by the Venetians in 1148. In 1379 the Genoese, after defeating the Venetians in a great naval battle off the coast, took and destroyed Pola, which disappears from history for the next four hundred and fifty years. It remained under Venetian supremacy down to 1797, and fell under Austria in 1815.

See T. G. Jackson, *Dalmatia, the Quarnero and Istria,* vol. iii. (1887).

POLABS (*Po*=on, *Laba*=Elbe), the Slavs (*q.v.*) who dwelt upon the Elbe and eastwards to the Oder. Except the Lithuanians they were the last Europeans to be Christianized; their chief sanctuary was at Arcona on the Isle of Riigen. They were converted and conquered in the 12th century and Germanized. By the 17th century Slavonic survived only in a tiny patch in the east of Hanover about Liichow; its scanty remains are corrupt.

POLAND (POLSKA), an independent republic, formally constituted on March 21, 1921, out of territories which had belonged since 1815 to Prussia, Austria and Russia. The northern, western and southern frontiers, marching with Germany, Czechoslovakia and Rumania, were fixed, mainly on ethnological principles, by the Treaty of Versailles. The north-east and eastern frontiers march with the frontiers of Lithuania, Latvia and the Soviet Union, and were determined by political and historical as well as ethnological considerations after the Treaty of Riga.

Geology. — The oldest rocks in the country outcrop in the south, forming the Lysa Gora, slightly to the east of Kielce. They form part of the Palaeozoic platform. often known as "the Polish platform," against which the younger Carpathian fold mountains to the south were niched up. The general south-east to north-west trend of the fold mountains was turned first to east and west and then, with further resistance from the Bohemian mass, almost north-east to south-west. The plateau of Tarnowice and other regions in the two provinces of Piotrkow and Rielce have Triassic, Jurassic and Cretaceous outcrops. The south-eastern section of the country has extensive Cretaceous outcrops centred around Lublin. These are interspersed by Tertiary rocks, particularly in the neighbourhood of Lwów. The valleys of the Upper Dniester and Vistula have Quaternary material, while on the northern slopes of the Carpathians, and in Galicia generally, there are deposits of fertile loess—a factor potent in the history and early settlement of the region. The entire northern section of the country has a covering of boulder clay, containing much marshland and myriads of small shallow lakes. The extensive Pripet marshes on the east of Poland, near Pinsk, have played a very important part in differentiating Poland and Russia.

Physical Features. — The undulating plain which forms the main part of the territory of Poland has no natural boundaries on the east and west, but connects the lowlands of Germany with the great plain of Russia. It extends from the Carpathian mountains in the south to the Baltic sea; it touches the Dvina in the north-east and just reaches the Oder in the south-west. But the Polish plain is not uniform. In the south the Carpathians form a mountainous belt reaching its highest point in the Tatra. North of this is the Carpathian plain, extending from west to east along the Upper Vistula, the San and the Dniester. North of this plain lie the southern uplands comprising the Silesian hills, the Cracow Jura, the Galician plateau, the Lysa Gora, the Lublin hills and the Podolian plateau, a region too diversified to be called a plain, and rising to heights of over 2,000 ft. above the sea. North of these uplands lies the central Polish plain—Poznan, Mazovia, Podlasia and Polesie, intersected by great rivers, and bounded on the north by a second belt of uplands, 600 to 700 ft. above the sea, covered with lakes, marshes and swamps extending from Pomerania through the Mazovian lakes to White Russia. The Baltic coast forms the northern limit of these uplands. Whereas the network of lakes and rivers, and the resulting facility of communication by land and water, together with the fertility of the soil, have made the great plain from Poznan to Warsaw the cradle of Polish nationality; the southern uplands, with their greater security and the vast mineral wealth, have been equally important.

Rivers, Lakes **and** Canals.—The basin of the Vistula comprises the central part of Poland. The Vistula rises in the western Beskids, flows through Cracow and Sandomierz, is joined by the San and Wieprz, which water the provinces of Ewow and Lublin respectively, then by the Pilica. It flows through the Mazovian plain past Warsaw and Plock, being joined by the Bug, rising in the Podolian plateau, and its tributary, the Narew. The tributaries of the Narew rise in the Lake district, most of which is in Prussia, and are connected by the Augustów canal with the river Niemen. The Bug is also connected by the Royal canal with the Pripet, and so with the Dnieper. The Vistula continues its course through the ancient land of Chelmno, near Torun, Bydgoszcz and Grudzianz, being connected with the Oder basin by the Bydgoszcz canal. Its estuary, the object of long struggles between Poles and Germans, lies in the Free City of Danzig.

The inundations of the Vistula, serious even at Cracow, are dangerous after it enters the plain, when the heavy rains in the Carpathians raise its level or the accumulations of ice in the lower course obstruct the outflow.

The west of Poland belongs partly to the basin of the Oder. The Warta, 450 m. in length, rises in the southern uplands, and with its tributaries, the Prosna and Notec, forms the fertile plain of Great Poland, in which the earliest capitals, Gniezno, Poznan and Kalisz grew up in the district of lakes of which Goplo, So m. long and 100 ft. deep, is famed in legend and history.

In the far north-east, Poland touches the basin of the Dvina. Part of the province of Vilna is drained by its tributary, the Disna, and contains a great region of swamps and lakes, of which Lake Narocz ($31\frac{1}{2}$ sq.m.), is the largest lake in Poland The area between the Niemen, the Narew and the Jasiolda contains the largest forests in Poland, and rafts of timber float down 311 these rivers. South of the Niemen basin is the basin of the Pripct, a tributary of the Dnieper.

It is the region of dense forests and wide swamps, and is connccted by the Oginski carial with the Niemen, and by the Royal canal with the Bug. Its right tributaries, such as the Styr, water the Volhynian plain.

Lastly, the river Dniester and its tributaries drain the southeast part of Poland down to the Rumanian and Russian frontiers, comprising the provinces of Tarnopol and Stanislawów and the oilfields of Lwow.

Climate.—The climate of Poland is dependent on her proximity to the Baltic and the Carpathian mountains. Abundant rainfalls are caused by the predominating western oceanic winds. Consequently, the snow in Poland is not very thick, and spring sets in early. Frosts of $-4°$ to $-22°$ F. are not uncommon, however, and the rivers are generally icebound for two and a half to three months.

The average yearly temperature varies from 46° in Poznan to 32° F. in Pinsk. The character of the climate is more continental in the eastern provinces.

In Warsaw, the central capital, the earliest frost is about Oct. 18, the latest frost about March 15.

The absolute maximum temperature is 95.5°, the absolute minimum temperature $-37.6°$ F.

The annual rainfall is about 22.8 inches.

Flora.—The flora of Poland is characteristic of the transitional position of Poland between east and west. All the floral zones of Europe are found here. Deciduous forests merge into coniferous forests; the western flora of the Baltic meets the steppe flora of the Black sea. Of the original Polish trees the pine (*Pinus sylvestris*) is found almost everywhere, together with the birch and the alder.

The yew and the larch, once so common, have disappeared. The fir has entered Poland from Siberia and is common. Among western European trees the oak, beech, hornbeam, elm, ash, lime tree, aspen and maple are common, the beech not appearing east of Brest-Litovsk and the fir only north of Lwow. The oak—a highly venerated tree, especially in the Lithuanian region—grows in forests only on the most fertile land, but it is of common occurrence in conjunction with the beech and elm.

The lime appears in groves only in the east. It is the most popular tree with the Poles; judgment of old was pronounced under its shade, and the folk songs repeat its name.

Ivy is characteristic of all parts of Poland, while the willow and orchard trees—apple, pear, plum and cherry—are cultivated everywhere.

Fauna.—The indigenous fauna of Poland has disappeared in historical times. The reindeer, the sable and the wild horse survive in tradition. The aurochs or bison. preserved in the great Bialowieź forest, disappeared in 1918. The elk is heard of in the northeast, and the beaver, once so common, is found only in the marshes of Polesie.

The chamois and marmot are found in the Tatra mountains, while the Carpathians still form a refuge for the bear, the wild cat, the lynx, the badger and the wild boar. Otherwise the bear and wolf are uncommon except in the northeast.

The fox is ubiquitous, while the marten, polecat, etc., are not uncommon.

The avifauna is similar to that of central Europe, and is slightly to westward of the most frequented route of the migratory birds in Russia.

HISTORY

We possess no certain historical data relating to Poland till the end of the 10th century. The earliest Polish chroniclers are of little help to us. The only facts of importance to be gleaned from them are that Prince Ziemovit, the great-grandfather of Mieszko (Mieczyslaw) I. (962–992), wrested from the vast but tottering Moravian empire the province of Chrobacyja (extending from the Carpathians to the Bug), and that Christianity was first preached on the Vistula by Greek Orthodox missionary monks. Mieszko himself was converted by Jordan, the chaplain of his Bohemian consort, Dobrawa or Bona, who became the first bishop of Poznan. The Slavonic peoples, whose territories then extended to the Elbe, and embraced the whole southern shore of the Baltic, were beginning to recoil before the vigorous impetus of the Germans in the West and the acceptance of Christianity might give them a respite from further attack. This was thoroughly understood by Mieszko's son Boleslaus I. (992–1025), who aimed at securing the independence of the Polish Church as an additional guarantee of the independence of the Polish nation, and elevated the church at Gnesen in Great Poland into a metropolitan see, with jurisdiction over the new bishoprics of Cracow, Breslau and Rolberg, created in territory which he had recently conquered. Boleslaus was the first Polish prince to bear the royal title, and his reign resulted in the formation of a vast kingdom extending from the Baltic to the Carpathians, and from the Elbe to the Bug. In the next generation much of the territory which he had won was lost, and Poland itself was ravaged by neighbouring enemies, but under Boleslaus II. (1058–79) and Boleslaus III. (1102–39) some of the lost provinces, notably Silesia and Pomerania, were recovered and Poland was at least able to maintain her independence against the Germans. Boleslaus III., moreover, with the aid of St. Otto, bishop of Bamberg, succeeded in converting the heathen Pomeranian~(1124–28), and making head against paganism generally.

Yartitional Period, 1138–1305.—The last act of Boleslaus III. was to divide his territories among his sons, whereby Poland was partitioned into no fewer than four, and ultimately into as many as eight, principalities, many of which (Silesia and Great Poland, for instance) in process of time split up into still smaller fractions all of them more or less bitterly hostile to each other. This partitional period, as Polish historians generally call it, lasted from 1138 to 1305, during which Poland lost all political significance, and became an easy prey to her neighbours. The duke of Little Poland, who generally styled himself duke of Poland, or *dux totius* Poloniae, claimed a sort of supremacy among these little States, a claim materially strengthened by the wealth and growing importance of his dapital, Cracow, especially after Little Poland had annexed the central principality of Sieradia (Sieradz). But Masovia to the north, and Great Poland to the north-west, refused to recognize the supremacy of Little Poland, while Silesia soon became completely germanized and Pomerania broke away from the Polish suzerainty. To ards the middle of the 13th century a horde of Tatars under their prince Batu invaded Poland, burned Sandomir and Cracow, defeated the Silesian princes at Leignitz, and finally entered Hungary, where they routed King Bela IV. on the banks of the Sajo. This invasion had an important influence upon the social and political development of Poland. The only way of filling up the gaps in the population of the ravaged land was to invite foreign immigrants of a superior class, chapmen and handicraftsmen, not only given to peaceful pursuits and accustomed to law and order, but capable of building and defending strong cities. Such immigrants could naturally be obtained only from the civilized west, and on their own terms. Thus it came about that a new Germanic middle class element was introduced into Polish society. Immediately dependent upon the prince, from whom they obtained their privileges, the most important of which were self-government and freedom from taxation, these traders soon became an important factor in the State, counterpoising, to some extent, the influence of the nobility and developing the resources of the country.

Most of these German citizens were ultimately absorbed by the Polish population. But they were not the only Germans with whom the Polish State had now to deal. In the first year of the 13th century, a powerful crusading order, the Knights of the Sword, had been established in Livonia for the reduction of the pagan Letts, and, in 1208, the still stronger Teutonic Order was invited by Duke Conrad of Masovia to settle in the district of Kulm (roughly corresponding to modern East Prussia) to protect his territories against the incursions of the savage Prussians, a race closely akin to the Lithuanians. Conrad has been loudly blamed by Polish historians for introducing this foreign, and as it ultimately proved, dangerous element into Poland. But the unfortunate prince had to choose between dependence and extermination, for his unaided resources were powerless against the persistent attacks of the unconquerable Prussians. By the compact of Kruschwitz in 1230, the Teutonic Order obtained absolute possession of the maritime district between Pomerania acd Courland, and southwards as far as Torun. So far mere the Poles from anticipating any danger from the Teutonic Order, that, from 1243 to 1255, they actually assisted it to overthrow the independent Pomeranian princes, the most formidable opponents of the Knights in the earlier years of their existence. A second Tatar raid in 1259, less dangerous, perhaps, but certainly more ruinous, than the first invasion—for the principalities of Little Poland and Sandomir were systematically ravaged for three months—still further depressed the land, and, at this very time, another enemy appeared in the east—the Lithuanians. (See LITHUANIA.)

Casimir the Great, 1333–70.—At the very time when Lithuania was becoming a compact, united, powerful State, it seemed highly probable that Poland would be completely germanized, like Silesia, or become a part of the new Bohemian empire which Wenceslaus II. (crowned king of Poland in 1300) had inherited from his father, Ottakar II. From this fate she was saved by the valour of Wladislaus Lokietek, duke of Great Poland (1306–33), who reunited Great and Little Poland, revived the royal dignity in 1320, and saved the kingdom from annihilation by his great victory over the Teutonic Knights at Plowce in 1332. The whole reign of Wladislaus I. was indeed an unceasing struggle against all the forces of anarchy and disintegration; but the fruits of his labours were richly reaped by his son Casimir III. the Great (1333–70), Poland's first great statesman in the modern sense of the word, who, by a most skilful system of matrimonial alliances, reintroduced Poland into the European system, and gave the exhausted country an inestimably beneficial breathing space of 37 years. A born ruler, Casimir introduced a whole series of administrative and economical reforms. He was the especial protector of the cities and the peasants. It is to him that Poland owed the important acquisition of the greater part of Red Ruthenia, or Galicia, which enabled her to'secure her fair share of the northern and eastern trade. In default of male issue, Casimir left the Polish throne to his nephew, Louis of Hungary, who ruled the country (1370–82) through his mother, Queen Elizabeth, Wladislaus Lokietek's daughter. Louis well deserved the epithet of "great" bestowed upon him by his contemporaries; but Poland formed but a small portion of his vast domains, and Polish interests were subordinated to the larger demands of an imperial policy which embraced half Europe within its orbit.

On the death of Louis there ensued an interregnum of two years marked by fierce civil wars, instigated by duke Ziemovit of Masovia, the northernmost province of Poland, which continued to exist as an independent principality alongside of the kingdom of Poland. Ziemovit aimed at the Polish crown, proposing to marry the infant princess Jadwiga of Hungary, who, as the daughter of Louis the Great and the grand-daughter of Wladislaus Lokietek, had an equal right, by inheritance, to the thrones of Hungary and Poland. By an agreement with the queen mother of Hungary at Kassa in 1383, the Poles finally accepted Jadwiga as their queen, and, on Feb. 18, 1386, greatly against her will, the young princess was wedded to Jagiello, grand duke of Lithuania, who had been crowned king of Poland at Cracow, three days previously, under the title of Wladislaus II.

The union of Poland and Lithuania as separate States under one king had been brought about by their common fear of the Teutonic Order. Five years after the death of Gedymin (*q.v.*), Olgierd, the most able of his seven sons, had been placed upon the throne of Lithuania by his devoted brother Kiejstut, and for the next 32 years (1345–77) the two princes still further extended the sway of Lithuania, principally at the expense of Muscovy and the Tatars. Kiejstut ruled the western portion of the land where the Teutonic Knights were a constant menace, while Olgierd drove the Tatar hordes out of the south-eastern steppes, and compelled them to seek a refuge in the Crimea. During Olgierd's reign the southern boundaries of Lithuania touched the Black sea, including the whole tract of land between the mouth of the Bug and the mouth of the Dnieper. Olgierd was succeeded by his son Jagiello as grand duke in 1377, while Kiejstut was left in possession of Samogitia, Troki and Grodno; but the Teutonic Order, alarmed at the growth of Lithuania, succeeded in estranging uncle and nephew, and Kiejstut was treacherously assassinated by Jagiełło's orders, at Krewo, on Aug. 1j, 1382. Three weeks later Jagiełło was compelled to cede Samogitia, as far as the Dubissa, to the Knights, and, in the following year they set up against him Kiejstut's son Witowt. At this point Jagiello made peace with his cousin, restored him his patrimony, and made overtures to Poland for the hand of Jadwiga, and received the Polish crown along with it, as already mentioned.

Beginnings of the Polish Constitution.—Before proceeding to describe the Jagiełłonic period of Polish history, it is necessary to cast a rapid glance at the social and political condition of the country in the preceding Piast period.

The paucity and taciturnity of our sources make it impossible to give anything like an adequate picture of Old Poland during these centuries. External pressure, here as elsewhere, created a patriotic military caste, and the subsequent partitional period, when every little prince had his own separate court, still further established the growing influence of the *szlachta*, or gentry. The first authentic *pacta conventa* made between the Polish nobility and the Crown dates from the compact of Kassa (Sept. 17, 1374), when Louis of Hungary agreed to exempt the *szlachta* from all taxation, except two Polish groschen per hide of land, and to compensate them for the expenses of all military service rendered beyond the confines of the realm. The clergy received their chief privileges much earlier. It was at the synod of Leczyca, nearly a century before the compact of Kassa, that the property of the church was first safeguarded against the encroachments of the State. The beneficial influence of the Church of Poland in these early times was incalculable. To say nothing of the labours of the Cistercians as colonists, pioneers and church-builders, or of the missions of the Dominicans and Franciscans, the church was the one stable and unifying element in an age of centrifugal particularism. Its frequent synods represented the whole of Poland, and kept alive, as nothing else could, the idea of national solidarity. Moreover the clergy, to their eternal honour, consistently protected the lower from the tyranny of the upper classes.

The growth of the towns was slower. During the heroic Boleslawic period there had been a premature outcrop of civil life. As early as the 11th century Kruszwica, the old Polish capital. and Gnesen, the metropolitan see, were of considerable importance, and played a leading part in public life. But in the ensuing anarchic period both cities were utterly ruined, and the centre of political gravity was transferred from Great Poland to Little Poland, where Cracow, singularly favoured by her position, soon became the capital of the monarchy, and one of the wealthiest cities in Europe. At the end of the 14th century we find all the great trade gilds established there, and the cloth manufactured at Cracow was eagerly sought after, from Prague to Great Novgorod. Towards the end of the 14th century the Polish towns even attained some degree of political influence, and their delegates sat with the nobles and clergy in the king's councils. Even the peasants, who had suffered severely from the wholesale establishment of prisoners of war as serfs on the estates of the nobles, still preserved the rights of personal liberty and free movement from place to place. The only portion of the community which had no privileges were the Jews, first introduced into Poland by Boleslaus the Pious, duke of Great Poland, in 1264, when bitter persecutions had driven them northwards from the shores of the Adriatic. Casimir the Great extended their liberty of domicile over the whole kingdom (1334). From the first they were better treated in Poland than elsewhere, though frequently exposed to outbreaks of popular fanaticism.

Wladislaus II and the Teutonic Order.—The transformation of the pagan Lithuanian chieftain Jagiello into the Catholic king of Poland, Wladislaus II, was an event of capital importance in the history of eastern Europe. Its immediate and inevitable consequence was the formal reception of the Lithuanian nations into the fold of the church. What the Teutonic Order had vainly endeavoured to bring about by fire and sword. for two centuries, was peacefully accomplished by Jagiello within a single generation, the Lithuanians, for the most part, willingly following a prince of their own blood. The conversion of Lithuania menaced the very existence of the Teutonic Knights, whose dominion was now little more than a German military forepost, extending from Pomerania to the Niemen, and cutting off the central Slavs from the sea. But if the Order had now become a superfluous anachronism, it had still to be disposed of, and this was no easy task For if it had failed utterly as a mission in partibus, it had succeeded in establishing on the Baltic one of the strongest military organizations in Europe. In the art of war the Knights were immeasurably superior to all their neighbours. Skilfully taking advantage of the jealousies of Poland and Lithuania, accentuated as they were by the personal antagonism of Jagiello and Witowt (*q.v.*), they even contrived (Treaty of Salin, 1378) to extend their territory by getting possession of the province of Samogitia, the original seat of the Lithuanians, where paganism still persisted. By this time, however, the prudent Jagiello had become convinced that Lithuania was too strong to be ruled by or from Poland, and yet not strong enough to stand alone, and by the compact of Vilna (Jan. 18, 1401, confirmed by the compact of Radowo, March 10) he surrendered the whole grand duchy to Witowt, on the understanding that the two States should have a common policy. and that neither of thkm should elect a new prince without the consent of the other. The wisdom of this arrangement was made manifest in 1410, when Jagiełło and Witowt combined their forces for the purpose of delivering Samogitia from the intolerable tyranny of the Knights. The issue was fought out on the field of Tannenberg, or Griinewald (July 15, 1410), when the Knights sustained a crushing defeat, which shook their political organization to its very foundations. A few weeks after the victory the towns of Thorn, Elbing, Braunsberg and Danzig submitted to the Polish king, and all the Prussian bishops voluntarily offered him homage. But the excessive caution of Jagiello gave the Knights time to recover from the blow; the Polish levies proved unruly and incompetent; Witowt was suddenly recalled to Lithuania by a Tatar invasion, and thus it came about that, when peace was concluded at Thorn, on Feb. 1, 1411, Samogitia, finally surrendered in 1422, Dobrzyn, and a war indemnity of 100,000 marks payable in four instalments, were the best terms Poland could obtain from the Knights. The solidarity of Poland and Lithuania was still further strengthened by the Union of Horodlo (Oct 2, 1413) which enacted that henceforth Lithuania was to have the same order of dignitaries as Poland, as well as a council of State, or senate, similar to the Polish senate. The power of the grand-duke was also greatly increased. He was now declared to be the equal of the Polish king, and his successor could be elected only by the senates of Poland and Lithuania in conjunction. The Union of Horodlo also established absolute parity between the nobility of Poland and Lithuania, but the privileges of the latter were made conditional upon their profession of the Roman Catholic faith, experience having shown that difference of religion in Lithuania meant difference of politics, and a tendency Moscowwards, the majority of the Lithuanian boyars being of the Greek Orthodox Confession.

Had Wladislaus II. been as great a warrior as Witowt he might, perhaps, have subdued the Knights altogether. But he was essentially a diplomatist, and as such he was hampered by the suspicion felt towards him by the emperor Sigismund, who as king of Bohemia feared that his subjects would be attracted towards the new power which had arisen in the north-east. As emperor, Sigismund resented Wladislaus's encroachments upon territory formerly in German occupation, and though he was careful to avoid giving to Wladislaus any excuse for accepting the Bohemian crown, his influence mas inevitably on the side of the Teutonic Order. Nevertheless the Order never recovered the position which it had held before the battle of Tannenberg and the conversion of its possessions into a territorial State was only a question of time.

Wladislaus II. died at Lemberg in 1434, at the age of 83. During his long reign of 49 years Poland had gradually risen to the rank of a great power. The next ten years proved the stability of his work. After the death at Varna, in 1444, of his eldest son and successor, Wladislaus III., the kingdom which he had founded was consolidated by his second son, already grand-duke of Lithuania, who ascended the Polish throne as Casimir IV. in 1447, thus reuniting Poland and Lithuania under one monarch.

Casimir IV., 1447–92.—The difficulties which confronted Casimir were great. He instinctively recognized not only the vital necessity of the maintenance of the union between the two States, but also the fact that the chief source of danger to the union lay in Lithuania. For political reasons, during the earlier years of his reign, Casimir was obliged to reside for the most part in Lithuania, and his interest in the grand-duchy was always resented in Poland, where, to the very end of his reign, he was regarded with suspicion. In particular, he could never rely on adequate Polish support in the struggle which he inherited from his predecessors, with the Teutonic Order.

The struggle assumed a new form in 1454, when Casimir accepted the suzerainty offered to him by the Prussian League, which had ejected the authority of the Order, and needed a protector. The acquisition of the Prussian lands was vital to the existence of Poland. It meant the command of the principal rivers of Poland, the Vistula and the Niemen, and the acquisition of a seaboard with its corollaries of sea-power and commerce. Yet, except in the border province of Great Poland, which was interested commercially, the king received little support, military or financial, and it was only with his victory at Puck (Sept. 17, 1462) that he obtained any decisive success against the Order. The war was ended in 1466 by the second treaty of Thorn (Oct. 14) by which Poland recovered the provinces of Pomerelia, Kulm and Michalow, with the bishopric of Ermeland, numerous cities and fortresses, including Marienburg, Elbing, Danzig and Thorn. The territory of the Knights was now reduced to Prussia proper, embracing, roughly speaking, the district between the Baltic, the lower Vistula and the lower Niemen, with Königsberg as its capital. For this territory each grand-master within nine months of his election was in future to render homage to the Polish king, who undertook not to make war or engage in any important enterprise without Prussian consent. Prussia had now become a Polish province, and Poland had acquired a seaboard.

The whole foreign policy of Casimir IV. was influenced by the Prussian question. At the beginning of the war both the empire and the pope were against him. He therefore allied himself with George of Podiebrad, whom the Hussites had placed on the throne of Bohemia On the death of George (1471), Casimir's eldest son Wladislaus was elected king of Bohemia by the Utraquist party, despite the determined opposition of Matthias Corvinus, the king of Hungary, who thenceforward deliberately set about traversing all the plans of Casimir. He encouraged the Teutonic Order to rebel against Poland; he entertained at his court anti-Polish embassies from Moscow; he encouraged the Tatars to ravage Lithuania; he thwarted Casimir's policy in Moldavia. His death in 1490 came therefore as a distinct relief to Poland, and all danger from the side of Hungary was removed when Casimir's son Wladislaus, already king of Bohemia, was elected king of Hungary also.

Poland and the Turks.—It was in the reign of Casimir IV. that Poland first came into direct collision with the Turks. The Jagiellos, as a rule, prudently avoided committing themselves to any political system which might irritate the still distant but much-dreaded Turk, but when their dominions extended so far southwards as to embrace Moldavia, the observance of a strict neutrality became exceedingly difficult. Poland had established a sort of suzerainty over Moldavia as early as the end of the 14th century; but at best it was a loose and vague overlordship which the Hospodars repudiated whenever they were strong enough to do so The Turks themselves were too much occupied elsewhere to pay much attention to the Danubian principalities till the middle of the 15th century, and it was not till 1484 that they became inconvenient neighbours to Poland. In that year a Turkish fleet captured the strongholds of Kilia and Akkerman, commanding respectively the mouths of the Danube and Dniester. This aggression seriously threatened the trade of Poland, and induced Casimir IV. to accede to a general league against the Porte. In 1485, after driving the Turks out of Moldavia, the Polish king, at the head of 20,000 men, proceeded to Kolomea on the Pruth, where Bayezid

II., then embarrassed by an Egyptian war, offered peace, but as no agreement concerning the captured fortresses could be arrived at, hostilities were suspended by a truce. During the remainder of his reign the Turks gave no trouble.

The death of Casimir was followed by the temporary separation of Poland and Lithuania, and by a strong aristocratic reaction in Poland itself. Casimir's third son, John Albert, was elected king of Poland, and his fourth son, Alexander, became grand-duke of Lithuania. On the death of John Albert in 1501, Alexander succeeded him as king, and the union of Poland and Lithuania assumed a more definite character, the senate of each country agreeing that in future the king of Poland should always be grand-duke of Lithuania. The acquiescence of Lithuania was due essentially to a new danger which had arisen in the East. Till the accession of Ivan III. in 1462 MUSCOVY had been a negligible factor in Polish politics. During the earlier part of the 15th century the Lithuanian princes had successfully contested Muscovite influence even in Pskov and Great Novgorod. Many Russian historians even maintain that, but for the fact that Witowt had simultaneously to cope with the Teutonic Order and the Tatars, he would have extinguished struggling Muscovy altogether. But since the death of Witowt (1430) the military efficiency of Lithuania had sensibly declined; and the natural attraction of the Orthodox-Greek element in Lithuania towards Muscovy threatened the integrity of the grand-duchy. During the reign of Alexander, who was too poor to maintain any adequate standing army in Lithuania, the Muscovites and Tatars ravaged the whole country at will, and were prevented from conquering it altogether only by their inability to capture the chief fortresses. In Poland, meanwhile, Alexander had practically surrendered his authority to an incapable aristocracy, while the dependent States of Prussia in the north and Moldavia in the south made strenuous efforts to break away. Fortunately for the integrity of the Polish State the premature death of Alexander in 1506 brought upon the throne his capable brother Sigismund, the fifth son of Casimir IV. Eminently practical, Sigismund recognized that the first need of Poland was a standing army, that Poland, in order to hold her own, must in future follow the example of the West, and wage her warfare with trained mercenaries. The wide financial and military liberties of the Polish aristocracy for long prevented both the organization of an adequate national army and the development of a modern fiscal system. Much of the internal history of Sigismund's reign turns on the various proposals made towards these ends, most of which were defeated or mutilated by the aristocratic opposition in the diet. The long, open frontiers of the Polish kingdom invited invasion, and the misfortunes which fell on Poland at a later time are largely due to the failure of the defensive measures proposed by Sigismund and his advisers. Throughout his reign, the king was hampered by lack of resources. In 152j he was compelled to grant autonomy to the province of Prussia instead of annexing it; he was unable to succour his unfortunate nephew, Louis of Hungary, against the Turkish peril, or to prevent the occupation of one Lithuanian province after the other by the Muscovites.

The Cossacks.—To this period belong the first attempts to provide for the defence of the *dzikie pola,* or "savage steppe," as the vast plain was called which extended from Kiev to the Black sea. Thus, in the reign of Alexander, the fugitive serfs who had escaped into this wilderness (they were subsequently known as Kazaki, or Cossacks, a Tatar word meaning freebooters) were formed into companies (c. 1504) and placed at the disposal of the frontier *starostas,* or lord marchers, of Kaniev, Kamenets, Czerkask on the Don and other places. But these measures proved inadequate, and in 1533 the lord marcher, Ostafi Daszkiewicz, the hero of Kaniev, which he had successfully defended against a countless host of Turks and Tatars, was consulted by the diet as to the best way of defending the Ukraine permanently against such inroads. The veteran expert advised the populating and fortifying of the islands of the Dnieper. But nothing was done officially. The selfish prudence of Queen Bona did more for the national defence than the Polish State could do. To defend her immense possessions in Volhynia and Podolia, she converted the castles of Bar and Krzemieniec into first-class fortresses, and placed the former in the hands of her Silesian steward, who acquitted himself so manfully of his charge that "the Tatars fell away from the frontier all the days of Pan Pretficz," and a large population settled securely beneath the walls of Bar, henceforth known as "the bastion of Podolia."

The most important political event in eastern Europe during the reign of Sigismund was the collapse of the ancient Hungarian monarchy at Mohacs in 1526. After the death of King Louis in the battle, the emperor Ferdinand and John Zapolya, voivode of Transylvania, competed for the vacant crown, and both were elected almost simultaneously. In Poland Zapolya's was the popular cause, and he also found powerful support in the influential and highly gifted Laski family, represented by the Polish chancellor and his nephews John and Hieronymus. Sigismund, on the other hand, favoured Ferdinand of Austria. He argued that the best way to keep the Turk from Poland was for Austria to incorporate Hungary, in which case the Austrian dominion would be a strong and permanent barrier against a Muslim invasion of Europe. History has more than justified him, and the long duel which ensued between Ferdinand and Zapolya (see HUNGARY: History) enabled the Polish monarch to maintain to the end a cautious but observant neutrality. More than once, indeed, Sigismund was seriously compromised by the diplomatic vagaries of Hieronymus Laski, who entered the service of Zapolya (since 1529 the protégé of the sultan), and greatly alarmed both the emperor and the pope by his disturbing philo-Turk proclivities It was owing to Laski's intrigues that the new hospodar of Moldavia, Petrylo, after doing homage to the Porte, intervened in the struggle as the foe of both Ferdinand and Sigismund, and besieged the Grand Hetman of the Crown, Jan Tarnowski, in Obertyn, where, however, the Moldavians (Aug. 22, 1531) sustained a crushing defeat, and Petrylo was slain. Nevertheless, so anxious was Sigismund to avoid a collision with the Turks, that he forbade Tarnowski to cross the Moldavian frontier, and sent a letter of explanation to Constantinople. On the death of John Zapolya, the Austro-Polish alliance was still further cemented by the marriage of Sigismund's son and heir, Sigismund Augustus, with the archduchess Elizabeth. In the reign of Sigismund was effected the incorporation of the duchy of Masovia with the Polish crown, after an independent existence of 500 years. In 1526 the male line of the ancient dynasty became extinct, and on Aug. 26 Sigismund received the homage of the Masovians at Warsaw, the capital of the duchy and ere long of the whole kingdom.

THE REFORMATION TO THE PARTITIONS

The Renaissance Era.—The reigns of Sigismund I. and his son Sigismund II. (1548–72) mark the transition from a splendid, but still essentially mediaeval phase of Polish civilization into the heyday of the Renaissance.

Already in the 15th century the University of Cracow had brought forth humanist scholars of European repute, and begun to attract distinguished lecturers and numerous students from abroad. Owing to Sigismund I.'s marriage to a Sforza of Milan, the royal court at Cracow became the home of the highest Renaissance art of Italy, and the royal castle on Wawel hill at Cracow, rebuilt by Italian architects and their Polish disciples, became one of the finest monuments of Renaissance style north of the Alps. Under Sigismund II., the third great spiritual factor of the age, next to humanist scholarship and Renaissance art—the doctrine of the Reformation--entered potently into Poland's intellectual life, uniting with Italian culture on the common ground of literature, and helping to produce the first great age of Polish poetry and prose. At the same time, the clash between the New Learning and the strong tradition of Poland's chivalrous Catholicism; the difficulties with the Scandinavian Powers and the rising empire of the Moscow tsars; the dilemma produced between the evolution of the Polish Parliamentary system, and the Renaissance tendency towards the strengthening of central Government authority: even a king of genius could be only partially successful in coping with all these tasks, and the reign of Sigismund II., in many respects one of the most brilliant in Polish annals, left the seeds of decay and failure behind it.

Reformation and Counter-Reformation.—The new king having shown his temper by marrying a lady of the noble house of Radziwill without asking for the opinion of the senate, the reign began in a storm of demands for constitutional guarantees to secure the parliamentary "gentry democracy" against the powers of the Crown and the nobility. The king resolutely allied himself with Austria abroad, and with the bishops and the nobles at home, against a threatened revolt of the gentry. In doing so, he had to take the bishops' side in the issue between the Reformation and Catholic orthodoxy, and he affirmed this by an edict against heresy in 1550. But this act only opened up the long-maturing dispute about the creation of a national Church after the recent example of Henry VIII. of England. The king, a man of enlightened mind, the first Polish monarch who habitually used the vernacular language instead of Latin at public functions, showed, in many ways a sympathetic understanding for the tendencies of the new era. The influence of the Bohemian Hussite movement of 100 years before, combined with nascent modern nationalism to inspire definite programmes for a Reformed Polish State Church with Polish ritual, independent of Rome, and with a priesthood subject to Government authority. The large Greek Orthodox element among the citizens of the eastern provinces of the monarchy furnished an additional stimulus, which gave strength to such demands as that for the abolition of clerical celibacy, in the Lutheran fashion. The bishops resorting to high-handed measures of repression, the Diet of Piotrków in 1552 voted, at the king's own suggestion, the suspension of clerical courts for a twelvemonth. This was afterwards extended, and solemnly renewed by another diet in 1555, during which Masses were actually said in Polish, and the Communion was administered in two kinds. A religious interim of about ten years followed, during which Protestantism in Poland flourished exceedingly. Presently reformers of every shade of opinion, even those who were tolerated nowhere else, poured into Poland, which speedily became the battle-ground of all the sects of Europe. Soon the Protestants became numerous enough to form ecclesiastical districts of their own. The first Calvinist synod in Poland was held at Pinczów in 1550. The Bohemian Brethren, expelled from their own country, ultimately coalesced with the Calvinist at the synod of Kozminek (Aug. 1555). In the diet itself the Protestants were absolutely supreme, and invariably elected a Calvinist to be their marshal. The king, however, perceiving a danger to the constitution in the violence of the gentry, not only supported the bishops, but quashed reiterated demands for a national synod. The diet of 1558–59 indicates the high-water mark of Polish Protestantism. From this time forward it began to subside, gradually but unmistakably, chiefly owing to the division among the reformers themselves. From the chaos of creeds resulted a chaos of ideas on all imaginable subjects, politics included. The Anti-Trinitarian heresy proved to be the chief dissolvent, and from 1560 onwards the relations between the Lutherans and the Calvinists, were fratricidal rather than fraternal: Jan Laski (*q.v.*), vainly strove to unite all Polish Protestants round the Helvetian standard; and a Federation of all Poles of the reformed faith—the "Concord of Sandomierz," 1570,—being predominantly Calvinist in character, met resolute Lutheran opposition and led to nothing.

SEVENTEENTH CENTURY MAP PRESENTED TO CHARLES II

While the strong individualism of the Polish national character thus thwarted all endeavours at Protestant consolidation, the wars against Orthodox Moscow, effectively united Poles round their old Catholic banners; and the vigorous Protestant propaganda conducted from Königsberg by Poland's vassal, Prince Albert of East Prussia, appeared to the bulk of the nation under the guise of a German menace. These political factors told in favour of Catholicism: so did presently the wiser policy of Rome. Pope Pius IV., unlike his predecessor, adopted a conciliatory attitude towards the Polish Crown in the matter of disputed appointments of bishops. The new bishops were holy and learned men, very unlike the creations of Queen Bona Sforza, and capable papal nuncios reorganized the scattered and faint-hearted Catholic forces in the land. From one of the ablest of them, Giovanni Commendone, the king, at the diet of 1564, accepted the book of the decrees of the Council of Trent, and immediately afterwards issued decrees banishing the more extreme heretics from the country. In 1565, the Jesuits, the vanguard of the Catholic Counter-Reformation appeared in Poland.

At their best, the various forms of Protestantism had never won more than a scanty noble and intellectual *élite* of the nation; they had never taken root among the peasantry or the petty bourgeoisie. Whilst the gradual effacement of reformed creeds removed a powerfully creative intellectual and literary factor from Poland's life, the re-establishment of Catholicism restored to the republic that spiritual unity which was to be the chief source of national strength in the coming struggle against the aggression both of Orthodox Russia and of Lutheran Germany.

The Struggle for the Baltic Provinces.—Access to the Baltic had been a vital question since the dawn of the Polish State in the 10th and 11th centuries. Poland's expansion eastward, which began definitely in the 14th century through the acquisition of Red Russia by Casimir the Great, and was continued in the 15th through the dynastic union with Lithuania, made an extension of her foothold on the Baltic shore imperative. At the same time, the knights of the Teutonic Order (*q.v.*) had threatened to cut Poland off from access to the sea altogether. They had been beaten down by the earlier Jagiellons, and access to the sea secured by way of Danzig. But in the 16th century, the foe survived and began to regain strength in the secular and Protestant duchy of East Prussia, formally owning allegiance to Poland. Sigismund II. was naturally attracted by an opportunity to outflank this foe and to gain a separate outlet to the sea.

In the middle of the 16th century the ancient order of the Knights of the Sword, whose territory embraced Estonia, Livonia, Courland, Semgallen and the islands of Dago and Oesel, was tottering to its fall. All the Baltic powers were more or less interested in the apportionment of this vast tract of land, whose geographical position made it not only the chief commercial link between east and west, but also the emporium whence the English, Dutch, Swedes, Danes and Germans obtained their corn, timber and most of the raw products of Lithuania and Muscovy. Poland and Muscovy as the nearest neighbours of this moribund state, which had so long excluded them from the sea, were vitally concerned in its fate. After an anarchic period of suspense, lasting from 1546 to 1561, during which Sweden secured Estonia, while Ivan the Terrible fearlessly ravaged Livonia, Sigismund II., to whom both the grand-master of the Order and the archbishop of Riga had appealed more than once for protection, at length intervened decisively. At his camp before Riga in 1561, the last grand-master, who had long been at the head of the Polish party in Livonia, and who had embraced Protestantism, and the archbishop of Riga, gladly placed themselves beneath his protection, and by a subsequent convention signed at Vilna (Nov. 28, 1561), Livonia was incorporated with Lithuania in much the same way as Prussia had been incorporated with Poland 36 years previously, that is to say, as a new Protestant duchy, and as a fief of the Polish Crown, with local autonomy and freedom of worship.

PARTITIONS IN THE 18TH CENTURY

Union with Lithuania, 1569.—The danger to Lithuania, revealed in the Baltic wars with Ivan the Terrible, as well as the apathy shown in these matters by the diet of Poland, must have convinced so statesmanlike a prince as Sigismund II. of the necessity of preventing any possibility of cleavage in the future between the two halves of his dominions. A personal union under one monarch had proved inadequate. A further step must be taken—the two independent countries must be transformed into a single state. The principal obstacle was the opposition of the Lithuanian magnates, who feared to lose their dominance in the grand-duchy if they were merged in the szlachta (gentry) of the kingdom. When things came to a deadlock in 1564, the king tactfully intervened and voluntarily relinquished his hereditary title to Lithuania, thus placing the two countries on a constitutional equality and preparing the way for fresh negotiations. The death, in 1565, of Black Radziwill, the chief opponent of the union, still further weakened the Lithuanians, but the negotiations, reopened at the diet of Lublin in 1569, at first also led only to rupture. Then Sigismund executed his master stroke. Knowing the sensitiveness of the Lithuanians as regards Volhynia and Podolia, he suddenly, of his own authority, formally incorporated both these provinces with the kingdom of Poland, whereupon, amidst great enthusiasm, the Volhynian and Podolian deputies took their places on the same benches as their Polish brethren. The hands of the Lithuanians were forced. Even a complete union on equal terms was better than mutilated independence. Accordingly they returned to the diet, and the union was unanimously adopted on July 1, 1569. Henceforth the kingdom of Poland arid the grand-duchy of Lithuania were to be one inseparable and indivisible body politic; all dependencies and colonies, including Prussia and Livonia, were to belong to Poland and Lithuania in common. The retention of the old duality of dignities was the one reminiscence of the original separation — and was only abolished in 1791, four years before the final partition of Poland.

The union definitely shifted Poland's political centre of gravity eastward: it created a common interest in the Russian menace to the long and naturally defenceless eastern frontier, and in the millions of Greek orthodox population in the eastern borderlands. Warsaw was appointed the future meeting-place of the joint diet, thus preparing the transfer of the capital from Cracow to Warsaw. The Union was the last great historical act of the Jagiellonian dynasty: it put the copingstone to the structure of a monarchy which, with growing consolidation, seemed to bear in it the promise of empire.

The Polish Constitution. — Simultaneously with the transformation into a great power of the petty principalities which composed ancient Poland, another and equally momentous political transformation was proceeding within the country itself.

The origin of the Polish constitution is to be sought in the *wiece* or councils of the Polish princes, during the partitional period (c. 1279–1370). The privileges conferred upon the magnates of whom these councils were composed, especially upon the magnates of Little Poland, who brought the Jagiellons to the throne, directed their policy, and grew rich upon their liberality, revolted the less favoured szlachta, or gentry, who, towards the end of the 14th century, combined for mutual defence in their *seymiki,* or local diets.

The first *seym* to legislate for all Poland was the Diet of Piotrków (1493), summoned by John Albert to grant him subsidies; but the mandates of its deputies were limited to 12 months, and its decrees were to have force for only three years. John Albert's second diet (1496), after granting subsidies the burden of which fell entirely on the towns and peasantry, passed a series of statutes benefiting the nobility at the expense of the other classes. These were followed by others of the same kind under his successor Alexander, which, by facilitating import and crippling export trade in the interests of the gentry, enfeebled and degraded the middle class and thereby seriously disturbed the social equilibrium of the State. Nevertheless, so long as the Jagiełło dynasty lasted, the political rights of the cities were jealously protected by the Crown against the usurpations of the nobility. The burgesses of Cracow, the most enlightened economists in the kingdom, supplied Sigismund I. with his most capable counsellors during the first twenty years of his reign (1506–26). Sigismund's predecessor Alexander had been compelled to accept the statute *nihil* novi (1505) which gave the seym and the senate an equal voice with the Crown in all executive matters. Under Sigismund I., some of the royal prerogatives were recovered; but in his later years the influence of the gentry returned, and the diet succeeded in controlling all the great offices of state. The Polish parliamentary system, vesting supreme powers in the two houses of the diet, was an established fact. Sigismund II. knew that only a strengthening of the central authority could save the State. But his endeavours to manoeuvre his way between the two rival powers of the magnates and the smaller gentry were, on the whole, unsuccessful. A patriotic party of "gentry democrats" arose, veiling its programme of democratic reforms under the conservative watchword of the "execution of the laws," and dealing further legislative blows at the trade of the towns and the social status of the middle class. The king, who at first sided with the great nobles against the "executionists," afterwards allied himself with the latter to curtail the power of the magnates by a repeal of former royal grants of land, and by the imposition of a tax on all tenants of Crown lands for the maintenance of the Army (1562–63). Beneficial as this was, it was only obtained at the price of further dependence of the Crown on the szlachta.

Interregnum, 1572–73. — The childless Sigismund II. died suddenly. Fortunately for Poland, the political horizon was unclouded. Domestic affairs, however, were in an almost anarchical condition. The Union of Lublin, barely three years old, was anything but consolidated, and in Lithuania it continued to be extremely unpopular. Worst of all, there existed no recognized authority in the land to curb its jarring centrifugal political elements. Civil war was happily averted at the last moment, and a national convention, assembled at Warsaw, in April 1573, for the purpose of electing a new king. Five candidates for the throne were already in the field. Lithuania favoured Ivan IV. In Poland the bishops and most of the Catholic magnates were for an Austrian archduke, while the strongly anti-German szlachta were inclined to accept almost any candidate but a German. It was easy, therefore, for the adroit and energetic French ambassador to procure the election of the French candidate, Henry, duke of Anjou. Well provided with funds, he speedily bought over many of the leading magnates. Having been one of the instigators of the St. Bartholomew massacre, he was looked at askance by the Protestants; the religious difficulty in Poland, however, had meanwhile been adjusted to the satisfaction of all parties by the compact of Warsaw (Jan. 28, 1573), which granted absolute religious liberty to all non-Catholic denominations without exception — a far more liberal measure than the Germans had made in the religious Peace of Augsburg 18 years before. Finally, early in April 1573, the election diet assembled at Warsaw, and Henry of Valois was elected king of Poland.

Henry **of** Valois, **1573–74.**—The election had been preceded by a correctura *iurum,* or reform of the constitution, which resulted in the famous "Henrician Articles" which converted Poland from a limited monarchy into a republic with an elective chief magistrate. The king was to have no voice in the choice of his successor. He was to marry a wife selected for him by the senate. He was to be neutral in all religious matters. He was not to lead the militia across the border without the consent of the szlachta, and then only for three months at a time. Should the king fail to observe any one of these articles, the nation was *ipso* facto absolved from its allegiance. Whatever its intrinsic demerits, the disastrous fruits of this reform were largely due to the precarious geographical position of Poland, and it must be remembered to Poland's credit that she alone with England preserved the tradition of parliamentary government in the increasingly absolutist Europe of the time.

The reign of Henry of Valois lasted 13 months. The tidings of the death of his brother Charles IX. determined him to exchange a thorny for what he hoped would be a flowery throne, and at midnight on June 14, 1574, he literally fled from Poland. Eighteen months later, the senate elected the Austrian prince Maximilian to the throne; but the "gentry democracy," at the suggestion of its new leader Jan Zamoyski, chose a prince of

Transylvania, Stephen Báthory, assigning him for husband to the last surviving princess of the Jagiełło dynasty, and enforced this election by arms.

Stephen **Báthory,** 1575–%.—The king elected by the "patriotic" party proved one of Poland's greatest kings. The glorious 11 years of his reign, too brief to be permanently effective, yet represent the high-water mark of Poland's international power, and the achievements of his genius both in foreign and domestic policy remain unsurpassed in Polish annals. *(See* STEPHEN, *King of Poland.)*

With the insight of a born statesman he focused his energy on two vital objectives: the maintenance of Poland's access to the sea by way of Danzig, and the defence of her newly-gained further sea-board in the north-east against the rising power of Moscow. Danzig, on Báthory's election, began to intrigue against him with the German emperor, who of course supported Báthory's Austrian rival, and with Russia and Denmark. In spite of a deplorable lack of understanding on the part of the Polish gentry for the issue at stake, Báthory, who had throughout the able and strenuous support of his chancellor Zamoyski, conducted a campaign against Danzig both by land and sed, and finally enforced its complete submission to his rule.

Before peace was made with Danzig, Ivan the Terrible had raided Livonia once more. Báthory for the first time in the history of Polish warfare using infantry rather than cavalry and calling peasants and burghers to arms together with the gentry, achieved in the operations against Russia the greatest military triumphs of his reign. In three successive expeditions he pushed his way north-eastward as far as Pskóv, and the tsar was fain to obtain the Pope's intervention by a promise of making Russia Catholic. As a result of Báthory's victories, Poland pushed Russia entirely away from the Baltic for a long time, and regained sway over nearly the whole of Livonia.

Brilliant as these foreign successes were, the greatness of Báthory's statesmanship is even more manifest at home. He conciliated in a most far-sighted way, by concessions and privileges, two of the monarchy's most important minority groups: the Ukrainian Cossacks and the Jews. The Cossacks were largely runaway serfs, who had organized into a sort of military republic on the vast and scantily inhabited plains of the "Ukraine" or "borderland," stretching from the south-east of the monarchy towards the Black sea along the river Dnieper. The Cossack community had been drawn into the Polish military system under Báthory's predecessors by registration and pay, and had already been granted exemption from taxation, as well as their own jurisdiction. Báthory, who needed them for his Russian wars, confirmed and enlarged these privileges. His successors used the Cossacks against the Russians, Turks and Tartars; but soon the Cossacks themselves were to grow into a factor of trouble for Poland, not without serious errors of policy on the Polish side.

The privileges which the Jews had obtained from former kings were augmented: from his day until 1764 the Polish Jews had a parliament of their own, meeting twice a year, with powers of taxation. It was also chiefly in the interest of the Jews that Báthory restricted, by special edict, the trading rights of Scottish pedlars, of whom as many as 30,000 were abroad in Poland at his time. Among other domestic measures, Báthory reformed the Polish judicial system by the creation of a supreme court of appeal for civil cases; and founded, in 1579, the University of Vilna as a bulwark of Western European culture in the East.

The growing Imperial ambitions of the house of Habsburg had developed into a menace to Poland's international position: they now threatened to outflank and encircle Poland on the southern side. Báthory proposed to counteract them by the project of a union with Russia and a joint crusade against Turkey under the auspices of the Pope. This grandiose plan would have given Poland again a firm footing on the shore of "her second sea"—the Black sea—which she had reached once before in the time of the Jagiełłos. But the idea was carried with Báthory to his grave on his sudden death in I j86

Sigismund III., **1587–1632.**—The Vasa period of Polish history, which began with the election of Sigismund, son of John III., king of Sweden and of a Jagiello princess, was the epoch of last and lost chances. The collapse of the Muscovite tsardom in the east, and the submersion of the German empire in the west by the Thirty Years' War, presented Poland with an unprecedented opportunity of consolidating, once for all, her hard-won position as the dominating power between central and eastern Europe: she might even have wrested the best part of the Baltic littoral from the Scandinavian powers, and pushed Russia back beyond the Volga. That this was not achieved, was partly due to the class spirit and blind selfishness of the Polish gentry. Apathetic towards vital problems of foreign policy, and unwilling to make material sacrifices to the cause of national defense, they persisted in a doctrinaire defense of "republican liberty" at the very time when the need of a strong central executive was more urgent than ever.

But other grave causes of failure were not wanting. One of them consists in the very personality of the new foreign-bred king: the tenacity with which he clung to his hereditary rights to the Swedish crown, involved Poland in unnecessary wars with Sweden at most inopportune times; and his bigoted devotion to the cause of Catholicism introduced a new spirit of religious fanaticism and persecution into the atmosphere of a country hitherto distinguished for toleration, while the same bigotry served Poland's interests very ill abroad. Poland's greatest statesman of the time, Jan Zamoyski, discovered in the earliest years of the reign that the king, who had married a Habsburg princess, was willing to surrender the crown of Poland to an Austrian archduke, and to return to his native Sweden in order to bring it back to the Catholic fold. Zamoyski, who had himself placed Sigismund on the throne by conquering a rival Austrian candidate, was naturally indignant, and the whole disgraceful affair of the king's secret negotiations with Austria culminated in his having to answer the charges of a special "Court of Inquisition" (1592)—the first time that the prestige of the crown in Poland was exposed to such an ordeal.

The Uniate Church.—It was only where the expansion of Catholicism served the interests of the Polish state that Zamoyski saw eye to eye with the king's Catholic zeal Thus, he became instrumental in creating, at the synod of Brześć in 1596, the Uniate Church as a half-way house for those of the republic's Greek Orthodox citizens who were willing to recognize the supremacy of Rome, but desired to preserve their accustomed Eastern ritual and Slavonic liturgy. The Uniate Church served the purpose of drawing a large section of the population of the Eastern border provinces out of the orbit of Russian and into that of Polish influences; but by the antagonisms which soon began between Uniates and Non-Uniates, it became in itself a source of new troubles for Poland Besides this, the pride of Poland's Roman Catholic prelates, who looked down on the Uniate hierarchy, forced the Uniate Church into the position of a "peasant religion" and contributed to making it the social nucleus of anti-Polish Ukrainian nationalism which it remains to-day. Even in Sigismund's time, Austria, competing with Poland for influence in the Eastern Balkans, began to seduce the Ukrainian element (represented in organized form by the military community of the Cossacks) against Poland—a policy which the same Austria was to resume later in changed form and under different conditions when mistress of Eastern Galicia.

War with Sweden, Moscow and Turkey.—The dispute over Sigismund's rights to the Swedish crown began, from the earliest years of the reign, to drag its weary course of alternate victories and defeats. At first the Estonia and Latvia of to-day were both territory and principal object of the strife; in the later stages, Gustavus Adolphus transferred the ground nearer to the heart of Poland by espousing the cause of the Calvinist elector of Brandenburg, who had come into possession of East Prussia and thus laid the foundation of a large Protestant power on the Baltic. The danger to Danzig and Poland's corn exports roused even the gentry from their apathy; but in spite of some brilliant victories by sea and land, an armistice towards the end of the reign was highly unfavourable to Poland.

Sigismund's persistent Swedish ambitions, his equally persistent

Austrian sympathies, but, more than all, his absolutist leanings and cherished plans for a drastic and arbitrary constitutional reform on foreign models and on anti-parliamentary lines, occasioned in 1606 an armed revolt of the Polish gentry against their king—the rokosz (or insurrection) of Nicholas Zebrzydowski, who was supported by the discontented Protestants. The rokosz was at last suppressed in 1607, but it left as its legacy such ruinous precedents as an enforced recognition of the doctrine of the subjects' right to depose their king (de *non* praestanda obedientia), and, being undertaken in justified defence of the native Parliamentary tradition against wholesale foreign innovations, it had the harmful effect of blocking the way towards any and every reform of the Parliamentary system.

Soon after the constitutional cataclysm of the rokosz Poland became embroiled in prolonged wars with Moscow. The motive was partly a vague conception of a Polish-Russian union as opposed to the king's Austrian propensities,—but partly also the very real desire of some border magnates for more and more land east of the Dnieper. An occasion was furnished by the extinction of the Rurik dynasty in Russia, and the subsequent struggle for the throne, particularly the emergence of one candidate—the ill-fated "false Demetrius"—whom certain Polish nobles, and finally also the king, supported. (See also ROMANOFFS.) The appearance of a second Demetrius after the fall of the first prolonged the strife. Throughout the campaigns against Moscow the king found himself at variance with some leading Polish statesmen and soldiers of the time, such as Zamoyski and, later, General Żółkiewski; he thought of the problem only in terms of conquest, of the establishment of Catholicism in Russia, apd of strong monarchical rule over the united kingdoms, while Żółkiewski, even at the height of military successes against Russia, had a union like that of Poland with Lithuania in his mind, and advocated tolerance of Russia's creed and social order. The Poles once actually held the Kremlin of Moscow for a time (1610), and once again laid siege to it (1617); Sigismund's son was elected tsar, and his opponent did homage to Sigismund as a prisoner. But a national insurrection in Russia and the establishment of the Romanoff dynasty checked the Polish advance, and only certain territorial gains (including Smolensk), as well as a good deal of influence of Polish customs and institutions on the Russian nobility, were definite results of the struggle in Sigismund's time. It was to be continued under his successors.

The wars with Moscow temporarily ended in armistice at the very moment (1618), when the Thirty Years' War broke out in Central Europe. In this Poland remained officially neutral, but Sigismund's favourable attitude towards the Habsburgs entangled Poland in renewed and long wars with Turkey, which the later Jagiellos and their first successors had managed to avoid. A definite success was attained against the Turks at Chocim (1621), a year after Żółkiewski's heroic death at Cecora,—but in the very same year the Swedish trouble began anew, and Sigismund's long and unlucky reign ended 11 years later amidst turmoil abroad and at home, set-backs to Polish power on all sides without, and of seriously increased Constitutional disorder within.

Wladislaus IV., 1632–48.—Sigismund's son, born in Poland and brought up as a Pole, enjoyed a popularity which had never been his father's share. As a crown prince, he had been successful in military operations against Moscow and Turkey; on his ascension to the throne he ingratiated himself with the gentry by some new concessions, including even exemption from income-tax. The "wisest of the Polish Vasas," as he has justly been called, intended to create a basis of public favour and confidence for the constitutional reforms which he planned.

But the international difficulties inherited from his father, diverted his energies largely into channels of foreign policy. The very first years of his reign are marked by new victories over Russia and the Turk; also by a new, and much more advantageous, truce with Sweden. He was less fortunate in a new conflict with Danzig—and with her supporter Denmark—over the tolls he intended to impose on the trade of the Baltic ports: no interest in these matters was to be awakened in the gentry, and the most powerful magnates—those of the Eastern border—thought more of expansion into the fertile Ukrainian regions than of sea power. Accordingly, the Polish navy, which had begun to develop in a promising manner under Sigismund III., was allowed to fall into permanent decay, and Wladislaus' plans for foreign action on a large scale were unrealized. He wavered in his diplomacy between Austrian and French influences, represented by his two successive queens; his tolerant and friendly attitude towards the Orthodox East caused serious trouble with the Vatican; and his projects of a great crusade against the Turks, although encouraged by the Venetian republic and acclaimed by the Southern Slav nations, in the end came to nothing.

The Cossack Revolt.—The chief obstacle which prevented Wladislaus' Turkish plans from maturing, was the impossibility of winning the help of the decisive factor—the Ukrainian Cossacks, who had become too numerous and powerful to be a willing instrument of Polish policy. Catholic intolerance towards this Orthodox population, in the time of Sigismund III., had combined with the proud and high-handed behaviour of Polish landowners to produce in the Cossacks a spirit of religious, racial and social enmity against the Polish element; the Polish parliament had not kept the financial terms of its compacts with the Cossacks; repressions inspired by the border magnates had infuriated them. Already in the earlier years of Wladislaus' reign terrible Cossack revolts had flared up, and been unwisely punished by abolition of ancient privileges. Now, instead of letting themselves be made the tools of Wladislaus' anti-Turkish plans, the Cossacks made common cause with the Tatars of the Crimea, who were the most immediate objective of the king's crusading plans; and the reign ended amidst a wave of Cossack insurrection, engineered by the sultan, assisted by Tatar hordes, and led by Bogdan Chmielnicki (*q.v.*), a country gentleman personally wronged by a Polish official, now the rising hero of Ukrainianism. It was only the resistance of the brave Polish burghers of Lwów (Lemberg) that stemmed the Cossack and Tatar tide from flooding the inner provinces of Poland; the same patriotic town was to arrest two other invasions—a Russian and a Transylvanian one—in the next few years. But the defence of Lwów only meant a respite, and on Wladislaus' death, his brother and successor, the last of the Polish Vasas, found himself faced by a powerful renewal of Chmielnicki's attack on central Poland.

John Casimir, 1648-68.—John Casimir, summoned to the throne from France. where he lived as a priest and had become a cardinal, was obliged to begin his reign by negotiating with his rebel subject Chmielnicki. But Chmielnicki's conditions of peace were so extravagant that the negotiations came to nothing. It was only after a second invasion of Poland, in 1649, by countless hosts of Cossacks and Tatars, that the compact of Zborów was concluded, by which Chmielnicki was officially recognized as Chief (*hetman*) of the Cossack community. A general amnesty was also granted, and it was agreed that all official dignities in the Orthodox palatinates of Lithuania should henceforth be held solely by the Orthodox gentry. For the next 18 months Chmielnicki ruled the Ukraine like a sovereign prince. He made Czehryń, his native place, the Cossack capital, subdivided the country into 16 provinces, and entered into direct relations with foreign powers. The Orthodox patriarchs of Alexandria and Constantinople were his friends and protectors. His attempt to carve a principality for his son out of Moldavia led to the outbreak of a third war between suzerain and subject in Feb. 1651. But fortune, so long Bogdan's friend, now deserted him, and at Beresteczko (1651) the Cossack chieftain was utterly routed by Stephen Czarniecki. All hope of an independent Cossackdom was now at an end; yet it was not Poland but Muscovy which reaped the fruits of Czarniecki's victory.

Chmielnicki, by suddenly laying bare the nakedness of the Polish republic, had opened the eyes of Muscovy to the fact that her ancient enemy was no longer formidable. Three years after his defeat at Beresteczko, Chmielnicki, abandoned by his Tatar allies and finding himself unable to cope with the Poles single-handed, very reluctantly transferred his allegiance to the tsar, and in the same year the tsar's armies invaded Poland. The mar thus begun, and known in Russian history as the Thirteen Years' War, far exceeded even the Thirty Years' War in grossness and brutality.

The Russian War and the Swedish Invasion.—In the summer of 1655, while the Republic was still reeling beneath the shock of the Muscovite invasion, Charles X. of Sweden. on the flimsiest of pretexts, forced a war to gratify his greed of martial glory, and before the year was out his forces had occupied the capital, the coronation city and the best half of the land. King John Casimir, betrayed and abandoned by his own subjects, fled to Silesia, and profiting by the cataclysm which, for the moment, had swept the Polish State out of existence, the Muscovites quickly appropriated nearly everything which was not already occupied by the Swedes. At this crisis Poland owed her salvation to two events—the formation of a general league against Sweden, brought about by the apprehensive court of Vienna, and a popular outburst of religious enthusiasm on the part of the Polish people. The first of these events, to be dated from the alliance between the emperor Leopold and John Casimir (1657) led to a truce with the tsar and the welcome diversion of all the Muscovite forces against Swedish Livonia. The second event, which began with the heroic and successful defence of rhe monastery of Czenstochowa by Prior Kordecki against the Swedes, resulted in the return of the king from exile, the formation of a national army, and the recovery of almost all the lost provinces from the Swedes, who were driven back headlong to the sea, where with difficulty they held their own. On the sudden death of Charles X., Poland seized the opportunity of adjusting all her outstanding differences with Sweden. By the peace of Oliva (1660), made under French mediation, John Casimir ceded Livonia, and renounced all claim to the Swedish crown. The war with Muscovy was then prosecuted with renewed energy and extraordinary success. In 1664 a peace congress was opened, and the prospects of Poland seemed most brilliant; but at the very moment when she needed all her armed strength to sustain her diplomacy, the rebellion of Prince Lubomirski involved her in a dangerous civil war, compelled her to reopen negotiations with the Muscovites and practically to accept the Muscovite terms. By the truce of Andruszowo (1667) Poland received back from Muscovy Vitebsk, Polotsk and Polish Livonia, but ceded in perpetuity Smolensk, Siewierz, Chernigov and the whole of the eastern bank of the Dnieper. The Cossacks of the Dnieper were henceforth to be divided between the dominion of the tsar and the king of Poland Kiev, the religious metropolis of south-western Russia, was to remain in the hands of Muscovy for two years.

The "truce" of Andruszowo proved to be one of the most permanent peaces in history, and Kiev, though only pledged for two years, was never again to be recovered. Henceforth the political influence of Russia over Poland was steadily to increase, without any struggle at all, although influences of Polish culture and manners, exercised chiefly through the academy of Kiev, still continued to permeate Russia for a time, until the advent of Peter the Great.

Growth of Political Corruption in Poland.—Poland had, in fact, emerged from the cataclysm of 1648–67 a moribund State, though her not unskilful diplomacy had enabled her for a time to save appearances. Her territorial losses, though considerable, were, in the circumstances, not excessive, and she was still a power in the opinion of Europe. But a fatal change had come over the country during the age of the Vasas. The period synchronized with, and was partly determined by, the new European system of dynastic diplomatic competition and the unscrupulous employment of unlimited secret service funds. This system, which dates from Richelieu and culminated in the reign of Louis XIV., was based on the old rivalry of the houses of Bourbon and Habsburg, and very soon nearly all the monarchs of the Continent and their ministers were in the pay of one or other of the antagonists. Poland was no exception to the general rule. To do them justice, the *szlachta* at first were not only free from the taint of official corruption. but endeavoured to fight against it. But they themselves unconsciously played into the hands of the enemies of their country by making the so-called *liberum veto* an integral part of the Polish Constitution. The *liberum veto* was based on the assumption of the absolute political equality of every Polish gentleman, with the corollary that every measure introduced into the Polish diet must be adopted unanimously. Consequently, if any single deputy believed that a measure already approved of by the rest of the house might be injurious to his constituency, he had the right to exclaim *nie pozwalam,* "I disapprove," when the measure in question fell at once to the ground. Subsequently this vicious principle was extended still further. A deputy, by interposing his individual veto, could at any time dissolve the diet, when all measures previously passed had to be re-submitted to the consideration of the following diet. Before the end of the 17th century the *liberum veto* was used so recklessly that all business was frequently brought t~ a standstill. Later it became the chief instrument of foreign ambassadors for dissolving inconvenient diets. as a deputy could always be bribed to exercise his veto.

THE AGE OF FOREIGN INFLUENCES

With the election of Michael Wiśniowiecki in 1669 a new era began. A native Pole was freely elected by the unanimous vote of his countrymen: but he was chiefly chosen for the merit of his father, a great border magnate who had victoriously kept down the Cossacks, and he proved to be a passive tool in the hands of the Habsburgs. In view of this the French party rallied round John Sobieski, a military commander of rising fame. The dissensions between the two camps cost Polsnd a new defeat at the hands of the united Turks and Cossacks. Sealed by a shameful treaty at Buczacz, this defeat was only wiped out by a brilliant victory of Sobieski's at Chocim, which also, after King Michael's early death, carried him to the throne against an Austrian candidate.

John III Sobieski, 1674–96.—Connected with France by marriage and by political sympathies, Sobieski, although he had half a lifetime of constant wars against the Turks behind him, at first, in accordance with French policy, stood for peaceful relations with Turkey, and directed his eyes towards the Baltic, attempting, with French help, to check the rising Hohenzollern power in that quarter. But his secret dealings with France turned his own subjects against him, while continuous Turkish invasions forced him into war, until an attack of unprecedented magnitude, aimed at the very heart of Europe, called forth that unprecedented outburst of Polish heroism—the gallant rescue of Vienna in 1683. That great act was the last noble reflex of the great crusading impulse of the middle ages; it was a unique service, rendered in the old chivalrous spirit by one nation to another in an age of Machiavellian diplomacy and growing national selfishness It won Poland offersof friendship from all the great powers. But its positive gains for Poland proved little. cessions of territory to Moscow did not buy any active support in further campaigns against Turkey, nor did the delivered Austria assist Poland in her endeavour to re-establish the Rumanian outpost against the Turk.

Augustus II, 1697–1733, and the Peace of **Karlowitz.**—On the death of John III no fewer than 18 candidates for the vacant Polish throne presented themselves. The successful competitor was Frederick Augustus, elector of Saxony, who cheerfully renounced Lutheranism for the coveted crown, and won the day because he happened to arrive last of all, with fresh funds, when the agents of his rivals had spent all their money. He was crowned, as Augustus II, in 1697, and his first act was to expel from the country his French rival, the prince of Conti, whose defeat was also partly due to the growing Russian influence which, from the accession of Peter the Great (1700), becomes a permanent factor in Polish domestic politics.

Good luck attended the opening years of the new reign. In 1699 the long Turkish war, which had been going on since 1683, was concluded by the peace of Karlowitz, whereby Podolia, the Ukraine and the fortress of Kamieniec Podolski were retroceded to the republic by the Ottoman Porte. But the permanent weakening of Turkey brought Poland little good, for the power of Russia soon became a greater menace to her than ever Turkey had been.

War with Charles XII of Sweden.—Shortly after the Peace of Karlowitz, Augustus was persuaded by the plausible Livonian exile. John Reinhold Patkul, to form a nefarious league with Frederick of Denmark and Peter of Russia, for the purpose of despoiling the youthful king of Sweden, Charles XII (*see* SWEDEN: *History*). This he did as elector of Saxony, but it was the unfortunate Polish republic which paid for the hazardous speculation of its newly elected king. Throughout the Great Northern War, which wasted northern and central Europe for 20 years (1700–20), all the belligerents treated Poland as if she had no political existence. Swedes, Saxons and Russians not only lived upon the country, but plundered it systematically. The diet was the humble servant of the conqueror of the moment, and the leading magnates chose their own sides without the slightest regard for the interests of their country, the Lithuanians for the most part supporting Charles XII, while the Poles divided their allegiance between Augustus and Stanislaus Leszczynski, whom Charles maintained upon the throne from 1704 to 1709. At the end of the war Poland was ruined materially as well as politically. Augustus attempted to indemnify himself for his failure to obtain Livonia, his covenanted share of the Swedish plunder, by offering Frederick William of Prussia Courland, Polish Prussia and even part of Great Poland, provided that he were allowed a free hand in the disposal of the rest of the country. When Prussia declined this tempting offer for fear of Russia, Augustus went a step farther and actually suggested that "the four eagles" (viz., the black ones of Austria, Prussia and Russia, and the white eagle of Poland) should divide the banquet between them. He died, however, before he could give effect to this shameless design.

Augustus III, 1733–63.—On the death of Augustus II, Stanislaus Leszczynski, who had, in the meantime, become the father-in-law of Louis XV, attempted to regain his throne with the aid of a small French army corps. Some of the best men in Poland, including the Czartoryski family, were also in his favour, and he was elected king for the second time. But there were many malcontents, principally among the Lithuanians, who solicited the intervention of Russia in favour of the elector of Saxony, son of the late king. A Russian army appeared before Warsaw and compelled a phantom diet (it consisted of hut 15 senators and 500 of the *szlachta*) to proclaim Augustus III. Stanislaus and his partisans were besieged by the Russians in Danzig, and with its surrender their cause was lost. He retired once more to his little court in Lorraine, with the title of king, leaving Augustus III in possession of the kingdom.

Augustus III left everything to his omnipotent minister, Count Heinrich Briihl, and Briihl entrusted the government of Poland to the noble family of the Czartoryskis, who had intimate relations of long standing with the court of Dresden. "The Family," as their opponents sarcastically called them, were to dominate Polish politics for the next half-century, and they were honourably determined to save the republic by a radical constitutional reconstruction which was to include the abolition of the *liberum veto* and the formation of a standing army.

Unfortunately, the other great families of Poland were obstinately opposed to any reform or, as they called it, any "violation" of the existing constitution. The Potockis, in particular, whose possessions in South Poland and the Ukraine covered thousands of square miles, hated the Czartoryskis, and successfully obstructed all their efforts. During the reigns of the two Saxon kings, every diet was dissolved by the hirelings of some great lord or, still worse, of some foreign potentate.

It was against this primitive state of things that the Czartoryskis struggled and struggled in vain. First they attempted to abolish the *liberum veto* with the assistance of the Saxon court where they were supreme, but fear of foreign complications and the opposition of the Potockis prevented anything being done. Then they broke with their old friend Brühl and turned to Russia. Their chief intermediary was their nephew Stanislaus Poniatowski, whom they sent, as Saxon minister, to the Russian court in the suite of the English minister Hanbury Williams, in 1755. The handsome and insinuating Poniatowski speedily won the susceptible heart of the Grand Duchess Catherine, but he won nothing else and returned to Poland in 1759 somewhat discredited. Nevertheless, the Czartoryskis looked to Russia again for support on the death of King Augustus III. They rejected with scorn and derision the pacific overtures of their political opponents, Prince Michal Czartoryski openly declaring that he preferred the tyranny of the Muscovite to the tyranny of his equals. He had in fact already summoned a Russian army corps to assist him to reform his country, nhich sufficiently explains his own haughtiness and the unwonted compliance of the rival magnates.

THE PERIOD OF THE PARTITIONS

The simplicity of the Czartoryskis was even more mischievous than their haughtiness. Their naïve expectations were very speedily disappointed. Catherine II and Frederick II had already determined (Treaty of St. Petcrsburg, 1764) that the existing state of things in Poland must be maintained, and as early as 1763 Catherine had recommended the election of Stanislaus Poniatowski as "the individual most convenient for our common interests." The personal question did not interest Frederick: so long as Poland was kept in an anarchical condition he cared not who was called king. Moreover, the opponents of the Czartoryskis made no serious attempt to oppose the entry of the Russian troops.

Stanislaus II Poniatowski, 1764–95.—Shortly afterwards Stanislaus Poniatowski was elected king and crowned. But at the beginning of 1766 Prince Nicholas Repnin was sent as Russian minister to Warsaw with instructions which can only be described as a carefully elaborated plan for destroying the republic. The first weapon employed was the dissident question. At that time the population of Poland was, in round numbers, 11,500,000, of whom about 1,000,000 were dissidents or dissenters. Half of these were the Protestants of the towns of Polish Prussia and Great Poland, the other half was composed of the Orthodox population of Lithuania. The dissidents had no political rights, and their religious liberties had also been unjustly restricted; but two-thirds of them being agricultural labourers, and most of the rest artisans or petty tradesmen, they had no desire to enter public life, and were so ignorant and illiterate that their new protectors, on a closer acquaintance, became heartily ashamed of them. Yet it was for these persons that Repnin, in the name of the cmprcss, now demanded absolute equality, political and religious, with the gentlemen of Poland. He was well aware that an aristocratic and Catholic assembly like the *Sejm* would never concede so preposterous a demand.

Early in 1767 the malcontents, fortified by the adhesion of the leading political refugees, formed a confederation at Radom, whose first act was to send a deputation to St. Petersburg, petitioning Catherine to guarantee the liberties of the republic. With a *carte blanche* in his pocket, Repnin proceeded to treat the diet as if it were already the slave of the Russian empress. But despite threats, wholesale corruption and the presence of Russian troops outside and even inside the chamber of deputies, the patriots, headed by four bishops, offered a determined resistance to Repnin's demands. Only when brute force in its extremest form had been ruthlessly employed, only when two of the bishops and some other deputies had been arrested in full session by Russian grenadiers and sent as prisoners to Kaluga, did the opposition collapse. The *liberum veto* and all the other ancient abuses were now declared unalterable parts of the Polish constitution, which was placed under the guarantee of Russia. All the edicts against the dissidents were, at the same time, repealed.

Confederation of Bar.—This shameful surrender led to a Catholic patriotic uprising, known as the Confederation of Bar, which was formed in 1768 at Bar in the Ukraine, by a handful of small squires. It never had a chance of permanent success, though, feebly fed by French subsidics and French volunteers, it lingered on for four years, until finally suppressed in 1772. But, insignificant itself, it was the cause of great events. Some of the Bar confederates, scattered by the Russian regulars, fled over the Turkish border, pursued by their victors. The Turks, already alarmed at the progress of the Russians in Poland, and stimulated by Vergennes, at that time French ambassador at Constantinople, at once declared war against Russia. Seriously disturbed at the prospect of Russian aggrandizement, the courts of Berlin and Vienna conceived the idea that the best mode of preserving the equilibrium of Europe was for all three powers to readjust their territories at the expense of Poland. Negotiations led to no definite result at first, till Austria took the first step by occupying, in 1769, the country of Zips, which had been hypothecated by Hungary to Poland in 1411 and never redeemed. This act decided the other confederates. In June 1770 Frederick surrounded those of the Polish provinces he coveted with a military cordon, ostensibly to keep out the cattle plague. Catherine's consent had been previously obtained.

First Partition, 1772.—The first treaty of partition was signed at St. Petersburg between Prussia and Russia on Feb. 6–17, 1772; the second treaty, which admitted Austria also to a share of the spoil, on Aug. 5–16 the same year. The consent of the *Sejm* to this act of brigandage was extorted by bribery and force in 1773. Russia obtained the palatinates of Vitebsk, Polotsk, Mscislaw: 34,616 sq mi. of territory, with a population of 550,000. Austria got the greater part of Galicia, minus Cracow: 32,045 sq.mi., with a population of 816,000. Prussia received the maritime palatinate minus Danzig, the palatinate of Kulm minus Torun, the northern half of Great Poland, and the palatinates of Marienburg and Ermeland: 14,025 sq mi., with a population of 378,000. In fine, Poland lost about one-fifth of her population and one-fourth of her territory.

