Aluminum bronzes can be welded by the metallic arc process and can be brazed, with special fluxes. Other applications are pickling crates and parts of plants dealing with dilute sulfuric, hydrochloric and hydrofluoric acids; papermaking machinery; in the electrical industry for brush holders and clamps for welding machines; heavy-duty gear wheels, worm wheels, metal forming dies and machine guides; nonsparking tools and nonmagnetic chains and anchors. Because of their golden colour and high resistance to tarnishing the alloys are also used for jewelry and in architectural work. (E. C. M.)

ALUNDUM, a hard material belonging to the class of abrasives (*q.v.*), also used for the manufacture of laboratory apparatus. It is obtained by fusing bauxite (*q.v.*) in an electric furnace.

ALUNITE or ALUM STONE, a hydrated basic aluminum and potassium sulfate mineral which has alternately served as a source of potash (during World War I) and as a source of alumina (during World War II). In Europe it was once used extensively to make potash alum, being mined for this purpose since its first recognition at Tolfa, near Rome, in the 15th century (see ALUM). Alunite occurs as pockets or seams in volcanic rocks such as rhyolites, trachytes and andesites, presumably formed by their chemical reaction with escaping sulfuriferous vapours. Large deposits occur near Beregszász, Hung., Almeria, Spain, and Bullah Delah in New South Wales, Austr. In the United States alunite has been mined at Marysvale, Utah, and Sulphur, Nev. Common colours are white, gray or reddish buff. The composition of alunite is $KAl_3(SO_4)_2(OH)_2$. Its hardness of 3.5 to 4 on Mohs' scale may be increased by admixtures of quartz and feldspar. (F. D. B.)

ALVAR, from a Tamil word implying absorption in devotion, designates a class of southern Indian saints, wandering singers intensely devoted to Vishnu, the second member of the Hindu trinity. Their earliest representatives lived in the 2nd century A.D. and the latest in the 10th. The Alvars, inspired by the teaching of Vishnuism, which traveled southward from the north, composed and sang poems in Tamil. Their doctrines, similar to the *bhakti* (love or devotion) mysticism of the Bhagavata Purana and the Bhagavad Gita, were embodied in psalms rather than philosophical treatises, and some of their hymns rate high in the world's treasury of devotional literature. Describing his insatiable love for God, Nam Alvar said:

My heart for his wonderful grace melts
How then can I my restless love suppress?

In the 7th and 8th centuries 12 Alvars wandered through the south, and the attractiveness of their school was strongly instrumental in the defeat and absorption of Buddhism in India. Theistic interpretations of the Vedanta Sutra (see INDIAN PHILOSOPHY: *Vedanta*), advanced by the passionate devotional hymns of the Alvars, culminated in the philosophy of Ramanuja, according to whom *bhakti* was the essential teaching of the Vedanta.

See K. W. Morgan (ed.), *The Religion of the Hindus*, pp. 36–37, 39–40 (1953); Surendranātha Dāsa-Gupta, *Hindu Mysticism*, pp. 149–150 (1927). (E. J. Ju.)

ALVARADO, PEDRO DE (1485?–1541), one of the conquerors of Mexico and Central America, was born at Badajoz, Spain, about 1485. He commanded one of the ships of Juan de Grijalva that were sent from Cuba in 1518 to explore Yucatán, and in Feb. 1519 he accompanied, also from Cuba, Hernan Cortés'

army that was to conquer Mexico. Alvarado was placed in charge of Tenochtitlán, or Mexico City, after its first occupation, and in 1522 he became the city's first *alcalde mayor*, or principal magistrate. When the Spaniards, because of Aztec hostilities, were forced to retire temporarily from the city on June 30, 1520 (la Noche Triste), Alvarado was in command of the rear guard. It has been said that during the flight of the Spaniards, Alvarado, with the use of his spear, vaulted across a broad opening in one of the city's causeways. This was the famous *Salto de Alvarado*, one of the several fables of the conquest.

In 1523, leading an army of Spaniards and Indian allies, Alvarado marched south from Mexico and conquered the Quichés and Cakchiquels of Guatemala. In the following year he founded the town of Santiago de los Caballeros de Guatemala, later capital of the captaincy general of Guatemala, which was to include much of Central America and to be governed for a time by Alvarado. In the same year, 1524, he carried the conquest into El Salvador.

In 1534 Alvarado led a fleet to Ecuador with the intention of conquering the area, but for 100,000 pesos, given to him by Diego de Almagro, one of Francisco Pizarro's captains, he agreed to forego this venture. Two years later Alvarado returned to Spain, where his contract for discovery in the Spice Islands, which he had received in 1527, was renewed, together with the privilege of sharing whatever discoveries Viceroy Antonio de Mendoza of New Spain (Mexico) might make on the northern borderlands of his viceroyalty. Alvarado thus became one of Mendoza's rivals in the search for the Seven Cities of Cibola. Alvarado did not live to share in either the northern discoveries of New Spain or in the Spice Islands, for he died in 1541 in or near Guadalajara as the result of a fall from a horse during the Mixton War. (R. C. E.)

ÁLVAREZ, JUAN (1790–1867), Mexican revolutionary patriot of Indian blood, was born at Concepción de Atoyac (now Ciudad Alvarez, Guerrero). He participated in many of the revolutionary movements between 1810 and 1855, creating for himself a sphere of influence in his native state. In 1811 Alvarez joined José María Morelos (*q.v.*) in the unsuccessful campaign for independence from Spain. He had a prominent part in the revolt of Antonio López de Santa Anna in 1822–23 which overthrew Agustín de Iturbide, and in 1847 he served in the war with the United States. Alvarez began his civil career in 1849 as the first governor of the new state of Guerrero, ostensibly as a liberal. He was sufficiently flexible, however, to accommodate himself to the revived dictatorship of Santa Anna in 1853 and 1854. Melchor Ocampo and Benito Juárez refused to do so and were exiled, but Alvarez tolerated the dictatorship as long as Santa Anna did not threaten his hegemony in Guerrero. When in 1854 Santa Anna moved against Guerrero, Alvarez declared himself in rebellion, launching the movement at (famous plan of) Ayutla. With the defeat of Santa Anna, Alvarez became provisional president, but his inability to provide strong national leadership led to his resignation in 1855. The movement he had begun, however, flowered in the liberal reform and in the constitution of 1857. Alvarez died on Aug. 21, 1867. See MEXICO: *Independent Mexico*. (R. E. Q.)

ÁLVAREZ DE PEREIRA Y CUBERO, JOSE (1768–1827), Spanish sculptor, whose best works are portrait busts of stylized neoclassical realism, was born on April 23, 1768, at Priego, Córdoba, famous for its rococo sculpture. Alvarez studied at Madrid. Between 1799 and 1826 he lived in Paris, where Napoleon rewarded him, and in Rome, where he was befriended by Antonio Canova. His academic art imitated in correct modeling and cold perfection the classical style, as in his marble group the "Defense of Saragossa" (Nestor and Antilochus). in the garden of the Museum of Modern Art in Madrid.

He died in Madrid on Nov. 26, 1827. Once renowned, his art is almost forgotten in the 20th century.

See Maria Elena Gómez Moreno, *Breve historia de la escultura española* (1951). (M. S. S.)

ÁLVAREZ QUINTERO, the name of two brothers, SERAFÍN (1871–1938) and JOAQUÍN (1873–1944), Spanish dramatists, whose plays are based upon direct observation of Andalusian life. Both were born at Utrera, Seville, Serafín on March 26,

1871, and Joaquín on Jan. 21, 1873. Writing in the traditional style of the 16th-century playwright, Lope de Rueda, and of González del Castillo (1763–1800), they produced comedies remarkable for the vivacity of their dialogue, though lacking depth. Among the most popular of their works were *Los Galeotes* and *El Patzo* (both 1900), *Las de Cain* (1908), *Malvaloca* (1912), *La Calumniada* (1919) and *Cancionera* (1924).

The success of some of their plays in London and New York—*Fortunato*, *El Centenario* (1909; *A Hundred Years Old*) and *La Puebla de las mujeres* (1912; *The Women Have their Way*)—owed much to the fine translations by Helen and Harley Granville-Barker, which were published in 1928. Both brothers died at Madrid, Serafín on April 12, 1938, and Joaquín on June 14, 1944. (W. F. S.)

ALVEAR, MARCELO TORCUATO DE (1868–1942), president of Argentina (1922–28), was descended from a distinguished and wealthy family. He was born at Buenos Aires, on Oct. 4, 1868. He joined the Radical (democratic) party at its inception (1889–91), became congressman in 1912 and minister to France from 1917 to 1922, during the presidency of the Radical leader, Hipólito Irigoyen. Advanced by Irigoyen as his successor in office, Alvear was elected as president in 1922. During his term of office his policies diverged from those advocated by Irigoyen; a complete break occurred between the two, leading to the establishment by Alvear of the Anti-Personalist Radical party. Despite the alliance of the Anti-Personalists with the conservatives, Irigoyen was elected to a second term in 1928. When Irigoyen's presidency was ended by a conservative revolution (1930), Alvear returned to the party and later to its leadership, but the Radicals were unable to regain the presidency prior to Alvear's death, on March 23, 1942. (T. F. McG.)

ALVERSTONE, RICHARD EVERARD WEBSTER, 1ST VISCOUNT (1842–1915), lord chief justice of England, who represented Great Britain on several international boundary commissions. He was born in London on Dec. 22, 1842, and died Dec. 15, 1915, at Cranleigh, Surrey. Educated at King's college and Charterhouse schools and Trinity college, Cambridge, he was called to the bar in 1868 and became a queen's counsel only ten years later. His practice was chiefly in commercial, railway and patent cases until (June 1885) he was appointed attorney general in the Conservative government. He sat in the house of commons first for Launceston and then for the Isle of Wight. Except for two brief periods of Liberal government Webster was attorney general from 1885 to 1900. During 1888–90 he was leading counsel for the *London Times* in the Parnell inquiry; in 1893 he represented Great Britain in the Bering sea arbitration and in 1898 in the matter of the boundary between British Guiana and Venezuela. In 1903 he was one of the members of the Alaska Boundary commission.