In return for these enormous concessions the partitioning powers presented the Poles with a new constitution. The most mischievous of the ancient abuses, the elective monarchy and the *liberum veto,* were of course retained. Poland was to be dependent on her despoilers, but they evidently meant to make her a serviceable dependent. The government was henceforth to be in the hands of a "permanent council" of 36 members, 18 senators and 18 deputies, elected biennially by the *Sejm* in secret ballot, subdivided into the five departments of foreign affairs, police, war, justice and the exchequer, whose principal members and assistants, as well as all other public functionaries, were to have fixed salaries. The royal prerogative was still further reduced. The king was indeed the president of the permanent council, but he could not summon the diet without its consent, and in all cases of preferment was bound to select one out of three of the council's nominces. Still, the new organization made for order and economy, and enabled Poland to develop and husband her resources, and devote herself uninterruptedly to the now burning question of national education. The shock of the first partition had a certain salutary effect on national mentality. Already in the darkest days of Saxon rule important educational reforms had been carried out in the schools of the Piarist order by Stanislaus Konarski. Now, the dissolution of the Jesuit order in 1773, putting its rich possessions and the system of schools conducted by it into the hands of the state, gave Poland opportunity to secularize as well as modernize the whole educational fabric of the nation. This huge task was admirably performed by the *Commission of National Education,* the first ministry of education in Europe. It reorganized both the program of teaching and the structure of the schools—including the decayed Universities of Cracow and Vilna—in a thoroughly modern and truly enlightened way. Less progress was made with the cause of constitutional reform: the Chancellor Andrew Zamoyski indeed drafted a new comprehensive code of laws, in which a beginning was made with the emancipation of the peasant serfs and of the town population, but this was rejected by the gentry in the diet (1780).

In the meantime, important events in the international field seemed to give Poland another chance of re-asserting her independence against her despoilers. The death of Frederick the Great, in 1786, loosened the bonds of the alliance between Prussia and Russia. Russia, drawing nearer to Austria, undertook, jointly with her, a war against Turkey which proved unexpectedly hard; and Russia was at the same time attacked by Sweden. Prussia, having changed her policy and concluded an alliance against Russia with England and Holland, was now emboldened by Russia's difficulties to go farther: she invited Poland also to forsake the Russian alliance, and offered to place an army corps of 40,000 men at her disposal.

Reform of the Constitution, **1788–91.**—It was under these exceptional circumstances that the "four years' diet" assembled (1788). Its leaders, Stanislaw Malachowski, Hugo Kollontaj and Ignacy Potocki, were men of character and capacity, and its measures were correspondingly vigorous. Within a few months of its assembling it had abolished the permanent council; enlarged the royal prerogative; raised the army to 65,000 men; established direct communications with the western powers; declared its own session permanent, and finally settled down to the crucial task of reforming the 'constitution on modern lines. But the difficulties of the patriots were commensurate with their energies, and though the new constitution was drafted as early as Dec. 1789, it was not till May 1791 that it could safely be presented to the diet. Meanwhile Poland endeavoured to strengthen her position by an alliance with Prussia. Frederick William II stipulated, at first, that Poland should surrender Danzig and Torun; but the Poles proving obstinate, and Austria simultaneously displaying a disquieting interest in the welfare of the republic, Prussia, in 1791, concluded an alliance with Poland which engaged the two powers to guarantee each other's possessions and render mutual assistance in case either were attacked.

Rut external aid was useless so long as Poland was hampered by her anarchical constitution. The most indispensable reforms had been frantically opposed, the debate on the reorganization of the army had alone lasted six months. It was only by an audacious surprise that Kollontaj and his associates contrived to carry through the new constitution. Taking advantage of the Easter recess, when most of the malcontents were out of town, they suddenly, on May **3**, brought the whole question before the diet and demanded urgency for it. Before the opposition could demonstrate, the marshal of the diet produced the latest foreign despatches, which unanimously predicted another partition, whereupon, at the solemn adjuration of Ignacy Potocki, King Stanislaus exhorted the deputies to accept the new constitution as the last means of saving their country, and himself set the example by swearing to defend it.

The revolution of May 3, 1791, converted Poland into an hereditary limited monarchy, with ministerial responsibility and biennial parliaments. The *liberum* veto and all the intricate and obstructive machinery of the anomalous old system were forever abolished. All invidious class distinctions were done away with. The towns, in a special bill confirmed by the new constitution, got full administrative and judicial autonomy, as well as a certain measure of parliamentary representation; the personal privileges of the gentry, such as possession of land and access to office in the state and in the Church, were thrown open to the townsmen. The peasants were placed under the protection of the law, and their serfdom was mitigated, preparatory to its entire abolition. Absolute religious toleration was established. Provision was made for further periodical reforms by subsequent parliaments.

Russia Overthrows the Constitution.—The constitution of May 3 had scarce been signed when Felix Potocki, Severin Rzewuski and Xavier Branicki, three of the chief dignitaries of Poland, hastened to St. Petersburg, and there entered into a secret convention with the empress, whereby she undertook to restore the old constitution by force of arms, but at the same time promised to respect the territorial integrity of the republic. Entering Polish territory with Russian troops, the conspirators formed a confederation at the little town of Targowica in the Ukraine, protesting against the new constitution as tyrannous and revolutionary, and at the same time the new Russian minister at Warsaw presented a formal declaration of war to the king and the diet. The diet met the crisis with dignity and firmness. The army was at once despatched to the frontier; the male population was called to arms, and Ignacy Potocki was sent to Berlin to claim the assistanre stipulated by the treaty of March 19, 1791. The king of Prussia, in direct violation of all his oaths and promises, declined to defend a constitution which had never had his "concurrence." Thus Poland was left entirely to her own resources. The little Polish army of 46,000 men, under Prince Joseph Poniatowski and Tadeusz Kosciuszko, did all that was possible under the circumstances. For more than three months they kept back the invader, and, after winning three pitched battles, retired in perfect order on the capital (*see* PONIATOWSKI, and KOSCIUSZKO). But the king, and even Kollontaj, despairing of success, now acceded to the confederation; hostilities were suspended; the indignant officers threw up their commissions; the rank and file were distributed all over the country; the reformers fled nbroad; and the constitution of May 3 was abolished by the Targowicians as a "dangerous novelty." The Russians then poured into eastern Poland; the Prussians, at the beginning of 1793, alarmed lest Catherine should appropriate the whole republic, occupied Great Poland; and a diminutive'. debased and helpless assembly met at Grodno in order, in the midst of a Russian army corps. "to come to an amicable understanding" with the partitioning powers.

Second Partition of Poland.—After every conceivable means of intimidation had been unscrupulously applied, the second treaty of partition was signed at three o'clock on the morning of Sept. 23, 1793. By this *pactum subjectionis,* as the Polish patriots called it, Russia got all the eastern provinces of Poland, extending from Livonia to Moldavia, comprising a territory of 96,751 square miles, while Prussia got Dobrzyn, Kujavia and the greater part of Great Poland, with Torun and Danzig. Poland was now reduced to one-third of her original dimensions, with a population of about 3,500,000.

Kosciuszko and the Third Partition.—The focus of Polish nationality was now transferred from Warsaw, where the Targowicians and their Russian patrons reigned supreme, to Leipzig, whither the Polish patriots, Kosciuszko, Kollontaj and Ignacy Potocki among the number, assembled from all quarters. From the first they meditated a national rising, but their ignorance, enthusiasm and simplicity led them to commit blunder after blunder. The first of such blunders was Kosciuszko's mission to Paris, in Jan. 1793. He was full of the idea of a league of republics against the league of sovereigns; but he was unaware that the Jacobins themselves were already considering the best mode of detaching Prussia, Poland's worst enemy, from the anti-French coalition. Kosciuszko received an evasive reply, and returned to Leipzig empty-handed. In the meantime, certain officers in Poland had revolted against the reduction of the Polish army to 15,000, imposed upon the country by the Partition Treaty. Kosciuszko himself condemned their hastiness; but the march of events forced his hand, and in March 1794, he came to Cracow, proclaimed a national insurrection and assumed the powers of a dictator. He called the peasants to arms, and they responded nobly, in return for which he supplemented the provisions of the Constitution of 1791 by a manifesto giving them complete freedom. At first, Kosciuszko's arms were almost universally successful. The Russians were defeated in more than one pitched battle; three-quarters of the ancient territory was recovered, and Warsaw, and Vilna, the capitals of Poland and Lithuania respectively, were liberated. The first serious reverse, at Szczekociny, was more than made up for by the successful defense of Warsaw against the Russians (July 9–Sept. 6). But even during that heroic defense, mob lawlessness in Warsaw and violent dissensions in the supreme council and in the army, began to frustrate the superhuman efforts of the unfortunate but still undaunted dictator. The appearance of overwhelming masses of Russian troops, together with the open hostility of Austria as well as Prussia did the rest, and Kosciuszko's insurrection received its death-blow on the battlefield of Maciejowice, where he himself was wounded and taken prisoner. Warsaw was taken amidst a terrible massacre of the population in the suburb of Praga, and the remainder of the troops capitulated a few weeks later.

The greed of the victorious powers nearly led to a rupture between Austria and Prussia; but after some dissensions, the third partition of Poland was effected by successive treaties in 1795 and 1796. Austria bad to be content with Western Galicia and Southern Masovia, while Prussia took Western Masovia with Warsaw. Russia annexed all the rest, and was afterwards to tear even parts of their booty from the two others. Thus the name of Poland was wiped out from the map of Europe, to reappear only after more than a century.

(R. N. B.; R. DY.)

THE NAPOLEONIC PERIOD AND AFTER

After the third partition, the more high-spirited Poles. chiefly officers and soldiers of Kosciuszko's army, emigrated and formed, on Italian soil, the Polish Legions, which, during the nest ten years, fought the battles of the French republic and of Napoleon all over Europe and even outside it, from Egypt to the West Indies. They were commanded by Dombrowski, one of Kosciuszko's ablest generals; but Kosciuszko himself stood aloof, distrusting Napoleon.

The Grand Duchy of Warsaw.—In 1806 and 1807, when Napoleon defeated Prussia and engaged in a war with Russia, Polish soldiers once more appeared on Polish soil, and the hopes of the nation seemed near fulfilment. In fact, the peace of Tilsit resulted in the reconstruction of a Polish state out of the central provinces of Prussian Poland; but Napoleon's anxiety to conciliate Russia effectually prevented him from making his new creation large enough to be self-supporting. The grand-duchy of Warsaw, as it rvas called. originally consisted of about 1,850 sq.mi., to which Western Galicia with Cracow, about goo sq.mi. more, were added in 1809, in consequence of Napoleon's mar against Austria. The constitution was dictated by Napoleon: it was framed on the French model and on very advanced lines. Equality before the law (implying personal freedom of the peasant), absolute religious toleration, and highly-developed local autonomy, were its salient features. The king of Saxony, as grand duke, took the initiative in all legislative matters; but the administration was practically controlled by the French. In spite of being subject to most burdensome financial and military exigencies for the purposes of Napoleon's continuous wars, the srnall grand duchy contrived. durinn the, few years of its existence, to do much peaceful, productive. organizing work, especially in the educational and rconomic spheres.

Poland's hopes for greater things revived once more when Napoleon announced his war against Moscow (1812), as his "second Polish war." The grand duchy, by an immense effort: put an army corps of nearly 80,000 men into the field. But the calamity which overtook Napoleon in Russia, also sealed the fortunes of the duchy. The remainder of the Polish troops faithfully followed Napoleon in his campaign of 1813–14, during which the heroic leader of the Poles, Prince Joseph Poniatowski (nephew of the last king), perished in covering the Emperor's retreat from Leipzig. The duchy was occupied by the Russians.

The Congress Kingdom, 1815–31.—Tsar Alexander I had been united by youthful friendship to the most eminent Polish noble of his time, Prince Adam Czartoryski, and had even made him, on his accession, foreign minister of the Russian empire. On Napoleon's downfall the Poles, to whom Alexander did not spare promises and flatteries, entertained the highest hopes.

It was not Alexander's fault, indeed, if the Congress of Vienna, owing to jealousy among the great powers and to the entanglement of the Polish question with that of Saxony and other territories, did not end in a re-union of Poland, even under the Russian sceptre, but confirmed the division of the country between the three partitioning pourers. Cracow only, with a small surrounding territory, was erected into a free city republic. Great Poland, with Poznan for its centre and a population of 810,000, was left to Prussia. Austria remained in pcssession of Galicia with 1,500,000 inhabitants. The eastern borderlands, from Lithuania and White Russia to Volhynia and the Ukraine, continued to be incorporated in Russia. The remnant of central Poland only—about three-fourths of the territory of Napoleon's grand duchy of Warsaw—was constituted as the so-called Congress kingdom under the emperor of Russia as king of Poland. Guarantees of home rule in all parts of the divided country, and of free communication between them, were given by all powers concerned, only to prove soon more or less futile.

Polish Constitution, 1815.—Alexander, who had a sentimental regard for freedom, so long as it meant obedience to himself, had promised the Poles a constitution. That constitution was soon duly drafted and signed. It contained 165 articles divided under seven heads. The kingdom of Poland was declared to be united to Russia, in the person of the tsar, as a separate political entity. Lithuania and the Ruthenian Palatinates continued to be incorporated with Russia as the Western Provinces and were divided from the Congress kingdom by a customs barrier till the reign of Nicholas I. The kingdom of Poland thus defined was to have at its head a lieutenant of the emperor (*namiestnik*), who must be a member of the imperial house or a Pole. The first holder of the office, General Zajonczek (1752–1826), was a veteran who had served Napoleon. Roman Catholicism was recognized as the religion of the state, but other religions were tolerated. Liberty of the press was promised, subject to the passing of a law to restrain its abuses. Individual liberty, the use of the Polish language in the law courts, and the executive employment of Poles in the civil government were secured by the constitution. The machinery of government was framed of a council of state, at which the imperial government was represented by a commissioner plenipotentiary, and a diet divided into a senate composed of the princes of the blood, the palatines and councillors named for life, and a house of nuntii elected for seven years. Poland retained its flag, and a national army based on that which had been raised by and had fought for Napoleon. The command of the army was given to the emperor's brother Constantine, a man of somewhat erratic character, who did much to offend the Poles by violence (see Constantine Pavlovich).

The diet met three times during the reign of Alexander, in 1818, in 1820 and in 1825, and was on all three occasions opened by the tsar. But the tsar and the diet soon quarrelled. The third session of the diet (May 13 to June 13, 1825) was a mere formality. All publicity was suppressed, and one whole district was disfranchised because it persisted in electing candidates who were disapproved of at court. All Europe at the time was seething with secret societies organized to combat the reactionary governments of the Holy Alliance. In Poland, the National Freemasonry, or National Patriotic society as it was afterwards called, had a large membership, especially among the students and the younger officers. Outside Congress Poland, a similar student movement arose in the University of Vilna. Severe measures—imprisonment, deportation, and exile—were taken against students and graduates of Vilna (including the great poet Mickiewicz), and they added to the excitement in Warsaw.

No open breach occurred during the reign of Alexander I, nor for five years after his death in 1825. On the death of the unpopular Zajonczek in 1826, the Grand Duke Constantine became imperial lieutenant. His brother, the new tsar, Nicholas I, soon became entangled in a war with Turkey. Austria, as usual, desirous of profiting by Russia's difficulties, hegan to court the favour of the Poles. Nicholas was crowned king of Poland in Warsaw, in 1829, and personally opened the diet in 1830. But the diet, already in 1828, had refused to sentence to death a group of Polish conspirators accused of dealings with the Russian "decembrists" who had plotted Nicholas' overthrow—and in 1829 there was even an abortive Polish plot to murder him at his coronation in Warsaw. Fresh excitement was created in Poland by the outbreak of the revolution in France, in July 1830, and the revolt of Belgium: a rumour was current—not without justification—that Nicholas, acting in concert with the other autocrats of the Holy Alliance, intended to use the Polish army to coerce the French and Belgian revolutionaries.

The *Rising* of 1830.—On Nov. 29, 1830, a military revolt broke out in Warsaw. It was started by the young hotheads of the Officers' Training school, and began with the murder of several senior officers loyal to the government. Regiments of the army and masses of the civilian population began to join the rising; the weakness of Constantine allowed it to gather strength. He evacuated Warsaw and finally left the country. The war lasted from January till Sept. 1831. The Poles began with some chances of success: they had a well-drilled and well-equipped army of about 30,000 men, which they increased by recruiting to about 80,000. Against this, the Russians, with considerable difficulty, succeeded in putting only about 114,000 men into the field. Their ultimate success was partly due to the friendly attitude of Prussia, partly to the fact that the Polish diet, having proclaimed the deposition of the tsar at an early stage of the conflict, received no response to its appeal for western European protection. But to a large extent the defeat of the insurrection was caused by certain faults on the Polish side: want of ability and decision on the part of the generals, a succession of rapid changes in the command of the army, fierce party strife within the civil government in the capital, a deplorable outbreak of mob violence in Warsaw at a critical moment of the war; finally, an irresolute attitude of the insurrectionary parliament towards the peasant claims.

After the suppression of the insurrection, certain remnants of a constitution were still granted to Russian Poland by the "Organic Statute" of 1832, but they were soon rendered illusory: the administration avowedly aimed at destroying the nationality, and even the language, of Poland. The universities of Warsaw and Vilna were suppressed, the Polish students compelled to go to St. Petersburg and Kiev. The recruits from Poland were distributed in Russian regiments, and the use of the Russian language was enforced as far as possible in the civil administration and in the law courts. The customs barrier between Lithuania and the former Congress Poland was removed, in the hope that Russian influence would spread more easily over Poland. A hostile policy was adopted against the Roman Catholic Church. But though these measures cowed the Poles, they failed to achieve their main purpose. Polish national sentiment was intensified. The Poles in Russia, whether at the universities or in the public service, formed an element which refused to assimilate with the Russians. In Poland itself the tsar left much of the current civil administration in the hands of the nobles, whose power over their Peasants was hardly diminished and was misused as of old. The Polish exiles who filled Europe after 1830 maintained a constant agitation from abroad. The stern government of Nicholas was, however, so far effective that Poland remained quiescent during the Crimean War.

Alexander* II *and the Rising of 1863.—The reign of the new tsar Alexander II began with certain concessions to Poland in the political and educational field. Exiles were allowed to return, administrative pressure was lightened, the Church was propitiated, an "Agricultural society" was allowed to be formed and to discuss important affairs of the community, a medical faculty, and later on, a complete university, was re-established in Warsaw. Finally even, a Polish council of state and a Polish administrative apparatus for the kingdom began to be organized. In their later stages, these reforms were the work of Count Alexander Wielopolski, who was installed in high office, and stood for a national policy of loyal union with Russia. But his autocratic temper lost him the sympathies of the moderate elements of the gentry; while, on the ardent minds of the young, Wielopolski's methods acted like fuel heaped on fire. Religious ceremonies were used as the occasion for demonstrative political processions, there were collisions with the Russian troops, and victims fell in the streets of Warsaw. Wielopolski had the unhappy idea of causing the revolutionary youth of the cities to be recruited en *masse* for the Russian army; the plan became known, numbers of the young people fled into the forests, and a Revolutionary committee, on Jan. 22, 1863, started an ill-prepared insurrection.

The struggle of the ill-equipped and ill-organized insurgent bands against the Russian garrisons in the country dragged on in the form of guerrilla warfare throughout the country for nearly two years. A secret National government was set up in Warsaw, the movement spread successfully into Lithuania, and the insurrection occupied the diplomatic attention of western Europe. But the assistance promised by Napoleon III never became effective; the rising was crushed; wholesale executions, confiscations and deportations followed its suppression, and Poland was now definitely turned into a Russian province.

After the insurrection of 1831, no remnant of Poland's independent political existence had been left except the minute city republic of Cracow, created by the Congress of Vienna. For 30 years, this miniature state led a flourishing existence. When the ferment of the approaching European revolution of 1848 was stirring most continental countries to their depths, there were active preparations for another rising both in Austrian and Prussian Poland. For Austria the menace was diverted by a huge peasant revolt in Galicia, which led to a massacre of thousands of landowners by the peasantry. At the same time, Austria availed herself of the unrest among her Poles to obtain the consent of Russia and Prussia to the suppression of the city republic of Cracow. But it was only in 1848, amid the thunders of the "springtide of nations," that Cracow was finally occupied by Austria and incorporated into Galicia.

After the disaster of 1863, the Poles of Prussian, Austrian and Russian Poland developed along such widely different lines that there is, for the next 60 years, little unity leit in Poland's national history. Certain features, however, are common to the life of the three sections of the nation during this period. The gentry, shattered by the insurrectionary disasters, ceases to be the dominant class in the community; the professional intelligentsia of the towns swelled by influxes from the ruined gentry assumes that part; and gradually, towards the end of the 19th century, the peasant masses, now fully enfranchised, rise into importance.

The Poles in Prussia.—The regime in Prussian Poland during the first 15 years after the Congress of Vienna had been endurable. A Polish nobleman related by marriage to the Prussian dynasty—Prince Radziwill—was appointed lieutenant-governor of the province; there was a provincial assembly and local representative bodies both urban and rural. The landowners were allowed to organize for economic purposes, and the peasants were fully eniranchised in 1823. After the insurrection of 1830, a period of more oppressive government by a German provincial president, Flottwell, set in; he revived Frederick the Great's method of German colonization of the Polish province; and he began to Germanize the administration and the school system. A period of new concessions to the Poles, under Frederick William IV, was interrupted by the revolution of 1846–48. The constitution with which Prussia emerged irom the revolution put an end to the self-government of Prussian Poland. Another interval of relaxation, in the first years of William I, was soon succeeded by the period of Bismarck's and Bülow's resolutely anti-Polish policy—characterized by the *Kulturkampf,* the "Colonizing Committee," the Września scandal, the schools' strike, the Expropriation bill and the like, for an account of which *see* POZNAN. The result of the Prussian methods was to create a sturdy class of peasants and small bourgeoisie, disciplined and economically and culturally advanced; and a fellow-feeling arose between the peasants and the landowning gentry, such as was hardly known in other parts of Poland.

The Poles in Austria.— Austria, under the old autocratic regime, had oppressed its Polish province politically and exploited it economically in the most ruthless fashion, till the revolution of 1848 brought a change. But not until the defeat of Austria by Prussia in 1866 was it realized at Vienna that only a more liberal policy could hold the tottering, mixed monarchy together. The relation with Hungary having been placed on a federal footing, concessions had to be granted to the strong Polish element in Austria. The Poles became a dominant nationality in the Austrian empire. The numerical strength of the group oi Polish deputies in the Vienna parliament was such that no Austrian government could be formed without it. Galicia (as Austrian Poland was officially called), containing a large Ruthenian element in its Eastern half, was granted a special minister to represent its interests in the Vienna cabinet. It also got a provincial legislative assembly and a governor, who was invariably appointed from the ranks of the Polish aristocracy. With purely Polish administration schools and courts of law, Galicia became indeed almost an independent Polish state within Austria, and successfully defied the centralizing efforts of the Vienna bureaucracy. The Polish landowning class, who practically governed the country for the next few decades, managed its affairs in a one-sidedly agrarian spirit: the interests of the towns were not properly considered, hardly any attention was given to the development of industries, and Galicia remained economically backward. Even its oilfields were largely developed by foreign capital. On the other hand, political and cultural activities had more scope than in the two other parts of Poland: Galicia became the "Piedmont" of the Polish national movement, and Cracow, with its old university and new Academy of Sciences, an intellectual, artistic and literary centre ior the whole nation. With the growth of a new educated class, and the introduction of universal suffrage in Austria (1896) the social structure of the country began to change, its politics were strongly democratized, new economic tendencies got the upper hand, and Galicia was at last on the road of material advance when World War I began.

The Poles in Russia.—All self-government in Congress Poland was suppressed in 1863; all education was Russified in 1869, justice in 1873. On the other hand, the abolition in 1851 of the customs frontier between Russia and Poland had laid the foundation for an extraordinary industrial expansion: Russian Poland became the chief industrial region for all Russia. Its vast market in agricultural Russia was protected against western competition by high tariffs; the Russian government took every possible measure (such as the introduction of specially favourable railway tariffs) to assist this expansion. The Poles, being excluded from state service in their own country, busied themselves with productive occupations, and the upper and middle classes achieved a well-being far superior to anything enjoyed by their cousins in Galicia. A second result of this expansion was the growth in Congress Poland of a large and radical proletariat which made common cause with the Russian Social Democratic movement. In the country districts, the agrarian policy of the Russian government was expressly calculated to stir up ill-feeling between the Polish peasants, whom the government demonstratively took under their protection, and the country gentry, whom it was determined to punish in every way for the leading part they had played in the insurrections. The peasant of Russian Poland officially got his freedom from the tsar in 1864. Each peasant, whatever his tenure had been, and the mass of the landless proletariat, became freeholders. The landlords received compensation in the form of Russian Treasury bonds. which stood far below par, and the peasants got the right to use the landlords' pastures and woods.

In the sphere of education, the most thoroughgoing system of Russification set in after 1863. All the revived Polish schools of the Wielopolski period were made Russian again, including the University of Warsaw, and no effort was spared to produce in the minds of youth a distorted image of Poland's past. Secret patriotic education, however, counteracted this policy successfully both in town and country; and private Polish schools, struggling against great difficulties, kept the great Polish cultural tradition alive.

The civil government of Russian Poland was reorganized strictly on the model of the rest of the Russian empire, the Poles being debarred, however, irom certain liberal institutions which the Russians by that time possessed, such as municipal self-government and trial by jury. The Russian language was made compulsory in all official relations. and at a later time even in the records of private institutions. A corrupt Russian bureaucracy filled all government offices, a severe censorship strangled every free utterance of the nation in the press and in literature, and a drastic police regime kept the prisons filled with political offenders.

After Russia's defeat in the Japanese war of 1904, the outbreak of a revolution in 1905 kindled all Polish hopes once more. A constitution was granted to Russia, and 36 Polish deputies sat in the first Russian parliament. A certain measure of freedom in the educational field was obtained and eagerly used for the foundation of new schools by a Warsaw society called "the Mother oi Schools" (*Macierz Szkolna*). The peasants of Russian Poland spontaneously introduced the Polish language in their self-governing bodies. In the Duma itself, the Liberals were not averse to granting Poland a large measure of autonomy within Russia. At the same time, persecution in Prussian Poland increased under Bülow, while the Ukrainian national movement, developing in Austrian Poland especially since the grant of universal suffrage in 1907, was unwelcome both to Poles and Russians. Under these circumstances, Russian propaganda, reviving the Pan-Slav ideals of 30 years ago, could count on some success even among the Poles. There were gestures of reconciliation at two Slav congresses, in 1908 and 1910, the Czechs willingly acting as mediators. The idea of uniting all Poles with autonomy within the Russian empire was widely preached: it became the program of the national Democratic, or all-Polish, party, led by Roman Dmowski, the head of the Polish representation in the Duma.

Opposite to Dmowski and the followers whom he found even among Austrian Poles, there stood the irreconcilable revolutionaries, led by Joseph Pilsudski. Both the insurrectionary movements started by Pilsudski in 1905, and the Constitutional endeavours of Dmowski and his friends in the Duma, were soon stifled by the Russian reaction of the Stolypin period. Pilsudski was obliged to flee to Galicia, and began to organize active resistance to Russia from that base. In the Duma, the Polish representation was lowered irom 36 to 10 deputies. In the country, all the liberties gained after 1905 soon disappeared. The government's purchase of the railway line from Warsaw to the Austrian frontier resulted in the removal of all Polish railwaymen from the service and was a great blow to the Polish element. In 1912 the separation of the district of Chelm, in the southeast of Russian Poland, from the body of the province and its incorporation in Russia proper was received with indignant protests by Polish opinion as a new division of Poland.

THE POLISH PROBLEM DURING WORLD WAR I

World War I found the Poles estranged from one another, and without a united national policy. Pilsudski, the "activist," crossed the frontier from Galicia with a iew hundred of his armed band and engaged the Russian empire in battle as forerunner of the army of an independent and united Poland. But the Polish National committee. formed in Cracow on Aug. 16, aimed at uniting Galicia and Congress Poland as a third party in the Dual Monarchy and required the Polish Legion to take the oath to the emperor. In Warsaw, another Polish committee under Dmowski denied the right of the Cracow committee to speak in the name of the Polish nation; protested loyalty to the tsar; and attempted to form a Polish Legion on the side of Russia. Meanwhile the Grand Duke Nikolai Nikolaievich issued a proclamation (Aug. 14) in which he promised to unite the three parts of Poland in an autonomous state with the Russian empire. When the Russian army occupied a great part of Galicia the Russophil party in Galicia (the National Democrats) accepted this program.

In the summer of 1915, however, the Central Powers conquered all Congress Poland. After the fall of Warsaw on Aug. 5. 1915, governments were set up on behalf of Germany at Warsaw, and Austria-Hungary at Lublin. It was now the Russian solution that was platonic. But fresh difficulties confronted the Austrian solution. The Polish Socialist Party (P.P.S.) under Pilsudski declared that no recruiting should take place for Polish legions until an autonomous

Polish government had been formed to conduct it. Meanwhile Tisza, the Hungarian Minister President, had vetoed the Austrian trialist scheme, which was also opposed by Germany. Vienna, again, rejected the plans put forward by Germany, of annexing Congress Poland to Germany, or of forming an independent Polish buffer state in economic military and political alliance with the Central Powers.

Formation of a Polish State.—In hug. 1916, however, after the defeat of the Austro-Hungarian troops at Luck, the German supreme command acquired complete control of policy on the eastern front. Ludendorff believed it possible to gain a large Polish army if his ideas were adopted. Germany and Austria-Hungary issued a proclamation on Nov. 5, 1916, holding out a prospect of the restoration of an independent Congress Poland as a hereditary constitutional monarchy closely attached to the Central Powers. Francis Joseph promised Galicia increased autonomy within Austria-Hungary. The discussion of details was shelved; the military governments at Warsaw and Lublin continued to administer the country. The German governor, General von Beseler, arranged for the election of a diet with fairly extensive powers in local administration, education and justice. Meanwhile, by decree dated Nov. 26, 1916, a Provisional Council of State was appointed, which was solemnly opened on Jan. 14, 1917. Pilsudski began to work out the plans for a national Polish army. He refused, however, to raise it for German use; and actually the German plan of raising a Polish army failed completely.

In March 1917 the Russian dynasty fell. On March 30 the new Russian government recognized Poland's right to self-determination and promised the creation of a new Polish state. These events altered the attitude of the Allies towards Poland, particularly as they were now reinforced by the entry of the United States into the war. The answer of the Entente Powers to the peace proposals of the Central Powers issued on Jan. 10, 1917 had already declared their adhesion to the tsar's manifesto to his armies (Dec. 25, 1916) which had spoken of "the formation of a free Poland in all parts into which it is at present divided."

The danger still threatening Poland from Russia vanished with the breakdown of Kerensky's offensive (July, 1917). The Central Powers were now the only enemy. In May 1917, the Polish members of the Austrian *reichsrat* unanimously demanded "an independent united Poland with an outlet to the sea," and declared that the Polish case was one for "international consideration." At the same time, the Polish council of state in Warsaw asked the occupants for a wideniсg of its powers, and split up over the German demand for a recruiting appeal and an oath of loyalty. Pilsudski resigned from the diet with his adherents, and set about turning his secret military organization against Germany.

On July 22 Polish discontent was increased by the arrest of Pilsudski. On Aug. 25 the diet, now discredited with the people, resigned. On Sept. 12 Germany and Austria-Hungary introduced a new project of a regency of three, a cabinet and premier and council of state, chosen by the regency, and enjoying limited powers, the German and Austrian military governments retaining the right oi veto. The regency was appointed on Oct. IS; it consisted of the Archbishop of Warsaw, Dr. Kakowski, Prince Lubomirski, and Józef Ostrowski, a large landowner. The first prime minister, Jan Kucharzewski, was appointed on Nov. 26 and formed his first ministry on Dec. 7.

While Polish affairs were taking this course under Austro-German occupation, Dmowski was making propaganda for the Polish cause in France and England, and Paderewski was working tirelessly in America. In Nov. 1916, a great Polish National Department in Chicago had united all the organizations of the 4,000,000 Poles in America; and under Paderewski's influence, President Wilson, in his tentative peace message of Jan. 22, 1917, alluded to a "united, independent and autonomous Poland." In the course of 1917, a Polish corps was organized by General Dowbór-Muśnicki in Russia, and a Polish army, afterwards known as General Haller's army, began to be formed in France. The Polish National committee, founded at Lausanne in Aug. 1917, and since established in Paris, was gaining increasing influence in the councils of the Allies. Between Sept. 20 and Dec. 1, 1917, France, Great Britain, Italy and the United States had recognized it as the official representative of the Polish people. The thirteenth of President Wilson's Fourteen Points (Jan. 8, 1918) declared that a Polish state should be erected which should include the territories inhabited by indisputably Polish population "with an outlet to the sea and an international guarantee of its independence and integrity."

In the meantime, the utter collapse of the Russian army had led to peace negotiations between the Central Powers and the Bolsheviks. The Bolshevik delegates who arrived at Brest-Litovsk (*q.v.*) in Dec. 1917, recognized, in theory, the right of the Polish people to self-determination; hut Polish delegates were not admitted to the deliberations. By the treaty as concluded on March 3, 1918, soviet Russia renounced all claims over Poland; but the treaty (Feb. g, 1918) between the Central Powers and the Ukraine allotted to the Ukraine the disputed province of Chelm, while Austria-Hungary further pledged herself in a secret clause to form East Galicia and the Bukovina into a separate Crownland. These clauses became known; Polish opinion was infuriated beyond measure; the Polish cabinet resigned; the Polish club in the Austrian *reichsrat* went over to the Opposition; the remnant of Pilsudski's legions still fighting for the Central Powers mutinied. Some were interned, some fought their way to the coast and joined the new Polish army in France. The elections for the council of state in Poland were held in April and it was opened in Warsaw on June 22. Little interest was taken in the elections, and general feeling in Poland tended to ignore this body in favour of the National committee in Paris. Even before the breakdown of the German offensive in July 1918, the prime ministers of Great Britain, France and Italy had declared in favour of an independent and united Poland at Versailles on June 3, 1918.

The Declaration of Independence.—On Oct. 6, the Polish Regency Council and minister president published a manifesto to the Polish nation declaring its intention of dissolving the council of state, forming a representative national government and summoning a diet for a "free and united Poland." On Oct. 15 the Polish representatives of the *reichsrat* declared themselves to be "subjects and citizens of a free and re-united Polish State." On the same day the council oi Regency in Warsaw summoned the Galician Poles to Warsaw to take part in forming the new Polish government. A cabinet was hurriedly iormed on Oct. 22. On Oct. 28 a commission of Austrian Poles met in Cracow to wind up relations with Austria. Assuming its authority to extend throughout Galicia, it appointed its next meeting for Nov. 2 in Lwow, where a Ruthenian government had already been formed, thus early coming into collision with its neighbours. On Nov. 3 the cabinet proclaimed the Polish Republic. On Nov. 10 Pilsudski, who had been released from imprisonment on Oct. 7, arrived in Warsaw. The German troops of occupation were disarmed and expelled, and the Poles assumed the executive power in Warsaw on Nov. 11. The council of Regency declared on the same day that it appointed Pilsudski to the supreme command of all Polish troops and on November 14 resigned in favour of Pilsudski.

THE NEW POLAND

Of all the new or resurrected states of Europe, Poland was in many respects in the most difficult position. The territory of Congress Poland and Galicia had been devastated in the war. Most of the factories were closed for lack of raw material, where they had not been actually dismantled. The fields of the peasants had been laid waste, their livestock slaughtered, their farms burnt. Many districts were actually famine-stricken, others swept by epidemics. Communications were disorganized, rolling stock in a deplorable state. Marks, roubles and kronen circulated ireely, but their values were low and uncertain, and public and private finances were chaotic. Owing to the past policy of Prussia and Russia, a national bureaucracy existed only in Galicia. Thirty thousand German troops were still in the country. On the east. Bolshevik Russia was in a highly unsettled state and exercised an unsettling influence on the masses in Poland. Radical propaganda of all sorts was rife, and political parties were as numerous as they were, on the whole, futile.

Pilsudski, the old revolutionary, had begun by appointing a cabinet of the Left, composed mainly of Galician socialists and peasants' representatives, under the presidency of J. Moraczemski. But the propertied classes refused him their support, and his attempt to float an internal loan met with little response. In December, M. Paderewski, the second man in Poland enjoying almost unlimited prestige, arrived in the country, composed his differences with Pilsudski and became premier on Jan. 17, 1919. Prussian Poland had come under complete control of its Polish inhabitants by Jan. 9. West Galicia was incorporated; East Galicia was occupied by Polish troops, which had entered Lwow on Nov. 22. It was possible to hold elections for a constituent assembly on Jan. 26, 1919. The constituent *Sejm* met on Feb. 10. It passed a vote of confidence in Paderewski's cabinet, and confirmed Pilsudski in his position as head of the state without, however, exactly defining his position. Paderewski proceeded to Paris to urge Poland's claims; Pilsudski raised an army to defend them. General Haller's troops, returning from France, formed the nucleus of this force. Poland soon had an army of 600,000, which was shortly increased to 800,000. On May 8 an offensive was opened in East Galicia against the Soviet Russian and Ukrainian forces.

The Treaty of **Versailles** and Frontier Problems.—On June 28, 1919 the Polish delegation signed the treaty of Versailles, under which Poland agreed to accept an agreement with the Principal Allied and Associated Powers for the protection of national minorities in Poland, and for the protection of freedom of transit and equitable treatment of the commerce of other nations. This Minorities Treaty was signed on June 28, 1919. Under the Treaty of Versailles, Poland received the larger part of Poznan and part of West Prussia. A plehiscite was to determine the settlement of Masuria and Upper Silesia. Danzig (*q.v.*) was to be a free city under the protection of the League of Nations. This city was to he included within the Polish customs frontiers and its foreign relations and the protection of its citizens abroad were to be entrusted to Poland, who also received other economic rights in this territory and was to have free access to the sea. The actual details were settled later hy treaties between Poland and the free city, in 1920, 1921 and 1923. Art. 87 of the treaty assigned to the Allied and Associated Powers the duty of fixing Poland's eastern frontier. As a signatory to the Treaty of Versailles, Poland was an original member of the League of Nations. The treaty was not popular in Poland but the *Sejm* ratified it on July 30–31 by 285 votes to 41. During the next three pears, however, Poland was almost exclusively occupied with questions arising directly or indirectly out of it, which it will he convenient to take in order.

The industrial district of Teschen (*q.v.*), with important coal mines, was claimed by both Poles and Czechoslovaks. Each nation attempted to assume practical control, and there was some fighting. A plebiscite commission arrived in the district on Jan. 30, 1920, but on July 28, 1920 the Supreme Council fixed a line of demarcation through this district, cutting the town in two, and through the neighbouring districts of Zips and Orava. In East Prussia (see ALLENSTEIN-MARIENWERDER) the plebiscite was held on July 11, 1920. The bulk of the districts were allotted to Germany on the basis of the vote.

Upper Silesia was the scene of grave troubles (see SILESIA). Art. 88 of the Treaty of Versailles provided that the inhabitants of this area, except in its purely German portions, should vote by plebiscite for adherence to Germany or Poland. Allied troops occupied the districts in the meantime. At the polls, 717,422 votes were cast for Germany, 483.514 for Poland. The towns and industrial districts voted German. In consequence of a rumour that only two districts were to be assigned to Poland, Korfanty, a prominent Pole, occupied southeastern Upper Silesia with an armed force. A commission of the Council of the League of Nations on Oct. 20, 1921 awarded the southeastern districts, including 7570 of the aggregate material wealth of the disputed territory, to Poland. A convention signed at Geneva between Poland and Germany May 15, 1922 provided guarantees for the continuity of the economic life of the country and the protection of minorities during a transitional period of 1j years.

Hostilities Against the Ukraine and Russia.—The disturbances on Poland's eastern frontier were on a larger scale. Polish troops, on occupying Lwow in Nov. 1918, had expelled the East Galician government, which took refuge in Vienna. General Petlura, who formed a government in the Ukraine in the same month, proclaimed the union of the Republics of Ukraine and West Ukraine (East Galicia). The East Galician troops placed themselves under his command. Throughout 1919 fighting continued between the Polish and Ukrainian troops, the former remaining in de *jacto* possession of the disputed territory. On Nov. 20, the Peace Conference assigned Eastern Galicia to Poland for 25 years, with a provision for local autonomy; after 25 years, the League of Nations was to decide its future.

Simultaneously with the campaign in Eastern Galicia, Poland was engaged in war with soviet Russia. The German troops of occupation had evacuated the White Ruthenian and Little Ruthenian territory in Chelm and Volhynia in such a way that the Bolshevik troops were able to occupy it before the Poles, to whom the inhabitants appealed for aid, could come up. In this year soviet Russia was engaged in war with most of her neighbours and with various expeditions, such as those of Kolchak or Denikin. Polish forces, as the largest and most successful of those opposed to Russia, enjoyed considerable support in western Europe. All the Allies desired a strong Poland; hut British statesmen considered that this aim would be best achieved if Poland's frontiers mere not excessively extended. In the autumn, Russia suggested an armistice which was declined.

The "Curzon line," of Dec. 8, attempted to define Poland's eastern frontier. It drew a line roughly following the ethnographical frontier and thus running some way further west than the actual line then occupied by Polish troops. The district of Vilna (Wilno), which the Poles had occupied in April 1919, was assigned to Lithuania.

In the spring of 1920 efforts were made to secure peace with Russia, but came to nothing. On April 25, having settled differences with Petlura in the Ukraine by a treaty dated April 22, Poland opened a strong offensive. On May 8 the Polish troops entered Kiev. The soviet army, however, having defeated Kolchak and Denikin, concentrated against Poland and opened a counter-offensive. By July the Polish forces were in a serious position. Poland appealed to the Allies for mediation; and the Allies suggested that Poland should retire to the Curzon line and that representatives of Poland, Russia, Finland, Lithuania and Latvia should meet in London to arrive at a general peace settlement of eastern Europe. Russia refused this offer, but agreed to negotiate directly with Poland. The beginning of these negotiations, however, was delayed by Russia, who believed that the military situation would become more advantageous to herself with delay. The Russian forces were actually at the gates of Warsaw when the Allies at last became perturbed by the Russian advance, and a French mission under General Weygand arrived in Warsaw to assist the Polish General Staff. The government issued an appeal to the country, which responded nobly. On Aug. 14 Pilsudski opened a counter-offensive, and drove the Russians back in confusion. Poland, backed by the Allies, was now able to reject the crushing peace terms which the Russian delegates at Minsk had suggested. The conference was moved to Riga, where the preliminary treaty of peace was signed on Oct. 12. The final treaty was signed at Riga on March 18, 1921 and ratified by the *Sejm* on April 17.

Both parties recognized each other's sovereignty and agreed to refrain from propaganda and from harbouring organizations directed against the other party. All art collections, libraries, historical documents, etc., which had been carried out of Poland since the first partition, and all industrial installations evacuated during the Russian retreat in World War I, were to be restored to Poland. Russia was to pay 30,000,000 roubles in gold as Poland's share in the assets of the former Russian empire. A number of mixed commissions were set up to carry out the terms of this treaty; but considerable difficulty was experienced in recovering the art and literary treasures, and hardly any progress made in recovering the industrial material or obtaining cash payments.

The new eastern frontier of Poland ran southeast from the Latvian frontier, then mainly due south, passing some 18 mi. west of Minsk, and, further south, some 70 mi. east of Pinsk: in the neighbourhood of Ostrog it turned slightly southwest and continued so for some 25 mi.; thence it ran due south again till reaching the river Zbrucz: this it followed till its junction with the Dniester, which separates Poland from Rumania. The Zbrucz section of the frontier coincided with the Austro-Russian frontier of 1914, and the whole of the new eastern frontier of Poland roughly corresponded to the frontier left to the historical Poland after the second partition in 1793.

Vilna.—Simultaneously, Poland was embroiled with Lithuania over the question of Vilna (*q.v.*). This town and district had been occupied by Poland on April 19, 1919, hut were assigned to Lithuania by the Curzon line. Russia recognized Lithuania's claims to them by a treaty with Lithuania dated July 12, 1920; but afterwards, in the Riga Peace Treaty with Poland, she declared her *désintéressement* in the dispute. During their advance after the victory over Russia in 1920, Polish troops came into conflict with the Lithuanians. An armistice convention of Oct. 7 laid down a line of demarcation, which was to come into force on Oct. 10. On Oct. 9, however, the Polish General Żeligowski took possession of the disputed districts by a coup *de main*. The Polish government disowned the general but made no serious effort to recall him. The territory was first organized as an autonomous province under the name of "Central Lithuania," then, a plebiscite having declared in favour of Poland, it was incorporated in Poland as "the Palatinate of Vilna." Finally, the Conference of Ambassadors assigned Vilna and district to Poland on March 14, 1923. Lithuania refused to recognize this decision and continued to consider herself as in a "state of latent war" with Poland, till at the autumn session of the League of Nations in 1927, she was prevailed upon to declare the state of war ended. This only opened the way for negotiations concerning railway communication, river transit, consular representation and diplomatic relations; all these things had been non-existent between the two countries since 1920, to the great economic detriment and inconvenience of the population.

The Ambassadors' Conference on March 14, 1923, not only assigned Vilna to Poland, but recognized the whole of Poland's existing northern, eastern and southeastern frontiers in the name of the Allied Powers, the United States subsequently notifying the Polish government of their acknowledgment of this decision. Thereby, previous provisions for the future of East Galicia were repealed, and the province became an integral part of Poland.

Little Entente, France, Rumania and the Baltic States.—Surrounded by foes, Poland could not stand alone. The most important *bloc* in Central Europe formed after World War I was that of the Little Entente (*q.v.*). Although Poland had many interests in common with the members of this alliance, she was unable to join it. She had no quarrel with Hungary; but the long drawn out disputes with Czechoslovakia on the Teschen, Zips and Javorzina frontier questions prevented a close alliance with that power. Furthermore, Czechoslovakia had received a mandate over Carpathian Russia and hoped to establish a direct frontier with Russia. So long as the fate of East Galicia remained in abeyance, Czechoslovak and Polish interests were bound to conflict. A commercial treaty between Poland and Czechoslovakia was indeed signed in 1921, but important economic antagonisms continued to exist. and relations between the two states only began to grow more cordial in the Locarno period (1925 and after).

From the first, France had designated Poland as the ally which should take over Russia's role on Germany's eastern frontier. France gave Poland military assistance against Russia in 1920, and diplomatic support in the Silesian and East Galician questions, helping her to acquire most valuable coal and oilfields and industrial regions. France assisted Poland to organize and equip her army, lent her instructors and staff officers and made her generous loans for the purchase of war material. On Feb. 19, 1921 Pilsudski signed a Franco-Polish Treaty in Paris for the "maintenance of the treaties . . . the peace of Europe. the security of their territories and their common political and military interests." The Polish *Sejm* ratified this political treaty on May 30, 1922. It was supplemented by six conventions concluded at various times before 1925, viz., a military one (unpublished), and a series of others, relating to commerce, to the possessions and rights of individuals, to the exploitation of the Polish oilfields by French capital, to the immigration of Polish workmen into France (four successive agreements, 1919–25), and to consular and juridical matters.

The treaty of March 3, 1921 with Rumania provided chiefly for mutual assistance in case of attack from the east; a military convention followed. A definite alliance between Poland and the Baltic States proved impracticable as, quite apart from the antagonism between Poland and Lithuania. the smaller states could not contemplate anything hut a defensive attitude towards Russia. In July 1921, however, representatives of Poland, Finland, Latvia and Estonia met at Helsingfors and determined to hold periodical conferences to exchange opinions on matters of policy and discuss the possibility of joint action. Such conferences were held every year since, but dealt mostly with minor financial and economic problems. An attempt to reach a political agreement in 1922 failed owing to the opposition of the Finnish diet. In Jan. 1925, a multilateral arbitration treaty was signed between Poland and the Baltic States. Commercial treaties were concluded with all the Baltic States individually, and commercial, as well as non-aggression treaties with all the three Scandinavian countries.

In the course of several years, commercial treaties were concluded by Poland with a large number of states, and in the case of some of them, arbitration treaties followed. During the years 1922–27, commercial treaties were concluded with 24 states, viz., Rumania, Italy, Switzerland, Austria, Yugoslavia, Japan, Belgium (and Luxembourg), Turkey, Finland, Great Britain (and the Dominions, treaty of July 1, 1924), Denmark and Iceland, Sweden, France (latest treaty, July 10, 1925), the United States (Feb. 10, 1925), Hungary, Greece, Czechoslovakia, Bulgaria, Norway, Estonia, Persia and Latvia.

The Minorities Questions. — Within her frontiers the new Poland, like the old, included a considerable proportion of minorities non-Polish in speech and race. They made up nearly one-third of the whole population (including approximately 3,883,000 Ruthenians, 2,123,000 Jews, 1,057,000 White Ruthenians, 1,036,000 Germans, 72,000 Lithuanians and 210,000 Russians, Czechs, Tatars, etc.), sufficient, under the system of proportional representation and *scrutin* de liste, to give the bloc of national minorities 89 deputies in the first regular *Sejm* of 444 deputies.

The Polish Minorities Treaty of June 28, 1919, signed by Poland at Versailles and guaranteed by the League of Nations, secured that all bona *fide* inhabitants of the districts allotted to Poland be admitted to Polish nationality and citizenship in the fullest sense (except in the case of recent German colonists); guaranteed the minorities the right to use their own language; to maintain their own institutions, to receive primary instruction in their own language, and where the proportion was considerable to receive "an equitable share in the enjoyment and application of public funds." The Jews are included among the "racial, religious or linguistic minorities"; Yiddish is recognized as a language, and the Jews are granted special protection as regards education and the keeping of the Sabbath.

The most difficult minorities questions, after the Jews, proved to be those of the Ukrainians. On Sept. 26, 1922 the *Sejm* passed a general law on provincial self-government which established local bodies (dietines) for dealing with purely local affairs. This law granted a small measure of autonomy to East Galicia, but not enough to prevent complaints.

Serious disputes arose, not only with the Ukrainians, but also with the German minorities. In 1924 a more conciliatory spirit began to prevail. On July 10 of that year a bill was passed providing for the use of Ukrainian, White Ruthenian and Lithuanian in government offices, law courts and schools in districts where the majority of population speaks one of those languages. In the summer of 1924 the government concluded a kind of pact with the Jewish leaders by which the government promised to promote the religious and educational interests of the Jewish community, while the Jewish leaders pledged themselves to abstain from anti-Polish propaganda abroad. But it was only the resolutely liberal policy of the government of Marshal Pilsudski from 1926 onward that achieved a greater measure of success in reconciling the minorities to Polish rule.

The Agrarian Question. — The first period of Poland's independent existence bore the marks of its origin, which had been to some extent revolutionary. The franchise promulgated in 1918 for the elections to the Constituent Assembly allowed the often untutored wishes of almost the entire adult population of Poland to find expression. The Constituent Assembly, which counted 337 members, was, in consequence, composed mainly of peasants (who form two-thirds of Poland's population). Between a group of only 32 socialists and of 107 nationalists, the peasants formed a sort of Centre Party, soon themselves divided into a right and a left wing.

The land reform bill was introduced in the *Sejm* on July 10, 1919, and was passed by a single vote in a House of about 360. It proposed the nationalization of forests and limited the amount of land to be held by an individual in Poland to from 148 to 248 ac., although in the borderlands a higher limit of 988 ac. was fixed. The land thus available was to be used for increasing "dwarf holdings" to economic small holdings and settling the landless in new small holdings. The reform, however, was not carried through as originally intended. It was impossible in any case to put through expropriation on a large scale, for financial reasons. The bill became a convenient asset in the political bargainings of the over-numerous parties of the Sejm. In 1925, it provided for the distribution of about 50,000 ac. a year to a period of 10 years. The maximum which an owner could retain was 148 ac. in the industrial centres, 740 ac. in the border provinces and 435 ac. in other areas. A series of remarkably good harvests fortunately diminished somewhat the acuteness of the problem.

The Labour Question. — Labour inspection was introduced on Jan. 3, 1919, the organization of the Labour Inspection Bureaux being slowly extended until the whole country was covered in 1923. The duties of labour inspectors include that of arhitration. Working hours were regulated by the Statute of Dec. 8, 1919, by an amendment to this statute of Feb. 14, 1922 and by various other statutes. The working day, with certain exceptions, is limited to 8 hours and the working week to 46 hours. The Decree of Feb. 8, 1919 introduced the freedom of coalition and defined the status of trade unions, which after that date grew rapidly in numbers and importance. At a later period, Poland took a very important part in the work of the International Labour Organization, being among the states to ratify most readily the draft conventions prepared by that office. Nevertheless, the position of workmen in Poland long remained distressful.

Constitution and Administration. — Under the constitution of March 17, 1921, amended in some of its articles on Aug. 2, 1926, Poland was a republic. The legislative power was vested in a diet (Sejm) and a senate, which were summoned, adjourned and dissolved, but not without their own consent, by the president. The diet was composed of paid members elected for five years, upon a system of proportional representation. Suffrage was universal, all who enjoyed full civic rights and who were over 21 being qualified to vote; soldiers on active service were excluded. Citizens over 25 were eligible for election to the diet, members of the civil service could not be elected for the district in which they held office. The minimum age for voting in senatorial elections was 30, while no one under 40 was eligible for election. Bills went to the senate after being passed by the diet and if no objection was raised within 30 days the bill became law. Taxes and customs duties could be established only by law and a supreme board of control superintended the management of state finance. The executive power was exercised by the president and a council of ministers who were responsible for his official actions. He was elected for seven years by the National Assembly, that is the diet and senate acting together.

For purposes of administration Poland was divided into 16 palatinates, which again were subdivided into districts, and urban and rural communes. The palatine or the *wojewoda* represented the executive government in the palatinate, the starosta in the district. Local legislation was to be exercised by *dietines* ("seymiki") in the palatinates, and by district councils in the districts. Economic autonomy was established by means of chambers of agriculture, commerce, industry, etc.; judicial control over the whole administration was vested in a supreme administrative tribunal.

Poland was reconstructed out of provinces of three empires in which widely different systems of law were operative. A codifying commission began to work out a body of uniform codes of law for the whole republic; in the meantime, Russian, German and Austrian codes remained in force in the different parts of the country. Gradually, many domains of legal relations were covered by parliamentary legislation, and, after 1926, by presidential decrees. A supreme court of justice in Warsaw was established at an early date, but it was only in 1928 that the country found itself in possession of a unified judicial organization and a uniform code of judicial procedure. Judges were nominated by the president, and irremovable except by judicial decision. Justices of the peace were locally elected by the people. Over property in land, forests and mineral wealth, however, a certain amount of state control was extended by special provisions of the constitution. State protection was given to labour, and insurance against unemployment, illness and accident was guaranteed. The exercise of religion was free, as far as it was in accordance with the law. The Roman Catholic religion, the predominant denomination of the country, was placed by the constitution in a privileged position.

The First Parliament. — The constituent Sejm had 13 political parties, as well as two independent members, and it was difficult to ensure a stable government. The resignation of Paderewski (Nov. 1919), was being followed by a succession of quickly changing cabinets, always based on unstable coalitions—chiefly between the Peasant Centre and either the Nationalist Right or the mainly Socialist Left. A cabinet under the former Galician peasant leader Witos (the first of three of which he was to be the head) succeeded at a critical moment in rousing the country—chiefly by lavish promises of agrarian reform to the peasants—to shake off the Bolshevik invasion. Another cabinet, headed by Professor Ponikowski, in 1922, being a non-party one, was unhampered by political conflict; accordingly, its foreign minister, Skirmunt (afterwards Polish ambassador in London), and its finance minister, Dr. Michalski, achieved certain successes—the latter by introducing a capital levy and temporarily stabilizing the currency.

Towards the end of 1922, the prolonged legislative period of the Constituent Assembly came to an end. An electoral law was passed on July 28, and in November, elections for the upper and lower house of the first regular parliament were held. They ended by distributing power in the chamber pretty evenly between the Nationalists (16.3) and the peasant groups (150); the Socialists obtained only 41 seats, but the National Minorities, by organizing a bloc for electioneering purposes, got 83 (of whom 36 were Jews) and accordingly, in spite of the large abstention of the Ukrainian element from the elections, became an important and occasionally a decisive factor in the parliamentary system.

The first business of the two houses of the new parliament was jointly to elect a president of the republic. Marshal Pilsudski refused to stand. The parties of the Left, supported by the National Minorities and the Witos Peasant Party, secured the election of Narutowicz, a friend of Pilsudski. who had acted as minister of foreign affairs in several cabinets. Polish nationalism was infuriated by the election of a president through the votes of the National Minorities, including the Jews; and on December 16 a fanatic assassinated H. Narutowicz. The new president was Wojcieshowski, an old member of the Polish Socialist party. General Sikorski became premier.

Financial Collapse and Reforms.—Poland's position in the early part of 1923 was still very unsettled. The Polish mark was affected by the collapse of the German currency. Relations with Russia remained unsatisfactory, being especially troubled by the soviet's persecution of Catholic priests. A government formed in the spring by Witos, on the basis of an alliance between the Peasant Party and the National Democrats, had to struggle against the resolute opposition of the Left and the National Minorities; in spite of an excellent harvest, the government proved unable to cope with the continued, disastrous fall of the mark; there was serious unrest in the country, culminating in riots at Cracow on November 6; and the government was obliged to resign on December 11. It was followed by a non-party one under Grabski, who, as prime minister and minister of finance, made financial reform his principal task. The political parties now at last agreed to subordinate all other problems to those of financial reconstruction. On Jan. 3, 1924, Grabski's government was granted emergency powers for the purpose. Fulfilling partly the recommendations of a British financial adviser, Mr. Hilton Young (now Lord Kennet), Grabski strenuously reorganized the financial system of the country. A bank of Poland was once more created on a basis of private subscription. The budget was balanced by draconic reductions in expenditure, the printing of paper money stopped, the currency became stabilized at the disastrous rate of exchange which it had reached (1,800,000 marks to the gold franc), and finally, a new currency unit, the zloty, was Introduced and declared equal to the gold franc. The drastic manner in which this financial reform was accomplished, inevitably brought about its revenge. The too high level at which the value of the new currency had been fixed, caused a period of heavy economic depression. The balance of the budget proved impossible to maintain, and finally the zloty fell to about half its value. The consolidation of the Polish debt to America (Nov. 14, 1924) and to Great Britain (Dec. 10, 1924) produced a favourable impression; but both an Italian and an American loan which the administration managed to obtain, were unsatisfactory; and the trading aw-ay of one asset of the state after another--such as the tobacco monopoly and the monopoly of matches—disquieted opinion at home. It was not till the force of events had corrected the errors of Grabski, that his achievements could be turned to profitable account by his successors, and the great work of financial stabilization completed.

Religious Matters.—One of the most important agreements concluded by Grabski was the Concordat reached with the Holy See on Feb. 10, 1925. The Catholic Church was granted absolute freedom of execution of her authority and jurisdiction in Poland; the assistance and support of the state being assured her in this respect. The state's interests in connection with nominations for the higher ecclesiastical posts were adequately protected. In religious education, the competencies of church and state were exactly defined. The division of Poland into ecclesiastical provinces was carried out in such a way that no portion of Polish territory remained subject to the jurisdiction of a bishop residing outside the borders of the state. An autocephalous Orthodox Church also established in Poland received the blessing of the Synod and of the Oecumenical Patriarchate in Constantinople on Nov. 11, 1924. The Protestant Church in Poland was likewise placed beyond reach of political influences from abroad.

Security.—Skrzyński, Poland's foreign minister for the second time in Aug. 1924, took an active part in the work of the Fifth Assembly of the League (Sept. 1924). The rejection of the Geneva protocol by Britain in 1925 alarmed Polish opinion. So did the German proposals to France in the spring of 1925, which treated the problems of Germany's western and eastern frontiers separately. The Polish thesis was that the question of security in western Europe was in'separably connected with that of the stability of frontiers in the east, as both were established by the Treaty of Versailles and any new agreements would have to be in strict accordance with the Peace Treaties and with the existing alliances.

Poland's relations with Germany were further troubled, firstly by the breakdown of negotiations for a commercial treaty, followed by a tariff war, secondly by a failure of the arrangements to receive the German natives of Poland who had not opted for Polish nationality, whom the Polish government called upon to leave Poland on or before July 31, 1925. Danzig was a perennial cause of friction. Its economic importance for Poland, its racial bonds with Germany, were never forgotten by either party.

The Locarno pact (*q.v.*) signed on Dec. 1, 1925, brought forward a fresh solution to the problem of Poland's security. Poland and Germany signed an arbitration treaty which included the recognition of the inviolability of the existing treaties, the recognition of the integrity of each contracting party's rights, and the elimination of war as a means of settlement of disputes and conflicts. In a separate treaty of guarantee between France and Poland, France is referred to as the guarantor of the Polish-German arbitration agreement. France undertook in the case of an unprovoked attack by Germany against Poland to abandon no means of assistance at her disposal and within the limits of the Covenant and of the agreements with Poland. Polish opinion was not easily reconciled to the idea of the Locarno pact. The arrangements mere accepted, but there was some feeling that Poland was being abandoned by France, which even brought about a temporary *rapprochement* with soviet Russia. Soon afterwards the breakdown of his financial policy caused the resignation of Grabski.

On Nov. 20, Count Skrzynski formed a new coalition cabinet. The treasury was almost empty, the shortage of private capital was very great, unemployment was rife, and the zloty continued to fall. The year 1926 opened amid violent controversy. The Socialists proposed economies on the aimy budget, but would not hear of a reduction in the number of railway employees, asked for a rise in salaries in the lower branches, and demanded a large program of public works to relieve unemployment. The Right, on the contrary, desired a reduction of civilian expenditure, while maintaining the army at full strength. Another storm-centre of embittered dispute was the question of re-instating Marshal Pilsudski in the position of commander-in-chief of the army. He had resigned the office of chief of staff during the government of the Nationalist-Peasant coalition.

In foreign affairs, the Skrzynski administration w-as under the shadow of a growing feeling of international insecurity for Poland. A large German espionape organization was discovered in Poland. When, a month after the ratification of the Locarno Treaty, the League of Nations proceeded to elect Germany a permanent member of the Council, the Polish delegates claimed a permanent seat for Poland as well. It was not till after a good deal of dramatic friction in the League that a solution was found—Germany getting a permanent, and Poland a so-called "half-permanent" seat in the Council. Apart from securing for Poland this important place in the League, the Skrzynski government endeavoured to strengthen Poland's international position by regional understanding with her neighbours: the alliance with Rumania was renewed; an exchange of visits took place between Skrzyński and Dr. Beneš, and a number of conventions, including an important political treaty, was concluded with Czechoslovakia; finally, as a result of Skrzyński's visit to Vienna, a new arbitration treaty was signed with Austria.

MARSHAL PILSUDSKI'S RULE, 1926-35

Meanwhile internal dissensions intensified while the conclusion of a new Russo-German treaty in Berlin (March 1926) increased the general nervousness. Pilsudski, in his retreat, was looked up to by large masses of the people as the only man who could secure a better future for the country. His adherents and opponents formed two opposing camps in the army. In parliament, the Right, since the days of his provisional presidency, had used every legislative device to limit his power and influence. Now, in the dispute over his commandership, the Right desired to frame the Army Organization bill in such a way as to bring the army under the direct control of parliament, while Pilsudski insisted on complete independence of the commander-in-chief.

Matters came to a crisis, when, owing to the dissensions over the budget, the Socialist ministers left the cabinet, and Count Skrzynski himself resigned in consequence. After a prolonged period of negotiations Witos succeeded in forming a ministry. Rumours were current that he meant to rely exclusively upon the support of the Right, and to settle the question of the commandership in the sense demanded by the Nationalists. Thereupon, on May 12, Pilsudski suddenly entered Warsaw at the head of troops. The government proclaimed him a rebel. The concentration of government troops in Warsaw, however, was hampered by a strong strike movement in the country, chiefly among the railwaymen; and after two days of heavy fighting in the streets of Warsaw, Pilsudski was master of the capital. The government resigned, and the president of the republic abdicated. Rataj, the marshal of the *Sejm*, became acting head of the state, in accordance nith the terms of the constitution. A provisional cabinet under Professor Bartel was appointed, pending the election of a new president. By May 17, the country was quiet, and when the two chambers met for the presidential election, there resulted an overwhelming majority in favour of Pilsudski. He, however, refused the office in favour of his nominee, Professor Ignacy Mościcki, a scientist not formerly engaged in politics, who was duly elected. Pilsudski himself became minister of war, and a few months later, officially assumed premiership in the cabinet.

Pilsudski met with little opposition when he proceeded to reform the constitution in the sense of limiting the powers of parliament, and strengthening the executive. In doing this, he stopped short, however, of the more thorough-going dictatorship established in Italy. Many points in state organization which it had proved impossible to get settled by parliament. were now settled by decree. Many personal changes were made in the higher posts both of the civil administration and of the army: they were not always improvements as far as professional efficiency was concerned, but they invariably strengthened the government's grip of the country. The freedom of political discussion in the press was curtailed by two severe decrees. On the whole, however, the home policy of the new government was liberal and democratic enough to cause no discontent among the masses.

Inflation, which had begun to reappear, was stamped out; the budget was strictly balanced, and reserves created. The urgent need for an increase in the salaries of the state servants was satisfied only gradually and by very economic instalments. This policy of circumspection, coupled with a fairly good harvest in 1926 and the favourable effect of the English coal strike that year on Polish coal export, produced good results: the rate of exchange of the zloty ceased to waver, and remained *de facto* stabilized at about 43.60 to the £, or 8.90 to the $. The government engaged the services of the American currency expert Professor Kemmerer, and the principal recommendations of his mission concerning reforms in financial administration were carried into effect by presidential decree. An American loan of $70,000,000 was obtained by Poland in autumn, 1927, and was used principally for the final stabilization of the currency system. The appointment of an American adviser as a member of the board of directors of the Bank of Poland established a useful permanent connection with American capital. In spite of frequent provocation, peace with Russia was steadily maintained; even after the murder of the soviet envoy in Warsaw by a Russian emigrant student, a rupture was avoided, and negotiations towards the conclusion of a commercial treaty were begun. Similarly, everything was done to produce better relations with Germany, although incidents which might have caused quarrels were frequent. With Germany also, negotiations for a commercial treaty were opened in 1927.

Constitutional Reform.—A year and a half after Marshal Pilsudski's *coup d'état,* a new parliamentary election became due in Poland. He had left the outward structure of the parliamentary system intact. The practical impotence, however, to which his rule reduced the sometime all-powerful parliamentary parties, had a profound effect on them. The largest groups began to disintegrate, and when the elections approached, as many as 35 different factions appeared in the field with lists of candidates of their own. This "pulverization of the party system" was the result of splits in the larger groups on the one issue that remained dominant under the circumstances, viz., the question: *for* Pilsudski or *against* him. In the midst of this re-shuffling of all former groupings, the government created a non-party *bloc* of its supporters of various shades of opinion. From the elections held on March 4 and 11, 1928, only the Socialists emerged with a substantial increase in the number of their seats (by about one-third); the other parties which had once been strong factors—the Peasant and the Nationalist Party—dwindled down to insignificant handfuls of deputies; the national minorities, largely placated by Pilsudski's liberal policy, did not form a solid anti-government *bloc,* as they had done in 1922, and therefore achieved no marked success, even in the eastern borderlands; the Jews, in particular, torn by dissensions between the Zionist intelligentsia and the Orthodox masses, lost heavily; and in the midst of all these considerably diminished factions, the government *bloc* entered parliament as the strongest of all groups. (R. Dy.)

The opposition, however, remained so strong that a normal co-operation of the parliament with Pilsudski proved impossible. In the autumn of 1930, the growing tension resulted in the arrest of some of the party leaders, who were imprisoned at Brzesc and treated there very badly. New elections held in November gave to the government *bloc* an absolute majority and after long discussion the draft of a revised constitution was voted, not without encroachment upon the existing rules of procedure.

That new constitution, finally sanctioned on April 23, 1935, was based on the following principles: the state being considered as the "common good" of all the citizens, the executive becomes considerably strengthened at the expense of the legislature; the president appoints and dismisses the prime minister and the commander of the army, can dissolve the parliament, and is responsible to none; the six "organs of the state"—government, diet, senate, army, courts of justice, and court of supervision—are accordingly under the president's control; the powers of the parliament are strictly limited, and the number of its members reduced to 208 in the lower and 96 in the upper house, one-third of the latter being nominated by the president. As a whole, it may be regarded as intermediary between plain democracy and personal government.

Bilateral Treaties.—During the first six years of Pilsudski's regime, A. Zaleski being minister of foreign affairs, Poland's policy was chiefly based upon the League of Nations and the close alliance with France. Poland which had proposed to the League's Assembly of 1927 a resolution outlawing wars of aggression, not only signed the Kellogg Pact of the next year, but even anticipated its realization by a special agreement with soviet Russia, in 1929. In 1932 that "protocol" was developed into a pact of non-aggression, which clearly expressed an imminent change in the methods of Poland's foreign policy. At the Disarmament conference of the same year, the Polish delegation had played an active part, submitting an elaborate plan of "moral disarmament"; but it became obvious that the idea of collective security had failed, and Poland sought better guarantees in bilateral agreements with her neighbours.

After 1932 this method was developed by the new minister of foreign affairs, Colonel Beck, and found its strongest expression in another 10 years' non-aggression pact, concluded on Jan. 26, 1934, with Germany. There was of course a reservation that the new treaty was not to affect Poland's previous engagements, particularly her alliance with France. Nevertheless it seemed to involve a change in Poland's general attitude, which might be explained by her opposition to the planned four-power pact and her tendency to greater independence in foreign policy. Seeing that nobody in Europe was prepared to fight the new Hitler regime, Pilsudski found it necessary to accept a direct understanding with Poland's western neighbour also, holding the balance between Russia and Germany.

1935–39

After Pilsudski's death on May 12, 1935, the form of government which he had established continued without much change. The voting regulations, as applied at the elections of 1935, without having been defined in the new constitution itself, again raised much discontent; but attempts were started to come to some co-operation with various groups of the opposition. The government *bloc* was dissolved and replaced by a "Camp of National Unity," the work of Colonel Koc. Both President Mościcki, who had been re-elected in 1933 for another 7 years' period, and Marshal Smigly-Rydz, Pilsudski's successor as commander of the army (who was appointed "the second person" in the republic), exercised their authority with moderation and in a conciliatory spirit. Such an appeal to internal unity was indeed indispensable in face of the increasing danger of the international situation.

The Origin and Outbreak of the War.—That danger resulted from the policy adopted by Germany. After the annexation of Austria and the destruction of Czechoslovakia, it was clear that Hitler wanted to isolate each of Germany's eastern neighbours to be attacked one after the other. Soon after Munich, when Poland had seized the opportunity to claim the contested territories in the Cieszyn (Teschen) region, there began a new tension between her and Germany. Yet on Jan. 30, 1939, Hitler reaffirmed the importance of the German-Polish non-aggression pact as a contribution to the peace of Europe; but he had already decided to annex the Free City of Danzig, and on March 27 he officially requested the Polish government to accept that solution as well as the construction of an extraterritorial motor road through the Polish province of Pomorze, the so-called "Corridor." Touched in her vital interest and realizing that it was a first challenge against her independence, Poland refused. making counter-proposals which were never taken into serious consideration. And as soon as Poland had exchanged with Great Britain reciprocal guarantees of independence and integrity, Hitler took it as a pretext to denounce, in his speech of April 28, the non-aggression pact of 1934.

During the next four months he tried to provoke Poland by various incidents in Danzig and started a propaganda campaign against an alleged ill-treatment of the German minorities in Poland. But it was not before having concluded, on August 23, a far-reaching "non-aggression" treaty with the soviets that he finally decided to attack Poland. Two days later a close alliance was signed between Poland and Great Britain which made it absolutely clear that Britain, as well as France, would support her ally in case of war; but in spite of a patient conciliatory effort made by British diplomacy, and proposals of a peaceful settlement put forward by various powers and accepted by Poland, Hitler invaded Poland on September 1.

Poland, which had postponed the general mobilization to the last moment, was unable to stand against the overwhelming German forces, the long open frontier stretching from East Prussia to Slovakia being already occupied by German troops; nevertheless she made a courageous resistance in the centre of the country until Sept. 17, when soviet Russia invaded her territory from the east, under the pretext that the Polish state, with which she had concluded and recently extended a non-aggression pact, was no more in existence. Even then in various regions desperate fighting was continued, and Warsaw, although hideously bombed, like so many other open places, defended itself heroically until September 27. The next day a German-Russian treaty was signed in Moscow involving a new partition of Poland: the eastern provinces, including purely Polish territories, were incorporated in the soviet republics of White Ruthenia and the Ukraine; the western part was left within the German sphere of influence, and the provinces which had belonged to Prussia before 1914 were annexed at once, not without a barbaric massacre of their Polish inhabitants. In the centre also, where Hitler tried in vain to form a pseudo-Polish "government" under his control, cruel persecution followed the hostilities.

Even before leaving Polish territory, President Mościcki resigned and designated W. Raczkiewicz as his successor. The new president appointed a new government, the former having been interned in Rumania. General Sikorski became prime minister, Zaleski minister of foreign affairs; and both president and government were established at Angers, France. The Polish army was also reconstituted in France, to fight with the Allies, while some Polish warships, having escaped, joined the British navy. (*See* World War II.) (O. Ha.; X.)

POLAND IN WAR

General Sikorski not only accepted the portfolio of military affairs, which later, in 1942, was given to the noted historian General Marian Kukiel, but also became the commander-in-chief of the reorganized Polish army. This was possible owing to the favourable circumstance that part of the Polish army passed into Hungary and Rumania, and succeeded in assembling in France, where their ranks were swelled by mobilization among the pre-war Polish emigrants in that country. The Polish army numbering nearly 100,000 was ready for battle by the spring of 1940. Some of its units had already distinguished themselves in the distant Norwegian expedition of the allies, especially in the battle of Narvik; but the Polish soldier covered himself with fresh glory, above all, in the share he took in the defense of France.

The collapse of France was likewise a heavy blow for Poland. In spite of fresh losses and the capitulation of one of the allies, the Polish army did not even now dream of ceasing to fight. About 15,000, who had heroically protected the retreat of one of the French armies, had to cross into Switzerland, where they were interned. A part of the Polish army was transported to England, where at the end of June 1940, the Polish government together with the president transferred themselves. The Polish troops, quartered chiefly in Scotland, undertook the defense of a certain part of the British coast, the Polish airmen began increasingly to distinguish themselves, acting with the royal air force, and simultaneously Polish divisions, dispersed through the world, as of old in the Napoleonic wars, have appeared in Palestine and on the fields of the Egyptian-Libyan battles, while Polish volunteers have not been absent even from the Greek front.

The break between Hitler and Stalin, between naziism and communism, whose joint action against Poland brought both attacks against this country, that of Sept. 1 and that of Sept. 17, 1939, started a new war on Polish soil and brought still more devastation and hardship to an already inhumanly suffering country. The war between Germany and Russia confronted the Polish government with a difficult decision. Taking into consideration the foremost necessity of defeating Germany and the common interests of all the allies, Poland not only agreed to make peace with Russia on July 30, 1941, but concluded with her a close alliance on Dec. 4 of the same year and decided effectively to assist the Russians.

Poland's hope for the complete restitution of her freedom and integrity received the strongest possible support by the second great event of 1941: by America's entry into the war after the aggression of Pearl Harbor on Dec. 7.

To that so-called "New Order" which the totalitarian powers desired to impose upon Europe, Poland, in co-operation with her allies, opposed her own political conception evolved from her history of a thousand years, especially from the epochs of her political greatness. It was clear that this conception could only be realized after a British-American victory. The declaration given out in common by the Polish and Czechoslovakian governments at the end of the Year 1940, proved that Poland had a full comprehension of the necessity of these independent states joining into federal unions, and that she-was conscious of her share of responsibility for precisely such a settlement of that most threatened part of Europe between Germany and Russia, in which the central key position had for centuries fallen to Poland. The promise of a closer Polish-Czechoslovakian collaboration towards that object had a deep significance, removing the unfortunate misunderstanding between these two nations, and at the same time offering a distinct encouragement to other nations of that region to join, obviously on the principle of equality for all, the projected federal system. Moreover, at the International Labour conference held in Washington one year later, these two nations decided closely to co-operate with two others, Yugoslavia and Greece, which concluded a similar agreement. Part of the Polish soldiers released from Russian prison camps reached England and the middle east by the end of 1942. Early in 1943 the Polish army numbered over 130,000. (J. Ci.)

BIBLIOGRAPHY.—1. *Political History.* The epoch-making book of Michal Bobrzyriski, *Dzieje Polski w zarysie* (2 vols., 1877; 4th edition, Warsaw, 1927) gave expression to the views of the so-called "Cracow School" whose leading idea was that inward political decay was the principal cause of the fall of Poland. These views have since been counterbalanced by those of the "Warsaw" and the "Lwow" (Lemberg) school, which placed emphasis on outside aggression. An up-to-date presentment of Polish history is given in a history of Poland which forms part of a *Polish Encyclopaedia* published by the Polish Academy at Cracow, *Historja polityczna Polski* (vol. I., 1920; vol. II., 1923).

POPULATION

The population of Poland in 1931 was 31,927,773. In 1939 it was estimated at 35,100,000. The detailed population returns for 1931 are shown in the subjoined table:

provinces	Area in Square Km.	Population	Density per Square Km.
Bialystok	32,134	1,640,374	51·0
Cracow	17,448	2,297,027	131·6
Kielce	25,741	2,935,680	114·0
Lwow	28,391	3,127,138	110·1
Lodz	19,034	2,632,434	138·3
Lublin	31,123	2,468,391	79·3
Nowogródek	23,169	1,054,846	45·5
Polesie	36,825	1,133,398	30·8
Pomorze	16,386	1,086,144	66·3
Poznan	26,528	2,112,871	79·6
Silesia	4,230	1,298,851	307·1
Stanislawów	16,909	1,475,954	87·3
Tarnopol	16,332	1,599,574	97·9
Vilna	28,948	1,272,851	44·0
Volhynia	35,729	2,081,501	58·3
Warsaw	29,463	3,710,739	125·9
Total	388,390	31,927,773	82·2

In regard to population Poland occupies sixth place among the countries of Europe, coming after Russia, Germany, Great Britain, France and Italy. The chief feature of recent years has been the movement of the rural population to the towns, of which 51 in 1931 had a population of over 25,000. The largest towns are Warsaw, the capital, with 1,289,000 inhabitants (est. 1939); Lodz, with 672,000; Lwow, with 318,000; Poznan, with 272,000; Cracow, with 259,000; and Vilna, with 209,000. The population is most dense in the industrial areas of Silesia, Lodz and Warsaw, and in the fertile agricultural districts of Cracow, Lwow, Tarnopol and Kielce; but it is far more scattered in the eastern provinces.

According to nationalities the population was made up as follows in 1931:—

Nationality	Total No.	Percentage
Poles	22,000,000	68·9
Ukrainians	3,200,000	10·1
Jews	2,700,000	8·6
Ruthenians	1,200,000	3·8
White Ruthenians	1,060,000	3·1
Germans	700,000	2·3
Lithuanians	100,000	0·3
Czechs	47,000	0·1
Others	920,000	2·8
	31,007,000	100.

In Poland the Poles form over two-thirds of the population, constituting the great mass of the inhabitants of all the western and central provinces, with a German minority in Silesia, Poznan and Pomorze. The Poles are in a minority in the Ruthenian provinces of Stanislawów, Tarnopol, Volhynia and Polesie, while the nationality of the White Ruthenians of Vilna and Nowogrodek is a matter of dispute, those who are Catholics being claimed as Poles. The Jews are scattered over the whole territory, being particularly numerous in Warsaw and Lodz and in the towns of the eastern provinces.

With the exception of the Kashubes of Pomorze, who are a relic of the old Pomeranians, the Polish people form one ethnological group. Certain peculiarities of geography or history give local differences to the Mazovians, who are well built, sturdy folk, drab in costume, tenacious of their ancient customs, democratic and great colonists; to the Gdrale or highlanders of the Carpathians; to the Kurpie of the Narew basin; and to the Poles of Silesia. But the attempts of hostile politicians to claim wide differences of dialect and custom have not been justified. The Poles are more uniform in language and customs than any other great nation.

POLES ABROAD

There are some 8,500,000 Poles living outside the frontiers of Poland, either as autochthonous inhabitants, or as emigrants who left their country in search of work. Of those autochthonous Poles living on the borders of Poland there are some 80,000 in former Czechoslovakia. In Lithuania there are about 200,000 around Kovno (Kaunas) and Kiejdany; in Latvia there are 75,000 near the Polish frontier and around Riga and Mitava, while there are 80,000 in Rumania in the former province of Bukovina.

The number of Poles in the U.S.S.R. reaches the figure of 1,000,000, half of them being autochthonous in White Russia and Ukraine, the remainder being the descendants of those Poles who for various reasons, mainly political, settled in the eastern province of the Russian empire.

The greatest centre of Polish immigration in Europe is France. In the year 1929 it was estimated that there were 800,000 Poles in France, but later, owing to the economic crisis, this number dropped to about 600,000. About two-thirds of these Poles work in the mines and textile mills in the northeastern departments of France, around Lens and Lille, while there are not a few living in Alsace.

Many Polish industrial workers are also found in and around Paris and Lyons. About one-third of the Polish immigrants work on the land, mainly in the southwestern districts, of which the centre is Toulouse. They are (1939) granted adequate educational facilities by the French government, and about 35,000 Polish children are taught in their own language. Three daily newspapers are published in the Polish language, as well as about a dozen other periodicals.

In Belgium there are about 35,000 Polish workers, mostly miners, concentrated in the province of Limburg. They also have schools for about 3,300 children.

Lastly, Holland accounts for 4,000 Polish workers, Denmark has 12,000, Yugoslavia 25,000 and Hungary 7,000, without counting the smaller groups of Poles in Bulgaria, Esthonia and Luxembourg.

Outside of Europe, the biggest Polish colony is in the United States. It is estimated that there are some 4,000,000 Poles, many of them settled in America for several generations, preserving their language and customs although remaining at the same time loyal citizens of the country which gave them their opportunities. The great majority of these Poles are industrial workers, while about one-fifth are farmers and agricultural workers.

The largest Polish population is in Chicago, where there are approximately 500,000 men and women. The estimated Polish population of other centres is as follows:

Detroit	200,000
Milwaukee	125,000
Cleveland	110,000
Buffalo	100,000
Philadelphia	75,000
Pittsburgh	75,000
New York	70,000
Toledo	40,000

The Polish agricultural population is to be found chiefly in the states of Texas, Michigan, Wisconsin, Missouri and North and South Dakota.

The Poles in America have formed important associations, the largest of which is the National Union of Poles ("Związek Narodowy Polski") with a membership of over 300,000, the Polish Roman Catholic association ("Zjednoczenie Polskie Rzymsko-Katolickie") with 160,000 members, and the Association of Polish Women, with about 60,000 members. About 800 Polish Catholic parishes exist in America, served by more than 1,000 clergymen, with some 600 primary schools and 20 higher schools, while many American universities have special Polish lecturers.

There are about 65,000 boys and girls in the Polish scout movement in the U.S.A. The "Polish-American Council" in Chicago, Ill., is the chief Polish organization in the United States.

Ninety-six Polish periodicals are published in the U.S. in Polish, including nine daily newspapers.

In Canada there are about 150,000 Poles, chiefly agricultural workers in the provinces of Ontario, Manitoba, Alberta and Saskatchewan. The Polish industrial workers are centred in Winnipeg, Toronto and Ottawa. The Canadian Poles have a number of Polish schools (about 30) and Polish organizations. They publish only three periodicals, as they read mainly those published in tne United States.

In Brazil there are about 300,000 Poles settled principally in the state of Parana (200,000), but there are also many in Rio Grande del Sul and in Santa Catharina. The centre of the Polish movement in Brazil is the town of Curitiba in Parana.

In the Argentine there are 70,000 Poles, mostly industrial workers. Apart from Buenos Aires, the greatest number of Poles are in the province of Missiones. There is only one daily paper and six periodicals, while there are very few Polish schools, attended by about 350 children.

In Paraguay there are about 18,000 Poles, mostly farmers in the country near the town of Fram. The number of Poles in other South American republics does not reach more than 1,000 or 2,000 in each country.

Two thousand Poles live in Australia—in Brisbane, Sydney and Ipswich, while a few thousand are in South Africa, and about 1,000 in Morocco and Algiers.

Owing to the unsettled political and economic conditions in China, it was impossible to obtain exact facts and figures in 1943, but there must be some scores of thousands of Poles in that country, especially in Shanghai and Charbin.

ECONOMIC AND FINANCIAL CONDITIONS

The economic organization of Poland by a political unit was kept in suspense, after 1918, until some definite basis could he created both for external and internal relations. In foreign affairs the essential preliminary of defined frontiers was not obtained until the defeat of the Bolshevist armies, in Aug. 1920, had been crowned by the Treaty of Riga (March 1921), and not put beyond question until Polish Upper Silesia was taken over in July 1922. At home a constitution and administration had to be created in the midst of the war with the bolshevists, and the damages of World War I repaired.

Agriculture.—Although industry has developed rapidly in Poland, agriculture is still the predominant occupation of her population, 65% of whom earn their living by the cultivation of the soil. World War I caused such devastation in all parts of Poland except the western provinces, that agriculture received a blow from which it recovered only shortly before World War II. It is estimated that 500,000 habitable wooden buildings and 1,248,000 agricultural buildings were destroyed, of which from 6; to 72% have been reconstructed. It must be remembered that the war in Poland lasted till 1921. The second great influence on Polish agrarian conditions was the Russian revolution, which caused the Polish government to make wide promises of land to peasants and ex-service men, such as were made in all central Europe. The Agrarian Act of 1920 was modified in 1925. It establishes a great area of land to be devoted to agrarian reform and parcellation among the peasants. This consists, firstly, of the vast state domains taken over from the governments of Russia, Prussia and Austria; secondly, of ecclesiastical lands and lands owned by public institutions; thirdly, of all other estates of an area larger than 444½ ac. (988½ ac. in Volhynia, Polesie and Nowogródek) in the country, and 148 ac. in urban or industrial areas. Peasant appropriations have gone steadily forward. The total area of land reallocated in accordance with the provisions of this act amounted to 200,000 hectares in 1926 and up to 2,654,800 hectares in the period 1920–38.

As is natural, small estates predominate, forming over 50% of the whole area, and being concentrated chiefly in Galicia and the former "Congress Kingdom." Large estates predominate in the western and eastern provinces. Large estates number 19,457 and occupy an area of 14,186,600 hectares, while small estates number 3,298,500 and occupy 24,646,200 hectares. Thus the greater part of agricultural land in Poland is owned by peasant proprietors, though there is still a large class of greater landowners. The area of land suitable for agricultural purposes shows that corn-growing is the chief feature of Polish agriculture:—

	Ha.	Per cent of total area
Arable land	18,307,800	48.6
Meadows	3,838,000	10·2
Pastures	2,528,600	6·7
Forests	8,943,762	24·1
Waste land	3,924,800	10·4

The chief agricultural products are rye, oats, wheat, barley and potatoes. The yields in 1937 and 1938 compared with those in the same territory before World War I were as follows:—

	Yield in thousands of metric tons		
	1909–13 average	1937	1938
Wheat	1,653	1,926	2,171
Rye	5,625	5,637	7,253
Barley	1,466	1,363	1,371
Oats	2,772	2,342	2,656
Potatoes	24,423	40,221	34,558

The farmers are greatly aided by government loans at low interest rates for the purchase of machinery, implements and artificial fertilizer.

The ravages of World War I were nowhere more seriously felt than in the destruction of livestock. The re-stocking of farms and estates, however, made excellent progress in 1925-27, so that in the latter year there were already a larger number of horses, cattle, pigs and sheep than in 1913. The export of live cattle and meat is rapidly growing. The export of packed meat rose from 2,000 metric tons in 1934 up to 17,000 metric tons in 1938. The export of bacon rose from 1,000 metric tons in 1928 to 21,000 metric tons in 1938.

Forests cover 24% of Polish territory and total 8,943,762 ac., of which 2,834,000 ac. are government owned. Pine trees form 65% of the forests and predominate in the western and central provinces. In the southeast deciduous trees prevail, of which the oak is the most important. Fir and beech trees appear in the southern provinces. The largest forests are those of Bialowieźa, where the trees are mostly 200 years old (pines, oaks of great height and diameter. elms. firs and alders), Augustów, Grodno, Kurpie, Tuchole, Polesie and the East Carpathian forest.

Manufactures and Mines. — Poland, as an economic unit, suffers from the diversity of origin of her industries. Poznan and Pomorze were utilized by Prussia as granaries and developed few industries. Galicia similarly found it hard to compete with Austrian and Czech factories, and remained predominantly agricultural. The "Congress Kingdom," on the other hand, developed certain industries in its days of independence, 1815-31, and after its incorporation in Russia produced a great textile industry for the Russian and eastern markets.

Polish industry adapted itself to new conditions within a comparatively short time. The ruined factories were rebuilt, a number of new industrial establishments were created, as well as new branches of industry — for example, the manufacture of aeroplanes, railway coaches and locomotives, chemical and electro-technical works, and the industry working for national defense.

The economic world crisis, 1929-33, strongly affected the Polish industry, causing a drastic decrease of production. The crisis did not, however, affect very much the technical development of Polish industry, some branches of which, as for instance, the chemical, electrotechnical, paper, textile and metal industries, began to produce many new articles which replaced those which hitherto had been imported from abroad. As a result of such activities, the foreign trade of Poland showed a decrease of the import of manufactured goods, and a steady increase of the import of raw material and semi-finished goods. There were in Poland 222,000 industrial establishments in 1935 The majority of them were small undertakings, and less than 9,000 establishments employed over 15 workmen each. At the beginning of the year 1939 approximately 800,000 workmen were employed by larger undertakings.

Besides industrial establishments there exist in Poland approximately 360,000 artisans' workshops which play a rather important part in the production of the country.

The largest decrease in industrial production caused by the economic crisis occurred in Poland in the years 1932 and 1933. From the middle of 1933 industrial production began to rise, which was particularly noticeable during the year 1936 and the beginning of 1937. The index of industrial production (taking as base-year 1928=100) reached the figure 119 in 1938 (annual average).

Metal Industry. — The metal industries in Poland operate 1,753 plants and employ approximately 156,000 workmen and 17,000 engineers and clerks. In the production of pig-iron Poland ranks ninth in Europe and eighth in the production of steel. The output of Poland's iron foundries surpasses the requirements of the home market and consequently a large part of its iron products is exported.

There are in Poland 16 iron foundries, 102 iron-casting foundries, 65 non-ferrous metal and casting foundries, 121 plants of machine parts, 104 plants of agricultural machinery, 87 plants of rolling stock, and a variety of other metal industry works.

The chief items of metal industry production in 1938 were:

Pig-iron	880,000	tons
Steel	1,441,000	"
Hot rolled iron	1,075,000	"
Drawn iron wire	80,000	"
Galvanized iron sheets	41,000	"
Zinc sheeting	30,000	"
Metal bedsteads	88,000	"
Iron wire nails	37,000	"
Goods wagons	579	"

Other metal products were: steam boilers, internal-combustion engines, pumps, wood and metal-working machines, agricultural and textile machines, electrical machines, radio receivers, telephone apparatus, etc.

A large quantity of the products of Polish metal industry is exported to foreign countries. In 1936, 356,671 tons of various metal products were exported, including 142,355 tons of iron and steel, 50,410 tons of tinware, 27,154 tons of rails and 65,290 tons of zinc.

Textile Industry. — The textile industry of Poland, developed in the second part of the 19th century, was almost entirely destroyed by World War I. After 1919 the ruined mills were restored, modern machinery installed, the quality of products improved. The home market was greatly developed and new branches of the textile industry *e.g.*, the silk industry, were created.

In the cotton industry on Dec. 31, 1935, there were 1,870,000 spindles and 47,000 looms; in the woollen industry 799,000 spindles and 14,000 looms; in the linen industry 36,500 spindles and 1,700 looms; in the jute industry 27,000 spindles and 1,700 looms; and in the silk industry 2,400 looms.

The textile industry in Poland is centred in three main groups— Lodz, Bialystok and Bielsko.

Lodz produces cotton goods, woollen rugs, haberdashery, natural and artificial silk, laces, curtains and embroideries. Bialystok specializes in woollen rugs, haberdashery and garments. Bielsko produces high quality combed-wool fabrics. The largest linen mills are in Warsaw, Zyrardów, Częstochowa and Cracow. Most of the plants producing knitted goods and hosiery are located in Lodz and Warsaw

In 1937 the output of yarn in Poland was 138,100 tons, of which 77,500 tons was cotton yarn. The production of textile fabrics was 95,300 tons, of which 51,500 tons was cotton fabrics. The output of knitted goods, excluding gloves and stockings was 2,924 tons. The total number of textile plants was 2,387, employing 157,067 manual and 6,617 white collar workers.

The export of textile raw materials and goods from Poland amounted in 1936 to 42,718 tons and in 1938 to 26,000 tons.

Chemical **Industry.**—The chemical industry of Poland is particularly developed in those branches of chemical production which have a basic importance for other national industries. The important fertilizer industry is centred in two state-owned factories: Moscice, near Tarnow, and Chorzow in Silesia. The production of fertilizers (nitrogenous, phosphorous and potassium) not only meets the demands of Polish agriculture but leaves a considerable surplus for export. Besides fertilizers, the chemical industry of Poland comprises: the coal derivative industry, dyestuffs, wood distillation, artificial fibre, oil, soap and scent, paint and lacquer, explosives, celluloid, plastic, compounds and rubber goods. The value of the total output of chemicals in Poland was in 1935 more than $150,000,000. The chemical industry of Poland employs 54,000 workers.

Poland's export of chemical products in 1938 included: potassium salt fertilizers, artificial silk, superphosphates, henzol, zinc white, tar, carbide, soda ash, ammonium, sulphate, oil cakes, explosives, oilcloth, glue, potassium carbonate, ammonium chloride and carbonate.

The value of the export of Polish chemicals amounted in 1938 to 195,000 tons, about $6,000,000.

Glass, Ceramics and Earthenware. — These industries operate 2,053 plants employing over 84,000 workers. There are in Poland: 1,099 brick-yards, 157 tile and ceramic works, 156 concrete and cement works, 69 glass works. 38 potteries and 170 quarries. Polish glassware is exported to 55 European and oversea countries, and Polish chinaware to over 40 countries.

Paper Industry. — The production of paper in Poland amounted to 113,000 tons in 1932, 128,000 tons in 1933, 136,000 tons in 1934, 142,000 tons in 1935, and 205,000 in 1938. The chief types of paper exported from Poland are: cigarette paper, wrapping paper, duplex boards, pasteboards and cardboards, grease-proof paper, etc.

Timber Industry. — The timber industry of Poland produces and exports the following articles: railway sleepers, telegraph-poles, pitprops, pulpwood, masts, battens, piles, hewed-edged wood, barrels, staves, beams, boards and planks. The timber manufacturing industries of Poland produce the following commodities: packing cases, flooring, barrels for wine, butter, edible fats, herring, cements, cobblers' materials, bentwood furniture, plywood and veneers.

Export of timber and wooden goods from Poland:

1935	1,733,046	tons
1936	1,678,575	"
1937	1,693,000	"
1938	1,688,000	"

Leather **Industry.**—The chief items of production were (1938): sole leather, 23,604 tons; butts for belts, 624 tons; saddlery and harness leather 400 tons; Upper Russian leather, 1,000,000 tons; calf skin and calf leathers 1,320,000 sq.m.; sheep skins, 814,000 sq.m. and 123 tons of bristles.

Footwear **Industry.**—The mechanical production of footwear amounted in 1938 to approximately 2,800,000 pairs of leather shoes, 2,400,000 pairs of boots, 2,900,000 pairs of rubber footwear and 2,700,000 pairs of galoshes. The production of the individual shoemakers has been certainly much larger than that of the footwear factories, but no detailed figures concerning it are (1943) available.

Crude Oil and **Oil** Products. — Poland is one of the three great oil-producing countries in Europe. The oil industry of Poland is the oldest in the world, dating back as far as 1853. Polish oilfields cover an area of over 9,000 sq.mi. along the Carpathian mountains. The chief centre of oil production is the Boryslaw region. The richest deposits of earth gas are in the Stryj and Jaslo district in southeastern Poland. The output of crude oil in 1936 reached 511,000 tons and the production of oil by-products was 450,000 tons, of which 40% was exported chiefly to the countries of central Europe. Oil refineries are concentrated around Drohobvcz. Deposits of paraffin wax are worked at Boryslaw. The possibilities of the Polish oilfields have not yet (1943) been fully examined and exploited. Prospecting for new oilwells was started with the application of modern methods of drilling and good results were being obtained. Foreign capital represented 87% of the stock invested in the oil industry in Poland.

Rock and Brine Salt.—The salt deposits in Poland are to be found in the Sub-Carpathian district and in the Warsaw (Ciechocinek), Poznan and Silesia districts. Over 50% of the salt output is rocksalt in the salt mines of Wapno near Inowroclaw (better qualities), of Wieliczka (near Cracow) and Bochnia. The balance is brine salt.

One of the oldest and richest salt mines of Europe is that of Wieliczka near Cracow. It has been known since 1040. It is state property. The excavations are on eight different levels, 3.5 mi. long and 1 mi. wide and nearly 400 ft. deep. The passages total more than 60 mi. The production of salt in 1938 was 643,000 tons.

Potassium Salts.—The deposits of potassium salts in Poland are very rich and are estimated at 450,000,000 tons. The production of potassium salts amounted in 1938 to 567,000 tons. Potassium salts are an important factor in the development of Polish agriculture and the chemical industry. They are mined in Kalusz, Holyn and Stebnik (southern Poland). The production ranked third in Europe (after Germany and France).

Ores.—Iron-ore deposits are located in the south of Poland, in the district of Kielce, near the Cracow coal basis, and in the district of Radom. They contain 35% Fe. The production of pig-iron was 394,000 tons in 1935, and 879,000 tons in 1938. The production of steel was 946,000 tons in 1935, 1,145,000 tons in 1936, 1,451,000 tons in 1937, and 1,441,000 tons in 1938. Zinc and lead ores are located chiefly in Upper Silesia and the voivodships of Kielce and Cracow. Approximately 90% of the total production is mined in Upper Silesia.

In 1935 Poland produced 85,000 tons of zinc and 19,000 tons of lead. in 1936, 93,000 tons of zinc and 15,000 tons of lead, and in 1938, 108,000 tons of zinc and 20,000 tons of lead. Poland occupied the fifth place in the world production of zinc, ranking after the United States, Belgium, Germany, Canada.

Other Minerals.—Among other deposits Poland possesses copper, sulphur, lime, chalk, fireproof clay, kaolin, building stones, coloured sandstones, marbles (in Silesia and in southern Poland), and granites (in Tatra mountains). The production of cement is an important branch of industry in Poland. In 1934 it amounted to 721,000 tons, in 1935 to 843,000 tons, in 1936 to 1,052,000 tons and in 1938 1,719,000 tons. The production of lime reached 554,000 tons in 1935 and in 1937, 769,000 tons.

There are also numerous mineral springs in Poland. Their main groups are salt, alcalic-oxalic, alcalic-salt and sulphuric waters. Most of them are found in southern Poland and some in the central voivodships (Ciechocinek, Inowroclaw). The Polish mineral springs are of great importance for the development of the health resorts.

Of industries depending on agriculture, the sugar industry is the most important, Poland coming after Germany, France and Czechoslovakia as a sugar-producing country. There were 62 sugar factories in 1938, producing 450,000 tons. Distilling is an important industry, since Poland has the second largest potato crop in Europe.

Coal.—The Polish coal district is near the junction of the Polish-German and Czechoslovakian frontiers. The area is not geologically

Mining of Coal in the Polish Coal Basins

Coal basins	1935	1936	1937	1938
	(in millions of tons)			
Silesia	21·1	22·1	27·4	28·8
Dąbrowa	5·4	5·6	6·5	6·7
Cracow	2·0	2·0	2·3	2.6
Total	28.5	29·7	36.2	38·1

uniform but falls into three distinct districts: (1) Silesia is the richest of the three, has coal of very good quality and easily workable; (2) Dąbrowa has coal of medium quality and, (3) Cracow basin produces coal of inferior quality. Of the coal produced, Silesia supplied 75%, Dqbrowa 18% and Cracow 7% of the total output.

About 60% of the capital invested is foreign, German capital being predominant in Silesia, French in Dqbrowa and Polish capital in Cracow.

In 1928, 117,000 men were employed in coal mines, but this number dropped to 75,000 in 1934. This considerable decrease was partly the result of the introduction of new methods of mining. While in 1934 a workman's daily output was 633 kg., in 1929 it was 1,264 kg. and in 1933 it rose to 1,571 kg., nearly two and a half times more than it was 10 years before.

In the world's coal production Poland stood seventh, ranking after the following countries (figures for 1936):

World	1,249,000,000 tons
U.S.A.	443,000,000 "
Great Britain	232,000,000 "
Germany	158,000,000 "
U.S.S.R.	124,000,000 "
France	45,000,000 "
Japan	42,000,000 "
Poland	30,000,000 "

The consumption of coal in Poland was divided between the industries (50 to 60%), the railways (about 15%) and private consumption. It was about 621 kg. per head of the population.

Of the 38,000,000 tons of coal produced in Poland in 1938, 26,000,000 were sold on the home market, and 12,000,000 exported to foreign countries. As a coal-exporting country Poland occupies the third place in Europe, after Great Britain and Germany. The exports went mainly to the Scandinavian, central and western European countries. In spite of the competition the Polish coal industry succeeded in maintaining its exports within the last few years, as shown by the following figures: coal exports in 1932, 10,223,000 tons; in 1933, 9,098,000 tons; in 1934, 9,880,000 tons; in 1935, 8,906,000 tons; and in 1938, 11,669,000.

Mining and Foundry Production in Poland

Products	1935	1938
	(in thousands of tons)

Tubes. drawn and welded	60	80

*Including Cieszyn Silesia.

TRANSPORT IN POLAND

The Polish nation has always been conscious of the importance of communications in the national life of the country. As early as the second half of the 18th century two canals—Królewski and Ogińskiego—were built, connecting the Baltic and the Black sea, through the Vistula and Dnieper and their tributaries. Between the years 1815 and 1863 the construction of metalled roads was started by the autonomous Polish government in the territory of the old Kingdom of Poland. The roads built during that time were even in 1943 in considerable use.

The first railway line in Poland, the so-called "Warszawa-Vienna" railway, was constructed by the same autonomous Polish government in the years 1815–1848. The length of this line was about 160 mi. Thus it can be seen that the traditions of the Polish communications system date back to the 18th century, *i.e.*, the beginning of the modern era in communication.

In 1918 Poland possessed a railway system consisting of three independent networks which had not only a varied rolling stock but different gauge lines. During the six years of war, moreover, 40% of railway bridges, 81% of water pumps, 63% of stations, 51% of goods stores and 48% of railway workshops were destroyed. The lines and the sleepers were in a bad condition.

During the 20 years, 1918–38, all war damages were repaired, the rolling stock renewed and increased, and 1,100 mi. of standard gauge railways and 225 mi. of narrow gauge railways built, to improve the railway system. The signal system was improved, and most stations (1943) possess all modern traffic safety devices. The total length of all the railways in Poland amounts to 12,580 mi. (20,118 km.), of which the narrow-gauge railways amount to 1,400 mi. (2,250 km.). The goods traffic on the standard gauge railways amounted in 1938 to 75,125,000 tons.

Roads.—In 1918 the total length of roads in Poland amounted only to about 27,315 mi. (43,700 km.), or to 11 km. per 100 sq.km. of the area. The roads were mostly in a bad condition, and 75% of the bridges were made of timber. The expansion of the road system to suit the national needs of the country, and the modernization of the existing roads was a problem which needed an enormous capital outlay.

The construction and modernization of roads in Poland began on a large scale only in 1934, and was increasing with every year. The length of new roads in Poland, constructed after 1920, was over 12,000 mi. (20,000 km.), this being an increase of 50% from 1918 on, and amounting to 16 km. of roads per 100 sq.km. of area. Poland is constructing 800 mi. (1,300 km.) of roads every year.

Airways.—Polish airways were established at the same time as in the western European countries. The airlines were operated mainly by the Polish company "LOT," which runs services connecting Warsaw with Berlin, Helsinki, Bucharest and Palestine.

FOREIGN TRADE

The official Polish foreign trade statistics, which are available in full from the year 1923, are shown in the table on p. 151.

The favourable balance of 136,000,000 zlotys in 1923 was due to

Foreign Trade Statistics of Poland, *1923-38*

	Imports to Poland	Exports from Poland	Balance of trade	Imports to	Exports from
	(in million zlotys)			(in thousand tons)	
1923	1,920	2,056			
1924	2,542	2,177	—365	3,197	17,678
1925	2,755	2,188	—567	3,711	15,770
1926	1,539	2,246	+707	2,738	13,603
1927	2,892	2,515	—377	4,903	22,304
1928	3,362	2,508	—854	5,165	20,356
1929	3,311	2,813	—298	5,088	20,723
1930	2,246	2,433	+187	3,571	18,922
1931	1,468	1,879	+411	2,931	18,703
1932	862	1,084	+222	1,787	13,504
1933	827	960	+133	2,356	12,985
1934	799	975	+176	2,555	17,565
1935	861	925	+ 64	2,573	13,442
1936	1,003	1,026	+ 23	3,066	12,964
1937	1,254	1,195	— 59	3,685	14,997
1938	1,300	1,185	—115	3,310	15,597

the depreciation of currency in Poland, which favoured export and made import less attractive. A new, stabilized currency was introduced in 1924, and this was at once reflected in the balance of trade; the rise in internal prices made export less profitable, and caused a decline in the outgoing trade (wholesale prices in Poland were 26% higher in 1924 than in 1923, and increased by a further 15% during the first half of 1925). On the other hand, the volume of imports rose owing to the greater competitive power of foreign goods. The outcome of the years 1924–25 was an adverse balance of 932,000,000 zlotys. This, no doubt, contributed to the subsequent collapse of the Polish currency. The rising tide of imports depleted the country's reserves of gold and foreign exchanges, and it became apparent that the zloty had been stabilized at too high a level. The failure of the harvests in 1924 aggravated the situation. The great reduction in treasury receipts which followed obliged the authorities to countenance a mild inflation of token money. After the collapse of the currency during the second half of the year 1925, the zloty was stabilized at a parity 42% below the original one.

During the year 1926 nominal and gold prices fell, with the result that Polish exports increased greatly (to 2,246,000,000 zlotys), while imports dropped (to 1,539,000,000 zlotys), yielding a favourable balance of 707,000,000 zlotys, which to a great extent offset the adverse balance for the years 1924–25.

A decided period of recovery ensued during 1927. Industrial output and commodity turnover grew in volume from month to month. Imports to Poland increased considerably (from 1,539,000,000 zlotys in 1926 to 2,892,000,000 zlotys in 1927); exports also rose, but at a much slower rate, with the result that in 1927 there was an adverse balance of trade, amounting to 377,000,000 zlotys. Conditions during 1928, the peak year of that period of prosperity, were still better, but an unfavourable balance of 854,000,000 zlotys was returned. The total adverse balance for these two years of prosperity and recovery, therefore, came to 1,231,000,000 zlotys. At that time Poland received very substantial foreign credits (in 1927, excluding other types of credit, 614,000,000 zlotys of foreign long-term credits, and in 1928, 327,000,000 zlotys long-term and 891,000,000 zlotys short-term credits), which were largely used for investments purposes. Of the total imports of 1928, which amounted to 3,362,000,000 zlotys, 885,000,000 zlotys represented raw materials and finished goods for the smelting industry, 312,000,000 zlotys for the chemical industry, 263,000,000 zlotys for the leather and tanning industry, 840,000,000 zlotys for the textile industry, and 102,000,000 zlotys for the paper industries; hence over 70% of the total imports was in respect of various kinds of raw materials, semi-manufactures, finished goods and plants for these industries. In the same year investment goods, such as machines, electrical equipment, transport vehicles, etc., were imported to the value of over 527,000,000 zlotys or 16% of the total import trade.

Business conditions in 1929 took a definite turn for the worse. The number of investment undertakings declined and imports fell off to some extent. Exports, however, grew in volume, particularly export of cereal and meat products, following on good harvests and a large increase in livestock. These changes in both divisions of trade resulted in the adverse balance being reduced to 298,000,000 zlotys.

During the years of 1930 to 1936, Poland's foreign trade balance was uniformly favourable. In this connection, however, two phases can be distinguished: the period ending in 1934, when Poland's foreign trade turnovers shrank from year to year, and that which began in 1935, when a gradual revival in trade set in. Since 1935 the increase in imports proceeded along with an increase in the rate of investment and it was expected that the growth in imports would continue to be marked for some time to come in view of investment activity. Exports, however, found difficulty in keeping pace with rising imports, the result being that the years 1937 and 1938 showed an adverse balance of trade. It will be noted that the turnover of Polish foreign trade was in common with most countries in the world, still considerably below the level of the pre-depression period.

One of the most striking features of Poland's foreign trade was its marked concentration on European countries, which together were responsible for 77.1% of the imports and 97.3% of the exports from Poland in 1928. This domination of Poland's foreign trade by European countries was gradually weakened by the policy of increasing direct trade with overseas countries and this was shown by the fact that Europe's share had fallen to 65.8% of the imports and to 84.5% of the exports in 1938.

The reduction in Germany's share is just as striking, for while Germany (including Austria) was responsible for about one-third (33.5%) of the imports and almost one-half (46.7%) of the exports in 1928, her share had diminished in 1938 to less than one-quarter of Poland's imports and exports—23.0% and 24.1% respectively.

Trade with Czechoslovakia showed a similar but less marked downward trend, the imports having fallen from 6.3% in 1928 to 3.1% in 1938, while the exports showed an even greater diminution from 11.8% to 3.6% in 1928 and in 1938 respectively. In contrast to the marked decline in German and Czechoslovak trade, the United Kingdom had steadily increased its influence throughout the greater part of the period—its share of the import trade having risen from 9.37 in 1928 to a maximum of 14.1% in 1936 and declined somewhat to 11.4% in 1938. Its share in Poland's export trade showed approximately similar trends, rising from 9.0% in 1928 to a maximum of 21.6% in 1936, falling slightly to 18.2% in 1938.

In spite of this important increment in the trade of the United Kingdom which was accompanied by a lesser but none the less significant rise in Belgium's trade, west and central European countries were then exerting less influence on Polish foreign trade than formerly.

On the other hand, south and southeast European countries were now playing a greater part. These countries practically doubled their share in Poland's foreign trade—their contribution having risen from 4.3% in 1928 to 7.6% of the imports in 1938, and from 5.5% of the exports in 1928 to 10.0% in 1938. In relation to the imports the rise was fairly evenly spread throughout these countries but was most marked in the case of Bulgaria, Greece and Yugoslavia. On the other hand, the increase in the exports was mainly due to considerably larger deliveries to Italy, Bulgaria and Turkey.

The Baltic lands took an increasing share in Poland's import trade—their proportion of the imports having risen from 4.9% in 1928 to 6.2% in 1938. This increase is attributable mainly to Sweden. On the other hand, the importance of the Baltic lands in Poland's export trade diminished slightly from 12.9% in 1928 to 11.4% in 1938 in spite of successive advances made by Sweden.

Extra-European countries, of course, played a correspondingly larger part in Poland's foreign trade throughout the period, but the advance was greatest in connection with Poland's exports, which increased from only 2.7% in 1928 to 15.5% in 1938. On the other hand, their share in Poland's import trade increased to a lesser extent from 22.9% to 34.2% in the same period. The majority of the increased proportion of Poland's imports provided by these extra-European countries was accounted for by quite substantial increases between 1928 and 1938 in the trade from Africa (0.9%—4.7%), Asia (3.6%—7.0%), Oceania (0.7%—2.7%) and South America (3.2%—6.5%).

In contrast to this general upward trend the proportion of Poland's import trade supplied by North America fell slightly from 14.2% in 1928 to 12.7% in 1938—a decline which can he attributed mainly to the lesser dependence of the Polish textile industry on United States cotton.

On the other hand, the marked rise in Polish exports to extra-European countries was much more universal with the exception of Oceania, which played a very minor role. During the period 1928–38, North America (mainly U.S.A.) led, and its share of Poland's exports increased from 0.8% to 5.4%, South America and Asia, with 2.8% each, were approximately equal in 1938, and these figures were a great advance on those for 1928 which were 0.4% and 0.3% for South America and Asia respectively. Similarly Africa took a larger share in Poland's export trade, which rose from only 0.2% in 1925 to 1.8% in 1938.

Thus, regarded broadly, Poland's foreign trade during this period was marked by a weakening of the former dominance by European countries and Germany in particular, accompanied by an expansion of Poland's trade in other parts of the world.

The increased share of the United States in Poland's foreign trade was confined mainly to Polish exports, which rose from 0.8% in 1928 to a maximum of 8.4% in 1937 and declined somewhat to 5.3% in 1938. Their share of Poland's imports was, however, slightly lower than formerly, 13.9% in 1928 and only 12.2% in 1938, and was below the maximum of 15.1% attained in 1934.

This slight diminution in Polish imports from the United States was to a large extent due to smaller imports of U.S.A. cotton and cotton-waste, tobacco, and fruits..which have not been balanced by larger imports of scrap-iron, machinery and electrical equipment and transport materials. The major items in the 1937 list of Polish imports from the United States were, accordingly, arranged as follows: cotton and cotton-waste, 46.7%; scrap-iron, 20.5%; machinery and electrical equipment, 6.6%; transport materials, 6.2%; copper and copper sheets, 3.9%; raw iurs, 2.5%; together accounting for 86.4% of the total.

The relatively great increase in Poland's exports to the United States was largely attributable to increased shipments of animal products from Poland,. which was, of course, directly associated with the expansion and improvement of the Polish animal industry.

THE PORT OF GDYNIA

The creation of the port of Gdynia is one of the most outstanding technical accomplishments of recent years. In 1924, when the port of Danzig proved insufficient for Poland's overseas trade, Poland decided to build another port in the bay of Gdynia, at that time a small fishing village. In ten years the Port of Gdynia became one of the largest harbours in Europe.

The overseas trade of Poland was steadily increasing. While in 1922 only 7.3% of Poland's foreign trade went by sea, in 1938 the percentage was 77.8% in bulk and 64.3% in value. The rapid shifting of Poland's foreign trade on to the sea-route resulted in the equally rapid increase of the turnover of goods in the ports of the Polish customs area, Gdynia and Danzig. These ports had in 1936 a turnover of 14,695,000 tons. Of that amount the share of Gdynia was 7,272,946 tons (76.2% of the whole bulk of Poland's foreign trade).

Gdynia's Overseas Goods *Traffic*

Year	No. of ships	Turnover of goods—tons
1924	58	10,167
1938	12,990	9,173,438

Owing to its favourable geographical position at the junction of the system of transit routes in central Europe, Gdynia served as a port not only for its immediate Polish hinterland, but also for the farther hinterland of Czechoslovakia, Rumania, Hungary, Austria and other countries. The shortest and most convenient route for goods traffic from the Scandinavian and Baltic countries to Rumania, the near and far east, and from North America to Rumania, the Baltic. states, southwest Russia and the near east passed through Gdynia. Of Gdynia's regular shipping lines, 12 were to Baltic ports, 12 to Baltic and North sea ports, 7 to English ports, 3 to French, 7 to Mediterranean, 2 to the near east and Palestine, 5 to North America, 3 to South America, 1 to South and West Africa and 1 to Asiatic ports.

The construction of the Port of Gdynia, which began in 1924 had reached the following stage in 1938; the length of the breakwaters is 3,948 m. (2 mi.), of the wharves 12,867 m. (over 7 mi.), the greatest depth is 12 m. (39 ft.). The whole harbour covers an area of 1,010 hectares (2,495 acres), of which the water space occupies 335 hectares (827 ac.). The length of railway tracks is 222 km. (138 mi.), the area covered by warehouses over go ac.

CONSTITUTION AND ADMINISTRATION

Poland is an independent, democratic republic (Rzeczpospolita), with a constitution based on the charter of April 23, 1935. The revival of a Polish state,·as a successor of the Polish kingdoms which disappeared in 1795 and 1830, was recognized by the Treaty of Versailles and the Treaty of Riga, but was originally the spontaneous act of the Poles after the collapse of the German and Austro-Hungarian empires in 1918. The constitution is based mainly on general contemporary ideas. The executive consists of the president of the republic, elected for seven years by an assembly of electors, elected by popular vote. He is the official representative of the republic, the head of the army, and nominates the ministers. But the real executive power is in the hands of a council of ministers responsible to the president of the republic. The parliament consists of two chambers: the senate and the Sejm. Elections to both chambers take place every five years by general ballot. Every citizen of either sex over the age of 24 has the right to vote in the elections to the Sejm. The senate with one-third of its members appointed by the president of the republic and two-thirds elected by citizens over 30 years of age, has a right of rejecting a bill passed by the Sejm.

The judiciary is independent of the executive. There are district and provincial courts and a supreme court for the whole republic. The republic is divided into 16 provinces (Wojewodztwa), which are divided into districts (Starostwa). The lowest unit of local administration is the rural commune (Gmina). Silesia has a special autonomous system.

EDUCATION

For administrative purposes the educational system in Poland was divided into nine school regions; those of: Cracow, Lublin, Lwow, Brzesc, Poznan, Warsaw, Wilno (Vilna), Rowno and Torun. Each circuit was controlled by a curator. The curators were responsible to the minister of education, who was in charge of the entire educational system of Poland.

The schools may be classified in the following groups:

1. Nursery schools.—These schools had to provide physical and mental care for children of three to seven years of age.

2. *Primary* schools.—The obligatory term of education was seven years, beginning with the year during which the pupil attains his eighth birthday. The schools were divided into seven classes. The educational program provided for three degrees of primary education: (1) the elementary course of general instruction, (2) a development of the first degree, and (3) a social and economic preparation of the pupils.

3. Secondary schools.—The period of study in secondary schools was six years. The school for general education was composed of a 4-year course in grammar schools and of a 2-year course in lyceums. To the grammar schools pupils over 12 years of age were admitted and to the lyceums pupils over 16 years of age.

Lyceums (state, municipal and private schools) were divided into four groups: humanistic, classic, mathematic-physical and scientific.

4. Professional schools.—The aim of the professional schools was to provide professional education (theoretical and practical) in the various lines of life for the youth of both sexes. The elementary and secondary professional schools in Poland adapted their programs and practical exercises in workshops, studios, laboratories and commercial offices to the practical requirements of the economic life. The professional schools possessed so many different categories and sections that they practically took into consideration all branches of industry and of trade, providing trained workers of all degrees. An artisan, a factory workman, a technical foreman, a dressmaker and milliner, a shop-assistant, a trained-clerk, all these positions were filled by those who received their education at the Polish professional schools, and they applied in practice the knowledge acquired at school. The building and fitting-up of machinery and motors, railways, motor-cars and aeroplanes; applied chemistry; electro-technic; wireless; mining and smelting; the building trade; gardening; agriculture; cattle-breeding; manufacture of foodstuffs; women's professions; home and foreign trade; road building; the study of foreign languages; etc. were on the program of professional schools, where great attention was paid to the intellectual and physical development of the young. It was only after the recovery of her independence that Poland could start the education of adults on a large scale, and then the government, communal institutions and social organizations were co-operating to this end.

The term of attendance in trades' schools was as follows: two to three years' course in the lower grade, two to four years' course in the secondary schools grade after graduation from primary school, two to three years' course of lyceum grade from a grammar school, supplementary courses upon graduation from primary school. In teachers' lyceums the course lasted three years and the pupils were admitted upon graduation from three classes of secondary school. In the teachers' colleges (pedagogia) the course lasted two years for pupils who completed their studies in the lyceum. Teachers of secondary education were university graduates.

5. Academic schools.

1. The Jagiellon university in Cracow (founded in 1364)
2. The Stefan Batory university in Vilna (1578)
3. The Jan Kazimierz university in Lwow (1668)
4. The Pilsudski university in Warsaw (1817)
5. The University of Poznan (1919)
6. The Engineering University college of Lwow (1844)
7. The Engineering University college of Warsaw (1901)
8. The High School of Agricultural Economy in Warsaw (1919)
9. The Academy of Veterinary Science in Lwow (1881)
10. The Mining academy in Cracow (1915)
11. The Academy of Arts in Cracow (1818)
12. The Academy of Arts in Warsaw (1922)
13. The Stomatologic academy in Warsaw (1920)
14. The Commercial high school in Warsaw (1906)
15. The Catholic university in Lublin (1918)
16. The Free university in Warsaw (1906)
17. The Academy of Commerce in Cracow (1915)
18. The Academy of Foreign Trade in Lwow (1922)
19. The Academy of Commerce in Poznan (1926)
20. The Academy of Political Science in Warsaw (1915)

"Non Academic" high schools which correspond to universities, but did not have similar rights:

1. High School of Journalism in Warsaw (1911)
2. School of Political Science in Vilna (1930)
3. School of the Eastern Institute in Warsaw (1933)

	Number of schools in 1935	Number of pupils in 1935 (in thousands)
Nursery schools	1,876	98
Primary	27,955	4,686
Secondary	770	166
Teachers colleges	187	12
Trades' schools	714	71
Lower aericultural	143	5
Continuation trades' schools	637	84
Academicschools.	24	48

The national minorities had a number of schools in which instruction was given in their respective languages. During the school-year 1937–38 the Ukrainians had 16 nursery schools, 461 primary schools, 24 secondary schools, 1 teachers' college, and 5 trades' schools. They also had the following number of bilingual schools (Polish and Ukrainian! : 3,064 primary schools and 2 secondary schools.

Instruction in the White Ruthenian language was given in 1 secondary school. The Germans in Poland had 49 nursery schools, 394 primary schools, 15 secondary schools, and 6 trades' schools. Yiddish was the language of instruction in 40 nursery schools, 226 primary, 12 secondary, 1 teachers' college and 14 trades' schools. Lithuanian was the language of instruction in 23 primary and 1 secondary school, Czech in 18 primary schools and Russian in g primary and secondary schools.

In the school-year (1934–35) the following number of pupils belonging to national minorities received in Poland instruction in their own language or bilingual schools (in round figures):

Ukrainians	473,000	White Ruthenians	2,300
Germans	72.000	Russians	1,700
Yiddish and Hebrew	70,000	Czechs.	1,000
Lithuanians	1,500		

Religious Denomination of Pupils in Poland
(School-year 1934–35)

Religious denominations	Primary schools	Secondary schools	Teachers' training schools	Trade schools	Academic schools
	(in percentage of the total number of pupils)				
Roman Catholic Latin Rite	68·5	73·0	86·6	76·4	76·4
Greek Catholic Rite	9·4	3·9	4·8	2·2	3·1
Protestant	2·2	2·7	2·1	2·0	2·7
Greek Orthodox	10·5	2·3	2·4	3·1	2·7
Hebrew.	9·1	18·0	4·0	16·2	14·8
Other	0·3	0·1	0·1	0·1	0·3
Total	100·0	100·0	100·0	100·0	100·0

The state and local governments spent the sum of 462,000,000 zlotys on public instruction in the school year 1938–39.

The average number of schools for 100,000 inhabitants (1930–31) was:

Nurseryschools	5·1	Teachers'trainingschools	0·7
Primary	86.3	Trade schools	2.5
Secondary	2.4	Academic schools	0·1

In the school year 1935–36, 4,681,345 pupils received primary instruction and 181,138 secondary instruction; in 1936–37, 4,743,605 pupils received primary instruction and 200,391 pupils secondary Instruction.

Number of Graduates in Schools in Poland, 1934

Primary schools	257,261
Secondary schools	14,836
Nursery-school teachers' traihing'schools	247
Teachers' training colleges	5,054
Trade instructors' training schools	199
Trade schools	23,156
Academic schools	6,400

SCIENTIFIC AND CULTURAL INSTITUTIONS IN POLAND

1. Scientific institutions.—The most important scientific institution in Poland is the Academy of Science in Cracow, founded in 1872. It is composed of 81 active members and 96 correspondents, of whom 54 are Poles and 42 foreigners. A president and a general secretary are at the head of the institution. The academy has three sections (philological, historical-philosophical and mathematical-scientific) and a number of special commissions. It maintains Polish scientific stations in Paris and Rome. The academy publishes reports of its activities in its own organ, The Annual, and issues also several other regular or occasional publications.

Similar societies exist in Lwow and Warsaw. The Lwow Scientific society dates from 1901. Besides the three sections (philological, historical-philosophical and mathematical-scientific), it has a history of art section.

The Warsaw Scientific society was re-opened in 1907 as a continuation of the erstwhile Royal Society of the Friends of Science, founded in the beginningof the 18th century. It comprises honorary, ordinary, and active members and correspondents, 20 of each of the 3 first categories in 4 sections: (1) Philology, history of literature, and art; (2) Historical, social and philosophic sciences; (3) Mathematics and natural sciences; (4) Biological sciences. Other sections and commissions maintain and conduct special establishments for scientific research. The society publishes works of its members and other scientific investigators and issues an annual and a report of the proceedings of the society.

There are also Societies of Friends of Science in Poznan and Vilna, and similar societies in Danzig, Katowice, Lublin, Plock, Przemysl and Torun.

Special societies exist in all the larger centres of Poland, such as the Historical society, the Polish Philosophic society, the Mathematical society, Botanic, and other societies. Their activities mostly cover the whole republic. The state institutes of research are the Chief Statistical office, the Military institute, the State Geological institute, the Curie-Sklodowska Radium institute and others. Private institutes are the Institute for the Investigation of National Problems, the East European Scientific Research institute, etc. There are also non-Polish societies, the most important of which is the Szewczenko Scientific Society in Lwow (founded 1873) in which Ukrainian scientists are grouped and organized on the model of the academy, the German societies: the Nistorische Gesellschaft fur Posen in Poznan, the Copernicus-Verein in Torun, the Jewish societies: the Society for the culture of Judaic Science in Warsaw and a Jewish Scientific institute in Vilna.

Besides these societies there are also some private institutions in Poland for the encouragement of science. The most important is the National Ossoliński Institute in Lwow (founded 1818), which publishes scientific works and school books, and maintains its own library and museum. Another institute is the Mianowski Fund in Warsaw (founded 1881, reformed 1930). Its object is to encourage science and literature, to help students engaged in research, and to publish works by authors of merit.

2. Archives.—Polish archives belong to the state, to local boards, religious bodies and to private owners. The state archives are under the authority of a chief director and are controlled by the ministry of education. The archives contain ample records of the activities of central and local authorities of the former Polish commonwealth, documents from the periods of partition and acts from the registers of various state offices. There are five of them in Warsaw and others in Bydgoszcz, Grodno, Kielce, Cracow, Lublin, Lwow, Piotrkow, Plock, Poznan, Radom and Vilna. About 60 archives of local boards, about 62 Catholic church and convent archives, 7 non-Catholic, 7 of synagogues, and 8 private archives are maintained in different towns.

3. *Libraries.*—The largest libraries in Poland are under state administration or that of state institutions (for instance, of academic schools). The state takes care of introducing rational methods of organization, of collecting printed publications, systematically and in complete editions, and also of supplying the libraries with the most important scientific appliances. The largest Polish library, containing the whole collection of present Polish publications, is the National library in Warsaw. It was opened in 1928, after several years' preparatory work, and includes the collections of Polish books retrieved from Russia as well as Polish libraries repatriated from foreign countries (the Załuski library, the Batignolles, Rappersvil and other libraries). There exist old libraries with priceless treasures of Poland's intellectual achievement dating from centuries back, as for instance: the Jagiellon library in Cracow (593,794 vols.), the Cracow university library, the Warsaw university library (797,000 vols.), the John Casimir library in Lwow (369,000 vols.), the Wróblewski library in Vilna (122,000 vols.). While the National library has the character of a central library possessing all publications appearing in the republic, these as well as the University library in Poznan and those in Torun and Katowice are of a more limited character containing all the publications of the respective districts. There is also a number of most valuable private book collections, either belonging to foundations or to individual book-lovers. Such are the Krasinski, the Zamoyski, the Przeździecki libraries, and also the Public library in Warsaw; the Ossoliński and Baranowski libraries in Lwow, the Czartoryski and the Cathedral libraries in Cracow; the Wielkopolska and Friends of Science library in Poznan, the Łopaciński library in Luhlin, etc

All the higher schools, state and private, possess libraries. The Bibliographical institute in the National library, besides its work in cataloguing, occupies itself with the international exchange of publications.

There are 22 state scientific libraries containing 3,158,400 vols., 15 local government scientific libraries with 469,380 vols., 22 theological libraries of various confessions with 579,760 vols., 28 social, foundation and private larger libraries with 1,290,000 vols., and 14 military-scientific libraries 268,000 vols. The total number of volumes in all libraries, including primary and secondary schools' libraries, amounts to about 20,000,000.

In 1933 the Polish Academy of Literature was founded in Warsaw, with 15 members.

CO-OPERATIVE MOVEMENT IN POLAND

On Jan. 1, 1938 there existed in Poland 13,741 co-operative societies belonging to the following unions:—

	Branches
1. Union of Agricultural and Credit Co-operative societies in Warsaw	5,261
2. Union of Consumers' Societies of Poland in Warsaw	1,254
3. Union of Military Co-operative societies in Warsaw	240
4. Union of Co-operatives and Associations of Workers	432
5. Volhynian Union of Co-operative societies "HURT"	26
6. Ukrainian Auditing Union of Co-operative societies in Lwow	3,097
7. Audit Union of Ruthenian Co-operative societies in Lwow	2,058
8. Union of German Co-operative societies (2)	768
9. Union of Jewish Co-operative societies (a)	78

In 1937 the Polish Co-operative societies had 2,157,000 members, the Ukrainian 661,000, the Jewish 141,000, and the German, 57,000.

The total balance-sheets of all the above co-operative societies amounted in 1935 to 1,122,258 zlotys, of which the capital owned was 227,294,000 zlotys. The credit co-operative societies extended to their members loans amounting to 585,478,000 zlotys and sold goods of a total value of 451,164,000 zlotys.

The number of Credit and Savings Co-operative societies in Poland was: in 1928, 4,586; in 1929, 5,925; in 1936, 5,423.

DEFENSE

Recruitment and Service.—All men in Poland, irrespective of nationality, are liable to be called up for service when they have completed their 21st year. This service is for 24 to 25 months in the regular army, according to the arm of the service, but only 18 months are spent with the colours. This is followed by service in the reserve up to the age of 40, during which period 14 weeks training are performed. From 40 to 50 years service in the territorial army follows, without further training. Certain exemptions and postponements are allowed for family and professional reasons, and volunteering is permitted for those not called up between the ages of 17 to 28. Each arm of the service has a cadet school for officers and there is also one for non-commissioned officers. There are also pre-military cadet corps for youths. Personnel not posted to the active army are subject (with a few exemptions) to a special military tax, collected either as a "basic tax" or as a sur-tax on income tax.

Strength and Organization.—The budget effectives in the regular army (1938) numbered 273,886, including 18,733 officers. The other armed forces organized on a military basis are the state police force of about 32,000, frontier defense corps of about 27,000, and customs guard of about 6,000.

The regular army is organized in 30 infantry divisions and 2 divisions of mountain troops; with 4 divisions and 12 independent brigades of cavalry. The Polish infantry division contains 3 regiments of infantry and 1 of field artillery. Each regiment contains a signal platoon, a battalion of pioneers, and 3 battalions of infantry or mountain troops. Battalions are organized in 3 companies and 1 machine-gun company. The Polish cavalry division contains 3 brigades, each comprising 2 regiments of cavalry, 2 groups of horse artillery, 1 pioneer sauadron and 1 automatic rifle sauadron (a special feature). independent cavalry brigades contain only 1 group of horse artillery and no automatic rifle squadron. Artillery regiments are (1) field, (2) heavy field, (3) mountain, (4) heavy, (5) anti-aircraft, (6) horse, or (7) foot artillery. Of these, Nos. (1) (2) (4) are organized in 3 groups each of 3 batteries; Nos. (3) and (5) in 2 such-groups, and No. (7) in 3 batteries. One group in each anti-aircraft regiment is motor-drawn. There is also an armoured train group with 3 trains. The engineer troops contain units charged with field engineering, railway work, signals, wireless telegraphy, motor transport, electro-technical work, and heavy bridging. Attached to the infantry there is a tank regiment containing a signal section, 3 tank battalions each of 3 companies, and a tank park.

Higher Command.—The supreme head of all the armed forces of Poland is the president of the republic, who presides over the committee of national defense, which contains the ministers for war, foreign affairs, interior, industry and commerce, and finance, the inspector general of the army and such other persons as the president, on the recommendation of the cabinet, may nominate. The committee can form no decisions without first hearing the opinion of the inspector general of the army. There are 10 military areas, each under a general officer with the title of "army corps area" commander. These areas are I. Warsaw, II. Lublin, III. Grodno, IV. Lodz, V. Cracow, VI. Lwow, VII. Poznan, VIII. Torun, IX. Brzesc, and X. Przemysl.

The army is distributed by units, on a population basis, over the above military areas. Of the other forces on a military basis the state police force is distributed in 3,273 communal police detachments in the smaller towns and villages and in 184 police commissariats in the larger towns, all under the chief of state police, who receives his orders from the minister of the interior. The frontier defense force carries out the duties of state and frontier guards on the eastern frontier where it guards the frontier, all members having had previous military training, and being armed as soldiers. The commander has the powers of an army corps area commander, and is under the minister of the interior. The customs guard, under the minister of finance, is responsible for the economic protection of the other frontiers, under the direction of commissions of customs.

Military Education.—Working under the chief of the general staff, there is a higher military college, a higher intendance college (military administration) and institutes of military geography and of military publications. Central institutions and military schools are under the area commanders except for use of material and technical training. One of the line companies of every infantry battalion forms a regimental non-commissioned officers school and there is also a central cadet school used for the training of non-commissioned officers. Besides the above-mentioned cadet-schools to provide officers for all arms of the service, there is a central musketry school and training centres for cavalry, artillery, engineers, railway engineers, and signallers, to provide for advanced training and specialization. There are also tank and motor schools and a gendarmerie school. For higher training of senior officers there is the "centre of higher military studies," the "higher school of military science," and the "higher intendance school" mentioned above.

Army Air Forces.—The army air force is administered by the air department of one of the under secretaries of state in the war ministry. The air service group is organized in 3 companies and a school company. The cost of military aviation which stood at 22,441,000 zlotys in 1926, was reduced to 13,633,000 in the estimates for 1927–28.

See also League of Nations *Armaments Year-book* (Geneva 1938). (G. G. A.; J. Cl.)

Navy.—The Polish navy consists of:

(a) The directorate of the navy;	(d) The Naval Officers' school;
(b) The high sea fleet;	(e) The various naval establishments;
(c) The river flotilla;	(f) 1 battalion of naval infantry.

The high sea fleet includes a fleet high command which is under the minister for military and naval affairs.

The naval port of Gdpnia is under the fleet high command. The naval port of Pinsk is under the commander of the river flotilla.

Budgetary effectives are (1938):

463	officers
5,628	noncomm. officers and men

In 1939 Poland had:

4 modern destroyers:	Błyskawica Grom Wicher Burza
5 submarines:	Orzeł Sep Wilk Ryś Zbik
5 torpedo-boats:	Kujawiak Krakowiak Podhalanin Slązak Mazur

miscellaneous: 11 units (gunboats, surveying vessel, transport, minesweepers, minelayer, training ship, submarine depot ship).

The river flotilla consisted of six monitors and eight river gunboats. (J. Cl.)

POLAR BEAR: *see* BEAR; CARNIVORA.

POLAR BODY: *see* CYTOLOGY.

POLARITY or **POLARIZATION.** For electrolytic polarization see BATTERY; ELECTROLYSIS; for optical see LIGHT.

POLAR REGIONS: *see* ARCTIC REGIONS; ANTARCTIC REGIONS.

POLDER, the Dutch name for a piece of artificially-drained low-lying land reclaimed from the sea or other water and protected by high embankments (*see* HOLLAND).

POLE (FAMILY). The family of the Poles, earls and dukes of Suffolk, which, but for Richard III's defeat at Bosworth, might have given the next king to England, had its origin in a house of merchants at Kingston-upon-Hull. The Poles were among the first English peers whose fortunes had been founded upon riches gained in trade. William atte Pole (d. *c.* 1329), a merchant of Ravensrode, settled in Hull. His sons, Sir Richard and Sir William atte Pole, were both famous for their wealth. Sir Richard (d. 1345), the king's butler in 1327, removed to London, and is styled a London citizen in his will. The male line of this, the elder branch of the Poles, failed with a grandson, John Pole, whose daughter was Joan, Lady of Cobham, the Kentish heiress, whose fourth husband was Sir John Oldcastle the Lollard.

Sir William atte Pole (d. 1366), the second son of William, joined his brother in advancing large sums to the government while keeping safely apart from politics. The first mayor of Hull, he sat for Hull in five parliaments, and was advanced to be knight banneret and a baron of the exchequer. He was counted "second to no merchant in England," but after his time his descendants left the counting-house, his four sons all serving in the French wars. The eldest son, MICHAEL POLE, 1st earl of Suffolk, who had fought under the Black Prince and John of Gaunt, became (1383) chancellor of England. In 1385 he was created earl of Suffolk, a grant from the Crown giving him the castle and honour of Eye with other East Anglian lands formerly held by the Ufford earls. In 1386 the opposition, led by Gloucester, the king's uncle, pulled him down. He was dismissed from his chancellorship, impeached, and convicted. Richard was forced to send his minister into ward at Windsor until the parliament was dissolved, when Suffolk once more appeared as the leader of the king's party. But the opposition was insistent, and Suffolk fled over sea to Calais. He died an exile in Paris in 1389.

The exile's son Michael, 2nd earl, was restored in 1397, died of dysentery at Harfleur, and his son Michael was killed at Agincourt. Michael was succeeded as 4th earl by his brother William. *(See* SUFFOLK, WILLIAM DE LA POLE, DUKE OF.)

John Pole (1442–1491), the only son of the 4th earl, should have succeeded to the dukedom, his father having died unattainted. But the honours were apparently regarded as forfeited, and the dukedom was formally restored to the boy in 1455, the earldom of Pembroke being allowed to lapse. He married King Edward IV.'s sister Elizabeth. The marriage confirmed him a partisan of the White Rose. Before he was of age he was steward of England at his brother-in-law's crowning, and at Queen Elizabeth's crowning he bore her sceptre. Having held many offices under Edward IV. he was ready to bear a sceptre at Richard's coronation, and, after Bosworth, to swear fealty to the Tudor dynasty and to bear another sceptre for another Queen Elizabeth. He died in 1491, having safely kept his lands, his dukedom, and his head through perilous years. *(See* SUFFOLK, EARLS AND DUKES OF and POLE, RICHARD DE LA.)

Another family of the name of Pole, having no kinship with the house of Suffolk, owed their advancement and their fall to a match with a princess of the royal house. Sir Richard Pole, a Buckinghamshire knight, was the son of Geoffrey Pole, a squire whose wife, Edith St. John, was sister of the half-blood to the mother of Henry VII. About 1490 or 1491 he married the Lady Margaret, daughter of George, duke of Clarence. He died in 1505, and in 1513 King Henry VIII. created the widow countess of Salisbury, as some amends for the judicial murder of her brother, the Earl of Warwick. Four years later, the barony of Montague was revived for her eldest son Henry. Until the king's marriage with Anne Boleyn, the countess of Salisbury was governess of her godchild, the Lady Mary. When her son, the famous Cardinal Pole, published his *Pro ecclesiasticae unitatis defensione* the whole family fell under the displeasure of the king, who resolved to make an end of them. The Lord Montague was the first victim, beheaded in 1539 on a charge of treasonable conversations, on evidence of his brother, Sir Geoffrey Pole. In 1541 the aged countess, attainted with her son Montague, was also executed. Sir Geoffrey Pole fled the country, and joined the cardinal in exile. He returned with him at Mary's accession, both dying in 1558. His sons Arthur and Edmund, taken in 1562 as plotters against Queen Elizabeth. were committed to the Tower of London, where they died after eight years of imprisonment.

POLE, **REGINALD** (1500–1558), English cardinal and archbishop of Canterbury, born at Stourton Castle, Staffordshire, was the third son of Sir Richard Pole and Margaret, countess of Salisbury, niece of Edward IV. Intended for the Church, he was sent for five years to the grammar school founded by Colet at Sheen. Here he had Linacre and William Latimer as teachers. In his thirteenth year he went to Magdalen College, Oxford, and two years after took his degree in arts. In 1517 Henry VIII. appointed his young kinsman to a prebend in Salisbury, and soon afterwards to the deaneries of Wimborne and Exeter. He was a friend of Sir Thomas More, who says that Pole was as learned as he was noble and as virtuous as he was learned. In 1519, at the king's expense, he went to Padua, the Athens of Europe, according to Erasmus; and there, where Colet and Cuthbert Tunstall had also been educated, he came into contact with the choicest minds of the later Italian Renaissance, so forming his friendships.

In 1525 he went to Rome for the Jubilee, and two years after returned to England and was initiated by Thomas Cromwell into the mysteries of statesmanship, that master telling him that the main point consisted in discovering and following the will of princes, who are not bound by the ordinary code of honour. When the divorce question arose, Pole seems at first to have been in its favour. He probably took the same view that Wolsey had, viz., that the dispensation of Julius II. was insufficient, as of two existing impediments only one had been dispensed. When, however, the king raised the theological argument which ended in disaster, Pole could not accept it; and, after the failure of Campeggio's mission, when the king asked him for his opinion, he excused himself on the score of inexperience, but went by Henry's order to Paris (1530) to obtain the judgment of the Sorbonne, insisting on the presence of a colleague to do the necessary business. On his return to England he spoke strongly against the project to the king, wha sought to propitiate him by the offer of the sees of York or Winchester, which were kept vacant for ten months for his acceptance. There was a stormy interview at York Place; but eventually Henry told him to put into writing his reasons against the divorce. This was done, and, recognizing the difficulties of the situation, the king gave him leave to travel abroad, and allowed him still to retain his revenues as dean of Exeter. In 1535, which saw by the deaths of Bishop Fisher and Sir Thomas More a change in Henry's policy, Pole received orders to send a formal opinion on the royal supremacy, and the king promised to find him suitable employment in England, even if the opinion were an adverse one. The parting of the ways had been reached. Pole's reply, which took a year to write, and was afterwards published with additions under the title *Pro ecclesiasticae unitatis defensione,* was sent to England (May 25, 1536), meant for the king's eye alone. It contained a severe attack upon the royal policy, and a warning of temporal punishment at the hands of the emperor and the king of France if Henry did not repent of his cruelties and return to the Church. Pole was again summoned to return to England to explain himself, but declined until he could do so with honour and safety; but he was on the point of going at all risks, when he heard from his mother and brother that the whole family would suffer if he remained obstinate.

Paul III., who had prepared a bull of excommunication and deposition against Henry, summoned Pole to Rome in October, and two months after created him cardinal. In January 1537 he received a sharp letter of rebuke from the king's council, together with the suggestion that the differences might be discussed with royal deputies either in France or Flanders, provided that Pole would attend without being commissioned by any one. He replied that he was willing and had the pope's leave to meet any deputies anywhere. Paul III. in the early spring of that year named him legate a *latere* to Charles V. and Francis I., to secure their assistance in enforcing the bull by helping a projected rising in England against Henry's tyranny. The mission failed, owing to the mutual jealousy of the sovereigns. Francis feared to allow his presence in France, and Pole passed over to Flanders, and awaited in vain royal deputies. In August 1537 the cardinal returned to Rome. There he was appointed to the commission established by Paul III. for considering the reforms necessary for the church and Roman curia. The report *Consilium delectorium cardinalium* is, in its plain-spoken directness, one of the most noteworthy documents of the history of the period. Towards the end of 1539, after Henry had destroyed the shrine of St. Thomas Becket, another attempt was made to launch the bull of deposition, and Pole again was sent to urge Charles V. to assist. Once more his efforts were in vain, and he retired to his friend Sadoleto at Carpentras. As Pole had escaped Henry's power the royal vengeance fell on his mother, who was executed on May 27, 1541.

On Aug. 21, 1541, the cardinal was appointed legate at Viterbo, and for a few years passed a happy and congenial life amid the friends that gathered round him. Here he came into close relations with Vittoria Colonna, Contarini, Sadoleto, Bembo, Morone, Marco Antonio, Flaminio, and other scholars and leaders of thought; and many of the questions raised by the Reformation in Germany were eagerly discussed in the circle of Viterbo. The burning question of the day, justification by faith, was a special subject of discussion. Pole's own attitude to the question of justification by faith is given by Vittoria Colonna, to whom he said that she ought to set herself to believe as though she must be saved by faith alone and to act as though she must be saved by works alone. In the excited temper of the times any defender of justification by faith was looked upon by the old school as heretical; and Pole, with the circle at Viterbo, was denounced to the Inquisition. Though the process went on from the pontificate of Paul III. to that of Paul IV., nothing was done against the cardinal until the time of the latter pope.[1]

While at Viterbo his rule was firm but mild; and he regained many heretics, such as his friend Flaminio, by patience and kindliness, to a reconsideration of their opinions. During this time also he was still engaged in furthering a proposed armed expedition to Scotland to aid the papal party, and in 1545 he was again asking help from Charles V. But the Council of Trent (*q.v.*) required all his attention. In 1542 he had been appointed one of the presiding legates and had written in preparation his work *De concilio;* and now in 1545, after a brief visit to Rome, he went secretly, on account of fear of assassination by Henry's agents, to Trent, where he arrived on May 4, 1545. At the council he advocated that dogmatic decrees should go together with those on reform as affording the only stable foundation. His views on the subject of original sin, akin as it is to that of justification, were accepted and embodied in the decree. He was present when the latter subject was introduced, and he entreated the fathers to study the subject well before committing themselves to a decision. On June 28, 1546, he left Trent on account of ill-health and went to Padua. While he was there frequent communications passed between him and the council and the draft of the decree on justification was sent to him. His suggestions and amendments were accepted, and the decree embodies the doctrines that Pole had always held of justification by a living faith which showed itself in good works. This effectually disproves the story that he left the council so as to avoid taking part in an adverse decree.

On the death of Henry (Jan. 28, 1547), Pole was excepted from the general pardon. At the conclave of 1549 Pole received two-thirds of the votes, but by a delay, he lost the election and Julius III. succeeded. He then retired to Magazzano on the Lake of Garda and occupied himself in editing his book *Pro unitate ecclesiae,* with an intended dedication to Edward VI.

On the accession of Mary he was appointed legate to the new queen, and began his negotiations. But he was still under attainder; and the temper of England was not yet ripe for the presence of a cardinal. The project of the queen's marriage was also an obstacle. A marriage between her and Pole, who was then only a deacon, was proposed by some, but this was opposed by the emperor. The marriage with Philip, of which Pole did not approve, having taken place (July 25, 1554), and Rome yielding on the practical difficulties of the lay holders of Church lands, Pole was allowed to return to England as cardinal. On his landing he was informed that the attainder had been reversed; and he was received with joy by Mary and Philip. He proceeded to parliament and there absolved the kingdom and accepted in the pope's name the demands respecting ecclesiastical property. He rectified the canonical position of those who had been ordained or consecrated since the breach with Rome. Those ordained in schism, indeed, but according to the old Catholic rite, were absolved from their irregularity, and, receiving penance, were reinstated; those ordained under the new rite were simply regarded as laymen and dismissed without penance or absolution. Pole was not responsible for the cruel persecution by which the reign was disfigured. On Nov. 4, 1555, Pole opened, in the chapel royal at Westminster, a legatine synod, consisting of the united convocations of the two provinces, for the purpose of laying the foundations of wise and solid reforms. In the *Reformatio Angliae* which he brought out in 1556, based on his Legatine Constitutions of 1555, he ordered that every cathedral church should have its seminary. He also ordered that the Catechism of Caranza, who, like him, was to suffer from the Inquisition for this very book, should be translated into English for the use of the laity. On Cranmer's deprivation, Pole became archbishop of Canterbury; and, having been ordained priest two days before, he was consecrated on March 22, 1556, the day after Cranmer suffered at Oxford. But the clouds began to gather round him. His personal enemy Caraffa had become pope under the name of Paul IV. and was biding his time. When Rome quarrelled with Spain, and France, on behalf of the pope, took up arms, England could no longer observe neutrality. Paul IV. deprived Pole of his power both as legate a *latere* and *legatus natus* as archbishop of Canterbury (June 14, 1557); he also reconstituted the process of the Inquisition against the cardinal, and summoned him to Rome to answer to the crime of heresies imputed to him. Mary, who had been warned by her ambassador to the pope that prison awaited Pole, prevented the breve ordering the cardinal to proceed to Rome from being delivered, and so Pole remained in England. Broken down as much by the blow as by ill-health the cardinal died at Lambeth on Nov. 17, 1558, twelve hours after Mary's death and under the unmerited disgrace of the papacy in defence of which he had spent his life. He was buried at Canterbury near the site of the shrine of St. Thomas Becket.

The chief sources for Pole's biography are his life written in Italian by his secretary Beccatelli, which was translated into Latin by Andrew Dudith as *Vita Poli cardinalis* (Venice, 1563), and his letters *(Epistolae Reginaldi Poli)* edited by Girolamo Quirini and published in 5 volumes (Brescia, 1744–57), a new edition of which is in preparation at Rome with additions from the Vatican Archives. *See* also the State Papers (foreign and domestic) of Henry VIII., Edward VI. and Mary; the Spanish and Venetian State Papers; vol. i. of A. Theiner's *Acta genuina S.S. Oecumenici Caecilii tridentini* (1874); the *Compendio dei processi del santo uffizio di Roma da Paolo III. a Paolo IV.* (Società romana di storia patria, *Archivio,* iii. 261 *seq.)*; T. Phillipp's *History of the Life of R. Pole* (Oxford, 1764–67); Athanasius Zimmermann, S.J., *Kardinal Pole sein Leben und seine Schriften* (Regensburg, *1893)*; Martin Hailie, *Life of Reginald Pole* (1910); and F. G. Lee, *Reginald Pole.*

POLE, RICHARD DE LA (d. 1525), pretender to the English crown, was the fifth son of John de la Pole (1442–1491), 2nd duke of Suffolk, and Elizabeth, second daughter of Richard, duke of York and sister of Edward IV. His eldest brother John de la Pole, earl of Lincoln (*c.* 1464–1487), is said to have been named heir to the throne by his uncle Richard III., who gave him a pension and the reversion of the estates of Lady Margaret Beaufort. On the accession of Henry VII., however, Lincoln took the oath of allegiance, but in 1487 he joined the rebellion of Lambert Simnel, and was killed at the battle of Stoke. The second brother Edmund (c. 1472–1513) succeeded his father while still in his minority. His estates suffered under the attainder of his brother, and he was compelled to pay large sums to Henry VII. for the recovery of part of the forfeited lands, and also to exchange his title of duke for that of earl. For his negotiations with the German King Maximilian in Tirol, Henry seized his brother William de la Pole, with four other Yorkist noblemen. Two of them, Sir James Tyrell and Sir John Wyndham, were executed, William de la Pole was imprisoned and Suffolk outlawed. Then in July 1502 Henry concluded a treaty with Maximilian by which the king bound himself not to countenance English rebels. Presently Suffolk fell into the hands of Philip, king of Castile, who imprisoned him at Namur, and in 1506 surrendered him to Henry VII. on condition that his life was spared. He remained a prisoner until 1513, when he was beheaded at the time his brother Richard took up arms with the French king.

Richard de la Pole joined Edmund abroad in 1504. and remained at Aix as surety for his elder brother's debts. The creditors

[1]Within the institution of the Inquisition his name continued to be regarded as that of a heretic and misleader of others, as is proved by the mass of evidence accumulated against him in the *Compendium inquisitorum (v archivio della società di storia patria* Rome, 1880).

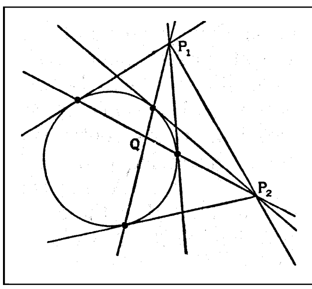
threatened to surrender him to Henry VII., but, more fortunate than his brother, he found a refuge with King Ladislas VI. of Hungary. He was excepted from the general pardon proclaimed at the accession of Henry VIII., and when Louis XII., went to war with England in 1512 he recognized Pole's pretensions to the English crown, and gave him a command in the French army. In 1513, after the execution of Edmund, he assumed the title of earl of Suffolk. In 1514 he was given 12,000 German mercenaries ostensibly for the defence of Brittany, but really for an invasion of England. These he led to St. Malo, but the conclusion of peace with England prevented their embarkation. Pole was required to leave France, and he established himself at Metz, in Lorraine, and built a palace at La Haute Pierre, near St. Simphorien. He had numerous interviews with Francis I., and in 1523 he was permitted, in concert with John Stewart, duke of Albany, the Scottish regent, to arrange an invasion of England, which was never carried out. He was with Francis I. at Pavia and was killed on the field on Feb. 24, 1525, so ending the male line.

See *Letters and Papers Illustrative of the Reigns of Richard III. and Henry VII.*, edited by J Gairdner (2 vols., "Rolls Series," 24, 1861); *Calendar of Letters and Papers, Foreign and Domestic, of the Reign of Henry VIII.;* and Sir William Dugdale, *The Baronage of England* (London, 1675).

POLE, WILLIAM (1814–1900), English engineer, was born at Birmingham on April 22, 1814. He spent some years as a professor of engineering in Bombay, returning to England in 1848, and in 1859 was appointed to the chair of civil engineering in University college, London. He was secretary to the Royal Commission on Railways (1865–67); the duke of Richmond's Commission on London Water (1867–69), also taking part in the proceedings for establishing a constant supply; the Royal Commission on the Disposal of London Sewage (1882–84); and the departmental committee on the science museums at South Kensington in 1885. In 1871 he was appointed consulting engineer in London to the Japanese Government. He was elected F.R.S. in 1861 for some investigations into colour-blindness. Music was also one of his chief interests, and in 1867 he took his doctor's degree, acting for many years as examiner for musical degrees at the University of London. In 1879 he published his *Philosophy of Music.* He died on Dec. 30, 1900.

POLE. For pole star *see* POLE STAR; for polar regions *see* ARCTIC REGIONS; ANTARCTIC REGIONS; for magnetic poles *see* MAGNETISM. *See* also BATTERY; CRYSTALLOGRAPHY; GEODESY; GEOMETRY; POLE VAULTING; SPHERE.

POLE AND POLAR, in mathematics. If from a point *P* outside a circle the two tangents to the circle be drawn, the line joining the points of contact is called the *polar* of the point *P,* and *P* is called the *pole* of the secant line. If *P* is on the circle, the two tangents coincide and the polar of P is the single tangent at P. For Q, a point inside the circle, draw two secants to the circle through it. The line joining their poles is called the polar of Q. If the polar of P passes through Q, the polar of Q passes through *P.* The same principle applies to any conic. In space there is a corresponding theory of points and polar planes as to a sphere or any fixed quadric surface. The idea is due to Brianchon, who first applied it in 1806, but it was developed by Poncelet, and presented in final form in 1829. More recently the concept has been extended to other curves and surfaces, and to other configurations.