In 1900 he became master of the rolls, being raised to the peerage as Baron Alverstone, and in October of the same year succeeded Lord Russell of Killowen as lord chief justice. He retired in Nov. 1913, when he was created a viscount. (W. T. Ws.)

ALVSBORG, a *län* (county) of southwest Sweden, is bounded by Lake Vänern (east), Goteborg och Bohus *liin* along the coast (west), the Norwegian frontier (north) and Småland (south). Pop. (1950) 358,988. It thus straddles the Gota river which drains over 19,000 sq.mi. and whose falls and rapids are harnessed for electricity, though a canal is necessary for navigation. The *lan* is a district of poor soils and three-quarters remains forested. The main wealth lies in industry. Borås (*q.v.*) is a textile and clothing centre, and Trollhattan (*q.v.*) is a hydroelectric centre with locomotive works. Dalsland, with a declining population, is the northern part and has the Dalsland canal, important when opened in 1868 but now little used. Vanersborg is the administrative centre of the *län*. (A. C. O'D.)

ALWAR, a city and district in northeast Rajasthan, India. The city (pop. 1951, 57,868) lies 98 mi. S.W. of Delhi on the Western railway. It was the capital of the former princely state of the same name founded in 1771 by Maharaja Pratap Singh of the Kachawa clan of Rajputs. Alwar is dominated by a fort on a conical hill, and is backed by a range of hills. A steep ascent leads

to the fort behind which stands a monument to the founder of the town. The palace, separated from the base of the hill by a picturesque tank or *sagar*, consists of a group of buildings in different styles. The museum which occupies a portion of this palace has a collection of Hindi, Sanskrit and Persian manuscripts, while the picture gallery has a valuable collection of Mogul and Rajasthani paintings.

ALWAR DISTRICT (area 3,241 sq.mi.) had a population of 1,089,333 in 1961. Its eastern part is open and highly cultivated; the western is diversified by the hills which are a continuation of the Aravalli range. These hills run in rocky and precipitous parallel ridges, in some places upward of 2,200 ft. in height. The Sabhi and Ruparel are the only streams of importance.

Alwar was the first princely state to accept a currency, struck at the Calcutta mint, of the same weight and assay as the imperial rupee, bearing the head of the British sovereign. Under British paramountcy it was controlled through the Jaipur subagency of the Rajputana agency. After India became independent it joined the Matsya union (March 18, 1948) and the union was merged with Rajasthan on May 15, 1949. (S. M. T. R.)

ALYATTES (7th–6th centuries B.C.), king of Lydia from 617 at the earliest to 560 B.C., was the son of Sadyattes, of the house of the Mermnadae (see LYDIA). On succeeding his father, he carried on the war against Miletus for five years. He next came into conflict with the rising power of Media; but after a pitched battle had been interrupted by an eclipse of the sun, a peace was concluded, through the mediation of the kings of Babylon and Cilicia, which fixed the Halys river (mod. Kizil Irmak) as the boundary between the two kingdoms. Alyattes drove the Cimmerians (*q.v.*) from Asia, subdued the Carians and captured Smyrna. His son Croesus succeeded him.

The tomb of Alyattes, described by Herodotus, still exists in the plain between the Gygaean lake (Marmara Gölü) and the Hermus (mod. Gediz) river in western Turkey, about 7 mi. N. of Sardis. A large mound of earth, with a substructure of huge stones, it was first excavated by H. Spiegelthal in 1854, who found that it covered a large vault of finely cut marble blocks approached from the south by a flat-roofed passage of the same stone. The site was further explored after 1910 by the American Society for the Excavation of Sardis, whose reports are published (from 1922) in the periodical *Sardis*.

ALYPIUS (c. A.D. 360), Greek writer on music whose *Introduction to Music* describes the 15 transcriptions of the scale in vocal and instrumental music in the diatonic and chromatic systems, and nine transpositions in the enharmonic system (see MUSIC: Non-harmonic and Greek Music), with tables of their method of notation. The treatise was published by I. Meursius in 1616, and by M. Meibom (with the tables of notation) in 1652. The authoritative edition is by K. von Jan in *Musici scriptores Graeci* (1895). (E. J. Wz.)

ALYSSUM, SWEET: see SWEET ALYSSUM.

ALZON, EMMANUEL MARIE JOSEPH MAURICE DAUDE D' (1810–1880), French ecclesiastic, founder of the order of Augustinians of the Assumption or Assumptionists, was born Aug. 30, 1810, at Le Vigan, Gard, the scion of one of the richest families of southern France. He was educated privately and at St. Louis and Stanislas colleges in Paris. In 1831 he entered Rlontpellier seminary and in 1832 continued his studies in Rome, where he was ordained on Dec. 26, 1834. He was named canon and vicar-general of his diocese of Nîmes, and retained this position under four bishops until his death.

In 1842, after a few years of preaching and other ministry, he acquired Assumption college in Nîmes. There also he founded, in 1845, the Congregation of the Augustinians of the Assumption, dedicated to education, missionary and social work. In 1863 he sent his first missionaries to the near east, especially to Bulgaria. To help in this work he also founded a congregation of women, the Oblates of the Assumption. He attended the Vatican council of 1869–70 as theologian to his bishop and was active in preparing the definition of papal infallibility. On Aug. 28, 1871, he started the Alumniates, apostolic schools for the ecclesiastical education of poor boys. He died at Nîmes on Nov. 21, 1880.

The Assumptionists are organized into seven provinces, spread through 27 countries, including the United States, Canada and Mexico. Their main apostolic works are colleges, journalism (La Bonne Presse, Paris) and pilgrimages. (A. A. DE.)

AMADEO (1845–1890), king of Spain from 1870 to 1873, was born at Turin, Italy, on May 30, 1845, the second son of Victor Emmanuel II (the future king of Italy) and was originally known as Amedeo, duke of Aosta. He married Maria Vittoria dal Pozzo della Cisterna in 1867. His candidature for the Spanish throne (vacant after the deposition of Isabella II in Sept. 1868) was supported by Juan Prim and Francisco Serrano (*qq.v.*) and triumphed on Nov. 16, 1870, when he was elected and proclaimed king by the Cortes. His arrival in Spain (Dec. 30, 1870) coincided with the assassination of Prim, his principal supporter, and his first public function was a visit to Prim's lying-in-state. Notwithstanding the king's good intentions, the political situation remained unstable and there was a succession of short-lived ministries. In 1872 a Carlist rising took place in the north of Spain, republican agitation increased and a large number of influential people made known their support for a petition asking Alfonso de Borbón (afterward Alfonso XII) to proclaim himself king. Abandoned by his supporters and attacked on all sides, Amadeo abdicated the throne on Feb. 11, 1873. He then returned to Italy and settled at Turin. The duchess Maria Vittoria having died in 1877, he married his niece Marie Létitia Bonaparte (daughter of his sister Clotilda and Jérôme Bonaparte's son Napoleon Joseph Charles) in 1888. He died at Turin on Jan. 18, 1890. (R. S. LL.)

AMADÍS DE GAULA, a famous Spanish romance of chivalry. The first known edition appeared in 1508. Its publication gave the medieval chivalresque romance of Celtic origin and French elaboration a further lease of life in a new and idealized form. Immediately followed by sequels and imitations in Spanish and Portuguese, it was widely read, adapted, and translated into French, Italian, German, Dutch and English and for four centuries exerted an influence that makes it one of the most important works in the history of the European novel and indeed of European sensibility.

Origins of the Work.—The authorship, date of composition and even the original language of the romance are in doubt. The 1508 edition was "corrected and emended" by Garcí Rodríguez de Montalvo. Montalvo, apparently writing shortly after the conquest of Granada in 1492, states that the work was already circulating in corrupt versions. The only extant remnants of any earlier text, however, are fragments of an early 15th-century Spanish manuscript. The earliest recorded reference to *Amadís de Gaula* occurs in a minor Spanish poet, Pero Ferrús, about 1380. From internal evidence, however, the novel was probably in circulation in the early 14th or even the 13th century. In book i of the novel we read that Prince Afonso of Portugal had a change made in one episode of the story. The prince in question could be none later than the son of King Dinis, who succeeded as Afonso IV in 1325. Further, in book ii there is a free translation of a poem (referring to one of the characters) known to be the work of the 13th-century Portuguese troubadour Jodo de Lobeira. This fact only came to light with the discovery in the 19th century of the early Portuguese lyric and lends some support to a Portuguese tradition, first recorded about 1460 by the Portuguese chronicler Gomes Eanes de Zurara, that the novel was of Portuguese origin, though Zurara calls the author Vasco de Lobeira and states that he wrote in the time of King Ferdinand (1367–83). Zurara's statement remained unpublished until 1792, but the same belief is recorded in the 16th century by the Portuguese historian Jodo de Barros and by Miguel, the son of the poet António Ferreira. Learned opinion has been fairly evenly divided on whether the extant Spanish text derives from a Portuguese original or not. It would be rash to dismiss the Portuguese claim, particularly since Zurara's reference to the novel is slightly disparaging and cannot be attributed to literary chauvinism; nevertheless the evidence remains inconclusive.

Character of the Work.—*Amadís de Gaula* owes much to the French romances of the Arthurian cycle on which it was modeled. Nevertheless it is distinct from the Arthurian romances, is not

based on any particular set of legends and in Montalvo's version exalts a new concept of chivalry which caught the imagination of polite society all over Europe. Amadís is the most handsome, upright and valiant of knights and the most constant of lovers, devoted to Oriana (daughter of Lisuarte, king of Great Britain) whom he eventually marries and who is his constant inspiration. Throughout the work his incredible feats of arms alternate with expressions of tender and often lachrymose sentiment. Amadís is more idealized and less human than such heroes as Lancelot and Tristan and needless to say, far more chaste. In the Arthurian legends (*q.v.*) the disruptive eroticism of the Celtic tales had been palliated by the courtly veneer their French elaborators gave them; with the Spanish *Amadís* medieval chivalry achieved complete respectability.

A certain Renaissance spirit can be discerned in the work. Amadís, himself a royal prince, only discovers this fact after he has established his fame by his own prowess. As in Renaissance pastoral, there is no particular sense of place or time, but rather a vague unspecified field for the interplay of idealized human relationships. Similarly, the concept of kingship is in accord with the new age. The anarchic individualism of earlier knights-errant reflects feudal society; the authority with which monarchy is invested in *Amadís* heralds the advent of absolutism.