POLECAT, the name given to any member of the Musteline genus *Putorius (see* CARNIVORA). Polecats are confined to the northern hemisphere. The European polecat, P. *foetidus,* inhabits the whole of the central and northern parts of the continent, though now rare in Britain. It is well known in its domesticated, albino variety as the ferret (*q.v.*). The wild polecat is dark brown above and black below, the face being variegated with white. The fur is long coarse, and of little commercial value. it is more powerful than the marten (*q.v.*) but less active, and rarely climbs trees. Its food consists of small mammals and any birds it can catch, especially poultry. It also eats snakes, lizards, frogs, fish and eggs. It is extremely blood-thirsty and hunts at night. From three to eight young are produced in April or May, after a two months' gestation. It is very tenacious of life and has a fetid smell.

It is replaced in north Asia by an allied species, *P. eversmanni,* and on the central plateau of the United States by a third form, P. *nigripes,* with creamy-yellow fur, brown legs and black feet and tail. *A* smaller species, *P. sarmaticus,* whose fur is white marbled with reddish spots above, extends from east Poland to Afghanistan. All these animals resemble P. *foetidus* in habits.

POLENTA, DA, the name of a castle in Romagna, from which came the noble and ancient Italian family of Da Polenta. The founder of the house is said to have been Guido, surnamed l'Antico or the Elder, who wielded great authority in Ravenna in the 13th century. His grandson Guido Novello upheld the power of the house and was also *capitano del popolo* at Bologna; he was overthrown in 1322 and died in 1323. In 1321 he gave hospitality to the poet Dante, who immortalized the tragic history of Guido's daughter Francesca, unhappily married to Malatesta, lord of Rimini, in an episode of the *Inferno*. Guido's kinsman Ostasio I. was lord of Cervia and Ravenna from 1322 to 1329, and, after being recognized as a vassal of the Holy See, again became independent and went over to the house of Este, whom he served faithfully in their struggles with the Church until his death in 1346. His son Bernardino, who succeeded him as lord of Ravenna in 1346, was deposed in 1347 by his brothers, Pandolfo and Lamberto II., but was reinstated a few months later and ruled until his death in 1359; he was famous for his profligacy and cruelty. His son Guido III. ruled more mildly and died in 1390. Then followed Ostasio II. (d. 1396), Obizzo (d. 1431), Pietro (d. 1404), Aldobrandino (d. 1406), all sons of Guido III. Ostasio III. (or V.), son of Obizzo, was at first allied with the Venetians; later he went over to the Milanese, and, although he again joined the Venetians, the latter never forgave his intrigue with their enemies, and in 1441 they deprived him of his dominions. He died in a monastery in 1447.

POLESIE (*i.e.,* "along the forest"), the largest and most sparsely populated province of Poland. Area, 14,219 sq.mi. Pop. (1931) 1,131,000. The bulk of the inhabitants are Ruthenians—the so-called Polesians or Pinchuks, forming a special branch of the Ukrainian nationality, and belonging to the Orthodox Eastern Church. Polesie was taken by the U.S.S.R. in 1939 and by Germany in 1941.

Polesie forms an eastward extension of the central Polish plain sloping up to the northern highlands and the plateau of Podolia. It forms the basin of the Prypet, a tributary of the Dnieper, into which flow numerous slow rivers from the Lithuanian forests of the north, and from the uplands of the south. The falls of the Lower Dnieper hinder the drainage of Polesie, and the deepening of the channel of the Dnieper tends to dry up the Pinsk marshes. In spring the whole country is flooded and has the appearance of a sea. In reality it consists partly of marshes and lakes, partly of damp meadows with islands of clay or sand, on which most of the villages are built. In such a dreary plain the main feature is the vegetation, which consists of wide pine forests on the sand or on the swamps, with invading firs from the north, of mixed forests and birch groves, and of damp meadows grown with grasses, reeds and stunted willows. It is the only remaining home of the beaver in Poland, and the elk is still found there. The inhabitants maintain a precarious existence mainly by fishing and hunting. With few horses. there is a special breed of cattle.

Polesie originally formed the early Russian principality of Turov or Pinsk. Conquered by the Lithuanians in 1320, it became, after the union with Poland in 1569, the province of Brest Litovsk. The north-west portion formed part of the estates of the great Polish magnates, the Radziwills and Sapiehas. Wolczyn was the seat of the Czartoryski family. The chief towns are Brest Litovsk, pop. (1931) 50,733, the capital; Pinsk, the seat of an ancient Orthodox bishopric; Kobryn, Kamenets Litovsk and Luninets, a junction of the two railways which traverse the marshes.

POLE STAR or **POLARIS,** the star nearest the pole in the northern hemisphere. (See ASTRONOMY: The Celestial Sphere.) It is the brightest star in the constellation Ursa Minor (*q.v.*), hence its Bayer equivalent α, Ursae Minoris.

POLE VAULTING, the art of springing over an obstacle with the aid of a pole. Originally a means of passing over obstacles as dikes and brooks, pole vaulting, for height, with the object of clearing a bar supported by two uprights set not less than 12ft. apart, has become a purely competitive athletic sport. The chief requirements of the athlete are great skill and courage, a high degree of co-ordination, speed and strength, and a good grip.

Up to the end of the "eighties" all the world's record holders in the sport came from the small town of Ulverston, in Lancashire. They gained their records by means of the extraordinary method they had evolved. It was not really "pole vaulting," but rather "pole climbing." This has now been barred.

The pole now employed is of female bamboo, no longer spiked, but has a plugged end which is thrust into a slide-way sunk in the ground a foot in front of a line directly below the cross-bar, and, moreover, a soft sand-pit, top-dressed with sawdust, is provided for the vaulter to land in.

The modern pole vaulter approaches the take-off very fast, carrying the pole with his hands about 3ft. apart. As the stride next before the spring is completed he thrusts the point of the pole into the slide-way, and lets the lower hand slip up the pole until it touches the upper hand. He is thus enabled to exert the full pulling power of both arms to raise his body and help the swing-up of his legs. It is noteworthy that this trick, efficiently performed, enabled Gold, former holder of the U.S.A. Western Conference record, to clear 12ft. 10in., although the grip of his upper hand upon the pole was no higher than 11ft. 2in., or 1ft. 8in. below the height he actually cleared.

Modern vaulters may be divided into two classes: (1) Those who prefer the single action in which the legs swing upwards and to the side in one single bound. This style requires great speed, and, using it, Charles Hoff (Norway) cleared 13ft. 11$\frac{3}{8}$in. (Finland, Sept. 27, 1925). (2) Those who prefer the double action. In this style the athlete's feet reach a point above the bar before the pole has arrived at a vertical position. At this stage the vaulter shoots his legs still higher by means of a strong arm-pull on the pole. He next turns his body face downwards by means of kicking one leg forward and the other back, and converts his pulling force into a pushing force. The bar lies in the concavity of the stomach, so that the feet, on one side, and his head and shoulders on the other side, are below the level of the bar. The athlete finally carries his body clear of the cross-bar by pushing strongly upwards from the upright pole. In this style, Sabin W. Carr, Yale university (U.S.A.) in 1927 established a world's record of 14ft., which R. Lee Barnes, U.S.A. (1928), using the single action, increased to 14ft. 1$\frac{1}{2}$in.

The use of the bamboo pole has added approximately a foot to the records, and modern methods have been responsible for another 18in. or so. An astounding improvement in performance has taken place recently and, although only U.S.A. and Japanese vaulters, so far, have exceeded 14ft., all the eleven men who tied for sixth place in the Olympic Games at Berlin in 1936 cleared 4 metres (13ft. 1$\frac{1}{2}$in.), a height which would have won the title at any of the previous Olympic celebrations except those of 1932. The finalists included F. R. Webster, the first British representative to reach an Olympic Pole Vault final.

N. Dole, U S A. (1904), was the first man to beat 12ft.; M. S. Wright, Dartmouth college, U.S.A. (1912), the first to clear 13ft.; while Sabin W. Carr, Yale university, U.S.A. (1927), was the first to clear 14ft. F. R. Webster (Cambridge university) was the first British athlete to exceed 13ft.

Records in 1936:—World's, K. Brown, U.S.A., 14ft. 5$\frac{1}{8}$in.; Olympic, E. Meadows, U.S.A., 14ft. 3$\frac{1}{4}$in.; G. Varoff, U.S.A., 14ft. 6$\frac{1}{2}$in. (awaiting acceptance); English record, F. R. Webster, 12ft. 9in. A Britjsh vaulter, A. W. Kinally, cleared 12ft. 6in. in 1936, the record standing at 11ft. 9in. in 1930.

POLIANTHES, one of the florists' flowers, commonly called tuberose, probably derived from P. tuberosa, which is unknown as a wild plant. (See TUBEROSE.)

POLICE. The term police designates that executive civil force of a state to which is entrusted the duty of maintaining public order and of enforcing regulations for the prevention and detection of crime. In a perfect system of civil administration the function of the police should be to curb the liberty of the subject only when it degenerates into licence—and any material variation from the standard is to be deprecated as being arbitrary and tyrannical. A civil organization, established by authority, for maintaining the essential tranquillity of the state and the security of its citizens in their lawful occupations is of high antiquity and has place alike in Egyptian, Greek and Roman law. In Rome, however, it was not until the time of Augustus that the police became a special institution in the city. In the hands of his unworthy successors it speedily became a terrible instrument of tyranny, justifying the dictum of Chateaubriand "la police par sa nature est antipathique à toute liberté." Upon the fall of Rome all traces of police administration disappeared under barbarian rule, only again to be revived in the capitularies of Charlemagne, which contain a large number of police regulations concerning weights and measures, tolls, markets, the sale of food, grain and cattle, the burial of the dead and measures to be taken in time of famine and pestilence. A recrudescence of anarchy on the death of the emperor of the west destroyed all these, but soon after the settlement of the Normans in France, that enterprising race established a highly repressive police system calculated to restore public safety at the expense of public liberty, and this system formed the basis of the police code introduced by William the Conqueror into England. Prior to the Norman conquest and for some time thereafter, the system of "frank pledge" was of general obligation in England. This provided that each district tithing should be divided up into associations of ten persons who were jointly answerable for the good behaviour of, or damage done by, any one of themselves. It seems probable (so far as London is concerned) that the existing police regulations of the Saxon kings, modified perhaps by an infiltration of Norman ordinances, were continued after the conquest, the charter of William the Conqueror to the city dated 1078 providing "I acquaint you that I will ye be all law-worthy as ye were in King Edward's days" An ordinance of the 13th year of Edward I (set out in the Liber Albus) enacts that strict watch and ward should be kept in London "by strong men with good arms" for the maintaining of the king's peace. In 1585 an act was passed for the better governance of the city and borough of Westminster and this statute was re-enacted and extended in 1737, to be succeeded in 1777 by another act containing wider and stricter provisions.

In spite of repressive measures until the end of the 18th century the conditions alike of London and the provinces were deplorable. Robbery and violence were rampant everywhere, highwaymen infested the roads, footpads lurked in the streets, whilst, but too often, both watchmen and innkeepers were accessories to the commission of crime. At the commencement of the 19th century it was computed that there was one criminal to every 22 of the population. Such was the state of affairs when, in 1829, Sir Robert Peel laid the foundation of that arganization on which is based the existing metropolitan police system. At first it encountered much opposition and was denounced as an insidious attempt to enslave the people by arbitrary and tyrannical methods. This unfavourable impression, however, soon diminished, especially as the conviction of criminals and speedy reduction in the number of offences evidenced the efficiency of the new force. Subsequent Acts of parliament extended the system throughout Great Britain. Statutes passed in 1839 and 1840 permitted the formation of a paid county police, to be appointed by the justices of the peace for the county.

The Police Act 1856 made the existence of an adequate force compulsory throughout England and Wales, whilst in Scotland the Police Act 1857 and the Burgh Police (Scotland) Act 1892 provided and regulated a satisfactory and sufficient police force throughout its counties and burghs.

The Criminal Investigation Department, now one of the most active and efficient branches of the police executive came into existence after the establishment of the present system. It is in direct descent from the old "Bow Street runners" who upon special requisition in the case of serious crime, varied their customary duties at the Bow Street Police Office (as it was then called) by acting as detective officers, either in London or the provinces. The first "detectives" appointed in the new department numbered only three inspectors and nine sergeants to whom, however, six constables were shortly added as "auxiliaries"; this number was subsequently enlarged as the manifold advantages of the system became more and more obvious. The system now attracts candidates of superior capacity and education.

The latest statistics (Dec. 31, 1934) show the strength of the metropolitan police to be 19,405, including the Criminal Investigation Department and the Thames (river) Police. The establishment of women police in the metropolitan district comprises (in addition) 1 superintendent, 3 inspectors, 7 sergeants and 45 constables; there were also 16,156 special constables attached to the Reserve on Aug. 31, 1934. The city of London has its own police establishment (about 1,200) under a commissioner and assistant commissioner; its functions extend over an area of 677 statute acres containing two courts of summary jurisdiction, those of the Guildhall and Mansion House, where the lord mayor and aldermen are the magistrates.

The total strength of the regular police force in England and Wales at the date of the latest available report is 58,303, not including 142 attested and 19 non-attested police women.

In 1931 Lord Trenchard succeeded Lord Byng as Chief Commissioner of the Metropolitan Police, and at once initiated certain reforms, the chief outcome of which was the new Police College at Hendon, opened in May 1934 as the basis of a new system of recruitment to the higher posts in the force. Another innovation was the recruitment of about 30% of the constables for a term of 10 years only, instead of 25 years or more.

British India is divided into police districts in which the general system of regular police resembles in most respects that of the police of Great Britain. There are, however, certain variations in minor details in the various provinces.

The total strength of the police at the last available date (1924) was 14,083 officers and 182,099 men. All are in uniform, drilled and trained in the use of firearms and may be called upon to perform *quasi* military duties. Many of the superior and nearly all of the inferior officers and men are Hindus. In Bombay they are chiefly Muslims.

The actual organization of the police force is not specifically dealt with by the Indian Penal Code, although it contains many provisions essential to efficiency and confers legal powers on the executive not only to take evidence but also to compel the attendance of witnesses. (W. W. P.)

THE UNITED STATES

Police organization in the United States had its origin in colonial days. The office of constable, invested with the powers and duties prescribed by the English common law, was established by the inhabitants of townships in the several Colonies. To this day the office of constable remains in rural localities and in many cities. His duties in 1929, however, are largely limited to the service of civil court processes. The first step in evolution from constable to modern police system came in colonial times with the establishment of night watches in the larger cities as a supplementary force and under supervision of constables. In New York the first police arrangements were set up in 1658 by the Dutch colonists, who maintained watchmen under the control of the local burgomaster. When New York passed to English control, a watchmen's organization under the command of a high constable assisted by subconstables was established.

The province of Massachusetts by legislation passed in 1699 provided that, in places where no military watch was in existence, the elected justices of the peace, acting in concert with the selectmen of a town, could order the establishment of a Suitable watch which would keep the peace from nine o'clock in the evening unti! sunrise of the next day and designate the places where such watch should be stationed. Provision was also made for a "ward" on Sunday and weekdays. All able-bodied male citizens above the age of 16 years and having certain property qualifications were made liable to keep watch and ward, the watch being night service and the ward day service, upon designation by the local governmental officers. At first no compensation was attached to the office of watch and ward, but later the way was opened for a paid force of regular watchmen. The night watch scheme spread throughout the larger cities of the Atlantic seaboard, and by 1800 had become well established.

With the rapid growth in population of cities and mixture of peoples resulting from heavy immigration, the problem of policing became increasingly complex. The night watch was not equal to its responsibilities under such conditions. Loosely organized, untrained, poorly disciplined, without good *esprit* de corps, the watch was held in low repute by the public. Employment on the watch was determined quite generally on the basis of political partisanship. A day force was created in New York which numbered only 16 regular men in 1844 and 108 special Sunday officers. In addition to these there were employed at that time about 100 mayor's marshals and 34 constables, two of whom were elected to serve for each of the 17 wards of the city. The night watch consisted of more than 1,100 men. A day watch was created in Philadelphia in 1833 and one for Cincinnati in 1842. The existence of two independently controlled police forces, one for day and the other for night, led inevitably to friction.

The New York State legislature enacted, in 1844, a law providing for a consolidated "day and night police." This action forms the basis of what is known as modern police organization in the United States. Police forces were consolidated and reorganized under a single executive head during the next few years in Boston, Philadelphia, Chicago, New Orleans, Baltimore, Newark and Providence. Even after these reorganizations the police were for a time without distinctive uniform and it was not until 1856 that the police forces in New York and Philadelphia adopted a standard uniform. The development of municipal police forces in the United States from this time on was, with a few exceptions, accompanied by a considerable degree of experimentation in respect to the fashioning of administrative control. Police organizations frequently were made the focus of political manoeuvring. Short terms of office for heads of police departments and, in many cases, for the lower offices and even the rank and file were the evil products of this political change. At first the common council of cities shared with mayors in the appointment of the police personnel and direction of their work. Later the mayor came to exercise a larger share of the control. About 1895 the civil service principle was widely adopted as a remedy for merely political changes.

On the administrative side, the control of the police organizations in earlier days was generally vested in a board of police commissioners ranging from three to four in number. These boards were usually appointed by the mayor, sometimes subject to the approval of the common council. It was held to be desirable to have bi-partisan control of police affairs in order to guard against domination by one party and the board form offered an opportunity for such a party representation. In a number of instances legislation was passed which took the appointing from the mayor and lodged it with the governor of a State. Generally, however, these moves were held to be in violation of the principle of local home rule. New York, Chicago, Detroit and Cleveland tried and abandoned the State control plan. In 1929, State control over appointment of the police commissioners is found in Boston, Baltimore, St. Louis, Kansas City and St. Joseph, Mo. There is no attempt at inspection of standards of police service by the State nor does the State contribute any moneys to the service. The only benefit expected from State control is that the governor will perhaps appoint administrators free from local political obligations

After 1900 a wide-spread change in the form of municipal government was brought about in cities of the United States. The commission form of government provides a commission of from five to seven men elected to manage municipal affairs, both legislative and executive. Under this arrangement, one of the elected commissioners is designated as director of public safety, having under his immediate charge police and fire administration and sometimes other more or less related functions. A chief of police serves as executive head of the police force under supervision of the director. Important cities having this form of government are Buffalo, Newark, New Orleans, Omaha, St. Paul and Portland, Ore. Unfortunately it does not guarantee exclusion of politics or permanent tenure.

In more recent years an improvement over commission government has come with the adoption of commission-manager charters. Under this scheme the commission serves as a local legislative body and appoints a manager who assumes entire charge of administering municipal departments. The manager in turn appoints a chief of police and all recruits to the police service generally in accordance with civil service regulations. The police have benefited almost without exception by this change. Among the larger cities having the commission-manager plan are included Cleveland, Cincinnati and Dayton in Ohio, Rochester, N.Y., and Norfolk, Va. In all some 300 cities and towns have adopted the city manager plan. In New York, Chicago, Philadelphia, Detroit, San Francisco and hundreds of other cities, the police are under control of the mayor and his appointees.

Despite all of the change in administrative devices, the plan of internal organization of police departments has remained much the same in all cities. The New York police system has served as the general pattern after which most police forces in the United States have been modelled. A uniformed patrol is distributed over cities on beats or territories as a first line of defence and protection against crime and disorder. The detective bureau is organized as a separate unit having to do with detection of the more serious crimes and apprehension of offenders. Special units of plain clothes operatives devote their attention chiefly to suppression of gambling, prostitution, illegal sale of narcotics and liquor law violations. Traffic regulation (*q.v.*) is a pressing problem in cities of the United States, and requirements in this direction have called for the employment of a large number of men. Policewomen are being employed in increasing numbers to look after the protection of women and children. Most large cities have training schools for instruction of new recruits and in some cases advanced instruction is given to older members of the force. Considerable progress has been made in the keeping of records, installation of systems of communication by signal and in the use of motor equipment in patrol and emergency service. Laboratories for scientific criminal investigation and identification are rapidly coming into vogue. With the passing of political interference definite progress is being made in the direction of professionalizing police service, and a higher type of man is being attracted to the service.

State constabularies have been created in Pennsylvania, New York, Massachusetts, Connecticut, Texas, West Virginia, Michigan, New Jersey, Colorado, Maryland and Delaware. These organizations recently established were built upon the experiences of municipal forces and so have avoided many difficulties and started on a generally high level of efficiency. Their work lies chiefly in patrol of rural areas and regulation of traffic on important rural highways. There is no Federal police force designated as such. In the Treasury Department of the Federal Government there are units comprising investigators armed with police powers who look after violations of the prohibition law, smuggling through customs, illegal narcotic importation and counterfeiting. A corps of investigators is maintained by the Post Office Department in tracing theft from the mails, illegal use of mails, etc. The Department of Justice maintains a criminal identification section. The Federal Congress has control over the Washington, D.C., municipal police force. (R. B. F.)

POLICE COURTS, courts of summary jurisdiction held in London and certain large towns in England and Wales by specially appointed and salaried magistrates.

Police magistrates are appointed by the Crown. They must have been practising barristers for seven years or stipendiary magistrates for some place in England or Wales. One police magistrate has the same powers as two justices.

The precedent of appointing salaried magistrates was adopted in certain provincial towns under particular acts, and in 1863 the Stipendiary Magistrates Act enabled towns and boroughs of 25,000 inhabitants and upwards to obtain a stipendiary magistrate. There are at the present time (excluding metropolitan magistrates' courts) 18 stipendiary magistrates' courts throughout England and Wales.

In the United States there are no so-called police courts in the Federal system of courts except in the District of Columbia, where the President appoints, subject to confirmation by the Senate, two judges of the police court. In the various States, police courts, the presiding official of which is either a judge or a magistrate, have been created for many cities. They are elected by the voters, and try the violators of municipal ordinances.

POLICE POWER, in American constitutional law, the reserved or inherent powers of the States to legislate for the health, safety and morals of the community. The requirements of the 14th amendment of the U.S. Constitution that no State shall deprive any person of life, liberty or property without due process of law and the interpretation of that amendment by the Supreme Court to give it a supervisory jurisdiction over all State legislation restricting the exercise of individual rights, brought to the forefront the concept of police power as a basis for sustaining the exercise of novel State legislation. The ultimate test of constitutionality under the due-process clause being the arbitrariness to the judicial mind of the State legislation, the relationship between the legislation and the admitted power of State governments to act for the protection of the community in ways reasonably adapted to secure those ends becomes of acute and decisive importance.

Resolving this relationship in terms of traditional concepts of constitutional law, legislation provided that it falls within the police power of the States even though it interferes with property or personal rights does not then run afoul of the due-process clause of the 14th amendment. The ultimate question, of course, remains, namely the extent of the police power viewed in the light of the object sought to be effected by the legislation and the means devised to secure that object. The extent of the police power remains as the least defined of State powers. With a political collectivistic philosophy gradually supplanting the individualistic philosophy of an earlier age, illustrated by the increasing regulatory activities of government, the content of police power becomes an ever-broadening one. Supreme Court decisions reflect this change in later cases that overruled earlier decisions declaring unconstitutional State legislation seeking to protect interests not then deemed within the legitimate scope of governmental regulation.

The extent of the police power is generally said to embrace the protection of the health, safety and morals of the community. Regulation of the practice of trades directly related to the health of the community, restrictions upon the use of property for sanitation purposes, prohibition of immoral amusements, requiring the installation of equipment designed to protect the safety of employees or the public, the regulation of traffic, the regulation of hours of labour, are all types of governmental activity within the recognized domain of State legislation. The police power, however, extends to purposes not so clearly related to the health, safety or morals of the community. The conservation of natural resources, zoning legislation, the protection of the public against fraud and waste, the enforced destruction of property adapted for illegal uses but capable of permitted uses, are examples of the uncharted scope of the police power. It is commonly said that the police power may not be exercised purely for aesthetic purposes, but as a better understanding of the organization of society may illustrate an intimate relationship between the promotion of aesthetical ends and general social welfare, the concept of police power may well be enlarged to include purely aesthetic considerations. The Federal Government is said to possess no general police power. Inasmuch as the Federal Government is one of limited powers and no general power for the protection of the health, safety and morals of the nation is granted to it under the Constitution, such a statement is accurate. But the Federal Government in the exercise of its granted powers may and does act for the promotion of ends within the concept of police power, and in this sense it has full freedom to protect the health, safety and morals of the community.

There are certain important differences between the exercise of the police power and other inherent State powers. The power of eminent domain, constitutionally restricted to employment for a "public use," can only take property by the payment of just compensation. The exercise of the police power may involve an equal "taking" of property but carries no obligation to compensate for such a taking. Again under the U.S. Constitution no State may pass legislation impairing the obligation of contracts already entered into. State action under the police power may, however, impair the obligation of contracts without conflicting with the constitutional prohibition, thus "taking" contract as well as property rights without compensation, (*See* CONSTITUTION AND CONSTITUTIONAL LAW.)

See Freund, *Police Power* (1904); Burclick, *Law of the American Constitution* (1922); Mott, *Due Process of Law* (1926).

(J. M. LA.)

POLIGNAC, an ancient French family, which had its seat in the Cevennes near Puy-en-Velay (Haute Loire). It can be traced to the 9th century, but in 1421 the male line became extinct. The heiress married Guillaume, sire de Chalançon (not to be confused with the barons of Chalançon in Vivarais), who assumed the name and arms of Polignac.

The first historically important member was Cardinal MELCHIOR DE POLIGNAC (1661–1742), a younger son of Armand XVI., marquis de Polignac, who became a distinguished diplomatist. In 1695 he was sent as ambassador to Poland, where he brought about the election of the prince of Conti as successor to John Sobieski (1697). In 1712 he was sent as the plenipotentiary of Louis XIV. to the Congress of Utrecht. During the regency he became involved in the Cellamare plot, and was sent to Flanders for three years. From 1725 to 1732 he acted for France at the Vatican. In 1726 he received the archbishopric of Auch, and he died at Paris in 1742.

Prince JULES DE POLIGNAC (1780–1847), son of Count Jules (d. 1817), played a conspicuous part in the clerical and ultra-royalist reaction after the Revolution. Under the empire he was implicated in the conspiracy of Cadoudal and Pichegru (1804), and was imprisoned till 1813. After the restoration of the Bourbons he held various offices, received from the pope his title of "prince" in 1820, and in 1823 was made ambassador to the English court. On Aug. 8, 1829, he was called by Charles X. to the ministry of foreign affairs, and in November became president of the council. His appointment was taken as symbolical of the king's intention to overthrow the constitution, and, with the other ministers, he was held responsible for the policy which culminated in the issue of the Four Ordinances which were the immediate cause of the revolution of July 1830. On the outbreak of this he fled for his life, but was arrested at Granville and condemned to perpetual imprisonment. The sentence was commuted to one of exile by the amnesty of 1836. During his captivity he wrote *Considérations politiques* (1832). He spent some years in England, but was permitted to re-enter France on condition that he did not live in Paris. He died at St. Germain on March 29, 1847.

POLIGNY, a town of eastern France, in the department of Jura, 18 m. N.N.E. of Lons-le-Saunier on the P.L.M. railway. Pop. (1936) 3,417. Under the name of *Polemniacum* the town seems to have existed at the time of the Roman occupation. It lies in the valley of the Glantine at the base of a hill crowned by the ruins of the old castle of Grimont, once the repository of the archives of the county of Burgundy. The church of Montivillard dates from the 12th century and has a fine Romanesque tower. The church of St. Hippolyte, early 15th century, and a convent-church serving as corn market are of some interest. Poligny has a national school of dairy instruction.

POLISH LANGUAGE. Together with Polabian—a now extinct language spoken by the Slavs of the Elbe before they became Germanized—Sorb or Wendish, and Czechoslovak, Polish belongs to the western branch of the Slavonic languages. The nearest relative of Polish is Polabian, with which it forms the Lech group, but in view of the fragmentary character of the remains of that language (a few words and sentences inexactly recorded), it is difficult to state with any detail more than the purely phonological agreements. Those which are shared by the Lech languages and Sorb are: extreme palatalization of consonants before front vowels, the absence of the vowels *r̥* and *l̥*, a particular development of *or* and *ol* between consonants, and the tendency to lose the old distinctions of quantity. In all these points there is a contrast with Czechoslovak which to some extent bridges the gap between the western and the southern branches; but the characteristic features of West Slavonic are naturally common to Polish and Czechoslovak. The features which are generally considered as belonging to common West Slavonic are: the development of *tj* and *dj* to *c* and *dz* (Polish and Slovak still have *dz*, but in Czech the sound has become *z*); the palatalization of consonants before *i*, *e*, *ę* and *ĭ* (only partially carried out in Czech, but Slovak agrees more completely with Polish); passage of *l* before back vowels and consonants to a sound like that in English "wall" (preserved also in Slovak dialects and in Old Czech, but the German *l* prevails in the modern language), loss of *j* between vowels, with compensatory development of a long vowel; shortening of long vowels which originally had a falling intonation; and the tendency to throw the stress away from the final syllable.

Polish is softer than Czech to the ear, owing to the predilection for palatal and sibilant sounds. The sentence melody, in spite of a regular accent on the penultimate, is in no way disagreeable, and the consonantal groups, which at first seem frightening, are easily pronounced after some practice. The survival of the old nasal vowels imparts to Polish an acoustic effect not unlike that of French.

The Slavonic inflexional type has been well preserved: there are seven cases in both singular and plural (the dual has almost disappeared). The verb is of the normal type, except that it has lost the imperfect and aorist. A peculiar feature in the syntax of Polish is the impersonal passive construction, where the logical subject is put in the accusative after the neuter of the participle. The vocabulary of Polish has been considerably influenced by earlier Czech and also by German and Latin, but in the main the Slavonic character has not been seriously affected, and the number of words from other languages is negligible.

Polish dialects are usually divided into two broad divisions. The group to which the literary language belongs has preserved the old pronunciation of *sz* and *ż* (as in English "ship" and "azure" respectively), while the other has altered them to *s* and *z*. Scholars are disagreed on the question of Kašube, which is spoken by fewer than a quarter of a million people in the neighbourhood of Danzig. In its modern form, it is very close to Polish, especially from the point of view of vocabulary, but it has several features which make it possible that at an earlier stage it was more closely connected with Polabian.

BIBLIOGRAPHY.—The historical grammar of Benni, Łoś Nitsch, Rozwadowski and Ułaszyn (*Gramatyka języka polskiego—Cracow*, 1923) is authoritative. It is slightly smaller than and covers a somewhat different field from the *Polish Language and its History* (in Polish), which is part III. of the *Encyklopedja Polska* (1915). Another excellent historical grammar is that by J. Łoś, *Gramatyka polska.* The grammar by St. Szober (Lwów—Warszawa, 1923) is the best descriptive work. The *Grammaire de la langue polonaise*, by A. Meillet and Mme. de Willman-Grabowska (Paris, 1921) is the best sketch in a western language. The most complete dictionary is that of S. B. Linde (*Slovnik języka polskiego*, Lwów, 1854–60), in 6 volumes. The *Handwörterbuch der deutschen und polnischen Sprache* in 4 vols., by Konarsky, Inlender, Goldschneider and Zipper (1st edition, 1904), is good but bulky. The *Dictionnaire complet français-polonais et polonais-français by W.* Janusz (Lwów, 1908) is excellent, and better than A. B. Chodźko's *Doktadny slownik polsko-angielski* (Berlin, 1912). *A Polish Phonetic Reader* by Arend-Choiński (London, 1924) supplements the larger works of Benni and other Polish phoneticians.

(N. B. J.)

POLISH LITERATURE. The Polish language belongs to the western branch of the Slavonic tongues, and exhibits the closest affinities with Czech, Slovak and Lusatian Wendish.

The earliest connected specimens of Polish prose are: the fragmentary Holy Cross Sermons, and the complete Psalter of *St.* Florian, both preserved in 14th century mss. which are probably copies of earlier originals. The beginnings of poetry are represented by the *Bogurodzica* song, a hymn in honour of the Virgin, often sung by the Poles of the middle ages when going into battle. Legend ascribed the origin of the song to St. Adalbert (Wojciech), in the 10th century. The oldest ms. of the song is dated 1408.

The 15th century brings a fuller development of religious poetry. A number of devotional songs are preserved, being mostly translations of Latin or Czech hymns. Many of these songs are the work of Ladislas of Gielniów, a Bernardine preacher, and of other friars of the same order.

The secular lyrics of the 15th century which have come down to us are not numerous but varied in contents, some being didactic in vein, such as the verses on table manners, some amatory and some in the nature of historical ballads on important public events; the victory over the German Knights in 1410, the defeat of Poles and Hungarians at the hand of the Turks in the battle of Varna (1444), Tartar invasions and other disasters, a riot of the Cracow citizens who kill an unpopular nobleman (1461)—such are the facts commemorated. The coming controversies of the Reformation period cast their shadows before them in a vivid poem by Andrew Galka, on the doctrines of Wycliffe, which had become known through the Hussite movement in Bohemia.

Prose works in the 15th century are scarce: Polish 15th century prose is largely devotional: its longest specimen is a translation of the Bible made for Sophia, queen of Poland, about 1455; several books of the Old Testament only are preserved.

Latin Literature in Mediaeval Poland.—If literature in Polish is scanty, Latin literature in Poland throughout the middle ages is fairly abundant, especially in the field of history. The first chronicle of Poland written in Latin is an early 12th century work by an anonymous foreign monk, whom tradition called "Gallus." It tells the story of Poland from the beginnings of the Polish State in the middle of the 10th century till 1113. A hundred years later, a continuation of this chronicle was undertaken by Vincent Kadlubek, bishop of Cracow.

In the 13th and 14th centuries, the number of chronicles increases: we may single out that of Jan of Czarnków (d. 1389), which gives a vivid account of conditions in later 14th century Poland. A great centre of intellectual and literary activities was created by the foundation of the University of Cracow. The university was originally erected as a legal college in 1364; in 1400 it was reorganised on a broader basis, mainly through the efforts of Queen Jadwiga, who, by her marriage with Duke Jagiello, united Poland and Lithuania in a powerful monarchy. It is in the shadow of Cracow university that Poland's most distinguished mediaeval historian, Johannes Dlugosz or Longinus (1415–1480) undertakes his great Latin work on the history of the country. Through diligent study of the royal and ecclesiastical archives, which were open to him, and of the works of native and foreign historians, Dlugosz produced in his *Historia* Poloniae the first monumental work of Polish historiography which unites critical scholarship with literary excellence. History is supplemented by the lives of saints, ever popular in the middle ages.

Latin poetry in mediaeval Poland, as in other European countries, is represented by church hymns as well as by the Latin carollings of the *clerici* vagantes. As the Renaissance approaches, the ground for the elegant Latin versification of the humanist scholars is prepared.

Early Polish Printed Books.—A printing-press was in existence at Cracow about 1474. But it was only about 1500 that a permanent printing office was established at Cracow by Jan Haller, followed by a number of others. Among the books they printed, Latin are still in the majority; but Polish books begin to appear in increasing numbers. A large part of them is devotional. Fiction, as elsewhere, is represented by "chap-books" on such subjects of international popularity as the fabulous histories of Alexander the Great and the stories collected in cycles like the Gesta Romanorum or the Seven Sages. Among the translators who provided this sort of literary food, Bernard (Biernat) of Lublin (*c.* 1515), takes a prominent place, chiefly by his rhymed paraphrase of Aesop's Fables and the romantic Life of Aesop. Next to him stands Jan of Koszyczki, who paraphrased the ancient jests associated with the names of King Solomon and his legendary opponent, the shrewd peasant Marculf: these humours of *Marchołt,* as he is called in Polish, are a fine specimen of racy popular speech. So are some religious songs, especially Christmas carols, interlarded, in the fashion of the time, with jocular details from contemporary life. With such literature, still essentially mediaeval in character, we may rank even the elaborate and widely-read Chronicle of the World (1551), written in Polish by Martin Bielski, as well as his Satires and his allegorical play *Justinus* and *Constantia,* the first morality in Polish.

Humanism and the Reformation.—A period justly called "the golden age" of Polish literature was prepared by the spread of Renaissance humanist culture, and of the doctrines of the Reformation. Poland, like other countries, began to produce Latin prose and poetry during the 16th century. The witty and licentious, satirical and erotic epigrams of Bishop Andrew Krzycki (d. 1537), the serious political and moral epistles of the diplomat Joannes Dantiscus (a burgher of Danzig, d. 1548), the tender elegies of Clement Janicki (Janicius), dead in his prime in 1543, rank with the best Latin poetry of modern Europe. The mediaeval historical work of Dlugosz is surpassed in grace by the humanist Latin of Martin Kromer's History of Poland (1555). Poland's greatest political thinker of the period, Andrew Frycz-Modrzewski, used Latin for his work De *republica* enzendanda (1551), a systematic treatise on social philosophy; and as late as the 17th century a Polish jesuit, Mathew Sarbiewski (d. 1640), became known throughout Europe as "the Christian Horace" for the beauty of his Latin religious lyrics. On their travels abroad, Polish students not only perfected their Latin and Greek, but witnessed the new growth of vernacular literatures based on classical models, and this awakened the ambition to rival foreign achievements by Polish verse and prose. Such ambitions were stimulated by a Protestantism which favoured the vernacular. After the council of Trent and the coming of the Jesuits (1564–1565), Protestantism began to decay: but what it had done for national literature remained effective. The Catholic Polish bible of Bishop J. Wujek (1599) has greatly influenced language and style.

The Poets of the Golden Age.—The year 1543 is a landmark, being the date of the appearance of the first important work of Nicholas Rej of Naglowice (1505–1569). After a somewhat idle youth he wrote a long series of poetical works. He turned Calvinist in middle age, and produced a translation of the Psalms. His principal and most mature works—the Image of an Honest Man's Life, in verse, and the more elaborate prose Life of an Honest Man—present his moral ideals, being those of a good-natured country gentleman. The latter work is also known as The Mirror.

Rej's popularity was outshone by the fame of Jan Kochanowski (1530–1584). He resided in Paris, where he met Ronsard. Returning to Poland, he became in 1564 secretary to the king. His less important early works, among which a paraphrase of Vida's poem on the Game of Chess may be singled out, were followed by epigrams called *Trifles* ("Fraszki") and by numerous Songs varied in tone, idea and form like the Odes of his master Horace, yet instinct with modern sentiment. In a longer poem, The Satyr, he deals with the serious political problems of Poland in his time, in *St.* John's Eve (Sobótka) he delights us with pictures of nature and country life. Kochanowski's only dramatic work, The Dismissal of the Grecian Envoys (Odprawa poslow greckich) (Eng. tr. Noyes and Merrill, Berkeley, Cal., 1918), is a verse tragedy in the Greek style, with choruses, on a subject from Iliad iii. Another work of Kochanowski's, his verse paraphrase of the Psalms, remains one of the masterpieces of religious lyrical poetry in Polish, only rivalled among his works by the Treny or Laments for his little daughter Ursula who died in childhood (Eng. tr. Prall, Berkeley, Cal., 1920). Another great lyrist of the period, Nicholas Sep Szarzyński (1550–1581) died in his prime. He introduced the sonnet into Polish poetry. The long descriptive and satirical poems, in Polish and Latin, by the townsman Sebastian Klonowicz (1545–1602) are interesting as illustrations of the social life of Poland. Simon Szymonowicz (or Simonides, 1554–1642), a burgher of Lwów, and an elegant Latin poet and dramatist, acquired fame as a Polish writer by his Pastorals which imitate Theocritus and Virgil, but contain vivid scenes from Polish life.

Prose Classics of the 16th Century. — Simultaneously with poetry, Polish prose rises into excellence. The religious and political controversies of the hot-blooded prelate Stanislas Orzechowski (1515–1566) were conducted in a style of admirable vigour. The version of Castiglione's *Il* Cortegiano, by Lucas Górnicki (1566) is a fine monument of Polish prose style. Ecclesiastical eloquence found its master in the Jesuit Peter Skarga (1536–1612), indefatigable as the protagonist of the Catholic cause in Poland. His Lives of Saints have remained a religious classic; but his Parliamentary Sermons published in 1597 are the crown of his life's work. It is here that Skarga, exposing the faults of the Polish national character and foretelling the downfall of the State, challenges comparison with the Hebrew prophets.

FROM BAROQUE TO CLASSICISM

The Age of Baroque. — The 17th century, although a period of wars and invasions, is rich in literary production. Italian models, with all the extravagance of the seicento manner, give to 17th century Polish literature, variety and colour, but at the expense of unity and moral elevation. Important works, censored by the clergy, have come to light only in recent times.

Poets of the 17th Century. — The military events of the period, together with the influence of Tasso's epic (translated into Polish, as was also Ariosto's, by Peter Kochanowski) inspired a number of epic poems dealing with contemporary history. The principal poet of the period, Wacław Potocki (1625–96) composed an enormous epic on the Chocim campaign of 1621 against the Turks and followed it up with The New *Mercury* and The *Turks'* Defeat at *Chocim* on the victories of John Sobieski. He also left behind in ms. two large collections of minor verse, The Garden and Moralia, and both illustrative of all aspects of the Polish life of his time. Potocki is also the author of a huge body of religious verse, and of several verse romances both original and translated. Potocki was preceded by Samuel Twardowski (1600–60) author of three interminable rhymed chronicles on the stormy events of the time. A fantastic verse story of his, The *Beaute*oars Pasqualina, is noteworthy as a paraphrase from Montemayor. A bitter satirist appeared in Christopher Opaliński (1610–56). His brother Lucas (1612–62) is also a satirist, and a better poet, as well as a political writer of merit. He wrote also an Art of Poetry. Vespasian Kochowski (1633–1700), in importance next to Potocki, surpasses him in artistic refinement. Having fought in many Polish wars, he told the story of some of them in voluminous epics. But neither these nor his long religious poems are as important as his *Polish* Psalmody, modelled on Kochanowski's verse Psalter, but written in poetic prose and embodying much of the poet's own inner life. A poet of peculiar charm and grace meets us in the person of Andrew Morsztyn (1613–93), who translated Tasso's Aminta, Corneille's Cid, and Marini's Psyche, and represents, in his own lyrics, the first instance of the deep influences of Italian and French literature. Simon Zimorowicz (1608–29), a burgher of Lwów, who died young, shines like a meteor by the freshness and poetic sentiment of his love lyrics *Roxolanki.* His elder brother Joseph Bartholomew (1597–1677), gives us delightful glimpses both of town and country life, and interesting accounts of quiet as well as of stormy times, in his Idylls.

18th Century Prose. — Among prose writers, we may single out: the Dominican preacher Fabian Birkowski (1566–1636), a baroque successor to Skarga; the learned and voluminous Latin and Polish writer Simon Starowolski (1585–1656), whose Latin works include the first history of Polish literature; Count Andrew Maximilian Fredro (1620–1697), whose Proverbs are a collection of maxims and observations comparable with the works of the French moralists of the time; Stanislas Heraclius Lubomirski (c. 1640–1702) who wrote several comedies based on Italian and Spanish originals, and finally, John Chrysostom Pasek (1630–1701), the king of Polish diarists, whose adventures in war and peace are embellished beyond the truth, yet simply and spontaneously narrated.

The Saxon Period. — The era of baroque is prolonged into the sad period of political decay and intellectual stagnation covered by the reigns of Augustus II. and III. (1697–1763). Specimens of literature worth recording, like the unpretending verse of Poland's first poetess Elizabeth Druzbacka (1695–1765), are isolated in this age. But even this darkest period of Polish civilisation is illuminated by such efforts as Stanislas Konarski's (1700–1773) reform of the secondary schools conducted by the Piarist fathers and his proposals for a thorough reform of Polish literary style (De *emendandis* eloquentiae *vitiis*, 1744).

The Era of Enlightenment: Poets. — The reign of the last king of Poland, Stanislas Augustus Poniatowski (1764–1795), is a period of literary development. Both the general atmosphere of the age of rationalism, and the peculiar conditions of Poland — the imminent danger of ruin to the commonwealth — gave the literature of the period a predominantly didactic character: satire, as elsewhere in Europe, is prominent. Thus, the representative writer of the age, Ignatius Krasicki (1735–1801) was, above all, a satirical poet. Krasicki is a typical eighteenth century prelate of the sort not uncommon in western Europe at the time. After his early heroic-comic poem, *Myszeis,* on the battle of the rats and mice against the cats, he soon rose to a higher level in his epic satire on monastic life, Monochomachia. This was followed by a biographical novel, The Adventures of *Doświadczyński,* which contains a good deal of satire on the Polish gentry. A second novel, Pan Podstoli, is more didactic in design: it draws Krasicki's picture of the ideal country gentleman. The high-water mark of Krasicki's work is reached in his Satires, the supreme achievement of 18th century classicism in Poland. They are followed by Epistles, but his most popular work is his Fables, which has made him the La Fontaine of Poland. His voluminous prose works include the first Polish survey of universal literature.

The poet next to him in the favour of his contemporaries, Stanislas Trembecki (1735–1812) is Krasicki's equal in clearness and expressiveness of language, but otherwise inferior to him. Trembecki excels in his Fables and Epistles by perfection of phrase and melody of verse. The fiery satirist Kajetan Wegierski (1755–84), who died in his prime after a youth of dissipation, was perhaps more deeply influenced than others by the French writers of the age, whom he loved to translate. The later poets of the period mark the transition from rationalism to romantic sentiment and include Francis Karpiński (1741–1825), and Francis Kniaznin (1750–1807).

Prose Writers of the 18th Century. — Bishop Adam Naruszewicz (1733–96), owes his chief title to fame to his ponderous history of mediaeval Poland, the first scholarly treatment of the subject. Stanislaw Staszyc (1755–1826), a liberal-minded priest, began his career with powerful pamphlets advocating political and social reform, and continued it after the partitions of Poland as a scientist and an organiser of research and industry. His fellow-reformer, Father Hugo Kollontaj (1750–1812), surpassed him as a political journalist and in his later work, as a philosopher.

The Theatre. — It was for school theatres that Francis Bohomolec wrote his comedies (1755–60), based on French models, chiefly Molière. At the same time, Wacław Rzewuski (1706–1779), wrote tragedies from Polish history in the French classical style for the private theatre at his residence. But it was only with the foundation of the first public theatre in Warsaw in 1765 that Polish dramatic literature got a permanent footing; and the manager of that theatre, Wojciech Boguslawski, himself a popular playwright, is the real creator of Poland's theatrical tradition. It was for this theatre that Francis Zoblocki (1754–1821) wrote his satirical comedies, drawing for subject-matter on obscure French sources, but presenting Polish figures and Polish ways. The Dandy's *Courtship* (Fircyk w zalotach) is his masterpiece. The famous comedy The Return of the Deputy (Powrót Posła) by Julian Ursyn Niemcewicz (1757–1841), was written to help the cause of political reform. Niemcewicz himself, aide-de-camp to Kościuszko, made his mark in many fields of literature. His *Songs of Polish History* (Spiewy historyczne) are still read and recited in schools. His *Fables* and *Satires,* comedies and tragedies belong to the 18th century, but by his translations of English ballads and romantic poems, as well as by his novels he heralds the coming of a new age. His *Memoirs* are a valuable chronicle of the transition period.

THE NINETEENTH CENTURY

The Romantic Era.—Soon after the disappearance of the old Polish State the vitality of the nation was manifested not only by military effort during the Napoleonic Wars, but also by intellectual and literary achievements. The University of Vilna (which had received its charter in 1579) entered on a flourishing period soon after 1800: the great poet Mickiewicz came from the ranks of its pupils. In the South-Eastern part of the borderlands, the Lyceum or public school of Krzemieniec in Volhynia displayed similar activities. In Warsaw itself a "Society of Friends of Learning" came into being in 1800, and a *Dictionary of the Polish Language* by Samuel Linde was among its many undertakings. Warsaw remained the capital of literary taste, and in the first decades of the century, the classicism of the former age still reigned there. It is represented by the poet and critic Kajetan Kozmian the author of Polish Georgics (*Ziemianstwo),* and bishop J. P. Woronicz (1757–1829) who, in his didactic poem *Sybilla,* drew comforting conclusions from a philosophical survey of Poland's history.

The strong didacticism of the classicist era also inspires the literary activities of Mme. Clementina Hofman (née Tanska), who produced the standard works of Polish educational fiction.

At the very end of its period classicism still gives Poland one great writer in Count Alexander Fredro (1793–1876) the author of the best Polish comedies. A soldier under Napoleon, he saw the masterpieces of French classical comedy in Paris and followed Molière. His first piece, *Pan Geldhab,* a satire on *nouveaux riches,* was produced in 1821. He wrote about twenty other comedies, and then abandoned production for fifteen years. At his death, however, he left behind a number of further plays in ms. His best-known works are: *Zemsta* (The revenge), which satirizes the mania for litigation among country gentlemen; *Śluby panieńskie* (Girlish Vows); *Damy i huzary* (Ladies and Hussars, Eng. trs. Noyes, 1925); *Mąz i zona* (Husband and Wife); *Dozywocie* (The Life Interest) and *Pan Jowialski* (The old Story Teller). The comedies, mostly in verse, portray the Polish country gentry to which Fredro belonged.

Midway between the classicists and the romantics stands the curious figure of Casimir Brodzinski (1791–183j). His verse idyl *Wiesław,* in which the manners of the peasants of the district of Cracow are portrayed, is classical in style and diction, but romantic in sentiment. His essay on *Classicism and Romanticism* and on *The Spirit of Polish Poetry* (1818) proclaimed the importance of national tradition and popular elements for literature, and in his lecture *On Polish Nationality* (1831) he partly anticipated the notion, fully developed by the great romantics, of Poland as a "chosen people." The boldness of new ideas was combined with supreme power of poetic achievement in Adam Mickiewicz (*q.v.*) (1798–1855), who soon became the acknowledged leader of the Romantic Movement.

Juljusz Słowacki (1809–49) is in many ways more representative of the essence of Romanticism than Mickiewicz. His genius develops under the influence of Byron. *Podróz na Wschdd* (A Voyage to the East), is a poem in the manner of *Childe Harold.* Slowacki's fantastic verse play *Kordjan* combines reminiscences of a Warsaw conspiracy against the tsar in 1829 with the influence of *Manfred* and of *Hamlet.* Mickiewicz's *Ksiegi Pielgrzymstwa* (Books of Pilgrimage), written in biblical prose for the comfort of Polish exiles in France, are paralleled by Slowacki's *Anhelli,* in which the Polish emigrant community in western Europe is represented under the allegorical disguise of a body of exiles in Siberia. It is, however, under the direct influence of Shakespeare that Slowacki attained his supreme poetic triumphs in drama.

His verse tragedies, *Balladyna* and *Lilla-Weneda* are placed in a legendary, pre-historic Poland: *Mazepa* takes place at the court of a Polish noble of the 12th century. The Polish world of the 12th and 18th centuries is the scene of two further plays of Juljusz Słowacki, *Horsztyński* and *Zbota Czaszka* (The Golden Skull), both unfortunately incomplete. The influence of Victor Hugo gives a sensational tinge to *Beatrix Cenci.* From Shakespeare and Victor Hugo, Słowacki passes under the influence of Calderon: he deals in Calderonian style with events from 18th century Polish history in his dramas *Ksiadz Marek* (Father Mark) and *Sen Srebrny Salomei* (The Silver Dream of Salomea). The last years of Slowacki's short life were spent among the Polish emigrants in Paris. The political and religious doctrines, the illusions, disillusionments and quarrels which agitated that little world, are mirrored in Slowacki's satirical epic *Beniowski,* which occupies, in his career, the place of *Don Juan* in Byron's. The mystical creed, which possessed the poet entirely in his latest years, inspired one of his most sublime works, the unfinished epic *Król Duch* (The Spirit King). The poet's complete spiritual philosophy of the mystical period is embodied in a prose treatise *Genesis z Ducha* (The Genesis from the Spirit), which curiously anticipates, in some of its ideas, the theory of evolution.

Zygmunt Krasinski (1812–1859)[1], long considered the equal of Mickiewicz and Słowacki, rose to an extraordinarily high level in his precocious early work. He became absorbed in meditations on the social revolution which after 1830 seemed to be threatening all Europe, and he put his vision of it, at the age of 21, into a drama *Nieboska Komedja* (The Un-Divine Comedy) (Eng. tr. Kennedy and Uminska, 1923). Krasinski's second work, the drama *Iridion* (Eng. tr. Noyes, 1927), placed in Rome in the second century of our era, has for its subject an attempted revolt of the Greeks against the Roman Empire. The attitude of the Christians, who refuse to fight, is the cause of failure. Krasinski links up his subject with philosophical speculations on the historical mystery of Poland's sufferings. His creed in this matter is embodied in a visionary poem called *Przedświt* (The Dawn), in which he extols the passive heroism of his oppressed country as the earnest of victory in the ideal sphere. These ideas are repeated in several didactic lyrics called *Psalmy Przyszłości* (Psalms of the Future). Krasiński's waning talent spent itself on political, religious and philosophical pamphlets and lyrics.

All the three great Romantic poets had come, for a time under the spell of an emigrant thinker named Andrzej Towianski (1799–1878) who had woven religious and patriotic mysticism together into the creed of a new sect, making of Poland a "messiah among nations." Krasiński's thought, in particular, also shows close relation to that of August Cieszkowski (1814–1894), the most distinguished and independent of a group of Polish philosophers who were disciples of Hegel. ("Our Father," selections in English by Dr. W. Rose, 1924.)

It is only in the 20th century that another Polish metaphysician of the Romantic period, Joseph Maria Hoene-Wronski (1778–1853), who wrote mainly in French, has won an increasing amount of international recognition.

Among the lesser romantic poets, the so called "Ukrainian school" forms a group apart. Its earliest representative, Antóni Malczewski (1793–1826), preceded even Mickiewicz as the author of a Byronic tale in verse. His romance *Marja* (Mary, 1825), breathes all the charm of chivalrous tradition and melancholy steppe landscape associated with Poland's south-eastern border.

Byronic colours are laid on more thickly by Seweryn Goszczynski (1803–1876) in his verse tale *Zamek Kaniowski* (Kaniow Castle), full of the horrors of age-old class war between the Ukrainian peasantry and the Polish borderland gentry. In his later work, he became a forerunner of realism.

The third most prolific singer of Ukrainian traditions and landscape in Polish poetry, Joseph Bohdan Zaleski (1802–1886), is a lyrical poet of great melody, but fatal facility. In his most ambitious effort, the philosophical poem *The Spirit of the Steppe* (Duch od stepu) he endeavours to reconcile the Romantic dreams

[1]*See* the study by Monica M. Gardner: *The Anonymous Poet of Poland* (Cambridge, 1919).

of the high dignity of Poland's sufferings with a moral and Christian view of her past errors and contemporary fate.

Another region of Poland's historical domains, the Masovian plains in the centre of the country with their purely Polish peasantry, are the subject of the lyric poetry of Teofil Lenartowicz (1822–1893): although he spent his later years as a sculptor in Florence, he never ceased to sing of Polish country life.

His counterpart is Wincenty Pol (1807–1872), who sings with equal persistence of the old-world life of the country gentry. A soldier in the insurrection of 1831, he commemorates this in a series of stirring and popular songs (*Pieśni Janusza*): a Professor of geography in his later days, he produces a picturesque descriptive account of Poland in verse (*Pieśn* o Ziemi Naszej) and several geographical works in very vivid prose.

What the Ukrainian group did for the South-East, and Lenartowicz and Pol for central Poland, was done for the North-Eastern domains of the historical Poland (Lithuania and White Ruthenia) by Ludwik Wladyslaw Kondratowicz, known as Syrokomla (1823–1862). A son of the minor gentry of those lands, he is at his best when drawing on his memories of his own youthful surroundings (as in the two charming longer poems on the Early Life and School-Days of Jan Debordg).

The romantic inspiration still produced a poet of action in Mieczyslaw Romanowski (1834–1863), who died a hero's death in the ranks of the insurgents of 1863. He had shown promise in a longer narrative poem of Polish town life in past ages (*Dziewczę z Sącza*), but this bears clear traces of the influence of Mickiewicz' epic masterpiece. It is echoes also of the song of the great Romantic masters that we catch everywhere in the poetry of Kornel Ujejski (1823–1897). He had made his mark, at the age of twenty with the verse tale Marathon. Not long afterwards, the national disaster of the Galician peasant riots of 1846 inspired him to write a series of elegies entitled The Lamentations of Jeremiah (Skargi Jeremiego), one of which, the Choral Song became the anthem of national woe. Before fading away utterly, the Romantic flame once more leaps up wildly in the enigmatic and convulsive, but intensely inspired poetry of Cyprian Norwid (d. 1885). The poet lived in disregard and neglect, and only came into his own long after his death through the efforts of a 20th century critic (Z. Przesmycki).

Of novelists of the romantic period, the very spirit of romance seems incarnate in Michael Czajkowski, who began active life as a Polish insurgent in 1831 and ended it as a Mussulman and a pasha in the Turkish Army. His novels, chiefly from the history of Poland's 18th century wars, are marred by wild improbabilities and artificial glitter. Higher literary value distinguishes the works of Count Henry Rzewuski (1791–1866), especially his stories from 18th century Polish life The Memoirs of *Severin Soplica* and November (*Listopad*).

We are on the road from romance to realism in the novel and plays of Joseph Korzeniowski (1797–1863). His drama The Carpathian Mountaineers (*Karpaccy* Gdrale) is aglow with the colours of folk-lore, his comedies, such as The Jews (Zydzi) or Miss and Mrs. (*Panna mężatka*) take us out of the region of old-fashioned comic types into the sphere of modern individualism in character-drawing, and his novels, e.g., The Schemer (*Spekulant*) or The *Neighbourhood* (*Kollokacja*) are satiric.

The transition from romance to realism is shown in Joseph Ignatius Kraszewski (1812–1887), whose untiring pen produced over 500 volumes of fiction, history, criticism and other literary matter. His historical novels have made him the Scott of Poland: but he deals with Polish contemporary life as well. The picture of the decay of the land-owning aristocracy in *Morituri* shows deep insight. Of his historical novels, those relating to the "Saxon period" of the early 18th century—such as *Brühl* or Countess Kosel—are the best. His influence on readers and other novelists has been enormous.

In the field of the historical novel, Kraszewski is almost equalled in popularity by Zygmunt Kaczkowski (1826–96), who excels in stories of the troublous partitions of Poland. Another popular novelist is Theodor Tomasz Jez (whose real name was Zygmunt Milkowski, 1824–1915), an insurrectionary soldier and an exile, who has described the history and folk-lore of the Balkans.

Of historians and essayists, Joachim Lelewel (1786–1861), laid the foundation of modern Polish historical research. Among his followers Karol Szajnocha (1818–68), is conspicuous for the literary qualities of his work, as shown chiefly in his monographs of Jadwiga and *Jagiełło* and of Two Years of *Polish* History (viz., 1647–48). History and literary criticism are combined in the brilliant writings of Maurycy Mochnacki, who became the historian of the insurrection of 1830. In Juljan Klaczko, Poland produced a distinguished student of Dante and of renaissance art: but his writings were mainly in French.

The Period of Realism.—The disaster of the second Polish insurrection, in 1863, produced violent reaction against all Romantic dreams both in politics and in literature. The mood of realism was fostered from abroad by the progress of natural science, of economic development, and of political liberalism in Western Europe. The few eminent poets of this age of prose make themselves the heralds of its ideals. The representative lyrist of the positivist generation, Adam Asnyk (1830–97) passed in his own career from the romantic exaltation of national martyrdom to the advocacy of positive social work for popular education. he even became the founder of the "People's School Society" (1891). His mature lyrics are lyrics of thought rather than feeling, and even in his nature poetry reflection predominates over enthusiasm. Feeling abounds in the verses of his most distinguished contemporary in Polish poetry, the poetess Marie Konopnicka (1840–1916): both in her lyrics and her short stories, the dominant note is one of profound pity for the poor. In her long epic, Mr. Balcer in Brazil (Pan Balcer w Brazylji), she tells the story of the sufferings of Polish peasant emigrants in the Brazilian forest.

The outstanding modern journalist, Aleksander Świętochowski (1849–1938) waged fearless war, both in his articles and his dramas, for the liberal ideals. His younger contemporary, Andrew Niemojewski (1864–1921) was chiefly preoccupied, in his journalism and his poetry, with the new industrial problem.

In the sphere of the novel, Madame Eliza Orzeszko (1842–1910), represents peasants, Jews, great industrialists, but she always returns to the life of the Polish country gentry in her native Lithuania. Bolestaw Prus (real name: Aleksander Gtowacki, 1847–1912) is, like Dickens, whom he resembles by his humour, a child of the city: the scene of his best social novels, like The Puppet (Lalka) and *The* Emancipated Woman (Emancypantki), is laid in his beloved Warsaw. But he also gave a touching account of the peasant's attachment to the soil in The *Outpost* (Placówka). In his largest work, The Pharaoh, he performed a *tour* de force by expressing modern ideas in a story of ancient Egypt. Poland's greatest modem writer is Henryk Sienkiewicz (*q.v.*) (1846–1916), whose Quo Vadis became known to all the civilised world, while his epic novels from Polish history—The Trilogy and The Knights of the Cross—together with the great historical paintings of Jan Matejko revived the romantic sense.

Younger novelists have imitated the extremes of the roman naturaliste in the fashion of Zola. Adolf Dygasiński (d. 1903) tells depressing stories of peasant poverty in Russian Poland: but he achieved his highest successes in his accounts of animal life in the Polish country-side, chiefly in The Feast of Life (Gody Zycia). The high-water mark of *naturalisme* in Poland is reached in the numerous plays and novels of Mme. Gabrielle Zapolska (d. 1923), an actress.

The historical verse play was cultivated with some effect by the illustrious Cracow scholar J. Szujski (1835–83), who, however, is notable chiefly as the author of a monumental History of Poland. He became one of the founders of the so-called "Cracow School" of moralising historians, represented beside him with distinction by Walerjan Kalinka (1826–86). Among later members of this group, the historian and iurist Michael Bobrzynski (1849–1935) must be mentioned. While the Cracow school chiefly stressed the faults which contributed to Poland's ruin, Warsaw historians like Tadeusz Korzon (d. 1917) and Władysław Smoleński (d. 1925) consciously emphasized the positive achievements of the nation. The stormy history of Poland in the 18th century found an able exponent in Ludwik Kubala (d. 1918), whose vivid pages inspired Sienkiewicz. More recently, the history of Poland's struggles for independence during the 19th century has been treated with brilliant talent in the writings of Professor Simon Askenazy. In recent decades, Count Stanislas Tarnowski, president of the Polish Academy (d. 1917), Professor Peter Chmielowski in Warsaw (d. 1905) and Professor Aleksander Briickner in Berlin (1856–) won distinction.

POLISH WRITERS OF RECENT TIMES

The "Young Poland" Group.—During the last decade of the 19th century a whole group of young exuberant talents appeared together in the forefront of Poland's literary life Dissatisfied with the utilitarian character of the art and poetry of the preceding period, they organised themselves into an independent body. soon known as "The Young Poland," with the view of working out a new theory of art, based on absolute individual freedom in form and matter. True to this principle, practically every one of them tried his best to find his own way of expression. The first among these young poets to gain fame was Kazimierz Tetmajer (b. 1865), whose love lyrics are comparable to the best work of the French Parnassians. The modern poetry of France and Belgium found a gifted and congenial interpreter in the person of Zenon Przesmycki, who wrote under the name of "Miriam" (b. 1861). The most forceful individuality of this group was Stanislaw Przybyszewski (1868–1927), who, having spent several years among the young Scandinavian and German writers, came back to Poland in 1898 to become at once the leader of the group and the editor of their organ, a weekly called Zycie (Life). His dramas full of fatalistic terror, and his prose poems, dealing with the mysteries of love and death, became the fashion of the day.

The art editor of the new weekly was Stanislaw Wyspianski (1869–1907), a painter of great originality, who became also the foremost Polish dramatic poet of his age His leading idea was to unite in the theatre the arts of painting, of architecture, and of poetic drama. Gradually his attention turned to national subjects, and especially to the problem of national strength and weakness, which is the root of the three dramas, Warszawianka (The Song of Warsaw), *Lelewel,* and *Noc* Listopadowa (The November Night). The Legion, a play of which the tragedy of Mickiewicz as the leader of Polish romanticism is the subject-matter—links the past with the present. In three powerful dramas—*Wesele* (The Wedding, 1901), *Wyzwolenie* (Deliverance), and *Akropolis,* he deals with Poland's deliverance

Jas Kasprowicz (1860–1926) was no doubt the greatest Polish lyrical poet of his day. With him, as with Thomas Hardy, the problem of evil and human suffering is the predominant subject. This problem finds expression in Chrystus (Christ), Na *Wzgórzu* Smierci (On the Hill of Death), and finally in the cycle of hymns *Ginącemu Światu* (To the Perishing World). In his later years, the poet attains the wisdom of a resigned sage, which speaks from every line of his last volumes called Ksigga Ubogich (The Book of the Poor) and *Mój* Swiat (My World).

The mood of spiritual calm is also the dominant note of Leopold Staff (b. 1878), who started his poetical career with *Sny* o *Potędze* (Dreams of Might): but struggles with the eternal mysteries are not absent even from his later volumes, e.g. Ucho Igielne (The Eye of the Needle, 1927).

Novelists.—Brought up under Russian oppression, Stefan Zeromski (1867–1925) indulges in pessimism. The most typical of his novels are "*Ludzie Bezdomni*" (The Homeless), *Popioły* (Ashes), dealing with the Napoleonic period, and the story-cycle *Wiatr* Od *Morza* (The Wind from the Sea)—with his final work, *Przedwiośnie* (Before Springtime) in which he gives a threatening picture of the new Poland.

The winner of the Nobel Prize for literature in 1924, Władyslaw Stanislaw Reymont (1868–1925) was a born realist. His early ambition was to draw a picture of life in a big industrial city. After a stay at Łódz, he produced a novel called *Ziemia Obiecana* (The Promised Land, Eng. tr. M. H. Dziewicki, 1927) which caused him to be hailed by critics as "The Polish Zola." Like Zola, but on a larger scale, he afterwards wrote a novel of peasant life: as the result of five years of incessant work there appeared his tetralogy "*Chłopi*" (The Peasants, Eng. tr. by M. H. Dziewicki, 1924). This great epic novel gives a rich and vivid picture of Polish peasant life especially in the Tatra mountains

The most talented representative of exoticism in Polish literature is Waclaw Sieroszewski (b. 1858) whose prolonged stay in political exile among the native tribes of north-eastern Siberia resulted in a series of fascinating short stories. An artist of rare subtlety and literary skill is Waclaw Berent (b. 1873). His novels *Próchno* (Rot) and *Ozimina* (The Winter Crop) contain a penetrating analysis of the late 19th century mood: his later work, Żywe *Kamienie* (Living Stones) is a rich and interesting picture of mediaeval life. Among disciples of Sienkiewicz, the most talented is Józef Weyssenhoff (1860–1932), whose hunting stories *Soból i* Panna (The Sable and the Girl, Eng. tr. Mme. K. Zuk-Skarszewska, 1928) describe Poland's Eastern borderland.

Literature in Poland After the World War.—With the reunion of Poland. her literature must lose influence as a national force. But even during the War, there came into being two notable groups of young poets, one in Poznan (the capital of the western provinces of Poland), another in Warsaw. The latter soon surpassed the former, and became the centre of a boldly aggressive and joyous view of life. Among these young poets the most promising are J. Tuwim, K. Wierzyński, J. Lechoń, A. Słonimski, and J. Iwaszkiewicz,

Another group, headed by E. Zegadlowicz and calling itself Czartak, looks for inspiration to the quietness and retirement of country life, and to the simple piety and legendary traditions of the folk In Miss I. K. Illakowicz the new Poland possesses a poetess of great lyrical charm, The terrible experiences of the war, and of Bolshevism on the Eastern border, found expression in some notable works by such writers as Mme. Z. Kossak-Szczucka (Pozoga—The Blaze—Eng. tr. 1926). The wanderings of Polish exiles in war-time over the vast territories of European and Asiatic Russia have born literary fruit in the vigorous and racy stories of F. Goetel, as well as in the spirited yarns of wild adventures in Mongolia by F. Ossendowski. Otherwise, the novels written since the War, like the comedies and dramas—the works of W. Perzyński and others—deal with daily reality. The tradition of poetic drama, in the fashion of Slowacki and Wyspianski, is kept up by the verse plays of K. H. Rostworowski, E Zegadlowicz and L. H Morstin. The reflective post war mood is shown most ably in the novelist Julius Kaden Bandrowski.

POLISH SUCCESSION WAR (1733–1735), the name given to a war which arose out of the competition for the throne of Poland between the elector August of Saxony, son of August II. (the Strong), and Stanislaus Leszcynski, the king of Poland installed 30 years before by Charles XII. of Sweden and displaced by August the Strong when Charles's projects collapsed. The claims of Stanislaus were supported by France, Spain and Sardinia, those of the Saxon prince by Russia and the empire, the local quarrel being made the pretext for the settlement of minor outstanding claims of the Great Powers amongst themselves The war was therefore a typical 18th century "war with a limited object," in which no one but the cabinets and the professional armies were concerned. It was fought on two theatres, the Rhine and Italy. The Rhine campaigns were entirely unimportant, and are remembered only for the last appearance in the field of Prince Eugène and Marshal Berwick—the latter was killed at the siege of Philippsburg—and the baptism of fire of the young crown prince of Prussia, afterwards Frederick the Great. In Italy, how ever, there were three hard-fought — though indecisive — battles. Parma (June 29, 1734), Luzzara (Sept. 19, 1734) and Bitonto (May 25, 1735), the first and last won by the Austrians, the second by the French and their allies. In Poland itself, Stanislaus, elected king in Sept. 1733, was soon expelled by a Russian army and was afterwards besieged in Danzig by the Russians and Saxons (Oct. 1734–June 1735).

POLITIAN (1454–1494). Angelo Ambrogini, known in literary annals as Angelo Poliziano or Politianus from his birthplace, was born at Montepulciano in Tuscany on July 14, 1454. His father, Benedetto, a jurist of good family and distinguished ability, was murdered by political antagonists for adopting the cause of Piero de' Medici in Montepulciano; this circumstance gave his eldest son, Angelo, a claim on the family of Medici. At the age of ten the boy came to study at Florence, where he learned Latin under Cristoforo Landino, and Greek under Argyropulos and Andronicos Kallistos. From Marsilio Ficino he imbibed the rudiments of philosophy. His genius for scholarship and poetry was early manifested. At 13 years of age he began to circulate Latin letters; at 17 he sent forth essays in Greek versification; at 18 he published an edition of Catullus. In 1470 he won for himself the title of *Homericus juvenis* by translating four books of the *Iliad* into Latin hexameters. Lorenzo de' Medici, who was then the autocrat of Florence and the chief patron of learning in Italy, took Poliziano into his household, made him the tutor of his children, and secured him a distinguished post in the University of Florence. Before he reached the age of 30, Poliziano expounded the humanities with almost unexampled lustre even for that epoch of brilliant professors. Among his pupils could be numbered the chief students of Europe, the men who were destined to carry to their homes the *spolia opima* of Italian culture. Not to mention Italians, it will suffice to record the names of the German Reuchlin, the English Grocyn and Linacre, and the Portuguese Tessiras.

Poliziano published the notes of his courses on Ovid, Statius, the younger Pliny, Quintilian, and the writers of Augustan histories. He also undertook a recension of the text of the *Pandects* of Justinian, which formed the subject of one of his courses; and this recension, though it does not rank high in the scale of juristic erudition, gave an impulse to the scholarly criticism of the Roman code. His versions of Epictetus, Herodian, Hippocrates, Galen, Plutarch's *Eroticus* and Plato's *Charmides* delighted contemporaries by a certain limpid fluency of Latin style and grace of manner which distinguished him also as an original writer. Of these learned labours the most universally acceptable to the public of that, time were a series of discursive essays on philology and criticism, first published in 1489 under the title of *Miscellanea.* They had an immediate, a lasting and a wide renown, encouraging the scholars of the next century and a half to throw their occasional discoveries in the field of scholarship into a form at once so attractive and so instructive. Poliziano was not, however, contented with these simply professorial and scholastic compositions. Nature had endowed him with literary and poetic gifts of the highest order. These he devoted to the composition of Latin and Greek verses, which count among the best of those produced by men of modem times in rivalry with ancient authors. The *Manto,* in which he pronounced a panegyric of Virgil; the *Ambra,* which contains a beautiful idyllic sketch of Tuscan landscape, and a studied eulogy of Homer; the *Rusticus*, which celebrated the pleasures of country life in no frigid or scholastic spirit; and the *Nutricia,* which was intended to serve as a general introduction to the study of ancient and modern poetry — these are the masterpieces of Poliziano in Latin verse, displaying an authenticity of inspiration, a sincerity of feeling, and a command of metrical resources which mark them out as original productions of poetic genius rather than as merely professorial lucubrations. Exception may be taken to their style, when compared with the best work of the Augustan or even of the Silver age. But what renders them noteworthy to the student of modern humanistic literature is that they are in no sense imitative or conventional, but that they convey the genuine thoughts and emotions of a born poet in Latin diction and in metre moulded to suit the characteristics of the singer's temperament.

Poliziano's principal Italian works are the stanzas called *La Giostra,* written upon Giuliano de' Medici's victory in a tournament; the *Orfeo,* a lyrical drama performed at Mantua with musical accompaniment; and a collection of fugitive pieces, reproducing various forms of Tuscan popular poetry. *La Giostra* had no plan, and remained imperfect; but it demonstrated the capacities of the octave stanza for rich, harmonious and sonorous metrical effect. The *Orfeo* is a slight piece of work, thrown off at a heat, yet abounding in unpremeditated lyrical beauties, and containing in itself the germ both of the pastoral play and of the opera. The Tuscan songs are distinguished by a "roseate fluency," an exquisite charm of half romantic, half humorous abandonment to fancy, which mark them out as improvisations of genius. It may be added that in all these departments of Italian composition Poliziano showed how the taste and learning of a classical scholar could be engrafted on the stock of the vernacular, and how the highest perfection of artistic form might be attained in Italian without a sacrifice of native spontaneity and natural flow of language.

Beyond the sphere of pure scholarship and pure literature Poliziano did not venture. He was present, indeed, at the attack made by the Pazzi conspirators on the persons of Lorenzo and Giuliano de' Medici, and wrote an interesting account of its partial success. He also contributed a curious document on the death of Lorenzo de' Medici. Otherwise, his uneventful life was passed as a house-friend of the Medici, as the idol of the learned world, and as a simple man of letters to whom (with truly Tuscan devotion to the Saturnian country) rural pleasures were always acceptable. He was never married; and his morals incurred suspicion, to which his own Greek verses lend a plausible colouring. He died, half broken-hearted by the loss of his friend and patron Lorenzo de' Medici, on Sept. 24, 1494.

POLK, JAMES KNOX (1795–1849), 11th president of the United States, was born in Mecklenburg county, N.C., on Nov. 2, 1795. In 1806 he crossed the mountains with his parents and settled in what is now Maury county, Tennessee. He graduated from the University of North Carolina in 1818, studied law in the office of Felix Grundy (1777–1840) at Nashville, Tenn., in 1819–20, was admitted to the bar in 1820, and began to practise in Columbia, the county seat of Maury county. After two years of service (1823–25) in the State house of representatives. he represented his district in the National house of representatives from 1825–39. In the party conflicts which succeeded the presidential election of 1824 he sided with the Jackson-Van Buren faction. and soon became recognized as leader of the Democratic forces. He was speaker from 1835 until 1839, when he retired from Congress to become governor of Tennessee. His administration (1839–41) was successful, but he was unable to overcome the popular Whig movement of that period, and was defeated in 1841 and again in 1843. When the Democratic national convention met in Baltimore in 1844 he was mentioned as a possible candidate for the vice presidency, but was suddenly brought forward as a "dark horse" and selected to head the ticket. Finding it impossible under the two-thirds rule to nominate their candidate, the followers of Van Buren brought forward Polk, who was popular in the South, in order to defeat Lewis Cass and James Buchanan. George Bancroft, the historian, has asserted that this suggestion came originally from him, and Gideon J. Pillow, Polk's intimate friend, did much to bring about the nomination.

The unequivocal stand of Polk and his party in favour of the immediate annexation of Texas and the adoption of a vigorous policy in Oregon contrasted favourably with the timid vacillations of Henry Clay and the Whigs. Polk was elected, receiving 170 electoral votes to 105 for his opponent Clay. In forming his cabinet he secured the services of James Buchanan of Pennsylvania as secretary of State, Robert J. Walker of Mississippi as secretary of the treasury, William L. Marcy of New York as secretary of war, and George Bancroft, then of Massachusetts, as secretary of the navy. There is no doubt that each of these men, and Bancroft in particular, influenced the policy of the administration, yet the historian, James Schouler, who has made a careful study of the Polk papers, is doubtless correct in saying that the president himself was "the framer of the public policy which he carried into so successful execution, and that instead of being led (as many might have imagined) by the more famous statesmen of his administration and party who surrounded him, he in reality led and shaped his own executive course." Bancroft's opinion is that Polk was "prudent, far-sighted, bold, exceeding any Democrat of his day in his undeviatingly correct exposition of Democratic principles."