Influence.—This new style of chivalresque romance was immediately and extraordinarily successful both in the Iberian peninsula and in Europe as a whole, particularly in France where the work became a textbook of chivalresque deportment and epistolatory style; the numerous editions, translations and adaptations of the work down to the 20th century prove its enduring influence. Among early readers were Charles V, Francis I, the humanist Juan Luis Vives, St. Teresa, Ignatius Loyola, Montaigne and Cervantes. In the 16th century there appeared in Spain and Portugal about 50 inferior sequels and feeble imitations; and though this literary fashion was given the deathblow by parody in *Don Quixote*, Cervantes himself held *Amadís* in high esteem, and much of its idealism was integrated into his own masterpiece. Cervantes indeed took the subject a stage further and in *Don Quixote's* character showed the idealized, oversimplified chivalry of Amadís in conflict with the realities of modern life; in the resultant clash, modern life as much as idealism came in for criticism. Thus the spirit of *Amadís de Gaula* was an important stimulus and an essential ingredient in the first great modern novel.

The first English adaptation appeared in 1567; the best English translation is Robert Southey's abridged version, first published in 1803.

Baret, *De l'Amadís de Gaula et de son influence sur les mœurs et la littérature au XVIe et au XVIIe siècle* (1853, 1873); M. Menéndez y Pelayo, *Orígenes de la novela*, vol. i (1905); H. Thomas, *Spanish and Portuguese Romances of Chivalry* (1920); A. Rodríguez-Moñino et al., *El primer manuscrito del Amadís de Gaula* (1957). (T. P. W.)

AMADOU, a soft tough substance once frequently used as tinder, derived from *Fomes fomentarius* (L.) Gill, a fungus belonging to the group Basidiomycetes and growing upon old trees, especially birch and beech. For use as tinder, the fungus is cut into slices and then steeped in a solution of nitre. Amadou is prepared on the continent of Europe, chiefly in Germany, but the fungus is a native of Britain and America. *Fomes ignarius* (L.) Gill and other species are also used, but yield an inferior product.

AMAGASAKI, Japanese industrial city contiguous to Osaka (*q.v.*) on the Inland sea coast of southeastern Hyōgo prefecture. Pop. (1960) 405,962. Once a feudal period castle town, in the 20th century it attracted many large, modern factories that produce the full range of iron and steel goods, machinery, heavy chemicals and such consumer items as foodstuffs and textiles. The main industrial belt lies along the coast on a river delta, where the threat of water damage necessitated the construction of costly protective dikes. The city has large electric plants, superb railroad facilities and canals and strong economic ties with Osaka.

(J. D. EE.)

AMAKUSA-RETTŌ, group of Japanese islands off western

Kyushu, administered by Kumamoto prefecture. The archipelago is formed by more than 90 islands, among which are Shimo, and Kami (separated by Hondo strait, which is only 218 m. wide) and Oyano. There is little farming because of the rough mountainous terrain, but forestry and offshore fisheries are actively pursued. Excellent quality bituminous coal is mined on the main islands and good pottery clay deposits are also worked. Hondo (pop. 41,896 in 1960) and Ushibuka (pop. 34,704 in 1960), both on Shimo Island, are the largest cities.

(J. D. EE.)

AMAL, the name of the royal family among the Ostrogoths, of which Theodoric (*q.v.*) the Great (d. 526) was the most famous member. The family is said to have been pre-eminent even in the 4th century A.D., but this may be a fabrication designed to flatter the 6th-century Ostrogothic kings.

(E. A. T.)

AMALARIC (died 531), king of the Visigoths, son of Alaric II (*q.v.*), was a child when his father fell in battle against Clovis, king of the Franks (507). He was carried for safety into Spain, which country, with southern Languedoc and Provence, were thenceforth ruled by his maternal grandfather Theodoric (*q.v.*) through his vice-regent, an Ostrogothic nobleman named Theudis. On Theodoric's death in 526, Amalaric assumed full royal power in Spain and a part of Languedoc, relinquishing Provence to his cousin Athalaric. He married Clotilda, daughter of Clovis, but his disputes with her, he being an Arian and she a Catholic, brought on a Frankish invasion, in which he lost his life in 531.

AMALASUNTHA (AMALASUENTHA) (498–535), queen and regent of the Ostrogoths, daughter of the Ostrogothic king of Italy Theodoric the Great. She married Eutharic in 515 and had a son, Athalaric, and a daughter, Matesuentha, by him, but he died soon after. When Athalaric became king in 526, Amalasuatha became regent. An educated woman, brave and intelligent, she favoured the Roman population in Italy, sought to remain on good terms with the emperor and the church, and gave her son a more civilized and literary education than the Ostrogoths at large approved. Her foreign policy favoured the Byzantines and was opposed by many Ostrogoths. Conscious of her unpopularity, she banished and afterward put to death three Ostrogothic nobles whom she suspected of intriguing against her, and also opened negotiations with the emperor Justinian with a view to transferring herself and the Gothic treasure to Constantinople if her position in Italy should become untenable. When Athalaric died on Oct. 2, 534, she invited her cousin Theodahad to share the throne, but he failed to support her. Either by his orders or with his connivance, she was banished to an island in the Tuscan lake of Bolsena, where in the spring of 535 she was murdered in her bath by the relatives of the Goths whom she had slain. According to Procopius, Theodora, wife of Justinian, intrigued to bring about the crime.

See J. B. Bury, *History of the Later Roman Empire*, vol. ii (1923).

(E. A. T.)

AMALEKITES, an ancient tribe or collection of tribes, of the nomadic type, familiar from their relations to Israel. Though Hebrew ethnology made them a subordinate branch of Edom (Gen. xxxvi, 12), and even connected them closely with the tribe of Ephraim in Judg. xii, 15, they are uniformly represented as enemies of Israel. They harried the fugitives as they escaped from Egypt at the exodus (Deut. xxv, 17–19); were included among the foes through whom a passage must be forced into southern Palestine from Kadesh (Num. xiv, 43–45); attacked Israel at Rephidim, where they were utterly defeated by Joshua (Ex. xvii, 8–16); formed part of the coalition which Eglon, king of Moab, used to oppress Israel (Judg. iii, 13); were included among the hordes of nomadic raiders defeated by Gideon (Judg. vi, 3, 33); and were condemned to annihilation by Samuel (I Sam. xv), though King Saul incurred the anger of Yahweh by sparing Agag and the cattle. Enough of them survived to raid Ziklag in David's absence and to be overwhelmed by his vengeance (I Sam. xxx); their remnant is reported to have been destroyed in the time of Hezekiah (I Chron. iv, 43). The Amalekites were made the object of a perpetual curse (Ex. xvii, 14–16, Num. xxiv, 20; Deut. xxv, 17–19).

The district over which the Amalekites ranged lay south of Judah, extending probably into northern Arabia; they may at times have been located farther east. The association of their name

with "Canaanites" suggests that it may have been used at times for an indistinct group that constituted an enemy of Israel in the early period. Even in one of the Psalms (lxxxiii, 7) Amalek is mentioned among the foes of Israel, and the same feeling is reflected in the book of Esther, where Haman the Agagite is pitted against Mordecai the Benjamite. The name of Amalek is celebrated in Arabian tradition, but the confused and conflicting stories are, for historical purposes, practically worthless.

(J. P. Hy.)

AMALFI, a town and archiepiscopal see in Campania, Italy, in the province of Salerno, lies about 12 mi. west-southwest from Salerno city on the north coast of the Gulf of Salerno. Pop. (1957 est.) 6,663 (commune). This picturesque old town and popular tourist resort lies in the ravine of the Valle dei Molini amid splendid coastal scenery. The cathedral of S. Andrea (begun 11th century) is in Lombard-Norman style with a façade in black and white stone, magnificent bronze doors executed at Constantinople before 1066, and a campanile (1276). The body of St. Andrew rests in the crypt. Above Amalfi and slightly to the west is the old Capuchin monastery (founded 1212), with fine cloisters. Partly destroyed by a landslip in 1899, it was remodeled as a hotel.

Although it was known in the 4th century, Amalfi had no importance until the middle of the 6th century. As a naval power in the 9th century it shared with Venice and Gaeta the Italian trade with the east, and in 848 its fleet went to the assistance of Pope Leo IV against the Saracens. It was then an independent republic with a population of about 70,000, but in 1131 it was subdued by King Roger II of Sicily. In 1135 and 1137 it was taken by the Pisans, and rapidly declined in importance, though its maritime code, known as the *Tavole Amalfitane*, was recognized in the Mediterranean until 1570. It now has no harbour. There are water-driven paper mills in the Valle dei Molini.

AMALGAM, an alloy composed of mercury and one or more other metals. Pliny in the first century said that all things float in mercury except gold which combines with it. Actually mercury (*q.v.*) will combine with many metals to form amalgams. Most amalgams are crystalline in structure and those with a large proportion of mercury are liquid. Amalgams of gold and silver have been found occurring in nature. Amalgams may be formed by one of four methods: (1) by direct contact of a metal with mercury; (2) by electrolysis of a mercurial salt solution using the metal to be amalgamated as the cathode; (3) by immersing the metal to be amalgamated in a solution of a mercurial salt; and (4) by bringing mercury into contact with a metallic salt whose amalgam is desired. The most common use of amalgam is in the silver fillings used by dentists, which are composed of filings of an alloy of silver (65%), copper (6%), zinc (2%) and tin (25%) (approximate proportion), mechanically mixed with mercury.

Garrod-Thomas, *Electrochemical Investigations of Liquid Amalgams of Thallium, Indium, Tin, Zinc, Cadmium, Lead, Copper, and Lithium* (1909); Eugene W. Skinner, *The Science of Dental Materials*, p. 316 (1943).
(W. J. MR.)

AMALGAMATION, in metallurgy, is the once widely used process of extracting gold and silver from their ores by means of mercury. It depends on the fact that mercury, or quicksilver, "wets" and adheres to metallic gold and silver and penetrates them, forming pasty amalgams of a silvery colour. Particles of amalgam readily adhere to each other, and the aggregates become large and heavy enough to sink in running water which carries away sand and other earthy materials. Pieces of gold, if not too small, sink perfectly well of themselves and adhere to mercury or amalgam lying at the bottom, and gold ores have been widely amalgamated on this principle. Coarse gold can be saved without the aid of mercury but finely divided gold is more likely to escape. Grains of silver naturally settle also, but most silver ores do not contain metallic silver. They contain compounds such as silver sulfide, which will not settle in water and must be decomposed to set free the silver before it can be amalgamated.

In amalgamation, ores are crushed in water and mixed with mercury with violent agitation in order to break up the mercury into minute globules and disperse them throughout the mass, and so

enable them to be brought into contact with the gold or silver. Afterward by dilution with water and gentle stirring, or by a running stream of water, the amalgam and surplus mercury are induced to coalesce and settle to the bottom, where they are caught in a pool of mercury or on the surface of copper plates to which they adhere. When the earthy matter has been washed away, the mixture of metals is put into filter bags and squeezed to remove the surplus mercury. The liquid mercury passes through, containing a minute quantity of gold and silver dissolved in it, and pasty amalgam containing from 25% to 50% of gold remains in the bag. The amalgam is heated in retorts (fig. 5), the mercury driven off as vapour and condensed for reuse, and the gold and silver are melted down and cast into bars. Since all gold ores contain some silver and silver ores some gold, the bars consist of a mixture of gold and silver which is afterward parted (see GOLD). The process is a very old one. The extraction of gold by mercury is mentioned by Pliny in his *Natural History*, and descriptions of amalgamation processes for both gold and silver are to be found in various 16th-century treatises. The history of the process was given in detail by John Percy in *Silver and Gold* (1880).

Mercury may, however, become so excessively subdivided, as the result of too violent agitation or pounding, especially when mixed with grease or certain kinds of ore, that it becomes "floured" or "sickened." Floured mercury is a white powder, although under the microscope it is seen to consist of minute globules of apparently ordinary mercury, heaped together. The globules will not coalesce and are carried away and lost in the tailings or

They are generally separated only by films of air, and may be made to coalesce by the action of acids or in other ways entailing expense or loss. Again, although earthy matter and mercury have no action on each

other, mercury attacks and amalgamates copper, lead, zinc and some other metals, especially when they are present in the metallic state. The amalgam thus becomes debased and powdery so that part is lost and the remainder is costly to refine. Also there are ores which do not yield a reasonable percentage of their values when treated by amalgamation; these are called refractory and those which are amenable to amalgamation are described as free-milling.

Patio or Mexican Process.—In Pachuca (*q.v.*), Mex., in the 16th century silver ore was ground by mule power in arrastras or shallow circular pits paved with stone (fig. 1). Large blocks of stone attached by beams to a central rotating post were dragged round the arrastra and reduced the ore to fine mud which was taken out and spread over a courtyard or patio in low heaps. It was then sprinkled with mercury and chemicals (common salt and copper sulfate) and mixed by mules, which were driven over every part of the

FIG. 1.—THE ARRASTRA, USED BY THE MEXICANS FOR HUNDREDS OF YEARS IN GRINDING SILVER ORE

FIG. 2.—IRON AMALGAMATION PAN USED FOR SILVER ORE IN THE UNITED STATES IN THE 19TH CENTURY

heaps. Complicated chemical reactions took place, never fully understood, the effect of which was to free the silver from its compounds and enable it to be taken up by the mercury. The heaps were trodden by the mules every day or two until the amalgamation was complete, which might require a month. Lastly the material was agitated with water in large tubs and the mud run off through the plug holes. The amalgam found at the bottom was collected and treated as already described. The process was especially suitable for the silver ores of the dry barren districts of Mexico, where water and fuel are scarce, and was not finally displaced by the cyanide process (*q.v.*) until early in the 20th century. It was used in the production of

FIG. 1.—THE ARRASTRA, USED BY THE MEXICANS FOR HUNDREDS OF YEARS IN GRINDING SILVER ORE

a large proportion of the world's silver for 350 years.

Pan Amalgamation Process.—The process was used for silver ores, especially in the United States, in the latter half of the 19th century and was superseded by the cyanide process and by smelting. Silver ore was ground to a fine paste with water in iron pans (fig. 2) by rotating iron shoes. The shoes were then raised a little, so as to agitate the pulp without further grinding, and mercury was sprinkled into the pan. Chemicals, especially common salt and copper sulfate, were added. The pan was heated with steam and agitation was continued until amalgamation was completed. The amalgam was separated by diluting the pulp and stirring and finally by running off the charge into large settling tanks. The amalgamation pans were about 5 ft. in diameter and the charge was 2,000 or 3,000 lb.

Complex silver ores containing minerals not amenable to amalgamation (such as the arsenical and antimonial sulfides, galena and blende) were roasted in furnaces at a red heat with common salt as a preliminary, when silver chloride was formed, a compound from which the silver can be extracted by mercury.

Amalgamation of Gold Ores.—This is simpler and cheaper than that of silver ores. The machine used more than any other for the reduction of gold ores after mid-19th century was the stamp mill or battery (fig. 3 and 4). The stamp mill is worked on the principle of the pestle and mortar. The mortar is long and narrow, and ore, water and mercury are fed into it continuously. Five heavy steel stampers, each weighing from 800 to 2,000 lb., are ranged in a row in one mortar. They are raised and let fall in succession, crushing the lumps of ore and driving the pulp through screens set in one side of the mortar. The old-fashioned wire screens were later replaced by perforated steel plates. The pulp coming from the screens is still further reduced by grinding in

BY COURTESY OF FRASER AND CHALMERS ENGINEERING WORKS

FIG. 4.—GENERAL SECTION OF A GOLD STAMP MILL ON A HILLSIDE, SHOWING SUPPLY OF ORE AND ITS PASSAGE THROUGH THE MACHINES

tube mills (rotating cylinders half filled with large pebbles, or lumps of unbroken ore) and then flows over sloping electro-silvered copper plates or tables, whose surface is amalgamated by rubbing with mercury. In older practice the copper plates were placed just outside the screens (fig. 4). The particles of gold adhere to the surface of the plate. Earlier still, amalgamated plates were fixed inside the mortar. The size and weight of stamps in the 20th century caused excessive loss of mercury by flouing and the addition of mercury and the fixing of plates in the mortars

were given up, the battery reverting to its original use as a mere crushing machine. Stamps forced down by springs or by power applied in various ways are sometimes used instead of gravity stamps and rotating crushers of various kinds (ball mills, tube mills, etc.) replaced them in some plants.

The cleanup takes place at intervals of a fortnight or a month. The stamps are hung up, the sand is washed away, the amalgamated plates are scraped and the amalgam after careful cleaning is squeezed and retorted (fig. 5). The percentage yield of gold varies with the conditions and the nature of the ore. Coarse gold is easily caught, but finely divided gold escapes in great part. Generally about 60% of the gold in the ore was recovered by amalgamation, and the remainder by cyanide. Ores containing only one-fourth of an ounce of gold or even less per ton of ore have been treated at a profit.

On the Rand in south Africa, amalgamation on copper plates had been generally discarded by 1921, owing to the difficulty of preventing the theft of the amalgam and the danger from mercury poisoning. Instead of passing the crushed ore from the tube mills over amalgamated plates it is concentrated on a surface of corduroy, which retains the heavy particles including all coarse gold. This is a reversion to the primitive practice of the gold diggers of California in 1849 who used their blankets in concentrating gold sands. At intervals the corduroy is taken up and washed in boxes and the coarse gold is extracted from the contents of the boxes by further concentration. The fine gold left in the ore is extracted in the cyanide plant. The corduroy also catches osmium and other valuable metals of the platinum group which had previously been lost.

The method of extracting gold from ores by solution in aqueous solutions of sodium cyanide which became increasingly used after 1900 has almost completely replaced amalgamation. The only important exception into the second half of the 20th century was its use at the Homestake mine, Lead, S.D. In south Africa and a few

other fields amalgamation plays a minor role for cleanup and recovery of gold from gravity concentrates.

Amalgamation of Other Metals.—Although historically, the use of mercury in metallurgy has been confined almost exclusively to amalgamating gold and silver, it is well known that numerous other metals form amalgams and the use of mercury for extracting such metals from ores or secondary products has frequently been suggested.

Technical success has been reached in some instances; for example, light metal scrap was refined by an amalgam process in Germany, but in general such methods have seldom attracted commercial interest.

A procedure having considerable merit was announced in 1957 by the U.S. bureau of mines in which mercury was used for recovering zinc from drosses and other by-products resulting from galvanizing operations. Material such as chloride skimmings in which the zinc is water soluble are leached and the resulting solu-

tion is used as electrolyte in an electrolytic cell with an insoluble anode and mercury cathode thus producing a zinc amalgam. This is maintained in a liquid condition and continuously circulated by pumping to an adjacent recovery cell where it becomes the anode with an aluminum cathode and zinc sulfate electrolyte. Zinc is deposited on the cathode in the solid state.

In treating by-products containing zinc in the metallic state, mercury is used to amalgamate and remove the zinc which is then recovered in a pure state in an electrolytic cell similar to the second cell referred to above.

In both of the above procedures zinc of high purity is obtained and there is little loss of mercury. (T. K. R.; C. R. H.)

AMALRIC I (d. 1174), king of Jerusalem, was the son of Fulk and Melisinda of Jerusalem and succeeded his elder brother, Baldwin III, in 1163. He was twice married: by his first wife, Agnes of Edessa, he had issue a son and a daughter, Baldwin IV and Sibylla; while his second wife, Maria Comnena, bore him a daughter, Isabella, who ultimately carried the crown of Jerusalem to her fourth husband, Amalric of Lusignan (Amalric II; *q.v.*). The reign of Amalric I was occupied by the Egyptian problem. It became a question between Amalric and Nureddin which of the two should control the discordant viziers who vied with one another for control of the decadent caliphs of Egypt. For some five years a contest was waged between Amalric and Shirkuh, the lieutenant of Nureddin, for the possession of Egypt. Thrice (1164, 1167, 1168) Amalric penetrated into Egypt; but the contest ended in the establishment of Saladin, the nephew of Shirkuh, as vizier—a position which, on the death of the puppet caliph in 1171, was turned into that of sovereign. The extinction of the Latin kingdom then seemed imminent, and anxious appeals for assistance were made both to Byzantium and the west. But though in 1170 Saladin attacked the kingdom and captured Aila on the Red sea, the danger was not so great as it seemed. Nureddin was jealous of his overmighty subject, and his jealousy bound Saladin's hands. This was the position of affairs when Amalric died, in 1174; but, as Nureddin died in the same year, the position was soon altered and Saladin began the final attack on the kingdom. Amalric I, the second of the native kings of Jerusalem, had the qualities of his brother Baldwin III (*q.v.*). Like him, he fostered the Byzantine alliance. He was something of a scholar, and it was he who set William of Tyre to work. He was more of a lawyer; he knew the *Assises* better than any of his subjects.