The four chief events of President Polk's administration were the final establishment of the independent treasury system, the reduction of the tariff by the Walker bill of 1846, the adjustment of the Oregon boundary dispute with Great Britain by the treaty concluded on June 15, 1846, and the war with Mexico and the consequent acquisition of territory in the south-west and west. The first three of these were recommended in his first annual message, and he privately announced to Bancroft his determination to seize California. The independent treasury plan originated during Van Buren's administration as a Democratic measure; it had been repealed by the Whigs in 1841, and was now re-enacted. Protectionists contend that the tariff legislation of 1846 was in direct violation of a pledge given to the Democrats of Pennsylvania in a letter written by Polk during the campaign to John K. Kane of Philadelphia. Briefly summarized, this letter approves of a tariff for revenue with incidental protection, whereas the annual message of Dec. 2, 1845, criticizes the whole theory of protection and urges the adoption of a revenue tariff just sufficient to meet the needs of the Government, conducted on an economical basis. It is difficult to determine whether this was always his idea of incidental protection, or whether his views were changed after 1844 through the influence of Walker and the example set by Sir Robert Peel in Great Britain, or whether he was simply "playing politics" to secure the protectionist vote in Pennsylvania.

The one overshadowing issue of the time, however, was territorial expansion. Polk was an ardent expansionist, but the old idea that his policy was determined entirely by a desire to advance the interests of slavery is no longer accepted. As a matter of fact, he was personally in favour of insisting upon 54° 40' as the boundary in Oregon, and threw upon Congress the responsibility for accepting 49° as the boundary. He approved the acquisition of California, Utah and New Mexico, territory from which slavery was excluded by geographical and climatic conditions. Furthermore a study of his manuscript diary shows that he opposed the efforts of Walker and Buchanan in the cabinet, and of Daniel S. Dickinson (1800–66) of New York and Edward A. Hannegan (d. 1859) of Indiana, in the Senate, to retain the whole of Mexico, territory in which slavery might have thrived. At the close of his term (March 4, 1849) Polk retired to his home in Nashville, Tenn., where he died on June 15, 1849.

See John S. Jenkins, *James Knox Polk* (1850), and L. B. Chase, *History of the Polk Administration* (1850), both of which contain some documentary material, but are not discriminating in their method of treatment. George Bancroft contributed a good short sketch to J. G. Wilson's *Presidents of the United States* (1894). He made copies of the Polk manuscripts and was working upon a detailed biography at the time of his death in 1891. These copies, now deposited in the Public library, New York city, contain a diary in 24 typewritten vols., besides some correspondence and other private papers. They have been used by James Schouler in his *Historical Briefs* (1896), and by E. G. Bourne in an article entitled "The Proposed Absorption of Mexico in 1847–1848," published in the *Annual Report of the American Historical Association for 1899*, i. 157–169 (1900). Bourne discusses the part which Polk took in preventing the complete absorption of Mexico. *See* also the *Diary of James K. Polk . . . 1845 to 1849* (1910), edit. by M. M. Quaife; R. L. Schuyler, "Polk and the Oregon Compromise of 1846," *Pol. Sci. Quart.*, vol. xxvi. p. 443–461 (Lancaster, Pa., 1911); E. I. McCormac, *James K. Polk* (1922); J. S. Bassett, *The Southern Plantation Overseer as Revealed in His Letters* (1925); A. Nevins, ed., *Polk: The Diary of a President, 1845–49* (1929). (W. R. SM.)

POLK, LEONIDAS (1806–1864), American general, was born at Raleigh, N.C., on April 10, 1806. He was educated at West Point, but afterwards studied theology and took orders in the Protestant Episcopal Church in 1831. In 1838 he became missionary bishop of the South-west, including Arkansas, Indian Territory, Louisiana, Alabama and Mississippi; in 1841 he was consecrated bishop of Louisiana. His work in the Church was largely of an educational kind, and he played a prominent part in movements for the establishment of higher educational institutions in the South. At the outbreak of the Civil War in 1861 he resigned his bishopric and entered the Confederate army. His rank in the hierarchy and the universal respect in which he was held in the South, rather than his early military education, caused him to be appointed to the important rank of major-general. He fortified the post of Columbus, Ky., the foremost line of defence on the Mississippi, against which Brigadier-general U. S. Grant directed the offensive reconnaissance of Belmont in the autumn. In the following spring, the first line of defence having fallen, Polk commanded a corps at Shiloh in the field army commanded by Albert Sidney Johnston and Beauregard. In Oct. 1862 he was promoted lieutenant-general, and thenceforward he commanded one of the three corps of the army of Tennessee under Bragg and afterwards was in charge of the Department of Alabama, Mississippi and East Louisiana. He was killed in the fighting in front of Marietta, while reconnoitring near Pine Mountain, Ga., on June 14, 1864.

See W. M. Polk, *Leonidas Polk, Bishop and General* (new ed., 1915).

POLKA, a lively dance of Bohemian origin, which at one period (about the middle of the 19th century) enjoyed extraordinary popularity throughout Europe. It is danced to music written in $\frac{2}{4}$ time. (See DANCE.)

POLLACK (*Gadus pollachius*), a fish that is distinguished from others of the cod genus by the long pointed snout, and the prominent lower jaw, without a barbel; the colour is greenish, with yellow markings. It ranges from Norway to the Mediterranean, but is most abundant southwards; it prefers rocky ground, and is piscivorous. It attains a weight of over 20 pounds.

POLLAIUOLO, the name of the brothers Antonio and Piero, sons of the goldsmith, Jacopo Pollaiuolo, Florentines who contributed much to Italian art in the 15th century, and of Simone, architect, the nephew of Antonio.

ANTONIO (1429–1498) distinguished himself as a sculptor, jeweller, painter and engraver, and did valuable service in perfecting the art of enamelling. He was apprenticed to Bartoluccio Ghiberti, a goldsmith (step-father of the great Ghiberti). It was not until later that Antonio took to painting. His chief achievement in that art is the "Martyrdom of St. Sebastian" (1475) in the National Gallery, London, in the execution of which he was helped by his brother. Here, too, is the fine small panel of "Apollo and Daphne." In the Uffizi, Florence, is his "Labours of Hercules." He aimed, above all, at the representation of the human figure in action, and he ranked as the foremost draughtsman of his time. He is said to have been one of the first artists who had recourse to dissection in his anatomical studies. But it was as a sculptor and metal-worker that he achieved his greatest successes. The museum of Florence contains the bronze group, "Hercules strangling Cacus," and the terra-cotta bust, "The Young Warrior." In 1489 Antonio took up his residence in Rome, where he executed the tomb of Sixtus IV. (1493). He died on Feb. 4, 1498, having just finished his mausoleum of Innocent VIII.

PIERO (1443–1496) was a painter, probably the pupil of Alesso Baldovinetti. His principal works were his "Coronation of the Virgin," an altarpiece painted in 1483, in the choir of the cathedral at San Gimignano; his "Three Saints," an altarpiece, and "Prudence" are both at the Uffizi Gallery.

SIMONE (1457–1508), nephew of Antonio Pollaiuolo, a celebrated architect, was born in Florence and went to Rome in 1484; there he entered his uncle's studio and studied architecture. On his return to Florence he was entrusted with the completion of the Strozzi palace, begun by Benedetto de Maiano, and the cornice on the façade has earned him lasting fame. His highly coloured accounts of Rome earned for him the nickname of *il* Cronaca (chronicler). About 1498 he built the church of San Francesco at Monte and the vestibule of the sacristy of Santo Spirito. In collaboration with Guiliano da Sangallo he designed the great hall in the Palazzo Vecchio. He was a close friend of Savonarola.

See Vasari, Vite (ed. Milanesi); Giovanni Morelli, *Italian* Masters in German Galleries (1883); and Maud Cruttwell, *Antonio* Pollaiuolo (1907).

POLLAN (*Coregonus pollan*), the only Irish fish of the genus Coregonus, with three forms inhabiting respectively Lough Neagh, Lough Erne and the Shannon. The jaws are equal in front. (See SALMON AND SALMONIDAE.)

POLLARD, ALBERT FREDERICK (1869–), English professor of history, was born at Ryde on Dec. 16, 1869, and educated at Felsted school and at Jesus college, Oxford. He was elected a fellow of All Souls college, Oxford, in 1898. From 1893 to 1901 he was assistant editor of the *Dictionary* of National Biography. From 1903 to 1931 he held professorial chairs of English history and constitutional history in the University of London, and in 1927 was appointed Honorary Director of the Institute of Historical Research.

His publications include Thomas Cranmer and the English Reformation (1898; new ed., 1926); Henry VIII. (1902); Factors in Modern History (1907; new ed., 1926); Evolution of Parliament (1920); Factors in American History (Cambridge, 1925).

POLLARD, ALFRED WILLIAM (1859–), English scholar, was born in London on Aug. 14, 1859, and educated at King's college school, London, and St. John's college, Oxford. In 1883 he entered the British Museum as assistant in the department of printed books, of which he became assistant keeper in 1909, and keeper from 1919–24. In 1916 he was appointed Sandars reader in bibliography in the University of Cambridge, and in 1919 professor of English bibliography at King's college, London, and held that chair until 1932.

His publications include Bibliographica (1894–96); Early Illustrated Books (1893); An Essay on Colophons (1905); Shakespeare's Folios and Quartos (1909); A New Shakespeare *Quarto* (Richard II. 1598) (1916); A Short Title Catalogue of English Books (1475–1640) with *G*. R. Redgrave and others (1926).

POLLENTIA, an ancient town of Liguria, Italy, 10 m. to the north of Augusta Bagiennorum, on the left bank of the Tanarus. Its position on the road from Augusta Taurinorum to the coast at Vada Sabatia, at the point of divergence of a road to Hasta (Asti) gave it military importance. Decimus Brutus managed to occupy it an hour before Mark Antony in 43 B.C.; and it was here that Stilicho on March 29, 403, fought the battle with Alaric which, though undecided, led the Goths to evacuate Italy. Considerable remains of ancient buildings still exist.

POLLINATION, a term used in botany for the transference of pollen (see FLOWER) to the stigma (the receptive surface) of the ovary of the flower. Such pollination brings about the fertilisation of the ovules in the ovary and their subsequent development into seeds; there are, however, a few cases in which parthenogenesis occurs, *i.e.,* the ovules develop without fertilisation. As the pollen-bearing parts of the stamens are rarely in contact with the stigma at the time when both of these are ripe, some mechanism is clearly necessary to bring the pollen to the stigma. The means in question is usually wind or insects, though sometimes other agencies such as water or birds may be responsible. The great variety in the form, colour and scent of flowers has been developed in relation to the particular agency of insects. Apart from the mechanism of pollination we can distinguish two types—self-pollination (autogamy) in which pollen is transferred from the stamens of one flower to the stigma of the same flower; and cross-pollination (allogamy) in which pollen is transferred to the stigma of another flower on the same plant (geitonogamy) or to the flower of another plant of the same species (xenogamy). Occasionally hybridization is possible, the pollen of one plant bringing about fertilisation of the ovary of the flower of another species or, more rarely, of the flower of a plant belonging to another genus; cases of hybridization between genera are known for example in cycads (see GYMNOSPERMS) and in orchids.

Cross Pollination and **Dichogamy.**—Cross pollination is the only possible method in the case of unisexual flowers whether the plant is *monoecious* (*i.e.,* with staminate and pistillate flowers on the same plant), as in birch, beech, elder, oak, or dioecious (*i.e.,* with staminate and pistillate flowers on different plants) as in the case of willows and poplars. In hermaphrodite flowers, bearing both stamens and carpels, either self-pollination or cross pollination can occur. It is interesting to note however, that many flowers have special arrangements to ensure that the pollinating mechanism, whatever it may be, causes cross pollination and not self-pollination. One of the commonest methods to achieve this is a separation in time of the sexes—the stamens dehisce and shed their pollen either before or after the stigma is receptive. This separation in time—and it may apply to the separate male and female flowers on the same plant—is known as dichogamy. When the stamens ripen first it is known as *protandry,* the more common case, while when the stigma is ready first, it is known as *proterogyny.* Protandry is very common in insect-pollinated (*entomophilous*) flowers, as in nearly all members of the Compositae (*q.v.*) and Umbelliferae, many Labiatae (such as dead-nettle [Lamium] and *Salvia*), the Caryophyllaceae, the large willow-herb (*Epilobium angustifolium*), etc. Proterogyny is found in the horse chestnut (*Aesculus*), the autumn crocus (*Colchicum*), many Araceae, and in wind-pollinated anemophilous flowers such as plantain (Plantago), meadow rue (Thalictrum) and many grasses, though here separation in time is very short and many are self-pollinated as wheat, barley and oats. It is often accepted that cross-pollination is of greater value to the plant than self-pollination in respect of weight and number of seeds; the question is, however, one of some difficulty. The numerous provisions in flowers for aiding cross-pollination and hindering self-pollination suggest the superiority of the former process, but there are numerous plants which normally and for generations are self-pollinated.

WIND POLLINATION (ANEMOPHILY)

The method of pollination of the earlier and more primitive flowers was probably by the wind, the insect pollinated flowers being derived from them in later stages of evolution. Some flowers such as plaintain and meadow rue mentioned above, are almost certainly anemophilous by reduction, all their congeners being entomophilous; other cases are *Poterium* among the Rosaceae and Kerguelen's Land cabbage (*q.v.*) among the Cruciferae.

Characters of **Anemophilous** Flowers.—These are such as might be expected. The flowers are usually inconspicuous (the corolla being commonly absent) for there is no advantage in their being easily seen, and they are without the scent or nectar so common in flowers visited by insects. Furthermore there is usually no tubular formation of the flower and no irregularities. On the other hand these wind-pollinated flowers form large quantities of pollen, since the greater proportion when consigned to the air must necessarily be lost. The large quantity of pollen produced by pines and other conifers is well known; in these plants the numerous stamens are massed in male cones often of considerable size, though smaller than the female cones. In other families, such as the grasses, Cyperaceae, Urticaceae, the number of stamens in each flower is small but the anthers are large. Again, in these flowers the pollen is dry and powdery and does not stick together in small masses as in entomophilous flowers; this enables the pollen to blow about easily. The pollen in this type of flower must be easily removed by the wind; the absence of floral envelopes facilitates this and so do the pendulous catkins (hazel, plane, etc.) which can sway in the wind. In addition the filament of the stamen is usually long so that the anthers hang out of the flower, and are also versatile (see FLOWER) so that the pollen is easily shaken from them.

Another common characteristic of the flowers in question is that the stigma is much larger and rougher than that of entomophilous flowers and it is freely exposed to the air so as to increase the chance of reception of the pollen; in maize, for example, the stigma is of very great length. In many catkin-bearing plants the flowering stage occurs before the leaves appear, so that accidental interception of pollen by the leaves is avoided. As already stated dichogamy is quite common in anemophilous flowers but proterogyny is much more common than protandry.

INSECT POLLINATION (ENTOMOPHILY)

The special characteristics of entomophilous flowers are the attractive colour of the floral envelope, the presence of scent and of nectar, and of pollen which is not powdery but sticky and is present in comparatively small quantities. The entomophilous is the most common type of pollination in flowering plants and special floral conformations and irregularities adapted to insect visitors are characteristic of the higher families of flowering plants, as will be seen below. The evolution of flowers and of insects must have gone hand in hand; such groups as Lepidoptera (butterflies and moths) and Hymenoptera (bees, wasps, etc.) could not have existed without the more elaborate and honey-bearing flowers and vice versa. Hermann Muller (see Bibliography) has divided flowers into various classes according to their degree of specialisation for different insects, so that a brief survey of the types of insects concerned must be given.

Types of Insects.—There are five important classes of insects which visit flowers. The *Hemiptera* (bugs, etc.) have a few flower-visiting species but they show no special adaptation to flowers; the Coleoptera (beetles) have many species which visit flowers but they have only short tongues (only a few species with a length of 3 to 6 mm.) and so are able to reach only honey which is fully exposed. The Diptera (flies) include many species which visit flowers. The short-tongued ones (with tongues under 4 mm.) show no special adaptation to a diet of floral origin and are not usually clever enough to find any nectar which is not fully exposed in the flower; many of these flies have also other sources of feeding. The long-tongued flies (such as hover flies or drone flies) have tongues from 4–12 mm. and confine themselves to a diet of nectar, and are clever in discovering it when concealed. The *Hymenoptera* (bees, wasps, sawflies, ants, etc.) include a very large number of flower-visiting forms. Bees are the only long-tongued members of the group, and it is bees which have played the most important part in the evolution of the more complex flowers. The hive bee (*Apis*) and the humble-bee (*Bombus*) have long tongues (over 6 mm.) while most of the other bees have shorter tongues, *i.e.,* less than 6 mm. The "cleverness" of bees, combined with the length of their proboscis, enables them to find and reach nectar which is deeply concealed in the flower. Bees do not confine themselves to sucking nectar from the flower; they also collect pollen (some flowers provide only pollen and no nectar), which is carried in small masses attached to the hairs of the hind legs. The Lepidoptera (butterflies and moths) are insects with tongues usually about as long as those of bees, but the hawk moths may have tongues, when unrolled, of enormous length. The British hawk moth, *Sphinx convolvuli,* has a tongue 80 mm. ($3\frac{1}{5}$ in.) long and some tropical moths a tongue of 300 mm. (12 in.).

Classes of Flowers.—The entomophilous flowers have been divided by H. Muller into nine classes based on the structure of the flower and its relation to particular insects.

(i.) Class A. Flowers *with* Exposed Nectar.—In this class come most Umbelliferae, many Saxifragaceae, the bedstraws (*Galium*), ivy (Hedera) and such trees as maple, elder and lime. The flowers are wide open and usually small and the visitors are mostly short-tongued; they are rarely visited by bees and butterflies. Such flowers run the risk of the nectar being washed away by rain.

(ii.) Class AB Flowers with Partially Concealed Nectar.—In this class fall the buttercups (*Ranunculus*), the Cruciferae, the strawberry (Fragaria) and the willows (*Salix*). The nectar is protected and concealed by the position of the stamens, by the development of hairs or scales, or by the flower being partially tubular, as in wallflower where the sepals stand erect and give a tubular form to the lower part of the flower.

(iii.) Class B. Flowers with *Fully* Concealed Honey.—In this class are the flowers of many Carophyllaceae (such as *Gypsophila,* Geranium), *Polemonium,* blackberry (*Rubus*), eyebright (*Euphrasia*) mint (Mentha), heather (*Calluna*). In these the nectar may be concealed by the stamens, by the calyx, by the receptacle becoming hollowed, or by the petals being united to form a sympetalous corolla. The insect visitors are the smaller bees with a few of the longer tongued flies. This type of flower is clearly the most effective of the classes so far mentioned. The bees show a high degree of skill in reaching the concealed honey and mostly confine themselves during a given flight to one or a few species of flower, and thus avoid the great waste of pollen caused by shorter tongued insects, which are liable to carry it indiscriminately from the flower of one species to another.

(iv.) Class B' is an extension of Class B and includes the flowers of the Compositae, most Dipsaceae and some Campanulaceae, in which the flowers have the same length of tube, etc., as Class B, but are aggregated into an inflorescence, which by the uninstructed might be mistaken for a flower, and which acts like a single flower as a unit of attraction.

(v.) Class F. Lepidoptera Flowers.—This includes those flowers in which the floral tube has been so deepened that short-tongued insects are excluded altogether and in many cases only Lepidoptera can reach the nectar. The alpine moss campion (*Silene* acaulis), for example, is adapted to butterflies, while the bladder campion (S. *inflata*) is adapted to moths and emits a scent at night. To the latter class belong also the honeysuckle (*Lonicera*), tobacco plant (*Nicotiana*), evening primrose (Oenothera), and night-scented stock and many others.

(vi.) Class H. Bee Flowers, are those which are visited mostly by long-tongued bees, the depth of the tube being 6 to 15 mm. The flowers are also often markedly zygomorphic (*i.e.,* having a special kind of irregularity; see FLOWER), providing a landing place for the bee; others are of such a shape that (as in the snapdragon and broom) it requires an insect like the humble-bee which is not only "clever" but of considerable size and weight in order to open the flower.

(vii. and viii.) The D and K classes of flowers include those adapted to small insects; they are pollinated by flies, beetles and small bees.

Lastly, there is (ix.) the Class Po, Pollen Flowers. These provide no nectar, but abundant pollen for which the flower is visited, mainly by bees; examples are Clematis, meadowsweet (*Spirea*), rock rose (Helianthemum) dog rose (Rosa *canina*), poppy. In some flowers, such as Cassia, some stamens provide "food-pollen" for insects, other stamens supply the fertile pollen for fertilization.

Nectar, Colour and Scent.—Nectar is a watery fluid secreted by certain parts of the flower and sometimes by other parts of the plant, as in the case of the extra-floral nectaries. It contains a sugar (glucose) sometimes to as much as 25%. It is from the nectar that the bee makes honey, which is a manufactured product with nectar as the raw material. As has already been indicated the position of the nectaries (the nectar-secreting glands) is very various; they may be fully exposed or hidden and deeply enclosed. In some cases the nectar is secreted by one organ and collected in another as in Viola, where it collects in the spur but is secreted by appendages of the stamens. In other cases there is no free nectar but the insect must pierce with its proboscis the juicy, sapid cells, which in the case of some orchids line the spur.

The importance of colour in attracting the attention of insects is obvious, but it does not follow that the flowers most striking or attractive to our eyes are those most conspicuous or alluring to the insect. The problem of the colour-sense of insects has been investigated by a number of workers and it seems clear that bees at least can distinguish some colours, such as blue and yellow, and do not merely depend on the different brightness between, say, a deep purple flower and a light yellow one. In the different flower classes (A to H) already defined, there is a tendency to a progression in colour; the simpler flowers in the A and AB classes tend to be white or yellow, while in the B class blues and purples are found. In class H, the bee flowers, blues and purples predominate, while in class F, the butterfly and moth flowers, pale tints of pink and purple are most common. The special colour markings on flowers, such as the yellow eye of forget-me-not (*Myosotis*), the darker lines on the petals of the violet and pansy, appear to assist the insect to find the nectar and are known as honey guides.

Scent is obviously of great importance and the olfactory sense of some insects such as moths is very much greater than ours. J. H. Fabre showed that moths when out of sight of honeysuckle would fly straight to it from a distance of several hundred yards. K. van Frisch has investigated elaborately the olfactory sense of the honey bee. Bees which had been drilled by association of oil of orange with sugar. could pick out this scent from 43 other ethereal oils. As stated by M. Skene (see p. 172) the general conclusion is "that colour is the guide to the flower, and that scent is useful in enabling the bee, flying among the many flowers of similar colour, to pick out the species it has formed the temporary habit of visiting." In this it is helped by the sense of form.

SPECIAL MECHANISMS OF ENTOMOPHILOUS FLOWERS

Pollination of Sage.—Such a plant as the sage (*Salvia pratensis*) has a typical humble-bee flower. The bee alights on the platform formed by the lower lip of the sympetalous corolla and pushes its head down the tube to reach the nectar at the bottom. Each of the two stamens is of special shape; the connective is very large and two-armed, and is hinged to the short filament. The longer arm bears a half anther while the short arm is sterile, the whole stamen having a lever mechanism. The bee, in probing for the honey, comes in contact with the short arm of the lever and in pressing this down brings the half anther at the end of the longer arm down upon its back where the pollen becomes deposited. The flower is protandrous and in a later stage the style elongates and is brought into the same position as occupied by the back of the bee when in contact with the anther. Cross pollination is thus brought about when the bee passes from a younger to an older flower.

Papilionaceous Type.—The Leguminosae (Pea family) show a very interesting series of pollination mechanisms. In this familiar type of flower to which the pea and gorse belong, the essential parts of the flower are enclosed in the keel. The nectar is secreted by the inner sides of the lower part of the staminal tube; one of the ten stamens is usually free and at its base are two openings leading to the nectar. The nectar is thus not only carefully concealed but is also at a considerable depth. Cleverness and length of proboscis are thus required so that as might be expected these flowers are bee flowers. An insect visiting the flower alights on the wings, thus depresses them and, as they are joined to the keel, this is depressed also. The stigma and stamens are thus forced out, the stigma usually first so that it has the chance of brushing off pollen from the under-side of the bee and thus being cross pollinated.

There are four different types. (1) Flowers in which the stamens and stigma return within the keel so that repeated visits are possible; examples are the clovers, melilot (*Melilotius*) and laburnum. (2) Flowers that are explosive, since the style and stamens are confined under tension in the keel and when it is depressed they are released with suddenness, thus scattering pollen on the undersurface of the bee. Only one insect visit is thus effective. Examples are broom (Genista), gorse (Ulex), lucerne (Medicago). (3) Flowers which display a piston mechanism—the pollen is shed early and the heads of the five outer stamens act as a piston so that the weight of the bee on the keel squeezes a narrow ribbon of pollen through the pore at the apex of the keel. A further pressure causes a protrusion of the stigma which is thus brought in contact with the bee. Examples are lupin (*Lupinus*), rest harrow (*Ononis*) and bird's foot trefoil (Lotus *corniculatus*). (4) Flowers which show a brush mechanism, for the pollen is again shed early and the style, which is provided with a brush of hairs, sweeps the pollen in small portions out of the tip of the keel. Flowers of this type usually allow of repeated insect visits.

Pinch Trap Flowers.—This type of flower is found in the Asclepiadaceae. The pollen is massed together into pollinia and pairs of these are attached to a sort of clip in which the leg of the insect (bees, wasps, etc.) becomes caught. The pollinia are thus carried away to another flower and are likely to come in contact with its stigmatic surface. Pitfall *flowers* are shown by the cuckoo pint (*Arum maculatum*), a common British plant, and by *Aristolochia* and *Asarum*. In A. *maculatum* there is a spathe surrounding a spadix which bears a fringe of stiff downwardly projecting hairs at the top. These hairs allow the entry of insects but not their return; the insects are thus trapped for a time in the spathe and pollinate the pistillate flowers; later the hairs wither and exit becomes possible. Flies are the common visitors.

Piston Mechanism of **Compositae.**—The flowers of this family show a very efficient pollination mechanism which. with the economy of material resulting from the massing of the flowers into heads and the effective method of seed dispersal, probably explains the dominant position of the family.

Pollination of Fig.—The fig shows a very remarkable interrelationship between an animal and plant. The flowers in the fig are unisexual and are borne in numbers together on the inside of the hollow inflorescence, which opens to the outside by a pore. The swollen and fleshy infructescence (as the inflorescence becomes) is the edible fruit; each "seed" being the product of a single flower and in reality a fruit. The female of a small wasp (*Blastophaga*) enters the inflorescence and deposits eggs in special "gall flowers" incapable of setting seed. The larvae are hatched out and undergo metamorphosis. The male wasps fertilise the female and then die without leaving the inflorescence. The female wasps leave the gall flowers and crawling out through the pore become dusted with pollen from the male flowers in the neighbourhood of the pore. They then enter other figs and pollinate the female flowers, which set seed. The fig and wasp are thus mutually dependent. When Smyrna figs were introduced into California it was found necessary to introduce the caprifig (non-edible fig) containing the wasp Blastophaga.

Pollination of Yucca.—This is another case of the complete interdependence of a flower and a moth. The large white flowers of this plant emit their perfume especially at night and are visited by a moth (*Pronuba* yuccasella). The female moth (see YUCCA-MOTH) collects pollen from the anthers of the flower and kneads it into a pellet about three times the size of its head. It flies to another flower and, piercing the ovary wall with its long ovipositor, lays a few eggs between the ovules. After this it climbs down the style of the hanging flower and presses the ball of pollen into the stigma; by this means fertilisation is ensured. Only a certain proportion of the seeds are destroyed by the developing insects, which, when mature, eat through the fruit wall, drop to the ground and remain dormant in a cocoon until the next flowering season, when the moth emerges. This seems to be the only method of pollination, for in the absence of the moth the plant is said to be completely sterile.

Pollination of Orchids.—The orchids show many and complicated adaptations to pollination by insects. A great impetus to their study was given by the publication in 1862 of Darwin's monograph on the various pollination mechanisms exhibited by this group. As is well known, in this flower there is generally only one stamen. which is two-lobed, and the pollen is in the form of two stalked masses, the pollinia which the insect carries away stuck to its head. As the insect flies away, the pollinia, if not already properly oriented, execute such a movement as brings them into position to touch the stick stigma of the next flower that is visited. There are, however, a great many variations in the details of this process. Nectar is not usually secreted by the orchid flower, but to obtain a sweet juice the insect has to pierce a special tissue. usually that of the labellum (the posterior petal), which is often spur-like.

Heterostylism.—In some cases the plant bears more than one type of flower. The primrose (*Primula vulgaris*) and the cowslip (P. *veris*) are dimorphic, *i.e.*, some plants have flowers with a long style bearing a knob-like stigma at the mouth of the corolla tube and the five stamens stand half-way down the tube: in others the flower has a short style with a stigma half-way down the tube while the stamens stand at the top. These two types of flower are known as "pin-eyed" or long-styled and "thrum-eyed" or short styled, respectively. From their correspondence in position, the insect tends to transfer pollen from the thrum-eyed to the stigma of the pin-eyed and *vice versa*. These two types of pollination are spoken of as "legitimate," and Darwin showed that this type produces more seed and more vigorous progeny than "illegitimate" pollination of thrum-eyed stigma by thrum-eyed pollen or pin-eyed stigma by pin-eyed pollen. In trimorphic plants such as the loosestrife (*Lythrum Salicaria*), there are three types of flower, short-styled, long-styled and those with styles of intermediate length. In each type the stamens are in two groups of different lengths; in the first type the stamens are long and intermediate, in the second type they are short and intermediate, and in the third they are short and long. Eighteen possible methods of pollination are possible, six being "legitimate" and 12 "illegitimate." Legitimate unions are found to yield a larger amount of seed than illegitimate.

POLLINATION BY AGENCIES OTHER THAN WIND AND INSECTS

In some water plants the pollen is brought to the stigma by the agency of water. In *Najas* the pollen grains sink in the water and are caught by the stigma. In the eel-grass (*Zostera*), the American water-weed (*Elodea canadensis*), and others, the pollen floats on the surface and so reaches the female flowers. In *Vallisneria*, the male and female flowers are on separate plants and the male becoming detached and floating free on the surface of the water, may reach and become entangled with the fixed larger female flowers, with the result that the anthers come in contact with the projecting stigmas.

In some cases animals other than insects are responsible for pollination. In some countries pollination by birds (humming birds, honeysuckers and sun birds) plays a considerable part. These *ornithophilous* flowers, as they are called, are not very different from insect flowers, many bird flowers being also visited by insects. A landing place is, however, not necessary, as the birds sip the nectar while hovering. The flowers are scentless, and the styles, stigma and filament often rigid. The colour red seems to be predominant in flowers of this type. Examples of ornithophilous flowers are *Strelitzea regina* in South Africa, species of *Salvia* and *Erythrina* in South America. In Java, species of *Freycznetia* and in Trinidad *Bauhınia megalandra*, are said to be pollinated by bats.

SELF POLLINATION (AUTOGAMY)

Self pollination is effected in various ways. In the simplest case the anthers are close to the stigmas, covering these with pollen when they open; this occurs in a number of small annual plants, also in *Narcissus, Crocus*, etc. In snowdrop and other pendulous flowers the anthers form a cone around the style and the pollen falls on to the underlying stigmas, or in erect flowers the pollen may fall on to the stigmas which lie directly beneath the opening anthers (e g , *Narthecium*). In very many cases the pollen is carried to the stigma by elongation, curvature or some other movement of the filament, the style or stigma, or some other part of the flower, or by correlated movements of two or more parts. For instance, in many flowers the filaments are first directed outwards so that self pollination is not possible, but later incline towards the stigmas and pollinate them (*e.g.*, numerous Saxifragaceae, Cruciferae and others); or the style which first projects beyond the anthers, shortens later on, so that the anthers come into contact with the stigmas (*e.g.*, species of Cactaceae); or the style bends so that the stigma is brought within the range of the pollen (e g , species of *Oenothera, Epilobium*, most Malvaceae, etc.). In *Mirabilzs Jalapa* and others the filaments and styles finally become intertwined, so that pollen is brought in contact with the stigma. Self-pollination frequently becomes possible towards the end of the life of a flower which during its earlier stages has been capable only of cross-pollination. This is well seen in the case of the flowers of the Compositae, where the stigma lobes later bend round and come in contact with the pollen held by the brush of the style below.

Cleistogamy.—The extreme case of autogamy is that of cleistogamous flowers which must necessarily be self-pollinated. The sweet violet (*Viola odorata*), the wood sorrel (*Oxalis acetosella*), *Lamium amplexicauli* and other British plants bear, in addition to the ordinary flowers, small bud-like flowers (cleistogamous flowers) which never open. The pollen germinates in the anthers and the pollen tubes pierce the walls and so reach the stigmas and the ovules are fertilised. Some plants such as *Salvia cleistogama* produce only cleistogamous flowers.

BIBLIOGRAPHY.—The classical compendium on flower pollination In English is P. Knuth, *Handbook of Floral Pollination* (Oxford, 1906, original German edition, 1898–1905). where a great mass of data is brought together. Good brief reviews of the subject are given in M. Skene, *The Biology of Flowering Plants* (1924) ; Kerner and Oliver, *The Natural History of Plants* (1895); the earlier editions (*e.g.*, the 2nd of 1904) of J. C. Willis, *A Dictionary of Flowering Plants*. Most text books of botany give some review of the subject. The earliest work on the subject was C. K. Sprengel's book entitled *Das entdeckte Geheimnis der Natur in Bau und in der Befrucktung der Blumen* (Berlin, 1793) ; Sprengel's first observation in this field was that of the presence of hairs in the throat of the corolla of a species of *Geranium*, which, he concluded, were for the purpose of preventing the nectar being washed out by rain; from this he was led on to consider the function of corolla markings such as the yellow centre of forget-me-not which he interpreted as honey guides to the insects. For the distinction of flower classes *see* H. Müller, *The Fertilisation of Flowers* (London, 1883). For the colour sense and olfactory sense of bees *see* K. von Frisch, *Der Farbensinn und Formensinn der Btene* (Jena, 1914) and *Über den Geruchsinn der Biene* (Jena, 1919). For a review of ornithophilous flowers *see* F. Werth, "Kürzer Überblick uber die Gesamtfrage der Omithophilie," *Bot. Jahrb.* (1915).

(V. H. B.)

POLLIO GAIUS ASINIUS (76 B.C.–A.D. 5; according to some, 75 B.C.–A.D. 4), Roman orator, poet and historian. In 54 he impeached unsuccessfully C. Porcius Cato. In the civil war Pollio sided with Caesar, was present at the battle of Pharsalus (48), and commanded against Sextus Pompeius in Spain. He subsequently threw in his lot with M. Antonius, for whom he governed *Gallia Transpadana*. In superintending the distribution of territory amongst the veterans, he saved Virgil's property from confiscation. In 40 he helped to arrange the peace of Brundisium by which Octavian (Augustus) and Antonius were for a time reconciled. In the same year he was consul; it was now that Virgil addressed the famous fourth eclogue to him. Next year Pollio conducted a successful campaign against the Parthini, an Illyrian people who adhered to Brutus, and celebrated a triumph on Oct. 25. From the spoils of the war he constructed the first public library at Rome, in the Atrium Libertatis, also erected by him (Pliny, *Nat. hist.* xxxv. 10). Thenceforward he withdrew from active life and devoted himself to literature He seems to have maintained an attitude of independence, if not of opposition, towards Augustus. He died in his villa at Tusculum, regretted and esteemed by all.

Pollio was a distinguished orator; his speeches showed ingenuity and care, but were marred by an affected archaism (Quintilian, *Inst.* x. 1, 113; Seneca, *Ep.* 100). He wrote tragedies also, which Virgil (*Ecl.* viii. 10) declared to be worthy of Sophocles, and a prose history of the civil wars of his time from the first triumvirate (60) down to the death of Cicero (43) or later. His writings are lost except a few fragments of his speeches (H. Meyer, *Orat. rom. frag.*, 1842), and three letters to Cicero (*Ad. Fam.* x. 31–33).

See Plutarch, *Caesar, Pompey;* Vell. Pat. ii. 36, 63, 73, 76; Florus iv. 12, 11; Dio Cassius xlv. 10, xlviii. 15; Appian, *Bell. civ.;* V. Gardthausen, *Augustus und seine Zeit* (1891), i.; P. Groebe, in Pauly-Wissowa's *Realencyclopiidie* (1896), ii pt. 2; Teuffel-Schwaben, *Hist. of Roman Literature* (Eng. trans.), § 221; M. Schanz, *Geschichte der römischen Literatur*, pt. 2, p. zo (2nd ed, 1899) ; Cicero, *Letters*, ed. Tyrrell and Purser, vi. introd. p. 80; E. D. Pierce, *A Roman Man of Letters* (New York, 1922).

POLLOCK, the name of a great English legal family. The well-known members are: SIR JONATHAN FREDERICK **POLLOCK** (1783–1870), chief baron of the exchequer. Born on Sept. 23, 1783 in London, the son of David Pollock, saddler, of Charing Cross, he was educated at St. Paul's and Trinity college, Cambridge, and was called to the bar in 1809. He took silk in 1827, and in 1831 was member of parliament for Huntingdon He was attorney-general in 1834, and again in 1841; in 1844 he succeeded Abinger as chief baron of the exchequer, and sat until 1866, when he retired. He died at Hatton, Middlesex, on Aug. 23, 1870. His greatest judicial triumph was in *Egerton* v. *Brownlow.*

See Sir F. Pollock (2nd Bart.) *Personal Remembrances* (1887).

SIR FREDERICK POLLOCK (1845–1937), born on Dec. 10, 1845, was educated at Eton and Trinity college, Cambridge. He was called to the bar in 1871, and was Corpus professor of Jurisprudence at Oxford from 1883–1903. He was made a Privy Councillor in 1911 and in 1914 became judge of the admiralty court of Cinque ports. In 1920 he was made a King's Counsel. His legal textbooks are standard; he wrote certain legalarticles for the Encyclopaedia Britannica. He edited the *Law Quarterly Review* from 1885 to 1919 and was Editor of the *Law Reports,* 1895–1935.

His works include *Principles of Contract* (1876, 9th ed. 1921); *Digest of the Law of Partnership* (1877, 12th ed. 1930); *The Law of Torts* (1887, 13th ed. 1929); *Possession in the Common Law* (with Sir *R.* S. Wright, 1888); *History of English Law* (with Prof. F. W. Maitland, 1895, 2nd ed. 1898); Selden's Table Talk (for Selden Society, 1927); *Spinoza, his Life and Philosophy* (1880, 2nd ed. reissued with additions, 1912); etc., etc.

POLL-TAX. A tax levied on the individual, and not on property or on articles of merchandise, so-called from the old English poll, a head. Raised thus *per capita,* it is sometimes called a capitation tax. The most famous poll-tax in English history is the one levied in 1380, which led to the revolt of the peasants under Wat Tyler in 1381, but the first instance of the kind was in 1377, when a tax of a groat a head was voted by both clergy and laity. In 1379 the tax was again levied, but on a graduated scale. John of Gaunt, duke of Lancaster, paid ten marks, and the scale descended from him to the peasants, who paid one groat each, every person over 16 years of age being liable. In 1380 the tax was also graduated, but less steeply. For some years after the rising of 1381 money was only raised in this way from aliens, but in 1513 a general poll-tax was imposed. This, however, only produced about £50,000, instead of £160,000 as was expected, but a poll-tax levied in 1641 resulted in a revenue of about £400,600. During the reign of Charles II., money was obtained in this way on several occasions. For some years after 1688 poll-taxes were a favourite means of raising money for the prosecution of the war with France.

In the United States the term "poll-tax" is generally understood as one which must be paid before the individual can vote. It was introduced into America by the British in the 17th century and was one of the grievances that led to the Mecklenburg Declaration of Independence in 1775. The tax disappeared for the most part after the American Revolution but was revived by southern States after adoption of the 15th amendment to the Constitution in 1870 which declared that the suffrage should be extended to all citizens regardless of "race, colour, or previous condition of servitude." Eight States in 1939 imposed a poll-tax ranging from $1 to $2, as follows: Arkansas, Alabama, Georgia, Mississippi, South Carolina, Tennessee, Texas, and Virginia. Florida repealed its poll-tax law in 1937, but a similar proposal in Arkansas was defeated by a large majority in 1938.

See S. Dowell, *History of Taxation and Taxes in England* (1888), vol. iii., and W. Stubbs, *Constitutional History* (1896), vol. ii. (For Am. Tax *see* C. B. Fullebrown, *Taxation,* 1914; E. *R.* Seligman, *Essays in Taxation,* 1925.)

POLLUX, IULIUS, of Naucratis in Egypt, Greek grammarian and sophist of the 2nd century A.D. He taught at Athens, where, according to Philostratus *(Vit. Soph.),* he was appointed to the professorship of rhetoric by the emperor Commodus on account of his melodious voice. His only surviving work is the *Onomasticon,* a Greek dictionary in ten books, which supplies much rare and valuable information on classical antiquity.

The chief editions of the *Onomasticon* are those of W. Dindorf (1824), with notes of previous commentators, I. Bekker (1846), containing Greek text only, and Bethe (1900). There are monographs on special portions; by E. Rohde (on the theatrical terms, 1870), and F. von Stojentin (on constitutional antiquities, 1875).

POLLUX or **POLLUCITE,** a rare mineral, consisting of hydrous caesium and aluminium silicate, $H_2Cs_4Al_4(SiO_3)_9$, and, being the richest source of caesium, in demand for the construction of thermionic valves. Caesium oxide (Cs_2O) is present to the extent of 30%–36%, the amount varying somewhat owing to partial replacement by other alkalis. chiefly sodium. It crystallizes in the cubic system, it is colourless and transparent, and has a vitreous lustre. There is no distinct cleavage, and the fracture is conchoidal, so that the mineral closely resembles quartz in general appearance. The hardness is $6\frac{1}{2}$ and the specific gravity 2.90. It occurs sparingly, together with the mineral "csstor" *(see* PETALITE), in cavities in the granite of Elba, and with beryl in pegmatite veins at Andover and Hebron in Maine. (L. J. S.)

POLO, MARCO (*c.* 1254–1324), Venetian traveller, was grandson of Andrea Polo of San Felice, and son of Nicolo Polo. The three Polos were presumably "noble," for Marco the traveller is officially so styled (*nobilis vir*). The three sons of Andrea Polo were engaged in commerce; the eldest suggests, by his will, a long business partnership with Nicolo and Maffeo.

About 1260, Nicolo with his wife and Maffeo were at Constantinople. The two brothers were led in their trading operations to the Crimea, and eventually to Bukhara, where they joined some envoys returning from a mission from Kublai Khan, with whom they journeyed to Cathay *(See* CHINA.) It was the first time that the khan had met Europeans and he was delighted with the Venetian brothers, whom he sent back to the pope, with letters requesting the despatch of a body of educated men to instruct his people in Christianity and the liberal arts Kublai saw the value of Christianity as a political weapon, and it was only when Rome failed him that he fell back upon Buddhism as his chief civilizing instrument.

On arriving at Acre in April 1269, the brothers learnt that no new pope had been appointed after the death of Clement IV. in the previous year; they therefore returned to Venice. The papal interregnum being exceptionally long the brothers resolved after two years, to start again for the East, taking with them Nicolo's son, Marco. They were furnished with letters authenticating their delay, but hearing of the papal election soon after their start, they returned to execute Kublai's mission. The new pope, however, could supply but two Dominicans, who soon lost heart and turned back.

Leaving Acre about Nov. 1271, Polo's book indicates that the party proceeded to Hormuz (Hurmuz) at the mouth of the Persian gulf, with the purpose of going on to China by sea; but that, abandoning their plans, they returned northward through Persia. Traversing Kerman and Khurasan they went on to Balkh and Badakshan and ascended the upper Oxus through Wakhan to the plateau of Pamir (a name first heard in Marco's book). These regions were hardly described again by any European traveller (save Benedict Goes) till the expedition in 1838 of Lieut. John Wood of the Indian navy. Crossing the Famir the travellers descended upon Kashgar, Yarkand and Khotan (Khutan). These are regions which remained almost absolutely closed to our knowledge till after 1860, when the temporary overthrow of the Chinese power, and the enterprise of British, Russian and other explorers, again made them known.

From Khotan the Polos passed on to the vicinity of Lop-Nor, reached for the first time since Polo's journey by Prjevalsky in 1871. Thence the desert of Gobi was crossed to Tangut, the region at the extreme north-west of China, within and without the Wall. In his account of the Gobi, or desert of Lop, as he calls it, Polo describes the waste, strikingly reproducing the description of the superstitious terrors of Suan T'sang, who crossed the desert six hundred years earlier.

Early in 1275 the Venetians were cordially received by the Great Khan at Shangtu, and Marco made rapid progress. The "young bachelor" studied the languages of the Khan's subjects and soon entered the public service. G. Pauthier found in the Chinese annals a record that in 1277 a certain Polo was nominated as a second-class commissioner or agent attached to the imperial council, a passage which we may apply to the young Venetian. On his public missions he travelled through the provinces of Shansi, Shensi, and Szechuen, and the wild country on the borders of Tibet, to the remote province of Yunnan, called by the Mongols *Karajang,* and northern Burma (Mien). Marco, during his stay at court, had observed the khan's interest in strange countries, and his disgust at the stupidity of envoys and commissioners who could tell of nothing but their official business. He made notes on facts likely to interest Kublai, which, on his return, he related. He encountered many semi-civilized and barbarous tribes, many of which interested Kublai greatly.

Marco rose rapidly in favour and was often employed on distant missions as well as in domestic administration; he held for three years the government of Yangchow; on another occasion he visited Kangchow, the capital of Tangut, just within the Great Wall, and perhaps Karakorum on the north of the Gobi, the former residence of the Great Khans: also Ciampa, or southern Cochin-China; and perhaps, once more, on a separate mission to the southern states of India. We are not informed whether his father and uncle shared in such employments, though they rendered great service to the khan, in forwarding the capture of Siang-yang (on the Han river) during the war against southern China, by the construction of powerful artillery engines—a story, however, perplexed by chronological difficulties.

The Polos had become rich, and after their exile they began to dread what might follow Kublai's death. The khan, however, was deaf to suggestions of departure and the opportunity only came by chance. Arghun, khan of Persia, a grand-nephew of Kublai, lost in 1286 his favourite wife. Her dying injunction was that her place should be filled only by a lady of her own Mongol tribe. Ambassadors were despatched to the court of Peking to obtain one. The lady Cocacin (Kukachin), a maiden of seventeen, was chosen. The overland road from Peking to Tabriz was then imperilled by war, and Arghun's envoys proposed to return by sea. Having met the Venetians, and being eager to profit by their experience, they begged the khan to send the Franks in their company. He fitted out the party nobly for the voyage, sending friendly messages to the potentates of Christendom, including the pope, and the kings of France, Spain and England. They sailed from *Zaiton* or Amoy harbour in Fukien (probably the modern Changchow), then one of the chief Chinese havens for foreign trade, in 1292. The voyage involved long detention on the coast of Sumatra, and in south India, and two years or more passed before they arrived in Persia. Two of the three envoys and most of their suite died by the way; but the three Venetians survived all perils, and so did the young lady, who had come to look on them with filial regard. Arghun Khan had died before they left China; his brother reigned in his stead; and his son Ghazan married the lady. The Polos went on by Tabriz, Trebizond, Constantinople and Negropont to Venice, arriving about the end of 1295.

The first biographer of hfarco Polo was John Baptist Ramusio, who wrote more than two centuries after the traveller's death. We need not hesitate to accept as a genuine tradition the substance of his story of the Polos' arrival at their family mansion in St. John Chrysostom parish in worn and outlandish garb, of the scornful denial of their identity, and the stratagem by which they secured acknowledgment from Venetian society.

We next hear of Marco Polo in a militant capacity. Jealousies had been growing between Venice and Genoa throughout the 13th century. In 1298 the Genoese prepared to strike at their rivals on their own ground, and a powerful fleet under Lamba Doria made for the Adriatic. Venice equipped a larger fleet under Andrea Dandolo. The crew of a Venetian galley at this time amounted to 250 men, under a *comito* or master. On one of the galleys of Dandolo's fleet Marco Polo served as *sopracomito* or gentleman commander. The hostile fleets met before Curzola Island on Sept. 6, and engaged next morning. The battle ended in victory for Genoa, and Marco Polo was taken there as a prisoner. The captivity lasted less than a year, and Marco returned to Venice in July or August 1299.

His captivity was the immediate cause of his *Book*. Up to this time he had related his experiences among his friends; and from these stories he had acquired the nickname of *Marco Millioni*. Yet he had written nothing. The narratives not only of Marco Polo but of other famous mediaeval travellers seem to have been extorted from them by pressure, and written down by other hands. In the prison of Genoa Marco Polo met Rusticiano or Rustichello of Pisa, also a captive of the Genoese, who was a respectable literary hack; he wrote down Marco's experiences at his dictation.

We learn little of Marco Polo's history after this captivity; at his death he left a wife, Donata, and three daughters, Eantina, Bellela and Moreta. One last glimpse of the traveller is gathered from his will. On Jan. 9, 1324, he sent for a priest and notary to make his testament, and died the same day. He was buried, according to his wish, in the Church of St. Lorenzo. The archives of Venice have yielded a few traces of our traveller. Besides his own will just alluded to, there are the wills of his uncles, Marco and Maffeo; a few legal documents connected with the house property in St. John Chrysostom, and two or three entries in the record of the Maggior Consiglio. Another document is a catalogue of curiosities and valuables in the house of Marino Faliero, which mentions several objects that Marco Polo had given to one of the Faliero family. The most tangible record of Polo's memory in Venice is a portion of the Ca' Polo—the mansion where the three travellers, after their long absence, were denied entrance. The court in which it stands was known in Ramusio's time as the *Corte del millioni*, and now is called Corte Sabbionera. That which remains of the ancient edifice is a passage with a decorated 13th century archway.

No genuine portrait of Marco Polo exists. There is a medallion portrait dated 1761 on the wall of the Sala dello Scudo in the ducal palace. The oldest professed portrait is one in the gallery of Monsignor Badia at Rome, which is inscribed *Marcus Polus venetus totius orbis et Indie peregrator primus*. It is a good picture, but of the 16th century. The Europeans at Canton have absurdly attached the name of Marco Polo to a figure in a Buddhist temple there containing a gallery of "Arhans" or Buddhist saints, and popularly known as the "temple of the five hundred gods." The Venetian municipality obtained a copy of this on the occasion of the geographical congress at Venice in 1881.

Polo was the first traveller to trace a route across the whole longitude of Asia, describing kingdoms which he had seen; the first to speak of the court at Peking; the first to reveal China in its wealth and vastness, and to tell of the nations on its borders; the first to tell more of Tibet than its name, to speak of Burma, Laos, Siam, Cochin-China, Japan, Java, Sumatra, etc.; the Nicobar and Andaman Islands, Ceylon, India, but as a country seen and partially explored; the first in mediaeval times to give any distinct account of the Empire of Abyssinia, and of the island of Sokotra, and to mention Zanzibar and Madagascar; whilst he carries us also to the remotely opposite region of Siberia and the Arctic shores, to speak of dog-sledges, white bears and reindeer-riding Tunguses.

Within the traveller's own lifetime, we find the earliest examples of the practical and truly scientific coast-charts (*Portolani*), based upon the experience of pilots, mariners, merchants etc. In two of the most famous of the 14th century Portolani, we trace Marco Polo's influence—in the *Laurentian* or *Medicean Portolano* of 1351 (at Florence), and in the *Catalan Atlas* of 1375 (now at Paris). Both represent a very advanced stage of mediaeval knowledge, a careful attempt to represent the known world on the basis of collected fact, and a disregard for theological or pseudo-scientific theory; in the *Catalan Atlas*, as regards Central and Further Asia, and partially as regards India, Marco Polo's *Book* is the basis of the map. His names are often much perverted, and it is not always easy to understand the view that the compiler took of his itineraries. Still we have Cathay placed in the true position of China, as a great empire filling the south-east of Asia. The trans-Gangetic peninsula is absent, but India proper is for the first time represented with a fair approximation to correct form and position. The map of Fra Mauro (1459) gives a much less accurate idea of Asia than the *Carta catalana*. Columbus possessed a copy of the Latin version of Polo's book made by Pipino, and on many pages of this there are manuscript notes in the admiral's handwriting, testifying to the influence of the work of the Venetian merchant upon the discoverer of the new world. As to the alleged introduction of important inven-

tions into Europe by Polo—although the striking resemblance of early European block-books to those of China seems clearly to indicate the derivation of the art from that country, there is no reason for connecting this introduction (any more than that of gunpowder or the mariner's compass) with the name of Marco. In the 14th century not only were missions of the Roman Church established in eastern China, but a regular overland trade was carried on between Italy and China. Many a traveller other than Marco Polo might have brought home the block-books, and some might have witnessed the process of making them. This is the less to be ascribed to Polo, because he so curiously omits to speak of the process of printing, when, in describing the block-printed paper money of China, his subject seems absolutely to challenge a description of the art.

The book indited by Rusticiano is in two parts. The first, or prologue, as it is termed, is unfortunately the only part which consists of actual personal narrative. It relates the circumstances which led the two elder Polos to the khan's court, together with those of their second journey (when accompanied by Marco), and of the return to the west by the Indian seas and Persia. The second part consists of a series of chapters of unequal length and unsystematic structure, descriptive of the different states and provinces of Asia (certain African islands and regions included), with occasional notices of their sights and products, of curious manners and remarkable events, and especially regarding the Emperor Kublai, his court, wars and administration, A series of chapters near the close treats of sundry wars that took place betueen various branches of the house of Jenghiz in the latter half of the 13th century. There is now no doubt that the original was written in French. A manuscript in rude and peculiar French, belonging to the National Library of Paris (Fonds Fr. 1116), which was printed by the *Société de géographie* in 1824, is evidently either the original or a close transcript. It shows characteristics of the unrevised product of dictation which would necessarily have disappeared in a translation or revised copy. Eighty-five mss. of the book are known, and their texts exhibit considerable differences. For a discussion of these *see* the authorities quoted in the bibliography.

We know from Gilles Mallet's catalogue of the books collected in the Louvre by Charles V., dating *c.* 1370–75, that five copies of Marco Polo's work were then in the collection; but on the other hand, the 202 known mss. and the numerous early printed editions of "Mandeville," with his lying wonders, indicates a much greater popularity. Dante, who lived twenty-three years after the book was dictated, never alludes to Polo; nor can any trace of Polo be discovered in the book of his contemporary, Marino Sanudo the Elder, though he is well acquainted with the work of Hayton the Armenian. "Mandeville" himself, who plundered right and left, hardly ever plunders Polo. The only literary works we know of the 14th century which show acquaintance with Polo's book or achievements are Pipino's *Chronicle,* Villani's *Florentine History,* Pietro d'Abano's *Conciliator,* the *Chronicle* of John of Ypres, and the poetical romance of *Baudouin de Sebouro.*

BIBLIOGRAPHY.—The *Recueil* of the Paris Geographical Society (1824), vol. i., giving the text of the fundamental ms. (Nat. Libr. Paris, Fr. 1116; *see* above), as well as that of the oldest Latin version; G. Pauthier's edition, *Livre . . . de Marco Polo . . .* (Paris, 1865), based mainly upon the three Paris mss. (Nat. Libr. Fr. 2810; Fr. 5631; Fr. 5649; *see* above) and accompanied by a commentary of great value; Baldelli-Boni's Italian edition, giving the oldest Italian version (Florence, 1827); Sir Henry Yule's edition, which in its final shape, as revised and augmerted by Henri Cordier (*. . . Marco Polo . . .* London, 1903), is the most complete storehouse of Polo learning in existence, embodying the labours of all the best students of the subject, and giving the essence of such works as those of Major P. Molesworth Sykes (*Ten Thousand Miles in Persia,* etc.) so far as these touch Marco Polo; the Archimandrite Palladius Katharov's "Elucidations of Marco Polo" from vol. x. of the *Journal* of the North China Branch of the Royal Asiatic Society (1876), pp. 1–54; F. von Richthofen, *Letters to Shangai Chamber of Commerce; E. C.* Baber, *Travels . . . in Western China; G.* Phillips, *Identity of . . . Zaitun with Changchau* in *T'oung Pao* (Oct. 1890), and other studies in *T'oung Pao* (Dec. 1895 and July 1896). There are in all 10 French editions of Polo as well as 4 Latin editions, 27 Italian, 9 German, 4 Spanish, 1 Portuguese, 12 English, a Russian, 1 Dutch, 1 Bohemian (Czech), 1 Danish and 1 Swedish. *See* also E. Bretschneider, *Mediaeval Researches from Eastern Asiatic Sources,* i. 239, 167; ii. 8, 71, 81–84, 184; Léon Cahun, *Introduction à l'histoire de l'Asie,* 339, 386; *C.* Raymond Beazley, *Dawn of Modern Geography,* iii. 15–160, 545–547, 554, 556–563; R. Allulli, *Marco* Polo (1923). (H. Y.; X.)

POLO, the most ancient of games with stick and ball. Its name is derived from the Tibetan *pulu,* a ball. Hockey, the Irish national game of hurling, and possibly golf and cricket, are derived from polo. The latter was called hockey or hurling on horseback in England and Ireland respectively, but historically hockey and hurling are polo on foot. The earliest records of polo are Persian. From Persia it spread to Constantinople, eastwards through Turkestan to Tibet, China and Japan. From Tibet polo travelled to Gilgit and Chitral, possibly also to Manipur. Polo also flourished in India in the 16th century. Then for 200 years its records in India cease, till in 1863 polo came into Bengal from Manipur by way of Cachar.

Chronology of Modern Polo.—Polo was first introduced to India in 1863 by Maj.-Gen. Sherar. He brought two teams of Manipuri natives from Manipur to Calcutta, where they played an exhibition match. In 1869 polo was brought to England by the 10th Hussars. In 1871 the first recorded match took place on Hounslow Heath between the 9th Lancers and the 10th Hussars with eight players on each side. An account of this match appeared in the *Morning Post* in July 1871. In 1873 the numbers on each side mere reduced to five. A match under these conditions took place at Lillie Bridge. The first code of rules was drawn up by the committee of the Hurlingham Club in 1874. In 1876 the height of ponies was fixed by Hurlingham at 14·0 hands and the Champion Cup was inaugurated at Hurlingham with five players on each side. In 1877 the first inter-regimental tournament was held in India, and in 1878 at Hurlingham. In the same year the first county cup tournament and the first Oxford *v.* Cambridge match were held at Hurlingham, and the first All-Ireland open cup at Phoenix park, Dublin. In 1882 the number of players on each side was reduced to four. In 1884 John Watson introduced the back-hand stroke to Hurlingham from India, and placed the players at No. 1, No. 2, No. 3 and No. 4 or back, thus laying the foundation of the modern combination game. In 1886 John Watson took the first team to America and won the Westchester Cup. He taught the Americans the back-hand stroke and the rudiments of the combination game. In 1888 the height of ponies in India was raised from 13·2 to 13·3. In 1895 the height of the ponies was raised by the Hurlingham committee to 14·2 and an official measurer appointed. In 1902 an American team first visited England and was defeated by England by two matches to one. In India the height of ponies was raised to 14·1. In 1909 America won the cup at I-Iurlingham. In 1910 handicapping was introduced into English polo, and offside was abolished. Both these innovations were copied from America. India adopted these alterations. In 1911 and 1913 England was defeated in America. In 1914 England beat America in America, and brought the cup back. In 1919 the height limit for ponies was abolished. In 1921 America regained the cup from England. In the same year a committee sat in London during the summer and evolved a code of universal rules. This code of rules has been adopted wherever polo is played, with local modifications as regards height of ponies and the duration of matches. In 1924, 1927 and 1930 England was defeated in America.

The Game.—A full-sized ground should not exceed 300yds. in length by 200yds. in width, if unboarded; and 300yds. in length by 160yds. in width, if boarded. The goals are not less than 250yds. apart, and each goal 8yds. wide.

Polo is played with four players on each side, on exactly the same principles as hockey or association football. A match lasts about one hour, divided into periods of play; during the intervals ponies are changed. In England seven periods of eight minutes are played for a full match; in America, eight periods of seven-and-a-half minutes. The players are placed at No. 1, No. 2, No. 3, or half-back, and No. 4 or back. So there are two forwards and two backs. But during the course of the game as the players pass the ball to one another these places are being constantly changed. The modern game is a most elastic one, but there should always be one player in each place. Two umpires are required in a first-class match to award the penalties for infringement of the rules, and in an important tournament a referee at the side of the ground decides disputes if the umpires disagree.

The Development of the Method of Play.—Previous to John Watson's teaching, the method of play was for one man on each side to be the goalkeeper, and for the others to play forward and to hit the ball when and how they could. He introduced the back-hand stroke, and placed his men at No. 1, No. 2, half-back or No. 3, and back. He also taught them to combine and hit to each other, But he taught the game on rather wooden and inelastic lines. Then the brothers Peat appeared on the scene, and soon found out and demonstrated how to play the game in a more scientific manner and with such success that they won the champion cup at Hurlingham on eight occasions. Then came the era of the Freebooters', Rugby, Old Cantab and Roehampton teams, and of the various good regimental teams, such as the 7th, 10th, 11th, 13th and 20th Hussars, the 9th and 17th Lancers and the Inniskilling Dragoons. The training both of men and ponies was rapidly improved. A very scientific game was developed, accurate combination being carefully taught; but too much importance was probably directed to defence, the principles of attack not being sufficiently developed.

While this was going on in England, polo was being rapidly improved in India, and many very fine players were produced there. The ponies were then much smaller, and consequently much more easy to train and ride. The grounds are harder and much easier to hit the ball on; also as the game is played in India all the year round far more practice is possible. Everything seemed to be in a satisfactory state as regards the game till 1909, when English polo players got a rude awakening from the American team at Hurlingham, who defeated the English representatives very easily.

The Americans had never adopted the offside rule. They consequently developed a very much faster game. They also perfected strokes that had hardly been attempted elsewhere. They met the ball on possible occasions and hit under their ponies' necks instead of hitting back-handers from the side of the ground. They played a most elastic game, hitting harder and passing more accurately. They had developed the science of the attack, galloped faster, and were much more accurate goal hitters.

In 1910 the Hurlingham Club decided to profit by the lessons learnt from the Americans in 1909, and made two most important alterations in their rules. Offside was abolished and handicapping was introduced. The abolition of offside quickened up the game to a very great extent, and the institution of handicapping resulted in much harder and more even matches. The periods of play were shortened from ten to eight minutes, seven periods being played for a match instead of six. English polo probably reached its zenith in 1914 when the English team which visited America brought the cup back.

The Effects of the World War.—Then came the World War which gave a set-back to English polo from which it has not yet recovered. The expenses of polo have vastly increased since the pre-war years. In 1919, owing to the pony wastage of the war, the troubles in Ireland, formerly the chief source of supply of high-class ponies, and the fact that the breeding of ponies in both England and Ireland had almost ceased, it was impossible to supply the demand for 14·3 ponies of the right stamp. This necessitated the abolition of the height limit. The big thoroughbred pony now in use in first-class polo is more expensive to buy, dearer to keep and much more difficult to train and to ride. Also, undoubtedly, the abolition of offside and the institution of handicapping has made the game more expensive. For the handy pony of moderate speed is now quite useless in an ordinary good game, and the handicap entails far more close matches, which means that more ponies are required. In spite of this polo is in a very flourishing condition. In Great Britain it is played at Hurlingham, Ranelagh, Roehampton, and at some 30 county clubs affiliated to the County Polo Association. It is played throughout the British empire, wherever sufficient players can collect together to make up a game. It is played all over India; many of the maharajahs and chiefs keep up teams in the native States. It is played on the Continent, and is fast becoming a national game in the U.S.A.

Polo Centres and Tournaments.—London has for a number of years attracted most of the best players of the world. During the season, May 1 to July 31, matches and tournaments for every class of player are held at Hurlingham, Ranelagh and Roehampton. These clubs maintain seven grounds, as well as three at Worcester park as an overflow. Since the war, first-class teams from America, India and the Argentine have taken part in the various tournaments, and as a rule there are two or three first-class English teams competing in all the principal events such as the Whitney Cup, the Champion Cup, the Ranelagh Open Cup and the Roehampton Open Cup. The second and third-class players are catered for equally well in a variety of lesser competitions; the soldiers have their own tournaments, *i.e.,* the inter-regimental at Hurlingham, the Subalterns' Cup at Ranelagh and the handicap military tournament at Roehampton. The whole organization is well-nigh perfect, controlled by professional polo managers. India has good tournaments at far separated places such as Calcutta, Delhi, Meerut, Amballa, Rawalpindi, etc., but there is no place in India where good polo can be concentrated for a lengthy period as in England. In England a good player can play at Minehead, Somerset, in April; he can then go to London for May, June and July; then come the county tournaments beginning at Cowdray in Goodwood week, Rugby in the first week in August, Cirencester, Cheltenham, Tidworth, and he can finish up with a month of good games at Minehead. A keen player can, weather permitting, get nearly six months on end of match play.

Organization.—The "Hurlingham Club Rules" and the "General and Field Rules of the U.S.A. Polo Association" are now practically identical, and except for minor differences, such as height of ponies and the duration of matches and periods of play, the Hurlingham rules are followed all over the world. The Hurlingham Polo Club committee consists of 38 members: 10 nominated by the Hurlingham Club; 5 by the Army Polo committee; 5 by the Indian Polo Association; 5 by the County Polo Association; 3 by the All-Ireland Polo Club; 2 by the South African Polo Association; 2 by the Egypt, Sudan and Palestine Polo Association; 2 by the New Zealand Polo Association; 2 by the Ranelagh Club; 2 by the Roehampton Club. There are two sub-committees: (1) general purposes, (2) handicapping. Five stewards are appointed annually, whose duties are similar to those of the "Stewards of the Jockey Club." The County Polo Association legislates for everything connected with county polo clubs in England, and to this body are affiliated practically every polo club in Great Britain. This organization was started in 1899.

For the purposes of organization, England and Scotland are divided into four divisions, each with an honorary divisional secretary, viz., Northern, 6 clubs; Midland, 10 clubs; South-Eastern, 7 clubs; South-Western, 7 clubs—total 30. The Army Polo Association committee, consisting of five members, is responsible as a sub-committee of the Hurlingham Club for the army organization. The Indian Polo Association, which sends five representatives to serve on the Hurlingham committee, is the governing body of Indian polo. This body organized and despatched the Indian Army teams to America in 1927.

Breeding of Polo Ponies.—The interest of the breeding of polo ponies is supervised by the National Pony Society. This society edits a stud book for all kinds of riding ponies, and holds an annual show at the Agricultural Hall, Islington. The society gives prizes and medals at many shows for polo pony classes. It has done for 35 years, and is still doing, a great work for the encouragement of the breeding of the best class of riding pony.

Up to the year 1909 nearly all the best polo ponies used in the game were bred in Ireland, England and Australia. The latter were chiefly used in India. In India, until about 1888, country-breds were relied on chiefly, very good animals, not more than 13.2 in height. Then Arabs began to be bred in greater numbers, only to be superseded in their turn by walers from Australia, which were imported in large numbers by dealers to Calcutta and Bombay. When the height was raised to 14·1 in 1902, only the very best Arabs and a few country-breds produced on the Government and regimental farms could compete with the Australian pony in high-class tournaments. Large numbers of easy, handy, rather common ponies were imported from 1892 to about 1909 from the Argentine to England. They were cheap and easy to play, but as a rule rather deficient in pace. Occasionally an absolutely first-class pony appeared, but they were few and far between. But in the last 20 years the class of pony bred in the Argentine has improved out of all recognition. Several generations of thoroughbred stallions have been used to such an extent that as good ponies as can be obtained anywhere are produced and exported. Many quite thoroughbred ponies are bred in the Argentine, and the remainder of the best animals have only a far back strain of the native pony in their pedigree on the dam's side. The best ponies are, whatever their nationality, thoroughbred or very nearly so. Probably the ideal breeding is for the sire to be thoroughbred and the dam nearly if not quite thoroughbred of the hardy old Irish stock. The National Pony Society in England, and the polo breeding societies in America and the Argentine are doing a great work in proving that polo ponies can be bred to type.

The Price of Ponies.—The increase in the price of polo ponies is illustrated by the following figures. In 1890 when the 17th Lancers left India they sold their very large stud of polo ponies by auction at an average price of about rupees 800, *i.e.*, £60. In 1891, Egyptian ponies were purchased in Cairo for an average of from £20 to £25. Some of these were sold at Tattersall's in 1893 for from 150 to 250 guineas apiece. In 1897 at a sale at Spring Hill, Rugby, by the brothers Miller, 32 ponies fetched an average of £281, the then record price being reached by Sailor—750 guineas. In 1913, in America, the duke of Westminster's best ponies were sold at from £600 to £700 apiece. In 1924 the first great rise in prices took place at an auction at Long Island when the English ponies fetched enormous prices. One pony sold for no less than $10,000, *i.e.*, £2,000. In 1925, the Argentine ponies belonging to an Argentine team which won the Champion Cup were sold on the same scale. In 1928 all records were broken when £4,400 was paid for a single first-rate pony.

BIBLIOGRAPHY.—Accounts of the oriental forms of polo will be found in the following works: Persia: Firdousi's *Shahnama;* A. Shirley, *Travels in Persia* (1569); J. Chardin, *Voyages en Perse* (1686); W. Ouseley, *Travels in various countries of the East, particularly Persia* (1810). There are many allusions to polo in the poets, notably Nizami, Jami and Omar Khayyam. Constantinople: *Cinnamus Joannes epitome rerum ab Ioanne et Alexio Comnenis gest.* (Bonn, 1836). India: *Ain-i-Akbari* (1555); G. F. Vigne, *Travels in Kashmir, Ladakh and Iskardo* (1842); A. Durand, *The Making of a Frontier* (1899). Gilgit and Chitral: "Polo in Baltistan," *The Field* (1888). Manipur: W. McCulloch, *Account of the valley of Manipore and the Hill Tribes* (Calcutta, 1859). China and Japan: H. A. Giles, *Adversaria Sinica* (Shanghai, 1905); B. H. Chamberlain, *Things Japanese* (1898); the *Ku Chin T'u Shu* (Encyclopaedia).

United States.—Attack has always been stressed in American play. The system of fractional fouls also aided speed. Instead of stopping the game on a foul, as at present, and allowing a free hit from varying distances for the goal, a fraction was deducted from the offending side's score and play continued without a break. In 1888 what has since been regarded as perhaps the most important legislative contribution to the sport came with the first handicapping of players. The game, until that time, had been pretty well monopolized by the better players and H. L. Herbert conceived the idea of the handicap to make possible a wider spread of play. The handicap, low at the start of a player's career, increases with his ability. Thus the beginners are able to play with the more experienced players on a far more even footing. Only the international matches and the open tournaments are played without handicap. In a game the handicaps of all four players are totalled and the team handicaps compared. One team (unless the totals are even) then receives the difference in total handicap. The handicapping system almost immediately resulted in new tournaments and new clubs, among them Myopia and the Dedham Polo and Country Club, two of the most famous of the Boston district.

Up to 1935 ten goals was the highest rating ever given to a player. This has been held in the American game at varying times by the following: Foxhall P. Keene, John E. Cowdin, Thomas Hitchcock, R. L. Agassiz, J. M. Waterbury, Jr., Lawrence Waterbury, Harry P. Whitney, Louis E. Stoddard, J. Watson Webb, M. Stevenson and D. Milburn; today only Thomas Hitchcock, Jr., Cecil Smith and Elmer Boeseke hold this rank.

The U.S. Polo Association had in 1928 86 members, these including the U.S. army, the Intercollegiate Association and several others which, in turn, had their member organizations. The handicap list of that year showed a total of 2,572 handicapped players in the country, 1,274 civilians, 1,152 on the army list and 146 on the Intercollegiate list.

After America, in 1909, won her first victory in the international series with England, the rules were assimilated. The Americans took over the British rule permitting the hooking of mallets, and the English abandoned their offside rules and adopted the handicap system. At the close of the World War in 1918 all effort at limiting the size of ponies was abandoned.

At first Americans played with native horses, mainly found in the South-west and descended, in part, from the Spanish barb left by those who penetrated that part of the United States in its early history, To-day, though Texas and Wyoming produce a great many polo horses, the thorough-bred is much in demand, with English and Irish blood prominent in a certain line of mounts. The ponies of Argentina have become perhaps the most popular among the higher-rated players. This is the result of visits to the United States by Argentine teams in 1922, 1926 and 1931, and of a return invasion of the Argentine in 1932. (R. F. K.)

POLONAISE, a stately ceremonious dance, usually written in $\frac{3}{4}$ time. As a form of musical composition it has been employed by such composers as Bach, Handel, Beethoven, and above all by Chopin. It is usual to date the origin of the dance from the election (1573) of Henry duke of Anjou, afterwards Henry III. of France, to the throne of Poland. The ladies of the Polish nobility passed in ceremonial procession before him at Cracow to the sound of stately music. This procession to music became the regular opening ceremony at royal functions, and developed into the dance.

The term is also given to a form of skirted bodice, which has been fashionable for ladies at different periods.

POLONIUM, a radioactive element of atomic number 84 and atomic weight (estimated) of about 210, also known as radium-F since it is one of the decomposition products of radium. (See RADIOACTIVITY.)

POLOTSK, a town of White Russia, at the confluence of the Polota and Dvina, in 55° 29' N., 28° 49' E. Pop. (1926) 21,455. It is on a railway junction and has saw-milling and timber industries and a flour-mill. Its position between central Russia and the west made it a storm centre. and little of the ancient town remains; both the upper castle, which had seven towers, and the lower one are in ruins and its 12th century cathedral fell in ruins in the 18th century.

Polotesk or Poltesk is mentioned in 862 as one of the towns given by the Scandinavian Rurik to his men. In 980 it had a prince of its own, Ragvald (Rogvolod or Rognvald), whose daughter is the subject of many legends. It remained an independent principality until the 12th century, resisting the repeated attacks of the princes of Kiev; those of Pskov, Lithuania, and the Livonian Knights, however, proved more effective, and Polotsk fell under Lithuanian rule in 1320. About 1385 its independence was destroyed by the Lithuanian prince Vitovt. It was five times besieged by Moscow in 1500–18, and was taken by Ivan the Terrible in 1563. Recaptured by Stephen Bathory, king of Poland, 16 years later, it became Polish by the treaty of 1582. It was then a large and populous city, and carried on an active commerce. Pestilences and conflagrations were its ruin; the plague of 1566 wrought great havoc among its inhabitants, and that of 1600 destroyed 15,000. The castles, the town and its walls were burned in 1607 and 1642. The Russians continued their attacks, burning and plundering the town, and twice, in 1633 and 1705, taking possession of it for a few years. It was not definitely annexed to Russia until 1772, after the first dismemberment of Poland. In 1812 its inhabitants resisted the French invasion. and the town was partially destroyed.

POLTAVA, a town in the Ukrainian S.S.R., Union of Soviet Socialist Republics, on the right bank of the Vorskla river, in 49° 36′ N., 34° 35′ E. Pop. (1939) 130,305.

It is the centre of an agricultural district in nhich grains, sugar beet, tobacco, vines and orchard fruits are grown. Leather is the chief manufacture, and there is an annual fair for the sale of skins, leather and leather goods. Other industries include smelting, stocking manufacture, distilling and brewing. The town is on the railway and is a grain collecting centre. The Russian annals mention Poltava in 1174 under the name of Ltava In 1430 it was given, together with Glinsk, to the Tatar prince Leksada by Gedimin, prince of Lithuania.

Under the Cossack chief, Bogdan Chmielnicki, it was the chief town of the Poltava "regiment"

Peter the Great defeated Charles XII of Sneden in the neighbourhood of Poltava in 1709.

POLTORATSK: *see* ASHKHABAD.

POLTROT, *JEAN* DE (*c.* 1537–1563), sieur de Méré or Mérey, a nobleman of Angoumois, who murdered Francis, duke of Guise. He had lived some time in Spain, and his knowledge of Spanish, together nith his swarthy complexion, which earned him the nickname of the "Espagnolet," procured him employment as a spy in the wars against Spain. Becoming a fanatical Huguenot, he determined to kill the duke of Guise and gained admission as a deserter to the camp of the Catholics nho were besieging Orléans. On Feb. 18, 1563, he hid by the side of a road along which he knew the duke would pass, fired a pistol at him and fled. He was captured the next day, tried, tortured and sentenced to be drann and quartered. On March 18, 1563, he underwent a frightful punishment. The horses not being able to drag off his limbs, he was hacked to pieces with cutlasses He had made several contradictory declarations regarding the complicity of Admiral Gaspard de Coligny, but his accusations seem to have had no foundation.

POLYAENUS, a Macedonian, who lived at Rome as a rhetorician and pleader in the 2nd century A.D. When the Parthian War (162–5) broke out, Polyaenus dedicated to the emperors Marcus Aurelius and Lucius Verus a work, stilt extant, called *Strategica* or *Strategemata,* a historical collection of stratagems and maxims of strategy written in Greek and strung together in the form of anecdotes. It is not strictly confined to warlike stratagems, but includes also examples of wisdom, courage and cunning drawn from civil and political life. The work is divided into eight books (parts of the sixth and seventh are lost), and originally contained 900 anecdotes, of which 833 are extant. His works on Macedonia, on Thebes, and on tactics (perhaps identical with the *Strategica)* are lost.

The best edition of the text is Wölfflin and Melber (Teubner Series, 1887, with bibliography and editio princeps of the *Strategemata* of the emperor Leo); annotated editions by Isaac Casaubon (1589) and A. Coraes (1809); I. Melber, *Ueber die Quellen und Werth der Strategemensammlung Polyäns* (1885); Knott, *De jide et fontibus Polyaeni* (1883), Eng. trans. by R. Shepherd (1793).