William of Tyre is the original authority: see xix, 2-3, for his sketch of Amalric. See also R. Grousset, *Histoire des croisades*, vol. ii (1935); and G. Schlumberger, *Campagnes du roi Amaury I en Egypte* (1906).

AMALRIC II (d. 1205), king of Jerusalem and Cyprus, was a son of Hugh the Brown of Lusignan and the brother of Guy of Lusignan. His second wife was Isabella, daughter of Amalric I, and he became king of Jerusalem in right of his wife in 1197. In 1198 he was able to procure a five years' truce with the Muslims, thanks to the struggle between Saladin's brothers and his sons for the inheritance of his territories. The truce was disturbed by raids on both sides, but in 1204 it was renewed for six years. Amalric died in 1205. The kingdom of Cyprus, which he had inherited from his brother, passed to Hugh, his son by his first wife, Eschiva; while that of Jerusalem fell to Mary, the daughter of Isabella by her previous marriage with Conrad of Montferrat.

AMALTHAEA, in Greek (originally Cretan) mythology, the foster mother of Zeus. She is sometimes represented as the goat that suckled the infant god in a cave in Crete, sometimes as a nymph of uncertain parentage who brought him up on the milk of a goat. This goat having broken off one of its horns, Amalthea filled the horn with flowers and fruits and presented it to Zeus, who placed it, together with the goat, among the stars. According to another story, Zeus himself broke off the horn and gave it to Amalthea, promising that it would supply in abundance whatever

she desired. Amalthea gave it to Achelous (her reputed brother), who exchanged it for his own horn, which had been broken off in his contest with Hercules for the possession of Deianira. Speaking generally, it was regarded as the symbol of inexhaustible riches and plenty, and became the attribute of various divinities and of rivers as fertilizers of the land. Cretan coins represent the infant Zeus being suckled by the goat; other Greek coins exhibit him suspended from its teats; others, carried in the arms of a nymph.

AMAMBAÍ, SERRA DE (Sp. SIERRA DE AMAMBAY), the range of heights forming the divide between the tributaries of the Paraguay river and those of the Paraná in southwest Mato Grosso, Brazil. The range forms the western side of the Brazilian plateau, held up by resistant diabase sheets which spread over a wide area of this part of South America. It is not properly described as a mountain range although its elevation is 1,312 ft. above sea level. This high margin of the plateau extends about 200 mi. S.S.W. from Campo Grande. Its southern end forms a part of the border between Brazil and Paraguay. (P. E. J.)

AMAMBAY, the northeastern department of Paraguay, is separated from Brazil by the Rio Apa and the Serra de Amambaí, the western flanks of which provide Paraguay's highest terrain (over 2,000 ft.). Drained to the Paraguay river, it forms part of the Paraguayan extension of the Brazilian plateau, with important forest resources. The population in 1960 was estimated at 22,808. The department produces cattle and maté, and practises subsistence agriculture. There are several links with communities across the Brazilian frontier, and a road from Pedro Juan Caballero, the capital, connects the department with the river port of Concepción, 125 mi. to the southwest. (G. J. B.)

AMANITA, a genus of mushrooms, important because of its deadly poisonous species. It is doubly dangerous because it contains fine edible species such as *Amanita caesarea* and *A. rubescens*. Amateur collectors should rigidly avoid collecting any species of *Amanita* for the table (see also MUSHROOM).

The brilliant colours of amanitas have attracted people since the dawn of history. Amanitas can be recognized by the following combination of characters: the presence of a universal veil; lamellae (gills) free from the stipe (stalk); white spore deposit; and bilateral gill trama. The universal veil is a thin protective layer covering the entire young fruiting body. It becomes ruptured as the pileus expands. If it is membranous and tough, a cup ("death cup") remains around the base of the stipe. If it is fragile, it breaks into warts or powdery particles which adhere for a time on the cap and around the base of the stipe. The lamellae are thin plates of tissue on the underside of the pileus.

Over 100 species are known. The poisons of a variety of

A. muscaria have been used by primitive peoples to produce intoxication. Muscarine is the principal active compound. *A. phalloides* and *A. verna* are deadly poisonous. (AR. H. S.)

AMANULLAH KHAN (1892-1960), king of Afghanistan from 1919 to 1929, was born at Paghman on June 1, 1892, the third son of the amir Habibullah Khan. When Habibullah was assassinated on Feb. 20, 1919, Amanullah was acting as his regent at Kabul. Taking advantage of his possession of the capital, he declared himself amir, ignoring the claim of his uncle Sirdar Nasrullah Khan, which was supported by his eldest brother, Inayatullah Khan. Established on the throne, he declared Afghanistan independent in both internal and external affairs, thus fulfilling the long-cherished desire of his people, and demanded recognition of this status by the government of India. The resulting negotiations

AMANITA MUSCARIA. SHOWN AT LEFT ARE THREE STAGES OF THE FRUITING BODY; SECOND FROM RIGHT, CROSS SECTION OF A GILL; RIGHT, SECTION THROUGH THE CAP

led to war with the British, which broke out, undeclared, on May 3, 1919. The fighting, however, was sporadic and inconclusive, and peace was signed at Rawalpindi on Aug. 8, 1919, Great Britain recognizing Afghanistan's independence. Amanullah assumed the title of king. In internal affairs Amanullah tried to introduce social reforms based on western models with a view to preparing his people for the requirements of modern international life, but in this he met strong opposition from reactionaries. Soon after his return from an extensive tour of Europe, tribal risings broke out, and in Dec. 1928 a notorious bandit named Habibullah took advantage of the chaotic situation to seize Kabul. Amanullah abdicated on Jan. 14, 1929, and, after an unsuccessful attempt to regain the throne, left Afghanistan for Europe in the following May, never to return. He died in Zurich, Switz., on April 25, 1960.

AMAPÁ, one of five federal territories in Brazil, the others being Acre, Fernando de Noronha, Rio Branco and Rondônia (formerly Guaporé). Formerly a part of the state of Pará, Amapi was created by decree law in 1943. It has an area of 53,013 sq.mi., and a population (1956 est.) of 53,000. Located on the equator in the north central part of Brazil, it is bounded on the north by a small bit of Surinam and by French Guiana, on the northeast by the Atlantic ocean, on the southeast by the north channel of the Amazon river, and on the southwest by the state of Pará. Its boundary with French Guiana is along the Oiapoque river. Its western boundary is the Jari river. Amapá includes an area of tropical rain forest with patches of savanna along the coast, an area that has long remained very scantily populated. The chief town and capital, Macapá is located on the bank of the Amazon (pop. [1950] 9,748). The chief products are cabinet woods, medicinal plants, skins of wild animals, rubber, Brazil nuts and fish. Gold is found in the stream gravels. Chief importance of the territory is the large deposits of manganese discovered during World War II inland from Macapá, now reached by rail from that port.

AMARAH (AL AMARAH), a town of Iraq and capital of a liwa (province) of the same name, stands on the left bank of the Tigris, 90 mi. above Qurnah and 126 mi. below Kut al Imara, on a low ridge enclosed between the Tigris on the west and the Masharah and Kahla' canals on the north and east. Pop. (1957) 53,311. Since the middle of the 19th century it has developed as the principal market and river port on the Tigris south of Baghdad. With the growth of irrigation, agriculture greatly expanded, and Amarah is a market for grain, fruit and vegetables, and for pastoral products (live sheep and cattle, wool, hides, etc.). These have usually been sent by river to Baghdad, though much of the river traffic has been diverted to road and rail as the result of the construction of a standard-gauge line between Baghdad and Basrah via Amarah. There is also some manufacturing: weaving of Arab dress and rugs, and the making of silverware, for which Amarah is widely known in the middle east. The population is mixed, consisting of an Arab majority but with numbers of Sabians, some Persians, Christians and Lurs.

The liwa (pop. [1957] 329,647; area 7,095 sq.mi.) corresponds closely to the boundaries of the Ottoman sanjak (district) and comprises the large irrigated area on both sides of the Tigris mainly south of Amarah town. Water is supplied by six major channels: the Masharah, Kahla' and Michariyah on the east bank, and the Butairah, Tabar and Mijar al Kabir on the west. There are also adjoining expanses of swamp, grazing areas and unused desert.

AMARANTH (AMARANT), a name chiefly used in poetry, and applied to certain plants which, because they do not wither rapidly, typified immortality (from the Gr. amarantos, "unwithering").

The plant genus *Amaranthus* (of the family Amaranthaceae) contains over 50 species of annuals, mostly weedy, and some well-known garden plants, chiefly of tropical origin. Love-lies-bleeding (*A. caudatus*) is a showy everlasting and a vigorous hardy annual, with dark-red flowers crowded in handsome drooping spikes. Another species, prince's-feather (*A. hybridus hypochondriacus*), has deeply veined lance-shaped leaves, purple on the under face, and deep crimson flowers densely packed on erect spikes. One of

the finest is Joseph's-coat (*A. tricolor*), a coarse annual two to four feet high, with variously coloured foliage. All the above are easily cultivated as garden annuals in rather sandy loam; richer soils produce larger leaves but less colour. Seeds should be sown one-fourth inch deep in full sun.

Globe amaranth belongs to an allied genus, *Gomphrena*, and is a native of the old world tropics. It is an annual about 18 in. high, with solitary round heads of flowers; the heads are violet, red, pink, white or yellow from the colour of the bracts which surround the small flowers. It is one of the best of the everlastings, if its chaffy blooms are picked in mid-August.

In North America more than 30 species of amaranth occur, chiefly in the southern and southwestern United States, several of them being introduced weeds, mostly from the tropics. Among the most widely distributed are the green amaranth or wild beet (*A. retroflexus*), the red amaranth or pigweed (*A. hybridus*), the thorny amaranth (*A. spinosus*), the prostrate amaranth (*A. graecizans*) and a tumbleweed (*A. albus*). In ancient Greece the amaranth (also called chrysanthemon and elichrysoe) was sacred to Pheesian Artemis. It was supposed to have special healing properties and as a symbol of immortality was used to decorate images of the gods and tombs.

In legend, Amarynthus (a form of Amaranthus) was a hunter of Artemis and king of Euboea; in a village of Amarynthus, of which he was the eponymous hero, there was a famous temple of Artemis Amarynthia or Amarysia.

AMARAPURA, a former capital of Burma, is now a suburb of Mandalay, Union of Burma. The Burmans call it Taung-myo, "the southern town," and Mandalay, Myauk-myo, or "northern town." Amrapura has long been famous for its silk-weaving industry, producing the colourful longyis (skirts for both sexes) in a distinctive heavy silk. Another famous industry is casting in bronze (actually bronze and lead), especially of statues of Buddha, bells and gongs. The work is extensively exported. Founded in 1782 by King Bodawpaya as a new capital about six miles north-east of Ava, it was estimated in 1810 to contain 170,000 inhabitants; but a fire in that year and the removal of the court back to Ava in 1823 caused a decline to about 30,000 by 1827. Tharrawaddy (1837-46) took the capital back to Amrapura but an earthquake in 1839 destroyed much of the city, which was finally abandoned in 1860, when King Mindon occupied Mandalay. Amrapura was laid out on much the same plan as Ava. The ruins of the city wall, long overgrown with scrub, show it to have been a square with a side about three-quarters of a mile long. At each corner stood a solid brick pagoda about 100 ft. high; a celebrated temple with 250 pillars of gilt wood contained a colossal bronze statue of Buddha. Amrapura has now little to show except the tombs of Bodawpaya and his successor Bagyidaw, both inscribed in English. The Burmans know the old fortified city as Myohaung, "the old city." It has a station on the Rangoon-Mandalay railway, and is the junction for Lashio and for Myitkyina.

AMARA SIMHA (c. 4th-6th centuries A.D.), Sanskrit lexicographer, who wrote the *Amara-kosa* ("Thesaurus of Amara"), a list of synonyms in verse containing about 13,000 words. Memorizing the *Amara-kosa* came to be an important part of the training of Sanskrit poets, and this kept the work popular despite its numerous imitations. Amara Simha was a Buddhist. He probably drew on earlier compilations, later lost, especially for his botanical and medical terms.

Of the many editions of the Sanskrit text perhaps the handiest is that with the commentary of Ksiravamin edited by Krishnaji Govind Oka (1913).

AMARAVATI, a ruined Buddhist site on the south bank of the Krishna river in the Guntur district of Andhra Pradesh, India. It stands on the outskirts of the ancient Dhanyakataka, a provincial capital of the Satavahana empire (2nd century A.D.) and of the early Pallavas and a Buddhist centre for many centuries. The great *stupa* (Buddhist memorial mound) of Amaravati was richly adorned with sculptured stone slabs dating from the 1st century A.D. (early phase) to the 3rd (late phase). These are now mainly housed in the Madras museum and in the British museum, London:

See D. Barrett, *Sculptures from Amaravati in the British Museum* (1954); C. Sivaramamurti, *Amaravati Sculptures in the Madras Government Museum* (1942). (F. R. A.)

AMARILLO, a city of northwest Texas, U.S., in the Texas Panhandle; seat of Potter county. Pop. (1960), city 137,969; standard metropolitan statistical area (Potter and Randall counties) 149,493. (For comparative population figures see table in TEXAS: Population.) The name Amarillo probably came from the Spanish word for yellow, the colour of nearby clay deposits; for the geography of the region see LLANO ESTACADO.

Amarillo's origins can be traced to a construction camp of the first railroad built across the region in 1887. Population in 1890 was only 482 and there was no organized government until 1899. About 1900 wheat growing became important in the Panhandle and during the 1920s an oil and gas industry grew rapidly. In the 1930s general economic depression and prolonged drought restricted growth. After 1940, however, extensive irrigation from underground water enlarged the region's agricultural output, especially in grain sorghums.

U.S. government installations in and around the city include a major helium plant, an air force base and an atomic energy project. In addition to various city recreation facilities, there is a large state park, containing the Palo Duro canyon, about 16 mi. S. of Amarillo. The city established a council-manager form of government in 1913. (C. C. TN.)

AMARNA TABLETS: see TEL EL AMARNA.

AMARYLLIDACEAE, the amaryllis family, a numerous group of monocotyledonous plants (those with a single seed leaf), closely allied to the lily family (Liliaceae). Familiar representatives are the daffodil, jonquil, snowdrop, tuberose (*qq.v.*) and snowflake. The family comprises about 86 genera and 1,050 species, found chiefly in tropical and subtropical regions. Many are bulbous plants of arid lands, leafing only in spring or after rains. A large number bear handsome lilylike flowers, often popularly called lilies, as Amazon lily (*Eucharis grandiflora*), spider lily (*Hymenocallis* sp., *Pancratium* sp.) and zephyr lily (*Zephyranthes* sp.).

Among the larger genera are *Agave*, *Crinum*, *Hippeastrum*, *Hypoxis* and *Narcissus*. Various species of *Agave* yield valuable fibres, as henequen, pita and sisal hemp; the bulbs of some species are used in medicine, while those of the South African belladonna lily (*Amaryllis belladonna*) and the buphane (*Buphane disticha*) are highly toxic, the latter furnishing a Kaffir arrow poison. Representatives of more than 40 genera are grown as ornamental plants in greenhouses and gardens. In North America there are more than 40 native species; these are found chiefly in the southern and the southwestern United States and belong mostly to the genera *Agave*, *Hymenocallis* and *Zephyranthes*. Of those native to the eastern United States, the best known are the atamasco lily (*Zephyranthes atamasco*), cultivated for its handsome flowers, and the yellow star grass (*Hypoxis hirsuta*), the only representative extending northward into Canada. Native plants of the family in the British Isles are the yellow daffodil (*Narcissus pseudo-Narcissus*), the snowdrop (*Galanthus nivalis*) and the summer snowflake (*Leucojum aestivum*).

See AGAVE; AMARYLLIS; HEMP; HIPPEASTRUM; LILIACEAE; NARCISSUS; SISAL FIBRE.

For a treatment of the genera see F. Pax and K. Hoffmann, "Amaryllidaceae"; Engler and Prantl, *Die Natürlichen Pflanzenfamilien*, 2nd ed., 15a: 391-430, fig. 163-187 (1930).

AMARYLLIS. Many lilylike plants, notably *Crinum*, *Hippeastrum* (including the Barbados lily), *Brunsvigia* (Josephine's-lily), *Sprekelia* (St.-James's-lily) and *Lycoris* (the hardy amaryllis), are often called Amaryllis by gardeners. The name refers to the genus *Amaryllis* which has a single species, the belladonna lily (*A. belladonna*), a South African bulbous plant of great beauty and widely cultivated. It has an enormous bulb and strap-shaped leaves which appear after the flowers have withered. The showy, fragrant flowers are lilylike, crowded in a terminal cluster (umbel) on a stout solid stalk. The perianth is funnel-shaped, about three and one-half inches long, typically rose-red, but blush, pink, purple or white-striped in horticultural

J. HORACE MCFARLAND CO.

BELLADONNA LILY (AMARYLLIS BELLADONNA)

varieties.

The culture of the belladonna lily and of all the above-mentioned amaryllis is essentially the same (except for *Lycoris*). They need greenhouse culture (or outdoors in frostless regions) and have a decided resting period. The bulbs should be planted in January or February in a rich soil, in large pots and kept well watered, in a temperature of 65° F. When bloom is finished, watering should be continued until the leaves have matured, and thereafter diminished until the leaves wither. Bulbs should then be taken out of the pots and stored over the winter. (N. TR.)

AMASIS, see AHMOSE.
AMASYA (AMASIA), the

chief town of the il (province) of the same name in northern Turkey, is beautifully situated on the Yesil Irmak (Iris) river. Pop. (1960) 28,188. It is a trade centre on the Samsun-Sivas road (about 90 mi. N.W. of Sivas and 50 mi. S.W. of Samsun) and railway. Unusually well-built, it has a good bazaar and khans (inns or lodging places), a clock tower and extensive fruit gardens. Amasya was one of the chief towns of the kingdom of Trebizond and of the Seljuks, under whom it was enriched with fine buildings and the castle restored, enabling it to withstand a seven months' siege by Timur. It was much favoured by the early Osmanli sultans, and Bayezid II built a fine mosque. The ancient town has left little trace except on the castle rock, where the acropolis walls and some rock-cut tombs are found, described by Strabo (who was born at Amasya) as those of the kings of Pontus. The last king to reign there was the father of Mithradates VI Eupator, "the Great"; the latter however used it as a base for his operations against the Romans from 89 to 67 B.C. Pompey made it a free city in 65.

The *il* of Amasya (pop. [1960] 256,853; area 2,129 sq.mi.), lying between the Black sea and inner Anatolia, contains fertile plains crossed by the Yesil Irmak, Cekerek and Tersakan rivers. The principal products are cereals, tobacco, poppy and sugar beet. Fruit growing is important; apples and grapes are the chief exports. Amasya ochre has long been famous. (N. TU.; S. ER.; E. TU.)

AMATEUR. The word "amateur" (Fr. amateur from Latin amatorem, "one who has a taste for anything") came into use in France in the middle of the reign of Louis XIV (1643-1715) to denote a connoisseur of the fine arts. The term was first recorded in Britain in 1784, again referring to one who appreciated the polite arts of painting and music. Its earliest sporting connotation is in a reference to ringside prize fight spectators as gentlemen amateurs in 1801. The original meaning of the word, indicating one who participates in any art, craft, game, sport or other activity solely for pleasure and enjoyment, has been largely supplanted by an acquired secondary meaning indicating a person of inferior or superficial skill, ability or proficiency, as compared with others who specialize in and are expert in any field.