POLYANDRY, the system under which a woman is married to several men at the same time (Gr. πολύς, many, and ἀνήρ, man). Cases of it have been noticed among certain South American Indians, and in North America among some Eskimo, the Tlingit, the Aleut and the Kaniagmiut on the Alaskan coast. In an old description of the conquest of the Guanches in the Canary islands in 1402 it is said that in the Island of Lancerote most of the women have three husbands, "who wait upon them alternately by months." Sporadic cases of polyandry have been found in Madagascar, among a few peoples on the African continent, in some places of the Malay archipelago and among certain South Sea islanders, while in the Marshall islands and the Marquesas it has been practised on a much larger scale. In Tibet polyandry has prevailed from time immemorial, the husbands being as a rule brothers, who live together with their common wife as members of the same household Fraternal polyandry is more or less frequent in vast districts of the Himalayan region from Assam to the dependencies of Kashmir, chiefly among people of Tibetan affinities, and in South India, where its prevalence among the Todas of the Nilgiri hills has attracted special attention: and it existed throughout the interior of Ceylon until it was prohibited by the British government about the year 1860. Among the Nayars or Nairs of Cochin, Malabar and Travancore we meet nith polyandrous unions of a different, non-fraternal type, the prevalence of which has been testified by a large number of travellers from the beginning of the 15th century onward. According to Nayar usage every girl, before she attained puberty, was subjected to a certain marriage ceremony, after which the nominal husband went his way and she was allowed to cohabit nith any Brahman or Nayar she chose; usually she had several lovers, who cohabited with her by agreement among themselves but did not live with her. Strabo asserts that polyandry prevailed in Arabia Felix, and some modern scholars think that they have found confirmation of this statement in Sabian and Minaean inscriptions.

Very frequently polyandry is modified in a monogamous direction, one, usually the first, husband being the chief husband; nay, in various cases any other man with whom he shares his wife acts as husband and master of the house only during the absence of the true lord. Where fraternal polyandry prevails the eldest brother is commonly regarded as the principal husband; he chooses the wife, and the contract he makes may implicitly confer matrimonial rights on all the other brothers. Among many polyandrous peoples the various husbands live or cohabit with their common wife in turn; and if they are brothers the eldest one is sometimes expressly said to take the lead.

Among many polyandrous peoples there are said to be more men than women, and their polyandry has in several cases been directly attributed to this fact; and even if some of these statements, in the absence of statistical data, are more or less hypothetical, there are others the accuracy of nhich is past all doubt. But pclyandry has also been traced to economic motives. In Tibet it has been said to obtain as a necessary institution, serving the end of checking the increase of population in regions from which emigration is difficult and also keeping the family property together; and similar reasons have been assigned for polyandry in Ladakh, Bhutan. South India and Ceylon. The polyandry of the Tibetans, the Himalayans and some peoples in the south of India seems also to be partly due to the dangers or difficulties nhich would surround a woman left alone in her home during the prolonged absence of her husband. The peculiar polyandry of the Nayars is most probably connected nith their military organization, which prevented their living the ordinary life of a husband and father of a family.

POLYANTHUS, the oxlip (*Primula elatior*); also any narcissus derived from *Narcissus tazetta.*

POLYBIUS (*c.* 201–*c.* 120 B.C.), Greek historian, mas born at Megalopolis in Arcadia, being the son of Lycortas, the friend and successor of Philopoemen as leader of the Achaean League. The precise dates of his birth and death are not known. but they can be inferred approximately. We have his own statement (xxiv. 6) that in 181 B.C, when he was appointed along with Lycortas and Aratus as an ambassador to Egypt, he was still under the legal age, which appears to have been 30 (xxix. 9). According to Cicrro. *Ad Fam.* v. 12, Polybius wrote a special history of the Numantine War, uhich ended in 132 B.C. Lastly in Lucian, *Macrob.* 22 we read that he dird in consequence of a fall from his horse at the age of 82.

The more notable events of his life may be briefly stated On the death of Philopoemen in Messenia (182 B C.) he took a leading part in conveying home the urn which contained his ashes (Plutarch, *Philopoem.* 21). In 169, during the war between the Romans and Perseus of Macedonia, when it was decided to send an Achaean force to assist the consul Q. Marcius. Polybius was appointed to command the cavalry. He was among the envoys sent to consult with the consul, and, although the proffered assistance was declined, he remained for a time in the Roman camp (xxviii. 13). The turning point in his life came when Perseus was finally defeated by the Romans at Pydna in 168. Polybius was one of 1,000 leading Achaeans who were carried to Rome, at the instigation of Callicrates, on the charge of having been lukewarm in their support of the Roman cause.

While the others were distributed among the Italian towns, Polybius was allowed, through the influence of L. Aemilius Paullus, and his sons Fabius (Q. Fabius Maximus Aemilianus) and Scipio (P. Cornelius Scipio Africanus minor) to remain in Rome (xxxii. 9., Pausan. vii. 10. 2). With Scipio he formed a close friendship and to his influence with Scipio it was due that in 151 B.C., the remnant of the Achaean exiles obtained permission to return to their homes (xxxv. 6). Polybius himself, after a short stay in Achaea, joined Scipio in Africa in 147 and was present at the siege and destruction of Carthage in 146. Meanwhile the mistaken attempt of the Achaean League to assert its independence of Rome had ended in disaster and the remaining public work of Polybius was devoted to alleviating so far as possible for his countrymen the consequences of their policy, and to facilitating the establishment of order under the new régime (xl. 8–10).

The manner in which he accomplished this was such as to earn the gratitude of his compatriots, as was attested by the statues erected in his honour at Mantineia (Pausan. viii. 9. 1.), Pallantium (Pausan. viii. 44. 5), Tegea (Pausan. viii. 48. 8), Megalopolis (Pausan. viii 30. 8)—where the inscription recorded that he "had roamed over all the earth and sea, and had been the ally of the Romans and had made them cease from their anger against Greece"—Acacesium, the inscription declaring that "Hellas would never have come to grief, if she had obeyed Polybius in all things, and, having come to grief, she found succour through him alone" (Pausan. viii. 87. 2). The base of a statue erected to him by Elis was discovered at Olympia in 1877 with the inscription:

ἡ πόλις ἡ Ἠλείων Πολύβιον Λυκόρτα Μεγαλοπολίτην.

The Histories (Ἱστορίαι), on which his reputation as a historian now rests, were in 40 books. Of these the first five are extant. For the remaining books we have excerpts from a collection of passages from the Greek historians, which was made by the order of Constantine Porphyrogenitus in the 10th century; excerpts of vi.–xviii. contained in another compilation of uncertain date, first printed at Basle in 1549; and a fragment of xi., 13–16, in a Berlin papyrus (3rd century A.D.).

The original intention of Polybius was to narrate the history of the 53 years (220–168 B.C.)—from the beginning of the Hannibalic War to the defeat of Perseus at Pydna—in which Rome made herself mistress of the world. The first two books are prefatory—a "preparation" (προκατασκευή I. 3)—dealing with the earlier history of Rome, the first Punic War, and contemporary events in other parts of the world. But the opening chapter of Book III. indicates an intention to modify his original plan by adding an account of the manner in which the Romans exercised their supremacy down to the destruction of Carthage in 146 B.C. Thus the history of the period 168–146 B.C. appears to have occupied the last ten books.

Scientific Conception of History.—With regard to the function of the historian, Polybius is one of those who consider history to be—in the phrase of Dionysius—"philosophy teaching by examples." Thus he says in i. 35: "Whereas there are for all men two ways of improvement, to wit by one's own disasters or those of others, the former is the more vivid, the latter is the less harmful. Therefore, one should never willingly choose the former, since the improvement which it brings is fraught with great danger and pain, but one should always pursue the latter, since in it one can discern the better way without hurt. And it is therefore to be considered that the best education for real life is the knowledge of affairs which accrues from practical history (πραγματικὴ ἱστορία) which alone, without personal hurt, makes men on every occasion and in all circumstances, true judges of the better way."

From this conception of history, which differs little, if at all, from that of Thucydides or the modern historian of the scientific school, it follows that the chief interest lies, not in the question of origins, in the legendary or semi-legendary traditions, by which states or nations, like individuals, when they have achieved greatness, are fain to decorate their origins, but in the actual transactions of historical times, the plain matters of fact which appeal to the plain man. This seems to be undoubtedly what Polybius means by the term "pragmatic" by which he several times characterizes his History. Thus in criticizing Phylarchus he writes (ii. 56. 7. seq.): "Endeavouring to excite his readers to pity and to make them sympathetic with his narrative, he introduces embracing of wives, disordered hair, baring of breasts, tears and lamentations of men and women haled away with their children and aged parents. This he does throughout his whole history, seeking always to give a vivid picture of horrors. The ignoble femininity of this design may be left out of the question; but we must consider what is proper and profitable in history. It is the function of the historian not to astonish his readers by prodigies nor to hunt up all possible tales and recount all the concomitants of his subjects, as tragedians do, but to narrate in their verity the things actually done and said, how modest soever they may be. For the end of history is not identical with that of tragedy, but quite the contrary. In tragedy the end is by the most plausible language to astonish and move the audience temporarily. In history the end is by real facts and real speeches to instruct and persuade for all time the lovers of knowledge: since in the former the leading motive is the plausible, even if the plausible be false, for the deception of the spectators; in the latter the leading motive is truth for the benefit of the student."

What Polybius himself means by "Pragmatic history" (i. 2. πόσα καὶ πηλίκα συμβάλλεσθαι πέφυκε τοῖς φιλομαθοῦσιν ὁ τῆς πραγματικῆς ἱστορίας τρόπος) is illustrated by his remarks (iii. 47) on those who have written of Hannibal's crossing of the Alps: "Wishing to astonish their readers by their marvellous account of the localities, they fall into two faults which are most foreign to all history; for they are compelled to tell falsehoods (ψευδολογεῖν) and to contradict themselves. On the one hand they introduce Hannibal as a general of inimitable daring and prudence, while they show him admittedly the most imprudent; and on the other hand, unable to reach a dénouement or an issue from their own mendacity, they introduce into pragmatic history gods and the children of gods. . . . Ignorant of these things they say that a hero (*i.e.*, a demigod) appeared and showed the Carthaginians the roads. Hence, naturally, they find themselves in the same position as the writers of tragedies. For the dénouements of their dramas need a god and a machine, because their first premises are false and contrary to reason; and historians must be in like case and must represent gods and heroes appearing when their premises are improbable and false."

Polybius (iii. 6) insists on the distinction between the remoter causes (αἰτίαι) of events and their immediate origins (ἀρχαί) and in the same spirit he emphasizes the necessity of taking a comprehensive or synoptic view of history, regarding history as a unity in so far as the interests of different nations mutually interact: "In previous times the actions of the world were sporadic . . . now history is, as it were, an organic whole; the affairs of Italy and Africa are intertwined with those of Asia and Greece and all have reference to one end" (i. 3). It is this conception of history which leads Polybius to prefix to his more immediate subject the preparatory narrative of his first two books: "The peculiarity of our study and the marvel of our times is this. Just as Fortune (τύχη) has bent almost all the affairs of the world to one end and has inclined them to one and the same goal, so by means of history we must bring under one conspectus for our readers the agency which Fortune has employed to accomplish the whole. For this consideration it is chiefly which incited and stimulated me to undertake my history, coupled with the fact that no one in our time has attempted a general history: otherwise I had been much less eager in this direction. But when I see that many writers occupy themselves with particular wars and some of the actions connected with them, while no one, so far as I know, has even attempted to examine the general and comprehensive economy of events—when and whence they originated and how they attained fulfillment—I considered it absolutely essential not to omit or allow to pass unnoticed the most beautiful and at the same time the most beneficial exhibition of the power of Fortune. For many as are her innovations and unceasingly as she engages in the affairs of men, absolutely never has she wrought such a work or engaged in such a struggle as in our time. This cannot be seen from sectional histories—unless it be that one who visits the most eminent individual cities or sees them represented in a picture, imagines straightway that he understands the form of the whole world, and its general position and arrangement" (i. 4).

Sources of Information.—Starting with the initial advantage of being himself conversant with public affairs, Polybius seems to have taken pains unusual for his time to equip himself with the knowledge requisite to ensure accuracy. In the first place he was a careful student of the practice of war, and indeed wrote a treatise on Tactics (ix. 20. 4. cf. Arrian, Tact. i. 1., Aelian, Tact. i. 2; iii. 4; xix. 10). He had an extensive first-hand acquaintance with geography (cf. the inscription on his statue at Megalopolis as quoted above); he accompanied Scipio in many campaigns (Arrian, Tact. l.c.) and, as he tells us himself, "it was mainly for this reason that I undertook the dangers and discomforts incident to travel in Africa and Spain and also Gaul and the Outer Sea (Atlantic) adjacent to those lands, in order that I might correct the ignorance of my predecessors in those matters and make known those parts of the world to the Greeks" (iii. 59). He also tells us (iii. 48) in discussing Hannibal's passage of the Alps, that he had himself seen the region and had travelled over the Alps for the sake of information and observation. His intimate study of constitutional matters is shown by his account of the Roman constitution in Book VI. Finally he made diligent use of the documentary and monumental evidence accessible to him. Thus in iii. 33, after giving the numbers of Hannibal's forces with a detail "suggesting the plausible mendacity of a historian" he explains that he took the numbers from a record in bronze left at Lacinium (in Bruttium) by Hannibal himself. In xvi. 15 he appeals to the evidence of a despatch preserved in the *prytaneum* of Rhodes; and the manner in which he quotes the terms of the treaty which ended the first Punic War (i. 62) and of that between Hannibal and Philip (vii. 9) implies that he is either translating or quoting a translation of an original document which he possibly obtained from official sources.

His enlightened conception of the function of history, his careful preparation for his task, entitle Polybius to an honourable place among historians. The completely impartial historian is an ideal, certainly unattainable and perhaps undesirable. No very serious charge on this ground is made against Polybius, nor can such charges in any case be either confuted or confirmed authoritatively. He has himself at all events forestalled criticism: "That historians may incline the balance in favour of their own country I would allow—not that they should make statements which contradict the facts. There are enough errors of ignorance to which historians are liable and which a man may hardly avoid. But if we write falsely from intention—be it for country or for friends or for favour—what better are we than those who make their living by such means? . . . On this tendency readers should keep a watchful eye, and historians themselves should guard against it" (xvi. 14).

The main criticism directed against Polybius from Dionysius of Halicarnassus (1st century, B.C.) to the present day is made on the ground of style. Dionysius, from the standpoint of a strict Atticist, writes of the later Greek historians who have so far neglected style that they "have left behind them compositions which no one endures to read to the end—Phylarchus, Duris, Polybius" (Dionys. De *comp.* verb. iv.). The modem reader, from a more general standpoint, would be inclined to think that his defects of style have been exaggerated. But his unfamiliar vocabulary, his intentional rejection of the picturesque concomitants of historical events, his anxiety to point a moral, combine to render him less popular than his merits deserve: one more proof that something more than knowledge, more than accuracy, more than serious purpose and moral earnestness, is required in the historian to whom the world will gladly listen.

POLYCARP (c. 69–*c.* 155), bishop of Smyrna and one of the Apostolic Fathers, derives much of his importance from the fact that he links together the apostolic age and that of nascent Catholicism. The sources from which we derive our knowledge of the life and activity of Polycarp are: (1) a few notices in the writings of Irenaeus, (2) the Epistle of Polycarp to the Church at Philippi, (3) the Epistle of Ignatius to Polycarp, (4) the Epistle of the Church at Smyrna to the Church at Philomelium, giving an account of the martyrdom of Polycarp. Since these authorities have all been more or less called in question and some of them entirely rejected by recent criticism, it is necessary to say a few words about each.

Sources.—I. The Statements of Irenaeus are found (a) in his *Adversus* haereses, iii. 3, 4, (*b*) in the letter to Victor, where Irenaeus gives an account of Polycarp's visit to Rome, (*c*) in the letter to Florinus—a most important document which describes the intercourse between Irenaeus and Polycarp and Polycarp's relation with St. John. The genuineness of (*c*) is not uncontested, but it is generally accepted.

2. The Epistle of *Polycarp.*—Though Irenaeus states that Polycarp wrote many "letters to the neighbouring churches or to certain of the brethren" only one has been preserved, viz., the well-known letter to the Philippians. The epistle is largely involved in the Ignatian controversy (see IGNATIUS). The rehabilitation of the Ignatian letters in modern times has, however, practically destroyed the attack on the Epistles of Polycarp. The date of the epistle depends upon the date of the Ignatian letters and is now generally fixed between 112 and 118. The language in this letter is simple but powerful.

3. The Epistle of Ignatius to *Polycarp.*—This epistle has of course been subjected to the same criticism as has been directed against the other epistles of Ignatius (see IGNATIUS); the general criticism, may now be said to have been completely answered by the investigations of Zahn, Lightfoot and Harnack. Some modern scholars feel a difficulty about the peremptory tone which Ignatius adopts towards Polycarp. There was some force in this argument when the Ignatian Epistles were dated about 140, as in that case Polycarp would have been an old and venerable man at the time. But now that the date is put back to about 112 the difficulty vanishes, since Polycarp was not much over forty when he received the letter.

4. The Letter of the Church at Smyrna to the Philomelians is a most important document, because we derive from it all our information with regard to Polycarp's martyrdom. Eusebius has preserved the greater part of this epistle (iv. 15), but we possess it entire with various concluding observations in several Greek mss., and also in a Latin translation. The epistle gives a minute description of the persecution in Smyrna, of the last days of Polycarp and of his trial and martyrdom; and as it contains many instructive details and professes to have been written not long after the events to which it refers, it has always been regarded as one of the most precious remains of the 2nd century. Certain recent critics, however, have questioned the authenticity of the narrative. The more moderate school of modern critics—*e.g.*, Lightfoot (Ignatius and Polycarp, 1589 seq.), Harnack (Gesch. d. altchrist. Lit. II. i. 341), and Krüger (Early Christian Lit., 1897)—is unanimous in regarding it as an authentic document, though it recognizes that here and there a few slight interpolations have been inserted. Besides these we have no other sources for the life of Polycarp.

Life.—Polycarp must have been born not later than the year 69, for on the day of his death (c. 155) he declared that he had served the Lord for eighty-six years (*Martyrium,* 9). Irenaeus tells us that in early life Polycarp "had been taught by apostles and lived in familiar intercourse with many that had seen Christ" (iii. 3, 4).

This testimony is expanded in the remarkable words which Irenaeus addressed to Florinus:

"I saw thee when I was still a boy (παῖς ἔτι) in Lower Asia in company with Polycarp . . . I can even now point out the place where the blessed Polycarp used to sit when he discoursed, and describe his goings out and his comings in, his manner of life and his personal appearance and the discourses which he delivered to the people, how he used to speak of his intercourse with John and with the rest of those who had seen the Lord, and how he would relate their words. And everything that he had heard from them about the Lord, about His miracles and about His teaching, Polycarp used to tell us as one who had received it from those who had seen the Word of Life with their own eyes, and all this in perfect harmony with the Scriptures. To these things I used to listen at the time, through the mercy of God vouchsafed to me, noting them down, not on paper but in my heart, and constantly by the grace of God I brood over my accurate recollections."

These words establish a chain of tradition (John-Polycarp-Irenaeus) which is without a parallel in early church history. Polycarp thus becomes the living link between the Apostolic age and the great writers who flourished at the end of the 2nd century. Recent criticism, however, has endeavoured to destroy the force of the words of Irenaeus. Harnack *(Chronologie,* i., 325–329), for instance, attacks this link at both ends. *(a)* The connection of Irenaeus and Polycarp, he argues, is very weak, because Irenaeus was only a boy (παῖς) at the time, and his recollections therefore carry very little weight. The fact, too, that he never shows any signs of having been influenced by Polycarp and never once quotes his writings is a further proof that the relation between them was slight. (b) The connection which Irenaeus tries to establish between Polycarp and John the apostle is probably due to a blunder Irenaeus has confused John the apostle and John the presbyter. Polycarp was the disciple of the latter, not the former. In this second argument Harnack has the support of a considerable number of modern scholars who deny the Ephesian residence of John the apostle. But in spite of much modern criticism there seems to be no solid reason for rejecting the statements of Irenaeus and regarding Polycarp as the link between the Apostolic age and the first of the Catholic fathers.

Though Polycarp must have been bishop of Smyrna for nearly half a century we know next to nothing about his career. We get only an occasional glimpse of his activity, and the period between 115 and 155 is practically a blank. The only points of sure information which we possess relate to (1) his relations with Ignatius, (2) his protests against heresy, (3) his visit to Rome in the time of Anicetus, (4) his martyrdom.

His Relations with **Ignatius.**—Ignatius, while on his way to Rome to suffer martyrdom, halted at Smyrna and received a warm welcome from the church and its bishop. Upon reaching Troas he despatched two letters, one to the church at Smyrna, another addressed personally to Polycarp. In these letters Ignatius charged Polycarp to write to all the churches between Smyrna and Syria (since his hurried departure from Troas made it impossible for him to do so in person) urging them to send letters and delegates to the church at Antioch to congratulate it upon the cessation of the persecution and to establish it in the faith. The letters of Ignatius illustrate the commanding position which Polycarp had already attained in Asia. It was in the discharge of the task which had been laid upon him by Ignatius that Polycarp was brought into correspondence with the Philippians. The Church at Philippi wrote to Polycarp asking him to forward their letters to Antioch. Polycarp replied, promising to carry out their request and enclosing a number of the letters of Ignatius which he had in his possession.

Polycarp's Attack on Heresy.—All through his life Polycarp appears to have been an uncompromising opponent of heresy. We find him in his epistle (ch. vii.) uttering a strong protest against certain false teachers (probably the followers of Cerinthus).

For every one who shall not confess that Jesus Christ is come in the flesh is antichrist; and whosoever shall not confess the testimony of the Cross is of the devil; and whosoever shall pervert the oracles of the Lord to his own lusts and say that there is neither resurrection nor judgment, that man is the first-born of Satan. Wherefore let us forsake their vain doing and their false teaching and turn unto the word which was delivered unto us from the beginning.

Polycarp lived to see the rise of the Marcionite and Valentinian sects and vigorously opposed them. Irenaeus tells us that on one occasion Marcion endeavoured to establish relations with him and accosted him with the words, "Recognize us." But Polycarp displayed the same uncompromising attitude which his master John had shown towards Cerinthus and answered, "I recognize you as the first-born of Satan." The steady progress of the heretical movement in spite of all opposition was a cause of deep sorrow to Polycarp, so that in the last years of his life the words were constantly on his lips, "Oh good God, to what times hast thou spared me, that I must suffer such things!"

Polycarp's Visit to Rome.—It is one of the most interesting and important events in the church history of the 2nd century that Polycarp, shortly before his death, when he was considerably over eighty years old, undertook a journey to Rome in order to visit the bishop Anicetus. Irenaeus, to whom we are indebted for this information *(Haer.* iii. 3, 4; *Epist. ad victorent, ap.* Euseb. v. 24), gives as the reason for the journey the fact that differences existed between Asia and Rome "with regard to certain things" and especially about the time of the Easter festival. Unfortunately all he says is that with regard to the certain things the two bishops speedily came to an understanding, while as to the time of Easter, each adhered to his own custom, without breaking off communion with the other. We learn further that Anicetus as a mark of special honour allowed Polycarp to celebrate the Eucharist in the church, and that many Marcionites and Valentinians were converted by him during his stay in Rome.

Polycarp's Martyrdom.— Not many months apparently after Polycarp's return from Rome a persecution broke out in Asia. A great festival was in progress at Smyrna. The proconsul Statius Quadratus was present on the occasion, and the asiarch Philip of Tralles was presiding over the games. Eleven Christians had been brought, mostly from Philadelphia, to be put to death. The appetite of the populace was inflamed by the spectacle of their martyrdom. A cry was raised, "Away with the atheists. Let search be made for Polycarp." Polycarp took refuge in a country farm. His hiding-place, however, was betrayed and he was arrested and brought back into the city. Attempts were made by the officials to induce him to recant, but without effect. When he came into the theatre, the proconsul urged him to "revile Christ," and promised, if he would consent to abjure his faith, that he would set him at liberty. To this appeal Polycarp made the memorable answer, "Eighty and six years have I served Him and He hath done me no wrong. How then can I speak evil of my King who saved me?" These words only intensified the fury of the mob. They clamoured for a lion to be let loose upon him there and then. The asiarch, however, refused, urging as an excuse that the games were over. When they next demanded that their victim should be burned, the proconsul did not interfere. Timber and faggots were hastily collected and Polycarp was placed upon the pyre. With calm dignity and unflinching courage he met his fate and crowned a noble life with an heroic death.

Eusebius in his *Chronicon* gives A.D. 166 as the date of Polycarp's death, and until the year 1867 this statement was never questioned. In that year appeared Waddington's *Mémoire sur* la *chronologie de la vie du rhéteur Aelius Aristide,* in which it was shown from a most acute combination of circumstances that the Quadratus whose name is mentioned in the *Martyrium* was proconsul of Asia in 155–156, and that consequently Polycarp was martyred on Feb. 23, 155. Waddington's conclusion has received overwhelming support amongst recent critics. His views have been accepted by (amongst many others) Renan *(Antéchrist,* 1873, p. 207), Hilgenfeld *(Zeitschr. f. wiss. Theol.,* 1874, p. 325), Gebhardt *(Zeitschr. f. hist. Theol.,* 1875, p. 356), Lipsius *(Jahrb. f. prot. Theol.,* 1883, *p.* 525), Harnack *(Chronologie,* i. 334–356), Zahn *(Zeitschr. f. wiss. Theol.,* 1882, p. 227), Lightfoot *(Ignatius and Polycarp,* i. 629–702) and Randell *(Studia biblica,* 1885, i. 175). Against this array of scholars only the following names of Importance can be quoted in support of the traditional view—Keim *(Aus dem Urchristentum, p.* go), Wieseler *(Die Christenverfolgungen der Caesaren,* 1878, p. 34) and Uhlhorn *(Studia Biblica,* 1890, ii., 105–156). The problem is too complex to admit of treatment here. There seems to be little doubt that the case for the earlier date has been proved.

The significance of Polycarp in the history of the Church is out of all proportion to our knowledge of the facts of his career. The violent attack of the Smyrnaean mob is an eloquent tribute to his influence in Asia. "This is the teacher of Asia," they shouted, "this is the father of the Christians: this is the destroyer of our gods: this is the man who has taught so many no longer to sacrifice and no longer to pray to the gods." And after the execution they refused to deliver up his bones to the Christians for burial on the ground that "the Christians would now forsake the Crucified and worship Polycarp." Polycarp was indeed, as Polycrates says, "one of the great luminaries" (μεγάλα στοιχεῖα) of the time. It was in no small degree due to his staunch and unwavering leadership that the Church was saved from the peril of being overwhelmed by the rising tide of the pagan revival which swept over Asia during the first half of the 2nd century, and it was his unfaltering allegiance to the Apostolic faith that secured the defeat of the many forms of heresy which threatened to destroy the Church from within.

Polycarp had no creative genius. He was a "transmitter, not a maker." As Irenaeus says (iii. 3, 4), "Polycarp does not appear to have possessed qualifications for successfully conducting a controversial discussion with erroneous teachers . . . but he could not help feeling how unlike their speculations were to the doctrines which he had learned from the Apostles, and so he met with indignant reprobation their attempt to supersede Christ's gospel with fictions of their own devising." It is this that constitutes Polycarp's service to the Church, and no greater service has been rendered by any of its leaders in any age.

BIBLIOGRAPHY.—J. B. Lightfoot, *Apostolic Fathers,* pt. ii. (2nd ed., 1889). Polycarp is dealt with in i. 417–459, 530–704; ii. 897-1086; G. Volkmar, *Epistula Polycarpi Smyrnaei genuina* (Zürich, 1885); T. Zahn, *Forschungen zur Geschichte des Kanons, &c.*, iv. 249, 279; J. M. Cotterill, "The Epistle of Polycarp to the Philippians," *Journ. of Philol.* (1891), xix., 241–285; Harnack, *Chronologie der altchristlichen Litteratur* (1897), and authorities quoted in the text. *See* also APOSTOLIC FATHERS. (H. T. A.; X.)

POLYCHAETA, a class of segmented worms (Annelida, *q.v.*). The name refers to the numerous bristles present along the sides of most species. The class includes the common lug worm *(Arenicola)* and the sea-mouse *(Aphrodite).*

POLYCLEITUS, the name of two Greek sculptors of the school of Argos; the first belonging to the fifth century, the second to the early part of the fourth.

1. The elder and best known Polycleitus was a contemporary of Pheidias, and in the opinion of the Greeks his equal. Whether he was actually a pupil of Ageladas is disputed; at any rate he carried on the tradition. He made a figure of an Amazon for Ephesus which was regarded as superior to the Amazon of Pheidias made at the same time; and his colossal Hera of gold and ivory which stood in the temple near Argos was considered as worthy to rank with the Zeus of Pheidias. It would be hard for a modern critic to rate Polycleitus so high: the reason is that balance, rhythm and the minute perfection of bodily form, which were the great merits of this sculptor, do not appeal to us as they did to the Greeks of the 5th century. He worked mainly in bronze.

As regards his chronology we have data in a papyrus published by Grenfell and Hunt containing lists of athletic victors. From this it appears that he made a statue of Cyniscus, a victorious athlete of 464 or 460 B.C., of Pythocles (452) and Aristion (452). He thus can scarcely have been born as late as 480 B.C. His statue of Hera is dated by Pliny to 420 B.C. His artistic activity must thus have been long and prolific. His two great statues, ideal athletic types rather than portraits, are the Diadumonos and the Doryphorus, copies of both of which are common. The Doryphorus was known as the Canon, because it embodied the correct proportions of the ideal male form. The completest copy is from Pompeii, and there is a copy of the Diadumonos from Vaison in the British Museum. Both are late Roman copies, unpleasantly heavy and square and in marble, thus giving little idea of the finish of Polycleitus' work in bronze. This has been enforced by the discovery at Delos, by the French excavators, of a diadumenus of far more pleasing type and greater finish, which also goes back to Polycleitus. The excavations at Olympia have widened our knowledge of his early work. Among the bases of statues found on that site were three signed by Polycleitus, still bearing on their surface the marks of attachment of the feet of the statues. This at once gives us their pose; and following up the clue, A. Furtwängler has identified several extant statues as copies of figures of boy athletes victorious at Olympia set up by Polycleitus. Among these the Westmacott athlete in the British Museum is conspicuous.

The Amazon of Polycleitus survives in several copies, among the best of which is one in the British Museum. The masterpiece of Polycleitus, his Hera of gold and ivory, has of course totally disappeared. The coins of Argos give us only the general type. Waldstein has identified the head of a girl in the British Museum as belonging to this type.

The want of variety in the works of Polycleitus was brought as a reproach against him by ancient critics. Varro says that his statues were square and almost of one pattern. Except for the statue of Hera, which was the work of his old age, he produced scarcely any notable statue of a deity. His field was narrowly limited; but in that field he was unsurpassed.

2. The younger Polycleitus was of the same family as the elder, and the works of the two are not easily to be distinguished. Some existing bases, however, bearing the name are inscribed in characters of the 4th century, at which time the elder sculptor cannot have been alive.

See A. Furtwangler, *Masterpieces of Greek Sculpture* (Eng. trans. 1895); P. Paris, Polyclète (Paris, 1895); Mahler, *Polyklit und seine Schule* (Athens, 1902).

POLYCRATES, tyrant of Samos (c. 535–515 B.C.). Having won popularity by donations to poorer citizens, he took advantage of a festival of Hera, which was being celebrated outside the walls, to make himself master of the city (about 535 B.C.). After getting rid of his brothers Pantagnotus and Syloson, who had at first shared his power, he established a despotism which is of great importance in the history of the island. He equipped a fleet of 100 ships and so became master of the Aegean basin. This ascendancy he abused by numerous acts of piracy which made him notorious throughout Greece; but his real aim was the control of the archipelago and the mainland towns of Ionia. He maintained an alliance with Lygdamis of Naxos, and dedicated to Delos the island of Rheneia. He also defeated a coalition of two great naval powers of the Asiatic coast, Miletus and Lesbos. He made an alliance, probably commercial in object, with Amasis of Egypt. But the squadron he sent to Amasis' support against Cambyses of Persia, being composed of pclitical opponents of Polycrates, suspected treachery and returned and attacked Polycrates. After a defeat by sea, Polycrates repelled an assault upon the walls, and subsequently withstood a siege by a joint armament of Spartans and Corinthians assembled to aid the rebels. He maintained his ascendancy until about 515, when Oroetes, the Persian governor of Lydia, who had been reproached for his failure to reduce Samos by force, lured him to the mainland and put him to death by crucifixion.

Beside the political and commercial pre-eminence which he conferred upon Samos, Polycrates adorned the city with public works on a large scale. He was also a patron of letters; he collected a library, and Anacreon lived at his court.

POLYGALACEAE, a family of dicotyledonous herbs, shrubs and small trees, comprising ten genera and about 700 species, not represented in New Zealand, Polynesia and the Arctic zone, but otherwise cosmopolitan. Polygala *vulgaris* is the British milkwort (*q.v.*), and P. *Senega,* the Senega snake-root, a North American medicinal plant. In North America some 50 species are found, chiefly in the southern and western United States.

POLYGLOTT or **POLYGLOT,** a book which contains side by side versions of the same text in several languages (Gr. **πολύς,** many, and γλῶττα, tongue). The most important polyglotts are editions of the Bible, or its parts, in which the Hebrew and Greek originals are exhibited along with the great historical versions. The famous *Hexapla* of Origen, in which the Old Testament Scriptures were written in parallel columns, probably suggested the later polyglotts, but though it gives six texts it is itself only in two languages. In the 16th and 17th centuries polyglotts became a favourite means of advancing the knowledge of Eastern languages as well as the study of Scripture. The series began with the *Complutensian* printed by Arnaldus Guilielmus de Brocario at the expense of Cardinal Jimenez (*q.v.*) at the university at Alcalá de Henares (Complutum). This contained for the Old Testament the Hebrew text, Latin Vulgate and the Septuagint and Chaldee versions with Latin renderings; for the New Testament, the Greek and Vulgate Latin. The six volumes bear dates ranging from Jan. 10, 1514, to July 10, 1517, but the work did not receive the papal sanction till March 1520, and was apparently not issued till 1522, probably because of the Imperial privilege obtained by Erasmus for his Greek Testament in 1516. The *Antwerp* Polyglott, printed by Christopher Plantin (1569–72, in 8 vols. folio), under the patronage of Philip II. of Spain, added a new language to those of the *Complutensian* by including the Syriac New Testament. Next came Le Jay's Paris Polyglott (1645), which embraces the first printed texts of the Syriac Old Testament and of the Samaritan Pentateuch. It has also a series of various Arabic versions. The last great polyglott was that edited by Brian Walton, published in London in 1657. This is much less beautiful than Le Jay's, but includes the Syriac of Esther and of several apocryphal books, Persian versions of the Pentateuch and Gospels, and the Psalms and New Testament in Ethiopic. It was in connection with this polyglott that E. Castell produced his famous Heptaglott Lexicon (2 vols. folio, London, 1669). Of the numerous polyglott editions of parts of the Bible it may suffice to mention the Genoa psalter of 1j16, edited by Giustiniani, bishop of Nebbio. This is in Hebrew, Latin, Greek, Chaldee and Arabic, and is interesting from the character of the Chaldee text, being the first specimen of Western printing in the Arabic character. (A. W. P.)

POLYGNOTUS, famous Greek painter, *c.* 470–440 B.C., son of Aglaophon, was a native of Thasos, but was adopted by the Athenians, and admitted to their citizenship. He painted for them, in the time of Cimon, a picture of the taking of Ilium on the walls of the Stoa Poecile, and another of the marriage of the daughters of Leucippus in the Anaceum. In the hall at the entrance to the Acropolis other works of his were preserved; and he collaborated with Mikon in paintings of Greeks and Amazons in the Theseum. The most important, however, of his products were his frescoes in the Lesche erected at Delphi by the people of Cnidus. The subjects of these were the visit to Hades by Odysseus, and the taking of Ilium. Fortunately the traveller Pausanias has left us a careful description of these paintings, figure by figure (Paus. x. 25–31); and we may form some idea of their style from contemporary vase decorations. The foundations of the building have been recovered in the course of the French excavations at Delphi. From this evidence some modern archaeologists have tried to reconstruct the composition of the paintings. The figures were detached and seldom overlapping, ranged in two or three rows one above another; and the farther were not smaller nor dimmer than the nearer. We learn also that Polygnotus employed but few colours. His excellence lay in the beauty of his drawing of individual figures; but especially in the "ethical" and ideal character of his art. His work must have had the same grandeur as the contemporary sculptures of Olympia, combined apparently with a new delicacy; for he is praised for his transparent garments, his head-dresses of variegated colours, and his speaking expressions. He was the great representative of Greek painting of the fifth century B.C., as Pheidias was of sculpture.

POLYGONACEAE, in botany, a family of dicotyledons, containing 40 genera with about 750–800 species, chiefly in the north temperate zone, and represented in Great Britain by three genera, Polygonum, *Rumex* (dock, *q.v.*) and Oxyria. They are mostly herbs characterized by the union of the stipules into a sheath or ocrea, which protects the younger leaves in the bud stage. Some are climbers, as, for instance, the British *Polygonum convolvulus* (black bindweed). In *Muehlenbeckia platyclada,* a native of the Solomon islands, the stem and branches are flattened, forming ribbon-like cladodes jointed at the nodes. The leaves are alternate, simple and generally entire; the edges are rolled back in the bud. They are generally smooth, but sometimes, especially in mountain species, woolly. The small regular, generally hermaphrodite flowers are borne in large numbers in compound inflorescences, the branches of which are cymose. The parts of the flower are whorled (cyclic) or acyclic. The former arrangement may be derived from a regular trimerous flower with two whorls of perianth leaves, two staminal whorls and a three-sided ovary—this type of flower occurs in the Californian genus Pterostegia. The flower of rhubarb (Rhsum) is derived from this by doubling in the outer staminal whorl and that of the dock (*Rumex*) by doubling in the outer staminal whorl and suppression of the inner whorl. Dimerous whorled flowers occur in Oxyria (mountain sorrel), another arctic and alpine genus, the flowers of which otherwise resemble those of *Rumex.* In the acyclic flowers a pentamerous perianth is followed by five to eight stamens as in Polygonum. The perianth leaves are generally uniform and green, white or red in colour. They are free or more or less united, and persist till the fruit is ripe, often playing a part in its distribution, and affording useful characters for distinguishing genera or species. Thus in the docks the three inner leaves enlarge and envelop the fruit as three membranous wings one or more of which bear on the back large fleshy warts. The number of the carpels is indicated by the three-sided (in dimerous flowers two-sided) ovary, and the number of the styles; the ovary is unilocular and contains a single erect ovule springing from the top of the floral axis. The fruit is a dry one-seeded nut, two-sided in bicarpellary flowers, as in Oxyria. The straight or curved embryo is embedded in a mealy endosperm. The flowers are wind-pollinated, as in the docks (*Rumex*), where they are pendulous on long slender stalks and have large hairy stigmas; or insect-pollinated, as in Polygonum or rhubarb (Rheum), where the stigmas are capitate and honey is secreted by glands near the base of the stamens. Insect-pollinated flowers are rendered conspicuous chiefly by their aggregation in large numbers, as for instance in bistort (Polygonum bistortu), where the perianth is red and the flowers are crowded in a spike. In buckwheat (*q.v.,* P. *fagopyrum*) the numerous flowers have a white or red perianth and are perfumed; they are dimorphic, *i.e.,* there are two forms of flowers, one with long styles and short stamens, the other with short styles and long stamens. In other cases self-pollination is the rule, as in knotgrass (P. *aviculare*), where the very small, solitary odourless flowers are very rarely visited by insects and pollinate themselves by the incurving of the three inner stamens on to the styles.

Polygonaceae is mainly a north temperate order. A few genera are tropical, *e.g.,* Coccoloba, which has 125 species restricted to tropical and sub-tropical America. *Polygonum* has a very wide distribution spreading from the limits of vegetation in the north ern hemisphere to the mountains of tropical Africa and South Africa, through the highlands of tropical Asia to Australia, and in America as far south as Chile. Most of the genera have, however, a limited distribution. In the British Isles, Polygonum has 14 species; *Rumex* (12 species) includes the various species of dock (*q.v.*) and sorrel (R. Acetosa); and *Oxyria* digyna, an alpine plant (mountain sorrel), takes its generic name (Gr. ὀξύς, sharp) from the acidity of its leaves. Rheum (rhubarb, *q.v.*) is central Asiatic.

In the United States the largest genus is Eriogonum, containing about 200 species, all natives of America, and most of them in the western United States. The other prominent genera occurring in America are *Rumex* (docks), and *Polygonum* (knotweeds). *Fagopyrum* (buckwheat) and *Rheum* (rhubarb or pie-plant) also are abundant but they are natives of the old aorld. The Mexican genus *Antigonon* is cultivated in the scuth as an ornamental.

POLYGONAL AND POLYHEDRAL NUMBERS: see FIGURATE NUMBERS.

POLYGONS. A polygonal *line,* also called a broken line, joining the point A_1 to the point An is any finite set of points A_1, A_2, . . . , A, and the segments A_1A_2, A_2A_3, . . . , $A_{n-1}A_n$. In this and the following definition of a polygon the phrase "a point A_i" means a point associated with the symbol A_i and the phrase "a segment A_iA_j" means the segment, whose ends are the points which are the associates of the symbols A, and A_j respectively, associated with the symbol A_iA_j. A segment is the set of all points of any (straight) line which are between any two points of that line. Each of the latter points is called an *end* of the segment. A polygon is any finite set of points A_1A_2, . . . , A, and the segments A_1A_2, A_2A_3 . . . , A_{n-1} A_n, A_nA_1. The points A_i and segments A_iA_{i+1}, A_nA_1, $i=1, 2, \ldots,$ n, are called respectively the vertices and sides of the polygon; similarly for a polygonal line.

The terms polygonal line and polygon are used also with meanings which are different from, although closely related to, those given above. A polygon as defined may have one of two senses assigned to it so that the first end and the second end of each side is specified in such a way that the vertex A_i is either the first end of the side A_iA_{i-1} and the last end of the side $A_{i-1}A_i$ if $i=1$, and A_nA_1 if $i=1$, or vice versa. A polygon with such an assignment of a sense is called an oriented or a sensed polygon. In an obvious way an oriented polygonal line is defined. Thus two sensed polygons or polygonal lines are associated with each polygon or polygonal line. In the sequel the phrase the oriented (or sensed) side AB of a sensed polygon indicates that A is the first end of the oriented side AB of that oriented polygon, and B the second. Polygonal lines and polygons according to the first definition are referred to as unoriented or *unsensed* polygonal lines and polygons respectively. In formulating a third meaning of the terms polygonal line and polygon it should be emphasized that the elements involved in the above definition are points and segments associated with symbols so that an unoriented or oriented polygon is neither a set of points and segments nor a set of points. The word polygon also is used to signify either certain sets of points and segments or certain set of points. The distinctions just pointed out although delicate are logically essential and even practically important. For the purpose of this article the single word "polygon" denotes any set of points which consists of the points which are the associates of the symbols $A_1, A_2, \ldots, A_n$ and the points which belong to the segments which are the associates of the symbols A_iA_{i+1}, $i=1, 2, \ldots, n$ and A_nA_1 of the first definition; *i.e.,* the definition of an unsensed polygon. Similarly in the case of a polygonal line.

The above definitions are of broad scope and define abstractions which are based on the phenomenon of the motion of a particle from point to point along intermediate rectilinear stretches. Important specializations of these ideas are the so-called simple polygons or polygonal lines according to any of the definitions given. A simple unoriented polygon is any unoriented polygon which is such that none of its vertices is an end of more than two of its sides and no side of the unoriented polygon contains a vertex or a point which belongs to another side of the unoriented polygon. The definitions of simple unoriented polygonal lines, simple oriented polygonal lines and polygons as well as those of simple polygons and polygonal lines in conformity with the third definition are apparent and consequently are not stated formally. Alternative definitions for the several concepts defined or indicated above may be given; for example a simple polygon may be defined as a finite set of points and segments such that (a) every point of the set is the end of two and only two segments of the set, (b) each end of every segment of the set is a point of the set, (c) no segment of the set contains a point of the set or a point of another segment of the set and (d) no (proper) subset of the given set satisfies (a), (b) and (c). It is easy to show that this definition is equivalent to the one indicated in introducing the third formulation of the idea of a polygon and it is valuable in that it admits of immediate generalization to the idea of a polyhedron in space.

Place of Polygons in Mathematics. — The theory of polygons as a special chapter in mathematics is chiefly concerned with the classification of unoriented and oriented polygons all of whose elements, — that is, vertices and sides, — are in the same plane. The corresponding question for space concerns polyhedrons and is taken up in the article on **SOLIDS, GEOMETRIC.** Polygons whose elements are not in one plane have not as yet formed the subject of any interesting theory. Such polygons, as well as plane polygons, however, serve as important aids, as in the study of continuous curves in general. This is largely because of the fact that any continuous arc contains the vertices of a polygonal line, the length of whose sides are all less than any preassigned positive number, and which is simple if the arc is simple. In particular, the length of an arc of a curve is defined by means of the lengths of the inscribed polygonal lines, — that is, polygonal lines which join the ends of the arc and whose vertices are on the arc and have an order which conforms to one of the two senses along the arc. In the geometry of the Euclidean plane, plane polygons, — that is, those having all of their points in one plane, — take on an added significance because of the fact that the Euclidean plane is separated into two regions by any simple polygon that is contained in it. This is a consequence of the basic fact that a line separates the Euclidean plane. Unless it is stated otherwise it is understood that in the following all configurations are in the Euclidean plane. A region is a set of points such that any point of the set is the centre of a circle which has only points of the set in its interior and such that the set is not composed of two sets having the latter property and also having no points in common. It follows easily that any two points of a region are joined by a simple polygonal line which is contained in the region. A precise statement of the important fact mentioned above is that if P is any simple plane polygon, then the plane is composed of P and two regions which have no points in common with each other or with P. One of these regions is of infinite extent and the other is not. A region such as the latter is referred to as a polygonal region and also as the interior of the polygon concerned and the latter is called the boundary of the polygonal region. Every circle which has a point of the boundary of the polygonal region as centre contains points of the region and any point which is such that any circle having it as centre contains points which belong to the region and also points which do not is a point of the boundary of the region. This property of the boundary of any polygonal region is used as the defining property of the boundary of a region in general. As a further consequence should be mentioned the fact that any polygonal region plus its boundary is composed of a finite number of triangles and their interiors, which have no points in common, and the vertices of the triangles are vertices of the bounding polygon. A region which is not a polygonal region is, however, approximated to by polygonal regions according to the following theorem: If Σ is any region, then there exists a sequence of polygonal regions $\Sigma_1, \Sigma_2, \Sigma_3, \cdots, \Sigma_n, \cdots$ such that (a) Σ_n and its boundary is contained in Σ and also in Σ_{n+1} for all (positive integral) values of n and (b) each point of Σ is contained in all but a finite number of the polygonal regions Σ_n. This theorem is easily proved by using as the polygonal regions regions which are composed of congruent squares which are formed by two sets of parallel lines, the lines of each set being equally spaced and intersecting orthogonally those of the other set. These acts indicate the importance of polygonal lines and polygons in the study of more general configurations.

THE THEORY OF PLANE POLYGONS

The Interior, Exterior and Peripheral Angles of a Plane Polygon. — We now proceed to the special theory of plane polygons. As remarked above, this theory concerns itself largely with unoriented and oriented polygons. In the case of a simple polygon the meaning of "an interior angle of a polygon" is immediate in virtue of the theorem concerning the separation of the plane by the polygon. This meaning leads to an interesting generalization in the case of an oriented polygon. In proceeding to this generalization and to related ideas it should be stated that all of the terms used are not defined with the mathematical completeness that would be possible with a greater allowance of space, but it has been aimed at least to indicate clearly the way to that completeness. Now it can be proved that if P is a simple oriented polygon and A any vertex of P then for the positive (counterclockwise) rotation of any side AB of P about its first end A, in accordance with the sense of P, which transforms the side AB into the other side of P having A as an end and which has a magnitude not exceeding 2π radians, then the points on the intermediate positions of AB which are within a certain distance of A are all in the interior of the polygon determined by P if the sense of P is the same as that of the rotation and all in the exterior in the contrary case. (Note that senses of oriented polygons are compared only in the case of simple oriented polygons.) Accordingly the interior angle at any vertex A_i of any oriented polygon P is defined as the positive angle (rotation) which has A_i as its vertex and whose initial side contains the side of P which has A_i

as its first end, say the side A_iA_{i+1}, whose terminal side contains the side with the ends A_i and A_{i-1}, if $i \neq 1$, and A_n if $i=1$, and whose magnitude does not exceed 2π. (See fig. 1.)

Further if A_i is any vertex of an oriented polygon P and the first end of the oriented side A_iA_{i+1} of P then there is a rotation about A_i of the half-line having A_i as its initial point and having the same direction as the oriented side $A_{i-1}A_i$ $(i-1 \equiv n$ if $i=1)$, that is the half-line of the line through A_{i-1} and Ai, which has A_i as its initial point and which does not contain A_{i-1}, into the half-line which contains the side A_iA_{i+1} which has a magnitude greater than $-\pi$ and less than or equal to π and there is another such rotation which is positive and has a magnitude not exceeding 2π. The former angle (rotation) is called the exterior angle and the latter the peripheral *angle* of the oriented polygon P at the vertex A_i. If α_i, β_i, γ_i are respectively the magnitudes of the interior, exterior and peripheral angles of the oriented polygon P at the vertex A_i then $\alpha_i+\beta_i=\pi$ and $\alpha_i+\gamma_i=\pi$ or 3π according as α_i is or is not less than π. If α_i is less than π then γ_i is and conversely. If the sum of all the β_i is set equal to $2a\pi$ and the sum of all the γ_i to $2a'\pi$ then a and a' are integers or zero as a simple consideration shows and $a'-a$ is the number of interior angles of P whose magnitudes are greater than or equal to π. If P' and P'' are two oriented polygons which differ only in orientation and if α_i', β_i', γ_i' and α_i'', β_i'', γ_i'' are respectively the magnitudes of the interior, exterior and peripheral angles of P' and P'' at the vertex A_i then $\alpha_i'+\alpha_i''=2\pi$, $\beta_i'+\beta_i''=0$ and $\gamma_i'+\gamma_i''=2\pi$. Hence the value of a for P'' is the negative of its value for P' while the value of a' for P'' is the number of vertices of P' (or P'') minus the value of a' for P'.

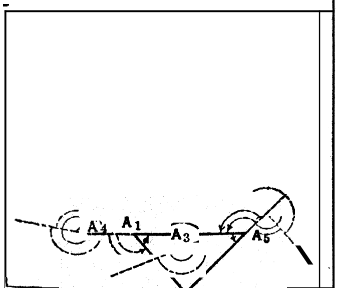

FIG. 1.—CONTINUOUS DEFORMATION OF AN ORIENTED POLYGON. WITH FIVE VERTICES

Classification of Plane Polygons.—In the classification of oriented polygons the numbers a and a' have been used to define the so-called types of such polygons. It is obvious how they may be used in the classification of unoriented polygons. There exist oriented polygons of any number n of vertices for which the value of a is any number whose absolute value does not exceed $\frac{1}{2}(n-1)$ except that for a triangle a cannot be zero. A more detailed scheme of classification is according to the values of a and $q=a'-a$. If all of the interior angles of an oriented polygon have magnitudes which do not exceed π then the polygon is called a convex oriented polygon. The unoriented polygon P is convex if and only if P with a sense assigned to it is convex. Both of these definitions are in conformity with the important notions of a convex simple polygon and a convex *polygonal* region. A convex region is a region such that all of the points of any segment whose ends belong to the region belong to the region also. A simple polygon is said to be convex if it is the boundary of a convex region, which is then a convex polygonal region. As theorems we have: A line which does not contain a side of a convex simple polygon contains not more than two points of the polygon and conversely. Also, no point of a convex simple polygon is on a particular one of the two sides of the line which contains any side of the polygon and conversely.

Another method of classification of unoriented and oriented polygons uses the notion of the continuous deformation of such polygons. Any one of two unoriented polygons with the vertices $A_1, A_2, \ldots, A_n$ and $B_1, B_2, \ldots, B_n$ respectively is deformable continuously into the other so that the vertex A_i corresponds to the vertex B_i and the side A_iA_{i+1} to the side B_iB_{i+1}. To obtain subclasses of unoriented polygons continuous deformations of such polygons, which satisfy any or all of the following conditions, are used: (1) no intermediate polygon of the deformation has two consecutive sides which lie in the same line and which have no points in common; (2) neither of two consecutive sides of any intermediate polygon of the deformation is contained in the other; and (3) no point is common to more than two sides of any intermediate polygon of the deformation. In the case of oriented polygons it is also required that sense be preserved by the deformation. Two oriented polygons that are transformable one into the other by a continuous deformation satisfying the first condition have the same value for a. If instead of the first condition the second is satisfied the oriented polygons have the same value for a'. If the deformation satisfies both the first and second conditions then the two oriented polygons are related so that if the magnitudes of one of two corresponding interior angles is less than π then the same is true of the other. Corresponding results for unoriented polygons follow easily. An interesting classification of unoriented polygons which satisfy the conditions on the intermediate polygons of the deformations satisfying all three conditions and which, in addition, have no vertex as the end of more than two sides and no side containing a vertex or a point belonging to more than two sides is that in which any unoriented polygon in one class is deformable into any other or into the symmetric image of any other in that class by a continuous deformation satisfying all three of the above conditions. For unoriented polygons of 4, 5 and 6 vertices there are respectively 3, 11 and 70 classes under this classification.

Non-metrical and Metrical Theories. Regular Polygons. Area of Polygons.—It should be pointed out that the above theory of the classification of unoriented and oriented polygons holds without essential modification in a more general plane than the Euclidean for only the order relations of the Euclidean plane are essential. Between this theory and the corresponding theory in the projective plane there are, because of the different kinds of linear order, some essential differences, but both theories are non-metrical. By making use of the metric properties of the Euclidean plane the consideration of regular polygons, oriented or not, becomes possible; also the question of the area of polygonal regions arises. An unoriented polygon is regular if any side is congruent to any other side and any angle of the polygon, *i.e.*, the figure consisting of a vertex and the two consecutive sides having that vertex as an end, congruent to any other "angle" of the polygon. The regular polygons are convex and there exists a circle circumscribed about and another inscribed in every regular polygon. Those regular polygons that are not simple also are called star polygons. If n points which are equally spaced on the circumference of a circle and numbered in order along that circumference are joined by segments so that the i-th point is joined to the $(i+d)$-th point, where d is a fixed positive integer, then the polygon resulting is a regular polygon for which the value of a, defined above, is d. Thus the number of "types" of regular polygons of n vertices is half of the number of positive integers which are less than and prime to n. Other kinds of regular polygons have been studied with particular reference to their classification along the lines explained above. For instance, there are the polygons which have the property that the figure composed of any vertex and the two sides of the polygon which have that vertex as an end is congruent to any other such figure and also the polygons which are such that the figure consisting of any side and two adjacent angles of the polygon is congruent to any other such figure. These polygons have an even number of vertices and a circle is circumscribable about any of those of the former kind and inscribable in any of those of the latter.

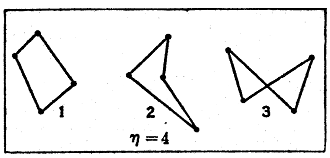

FIG. 2.— DEFORMATION OF A POLYGON OF FOUR VERTICES INTO THREE TYPES

Assuming the fact that the area of any plane simple polygon or rather polygonal region is the sum of the areas of the triangles of any finite set of triangles which have no interior points in common and which are such that every point of the polygonal region belongs to a triangle of the set or to the interior of one and every point of any triangle of the set or of the interior of any belongs to the polygonal region or its boundary the notion of the area of any plane unoriented or oriented polygon is approached. In the case of an unoriented or oriented polygon in general there is no region uniquely determined as in the case of simple polygons. In the following only the case of oriented polygons is considered for that essentially covers the case of unoriented polygons. If the area of a triangle according to the usual meaning is a then the area of that triangle with a sense assigned to it is defined as a or $-a$ according as that sense is positive or negative, *i.e.*, the same or not the same as the counterclockwise sense along the circumference of a circle. Using the symbol $A_1A_2 \dots A_n$ to denote

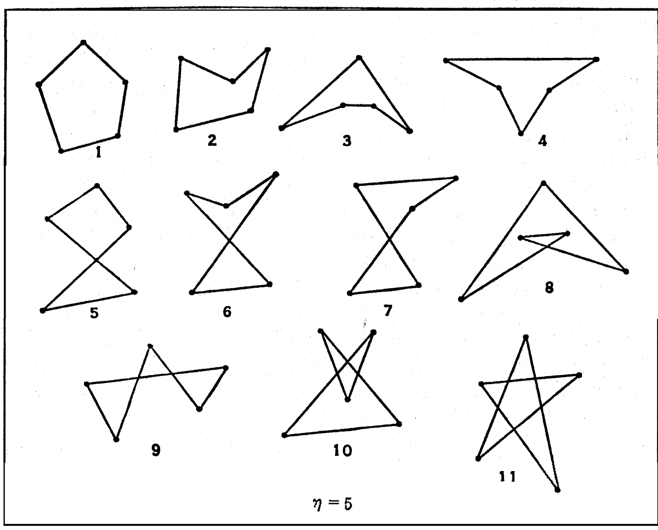

FIG 3 — DEFORMATION OF A POLYGON OF FIVE VERTICES INTO ELEVEN DIFFERENT TYPES

the oriented polygon with the vertices $A_1, A_2, \dots, A_n$ and the sensed sides A_iA_{i+1}, the area of the oriented polygon $A_1A_2 \dots A_n$ is defined as the sum of the areas of the oriented triangles $OA_1A_2, OA_2A_3, \dots, OA_nA_1$ where O is any point of the plane. It is, of course, proved that the value of the area thus defined does not depend on the position of O and that if $A_1A_2 \dots A_n$ is simple, this definition agrees with the area of a simple polygon according to the fundamental definition. An oriented polygon P determines a finite number of polygonal regions in its plane which have no points in common and whose boundaries are composed of points belonging to P. One and only one of these regions is of infinite extent. Now the following interesting facts pertain: Let the regions, or cells, of finite extent be denoted respectively by $S_1, S_2, \dots, S_k$, and let the area of the cell S_i according to the fundamental definition of the area of a polygonal region be σ_i so that σ_i is a positive number; then there exists a set of numbers $c_1, c_2, \dots, c_k$ which are either integers or zero such that the area of the oriented polygon P is $c_1\sigma_1+c_2\sigma_2+ \dots +c_k\sigma_k$. Further, c_i is the number of complete positive revolutions minus the number of complete negative revolutions made by the radius vector, having any point O of S_i as its initial point, as its terminal point describes once the oriented polygon P in the assigned sense. c_i is called the coefficient of the cell S_i.

POLYGYNY, the system under which a man is married to several women at the same time (Gr. πολύς, many, and γυνή, woman), popularly called polygamy (γάμος, marriage), which derivatively also includes the practice of polyandry. Polygyny is nowhere the exclusive form of marriage, and among most peoples who practise it the large majority of men live in monogamy. It may be modified in a monogamous direction both from the social and the sexual point of view. Very frequently one of the wives, generally the one first married, holds a higher position than the rest or is regarded as the principal wife. In some cases this position implies certain sexual privileges; but more often we are told that it is the custom for the husband to cohabit with wives in turn, or that this is actually required of him. Another matter is how far theory and practice coincide. We have reason to suspect that one of the wives is for a time the favourite.

Lower Culture Groups.—Among the uncivilised races polygyny does not seem to be practised on a large scale by any of the lower hunters and food-collectors, except some Australian and Bushman tribes, nor by any incipient agriculturists, at least among those of the lower type. On the other hand, a considerable number of these low hunting and slightly agricultural tribes—such as some of the South American Indians, the aboriginal tribes of the Malay Peninsula, most of the Andaman islanders, the Veddas of Ceylon, certain tribes in the Malay archipelago, most of the Negritos of the Philippine islands, and some at least of the Central African Pygmies—are represented as strictly monogamous. Among the higher hunters polygyny is more frequent, although in the majority of their tribes it is practised only occasionally; and exclusive monogamy is very rare, though perhaps not unknown. Among pastoral peoples there seems to be no one who can be regarded as strictly monogamous; and both among them and the higher agriculturists polygyny is undoubtedly more frequent than among the hunters and incipient agriculturists, although cases of regular monogamy are more frequent among the higher agriculturists than among the higher hunters. The cases in which polygyny is represented as "general" are comparatively much more numerous among African than among non-African pastoral peoples and higher agriculturists. Polygyny is at its height in Africa, both in point of frequency and in number of wives. King Mtēssa of Uganda and the king of Loango are said to have had 7,000 wives. This is apparently the high-water mark of polygyny anywhere.

Archaic Civilizations.— Polygyny, or a sort of concubinage hardly distinguishable from genuine polygyny, is found among most peoples of archaic civilization. In China there are, or have been, besides the legal principal wife, so-called wives "by courtesy" or lawful concubines. In Japan concubinage of the Chinese type existed as a legal institution until 1880. In ancient Egypt polygyny seems to have been permitted but to have been unusual, except in the case of kings. The Babylonian Code of Ḫammurabi assumes that marriage shall be monogamous; yet "if a man has married a wife and a sickness has seized her," he may take a second wife; and if she remained childless he might take a concubine. Among the Hebrews a man could in any circumstances have a plurality of wives, and there was no difference in the legal status of different wives, nor was there any limit to the number of wives a man might take. In Arabia Mohammed ordained that a man's legal wives should be not more than four. Polygyny has been permitted among many of the Indo-European peoples—among ancient Slavs and Teutons, the ancient Irish and the Vedic Indians—though it seems to have been as a rule confined to kings or chiefs or nobles. None of the Hindu law-books restricts the number of wives a man is allowed to marry; yet some preference is often shown for monogamy, and at the present day most castes object to their members having more than one wife, except for some cogent reason. On the other hand, there can be little doubt that monogamy was the only recognized form of marriage in Greece; concubinage existed in Athens, but it was well distinguished from marriage, conferring no rights on the concubine. Roman marriage was strictly monogamous; liaisons between married men and mistresses were not uncommon by the close of the Republic, but such a relation was not considered lawful concubinage in after-time.

Christian and Modern Times.—Polygyny has been found even in Christian Europe. No obstacle was put in the way of its practice by kings in countries where it had occurred in the times of paganism. In the middle of the 6th century Diarmait, king of Ireland, had two queens and two concubines. Polygyny was frequently practised by the Merovingian kings. Charlemagne had two wives and many concubines; and one of his laws seems to imply that polygyny was not unknown even among priests. In later times Philip of Hesse and Frederick William II. of Prussia contracted bigamous marriages with the sanction of the Lutheran clergy. In 1650, soon after the Peace of Westphalia, when the population had been greatly reduced by the Thirty Years' War, the Frankish *Kreistag* at Nuremberg passed the resolution that thenceforth every man should be allowed to marry two women. The Anabaptists and the Mormons have advocated polygyny with much religious fervour.

Causes.—One cause of polygyny is an excess of marriageable women; we may safely say that whenever there is a marked and more or less permanent majority of women in a savage tribe polygyny is allowed But while the existence of available women makes polygyny possible, the direct cause of it is generally the man's desire to have more than one wife. There are various reasons for this desire. Among many of the simpler peoples the husband has to abstain from his wife not only for a certain time every month, but during her pregnancy, or at least during the latter stage of it, and after child-birth until the child is weaned, which often means an abstinence lasting for a couple of years or more. Other causes of polygyny are the attraction which female youth and beauty exercise upon the men, the latter's taste for variety, their desire for offspring—which is one of the principal causes of polygyny in the East—and the fact that polygyny contributes to a man's material comfort or increases his wealth, and thereby also his social importance and authority, through the labour of his wives. The usefulness of wives as labourers partly accounts for the increasing practice of polygyny at the higher grades of economic culture. But it should also be noticed that economic progress leads to a more unequal distribution of wealth, and this, combined with the necessity of paying a bride price the amount of which is more or less influenced by the economic conditions, makes it possible for certain men to acquire several wives while others can acquire none at all.

POLYHEDRON: see SOLIDS, GEOMETRIC.

POLYMERIZATION, in chemistry, is the process whereby two or more atoms or molecules of the same substance unite to give a more complex molecule; the resulting "polymeride" therefore has the same percentage composition as the original substance, but a molecular weight which is 2, 3 or 4, etc., times as great. This is the sense in which the term was originally used (see the articles ISOMERISM and ASSOCIATION). But there is a tendency to restrict its use to cases in which the chemical and physical properties of the substance are altered in the process, the term association being conveniently applied to cases in which it has not hitherto been possible to distinguish clearly between the properties of the simple and the more complex substance. Moreover, once a substance has polymerized it is not readily reconverted to the simpler compound, whereas in association the two are in a constant state of change into one another, *i.e.,* they are in equilibrium. Water (*q.v.*) is undoubtedly a mixture of (probably) H_2O, $(H_2O)_2$, and $(H_2O)_3$ molecules which have not yet been obtained as separate liquids; it is therefore said to be associated. On the other hand when acetylene gas, C_2H_2, is passed through a red-hot tube, some of it is polymerized into liquid benzene, C_6H_6; or when the volatile, mobile liquid isoprene, C_5H_8, is warmed, or even kept for a short time, it polymerizes first to dipentene, $C_{10}H_{16}$, and then to a rubber-like substance, $(C_5H_8)_n$, of very high molecular weight (see TERPENES). In these two cases the properties of the polymerides are very different from those of the original substances, and separation of the two is easy. It should be emphasized, however, that there is no very clear line of demarcation between association and polymerization, and the distinction is chiefly one of convenience.

Cases of polymerization among inorganic substances are dealt with under the heading of ASSOCIATION, since it is only in a few cases, such as sulphur and phosphorus, that different polymerides, *e.g.,* S_4, S_6 and S_8, can be identified and shown to have different properties (*see* ALLOTROPY). The following examples are therefore restricted to organic compounds.

Formaldehyde (*q.v.*), CH_2O, a gas which is usually sold as a 40% aqueous solution ("formalin"), polymerizes to paraformaldehyde, probably $(CH_2O)_2$, when the solution is concentrated. When this is carefully heated it gives rise to trioxymethylene, $(CH_2O)_3$, a white crystalline solid which is also formed spontaneously and rapidly by anhydrous liquid formaldehyde when kept below its boiling point ($-21°$ C). Further, when formalin is kept with milk of lime at the ordinary temperature, it gradually changes to "formose," "methylenitan," or "a-acrose," a complex mixture of sugars of the formula $C_6H_{12}O_6$ or $(CH_2O)_6$. Acetaldehyde (*q.v.*), $CH_3{\cdot}CHO$, also gives rise to a number of polymerides, *e.g.,* (1) aldol, $CH_3{\cdot}CH(OH){\cdot}CH_2{\cdot}CHO$, which is produced by the action of dilute hydrochloric acid or of zinc chloride at the ordinary temperature, (2) paraldehyde, $(C_2H_4O)_3$, formed by the addition of one drop of concentrated sulphuric acid; it has a much higher boiling point than acetaldehyde (124° C as compared with 21° C), and is used as a soporific, (3) metaldehyde, also $(C_2H_4O)_3$, produced by the action of acids at low temperature, a crystalline solid which sublimes unchanged but is reconverted to acetaldehyde on long heating. *Acrolein,*

$$CH_2{:}CH{\cdot}CHO,$$

a volatile liquid, polymerizes slowly to disacryl, a white amorphous mass; or when warmed with alkalis it gives metacrolein, $(C_3H_4O)_3$, a solid melting at 45° C which is of use in the manufacture of synthetic resins (*q.v.*).

Cyanic acid, cyanamide and their derivatives furnish examples of ready and complex polymerization. The acid is $N{\vdots}C{\cdot}OH$ (or $HN{:}CO$), isomeric with fulminic acid ($C{:}N{\cdot}OH$); at ordinary temperatures its aqueous solutions rapidly give cyamelide, a white, porcelain-like insoluble mass. The esters of cyanic acid are unknown, but the isomeric isocyanic esters, *e.g.,* $CH_3{\cdot}N{:}C{:}O$, rapidly polymerize to isocyanuric esters

$$CO\left\langle\begin{matrix}N(CH_3)\cdot CO\\ N(CH_3)\cdot CO\end{matrix}\right\rangle N\cdot CH_3.$$

Cyanuric acid on distillation gives cyanic acid,

$$\begin{matrix} & N{=}C{\cdot}OH & \\ HO{\cdot}C & & N \\ & N{-}C{\cdot}OH & \end{matrix} \rightarrow 3N{\vdots}C{\cdot}OH,$$

and was the first polymeride to be investigated (Wohler). Cyanuric chloride is formed when cyanogen chloride is kept in a sealed tube: $3ClCN \rightarrow \begin{matrix}CCl{=}N{-}CCl\\ | \qquad\quad \|\\ N{=}CCl{-}N\end{matrix}$. Cyanamide, $CN{\cdot}NH_2$ or $NH{:}C{:}NH$, is converted into dicyandiamide, $HN{:}C\left\langle\begin{matrix}NH_2\\ NH{\cdot}CN\end{matrix}\right.$ on standing or on evaporation of its aqueous solution; either of these gives tricyantriamide, or melamine, $\begin{matrix} & N{=}C{\cdot}NH_2 & \\ NH_2{\cdot}C & & N \\ & N{-}C{\cdot}NH_2 & \end{matrix}$, on heating at 150° C. Further, just as acetylene gives benzene, so bromoacetylene, $CH{\vdots}CBr$, gives tribromobenzene, $C_6H_3Br_3$, but even more readily, since the change in this case occurs at the ordinary temperature. Many of the higher olefines (see CHEMISTRY, ORGANIC: Aliphatic *Division*) polymerize readily under the influence of dilute acids; thus *iso*amylene, C_5H_{10}, gives di- and tri-isoamylenes, $C_{10}H_{20}$ and $C_{15}H_{30}$. Esters of cinnamic acid slowly polymerize on keeping, but more rapidly in sunlight, to truxillic and truxinic esters:

$$2C_6H_5{\cdot}CH{:}CH{\cdot}CO_2Et \rightarrow \begin{matrix}C_6H_5{\cdot}CH{-}CH{\cdot}CO_2Et\\ | \qquad |\\ EtO_2C{\cdot}CH{-}CH{\cdot}C_6H_5\end{matrix} \text{ or } \begin{matrix}C_6H_5{\cdot}C{-}CH{\cdot}CO_2Et\\ | \qquad |\\ C_6H_5{\cdot}C{-}CH{\cdot}CO_2Et\end{matrix}$$

The foregoing examples illustrate the great variety of possibilities in polymerization. Many synthetic resins which are finding increasing industrial application, owe their characteristic properties to the fact that their high molecular weight is the result of polymerization. (A. D. M.)

POLYMETRYLENES: *see* CHEMISTRY: *Organic: Homocyclic Division.*

POLYNESIA, the easternmost of the three main divisions of the island groups of the South Pacific, the others being Melanesia and Micronesia (*qq.v.*). It includes the numerous groups and small islands situated south of the Equator and falling roughly between 170° E. and 110° W. longitude. The two islands of New Zealand are the largest and most important homelands of the Polynesians, other groups being the Hawaiian (U. S. A.), Society and Marquesas (French), Tonga, or Friendly islands (British), and Samoa (British and U. S. A.). For an account of the structure, geology, climate, flora and fauna and economic conditions of Polynesia, see the treatment of the various island groups under PACIFIC ISLANDS.

Ethnology. — The Polynesians are a Caucasian people, in contrast to the Negroid Melanesians, their island neighbours to the west, with whom they have intermingled to some extent. They are scattered over the widest expanse of free ocean in the globe; there are so few bits of land between Hawaii and New Zealand, between Easter island and Tonga, that navigators have crossed this wide body of water without seeing a trace of land. Brown in colour, with black hair, tall in stature, governed by chiefs in hereditary line through the father (in contrast to the matriarchal Melanesians), the Polynesians have been warlike and adventurous in their history, while at the same time responsive to foreign influence.

The origin of this Pacific island race has fascinated and perplexed students of ethnology, anthropology and archaeology. Only a people with considerable skill in navigation could have reached these islands; yet they have maintained through centuries a very primitive form of economy, without a trace of commercial intercourse or money.

The preponderance of scientific opinion is that the Polynesians migrated from Asia, not from the American continent. The absence of any trace, among the Polynesians, of the religions of the east indicates that the migration took place at a very early period. It seems probable that at some dim pre-historic time they practised a primitive form of "island hopping," moving from one new place of settlement to another in the large canoes which they are traditionally expert in operating until they found their present home in the eastern part of Oceania. There seems to be some reason to believe that Java was the home of these migrants for a time and that they were forced by Malayan invaders to seek a refuge farther east.

Traditions are still retained of a mythical land of the Polynesian forefathers, called Hawaiki (which can be linguistically connected with the word Java as we know it to-day), to which the souls of the dead return. Moreover, the peoples of all the important islands place to the west the locality whence the departed souls commence their journey. Research among the Nagas of Assam, and archaeological research by the French Colonial authorities in Cambodia indicated that there is a linking up with the immigrants, particularly with the Nagas, who apart from their stoneworking, practise many Polynesian customs. The massive stone ruins at Ponape in the Carolines (see MICRONESIA), which are a mystery in their own right, may indicate a stage in the long journey of the Polynesians over thousands of miles of ocean to their present homelands.

Physical Characteristics. — The Polynesians, with their simple outdoor life, often develop fine bodies and are almost always expert swimmers. They are taller than the Melanesians (except for the natives of Fiji, where there is some intermixture of the two races), with long, black hair and black, expressive eyes. Tattooing is much in vogue. The Polynesians attach great importance to the shape of the head, and the head of every baby is moulded into the desired form, flat-backed, dome-topped, sloping-browed and round, by means of a process of massaging. The nostrils are deliberately flattened, which is a tribute to the Negroid Melanesians and is a result of the frequent bringing back of Melanesian wives for the harems of the chiefs after raids on Melanesian islands. The Polynesians, especially the women, tend to become stout as they grow older; this is considered a desirable sign of beauty in a woman.

Religion. — The Polynesian religion, like the Melanesian, is simple and animistic, but is enriched with a larger number of imaginative myths. Survivals of sun worship are found in some of the islands, and this is considered an indication of the Indonesian origin of the natives. A fine wooden reproduction of Tangaroa, god of the sea, is preserved in the British museum, and the Polynesians also adored Ra, the sun god, and Io, the supreme being. However, these supreme deities are far away from the consciousness of the average Polynesian, who is more inclined to worship the spirits of departed chiefs and ancestors and natural objects in which supernatural power is supposed to reside.

Throughout the Pacific islands there is a general fear of the ***aitu,*** or supernatural beings, who are conceived as possessing some of the qualities both of gods and of ghosts. Every house has its ghost, and Polynesian folklore contains legends of mysterious lights at sea and of sirens who lure unwary youths to destruction. The souls of great men who have died are invoked by the living, and stones and trees are sometimes regarded as sacred and propitiated with offerings of fruit and pigs. In the past, human sacrifices were sometimes offered; but this practice disappeared as the Polynesians came under the rule of foreign powers.

Social Structure. — The Polynesians, in contrast to the Melanesians, displayed a considerable aptitude for social organization. The power of the chief, who is supposed to be in contact with the gods, is very great; in some of the larger islands the landowners constitute a kind of native nobility, while the practice of organizing castes or classes of hereditary carpenters, fishermen and persons engaged in other occupations is quite familiar. Foreign visitors to Polynesian islands are often impressed by the dignity and decorum with which general tribal assemblies are conducted. The liquid Polynesian language, with its many vowels, lends itself to oratory. This language is widely understood throughout Polynesia, while in Melanesia there is a babel of local dialects, people of one island often being unable to understand their neighbours on another.

The Polynesians were less addicted to cannibalism than the Melanesians, although this practice prevailed in the Marquesas islands and in New Zealand. The art of the New Zealand Maori wood carvers is the finest in the South Pacific. In the figure-heads and stern-pieces of the larger Maori canoes and sometimes in the lintels of the doors, one often finds delicate and refined open-work carving, consisting sometimes of tree-fern spirals, sometimes of interlacing human figures.

There are some remarkable stone ruins throughout Polynesia, and an elaborate system of drains was discovered in a swampy region of northern New Zealand. The Polynesians have long been acquainted with the art of working stones; the remains of huge sanctuaries and stone platforms have been found in Hawaii, the Society islands, Rarotonga and even on tiny Easter island. It is possible that the latter represents the remnant of a larger body of land that has been submerged in the ocean, since it is difficult to conceive how the necessarily small population of the present tiny island could have carried out such elaborate construction work. All these stone ruins convey the impression that Polynesia may have possessed a more numerous population and a more developed political and social organization in the past.

Polynesian daily life is strongly affected by the widespread practice of tabu (*q.v.*) which is so prevalent among primitive peoples all over the world. It is in the hands of the kings and priests. For instance, when Captain Cook wanted to set up an observatory on one of the islands, the priests made the proposed site tabu by waving wands over it.

Some chiefs in New Zealand are considered tabu, with the consequence that they must be fed, instead of feeding themselves, and in some Polynesian communities men are given this semi-sacred status. In Rapa, in the southern part of French Oceania, women are supposed to pop morsels of food into the mouths of the men, but are not permitted to eat with them, as this would be considered a profanation. Before 1819 it was an offense punishable with death for a woman in the Hawaiian group to join in the meal of male relatives.

Tongan Group. — This western outpost of Polynesia is one of the healthiest and most prosperous of the island groups. Elementary education was widely developed, and the people are noted for their comparatively high standard of intelligence. The Tongans are among the most daring navigators of Polynesia and have sent out migrants to

distant islands, such as Rotumah and Ellice, while storm-tossed Tongan canoes landed settlers and raiding parties in the outlying Solomons and New Hebrides. Tongan expeditions to Fiji for the purpose of obtaining wood foı war canoes were frequent in the years when there was no foreign authority to enforce law and order in the islands.