In the first half of the 19th century the distinction in sport in Great Britain between an amateur and a professional was not so much financial as social; e.g., in 1831 the teams of Oxford and the Leander club rowed at Henley for £200 a side yet there was no question of professionalism, for indeed such oarsmen underlined their amateurism by showing that they, unlike artisans, could well afford to lose. Conversely as late as 1871 the Henley committee declined a local entry for the Wyfold cup on the grounds that the crew included people who were or had been mechanics, artisans and labourers. There was no question of their having rowed for money but merely that they were not gentlemen amateurs.

With the formation of the Football association (1863) and the Amateur Athletic club (1866), sport ceased to be a gentleman's preserve. Though mixed games of players and gentlemen had

been successfully played in cricket for over a century, an incursion of artisans into other sports brought a number of abuses including disorderly gambling, bribery and impersonation. The gentlemen amateurs, now merely amateurs, reacted against this: since they could not apply social sanctions against corruption and the threat of being outclassed by whole-time performers, they resorted to monetary ones, so that by 1880 the distinction between amateurs and professionals had generally, though not in rowing, become a financial one. The social stigma of being a professional may, however, be said to have persisted in Great Britain until the conferring of knighthoods upon Jack Hobbs in cricket and Gordon Richards in horse racing in 1953.

It is in the realm of athletics, where both amateurs and professionals coexist, that the meaning of the word most often comes into question, as participation in amateur sports (which include the Olympic games and other international competitions as well as the national and collegiate championships of most nations) must obviously be confined to amateurs. However, the fact that the various sports federations and bodies governing national sports have adopted different definitions (and often different interpretations) of what constitutes an amateur has on occasion led to confusion and controversy.

There is no problem with respect to the outright professional, who participates in professional competitions as his sole or principal means of livelihood and thus presumably can and does devote most of his time and energies to perfecting his athletic skills. He is never eligible to participate in amateur competitions in his own sport and, with few exceptions, neither is he eligible for amateur competitions in any other sport. However, even without becoming an outright professional as above, there are various acts by which an athlete may nevertheless render himself ineligible for further competition as an amateur. The word "non-amateur" would better characterize such athletes than the word "professional."

The basic distinction between the amateur and the non-amateur in athletics is that the amateur, according to the International Amateur Athletic Federation, is "one who competes for the love of sport and as a means of recreation, without any motive of securing any material gain from such competition." The Amateur Athletic Union of the United States defines the amateur as "one who engages in sport solely for the pleasure and physical, mental or social benefits he derives therefrom, and to whom sport is nothing more than an avocation." The Amateur Athletic Association of England defines him as "one who has never competed for a money prize or monetary consideration in any Athletic Sport or Game—who has never engaged in, assisted in or taught any athletic exercise for pecuniary consideration, or in any way exploited his athletic ability for profit."

The principal acts by which an athlete may render himself ineligible for amateur competition include: (1) competing, coaching or officiating for money; (2) demanding or receiving excessive or improper expenses; (3) fraud or grossly unsportsmanlike conduct in connection with any competition; (4) selling or pawning of prizes; (5) entering into an agreement for professional competition, which may be evidenced by permitting his name to be used for advertisement of any specific professional competition; (6) knowingly competing with or against ineligible persons without special permission; (7) capitalization of athletic fame, including employment where the athlete's sole or chief value is the publicity given to his athletic fame; (8) permitting use of name or photograph for advertising any product; (9) participation, without special permission, in radio or television broadcast for advertisement of any product; (10) selling or soliciting sale of sporting goods, prizes, trophies, etc., used chiefly in or in connection with sports.

An athlete competing away from his home territory may be reimbursed for his actual traveling expenses, lodging and meals. In international competitions he may receive a pocket-money allowance equivalent to \$2.00 per day. Under the rules of the Amateur Athletic Union of the United States the allowance for lodging and meals in addition to traveling expenses may not exceed a total of \$15.00 per day, though upon special application showing actual

necessity an additional allowance up to \$5.00 per day may also be permitted.

Aiter 1946 a new element entered international sport with the arrival of the state amateur. In the U.S.S.R. and other eastern European countries a sport is run by government agencies and is the subject of political control. In such planned societies every permitted activity has a political significance and the distinction between the professional and the amateur becomes meaningless. Since sport has been officially acknowledged as "an excellent vehicle of propaganda in capitalist countries" and one which "helps in the work of foreign diplomatic missions and trade delegations." it is a simple matter for the state committee for sport and physical culture to command leave of absence for any athlete to prepare himself adequately.

Hundreds of athletes each year voluntarily relinquish their amateur status, most of them because they desire in one way or another to profit by their athletic skills or reputations. It is usually only the case of the athlete who desires both to retain such benefits and at the same time retain his status as an amateur that reaches the controversial stage and receives any publicity. The great all-round athlete, Jim Thorpe, lost his amateur status and thereby forfeited the Olympic gold medals won at Stockholm in 1912 because he had admittedly previously received pay for playing with a professional baseball team, an act permanently depriving an athlete of his amateur standing under any rules.

Many of the publicized cases of prominent athletes who have been deprived of their amateur status have been based upon proof of their having demanded or accepted payments in the guise of grossly excessive "expenses." Such was the case with Paavo Nurmi of Finland, Jules Ladoumege of France, Gunder Hägg and Arne Andersson of Sweden and Wes Santee of the United States. The latter's attempt, by court action, to enjoin the Amateur Athletic union from enforcing its rules pertaining to amateurism was emphatically rejected by the supreme court of the state of New York, on May 11, 1956.

The celebrated and oft-cited case of swimming star Eleanor Holm, while often incorrectly referred to as one involving amateur status, in fact involved only her suspension by the U.S. Olympic committee from the 1936 Olympic team for infraction of training rules. No question of amateurism was involved and, until she subsequently embarked upon a professional career, Miss Holm could have competed as an amateur in other competitions.

Suspension of an athlete for some of the above violations, where not involving acceptance of money for competing or coaching, or an act of fraud, etc., may under certain circumstances and conditions be lifted, but usually not prior to a designated period after commission of the last disqualifying act.

Formerly all teachers in any sport were disqualified from amateur competition, but by the second half of the 20th century even physical education teachers who coach athletes for competition were eligible provided they were not paid, directly or indirectly, for such coaching. Similarly lifeguards, playground attendants, camp counselors, etc., who formerly, even if they did not coach or instruct in athletics, were ineligible for amateur competition until after a specified time after termination of such employment, were eligible if not capitalizing upon their athletic fame or ability. The most controversial unresolved issue was that of so-called broken-time payments; *i.e.*, compensatory payments for time lost from business while training for, traveling to and from, or competing in any competition. Such payments remained forbidden, but there were recurrent efforts to relax this rule.

So long as regulation of the rules of amateurism in sport is primarily the responsibility of the bodies governing separate sports in each separate nation, it will obviously remain difficult to obtain a single, uniform, hard and fast code of interpretation and enforcement in each nation, much less throughout the world. See also OLYMPIC GAMES; BOXING; CRICKET; ROWING; TRACK AND FIELD SPORTS; etc. (N. D. M.; Ps. Sr.)

AMATHUS, an ancient city founded by the Phoenicians about the middle of the 2nd millennium B.C. on the south coast of Cyprus, on a site about 30 mi. S.W. of Larnaca and 6 mi. N.E. of Limassol, among sandy hills and sand dunes, which perhaps explain its name

(Gr. *amathos*, "sand"). The earliest remains found there date from a period soon after the beginning of the Iron Age (c. 1500 B.C.). Amathus maintained strong sympathies with the Phoenician mainland and refused to join the revolt of Cyprus against Persia (500–494 B.C.). Similarly, in conjunction with the cities of Citium and Soli about 385–380 B.C., it opposed Evagoras of Salamis who was in revolt against Persia. When, after the death of Alexander the Great, the rest of Cyprus was annexed to Egypt, Amathus resisted annexation. It derived its wealth from grain and from copper mines, of which traces can be seen inland. The rich necropolis has yielded valuable works of art, but the city itself had by the middle of the 20th century not been fully excavated. Its temple of Adonis and Aphrodite was famous in Roman times; hence the Latin epithet "Amathusia" applied to Venus. The city still flourished in the 7th century A.D. but was almost deserted by the 12th.

See C. D. Cobham, *Excerpta Cypria* (1908); E. Gjerstad et al., *The Swedish Cyprus Expedition*, vol. ii (1935). (P. Ds.)

AMATI, the name of a family of celebrated Italian violin makers in Cremona in the 16th and 17th centuries.

ANDREA (c. 1520–c. 1578), the founder of the Cremona school of violin making, was perhaps originally influenced by the work of slightly earlier makers from Brescia. His earliest known violins are dated about 1564. In essentials, they set the style for all the models made by later members of the family and, with the modifications introduced by Antonio Stradivari (*q.v.*), for the modern violin. Andrea, like his descendants, made violins in two sizes, the larger of which later became known as the "grand Amati." He also introduced the characteristic amber varnish. Like all the family he was born and died in Cremona.

His two sons ANTONIO (c. 1550–1638) and GIROLAMO (Hieronymus) (1551–1635) worked together until the latter's death, and are known as the brothers Amati.

NICOLO (1596–1684), the son of Girolamo, was born on Sept. 3, 1596, and died on Aug. 12, 1684. The most famous of the family, he produced instruments notable for beauty of workmanship and tone! and was the master from whom Stradivari and Andrea Guarneri (*q.v.*), among others, learned their craft. He was succeeded by his son GIROLAMO (1649–1740), who was born on Feb. 26, 1649, and died on Feb. 27, 1740. Although the instruments made by him are as fine as those of his father and grandfather, they suffered in comparison with those made by Stradivari.

The great contribution of the Amatis to the development of the violin was their evolution of the flat, shallow model, which, as improved by Stradivari, proved the fittest to survive in modern concert conditions by reason of the brilliant soprano tone of which it is capable. See also VIOLIN FAMILY. (E. HA.)

AMAUROSIS, a term for loss of vision, limited chiefly to those diseases not directly involving the eye, or the optic nerve. See BLINDNESS; EYE, HUMAN; VISION.