Declining Islands of Polynesia. — In some of the islands of French Oceania, especially in Tahiti and in the Marquesas group, one finds the spectacle, at once melancholy and curious, of a formerly virile and physically fit people wasting away and tending toward extinction. The native population of Tahiti, according to the census of 1911, was less than the number of warriors who turned out from two small districts at the time of Cook's second visit to that island. The physical deterioration after that time was also very marked.

There are two main causes for this decline in population (still more striking in the Marquesas islands than in Tahiti) and for the deterioration in health. Foreigners brought with them into these islands infectious diseases for which the natives possessed no immunity and to which they proved very susceptible. Measles, smallpox and phthisis carried out ravages.

Moreover, the deterioration had set in even before the coming of the foreigners brought the scourge of epidemics for which medical science provided remedies only slowly. The second important cause of the decline of some of the Polynesian islands was the indolence of the natives and the gradual evaporation of their vital energies. This indolence was promoted, because life on these islands, with their luxuriant tropical vegetation, could be maintained with extremely little physical effort. The breadfruit tree, which grows abundantly without artificial cultivation, provides the native with almost everything he needs for his simple food and clothing.

Tribal war was a former stimulus to action among the islanders of the South Seas. When war was repressed by the French authorities, the natives in the islands with the most abundant free food supply lost the last antidote to the life of complete sloth that atrophied all their vital faculties and led naturally to overwhelming decline of population through the double effect of a high death-rate and a low birth-rate. It is interesting to note that in the southern islands of French Oceania, where climatic and physical conditions make it necessary for the natives to work for a living, the symptoms of depopulation are absent.

Megalithic Remains. — There is a fascinating reflection of vanished empires, races and civilizations, in the great stone remains found sporadically all the way across the Pacific, from the islands near Japan to tiny Easter island, in eastern Polynesia. There is the deserted Venice of Ponape, there are the stepped pyramids of Samoa, Tonga and Tahiti, the *maraes*, or great stone temples of Rarotonga, the Marquesas and Pitcairn island, refuge of the mutineers against Captain Bligh of the "Bounty." The process reaches a climax in Easter island, which has been described as "the most astonishing collection of mortuary monuments in the world."

POLYNESIAN LANGUAGES, a general term for one branch of the great Oceanic family of speech, the other branches being Melanesian, Micronesian and Indonesian. These four divisions are so clearly marked off from each other and so definitely spring from one common parent that it is customary to refer to the individual languages of each group as mere dialects. The existing differences between the languages as we know them, however, are such as to justify the use of the term languages.

The principal members of the Polynesian group are (a) Samoan (probably the oldest form of Polynesian speech extant), (b) Maori, (c) Tahitian, (d) Hawaiian, (e) Tongan, (f) Mangarevan, (g) Nukuhivan (of the Marquesas Islands) and (h) the dialects of the Paumotu archipelago. From these main tongues dialects and sub-dialects have developed until Polynesia has almost a hundred variants of the original tongue.

Phonetics. — The Polynesian languages are amazingly rich in vowels with striking consonantal poverty. Although possessing only the five vowels *a, e, i,* o, *u,* in a short and long form the musical register of the Polynesian voice is so wide as to produce the illusion of numberless variants of these vowels. The *i* in particular is occasionally so shrill that no European can satisfactorily reproduce it.

The consonants are *k, t, p, s, (h), l, (v), ṅ, n, m,* f, *(v), (w).* No single Polynesian tongue contains all these consonants, those in parentheses being alternatives in some languages for the letter immediately preceding. Fakaafo is one of the richest of these tongues having *k, t, p, s, f,* v, *l, ṅ, n, m;* most of the others lack two or three of this number. Maori has, in addition, a compound or aspirated consonant *wh* which sounds very like an aspirated *v*, as in *whaka-*, the prefix of causative verbs. A tabular view of the phonetics of the chief Polynesian languages follows.

A. Vowels

Hawaiian	Fakaafo	Samoan	Tongan	Maori	Rarotongan	Mangareva	Paumotu	Tahiti	Nukuhiva
a, o	*a*	*a*	*a, e*	*(l, e*	*a*	*a*	*a*	*a*	*a, e*
e	*e*	*e*	*e*	*e*	*e*	*e*	*e*	*e*	*e*
i	*i*	*i*	*i*	*i*	*i*	*i*	*i*	*i*	*i*
o	*o*	*o*	*o*	*o*	*o*	*o*	*o*	*o*	*o*
u	*u*	*u*	*u*	*u, i*	*u*	*u*	*u*	*u, i, o*	*u, o*

Thus, *e, i,* and *o* are constant; *a* and *u* variable. But so jealously are vowel-values guarded by Polynesian speakers that these changes are constant within the bounds set by any particular language and it is possible for the speaker of one idiom to say definitely what form a word will take in another whose phonetic system he knows.

B. Consonants

Hawaiian	Fakaafo	Samoan	Tongan	Maori	Rarotongan	Mangareva	Paumotu	Tahiti	Nukuhiva
. .	*k*	. .	*k*	*k*	*k*	*k*	*k*	. .	*k*
k	*t*	*t*	*t*	*t*	*t*	*t*	*t*	*t*	*t*
p	*p*	*p*	*p*	*p*	*p*	*p*	*p*	*p*	*p*
h	*s*	*s*	*h*	*h*	. .	. .	*h*	*h*	*h*
h	*f*	*f*	*f*	*w, h*	. .	. .	*f, w*	*f, h*	*f, h*
w	*v*	*v*	*v*	*W*	*v*	*v*	*v, w*	*v*	*v*
l	*l*	*l*	*l*	*r*	7	7	*r*	*r*	7
ṅ	*ṅ*	*ṅ*	*ṅ*	*ṅ*	*ṅ*	*ṅ*	*ṅ*	. .	*ṅ, k, n*
n	*n*	*n*	*n*	*n*	*n*	*n*	*n*	*n*	*n*
m	*m*	*m*	*m*	*m*	*m*	*m*	*m*	*m*	*m*

Variability is much more frequent among the consonants than with the vowels, which are the backbone of Polynesian speech. *k* is constant except in Hawaiian, Samoan and Tahiti speech where it is replaced by a glottal check; *t* is constant except in Hawaiian where it becomes *k, e.g.,* Maori *taṅata,* a man, Hawaiian *kanaka,* Nukuhiva *kenata, enata.* P, *n* and *m* do not change at all and *l* and *r* appear alternately. The Samoan and Fakaafo *s* for *h* in the other languages, betrays the sibilant sound of h before a weak vowel (an analogy is found in Luchuan and Japanese *hito, fito,* pronounced *shto).* All the changes illustrated in the table are regular and very few exceptions are found.

Morphology. — Syllables in Polynesian tongues may begin with a consonant or a vowel but must always end in a vowel. From this it results that many vowels come together in words of several syllables; extreme cases are *hooiaioia, mou'a, kauikeaouli.* Here, however, each successive vowel is a syllable, there being no true diphthongs in these languages. There is no vowel elision, and the accent (penultimate), is very light, so that each syllable is clearly enunciated. But owing to the Polynesian distaste for consonants many homophones are created, mostly consisting of two vowels, *e.g.,* Nukuhivan *ua* means "rain," "two," "to heat," "lobster," etc., from elision, the original words being *uka* or *usa, rua, ura,* and *uka.* The genius of the language can be clearly seen from the borrowings from foreign languages, chiefly from English, *e.g.,* the word "quarter" appears as *tuafa,* "governor" as *tavana* or *kavana,* "doctor" as *taote,* etc.

In normal words, when compounds are made the accent shifts so as to fall still on the penultimate syllable, *e.g.,* Samoan, *áve* to give, *aveṅía* to be given; Hawaiian, *ldhe* to hear, *lohéa* to be heard. But there are exceptions to the rule of penultimate accent, which must be learnt by practice only; most of these, which are not numerous, arise from the difficulty of distinguishing between homophones or from the need of distinguishing a common word from one which has become *tapu* as the name of a chief or other prominent person.

One phenomenon of Polynesian speech deserves attention, viz., reduplication, complete or partial. Many new words are built up in this way and delicate nuances are conveyed by the doubling of a single syllable. In Maori *haere* conveys the idea "going," haerehaere means "roaming about, take a walk"; Samoan tufa, "divide," yields, *tufatufa,* "to split up into many pieces," etc.; Maori *inu,* "to drink" gives *iinu,* "to tipple, soak"; Tahiti parau, "to speak" gives *paraparau,* "to chatter"; from Tonga *nofo,* "to live" comes nonofu, "to live with someone." Adjectives are treated in the same way: Rarotongan nui, "big" gives *nunui,* "very big"; Hawaiian lii, "small," gives *liilii,* "very small."

Word-building is simple. From tama, "a child" and arzki, "a chief" is made *tamariki,* "a son" (lit. a princeling. noble child); from tanta, "a child" and *wahine,* "a woman," comes tantahine, "a daughter, a girl"; *uritaata,* "an ape" is made up of *uri,* "a dog," and taata, "a man."

The article differs from language to language; the indefinite article is usually identical with the numeral one, (sa, se). This is not used, however, unless absolutely necessary, although the definite article (Samoan, *o* le or *le;* Hawaiian, he; Maori, te; Tahiti, Rarotongan, Mangarevan, Nukuhiva e), usually appears before a noun. Maori has a plural article *ṅa* (nga), and the other languages have prefixes which mark the noun as plural although nouns undergo no change in form from singular to plural.

There are cases in the language marked by prefixes. The noun as agent is preceded by ko (*'o*), the genitive is occasionally still shown by position (as was the original method), although the prefixes *na, a, no, o* are now usually employed. The dative case is shown by a prefixed particle *ki* (before proper names and pronouns *kia*) and the accusative (when it is marked at all) is preceded by *i* or *ia.* The particle preceding the noun in the ablative case is e and in one or two languages there are other prefixes, but these do not actually form part of a genuine declension. The vocative case is marked by the syllable e preceding the name or noun.

The adjective suffers no change in any of the languages and it follows its noun except when it is used as a predicate when it precedes it; Samoan *laau* tele, "a big tree" When the adjective follows its substantive as attribute, the plural of the whole phrase is accomplished by the reduplication of the adjective: Maori, ika *pai,* "a good fish," ika *papai,* "good fish"; Hawaiian, hale *nui,* "a big house," *hale nunui,* "big houses."

The pronouns are complex in Polynesian speech, there being singular, dual and plural forms with inclusive and exclusive varieties. The normal forms are:—

	1st person	2nd person	3rd person
Dual (inclusive)	*ta-rua*	*ko-rua*	*ra-rua*
Dual (exclusive)	*ma-rua*	*mo-rua*	*ra-rua*
Plural (inclusive)	*ta-toru*	*ko-toru*	*ra-toru*
Plural (exclusive)	*ma-toru*	*mo-toru*	*na-toru*

These forms vary according to the dialect and the consonant-changes tolerated therein There are full and contracted forms for the possessive and demonstrative pronouns which are also complicated The interrogative pronoun serving many purposes is wai (Maori and Hawaiian); *vai* (Tahiti); *hai* (Tongan); and *ai* for the other dialects, used only for living things and for inanimate objects, aha (Maori, Hawaiian, Nukuhiva); *ha* (Tongan); aa (Rarotongan), and *ā* in the other tongues. There is no relative pronoun in any of the languages—either it remains unexpressed or a circumlocution is employed with the personal or demonstrative pronoun.

The Polynesian verb, like the noun and adjective, undergoes no change in form, and all moods and tenses are indicated by participles prefixed to the root form of the verb. The verb has no special form to distinguish it from other parts of speech and, indeed, many adjectives are used as verbs without change.

The passive voice is constructed from the active by the use of the participle prefix *ia* (hia, *lia, kia,* kina, *mia,* etc); the causative is similarly produced by the prefix fa'a (*whaka, ha'a,* aka, etc.). A desiderative is formed by the prefix *fia* (fie, *hia*), and one verbal suffix exists whereby a reciprocal form is made (-aki, *-faki, -laki, -taki, -raki*).

The present indicative is shown by the participle e or te, the future by a, and the preterite by *na.* The moods are few and vary greatly between the languages, the most common being ia (kia, ke) for the conjunctive: a, ka, kite, pea, poo, *ahiri, ina,* etc., for the conditional and *fau* (Tonga only) for the potential. The particle *ana,* a'a makes the participle.

Numerals

	Hawaiian	Fakaafo	Samoan	Tongan	Maori	Rarotonga	Tahiti	Nukuhiva
1	*kahi*	*tasi*	*tasi*	*tahu*	*tahi*	*tai*	*tahi*	*tahi*
2	*lua*	*lua*	*lua*	*ua*	*rua*	*rua*	*rua*	*ua*
3	*kolu*	*tolu*	*tolu*	*tolu*	*toru*	*toru*	*toru*	*tou*
4	*ha*	*fa*	*fa*	*fa*	*wa*	*a*	*ha*	*fa, ha*
5	*lima*	*lima*	*lima*	*nima*	*rima*	*rima*	*rima*	*ima*
6	*ono*	*ono*	*ono*		*ono*	*ono*	*ono*	*ono*
7	*hiku*	*fitu*	*fitu*		*witu*	*itu*	*hitu*	*fitu, hitu*
8	*walu*	*valu*	*valu*	*valu*	*waru*	*varu*	*varu*	*vau*
9	*iwa*	*ioa*	*iva*	*hiva*	*iwa*	*ioa*	*iva*	*iva*
10	*'umi*	*fulu*	*sefulu*	*hoṅofulu*	*ṅahuru*	*ṅauru*	*ahuru*	*onohuu*

The word for "five" (lima), is the general word for "hand" in Polynesia, the word for "ten" is borrowed from Malay *puloh* The identity between the words of the languages is rarely so close as it is with the numerals and a few terms of relationship The ordinal numbers are formed by placing the definite article before the cardinals, *e.g.,* Tahiti, *o te rima* (lit. "the five") "fifth"; Samoan, *o le lua,* "the second," etc.

Vocabulary.—The Polynesian tongues are rich in terms of relationship, in names of natural objects, fish, birds, plants, flowers and phenomena of nature, all the winds and zephyrs, all kinds of clouds, waves, streams, hills, shores and so on having special names. There is a shortage of abstract terms, metaphor is common, a concrete noun doing double duty. Maori and Samoan, however, in the philosophical chants (*see* POLYNESIAN LITERATURE) have developed a definitely abstract vocabulary There is a decided lack of direct, forceful words and in translation from European languages it is difficult to turn decisive phrases into Polynesian equivalents. The vocabularies suffice for all ordinary purposes and a little ingenuity often turns an English phrase into a telling South Seas equivalent.

POLYNESIAN LITERATURE. A few decades ago this title would have been deemed an anachronism, or worse, but since the publication of the Sacred Songs of the Hula by Dr. N. B Emerson under the title Unwritten Literature of Hawaii (1909), it has been generally conceded that the Polynesians, like other illiterate races, may have a literature in the truest sense of that term. The old Polynesian priests with their extraordinary memories held every word of the old traditions as flawlessly as papyrus or paper could have done; the proof of this lies in the presence, in texts taken down from native lips, of words so archaic that even the hierarchs have forgotten their meanings. It soon came to be realized that this wealth of literature was rapidly dying with the chiefs who were its last repositories, and numerous legends and collections of songs were taken down from the lips of the *kahuna* or sorcerers.

The literature of the Samoan islands is probably older than that of any other part of Polynesia and is wonderfully akin to the old Maori philosophical chants. *The* Creation Song in Samoan is not only interesting as folk-lore; it is a marvellously dignified piece of poetic literature. Long genealogies interspersed with legends of philosophic and historic import are now available in Roman script, providing much material for the study of the history and language-development of the Pacific islanders. Many migration songs and legends are known and there is still time to collect others. The whole text of the *'ava* ceremonial and similar ritual texts are now in our hands and there is reason to believe that a close study of others in process of being collected will prove of the greatest possible value in the solution of problems of migration and tribal mixing.

Maori literature is of two kinds, philosophic and traditional-historical. The Maori Chant of Eternity is, in places, identical with the Samoan Creation Song but has a definite individuality. Speculation on life and its problems appears in many of the legends centred round Maui, the great common Polynesian Ancestor, the Divine Angler, whose hook caught on the islands of New Zealand and brought them to the surface as an abode for his children. Hawaiki, that mysterious, far land, renowned in Polynesian song, is vaguely glimpsed, now as a paradise to which men's souls shall go, now as the Eden from which the ancestors of the singers emerged countless centuries before. The stories of the creation of the cosmos and its peopling are all before us in Maori speech, put together with a reverence and delicacy of phrase worthy of any literature.

Hawaiian literature is essentially romantic. The hula, a religious performance, was in its essence an ebullition of joyous animal-spirits, outflowing toward Nature. The "abandonment" seen by some in the dance and in the words of the songs is largely imaginary although it is undeniable that much of the *hula* and mele literature of Hawaii is made up of protracted double-entendres. In the Hawaiian one can observe a close love of nature through understanding; the trees wave in a warm breeze and the sunlight glints on azure waves because the singer is happy and because the gods are weaving anew their ancient spell of poetic song. Even the dread voice and searing tongue of Pele, the awful volcano-goddess, can be wooed by song and dance, to rest. The allusions in the songs and prose of Hawaii point to a long cultural experience and deep reverence for tradition. The lyrics of Hawaii rank high among the pure rhapsodies of the world.

The literature of other Polynesian islands is largely a repetition of that outlined above. The traditions of Tonga supply lacunae in the stories of Samoa and New Zealand and those of Tahiti supplement those of Hawaii and the Gambier islands. In all, however, they are distinctive songs and chants, as full of beauty as they are of scientific interest.

POLYNOMIAL, in elementary algebra, an expression composed of two or more terms combined by operations of addition or subtraction. Thus $\frac{1}{2}a+7b+c$ and $2+a-\sqrt{(\frac{1}{2}xy)}+z^2$ are polynomials. A polynomial of two terms is called a binomial, and one of three terms is called a trinomial. An expression consisting of a single term is called a monomial.

The word polynomial is often used with a more technical meaning, particularly in higher mathematics, to characterize the manner of dependence of an expression on one or more quantities regarded for the time being as independent variables. Importance attaches then to the nature of the operations performed on the variables, rather than to the number of terms, and monomial expressions of suitable form are admitted as special cases. Under this interpretation, which will be adopted throughout the rest of the article, a polynomial in one variable is a sum of terms, each consisting of a power of the variable multiplied by a coefficient independent of the variable, or, as an extreme case, a single such term; in a polynomial in several variables, each term contains a power of one of the variables or a product of powers of two or more of them. By a power in this connection is meant a power with exponent equal to a positive whole number or zero. The highest exponent that occurs, or, in the case of more than one variable, the highest value attained by the sum of the exponents in a single term, is the degree of the polynomial. Thus ax^2+bx+c is a polynomial of the second degree in x (if $a\neq 0$), and $x^5+3xy^2-8x^3y^4$ is a polynomial of the seventh degree in x and y. The latter is also said to be of the fifth degree in x, and of the fourth degree in y.

Having fundamentally a relative sense, the definition is applicable to characterize the manner of dependence on quantities which may themselves be more or less complicated expressions of any form. Thus ax^2+bx+c, $a(1+\sqrt{x})^2+b(1+\sqrt{x})+c$, $a/x^2+b/x+c$, $a(\log x)^2+b\log x+c$ are polynomials with respect to x, $1+\sqrt{x}$, $1/x$, and $\log x$ respectively, though the last three are not polynomials with respect to x; and ax^4+bx^2+c, a polynomial in x, can also be regarded as a polynomial in x^2. The sum, difference, or product of two *polynomials* is a polynomial; their quotient in general is not. Polynomials and quotients of polynomials are known collectively as rational *functions.*

In elementary algebra, expressions coming under the more technical definition of polynomials are studied largely in connection with the equations formed by setting them equal to zero. If $f(x)$ denotes the polynomial

$$a_0x^n+a_1x^{n-1}+a_2x^{n-2}+\dots+a_{n-1}x+a_n,$$

where $a_0\neq 0$, the equation $f(x)=0$ has n roots, $r_1, r_2, \dots, r_n$ (which may or may not be all different from each other); and then $f(x)$ can be factorized in the form

$$f(x)\equiv a_0(x-r_1)\ (x-r_2)\ \dots\ (x-r_n).$$

Thus every polynomial of the nth degree in a single variable can be resolved into n factors of the first degree. A corresponding resolution into factors of the first degree is not possible in general for polynomials in more than one variable. A polynomial (such as x^2+y) which cannot be expressed as a product of polynomials of lower degree is said to be irreducible. Every polynomial which is not itself irreducible can be resolved into irreducible factors, and apart from the order of the factors, and from factors which are merely constant, can be so resolved in only one way.

It is an important fact in trigonometry that the cosine of n times an angle, when n is a whole number, can be expressed as a polynomial of the nth degree in terms of the cosine of the angle itself; *e.g.,*

$$\cos 2x=2\cos^2 x-1,\ \cos 3x=4\cos^3 x-3\cos x,$$
$$\cos 4x=8\cos^4 x-8\cos^2 x+1.$$

The sine of nx can be expressed as the product of $\sin x$ by a polynomial of degree $n-1$ in $\cos x$; when n is odd, but not when n is even, it can also be expressed as a polynomial of the nth degree in $\sin x$; *e.g.,*

$$\sin 2x=2\sin x\cos x,\ \sin 3x=\sin x\,(4\cos^2 x-1)=3\sin x-4\sin^3 x.$$

The relation between algebra and trigonometry was emphasized by Vieta (1540–1603), who contributed largely to the advancement of both branches.

Analytic geometry is largely concerned with the geometric interpretation of the equations obtained by setting polynomials in the co-ordinates equal to zero. In the plane, an equation of the first degree, of the typical form $Ax+By+C=0$, represents a straight line; *i.e.,* if (x, y) are the rectangular co-ordinates of a point, all points whose co-ordinates satisfy the equation lie on a straight line, and all points of the line have co-ordinates satisfying the equation. The conic sections (*q.v.*),—ellipse, circle (which may be regarded as a special case of the ellipse), parabola, hyperbola (*qq.v.*), and certain "degenerate" forms (pairs of straight lines)—are represented by equations of the second degree, of the form

$$Ax^2+Bxy+Cy^2+Dx+Ey+F=0,$$

where in particular cases one or more of the coefficients may be equal to zero. Descartes (*Géométrie,* 1637) and his contemporary, Fermat, are regarded as the founders of analytic geometry (*q.v.*). The curves represented by equations of the third degree were systematically studied by Newton (1704). In three dimensions, an equation of the first degree, $Ax+By+Cz+D=0$, represents a plane, and one of the second degree a *quadric surface*—ellipsoid, sphere (a special case of the ellipsoid), hyperboloid (of one sheet or of two sheets), paraboloid (elliptic or hyperbolic), cone, cylinder (*qq.v.*), or, as a degenerate form, a pair of planes.

The theory of the transformation of homogeneous polynomials, or *forms* (see ALGEBRAIC FORMS) by linear substitutions in the variables, and of the invariants and covariants associated with such transformation, is an important branch of modern algebra with numerous applications. For example, if x, y in the polynomial $ax^2+bxy+cy^2$ are expressed, in terms of a new pair of variables u, v, by the relations

$$x=\alpha u+\beta v, \qquad y=\gamma u+\delta v,$$

where $\alpha\delta-\beta\gamma=1$, it is found that $ax^2+bxy+cy^2$ is identically equal to an expression of the form $Au^2+Buv+Cv^2$, in which $B^2-4AC=b^2-4ac$, a fact which is of fundamental significance in analytic geometry. More generally, for any values of a, β, γ, 6,

$$B^2-4AC=(\alpha\delta-\beta\gamma)^2\,(b^2-4ac).$$

The expression b^2-4ac, itself a polynomial in terms of the coefficients a, b, c, is called an *invariant.*

Polynomials in one variable are the simplest class of functions from the point of view of the calculus, because the rules for their differentiation and integration are particularly simple, and are obtained immediately from the definitions of these processes. The result of differentiating or integrating a polynomial with respect to its independent variable is always a polynomial.

In the modern theory of functions (see FUNCTION), any polynomial is a continuous and analytic function of its variables. If a function of a single complex variable z is analytic for every finite value of z, and becomes infinite when z, represented by a point in a plane, goes to infinity in an arbitrary manner, the function is necessarily a polynomial.

One of the chief investigators of the properties of polynomials during the 19th century was the Russian mathematician Chebichev (Tschebyschef) (1821–94). Among theorems discovered only recently may be mentioned (a) the one which states that, if a polynomial of the nth degree in x does not exceed a number L in absolute value for values of x in the interval from -1 to $+1$, the absolute value of its derivative can not exceed $nL/\sqrt{1-x^2}$ in the same interval (S. Bernstein, 1912), and (b) some results on the relation between the roots of a polynomial and those of its derivative in the complex plane (J. L. Walsh, Annals of Mathematics, 1920, and subsequent papers in the Bulletin and Transactions of the American *Mathematical Society*).

Applications.—Apart from their specific properties, polynomials are of fundamental importance from their use in the approximate representation of other functions. The standard functions of elementary analysis can be represented by power series (see SERIES), of the form

$$c_0+c_1x+c_2x^2+c_3x^3+\ldots \text{ (Maclaurin's series)},$$

or, more generally,

$$c_0+c_1(x-a)+c_2(x-a)^2+c_3(x-a)^3+\ldots \text{ (Taylor's series)},$$

which reduces to the preceding when $a=0$; the sum of an infinite series is by definition the limit approached by the sum of a finite number of its terms, as the number of terms is taken larger and larger, and the sum of a finite number of terms of a power series is a polynomial. Representation by power series can be made the basis for a systematic treatment of analytic functions of a complex variable. Another important form of development in series, theoretically applicable with greater generality, proceeds in terms of the polynomials of Legendre (1752–1833) or Legendre's coefficients. These may be defined as the coefficients of successive powers of r in the power series for $(1-2xr+r^2)^{-\frac{1}{2}}$. One of their most striking properties is that the product of any two of them, integrated over the interval from -1 to $+1$, gives zero. The theory of Legendre series is still under investigation. Approximations in terms of the polynomials of Hermite (1822–1901) are of importance in the theory of probability. Weierstrass (1885) proved that an arbitrary continuous function can be uniformly approximated by a polynomial with any assigned degree of accuracy.

The ordinary process of simple interpolation (*q.v.*), is equivalent to the replacement of the tabulated function by a polynomial of the first degree, over the interval in which the interpolation is performed. Formulae for interpolation by means of higher differences depend for their derivation on the fitting of polynomials of higher degree to the tabulated values. Formulae of numerical integration or *mechanical* quadrature likewise depend on the fitting of polynomial approximations. In connection with the use of polynomials for interpolation, it is an important fact that, if the values of a polynomial of the nth degree are tabulated for equally spaced values of the variable, the nth differences are constant. Consider for example the following table of values of the polynomial $y=x^2+7x+3$:

x = 0	y = 3		
		$\Delta y=8$	
1	11		$\Delta^2 y=2$
		10	
2	21		2
		12	
3	33		2
		14	
4	47		2
		16	
5	63		

The first column contains values of x, and the second, the corresponding values of y. The entries in the third column, obtained by subtracting each y from the following, are the first differences. The last column is made up of the differences of the first differences, which are called second differences, and in the present instance are all equal. It is clear that by means of this property the table could be continued further, without direct substitution in the original formula. (*See* CALCULUS OF DIFFERENCES.)

Smith, History of Mathematics (Boston, 1923); W. Le R. Hart, College Algebra (1926); L. E. Dickson, Modern *Algebraic* Theories (1926). (D. JA.)

POLYP, the name applied technically to an individual animal of given form, which is of frequent occurrence among those creatures known as the Coelenterata (*e.g.,* sea anemone, coral polyp, Hydra). The form of a polyp is outlined in the article COELENTERATA. (*See* also HYDROZOA; SCYPHOZOA; ANTHOZOA.)

POLYPHEMUS, the most famous of the Cyclops, son of Poseidon and the nymph Thoosa. Odysseus, having been cast ashore on the coast of Sicily, fell into the hands of Polyphemus, who shut him up with twelve of his companions in his cave and blocked the entrance with an enormous rock. Odysseus at length succeeded in making the giant drunk, blinded him by plunging a burning stake into his eye while he lay asleep, and with six of his friends (the others having been devoured by Polyphemus) made his escape by clinging to the bellies of the sheep let out to pasture. *See* CYCLOPES; ACIS; ODYSSEUS.

POLYPODIUM, an inclusive genus of ferns containing about 600 species, widely distributed throughout the world, but specially developed in the tropics. Sometimes it is divided into ten or more "natural" genera. The name is derived from Gr. πολύς, many, and πόδιον, a little foot, on account of the foot-like appearance of the rhizome and its branches. The species differ greatly in size and general appearance and in the character of the frond; the sori or groups of spore-cases (sporangia) are borne on the back of the leaf, are globose and naked, that is, are not covered with a membrane (*indusium*). The common polypody (P. *vulgare*), of Europe, Asia and western North America, is widely diffused in the British Isles, where it is found on walls, banks, trees, etc.; the creeping, densely-scaly rootstock bears deeply pinnately cut fronds, the fertile ones bearing on the back the bright yellow naked groups of sporangia. It is also known as adder's foot, golden maidenhair and wood-fern. There are a large number of varieties, differing chiefly in the form and division of the pinnae; var. *cambricum* (originally found in Wales) has the pinnae themselves deeply cut into narrow segments; var. serratunz has the pinnae serrate. Besides the well-known polypody of eastern North America (P. virginianum), very similar to the foregoing, several other species occur in the southern and western states.

POLYPUS, a term signifying a tumour which is attached by a narrow neck to the walls of a cavity lined with mucous membrane. (See TUMOUR.)

POLYTECHNICS. Polytechnic is a term used in modern phraseology to describe an educational institution equipped to teach many scientific and technological processes (Gr. πολυς, many, and τέχνη, an art). The word, however, has no common meaning either in Great Britain or in other countries. In France, the name *école polytechnique* was applied in 1795 to the École des Travaux publics, which had been founded by the National Convention a year earlier as a protest against the almost exclusive devotion to literary and abstract studies in places of higher education. The école polytechnique was devoted largely to the instruction of recruits for civil and military engineering, In Germany also, numerous technical colleges were founded for a like purpose. In Switzerland, the Zurich Polytechnikum has been provided by the Federal Government as an institution of university rank teaching commercial and industrial processes.

In London, the word polytechnic connotes an institution providing not only technological instruction in many forms, but also one which has definite social and civic ideals. In the report to the special committee on technical education of the London County Council in 1892 Llewellyn Smith (now Sir Hubert Llewellyn Smith, G.C.B.) defined a polytechnic institute in London as an "institute carrying out the double purpose of providing evening recreation and education for persons of both sexes engaged in industry in the day. Such of these institutes as already exist and others for which funds are now being collected are governed by, or for the most part conform to, certain schemes of the charity commissioners framed under the City Parochial Charities Act, and most of them are endowed to some extent out of the funds of the city parochial charities applicable under that act to the benefit of the 'poorer classes' of London." In other parts of England the term "polytechnic" is frequently used as an alternative title for a technical school; in Glasgow it is the name appropriated by a large and popular store or shop. In America the word is seldom used; for a discussion of American technical education see ENGINEERING EDUCATION and TECHNICAL EDUCATION.

The London Polytechnics. — The London polytechnics, with their distinctive purpose and organization, spring from the social ideals of Quintin Hogg, an old Etonian, who, in 1865, began classes for street urchins under the Adelphi arches by the side of the Thames. Later, in 1882, he purchased a disused building in Regent street which had been called the Polytechnic, and had enjoyed an ephemeral popularity as an institution for the exposition of Pepper's Ghost and other scientific novelties. This enterprise rapidly developed from an evangelistic effort into an educational institution which provided instruction in many subjects and promoted spiritual, intellectual, athletic and social ideals. In 1927 the Regent street polytechnic was attended by over 13,000 day and evening students, taught by 350 full-time or part-time lecturers and instructors, while its social activities covered athletics and social organizations of all kinds.

The success achieved by the Regent street polytechnic led to the formation of other institutions, which were also called "polytechnics." In 1878 a royal commission was appointed to report on the parochial charities of the City of London, as it appeared that by reason of the increase in the funds and the diminution or extinction of the objects of these charities the income was far more than sufficient to provide for all the proper objects of such charities. The outcome of the report was the City of London Parochial Charities Act, 1883. Among other things, the act provided that the charities in 107 parishes of the City of London should, after seven years, be administered by a corporate body (the trustees) of the London Parochial Charities. Schemes were drawn up for the utilization of the secular part of the income derived from the consolidation of the charities towards the establishment and maintenance of polytechnics and kindred institutions. Before handing over the funds to the trustees, the charity commissioners made certain capital grants out of the corpus of the charities. They also made offers of annual endowments for the establishment of institutions in a number of districts generally on condition that an amount representing approximately the capitalized value of the endowment offered was subscribed for capital purposes. Local committees were set up to secure the foundation of institutes in the various parts of London. Valuable sites were given by private benefactors and subscriptions were received from city companies, charities and other voluntary sources towards the cost of building. Altogether, including grants made by the charity commissioners and the trustees of the London Parochial Charities, over £500,000 was secured for capital expenditure while from 1900 to the present time the trustees of the London Parochial Charities have contributed over £1,000,000 towards the maintenance of the polytechnics.

The general aim of the polytechnic institutions may be stated briefly to be the promotion of industrial skill, general knowledge, health and well-being of young men and women belonging to the poorer classes by (1) instruction in the general rules and principles of the arts and sciences and the practical application of such rules and principles in any handicraft, trade or business; (2) instruction in such other branches and subjects of art, science, language, literature, general knowledge, as may be approved by the governing body; (3) instruction and practice in gymnastics, drill, swimming and other bodily exercises; (4) facilities for the formation and meeting of clubs and societies; (5) provision of library, museum and reading rooms.

The London County Council was empowered under the Technical Instruction Act, 1889, to give grants-in-aid to the polytechnics, and since then an increasing percentage of their revenue has been derived from public moneys. The passing of the Education Act, 1902, as applied to London by the act of 1903, has tended to diminish the distinction between the polytechnics, which are "aided" or partly supported by the London County Council, and other technical institutes which are "maintained" or entirely supported by the London County Council. The Education (Consolidation) Act, 1921, empowers the London County Council, in common with other local education authorities, to promote social and physical well-being and to co-ordinate all forms of education within its area. The social and recreative activities, a characteristic feature of the organization of the polytechnics, created by reason of the funds granted by the trustees of the London Parochial Charities, are likely, therefore, to be developed in other institutions. The distinction between a polytechnic and a technical institute is slowly becoming managerial rather than educational. The greater part of the expenditure of polytechnics is now met by a grant from the London County Council, towards which the Board of Education contributes 50%. Towards building and equipment the London County Council has, in the past, contributed over £600,000, while its maintenance grants to these institutions amount to nearly £350,000 a year.

The table on next page shows the chief polytechnic institutions in London and the number of students and gross expenditure of each polytechnic.

The expenditure is met by students' fees to the extent of 19%, by grants from the London County Council and Board of Education to the extent of 70%, and by income from other sources (including the City Parochial Foundation) to the extent of 11%.

Battersea, Chelsea, Northampton, Northern and Woolwich polytechnics, together with the City of London college and Sir

	No. of students, 1927	Gross expenditure, 1927

Woolwich polytechnic . . .	2,440	44,880

John Cass Technical institute, present students for the internal degree examinations of the University of London, certain members of the teaching staff ranking as recognized teachers of the university. The subjects taught embrace the chief technological and commercial processes required for industrial and scientific processes in the London trades, varied according to local requirements. Careful attention has been given by the London County Council to secure that in the larger polytechnics and technical institutes there should be an organized concentration of effort; that an institution whose circumstances were such that it could with advantage, for regional or other reasons, specialize in branches of instruction affecting one trade or group of trades should seek development in the direction suitable to it, rather than indulge in competition in other directions in which adequate provision is made by another institution. In accordance with these principles the governing bodies have accepted suggestions from the London County Council involving important revisions in the educational programmes of the different institutions. Evening classes for commercial instruction have, in many cases been transferred to the council's evening institutes. Various branches of technology and art have been concentrated at certain institutions, and secondary schools previously housed in certain polytechnics have, with one exception, been removed.

Most of the polytechnics have now developed characteristic features. Battersea polytechnic has important departments of engineering and chemistry and also a training college for domestic science teachers. The Borough polytechnic has achieved notable success in the training of the artisan; it also conducts an important school of bakery and confectionery in co-operation with the National Association of Master Bakers and Confectioners. At the Chelsea polytechnic there is a natural science department and a chemistry department (including a school of pharmacy); there is also a training college for physical education. The City of London college deals exclusively with commercial studies and the marketing of commodities. Engineering, telegraphy and telephony, aeronautics and technical optics are taught at Northampton polytechnic. The Northern polytechnic has an important architectural and building department and also gives instruction in the rubber and musical instrument trades.

The programme at Regent street polytechnic embraces a wide field of activity and includes important departments of architecture, art, chemistry, commerce, engineering, modern languages, photography, carriage and motor-body building, hairdressing and tailoring; a large secondary school for boys is also conducted at the polytechnic. There is an important chemistry department at the Sir John Cass Technical institute and among the special features are classes in petroleum technology and the fermentation industries. Engineering is the foremost subject of instruction at the Woolwich polytechnic, and special courses are held for apprentices at the Royal Arsenal. Provision was made under the original schemes of the Charity Commission for the erection of the North-Western polytechnic in Kentish Town. Owing to the delay in securing the site and later owing to war difficulties, building operations for the erection of this polytechnic were only commenced in 1927. The building is now nearing completion and the polytechnic will be opened in 1929. Birkbeck college was connected with the polytechnic movement, but this connection ceased in 1920, when the college became a School of the University of London, in the Faculties of Arts and Science, for evening and part-time students. (G. H. GA.)

POLYTONALITY, a comparatively recent addition to musical terminology, signifying the simultaneous employment of conflicting keys. (See HARMONY; KEY.)

POLYXENA, daughter of Priam and Hecuba. The shade of Achilles appeared to the returning Greeks in the Thracian Chersonese and demanded Polyxena, who was put to death on his tomb. As a prominent leader he claimed a prominent female prisoner for his share of the booty, as Agamemnon did Cassandra (*q.v.*). Hence, in Philostratus, Dictys and other late authors, the story of a romantic affection between Achilles and Polyxena.

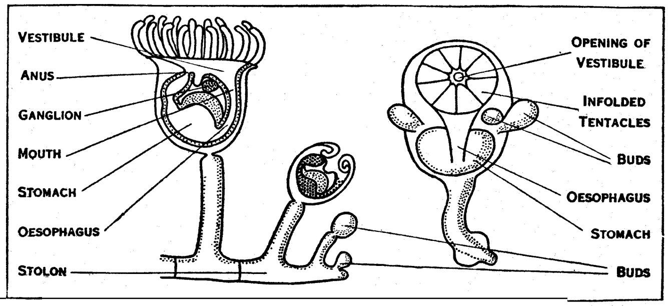

FIG. 1.—ENTOPROCTA; SHOWING PEDICELLINA ON LEFT, AND LOXOSOMA ON RIGHT

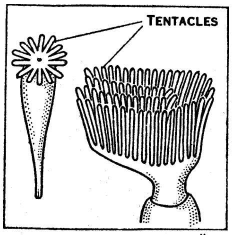
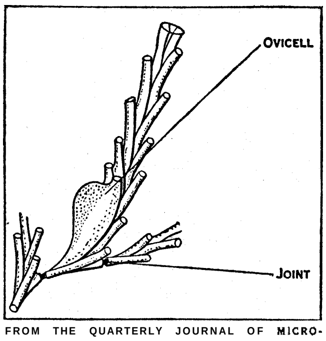
POLYZOA. A group of animals so called from the fact that numerous individuals, formed by budding, remain united in a colony. They were mostly included in the Zoophyta of the older naturalists, in consequence of their plant-like appearance, a feature which is emphasized in their alternative name, Bryozoa, or moss-like animals. They are here regarded as a primary group of invertebrates, although they have been placed with the Brachiopoda in a larger group, hfolluscoidea—an association which rests on insufficient evidence. Certain characters of their larvae suggest that they may be distantly related to the Mollusca and Rotifera. They are pre-eminently marine, but a small proportion are confined to fresh water. A colony may have a diameter of a foot, but this size is exceptional in recent forms; and in many cases the longest measurement does not exceed an inch, the individuals ("zooecia") being commonly less than a millimetre long. The walls are generally stiffened with calcareous matter, and the Polyzoa are accordingly represented by numerous fossil species. It is probable that as their study advances they will take an increasingly important part in the determination of the geological age of strata. They may be defined as aquatic animals, forming colonies by budding, with ciliated tentacles which can be infolded or retracted into a depression of the body-wall, with a U-shaped alimentary canal and a ganglion lying between the mouth and anus. Specific excretory organs are found in the Entoprocta alone.



FROM KRAEPELIN, "DIE SÜSSWASSER BRYOZOEN IN ABHANDLUNGEN AUS DEM GEBIETE DER NATURWISSENSCHAFTEN" (FRIEDERICHSEN, DE GRUYTER)

FIG. 2.—ECTOPROCTA Left, Gymnolaemata (*Paludicella*), right, Phylactolaemata (*Lophopus*)



FROM THE QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE

FIG. 3.—CYCLOSTOMATA (CRISIA), AFTER HARMER

Classification.—Sub-class I. Entoprocta.—Lophophore (the part bearing the tentacles) circular, including both mouth and anus. Tentacles infolded, during retraction, into a "vestibule," which can be closed by a circular muscle. Body-wall not calcified, body-cavity absent. Definite excretory organs present. Reproductive organs continuous with ducts, which open into the vestibule.

Loxosoma (fig. 1), marine, is unique among the Polyzoa in the fact that the colony consists merely of a single individual, with its system of buds, which are produced in two series, each bud breaking off on reaching maturity. It is of minute size, and nearly always occurs on other animals, Sponges, Polychaet and Sipunculid worms, Ascidians or even Polyzoa. As in other Entoprocta, the individual consists of a muscular stalk bearing a "calyx" or body, which contains the viscera and bears the tentacles. *Pedicellina* (fig. 1), marine, has the individuals arranged in a linear series on an attached, narrow "stolon." The calyces are deciduous and can be regenerated, a process analogous to the formation of "brown bodies" in the Ectoprocta. *Urnatella,* a fresh water species.

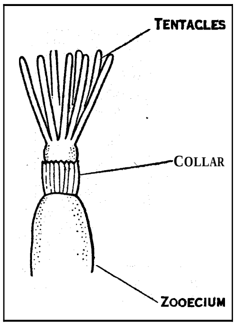


FIG. 4.—CTENOSTOMATA, (BOWERBANKIA)

Sub-class II. Ectoprocta.—Lophophore circular or shaped like a horseshoe (fig. 2), including the mouth but not the anus. Tentacles retractile into a delicate, flexible "introvert" ("tentacle-sheath") of the body-wall (fig. 6). Remainders of the body-wall membranous or calcified, the body-cavity spacious, containing the reproductive organs, which are not continuous with ducts. Specific excretory organs absent. Zooecia usually closely apposed to their neighbours, with which they are in organic connection by means of threads of living tissue, traversing "communication-pores" in the separating walls. There is naturally no evidence as to the anatomy of the two exclusively fossil Orders.

Tribe I. Gymnolaemata. Lophophore circular (fig. z), without an "epistome" or lip. Body-cavities not continuous with one another, body-wall not muscular.

Order 1. Trepostomata. Fossil, Palaeozoic. Zooecia long, coherent, their cavity traversed by many transverse partitions, which become more numerous near the terminal orifice. Surface of colony with regularly distributed elevations or "monticules." The reference of these organisms, which include the Rfonticuliporidae, to the Polyzoa has been disputed, but the characters of the primary individual of the colony are in favour of this association.

Order 2. Cryptostomata. Fossil, Palaeozoic. Zooecia usually shorter than in the Trepostomata, sometimes with transverse partitions. Orifice at the bottom of a vestibular shaft, which may be traversed by diaphragms. This order, which includes the net-like Fenestellidae, has been regarded by palaeontologists as ancestral to the Cheilostomata.

Order 3. Cyclostomata. Zooecia elongated, prismatic or cylindrical (fig. 3), with terminal, typically circular orifice, of the full width of the tubular part. The ovicells are modified, greatly enlarged zooecia, and, in the recent species investigated, contain numerous embryos, produced by the division of a single, primary embryo. The polypide is protruded with the aid of a "membranous sac," which surrounds it. The Cyclostomata are known from early Palaeozoic strata (Ordovician) onwards and are represented in the Cretaceous by specially numerous species; their highly calcareous zooecia being well preserved as fossils. They form a comparatively small proportion of the recent marine fauna, in which *Crisia, Tubulipora, Idmonea, Entalophora, Hornera* and *Lichenopora* are represented by many species.

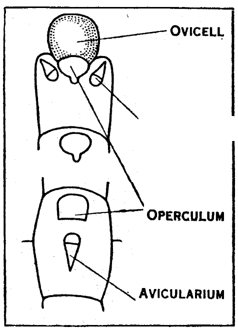

FIG. 5.—AVICULARIA AND OVICELL OF ENCRUSTING CHEILOSTOMATA

Order 4. Ctenostomata. Walls soft and uncalcified, the orifice being closed by a membranous "collar" (fig. 4), with folded walls, which surrounds it. Encrusting or erect and broadly lobed, the zooecia connected with one another (*Alcyonidium, Flustrella*); or erect and delicate, the zooecia arising separately from a connecting stem (*Amathia, Bowerbankia*). The preceding are marine, but *Victorella* and Paludicella, belonging to the second group, occur in fresh water. Certain Palaeozoic fossils (*Rhopalonaria, Vinella*) have been referred to this order.

Order 5. Cheilostomata. Much or little calcified, the orifice closed by a chitinous operculum (fig. 5). Polymorphism usually occurs, certain individuals being modified as "avicularia" or "vibracula." A prominent, globular "ovicell" is commonly found at the distal ("upper") end of the fertile zooecium, serving as an external brood-cavity in which an egg develops. This order is first known in the Mesozoic period (Jurassic), but its species become extremely numerous in the Cretaceous. In the Tertiary period, as at present, it is the dominant group of Polyzoa, chiefly marine but occasionally found in brackish water. Representative genera are: *Membranipora, Flustra, Onychocella, Cellaria, Scrupocellaria, Bugula, Schizoporella, Retepora, Cellepora.*

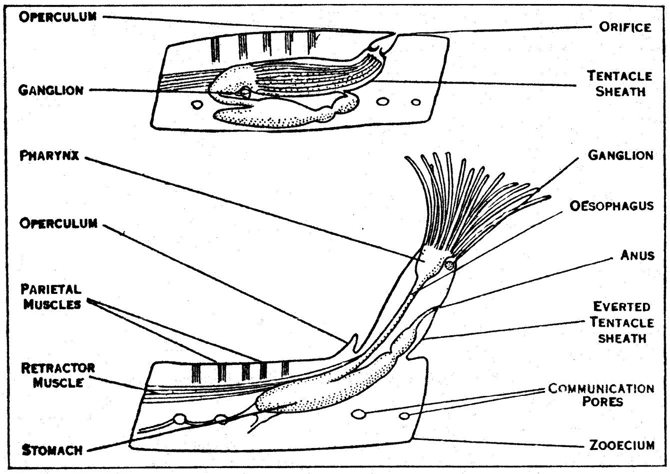

FIG. 6.—CHEILOSTOMATA ANASCA (ELECTRA), SHOWING ABOVE, POLYPIDE RETRACTED; BELOW, POLYPIDE EXPANDED

Tribe II. Phylactolaemata. Lophophore horseshoe-shaped (fig. 2), except in *Fredericella,* the mouth guarded by a lip or "epistome." Body-wall muscular, uncalcified, the body-cavities continuous with one another. Reproduction sexual and by means of "statoblasts" (fig. 12), internal buds protected by a chitinous shell. Fredericella, *Plumatella, Lophopus, Cristatella.* The colony can move slowly from place to place in the last two.

Structure of Ectoprocta.—The colony may assume several distinct forms: (*a*) Encrusting, the zooecia in close contact with one another, usually in a single layer, attached to a stone or seaweed by the basal surface, the orifices on the exposed or "frontal" surface, sometimes becoming multilaminar by the addition of new layers, each of which completely covers its predecessor, sealing the orifices; (b) erect, with broad lobes or branches, unilaminar or bilaminar, the zooecia correspondingly opening on one or both surfaces. Both these conditions are found in *Flustra* and its allies, in which there is little calcification and the branches are flexible. Retepora is a highly calcified unilaminar type, the branches of which form an elegant network. In other genera the branches are cylindrical, the orifices arranged all round the curved surfaces; (c) erect and more slender, resembling Hydroids, mostly unilaminar or with cylindrical branches, often with flexible joints; (d)

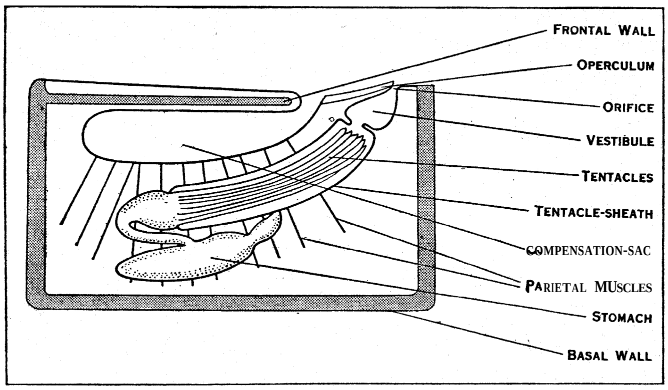

FIG. 7.— CHEILOSTOMATA ASCOPHORA, ILLUSTRATING THE METHOD OF PROTRUSION OF THE POLYPIDE

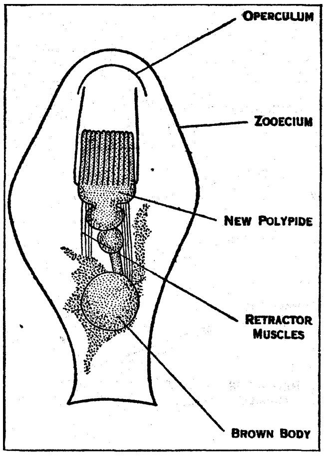
not rigidly attached, unilaminar, discoidal or conical.

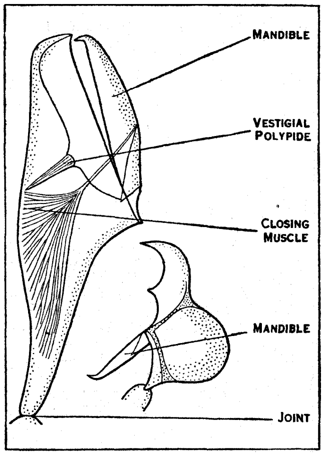
The zooecium of the Cheilostomata (fig. 6) resembles a shallow box, having the "orifice" near the distal end, the one further from the base or commencement of the colony. The orifice is the external opening of a thin-walled "tentacle-sheath," really a flexible, uncalcified part of the body-wall, pushed into the body-cavity. The tentacles arise from the blind end of the retracted sheath; and these parts, with the U-shaped alimentary canal and the nerve-ganglion which lies between the mouth and anus, constitute the "polypide." Retraction of the tentacles takes place rapidly by means of retractor muscles, but protrusion is a more gradual process and is effected by "parietal muscles," the contraction of which increases the fluid pressure in the body-cavity and forces out the tentacles. Some part of the body-wall must accordingly be flexible, and in the division Anasca (fig. 6) this is the whole or part of the frontal surface. In the Ascophora (fig. 7) most of the frontal wall is calcified and rigid, but the part which lies on the proximal side of the operculum has been pushed in as a very delicate "compensation-sac," into the basal wall of which the parietal muscles are inserted. The contraction of these muscles dilates the sac, into which water enters from the outside, and the mechanism of protrusion is thus the same as in the Anasca In the erect Ctenostomata the whole body-wall is flexible, and the parietal muscles produce their effect by passing from one part of it to another, across the body-cavity. In the Phylactolaemata the flexible body-wall is itself muscular. The calcareous Cyclostomata have a special, rather complicated arrangement for protrusion (see Borg, 1926).



FROM THE "QUARTERLY JOURNAL OF MICROSCOPIC SCIENCE"

FIG 8.—CHEILOSTOMATA; REGENERATION OF THE POLYPIDE (CARBASEA), AFTER HARMER

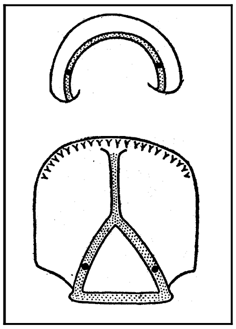
Regeneration of the **Polypide.**—The duration of life of the polypide does not correspond with that of the zooecium, which has a succession of polypides. This curious fact is probably the result of the absence of definite excretory organs, the function of which seems to be performed largely by the stomach. The wall of this organ becomes charged with brown granules (probably excretory), and after a time the entire polypide degenerates, decreasing in size and ultimately becoming a small, rounded "brown body" (fig. 8). which owes its colour to these granules The substances of nutritive value have probably been absorbed, for future use, by the cells which surround the degenerating polypide. An internal polypide-bud is simultaneously developed, and in some species its stomach envelopes the brown body, which passes into its cavity and is rejected with the faeces. In other cases the brown body remains as an inert mass in the zooecium, and the occurrence of several brown bodies indicates a corresponding number of degenerated polypides.



AFTER HARMER

FIG. 9.—CHEILOSTOMATA; LEFT, STALKED AVICULARIA OF CORNICOPINA, RIGHT, OF BUGULA

Polymorphism. — In the majority of Cheilostomata, certain zooecia have merely a vestige of a polypide, and the operculum, now known as the "mandible," and its muscles become modified for prehension. These units are known as "avicularia," from their resemblance to the head of a bird, in *Bugula* (fig. g) and other genera in which they attain their highest development. The avicularia may be "vicarious," in series with the zooecia, which they may surpass in size, the mandibles being often much larger than the opercula (fig. 10); or they are "adventitious" (fig. j), when they occur as appendages of ordinary zooecia. They are either "sessile," closely attached to the zooecia (fig. 5) or stalked (fig. g), and they show a wide range of form, in different species The "vibracula" (fig. 11), which are found in a small number of Cheilostomata, have the operculum transformed into a long "seta," which sweeps through the water. In Caberea the vibracula of a branch have been observed to move in unison, but this is exceptional. The avicularia and vibracula appear to be defensive organs, and they doubtless ward off the attacks of some predacious animals. They probably prevent the overgrowth of the colony by encrusting organisms, by discouraging the attachment of larvae, and they may also serve to keep the colony clean, by dislodging foreign particles which might otherwise settle on it.



AFTER HARMER

FIG. 10.—CHEILOSTOMATA (STEGANOPRELLA) Above, operculum, below, mandible of avicularium

Reproduction. — The reproductive organs occur in the body-cavity in Ectoprocta; and organs of both sexes may be produced by a single zooecium, simultaneously or successively. The colony seems to be generally bisexual, even when testes and ovaries are found in different zooecia. The ciliated larvae, in this group, rarely possess an alimentary canal. If this is present they are known as *Cyphonautes,* a common constituent of the floating fauna, especially of coastal waters. If it is absent the tissues are charged with nutritive yolk. In either case, the larva attaches itself, loses its larval organs and becomes the "ancestrula" or first zooecium of the colony, developing a polypide as an internal bud. The ancestrula buds off other zooecia, which repeat the process, thus building up the colony; and the zooecia develop their polypides in the same way as the ancestrula. In species with a *Cyphonautes* the egg develops in the water, but in most cases it develops in the parent colony. The characteristic "ovicells" of Cheilostomata (fig. 5) are external brood-spaces into which the egg passes when it is laid, and are formed in part by the distal end of the fertile zooecium, but principally by the frontal surface of the succeeding zooecium The egg passes from the body-cavity to the exterior (in the few cases where the process has been observed) through the "intertentacular organ," a ciliated tube between the bases of the two tentacles nearest the anus, or through a pore found in the same position. The Cheilostome ovicell nearly always contains a single egg, but in the Cyclostomata the ovicell (fig. 3) contains very numerous embryos, which have been produced by the fission of a primary embryo, developed from an egg In Phylactolaemata the polypide is produced by the larva while it is still free, several polypides occurring in *Cristatella* before the larva attaches itself. Another form of reproduction is found in this group, where the zooecium produces internal buds from the "funiculus," a cord connecting the blind end of the stomach with the body-wall These special buds are known as "statoblasts" (fig 12), and each is protected by a strong chitinous shell, the outer part ("annulus") of which is modified as a ring containing air-

POMBAL, SEBASTIÃO JOSE DE CARVALHO E MELLO, MARQUESS OF (1699–1782), Portuguese statesman, was born at Soure near Pomba, on May 13, 1699. In 1739 he was sent as Portuguese ambassador to London, where he remained until 1745. He was then transferred to Vienna. In 1749 he took up the post of secretary of state for foreign affairs and war. Though he came into power only in his 51st year, without previous administrative experience, he was able to reorganize Portuguese education, finance, the army and the navy. He also built up new industries, promoted the development of Brazil and Macao. and expelled the Jesuits. His complete ascendancy over the mind of King Joseph dates from the time of the great Lisbon earthquake (Nov. 1, 17jj). In Sept. 1770 he was made marquess of Pombal.

Soon after the death of King Joseph, in 1777, Pombal was dismissed from office; and he was only saved from impeachment by the death of his bitterest opponent, the queen-mother, Mariana Victoria, in Jan. 1781. On Aug. 16, a royal decree forbade him to reside within 20 leagues of the court. He died at Pombal on May 8, 1782.

See in addition to the works dealing with the period 1750–77 and quoted under PORTUGAL: *History;* S.J.C.M. (Pombal), *Relação abreviada,* etc. (Paris, 1758); *Memoirs of the Court of Portugal,* etc. (1765); *Anecdotes du ministère de Pombal* (Warsaw, 1781); *Administration du marquis de Ponzbal (4* vols., Amsterdam, 1787); *Cartas . . . do marques de Pombal* (3 vols., Lisbon, 1820–24); J. Smith, Count of Carnota, *Menzoirs of the Marquess of Pombal,* etc. (1843); F. L. Gomes, *Le Marquis de Pombal,* etc. (1869); B. Duhr (S.J.), *Pombal,* etc. (Freiburg im Breisgau, 1891); C. POMEGRANATE. Throughout the orient this fruit has since earliest times occupied a position of importance alongside the grape and the fig. It is produced by a bush or small tree, *Punica granatum,* only member of the family Punicaceae.

King Solomon possessed an orchard of pomegranates; and when the children of Israel, wandering in the wilderness, sighed for the abandoned comforts of Egypt, the cooling pomegranates were remembered longingly. Centuries later, the prophet Mohammed remarked sententiously: "Eat the pomegranate, for it purges the system of envy and hatred." It will thus be seen that this fruit is of exceptional interest because of its historic background.

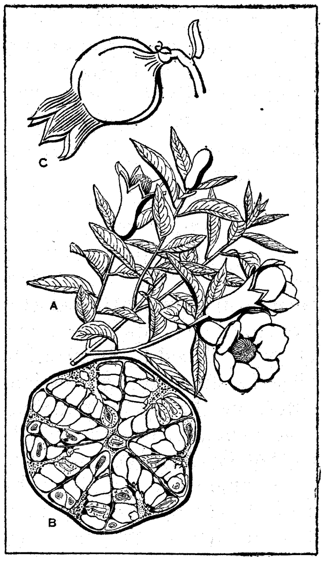
While the pomegranate is considered to be indigenous in Persia and perhaps neighbouring countries, its cultivation long ago encircled the Mediterranean and extended through Arabia, Afghanistan and India.

There is something in the character of the juicy subacid pomegranate which makes it particularly agreeable to inhabitants of hot arid regions — which are precisely those in which it attains its greatest perfection.

The ancient Semitic name rimmon was adopted by the Arabs as *rumman,* from which the Portuguese in turn formed *romão* or roman. From the early Roman names *malum punicum* (apple of Carthage) and *granatum* have come the modern botanical binomial and the common name *granada,* used in Spanish-speaking countries.

The plant, which may attain 15 or 20 ft. in height, has elliptic to lanceolate bright green leaves about 3 in. long, and handsome axillary orange-red flowers borne toward the ends of the branchlets. The calyx is tubular, persistent, 5- to 7-lobed; the petals lanceolate, inserted between the calyx-lobes. The ovary is embedded in the calyx-tube and contains several locules in two series, one above the other.

The fruit is the size of an orange and often larger, obscurely six-sided, with a smooth leathery skin which ranges from brownish yellow to red in colour. Within it is divided into several cells, containing many thin transparent vesicles of reddish juicy pulp, each surrounding an angular elongated seed. A ripe pomegranate has a delightful subacid flavour.



POMEGRANATE (PUNICA GRANATUM), A. BRANCH WITH FLOWERS. B. TRANSVERSE SECTION THROUGH FRUIT SHOWING SEEDS, C. YOUNG FRUIT

Presumably the plant was introduced into the new world by the early Spanish colonists. It is commonly cultivated in gardens from the warmer parts of the United States to Chile. Small commercial plantings have been made in California. Though it will grow in a wide range of climates, good fruit is produced only where high temperatures and dry atmosphere accompany the ripening period. Deep, rather heavy loams are probably the best soils. Propagation is effected by seeds, cuttings and layers: the first-named can readily be grown, but choice varieties cannot be reproduced in this manner. Commercial propagation is by hardwood cuttings 10 to 12 in. long, which can be rooted in the open ground.

The varieties of the pomegranate are numerous. Ibn-al-Awam, a Moor who wrote in the 13th century, described some ten which were grown in southern Spain at that time. The three leading ones which have been cultivated commercially in the United States are Wonderful, Paper-Shell and Spanish Ruby. There are also dwarf forms which produce fruit of no value but are grown for their handsome scarlet flowers. (W. Po.)

POMERANIA (German, Pommern), a territory of Germany and a maritime province of Prussia, bounded on the north by the Baltic, on the west by Mecklenburg, on the south by Brandenburg, and on the east by Poland. Its area, with the border province (Grenzmark Posen-Westpreussen), is 14,870 sq.mi. and the population in 1939 was 2,405,048, showing a density of 162 inhabitants to the square mile. Pomerania is one of the flattest parts of Germany, although east of the Oder it is traversed by a range of low hills, and there are also a few isolated eminences to the west. Off the west coast, which is very irregular, lie the islands of Rügen, Usedom and Wollin; the coast of Farther Pomerania is smooth in outline and is bordered with dunes, or sandbanks. Besides the Oder and its affluents, the chief of which are the Peene, the Ücker and the Ihna, there are several smaller rivers flowing into the Baltic; a few of these rivers are navigable for ships, but the greater number only carry rafts.

The soil of Pomerania is for the most part thin and sandy, but patches of good land are found here and there. The principal crops are potatoes, rye and oats, but wheat and barley are grown in the more fertile districts; tobacco, flax, hops and beetroot are also cultivated. Horses for farmwork, sheep for both wool and mutton, cattle, pigs, geese (for flesh and feathers) are features of local agriculture. Owing to the long line of coast and the numerous lakes, fishing forms an important industry. Linen weaving is practised as a domestic industry. Shipbuilding is carried on at Stettin and at several places along the coast. The chief commercial ports of Pomerania are Stettin, Stralsund and Swinemünde. Education is provided for by a university at Greifswald and by numerous schools.

History.— In prehistoric times the southern coast of the Baltic seems to have been occupied by Celts, who afterwards made way for tribes of Teutonic stock. These in their turn were replaced, about the end of the 5th century A.D. by Slavonic tribes, the Wilzi and the Pomerani. The name of Pomore, or Pommern, meaning "on the sea," was given to the district by the latter of the tribes about the time of Charlemagne. Originally it seems to have denoted the coast district between the Oder and the Vistula. Afterwards Pomerania extended much farther to the west, while being correspondingly curtailed on the east, and a distinction was made between Slavinia, or modern Pomerania, and Pomerellen. The latter, corresponding substantially to the so-called Polish corridor, remained subject to Poland until 1309, when it was divided between Brandenburg and the Teutonic Order.

The history of Pomerania, as distinct from that of Pomerellen, consists mainly in a succession of partitions and in constant hostilities with the elector of Brandenburg, who claimed to be its immediate feudal superior. During the Thirty Years' War Pomerania was devastated and by the peace of Westphalia the elector of Brandenburg acquired eastern Pomerania (Hinterpommern), and the western part (Vorpommern) was awarded to Sweden. In 1720 Swedish Pomerania was curtailed by extensive concessions to Prussia, but the district to the west of the Peene remained in the possession of Sweden until the general European settlement of 1815. Then Sweden assigned her German possessions to Denmark in exchange for Norway, whereupon Prussia, partly by purchase and partly by the cession of the duchy of Lauenburg, finally succeeded in uniting the whole of Pomerania under her rule.

See F. W. Barthold, *Geschichte von Rügen und Pommern* (Hamburg, 1839–45); the *Codex Pomeraniae diplomaticus,* edited *by* K. F. W. Hasselbach and J. G. L. Kosegarten (Greifswald, 1862); H. Berghaus, *Landbuch des Herzogtums Pommern* (1865–76); K. Mass, *Pommersche Geschichte* (Stettin, 1899); J. Bugenhagen, *Pomerania,* edited by O. Heinemann (Stettin, 1900); M. Wehrmann, *Geschichte von Pommern* (Gotha 1904–6).

POMFRET, JOHN (1667–1702), English poet, born at Luton, became rector of Maulden, Bedfordshire, in 1695, and of Milibrook in the same county in 1702. His poems were printed in Johnson's *English Poets* (1779, vol. xxi.).

POMMER or **BOMBARD,** the alto, tenor and basses of the shawm or schalmey family, and the forerunners respectively of the cor-anglais, bassoon or fagotto, and double bassoon or contrafagotto. (See Bassoon and Oboe.)

POMO. This group of American Indians, speaking seven dialects of Hokan (*q.v.*) lineage, on Russian river and Clear lake, California, is noted for its basketry, which is perhaps the finest and most varied made on the continent. The general culture was central Californian as typified by the Maidu (*q.v.*). The Pomo have decreased from about 8,000 to 800. *See* S. A. Barrett, *Univ. Calif. Publ. Am. Arch. Ethn.*, vols. vi., vii. (1908); E. W. Gifford, *ibid.*, vol. xviii. (1926); E. M. Loeb, *ibid.*, xix. (1926).

POMONA, an old Italian goddess of fruit and gardens. Pomona had a special priest at Rome, the *flamen Pomonalis,* and a sacred grove near Ostia, called the Pomonal.

POMONA, a city of Los Angeles county, California. U.S.A., 30 mi. E. of Los Angeles, at an altitude of 850 feet. It is served by the Santa Fe, the Southern Pacific, and Union Pacific and electric railways, and by motor coach lines. Pop. 13,505 in 1920 (88% native white); in 1940 it was 23,539 by the federal census. It is one of the principal shipping points in the state for citrus fruits and walnuts. At Claremont, 4 mi. N., is Pomona college, incorporated under the auspices of the Congregational churches of Southern California in 1887. Pomona was founded by fruit-growers in 1875 and was chartered as a city in 1875.

POMONA or **MAINLAND,** central and largest island of the Orkneys. Scotland. Pop. (1931) 13,352. It is 25 in. long from N.W. to S.E. and 15 m. broad from E. to W.; area, 190 sq.m.; hut where the coast is cut into, on the N. by Kirkwall Bay and on the S. by Scapa Flow, the land is less than 2 in. across. The west coast is almost unbroken, the bays of Birsay and Skaill being the only bays of any importance, but the east and south shores are much indented. The highest points of the watershed from Costa Head to the Scapa shore are Milldoe to the north-east of Isbister and Wideford Hill to the west of Kirkwall. There are also a few eminences towards the south-west, Ward Hill (880 ft.) in the parish of Orphir being the highest peak in the island. There are numerous lakes, some of considerable size and most of them abounding with trout. Kirkwall, the capital of the Orkneys, and Stromness are the only towns.

In Harray, the only parish in the Orkneys not trenched at some point by the sea, Norse customs have survived longer than elsewhere in the group save in North Ronaldshay.

The antiquities of Pomona are of great interest. The examples of Pictish remains include *brochs,* chambered mounds and weems, or underground dwellings afterwards roofed in. North-east of Stromness, and within a mile of the stone circles of Stenness, stands the great barrow or chambered mound of Maeshowe. The tumulus has the form of a blunted cone, 300 ft. in circumference, and at a distance of 90 ft. from its base is encircled by a moat. The ground-plan shows that it was entered from the west by a passage, which led to a central apartment, the walls of which ended in a beehive roof. The barrow is variously ascribed to the Stone Age and to 10th century Norsemen.

The stone circles forming the Ring of Brogar and the Ring of Stenness lie $4\frac{1}{2}$ m. N.E. of Stromness. The Ring of Brogar, once known as the Temple of the Sun, stands on a raised circular platform of turf, surrounded by a moat and a grassy rampart. The ring originally comprised 60 stones, varying from 9 to 14 ft. in height, set up at intervals of 17 ft. Only 13 are now erect. The Ring of Stenness—the Temple of the Moon of local tradition—is of similar construction. The Stone of Odin, the great monolith, pierced by a hole at a height of 5 ft. from the ground, which figures so prominently in Scott's *Pirate,* stood 150 yd. to the north of the Ring of Stenness.

POMORZE or **POMERANIA** (*i.e.,* "along the sea"), a province of Poland, bounded on the N. by the Baltic, on the E. by East Prussia, on the S. by the provinces of Warsaw and Poznan, on the W. by Germany. Area, 9,917 sq.mi.; pop. (1931), 1,086,000. Germany seized the province in 1939.

Pomorze, which has been, in modern times, very incorrectly called West Prussia and the "Polish corridor," consists of two quite distinct units. West of the Vistula is eastern Pomerania, which was colonized by Poland when West Pomerania became a German colony, was seized by the Teutonic Order in 1309, recovered by Poland in 1466 and held till 1773, when it was seized by Prussia. East of the Vistula is the territory of Chelmno or Kulm, a Polish border province ceded to the Teutonic Order in the 13th century and recovered in 1466. Both these territories remained mainly Polish despite the colonizing efforts of the Prussian government in the 19th century. Danzig, which had a German majority, was made into a Free State by the treaty of Versailles; mixed areas decided their future by a plebiscite, and the remaining territory was reunited to the other parts of Poland, to which it was essential as the only outlet of Poland on the sea. The Prussian rule of over 140 years left a German minority, forming 11% of the population; the Poles formed 89% (1935).

Pomorze is mainly an agricultural country, its industries depending on agriculture. Together nith Poznan, it was formerly one of the chief sources of foodstuffs for Germany. The peasant is highly educated and well organized, the agricultural co-operative societies having been a great economic and national asset. Forestry is well organized in the great Tuchola forest. Distilling, brewing and sugar refining are important industries. The province is famous for stockbreeding, having a greater number of sheep per acre than any other part of Poland. The fisheries are extensive, but not well organized. The province is well served by railways. A constantly growing traffic by rail and river descends to Danzig and the new port of Gdynia. The chief towns are Gdynia (pop. 120,000 in 1939), Torun (pop. 54,000 in 1939), Grudziadz (pop. 54,000) in the east; Chojnice, Puck, Tuchola, Starograd and Swiecie in the west. Pomorze, tactically difficult to defend, was rapidly conquered by Germany in World War II.

POMPADOUR, JEANNE ANTOINETTE POISSON LE NORMANT D'ÉTIOLES, MARQUISE DE (1721–1764), mistress of Louis XV., was horn in Paris on Dec. 29, 1721, and baptized as the legitimate daughter of François Poisson, an officer in the household of the duke of Orleans, and his wife, Madeleine de la Motte, in the church of St. Eustache; but she was educated at the charge of a wealthy financier and farmer-general of the revenues, Le Normant de Tournehem. He declared her "un morceau de roi," and specially educated her to be a king's mistress. This idea was confirmed in her childish mind by the prophecy of an old woman, whom in after days she pensioned for the correctness of her prediction In 1741 she was married to a nephew of her protector and guardian, Le Normant d'Étioles, who was passionately in love with her, and she soon became a queen of fashion. The king met her at a ball given by the city to the dauphin in 1744, and he was immediately subjugated. She at once gave up her husband, and in 1745 was established at T'ersailles as "maîtresse en titre." Louis XV. bought her the estate of Pompadour, from which she took her title of marquise (raised in 1752 to that of duchess).

She was hardly established firmly in power before she began to mix in politics. Knowing that the French people of that time were ruled by the literary kings of the time, she paid court to them, and tried to play the part of a Maecenas. T'oltaire was her poet in chief, and the founder of the physiocrats, Quesnay, was her physician. The command of the political situation passed entirely into her hands; she it was who brought Belle-Isle into office with his vigorous policy; she corresponded regularly with the generals of the armies in the field, as her letters to the Comte de Clermont prove; and she introduced the Abbé de Bernis into the ministry in order to effect a very great alteration of French politics in ijj6. The continuous policy of France since the days of Richelieu had been to weaken the house of Austria by alliances in Germany; but Mme. de Pompadour changed this hereditary policy for the alliance with Austria which brought on the Seven Years' War, with all its disasters.

But it was to internal politics that this remarkable woman paid most attention. She made herself indispensable to Louis. She died on April ij, 1764, at the age of forty-two

See Capefigue, *Madame la marquise de Pompadour* (1858); *E.* and J. de Goncourt, *Les Mattresses de Louis XV.*, vol. ii. (1860); and Campardon, *Madame de Pompadour et la cour de Louis XV. au milieu du dix-huitidnze siècle* (1867). Far more valuable are Malassis's two volumes of correspondence, *Correspondance de Madame de Pompadour avec son père M. Poisson, et son frère M. de Vanditres,* etc. (1878), and Bonhomme, *Madame de Pompadour, général d'armée* (1880), containing her letters to the Comte de Clermont. *See* also P. de Nolhac, *La Marquise de Pompadour* (1903).

POMPEII, an ancient town of Campania, Italy, near the river Sarnus, almost at the foot of Mt. Vesuvius. Its foundation was ascribed by Greek tradition to Heracles, in common with the neighbouring city of Herculaneum, but it was not a Greek colony. Strabo, in whose time it was a populous and flourishing place, tells us that it was first occupied by the Oscans, afterwards by the Tyrrhenians (*i.e.,* Etruscans), to whom it probably owes its rectangular ground plan, and Pelasgians, and lastly, by the Samnites. (See CAMPANIA.) No doubt, Pompeii shared the fate of the neighbouring cities, and afterwards passed in common with them under the yoke of Rome. But its name is only mentioned incidentally during the wars of the Romans with the Samnites and Campanians only when a Roman fleet landed near Pompeii in 309 B.C. and made an unsuccessful marauding expedition up the river valley as far as Nuceria. At a later period, however, it took a prominent part in the Social War (91–89 B.C.), when it withstood a long siege by Sulla, and was one of the last cities of Campania that were reduced by the Roman arms. The inhabitants were admitted to the Roman franchise, but a military colony was settled in their territory in 80 B.C. by Sulla (Colonia Cornelia Veneria *Pompeianorum*), and the whole population was rapidly Romanized. Before the close of the republic many Roman nobles acquired villas in the neighbourhood, among them Cicero, whose letters abound with allusions to his Pompeian villa. The same fashion continued under the empire, and during the first century of the Christian era, Pompeii had become a flourishing place with a considerable population. In AD. 59 a tumult took place in the amphitheatre between the citizens and visitors from Nuceria. Many were killed and wounded on both sides. The Poinpeians were punished for this violent outbreak by the prohibition of all theatrical exhibitions for ten years. A painting on the walls of one of the houses represents this event.

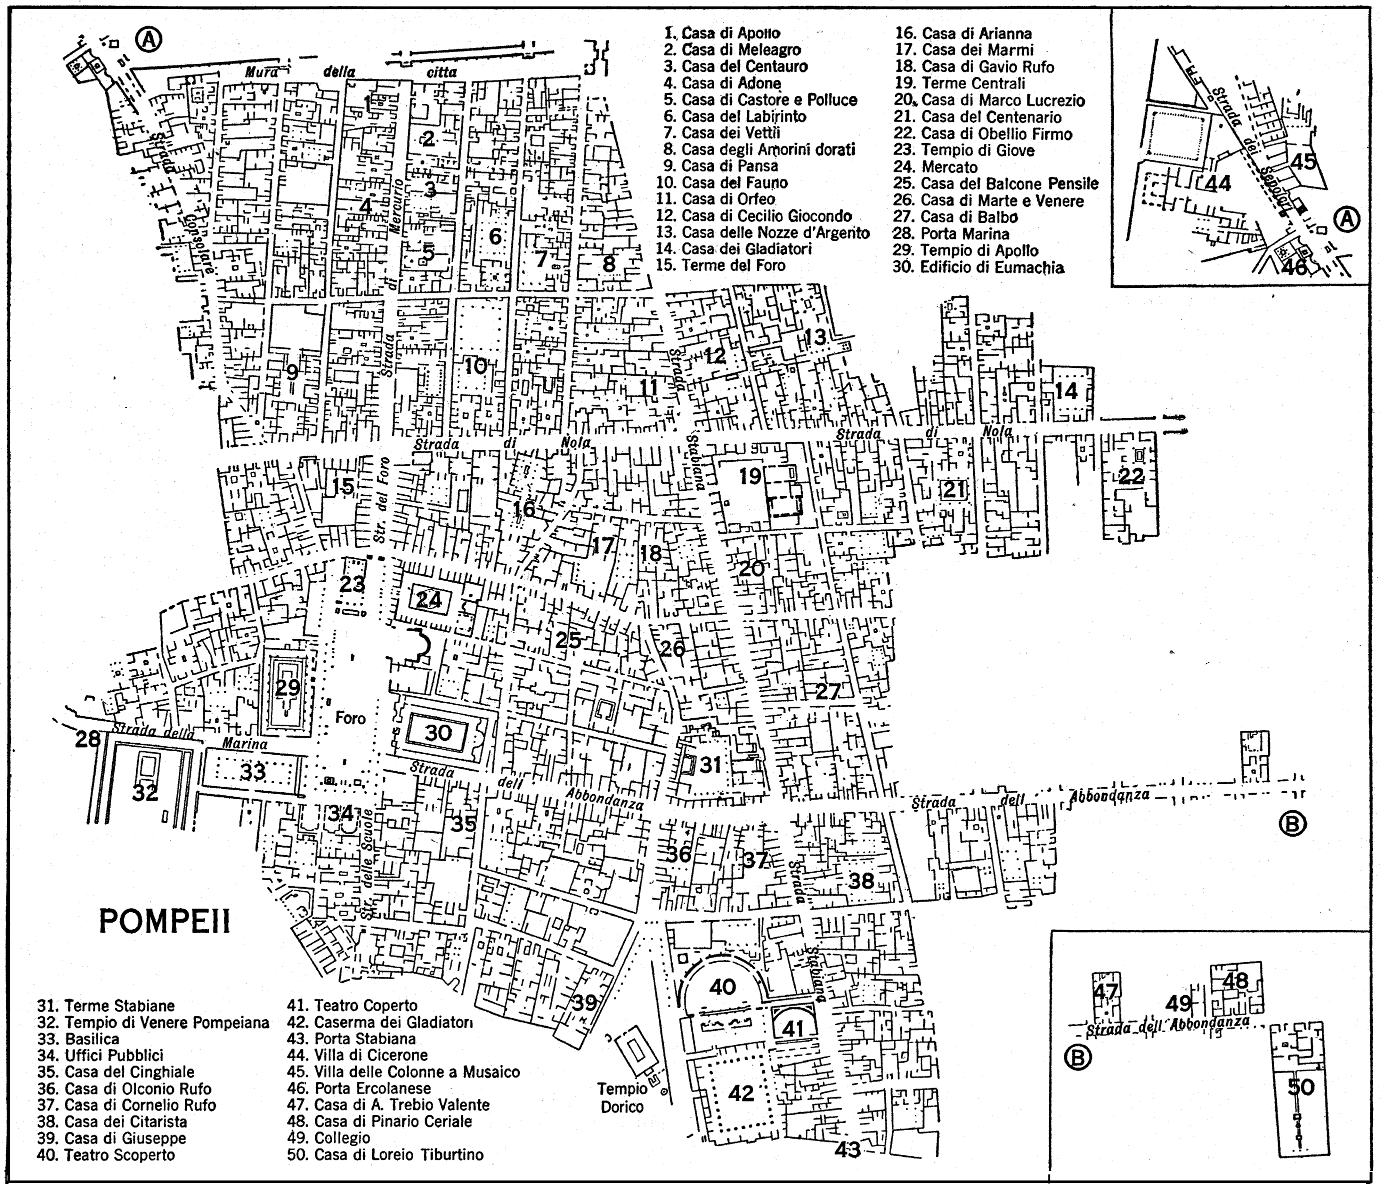
Four years afterwards (A.D. 63) an earthquake vented its force especially upon Pompeii, a large part of which, including most of the public buildings, was either destroyed or so seriously damaged as to require to be rebuilt. The inhabitants were still actively engaged in repairing and restoring it, when the whole city was overwhelmed by the great eruption of Vesuvius (*q.v.*), A D 79. Pompeii was merely covered with a bed of lighter substances, cinders, small stones and ashes, which fell in a dry state, while at Herculaneum the same substances, being drenched with water, hardened into a sort of tufa, which in places is 65 ft. deep. The whole of this superincumbent mass. attaining to an average thickness of from 18 to 20 ft., was the product of one eruption, though the materials may be divided generally into two distinct strata, the one consisting principally of cinders and small volcanic stones (called in Italian *lapilli*), and the other and uppermost layer of fine white ash, often consolidated by the action of water from above so as to take the moulds of objects contained in it (such as dead bodies, woodwork, etc.), like clay or plaster of Paris. It was found impossible to rebuild the town, and its territory was joined to that of Nola. But the survivors returned to the spot, and by digging down and tunnelling were able to remove all the objects of value, even the marble facing slabs of the large buildings.

In the middle ages, however, the very site was forgotten. Ruins and inscriptions were found by the architect Domenico Fontana in making an underground aqueduct across the site in 1594–1600, but only in 1748 a more careful inspection of this channel revealed the fact that beneath there lay entombed ruins far more accessible than those of Herculaneum. Only in 1763 systematic excavations were begun; the work, which had received a vigorous stimulus during the period of the French government (1806–14), was prosecuted under the Bourbon kings (1815–61). Since 1861 it has been carried on under the Italian government on a system devised by G. Fiorelli, according to which the town is for convenience divided into 6 or g regions, which are subdivided into *insulae* (blocks), the gates, streets and houses being also named for convenience, though often incorrectly.

The town was situated on rising ground less than a mile from the foot of Vesuvius. This eminence is itself due to an outflow of lava from that mountain, during an eruption in prehistoric times, for we know that Vesuvius had been quiescent ever since the Greek settlements in this part of Italy.

The area occupied by the ancient city was of an irregular oval form, and about 2 m. in circumference. It was surrounded by a wall, which is still preserved for more than two-thirds of its extent, but no traces of this are found on the side towards the sea, and there is no doubt that on this side it had been already demolished in ancient times, so as to give room for the free extension of houses and other buildings in that direction. It consisted of two parallel stone walls with buttresses, about 15 ft. apart and 28 in. thick, the intervening space being filled with earth, and there being an embankment on the inner side. These walls are strengthened at intervals by numerous towers, occupying the full width of the wall. They appear to have been added at a later period, probably that of the Social War. Similar evidences of the addition of subsequent defences are to be traced also in the case of the gates, of which five have been cleared, while at least one (and perhaps three) more are unexcavated

The general plan of the town is very regular, the streets being generally straight, and crossing one another at right angles or nearly so. But exceptions are found in the south-west corner, where a small irregular group of streets represents the original Oscan settlement, and on the north-west in the street



FROM "GUIDA D'ITALIA DEL TOURING CLUB ITALIANO"

leading from the Porta Ercolanese (gate of Herculaneum) to the forum, which, though it must have been one of the principal thoroughfares in the city, was crooked and irregular, as well as very narrow, in places not exceeding 12 to 14 ft. in width. Another exception is to be found in the Strada Stabiana (Stabian Street) or Cardo, which, owing to the existence of a natural depression which affects also the line of the street just east of it, is not parallel to the other north and south streets. The other main streets are in some cases broader, but rarely exceed 20 ft. in width, and the broadest is about 32 ft., while the back streets running parallel to the main lines are only about 14 ft. (the standard width of a Roman highroad). They are uniformly paved with large polygonal blocks of hard basaltic lava, fitted very closely together, though now in many cases marked with deep ruts from the passage of vehicles in ancient times. They are also in all cases bordered by raised footways on both sides, paved in a similar manner; and for the convenience of foot-passengers, these are connected from place to place by stepping-stones raised above the level of the carriage-way. The careful investigation in recent years of the buildings in the eastern portion of the Strada dell' Abbondanza has shown that previous conceptions of the appearance of the exterior of the houses were entirely erroneous. The upper stories were diversified by balconies, open loggias, colonnades, etc., while the lower portions of the façades were painted, often with scenes of considerable interest. The streets were also diversified by fountains, small water-towers and shrines.

The first-mentioned of the two principal streets was crossed, a little before it reached the forum, by the street which led directly to the gate of Nola (Strada delle Terme, della Fortuna, and di Nola). Parallel to this last to the south is a street which runs from the Porta Marina through the forum, and then, with a slight turn, to the Sarno gate, thus traversing the whole area of the city from east to west (Via Marina, Strada dell' Abbondanza, Strada dei Diadumeni). These two east and west streets are the two *decumani.*

The population of Pompeii was mixed; both Oscan and Greek inscriptions are still found up to the last, and evidences of the presence of Jews are not lacking—such are a wall-painting, probably representing the Judgment of Solomon, and a scratched inscription on a wall, "Sodoma, Gomora." From the number of skeletons discovered, about 2,000 persons may have perished in the city itself in the eruption of A.D. 79.

The whole portion of the city which lies to the west of the Strada Stabiana, towards the forum and the sea, has been completely excavated. It is over one-half of the whole extent, and that the most important portion, inasmuch as it includes the forum, with the temples and public buildings adjacent to it, the thermae, theatres, etc. The greater part of that on the other side of the Strada Stabiana remains still unexplored, with the exception of the amphitheatre, a small space in its immediate neighbourhood and the buildings on each side of the Strada dell' Abbondanza and the Strada di Nola.

The forum at Pompeii was the centre of the life and movement of the city. Hence it was surrounded on all sides by public buildings or edifices of a commanding character. It was not, however, of large size, only 467 ft. in length by 126 in breadth (excluding the colonnades). The nature of its pavement, composed of broad flags of travertine, into which was let an inscription in large bronze letters, shows that it was only intended for foot-passengers. It was adorned with numerous statues. It was surrounded on three sides by a series of porticos supported on columns; and these porticos were originally surmounted by an upper storey, traces of the staircases leading to which still remain. Both this portico and the adjacent buildings were undergoing a process of restoration after the earthquake of 63, involving material changes in the original arrangements, which was still incomplete at the time of their final destruction. The north end of the forum, where alone the portico is wanting, is occupied in great part by the imposing temple of Jupiter, Juno and Minerva, or Capitolium. It was raised on a podium 10 ft. high, and had a portico with six Corinthian columns in front. This magnificent edifice had, however, been evidently overthrown by the earthquake of 63, and is in its present condition a mere ruin, the rebuilding of which had not been begun at the time of the eruption. On each side of it were two arches, affording an entrance into the forum, but capable of being closed by gates. On the east side of the forum were four public edifices. The first (from the north), is a *macellum* or meat-market, consisting of a rectangular court surrounded by a colonnade, with a twelve-sided roofed building (*tholus*) in the centre. On the south side were shops, and in the centre of the east side a chapel for the worship of the imperial house. Next to this comes the sanctuary of the Lares of the city, a square room with a large apse; and beyond this a small temple. Beyond this again, bounded on the south by the Strada dell' Abbondanza, is a large and spacious cloth-exchange, erected by a priestess named Eumachia. It is an open court, oblong, surrounded on all four sides by a colonnade; in front is a portico facing the forum, and on the other three sides there is a corridor behind the colonnade with windows opening on it. On the south side of the Strada dell' Abbondanza was the Comitium. At the south end of the forum are three halls side by side, similar in plan with a common façade —the central one, the curia or council chamber, the others the offices respectively of the duumvirs and aediles, the principal officials of the city; while the greater part of the west side is occupied by two large buildings—a basilica, which is the largest edifice in Pompeii, and the temple of Apollo, which presents its side to the forum. The former, a building of the 2nd cent. B.C., was an oblong edifice divided by columns into a central hall and a corridor running round all the four sides with a tribunal opposite the main entrance; and, unlike the usual basilicae, it had, instead of a clerestory, openings in the walls of the corridor through which light was admitted, it being almost as lofty as the nave. The temple was an extensive edifice, having a comparatively small *cella*, raised upon a *podium*, and standing in the midst of a wide space surrounded by a portico of columns, outside which again is a wall, bounding the sacred enclosure. Between this temple and the basilica the Via Marina leads off direct to the Porta Marina.

The remains of five other temples have been discovered. The most interesting, though the least perfect, is not only by far the most ancient edifice in Pompeii, but a true Greek temple (6th century B.C.). Unfortunately only the foundation and a few Doric capitals and other architectural fragments remain; they were coated with brightly painted stucco. The reverence attached to it in later periods is shown by its being left standing in the midst of a triangular space adjoining the great theatre, which is surrounded by a portico, so as to constitute a kind of forum (the so-called Foro Triangolare). Not far off, and to the north of the great theatre, stood a small temple, dedicated to Isis, rebuilt after the ruinous earthquake of 63. It is interesting as the only temple of Isis that has come down to us in a good state of preservation. The decorations were of somewhat gaudy stucco. The plan is curious, the internal arrangements being adapted for the performance of the peculiar rites of this deity. Close to this was the small temple of Zeus Milichius. The temple of the Fortune of Augustus (Fortuna Augusta), which stood north of the Forum, suffered very severely from the earthquake, but we learn from existing remains that its walls were covered with slabs of marble, and that the columns of the portico were of the same material. The fifth temple, that of Venus Pompeiana, to the west of the basilica, was in process of rebuilding at the time of the eruption. Before the earthquake of 63 it must have been the largest temple of the whole city. It was surrounded by a large colonnade, and the number of marble columns in the whole block has been reckoned at 296. Venus was the protectress of the young men of Pompeii, who had formed a society for gymnastics and other sports. They met in a hall (the Schola Iuventutis Pompeianae) in the Strada dell' Abbondanza.

All the temples above described, except that ascribed to Hercules, which was approached by steps on all four sides, agree in being raised on an elevated *podium* or basement—an arrangement usual with all similar buildings of Roman date. Among the other public buildings, the most conspicuous are the theatres, of which there were two, placed, as was usual in Greek towns, in close juxtaposition with one another. The largest of these, which was partly excavated in the side of the hill, was in great part cased with marble, with seats of the same material for about 5,000 spectators. It was erected in Roman times by two members of the same family, M. Holconius Rufus and M. Holconius Celer, both of whom held important municipal offices at Pompeii during the reign of Augustus. Their work was only a reconstruction of a more ancient edifice (probably 5th cent. B.C.), while its first alteration belongs to the "tufa" period, and three other periods in its history can be traced. The smaller theatre (for 1,500 spectators) was erected by two magistrates specially appointed for the purpose by the decuriones of the city, soon after the establishment of the Roman colony under Sulla. It was permanently covered.

Adjoining the theatres is a large rectangular enclosure, surrounded by a portico, at first the colonnade connected with the theatres, and converted, about the time of Nero, into the barracks of the gladiators. Remains of armour and weapons were found in some of the rooms, and in one, traces of the stocks used to confine insubordinate gladiators with three skeletons in them (63 were found in the whole building). The amphitheatre was erected by the same two magistrates who built the smaller theatre, C. Quinctius Valgus and M. Porcius when no permanent edifice of a similar kind had yet been erected in Rome itself, and is indeed the oldest structure of the kind known to us. It is in great part excavated in the surface of the hill, instead of the seats being raised on arches. Nor are its dimensions (460 by 34; ft.) such as to place it in the first rank, nor are there any underground chambers below the arena. The seating capacity was about 20,000 (for illustration see AMPHITHEATRE).

Among the more important public buildings of Pompeii were the public baths (*thermae*). Three different establishments of this character have been discovered, the first, the baths near the forum, though the smallest of the three. is in some respects the most complete and so well preserved that we trace without difficulty all the separate apartments described to us by Roman authors—the apodyterium, *frigidarium, tepidarium*, caldarium, and so on. (See BATHS.) The greater thermae (the so-called "Stabian" baths), which were originally built in the 2nd century B.C., and repaired about 80 B.C., are more extensive and combine a palaestra in the centre and other apartments for exercise or recreation. An inscription records the repair and restoration of the edifice after the earthquake of 63. These two establishments were inadequate to supply the wants of the inhabitants, and a third edifice, the so-called central baths, at the corner of the Strada Stabiana and the Strada di Nola, but on a still more extensive scale, intended for men only, was in course of construction in A.D. 79.

Far more interesting is the insight afforded us by the numerous private houses and shops into the ordinary life and habits of the population of an ancient town. The houses at Pompeii are generally low, rarely exceeding two storeys in height; the upper storey is generally of a slight construction, and occupied by small rooms, serving as garrets, or sleeping places for slaves. From the mode of destruction of the city these upper floors were in most cases crushed in and destroyed. The principal living rooms, as well as those intended for the reception of guests or clients, were all on the ground floor, the centre being formed by the atrium, or hall, which had an opening in the centre—the *compluvium*, so-called because the rain from the roofs was collected by it and fell into a basin (the *impluvium*). In the larger houses it was often surrounded with columns. Into this opened other rooms, the entrances to which, rarely protected by doors, were only closed by curtains. At the back was a garden. Later, under Greek influences, a peristyle with rooms took the place of the garden.

All the apartments and arrangements described by Vitruvius and other ancient writers may be readily traced in the houses of Pompeii, and in many instances these have for the first time enabled us to understand the technical terms and details transmitted to us by Latin authors. We must not, however, hastily assume that the examples thus preserved to us by a singular accident are to be taken as representing the style of building in all the Roman and Italian towns—in fact, the excavations at Ostia (*q.v.*) have shown us the contrary. We know from Cicero that Capua was remarkable for its broad streets and widespread buildings, and it is probable that the Campanian towns in general partook of the same character. At Pompeii indeed the streets were not wide, but they were straight and regular, and the houses of the better class occupied considerable spaces, presenting in this respect no doubt a striking contrast, not only with those of Rome itself, but with those of many other Italian towns, where the buildings would necessarily be huddled together from the circumstances of their position. Even at Pompeii itself, on the south side of the city, where the ground slopes somewhat steeply towards the sea, houses are found which consisted of three storeys or more, and with the inner walls painted black (with white designs on them) owing to the brilliancy of the light.

The excavations have provided examples of houses of every description, from the humble dwelling-place of the artisan or proletarian, with only three or four small rooms, to the stately mansions of Sallust, of the Faun, of the Golden Cupids, of the Silver Wedding, of the Vettii, of Pansa, etc.—the last of which is among the most regular in plan. But the general similarity in their plan and arrangement is very striking, and in all those that rise above a very humble class the leading divisions of the interior, the *atrium, tablinum,* peristyle, etc., may be traced with unfailing regularity. In all the more considerable houses in Pompeii the front, where it faces one of the principal streets, is occupied with shops, usually of small size, and without any communication with the interior of the mansion. In general the shop had a very small apartment behind it, and probably in most cases a sleeping chamber above it, reached by a staircase. The front of the shop was open to the street, but was capable of being closed with wooden shutters. Not only have the shops of silversmiths been recognized by the precious objects of that metal found in them, but large quantities of fruits of various kinds preserved in glass vessels, various descriptions of corn and pulse, loaves of bread, moulds for pastry, fishing-nets and many other objects too numerous to mention, have been found in such a condition as to be identified without difficulty. Inns and wine-shops appear to have been numerous; one of the latter we can see to have been a *thermopolium,* where hot drinks were sold. Bakers' shops are also frequent, though arrangements for grinding and baking appear to have formed part of every large family establishment. In other cases, however, these were on a larger scale, provided with numerous querns or hand-mills of the well-known form, evidently intended for public supply. Other establishments on a large scale were *fullonicae* (fullers' shops), where all the details of the business were illustrated by paintings still visible on the walls. Dyers' shops, a tannery and a shop where colours were ground and manufactured are of special interest, as is also the house of a surgeon, where numerous surgical instruments were found, some of them of a very ingenious and elaborate description, but all made of bronze. A blacksmith's shop was also found, with many tools that had been brought in for repair: here were discovered the remains of a groma, the instrument used by Roman land-surveyors, which has been successfully reconstructed (Dells Corte in *Monumenti* dei *Lincei*, 1922). Another curious discovery was that of the abode of a sculptor, containing his tools, as well as blocks of marble and half-finished statues.

Of the numerous works of art discovered in the course of the excavations the statues and large works of sculpture, whether in marble or bronze, are inferior to those found at Herculaneum, but some of the bronze statuettes are of exquisite workmanship, while the profusion of ornamental works and objects in bronze and the elegance of their design, as well as the finished beauty of their execution, are such as to excite the utmost admiration—more especially when it is considered that these are the casual results of the examination of a second-rate provincial town, which had, further, been ransacked for valuables (as Herculaneum had not) after the eruption of 79. The same impression is produced in a still higher degree by the paintings with which the walls of the private houses, as well as those of the temples and other public buildings, are adorned, and which are not merely of a decorative character, but in many instances present us with elaborate compositions of figures, historical and mythological scenes, as well as representations of the ordinary life and manners of the people, which are full of interest to us, though often of inferior artistic execution. It has until lately been the practice to remove these to the museum at Naples; but the present tendency is to leave them (and even the movable objects found in the houses) in *situ* with all due precautions as to their preservation, which adds immensely to the interest of the houses; indeed, with the help of careful restoration, their original condition is in large measure reproduced. In some cases it has even been possible to recover the original arrangement of the garden beds, and to replant them accordingly, thus giving an appropriate framework to the statues, etc., with which the gardens were decorated, and which have been found in situ. The same character of elaborate decoration, guided almost uniformly by good taste and artistic feeling, is displayed in the mosaic pavements, which in all but the humbler class of houses frequently form the ornament of their floors. One of these, in the House of the Faun, well known as the battle of Alexander, presents us with the most striking specimen of artistic composition that has been preserved to us from antiquity.

The architecture of Pompeii presents in general a transitional character from the pure Greek style to that of the Roman Empire. The temples (as already observed) have always the Roman peculiarity of being raised on a podium of considerable elevation; and the same characteristic is found in most of the other public buildings. All the three orders of Greek architecture—the Doric, Ionic and Corinthian—are found freely employed in the various edifices of the city, but rarely in strict accordance with the rules of art in their proportions and details; while the private houses naturally exhibit still more deviation and irregularity. In many of these indeed we find varieties in the ornamentation, and even in such leading features as the capitals of the columns, which remind one rather of the vagaries of mediaeval architecture than of the strict rules of Vitruvius or the regularity of Greek edifices. One practice which is especially prevalent, so as to strike every casual visitor, and dates from the early years of the empire, is that of filling up the flutings of the columns for about one-third of their height with a thick coat of stucco, so as to give them the appearance of being smooth columns without flutings below. The architecture of Pompeii suffers from the inferior quality of the materials generally employed. No good building stone was at hand; and the public as well as private edifices were constructed either of volcanic tufa, or lava, or Sarno limestone, or brick (the latter only used for the corners of walls). In the private houses even the columns are mostly of brick, covered merely with a coat of stucco. Marble was sparingly employed.

These materials are used in several different styles of construction belonging to the six different periods which Mau traces in the architectural history of Pompeii.

1. That of the Doric temple in the Foro Triangolare (6th cen-

tury B.c.) and an old column built into a house in Region vi., Insula 5; also of the older parts of the city walls—date uncertain (Sarno limestone and grey tufa).

2. That of the limestone atriums (outer walls of the houses of ashlar-work of Sarno limestone, inner walls with frame ork of limestone blocks, filled in with small pieces of limestone). Date before zoo B.C.

3. Grey tufa period; ashlar masonry of tufa, coated with fine white stucco; rubble work of lava. The artistic character is still Greek, and the period coincides with the first (incrustation) style of mural decoration, which (coming from Asia Minor or Greece perhaps by way of Sicily) aimed at the imitation in stucco of the appearance of a wall veneered with coloured marbles. No wall paintings exist, but there are often fine floor mosaics. To this belong a number of private houses (*e.g.*, the House of the Faun), and the colonnade round the forum, the basilica, the temples of Apollo and Jupiter, the large theatre with the colonnades of the Foro Triangolare, and the barracks of the gladiators, the Stabian baths, the Palaestra, the exterior of the Porta Marina, and the interior of the other gates—all the public buildings indeed (except the Doric temple mentioned under [:], which do not belong to the time of the Roman colony). Date, end of 2nd century B.C.

4. The "quasi-reticulate" period—walling faced with masonry not yet quite so regular as opus reticulatum, and with brick quoins, coinciding with the second period of decoration (the architectural, partly imitating marble like the first style, but without relief, and by colour only, and partly making use of architectural designs framing pictorial scenes, which are conceived as seen through openings). It is represented by the small theatre and the amphitheatre, the baths near the forum, the temple of Zeus Milichius, the Comitium and the original temple of Isis, but only a few private houses. This style probably owes much to Hellenistic theatrical decoration. Date, from 80 B.C. until nearly the end of the Republic.

5. The period from the last decades of the Republic to the earthquake of A.D. 63. No homogeneous series of buildings—we find various styles of construction (quasi-reticulate, *opus reticulatum* of tufa with stone quoins, of the time of Augustus, opus *reticulatum* with brick quoins or with mingled stone and brick quoins, a little later); and three styles of wall decoration fall within its limits: the later stage of the second, already mentioned, the third or ornate, with its freer use of ornament and its introduction of designs which suggest an Egyptian origin (originating in the time of Augustus), and the fourth or intricate, with a return to architectural forms, dating from about A.D. 50. Marble first appears as a building material in the temple of Fortuna Augusta (c. 3 B.C.).

6. The period from the earthquake of A.D. 63 to the final destruction of the city, the buildings of which can easily be recognized. The only wholly new edifice of any importance is the central baths.

Outside the Porta Ercolanese, or gate leading to Herculaneum, is found a house of a different character from all the others, undoubtedly a large villa; its remains are of interest as aiding us in understanding the description of ancient authors, such as Vitruvius and Pliny, of the numerous appurtenances frequently annexed to houses of this description.

In the cellar of this villa were discovered no less than twenty skeletons, and fourteen in other parts of the house. Almost all the skeletons and remains of bodies found in the city were discovered in similar situations, in cellars or underground apartments—those who had sought refuge in flight having apparently for the most part escaped from destruction, or having perished under circumstances where their bodies were easily recovered by the survivors. It has been found possible in many cases to take casts of the bodies found.

An interesting farm-house (few examples have been so far discovered in Italy) is that at Boscoreale excavated in 1893–94, which contained the treasure of one hundred and three silver vases now in the Louvre. The villa of P. Fannius Synhistor, not far off, was excavated in 1900; it had fine wall paintings, which were exported, and sold by auction in Paris (some now in the Louvre, while others are in New York). (See F. Barnabei, La Villa *pompeiana* di P. *Fannio Sinistore;* Rome, 1901.) Another, closer to Pompeii, in the so-called Villa Item, contains remarkable life size frescoes representing scenes of initiation into the mysteries of Dionysus or of Orpheus.

The road leading towards Herculaneum is bordered on both sides for a considerable extent by tombs, in many instances monuments of considerable pretension, and of a highly ornamental character, which present in the highest degree the advantage common to all that remains of Pompeii, their perfect preservation.

There appears to have been in the same quarter a considerable suburb, outside the gate, extending on each side of the road towards Herculaneum, apparently much resembling those which are now found from thence to Naples. Other suburbs were situated at the harbour and at the saltworks (salinae).

No manuscripts have been discovered in Pompeii. Inscriptions have been found in considerable numbers, and give much information concerning the municipal arrangements of the town, as well as the construction of various edifices and other public works. The most interesting of these are such as are written in the Oscan dialect, which appears to have continued in official use down to the time when the Roman colony was introduced by Sulla. From that time the Latin language was the only one officially employed. Still more curious are the numerous writings painted upon the walls, which have generally a semi-public character, such as recommendations of candidates for municipal offices, advertisements, etc., and the scratched inscriptions (*graffiti*), which are generally the mere expression of individual impulse and feeling, frequently amatory, and not uncommonly conveyed in rude and imperfect verses. In one house also a whole box was found filled with written tablets—diptychs and triptychs—containing the record of the accounts of a banker named L. Caecilius Iucundus.

See A. Mau, *Pompeii: its Life and Art* (trans. by F. W. Kelsey, 2nd ed., New York and London, 1902; 2nd revised edition of the German original, *Pompeii in Leben und Kunst,* Leipzig, 1908) with *Anhang* (1913), with full references; and, for later excavations, *Notizie degli Scavi* and *Romische Mitteilungen, passim. POMPEIUS, GNAEUS, surnamed STRABO (squint-eyed), Roman statesman, father of the triumvir. He was successively quaestor in Sardinia (103 B.C.), praetor (94), propraetor in Sicily (93) and consul (89). He fought with success in the Social War, and was awarded a triumph for his services. Probably towards the end of the same year he brought forward the law (lex *Pompeia* de Gallia *transpadana*), which conferred upon the inhabitants of that region the privileges granted to the Latin colonies. During the civil war between Marius and Sulla he seems to have shown no desire to attach himself definitely to either side. He set out for Rome; the engagement which he fought before the Colline gate, although hotly contested, was indecisive. Soon afterwards he was killed by lightning (87).

See Plutarch, *Pompey,* 1; Appian, *Bell. civ.* i. 50, 52, 66–68, 80; Vell. Pat. ii. 21; Livy, *Epit.* 74–79; Florus iii. 18.

POMPEIUS, GNAEUS, surnamed MAGNUS (c. 75–45 B.C.), the elder son of the triumvir. In 48 B.C. during the civil war he commanded his father's fleet in the Adriatic. After the battle of Pharsalus he set out for Africa with the remainder of the Pompeian party, but, meeting with little success, crossed over to Spain. Having been joined by his brother Sextus, he collected a considerable army, the numbers of which were increased by the Pompeians who fled from Africa after the battle of Thapsus (46). Caesar, who regarded him as a formidable opponent, set out against him in person. A battle took place at Munda on March 17, 45, in which the brothers were defeated. Gnaeus managed to escape, but was soon (April 12) captured and put to death

See Pseudo-Oppius, *Bellum hispaniense,* 1–39; Lucan, *Pharsalia,* ix. 120; Dio Cassius, xliii. 28–40.

POMPEIUS, SEXTUS, surnamed MAGNUS (75–35 B.C.), the younger son of the triumvir. After his father's death he continued the struggle against the new rulers of the Roman empire. From Cyprus, where he had taken refuge, he made his way to Africa, and after the defeat of the Pompeians at Thapsus (46) crossed over to Spain. After Caesar's victory at Munda (45), he abandoned Corduba (Cordova), though for a time he held his ground in the south, and defeated Asinius Pollio, the governor of the province. In 43 he was proscribed by the triumvirate and put himself at the head of a fleet manned chiefly by slaves or proscribed persons, with which he made himself master of Sicily, and from thence ravaged the coasts of Italy. Rome was threatened with a famine, as the corn supplies from Egypt and Africa were cut off by his ships, and it was thought prudent to negotiate a peace with him at Misenum (39), which was to leave him in possession of Sicily, Sardinia and Achaea, provided he would allow Italy to be freely supplied with corn. But the arrangement could not be carried into effect, as Sextus renewed the war and gained some considerable successes at sea. However, in 36 his fleet was defeated and destroyed by Agrippa at Naulochus off the north coast of Sicily. After his defeat he fled to Mytilene, and from there to Asia Minor. In the attempt to make his way to Armenia he was taken prisoner by Antony's troops, and put to death at Miletus.

See Dio Cassius, xlvi.–xlix.; Appian, Bell. civ. iv. 84–117, v. 2–143; Vell. Pat. ii. 73–87; Plutarch, Antony; Livy, Epit. 123, 128, 129, 131; Cicero, Philippica, xiii., and many references in Letters to *Atticus*.

POMPEY, the common English form of Pompeius, the name of a Roman plebeian family.

POMPEIUS, GNAEUS (106–48 B.C.), the triumvir, the first of his family to assume the surname MAGNUS, was born on Sept. 30, in the same year as Cicero. When only 17 he fought together with his father in the Social War. He took the side of Sulla against Marius and Cinna, but for a time, in consequence of the success of the Marians, he kept in the background. On the return of Sulla from the Mithridatic War Pompey joined him with an army of three legions, which he had raised in Picenum. Thus early in life he connected himself with the cause of the aristocracy, and a decisive victory which he won in 83 over the Marian armies gained for him from Sulla the title of imperator. He followed up his successes in Italy by defeating the Marians in Sicily and Africa, and on his return to Rome in 81, though he was still merely an eques and not legally qualified to celebrate a triumph, he was allowed by general consent to enjoy this distinction, while Sulla greeted him with the surname of *magnus,* a title he always retained and handed down to his sons. Latterly, his relations with Sulla were somewhat strained; after Sulla's death he resisted the attempt of the consul M. Aemilius Lepidus to repeal the constitution. In conjunction with A. Lutatius Catulus, the other consul, he defeated Lepidus when he tried to march upon Rome, and drove him out of Italy (77). He retained his army, and jockeyed the senate into sending him to Spain pro *consule* (though he had as yet held no magistracy) to deal with Sertorius. Pompey was fighting in Spain from 76 to 71. After Sertorius had fallen a victim to assassination, Pompey easily defeated his successor Perperna and put an end to the war. On his way back he met and cut up a body of slaves, part of Spartacus' defeated forces, in flight northwards. He demanded a triumph, and permission to stand for the consulate.

The Consul. — The senate was inclined to grudge it, so he entered into a coalition with Crassus, and as both had armies at the gates, there was no more to be said. Pompey and Crassus were consuls together in 70, and that year saw the work of Sulla undone; the tribunate and censorship were restored, and the administration of justice was shared between the Senate, the equites, and the *tribuni aerarii.*

Pompey rose still higher in popularity, and on the motion of the tribune Aulus Gabinius in 67 he was entrusted with an extraordinary command over the greater part of the empire, specially for the extermination of piracy in the Mediterranean, by which the corn supplies of Rome were seriously endangered, while the high prices of provisions caused great distress. He was completely successful; the price of corn fell immediately on his appointment, and in 40 days the Mediterranean was cleared of the pirates. Next year, on the proposal of the tribune Manilius, his powers were still further extended, the care of all the provinces in the East being put under his control for three years together with the conduct of the war against Mithridates VI., who had recovered from the defeats he had sustained from Lucullus and regained his dominions. Both Caesar and Cicero supported the tribune's proposal, which was easily carried in spite of some opposition in the senate. Pompey was entirely successful. Mithridates was beaten and driven into the Crimea, and there was a general settlement of affairs in the East. Syria and Palestine were annexed in 64 and 63. Tigranes of Armenia submitted and was confirmed as a vassal king, and an agreement was reached with Phraates of Syria whereby the Euphrates marked the boundary between them.

Pompey, now in his 45th year, returned to Italy in 61 to celebrate the most magnificent triumph which Rome had ever witnessed, as the conqueror of Spain, Africa and Asia.

Politics. — This triumph marked the turning-point in his career. As a soldier everything had gone well with him; as a politician he was a failure. He found a great change in public opinion, and the people indifferent to his achievements abroad. The senate had a unique chance to secure his support, but refused to ratify the arrangements he made in Asia or to provide money and lands for distribution amongst his veterans. In these circumstances he drew closer to Caesar on his return from Spain, and became reconciled to Crassus. The result was the first triumvirate. He was married to Caesar's daughter Iulia, and as yet the relations between the two had been friendly. Pompey was now in fact ruler of the greater part of the empire, while Caesar had only the two provinces of Gaul. But being no political tactician, Pompey made no use of this advantage, and all this time the balance of power was steadily turning in Ceasar's direction. The senate and the aristocracy disliked and distrusted Pompey, but they felt that, should things come to the worst, they might still find in him a champion of their cause. Hence the joint rule of Pompey and Caesar was not unwillingly accepted, and anything like a rupture between the two was greatly dreaded as the sure beginning of anarchy throughout the Roman world. In 55 Pompey was consul again, in accordance with the arrangement with Caesar when the triumvirate was renewed at Luca in 56. As proconsul he should have left for his province, but he remained in charge of the corn-supply, virtually master of Rome, and governed Spain by his legati. With the death of Pompey's wife Iulia (54) and of Crassus (53) the relations between him and Caesar became strained, and soon afterwards he drew closer to the conservative party and married into the house of Scipio. In 52, in the utter disorder that followed the death of Clodius, he was elected sole consul, carried through the trial of Milo, and started a programme of administrative and provincial legislation threatening Caesar's position.

Civil War. — The crisis arrived with the approaching end of Caesar's command at the end of 50. Pompey nearly compromised by accepting the Parthian command and leaving Rome, but Marcellus forced his hand, and civil war began. Pompey, wisely or unwisely, abandoned Italy. His cause, with that of the senate and aristocracy, was finally ruined by his defeat by Julius Caesar in 48 in the neighbourhood of Pharsalus. That same year he fled with the hope of finding a safe refuge in Egypt, but was treacherously murdered by one of his old centurions as he was landing. He was five times married, and three of his children survived him — Gnaeus, Sextus, and a daughter Pompeia.

POMPONAZZI, PIETRO (PETRUS POMPONATIUS) (1462–1525), Italian philosopher, was born at Mantua on Sept. 16, 1462, and died at Bologna on May 18, 1525. He took his M.D.

at Padua in 1487 and was elected extraordinary professor of philosophy. From about 1495 to 1509 he occupied the chair of natural philosophy and when the schools of Padua closed, he took a professorship at Ferrara where he lectured on the *De anima.* From 1512 to his death he was at Bologna where he produced all his important works. In 1516 appeared his *De immortalitate animi,* which gave rise to a storm of controversy between the orthodox Thomists, the Averroists headed by Agostino Nifo, and the so-called Alexandrist School. The treatise was burned at Venice, and Pomponazzi himself ran serious risk of death. Two pamphlets followed, the *Apologia* and the *Defensorium,* wherein he explained his paradoxical position as Catholic and philosophic materialist. His last two treatises, the *De incantationibus* and the *De fafo,* were posthumously published in an edition of his works printed at Basel.

See A. H. Douglas, *Philosophy and Psychology of Pietro Pomponazzi* (1910) ; J. A. Symonds, *The Renaissance in Italy;* L. Ferri, *La Psicologia di P. Pomponazzi* (1877) ; Überweg, *Grundriss der Gesck. der Philosophie* p. 1–3.

POMPOSA, an abbey of Emilia, Italy, in the province of Ferrara, 2 m. from Codigoro, which is 30 m. E. of Ferrara in the delta of the Po. The fine church, a work of the 6th century, rebuilt in the 11th, with interesting sculptures and terra cotta decorations on the façade and a splendid Romanesque campanile 163 ft. high (1063) contains a good mosaic pavement (1036) and interesting frescoes of the 14th century—a "Last Judgment" of the school of Giotto and others; and there are also paintings in the refectory. It was abandoned in 1650 on account of malaria.

See G. Agnelli, *Ferrara e Pomposa* (Bergamo, 1902), and F. R. Hiorns in *Journal of the Royal Institute of British Architects* xxxiv. (1927) 355 *sqq.*

POMPTINE MARSHES, a low tract of land in the province of Rome, Italy, varying in breadth between the Volscian mountains and the sea from 10 to 16 m , and extending north-west to south-east from Velletri to Terracina (40 miles). In ancient days this tract was fertile and contained prosperous cities (Suessa Pometia, Ulubrae—perhaps the mod. Cisterna—etc.), but it had already become unhealthy at the end of the Republican period. Attempts to drain the marshes were made by Appius Claudius in 312 B.C., when he constructed the Via Appia through them and at various times during the Roman period. A canal ran through them parallel to the road and was used in preference to the road during the Augustan period. Trajan repaired the road, and Theodoric did the same some 400 years later. But in the middle ages it had fallen into disrepair. Popes Boniface VIII., Martin V., Sixtus V., and Pius VI. all attempted to solve the problem, the last-named reconstructing the road admirably. By a law passed in 1919 the special provisions for the obligatory improvement of the Roman Campagna had been extended to the Pomptine territory.

See T. Berti, *Paludi pontine* (Rome, 1884) ; R. de la Blanchère, *Un Chapitre d'histoire pontine* (Paris, 1889).

PONCA CITY, a city of Bay county, Oklahoma, U.S.A., on the Arkansas river, at an altitude of 1,000 ft., 90 mi. N. by E. of Oklahoma City. It is on federal highways 60 and 77; has a municipal airport and is an air-mail station on the Chicago-Dallas route; and is served by the Rock Island and Santa Fe railways. The population in 1940 was 16,794. It is the second largest city in the historic Cherokee strip; the trading point for six Indian tribes; and the centre of one of the greatest light oil-producing districts in the country. The two large refineries located there, the Continental Oil company and the Cities Service Oil company, are connected by pipe lines to fields producing under proration more than 200.000 bbl. of oil per day. but potentially capable of yielding much in excess of that amount. The two refineries have a combined capacity of 40.000 bbl. per day. Both are connected with the Great Lakes Pipe line. the first major pipe line in the country, which transports the refined products to the principal cities in the midwest and Great Lakes region. The city is the home of the famous Pioneer Woman statue, donated to the state by former Governor E. W. Marland, founder of the old Marland Oil company, and resident of the city. Nine miles south of the city is the old Miller Brothers 101 Ranch, now being broken up into small farming tracts by the Farm Security administration (1941). The site of Ponca City was visited by one of General Pike's lieutenants in 1806. The city was founded on Sept. 16,1893, when the Cherokee strip was opened to white settlement, and was incorporated in 1899. Oil was discovered in 1911. In 1940 the city had an assessed valuation of $6,000,000, and the school district, $14,000,000. The city owns its electric light and water plants, the profits from which meet all the expenses of the municipal government, and no city tax of any kind has been levied since 1931.

PONCE, the largest and most important city on the southern coast of Puerto Rico and the second city in size and importance on the island. The population in 1940 was 65,182. The population of the municipal district in 1940 was 105,116.

Although the name of the city appears in public documents since early in the history of Spanish colonization, it was not until 1836 that it became an independent municipality. After that its growth increased and its importance was greatly magnified. Ponce was one of the first places at which the American forces landed in Puerto Rico during the Spanish-American War. They were most cordially and enthusiastically welcomed by the citizens. They took possession of the city, after having entered into an agreement with the Spanish forces who withdrew into the interior of the island.

Ponce has an agreeable climate, the temperature being moderated by the constant breezes prevailing during the greater part of the year. Industrially and commercially it is one of the foremost cities of the island. It is the principal shipping port on the Caribbean sea, and has an increasing commerce with the southern islands and the northern countries of South America. This importance has been recognized by the Government at Washington, and extensive improvements of the harbour are now under way under the direction of the U.S. service.

Ponce is a well managed city and its streets, plazas, parks and recreation grounds are well kept and attractive. Its public buildings and private residences are well built, and the beautiful setting among the tropical foliage and blossoms excite admiration.

The city is on the line of the American railroad, and is the terminus of important highways, north, east and west. There are several banks and some important commercial and industrial firms, producing cigars and cigarettes, bay rum, mineral waters, hats, shoes, clothing, laces, embroidery, cut diamonds, foundry and iron products, ice, brick, chocolate, soap and candy. The city has water-works, electric light and power, telegraph, telephone and cable service. It has two daily newspapers and several weekly publications. (H. M. T.; X.)

PONCE DE LEON, JUAN (c. 1460–1521), discoverer of Florida, was born in Servas, Spain, about 1460. He took part in the Moorish wars and then sailed for America with Columbus on his second voyage (1493). In 1509 he conquered Porto Rico and was appointed governor. As soon as the island was under control and pacified he set out with three ships to search for the land of "Bimini," wherein, as the Indian legend told him, there was a fountain with waters of marvellous curative power. On Mar. 27, 1513, he discovered the mainland which he named Florida because the day was Easter Sunday (*Pascua Florida*). He landed north of the present site of St. Augustine on April 2, and on April 8 took possession in the name of the Spanish king. He afterwards explored the coast southward to the cape and up the west shore of the peninsula to at least 27° 30′, and perhaps to where the coast trended westward. He returned to Spain in 1514, and received an appointment from Ferdinand V. as governor of "The Island of Florida." In 1521 he set out to conquer and colonize his possession but the fierceness of the natives prevented his success. In a sharp engagement Ponce de León was mortally wounded and his force driven to the ships. He died in Cuba in June 1521.

See F. A. Ober, *Ponce de Ledn* (1908) ; Justin Windsor, *Narrative and Critical History of America,* vol. ii. chap. iv. (1886) ; "The Track of Ponce de León," *Amer. Geog. Soc. Bulletin, xlv.,* pp. 721–735 (1913) ; *Boletin histórico de Puerto Rico, Año I;* pp. 118–161 (1914).

PONCELET, JEAN VICTOR (1788–1867), French mathematician and engineer, was born at Metz on July 1, 1788. From 1808 to 1810 he attended the *École polytechnique,* and afterwards, till 1812, the *École d'application* at Metz. He then became lieutenant of engineers, and took part in the Russian campaign, during which he was taken prisoner arid was confined at Saratov on the Volga until 1814, when he returned to France. During his imprisonment he began his researches on projective geometry which led to his great treatise on that subject. This work, the *Traité des propriétés projectives des figures,* which was published in 1822 (2d ed., 2 vols. 1865–66), is occupied with the investigation of the projective properties of figures *(see* GEOMETRY), and entitles Poncelet to rank as one of the greatest of those who took part in the development of the new geometry of which G. Monge was the founder. Poncelet developed the principle of Duality, and discovered the circular points at infinity, so causing the principle of continuity to be recognized. From 1815 to 1825 he was occupied with military engineering at Metz; and from 1825 to 1835 he was professor of mechanics at the *Bcole d'application* there. In 1834 he became a member of the *Acade'mie;* from 1838 to 1848 he was professor to the faculty of sciences at Paris, and from 1848 to 1850 commandant of the *École polytechnique.* He died at Paris on Dec. 22, 1867.

Poncelet's works include *Cours de méchanique, applique'e aux Machines* (1826) ; and *Mémoire sur les roues hydrauliques à aubes courbes* (1826). *See* J. Bertrand, *Éloge historique de Poncelet* (1875).

PONCHIELLI, AMILCARE (1834–1886), Italian musical composer, was born near Cremona on Sept. 1, 1834, and studied at the Milan Conservatoire. He attained his fame with *La Gioconda* (1876), written to a libretto founded by Arrigo Boito upon Victor Hugo's tragedy, *Angelo, Tyran de Padoue. La Gioconda* was followed by *Il Figliuol prodigo* (1880) and *Marion Delorme* (1885). In 1881 Ponchielli was made maestro di cappella of Piacenza cathedral. He died at Milan on Jan. 17, 1886.

POND, JOHN (*c.* 1767–1836), English astronomer-royal, was born about 1767 in London. After leaving Trinity college, Cambridge, he settled at Westbury near Bristol, and began to determine star-places with a fine altitude and azimuth circle of 23 ft. diameter by E. Troughton. His demonstration in 1806 *(Phil. Trans.* xcvi. 420) of a change of form in the Greenwich mural quadrant led to the introduction of astronomical circles at the Royal Observatory, and to his own appointment as its head. He was elected a fellow of the Royal Society on Feb. 26, 1807; he married and went to live in London in the same year, and in 1811 succeeded Maskelyne as astronomer-royal.

Under Pond the instrumental equipment at Greenwich was completely changed, and the number of assistants increased from one to six. The superior accuracy of his determinations was attested by S. C. Chandler's discussion of them in 1894, in the course of his researches into the variation of latitude (*Astron. Journ.* Nos. 313, 315). Pond received many academic honours. He published eight folio volumes of *Greenwich Observations,* translated Laplace's *Système du monde* (in 2 vols. 8vo., 1809), and contributed thirty-one papers to scientific collections. His catalogue of 1.112 stars (1833) was of great value. He retired in 1835 and died at Blackheath on Sept. 7, 1836, and was buried beside Halley in the churchyard at Lee.

Airy's *Autobiography,* p. 127; *Observatory,* xiii. 204, xxii. 357; *Annual Biography and Obituary* (1837); *R.* Grant, *Hist. of Phys. Astron.* p. 491; Royal Society's *Cat. Scient. Papers;* Maunder, *The Royal Observatory Greenwich.*

POND, a small pool of standing water; the name is usually applied to one for which the bed has been artificially constructed. The term is a variant of "pound" (*q.v.*), an enclosure.

PONDICHERRY, the capital of the French possessions in India, situated on the Coromandel or western coast, 122 m. by rail S. of Madras. The territory, which is entirely surrounded by the British district of South Arcot, has an area of 113 sq.m. with a population (1936) of 179,890. It is ruled by a governor, with a Privy Council, and a General Council, and is represented in the French senate and chamber. The chief crops are dry grains, rice, earth-nuts and a little indigo. The territory is traversed by a branch of the South Indian railway from Villapuram. The town (pop. [1936] 48,896) is well laid out with fine public buildings, and lit by electricity; the water-supply is derived from artesian wells. There is a college, and a fine Court of Appeal building was begun in 1927.

Pondicherry was founded in 1683 by François Martin, on the site of a village given him by the governor of Gingee. In 1693 the Dutch took Pondicherry, but restored it, with the fortifications greatly improved, in 1697, at the peace of Ryswick. In 1748 Admiral Boscawen laid siege to it without success, but in 1761 it was taken by Colonel Coote from Lally. In 1763 it was restored to the French. In 1778 it was again taken by Sir Hector Munro, and its fortifications destroyed. In 1783 it was retransferred to the French, and in 1793 recaptured by the English. The treaty of Amiens in 1802 restored it to the French, but it was retaken in 1803. In 1816 it was restored to the French.

PONDO, a Kafir people who have given their name to Pondoland, the country comprising much of the seaboard of Kaffraria, Cape province, immediately to the south-west of Natal.

PONDWEED, a popular name for *Potamogeton natans,* a cosmopolitan aquatic plant found in ponds, lakes and ditches, with broad, more or less oblong-ovate, olive-green, floating leaves. The name is also applied to other species of *Potamogeton,* one of the characteristic genera of lakes, ponds and streams all over the world, but more abundant in temperate regions, embracing about 90 species. It is the principal genus of the family Potamogetonaceae, and contains plants with slender branched stems, and submerged and translucent, or floating and opaque, alternate or opposite leaves, often with membranous united stipules. The small flowers are borne above the water in axillary or terminal spikes; they have four stamens, which bear at the back four small herbaceous petal-like structures, and four free carpels, which ripen to form four small green fleshy fruits, each containing one seed within a hard inner coat; the seed contains a large hooked embryo. An allied genus *Zannichellia,* occurring in fresh and brackish ditches and pools in Great Britain and nearly throughout North America, and also widely elsewhere in temperate and tropical regions, is known as horned pondweed, from the curved fruit.

FROM STRASSBURGER, "LEHRBUCH DER BOTANIK FUR HOCHSCHULEN" (GUSTAV FISCHER)

PONDWEED (POTAMOGETON NATANS) SHOWING FLOWERING STEM AND LEAVES

See P. Ascherson and P. Graebuer, "Potamogetonaceae," *Pflanzenreich* 31 (iv, ii): 1–184, fig. 1–36 (1907).

PONGEE, a plain-weave fabric made of *tussah* or wild silk, originated with the Chinese in ancient times. Its sphere of usefulness has been broadened due chiefly to the increase in standard width from 18 to 36 or more inches, and the variety of colours extended. The Japanese buy from the Chinese the wild silk and work it up in their own plants. *Shantung,* a variety of pongee, derives its name from the province which is the centre of the wild silk industry. It differs from true pongee in that the former must be a plain weave, while Shantung may include many types, even adding coloured threads for decoration. Because of the ease with which they can be laundered and their durability pongees are among the most practical of silks.

PONIARD, a dagger, particularly one of small size, used for stabbing at close quarters. The French word *poignard,* from which the English is a 16th century adaptation, is formed from *poing,* fist, in which the weapon is grasped. *(See* DAGGER.)

PONIATOWSKI, the name of a Polish princely family of Italian origin, tracing descent from Giuseppe Torelli, who married about 16jo an heiress of the Lithuanian family of Poniatov, whose name he assumed.

STANISLAUS PONIATOWSKI (1677–1762), only belonged to the family by adoption, being the reputed son of Prince Sapieha and a Jewess. He was born at Dereczyn in Lithuania, and was adopted by Sapieha's intendant, Poniatowski. Attaching himself to the party of Stanislaus Leszczynski, he became major-general in the army of Charles XII. of Sweden, who also employed him as diplomatic intermediary to the Sultan. He next became governor of the duchy of Zweibriicken, Bavaria. After the death of Charles XII. in 1718 he visited Sweden; and was subsequently reconciled with Leszczynski's rival on the throne of Poland, Augustus II., who made him grand treasurer of Lithuania in 1724. On the death of Augustus II. he tried to secure the reinstatement of Leszczynski, but presently gave his allegiance to Augustus III., by whom he was made governor of Cracow. He died at Kyki on Aug. 3, 1762.

His second son Stanislaus Augustus became king of Poland. *(See* STANISLAUS II.) Of the other sons, Casimir (1721–1780) was his brother's chancellor; Andrew (1735–1773) became feldzeugmeister in the Austrian service; and Michael (1736–1794) became archbishop of Gnesen and primate of Poland. Joseph Anthony (*q.v.*), son of Andrew, became one of Napoleon's marshals.

STANISLAUS PONIATOWSKI (1757–1833), son of Casimir, was grand treasurer of Lithuania, starost of Podolia and lieutenant-general of the royal army In 1793 he settled in Vienna, and subsequently in Rome, where he made a magnificent collection of antique gems, subsequently sold. He died in Florence, Feb. 13, 1833, and the Polish and Austrian honours became extinct.

His natural, but recognized, son, JOSEPH MICHAEL XAVIER FRANCIS JOHN PONIATOWSKI (1816–1873), was born at Rome and in 1847 was naturalized as a Tuscan subject. He received the title of prince in Tuscany (1847) and in Austria (1850). He represented the court of Tuscany in Paris from 1848, and he was made a senator by Napoleon III., whom he followed to England in 1871. He also wrote numerous operas. He died on July 3, 1873. His son, Prince Stanislaus Augustus, married and settled in Paris. He was equerry to Napoleon III., and died in Jan. 1908.

PONIATOWSKI, JOSEPH ANTHONY (1763–1813), Polish prince and marshal of France, son of Andrew Poniatowski and the countess Theresa Kinsky, was born at Warsaw in 1763. He served with distinction in the imperial forces against the Turks in 1788, then becoming major-general and subsequently lieutenant general in the Polish army under his uncle, King Stanislaus. In 1789 he commanded the Ukrainian division; and after the proclamation of the constitution of May 3, 1791, was made commander-in-chief. Aided by Kosciuszko, he conducted the operations against Russia with much skill, but when the king acceded to the confederation of Targowica *(see* POLAND: *History),* at the same time guaranteeing the adhesion of the army, Poniatowski, and most of the other generals threw up their commissions and emigrated. During the Kosciuszko rising he again fought gallantly for his country under his former subordinate, and after the fall of the republic lived in retirement. After the evacuation of the Polish provinces by Prussia, Poniatowski became commander of the National Guard, and on the creation of the grand duchy of Warsaw he was nominated war minister.

During the war of 1809, he operated successfully against the Austrians. In Napoleon's campaign against Russia in 1812 Poniatowski commanded the fifth army corps; and after the disastrous retreat of the grand army remained faithful and formed a new Polish army of 13,000 men, with which he joined the emperor at Liitzen. In 1813 he guarded the passes of the Bohemian mountains and defended the left bank of the Elbe. As a reward for his brilliant services at Leipzig he was made a marshal of France and entrusted with the duty of covering the retreat of the army, in the course of which he perished, fighting heroically against overwhelming odds. His relics were conveyed to Poland and buried in Cracow Cathedral, where he lies by the side of Tadeusz Kosciuszko and Jan Sobieski. Poniatowski's *Mes souvenirs sur la campagne de 1792* (Leinberg, 1863) is of historical value.

See *Correspondence* , *Poniatowski* (ed. E. Raczynski, Posen, 1843); Bronislaw Dembinski, *Stanislaus Augustus and Prince Joseph Poniatowski in the light of their Correspondence* (Fr.; Lemberg, 1904); Szymon Askenazy, *Prince Joseph Poniatowski* (Pol.; Warsaw, 1905).

PONS, JEAN LOUIS (1761–1831), French astronomer, was born at Peyres (Hautes Alpes) on Dec. 24, 1761. He entered the Marseilles observatory in 1789, and in 1819 became the director of the new observatory at Marlia near Lucca, which he left in 1825 for the observatory of the museum at Florence. Here he died on Oct. 14, 1831. I-Ie spent his time searching for comets, of which he discovered a record number; some bear his name, *e.g.*, Pons-Winnecke's comet.

See M. *R. A.* Henrion, *Annuaire biographique*, i. 288 (1834): *Memoirs Roy. Astron. Soc.* v. 410; *R.* Wolf, *Geschichte der Astronomie*, p. 709; *J.* C. Poggendorff, *Biog. lit. Handworterbuch.*

PONSARD, FRANÇOIS (1814–1867), French dramatist, was born at Vienne, Isère, on June 1, 1814, and studied law. His translation of *Manfred* was published in 1837. His play *Lucrdce* was represented at the Théâtre Français on April 1, 1843. This date marks a reaction against the romantic style of Dumas and Hugo. He received, in 1845, the Academy's prize for a tragedy "to oppose a dike to the waves of romanticism." Ponsard combined the liberty of the romantics with the sober style of earlier French drama. The success of his plays was aided by the impersonation of many of the principal rôles in them by Rachel. He followed up *Lucrèce* with *Agnès de Méranie* (1846), *Charlotte Corday* (1850), and others. *L'Honneur et l'argent,* one of his most successful plays, was acted in 1853, and he became an academician in 1855. In 1866 he obtained great success with *Le Lion Amoureux,* another play dealing with the revolutionary epoch. His *Galilée,* which excited great opposition in the clerical camp, was produced in 1867. He died in Paris on July 7, 1867.

His *Oeuvres complètes* were published in Paris (3 vols., 1865-76). *See* C. Latreille, *La Fin du théâtre romantique et François Ponsard d'après des documents inédits* (1899).

BONSONBY OF SHULBREDE, ARTHUR AUGUSTUS WILLIAM HARRY PONSONBY, 1ST BARON (1871–), British author and politician, was born on Feb. 16, 1871, and educated at Eton and at Balliol college, Oxford. In 1894 he entered the diplomatic service, and after holding posts in Constantinople and Copenhagen, returned in 1902 to join the staff of the Foreign Office. In 1906 he became principal private secretary to Sir Henry Campbell-Bannerman, and two years later was elected Liberal M.P. for Stirling. He represented this constituency until 1918, and in 1922 was elected Labour member for the Brightside division of Sheffield, and held various minor posts in the Labour Governments of 1924 and 1929–31. He was raised to the peerage in 1930, and was leader of the opposition in the House of Lords from 1931 to 1935.

His works include *The Decline of Aristocracy* (1912); *Democracy and Diplomacy* (1915); *Wars and Treaties (1815–1914)* (1917); *Religion in Politics* (1921); *Now is the Time* (1925).

PONSONBY, English family. PONSONBY, JOHN (1713–1789), Irish politician, was born on March 29, 1713. In 1739 he entered the Irish parliament, where he became first commissioner of the revenue (1744), a privy councillor (1746), and in 1756 Speaker. Belonging to one of the great families which at this time monopolized the government of Ireland, Ponsonby was one of the principal "undertakers," men who controlled the whole of the king's business in Ireland, and he retained the chief authority until the marquess Townshend became lord-lieutenant in 1767. A struggle for supremacy between the Ponsonby faction and the party dependent on Townshend followed, which caused Ponsonby to resign the speakership in 1771. He died on Dec. 12, 1789. His wife was Elizabeth, daughter of William Cavendish, 3rd duke of Devonshire, a connection of advantage to the Ponsonbys.

Ponsonby's third son, GEORGE PONSONBY (1755–1817), lord chancellor of Ireland, was born on March 5, 1755, and educated at Trinity College, Cambridge. A barrister, he became a member of the Irish parliament in 1776 and was chancellor of the Irish exchequer in 1782, afterwards taking part in the debates on the question of Roman Catholic relief, and leading the opposition to the union of the parliaments. Ponsonby represented Wicklow and then Tavistock in the united parliament; in 1806 he was lord chancellor of Ireland, and from 1808 to 1817 he was the official leader of the opposition in the House of Commons

He left an only daughter when he died in London on July 8, 1817.

George Ponsonby's elder brother, WILLIAM BRABAZON PONSONBY, 1st Baron Ponsonby (1744–1806), was also a leading Whig politician, being a member of the Irish, and after 1800, of the British parliament. In 1806 shortly before his death he was created Baron Ponsonby of Imokilly. On the death of his grandson, WILLIAM BRABAZON PONSONBY (1807–1866), the barony became extinct.

PONTA DELGADA, the capital of an administrative district, comprising the islands of St. Michael's and St. Mary in the Portuguese archipelago of the Azores. Pop. (1930), 18,022. Ponta Delgada is built on the south coast of St. Michael's, in 37° 40' N. and 25° 36' W. Its mild climate, and the fine scenery of its mountain background, render it very attractive to visitors; it is the commercial centre, and the most populous city of the archipelago. Great improvements in the harbour were effected after 1860 by the construction of a breakwater 2,800 ft. long.

PONT-À-MOUSSON, a town of northern France in the department of Meurthe-et-Moselle, 17 mi. N.N.W. of Nancy by rail. Pop. (1936) 11,036. Dating from the 9th or 10th century, Pont-à-Mousson constituted a lordship, which was made a marquisate in 1354. It mas from 1572 to 1763 the seat of a well-known university. The Moselle divides the town into two quarters, united by a 16th century bridge. The church of St. Martin dates from the 13th, 14th and 15th centuries. The lower ecclesiastical seminary occupies the building of an old Premonstratensian convent. The town has engineering workshops, blast furnaces, and manufactures of lacquered ware, paper, cardboard, cables and tin- and iron-\\are. It is an agricultural centre.

PONTANUS, JOVIANUS (1426–1503), Italian humanist and poet, was born in 1426 at Cerreto, in the duchy of Spoleto, and educated, after the death of his father in a civil disturbance, at Perugia. At the age of 22 he went to Naples, where he remained for the rest of his life. He became a friend of the famous scholar Beccadolli, and was introduced by him to Alphonso the Magnanimous, who made him tutor to his sons. Thereafter he was political adviser, military secretary and chancellor to the Aragonese dynasty. He illustrates very clearly the importance of men of letters in Italy. He arrived in Naples a penniless scholar, and became almost immediately one of the most important men in the kingdom. He founded an academy for the meetings of scholars in Naples, which lasted long after his death. In 1461 he married Adriana Sassone, who bore him one son and three daughters and died in 1491. Soon after this he married a girl from Ferrara, only known to us as Stella. He was passionately fond of wife and children, and much of his verse, especially *Eridanus,* written after his second marriage, tells of his love for them. He outlived Stella also, and died in 1503 at Naples, where a group of life-size terra-cotta figures is still to be seen on his tomb at Monte Oliveto church. Pontanus had a good Latin style and the faculty, rare among his contemporaries, of expressing the facts of modern life, the actualities of personal emotion, in language sufficiently classical yet always characteristic of the man. His ambitious *Urania* embodies the astronomy of the day. His most original compositions in verse, however, are elegiac and hendecasyllabic pieces on personal topics—the *De conjugali amore, Eridanus, Tumuli, Naeniae, Baiae, etc.*—in which erotic freedom is condoned by a passionate sincerity. Pontanus' prose and poems were printed by the Aldi at Venice. For his life *see* Ardito, *Giovanni Pontano e i suoi tempi* (Naples, 1871) ; for his place in the history of literature, Symonds, *Renaissance* in *Italy* (1875, etc.).

PONTARLIER, capital of an arrondissement in the department of Doubs, eastern France, 36 mi. S.E. of Besançon. Pop. (1936), 12,639. It is 2,750 ft. above sea-level on the Doubs, about 4 mi. from the Swiss frontier, and forms an important strategic point at the mouth of the defile of La Cluse, one of the principal passes across the Jura. Pontarlier is the seat of a subprefect. It is the junction of railway lines to Neuchâtel, Lausanne, Lons-le-Saunier, Dole and Besançon, and has an airfield. At Pontarlier the French army of the East made its last stand against the Prussians in 1871 before crossing the Swiss frontier. The distillation of herbs, largely grown for kirsch and other liqueurs, is the chief industry. Clocks and watches are manufactured.

PONT AUDEMER, a town of northwestern France, in the department of Eure, 39 mi. N.W. of Evreux, on the railway to Honfleur. Pop. (1936) 6,279. The town owes its name to Audomar, a Frank lord, who in the 7th or 8th century bridged the Risle there. The church of St. Ouen, which has fine stained glass of the 16th century, combines the late Gothic and Renaissance styles; its choir is Romanesque. Manufacturing includes the founding of malleable metal; also glue and paper, cotton-spinning and leather goods. There is trade in flax, wool, grain, cattle, cider, paper, iron, wood and coal. The port has a length of over half a mile on the Risle, which is navigable for small vessels from this point to the Seine (10 mi.).

PONTECORVO, a city of Lazio, Italy, in the province of Frosinone, on the Garigliano, about 48 mi. from Caserta and 3 mi. from Aquino on the railway from Rome to Naples. Pop. (1936), 14,437 (town and the commune). The principality of Pontecorvo (about 40 sq.mi. in extent), once an independent state, belonged alternately to the Tomacelli and the abbots of Monte Cassino. Napoleon bestowed it on Bernadotte in 1806, and in 1810 it was incorporated with the French empire.

PONTECOULANT, LOUIS GUSTAVE LE DOULCET, COMTE DE (1764–1853), French politician, was born at Caen on Nov. 17, 1764. He entered the army in 1778. A moderate supporter of the revolution, he was returned to the convention for the department of Calvados in 1792, and became commissary with the army of the North. He attached himself to the party of the Gironde, and in Aug. 1793 was outlawed. He refused to defend his compatriot Charlotte Corday, who wrote him a letter of reproach on her way to the scaffold. He returned to the convention on March 8, 1795, and became its president in July; he was for some months a member of the council of public safety. He was elected to the council of five hundred, but was suspected of royalist leanings, and spent some time in retirement before the consulate. Becoming senator in 1805, and count of the empire in 1808, he organized the national guard in Franche Comté in 1811, and the defense of the northeastern frontier in 1813. He sat in the upper house under the Restoration. He died in Paris on April 3, 1853. *See* his *Souvenirs historiques et parlementaires 1764–1848* (4 vols., 1861–65).

PONTEFRACT (pronounced and sometimes written "Pomfret"), market town, municipal borough, in the West Riding of Yorkshire, England, 21 mi. S.W. from York, served by the L.M.S. and L.N.E. railways. Pop. (1938) 21,340. Area, 7.6 sq.mi. It is well situated, on an eminence, near the junction of the Aire and the Calder. The most important remains are those of the famous castle situated on a rocky height, and containing eight round towers. The remains are principally of Norman date, and an unusual feature is the existence of various subterranean chambers in the rock. Below the castle is All Saints church, which suffered severely during the siege of the castle, but still retains some work of the 12th century. In 1837 the tower and transepts were fitted for divine service. In Southgate is an ancient hermitage and oratory cut out of the solid rock, which dates from 1396. At Monkhill there are the remains of a Tudor building called the Old Hall. A grammar school of ancient foundation, renewed by Elizabeth and George III, occupies modern buildings. The town hall (18th century) occupies the site of one erected in 1656, which succeeded the old moot-hall dating from Saxon times. Among other buildings are the court house, the market hall, the assembly rooms, and large barracks. The foundation of the principal almshouse, that of St. Nicholas, dates from before the Conquest. Trinity Hospital was founded by Sir Robert Knolles (d. 1407). At Ackworth is a Society of Friends' school (1778), in the foundation of which Dr. John Fothergill (1712–1780) was a prime mover. There are extensive gardens and nurseries in the neighbourhood of Pontefract, and liquorice is grown for the manufacture of the celebrated Pomfret cakes. The town possesses iron-foundries, sack and matting manufactories, tanneries, breweries, corn mills and brick and terra-cotta works.

The remains of a Roman camp have been discovered near Pontefract. At the time of the Domesday Survey Tateshall (now Tanshelf, a suburb of the town) was the chief manor while Kirkby, afterwards the borough of Pontefract, was one of its members. The change of status was probably owing to the founding by Ilbert de Lacy, of a castle at Kirkby. The town was known as Pontefract in 1140 when Archbishop Thurstan died there. The manor remained in the Lacy family until it passed by marriage to Thomas, duke of Lancaster, who was beheaded after the battle of Boroughbridge. His estates were restored to his brother Henry, earl of Lancaster, on the accession of Edward III., and the manor thereafter formed part of the duchy of Lancaster. The town took part in most of the rebellions in the north of England, and in 1399 Richard II. was imprisoned and secretly murdered in the castle. During the Wars of the Roses the town was loyal to Henry VI., and several of the Yorkist leaders were executed here after the battle of Wakefield. It was taken by Robert Aske, leader of the Pilgrimage of Grace, in 1536. In 1642 the castle was garrisoned for Charles I. and sustained four sieges, the second in 1644, being successful, but two years later it was retaken by the royalists, who held it until after the execution of the king, when they surrendered to General Lambert and the castle was destroyed.

Roger de Lacy in 1194 granted a charter and in 1484 Richard III. incorporated the town. The market rights are still held under his charter. The privilege of returning two members to parliament which had belonged to Pontefract at the end of the 13th century was revived in 1620–21. Between 1885 and 1918 it returned one member, when its representation was merged in that of the county, its name being given to the division.

PONTEVEDRA, a maritime province of north-western Spain, before 1833 a part of Galicia. Pop. (1939), 599,149; area, 1,695 sq.mi., with a density of population, 353.4 inhabitants per square mile. The surface is mountainous. The coast line is deeply indented; navigation is rendered difficult by fogs in summer and storms in winter. Large agricultural fairs are held in the chief towns, and there is export of cattle, hams, salt meat and fish, eggs, breadstuffs, leather and wine. Vigo is the chief port and there are harbours at Bayona, Carril, Marin, Viliagarcia and elsewhere among the deep estuaries of the coast. At Tuy the Spanish and Portuguese railways meet.

PONTEVEDRA, the capital of the Spanish province of Pontevedra; on the Tuy-Corunna railway, and on the river Lerez, which here enters the Ria de Pontevedra, an inlet of the Atlantic. Pop. (1940) 32,120. The name of the town is derived from the ancient Roman bridge (pons *vetus*) of twelve arches, which spans the Lerez near its mouth. Pontevedra is mainly built of granite, and still partly enclosed by mediaeval fortifications. There is an active trade in grain, wine and fruit: cloth, hats, leather and pottery are manufactured.

PONTIAC (c. 1720–1769), famous chief of the Ottawa Indians and leader in the "Conspiracy of Pontiac" in 1763–64, was born about 1720, probably on the Maumee river, in what is now northwestern Ohio. His father was an Ottawa, and his mother an Ojibwa. By 1755 he had become a chief of the Ottawa and a leader of the loose confederacy of the Ottawa, Potawatomi and Ojibwa. As an ally of France, he possibly commanded the Ottawa in the defeat (1755) of Gen. Braddock. In 1760 he met Maj. Robert Rogers, then on his way to occupy Michilimackinac and other forts surrendered by the French, and agreed to let the English troops pass unmolested on condition that he should be treated with respect by the British. Like other Indians he soon realized the difference between French and English rule—that the Indians were no longer welcomed at the forts and that they would ultimately be deprived of their hunting grounds by encroaching English settlements. French hunters and traders encouraged Indian disaffection with vague promises of help from France; and in 1762 Pontiac enlisted the support of practically all the Indian tribes from Lake Superior to the lower Mississippi for a joint move to expel the British. He arranged for each tribe to attack the fort nearest to it in May 1763, and then to combine to wipe out the undefended settlements. Pontiac himself decided to capture Detroit, but his carefully laid plans for a surprise attack on May 9 were betrayed to the commanding officer, Maj. Gladwin, and he was forced to lay siege to the fort. The siege coneinued for five months, marked by desultory attacks and sorties. Schooners sent through Lake Erie with supplies and provisions were captured by the Indians, but Pontiac could not prevent reinforcements from Fort Niagara under Capt. Dalzell from reaching Detroit. However, when the besieged made a night attack on the Indian encampment, Pontiac, apprised of their coming, inflicted heavy losses on them at Bloody Run, July 31. The Indians were unused to making long sieges and, after a few months, several of the associated tribes made peace. With his own Ottawa, Pontiac continued to camp around Detroit until Oct. 30 when, hearing that no aid from the French could be expected owing to the signing of the peace treaty with the English, he withdrew to the Maumee river.

Pontiac's larger plan was more successful. Of the 12 fortified posts attacked by the Indians, all but four were captured; most of the garrisons were massacred; several relief expeditions were nearly annihilated, and the frontiers were desolated and plundered. Col. Bouquet, however, succeeded in defeating the Indians at Bushy Run, when on his way to relieve Forts Pitt and Ligonier, and in 1764, he led a second expedition into Ohio from Pennsylvania, and forced the Indian tribes to sue for peace and release their prisoners. Pontiac still hoped to arouse other tribes to continue the fight, but after another year he saw that the English were the real masters of the situation and, on behalf of the tribes lately banded in his league, he concluded a treaty of peace and amity with Sir William Johnson at Oswego, N.Y., July 25, 1766. Pontiac, laden with gifts from the enemy, returned to his home on the Maumee. He met his death in 1769 at the hands of an Illinois Indian bribed by an English trader to murder him at Cahokia (nearly opposite St. Louis). His death occasioned a bitter war among the Indians, and the Illinois group was all but annihilated by his avengers. Pontiac was one of the most remarkable men of the Indian race in American history, possessing a commanding energy and force of mind combined with subtlety and craft, and a power of organization.

PONTIAC, a city of Illinois, U.S.A., on the Vermilion river, 92 mi. S.W. of Chicago; the county seat of Livingston county. It is on highways 66, 116 and 23, and is served by the Chicago and Alton. the Illinois Central and the Wabash railways. Pop. 8,272 in 1930 (87% native white); 1940 population 9,585 by the federal census. It is the trading and shipping point for a rich agricultural region. Creameries, hatcheries, shoe factories, corn grinders and printing are its chief industries. It is the seat of a state penitentiary. The city was founded in 1837 and incorporated in 1872.

PONTIAC (pŏn′tĭ-ăc), a city of Michigan, U.S.A., 26 mi. N.W. of Detroit, on federal highways 10, 24 and state highway 59; the county seat of Oakland county. It is served by the Grand Trunk Western railroad and by intercity motor coach and truck lines. The population in 1940 was 66,626 by federal census. Pontiac is an important automobile manufacturing centre in the midst of a picturesque summer resort region. There are 11 state parks and one county park in the county which contains over 400 lakes. At Orchard lake (5 mi. S.E.) is Apple island, formerly the home of the famous Chief Pontiac, and on its shores are ancient burial grounds of the Sac, Huron and Wyandot Indians. The city's industries include automobiles, motor trucks, motor coaches, automobile engines, bodies, parts and accessories, drop forgings, tools and dies, paints and varnishes. The city has a land area of 19.8 sq.mi. and had an assessed property valuation in 1940 of $72,535,000.

There are more than 800 retail establishments. The city operates a municipal airport, six parks, one golf course, 26 schools with an enrolment of 14,837 and a public library. The Eastern state hospital for the insane is there. Pontiac was first settled in 1818, became the county seat in 1820, and was chartered as a city in 1861.

PONTIANUS, pope from 230 to 235. He was exiled by the emperor Maximinus to Sardinia. and in consequence of this sentence resigned (Sept. 28, 235). He was succeeded by Anteros.

PONTIFEX. The collegium of the pontifices was the most important priesthood of ancient Rome, being specially charged with the administration of the jus *divinum;* i e., that part of the civil law which regulated the relations of the community with the deities recognized by the State officially, together with a general superintendence of the worship of gens and family. The name is clearly derived from pons and *facere,* but whether this indicates any special connexion with the sacred bridge over the Tiber (*Pons* Sublicius) cannot now be determined. The college existed under the monarchy, when its members were probably three in number; they may be considered as legal advisers of the rex in all matters of religion. Under the republic they emerge into prominence under a pontifex *maximus,* who took over the king's duties as chief administrator of religious law, just as his chief sacrificial duties were taken by the rex *sacrorum;* his dwelling was the regia, "the house of the king." During the republican period the number of pontifices increased, probably by multiples of three, until after Sulla (82 B.C.) we find them 15; for the year 57 B.C. we have a complete list of them in Cicero (Harusp. *resp.* 6, 12). Included in the collegium were also the rex sacrorum, the *flamines,* three assistant pontifices (minores), and the vestal virgins, who were all chosen by the pontifex *maximus.* Vacancies in the body of *pontifices* were originally filled by co-optation; but from the second Punic war onwards the *pontifex maximus* was chosen by a peculiar form of popular election, and in the last age of the republic this held good for all the members. They all held office for life.

The immense authority of the college centred in the *pontifex maximus,* the other pontifices forming his *consilium* or advising body. His functions were partly sacrificial or ritualistic, but these were the least important; the real power lay in the administration of the *jus divinum,* the chief departments of which may briefly be described as follows: (1) the regulation of all expiatory ceremonials needed as the result of pestilence, lightning, etc.; (2) the consecration of all temples and other sacred places and objects dedicated to the gods by the State through its magistrates; (3) the regulation of the calendar both astronomically and in detailed application to the public life of the State; (4) the administration of the law relating to burials and burying-places, and the worship of the Manes, or dead ancestors; (5) the superintendence of all marriages by *confarreatio; i.e.,* originally of all legal patrician marriages; (6) the administration of the law of adoption and of testamentary succession. They had also the care of the State archives, of the lists of magistrates, and kept records of their own decisions (*commentarii*) and of the chief events (*annales*).

It is obvious that a priesthood with such functions and holding office for life, must have been a great power in the State, and for the first three centuries of the republic it is probable that the pontifex *maximus* was in fact its most powerful member. The office might be combined with a magistracy, and, though its powers were declaratory rather than executive, it may be described as quasi-magisterial. Under the later republic it was coveted chiefly for the great dignity of the position; Julius Caesar held it for the last 20 years of his life, and Augustus took it after the death of Lepidus in 12 B C, after which it became inseparable from the office of the reigning emperor.

See Marquardt, *Staatsverwaltung,* iii. 235 et seq.; Wissowa, Religion *u. Kultus* der *Römer,* 501 seq.; Bouché-Leclercq, Les *Pontifes,* passim.