AMAZON, in Greek mythology, one of the fabulous women warriors. The etymology is uncertain, the ancients fancifully deriving the word from the Greek for "breastless," it being said that they destroyed the right breast of their children to prevent it from getting in the way of the bowstring.

The only plausible explanation of the story of the Amazons is that it is a variety of the familiar tale of a distant land where everything is done the wrong way about; thus the women fight, which is man's business. The habitat of the Amazons becomes more remote as Greek geographical knowledge develops. In Homer's *Iliad* they are in Phrygia and Lycia, where Priam and Bellerophon respectively meet them; they are also associated with various legends of Ionia. In the cyclic *Aethiopis* their queen Penthesileia brings a contingent from Thrace to help Priam, and is slain by Achilles.

When the Black sea was colonized by Greeks, this region became the usual Amazon district, the precise place being Themiscyra on the Thermodon river. As there were in fact no Amazons there, it was necessary to explain what became of them, and one of the traditional labours of Hercules was an expedition to get the girdle of their queen for Eurystheus, as a result of which he conquered and expelled them. Subsidiary tales grew up, as that

the Amazons mated with men of another people, kept the female children and sent the males away to their fathers (Strabo, *Geography* xi, 5, 1; see the whole chapter for more legends and Herodotus iv, 110 ff. for an earlier form of the story; clearly it is meant to explain why, if the whole nation consisted of women, it did not die out in a generation).

Later than the story of Hercules, an Attic imitation of it arose, in which Theseus attacks the Amazons either with Hercules or independently. The Amazons in turn invade Attica but are finally defeated; at some point in the story Theseus marries one of them, Antiope. Latest of all, in Hellenistic times, the Amazons are associated with Dionysus, either as his allies or, much more commonly, as his opponents. Since the conquests of Dionysus are largely modeled on those of Alexander, it is not surprising that the latter meets an Amazonian queen, who claims to be the noblest of women and wants a child by the noblest of men.

ALINARI PHOTO

AN AMAZON. VATICAN
MUSEUM

latter meets an Amazonian queen, who claims to be the noblest of women and wants a child by the noblest of men.

In works of art, combats between Amazons and Greeks are placed on the same level as, and often associated with: combats of Greeks and centaurs. Their arms were the bow, spear, light double ax, a half shield, nearly in the shape of a crescent, called *pelta*, and in early art a helmet, the model before the Greek mind having apparently been the goddess Athena. In later art they approach the model of Artemis, wearing a thin dress, girt high for speed; while on the later painted vases their dress is often peculiarly Persian—that is, close-fitting trousers and a high cap called the *kidaris*.

The battle between Theseus and the Amazons is a favourite subject on the friezes of temples (e.g., the reliefs from the frieze of the temple of Apollo at Bassae, in the British museum), vases and sarcophagus reliefs; at Athens it was represented on the shield of the statue of Athena Parthenos, on wall paintings in the Theseum and in the Stoa Poikile.

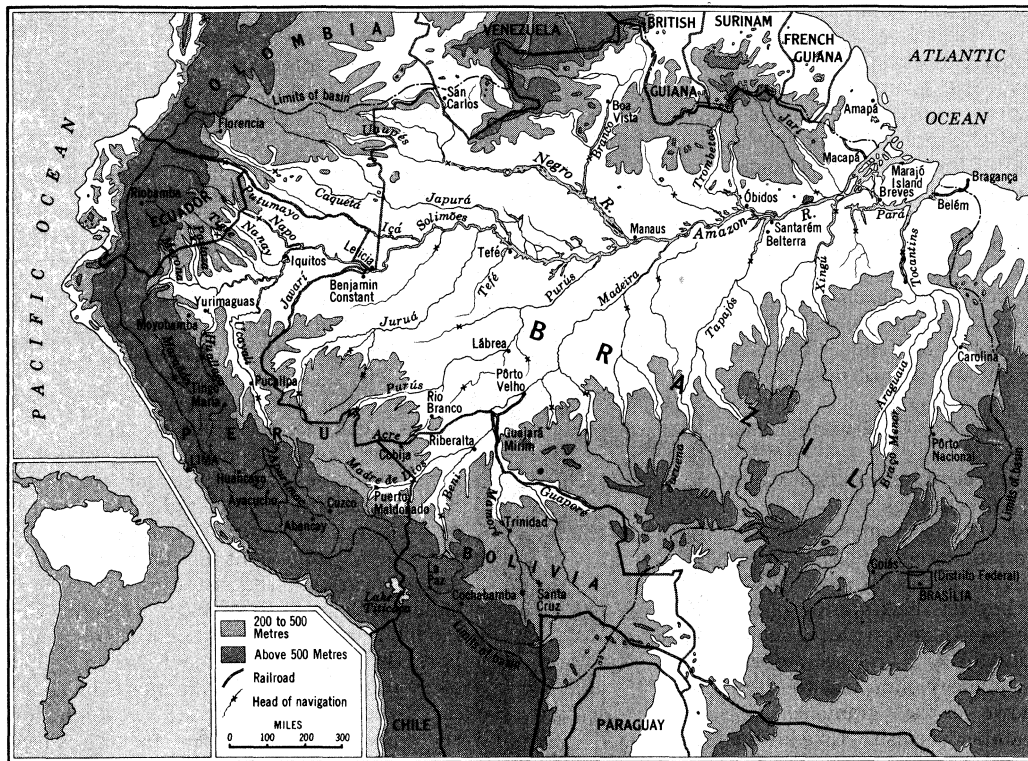

In the 16th century the Spanish explorer Francisco de Orellana asserted that he had come into conflict with fighting women in South America on the Marañón river which was named after them the Amazon, or river of the Amazons, although others derive its name from the Indian *amassona* (boat destroyer), applied to the tidal phenomenon known as the bore. The existence of "Amazons" (in the sense of fighting women) in the army of Dahomey in Africa in modern times is certain, but they are said to have died out during the French protectorate.

BIBLIOGRAPHY.—G. Grote, *History of Greece*, part i, ch. xi; L. Whibley, *Companion to Greek Studies*, 4th ed. (1931); Plutarch, *Greek Questions*, trans. by W. R. Halliday (1928). (H. J. R.; X.)

AMAZON (AMAZONAS), the greatest river of South America and the largest river in the world in volume and in the area of its drainage basin. While the name Amazon, or Xamazonas, is popularly employed for the whole of the main stream, in Peruvian arid Brazilian nomenclature it is properly applied only to sections of it. In Peru the upper stream, from its source to Iquitos, is called Marañón (Port., Maranhão) and from there to the sea, Xamazonas. In Brazil the name Solimões is used from Iquitos to the mouth of the Negro river and Amazonas only from the Negro river to the sea.

In 1500, Vicente Yáñez Pinzón, in command of a Spanish expedition, discovered and ascended the principal mouth of the Amazon to a point about 50 mi. from the sea. He called it the Rio Santa María de la Mar Dulce, which soon became abbreviated to Mar Dulce. The companions of Pinzón, in giving evidence in 1515, mention it as El Rio Marañón, a name originally applied to the mouth of the Pará south of Marajó Island and later to the upper part of the main stream.

The first descent of the river from the Andes to the Atlantic

AMAZON RIVER BASIN AND DRAINAGE SYSTEM

ocean was made in 1541 by Francisco de Orellana (*q.v.*), who reached the main stream by way of the Napo river. It is rather generally accepted that the name Amazonas was given to the river by Orellana after a battle with the Tapuyan Indians in which he believed that the women of the tribe fought side by side with the men. The first ascent of the river was made in 1638 by Pedro Teixeira, a Portuguese, who reversed the route of Orellana and reached Quito by the Napo.

The Amazon river has a drainage area of about 2,722,000 sq. mi. if the Tocantins river is included. This is nearly twice as large as the area drained by any of the other great rivers of the earth. It drains four-tenths of South America, including the world's largest continuous block of tropical rain forest, and gathers its waters from 5° 4. to 20° S. latitude.

The source of the Amazon has long been the subject of speculation on the part of geographers and explorers. The main stream rises in a chain of glacier-fed lakes near the western edge of the Andes in central Peru about 100 mi. from the Pacific ocean; and flows for 3,915 mi. across Peru and Brazil to enter the Atlantic on the equator. The Ucayali-Apurimac-Amazon system, which heads near Lake Titicaca, is somewhat longer, but not long enough to challenge the 4,157-mi. Nile for the title of world's longest river.

The discharge of the Amazon has never been accurately measured, but on the basis of the amount of precipitation falling on its drainage area it is believed to exceed 4,200,000 cu. ft. per second, seven times that of the Mississippi. During the rainy season it probably exceeds 7,000,000 cu. ft. per second. Its discharge is detectable 200 mi. at sea and tides are felt upriver 600 mi., as far as Óbidos. It has been estimated that the Amazon carries nearly one-fifth of all the fresh water that runs off the earth's land surface. This tremendous volume results from the fact that the Amazon and its tributaries drain an area of equatorial lowlands where rainfall ranges from 70 to 120 in. annually. More than two-thirds of the immense Amazon basin lies within Brazil, but it also embraces large areas of Peru, Bolivia, Ecuador, Colombia and Venezuela. The main stream is navigable for large ocean-going vessels as far as Iquitos, 2,300 mi. from the sea, and for smaller ships 486 mi. further to the Pongo de Manseriche. With its tributaries, many of which approach the size of the main stream, it composes a fluvial net unequalled in the world.

The Amazon is less a single river than a network of rivers draining the largest area of equatorial rainy climate in the world. Seventeen of its tributaries have lengths in excess of 1,000 mi. Beginning with the lower river the major tributaries to the main stream will be discussed in order, beginning with the southern or larger affluents.

TRIBUTARIES

The TOCANTINS is not really a branch of the Amazon. It is the central fluvial artery of Brazil, running from south to north for a distance of 1,677 mi. It rises in the Planalto Central, near the city of Goiás and the site of the new capital of the republic at Brasília. Its more ambitious western affluent, the Araguaia, has its headwaters even farther south and flows 1,366 mi. before its junction with the parent stream, which appears almost to equal it in volume. Above the junction of the Araguaia with the main stream the Tocantins is interrupted in many places by rapids and sand bars. It is navigable

only in its lower course. The Pará river, generally called one of the mouths of the Amazon, is really the estuary of the Tocantins, linked with the Amazon by the navigable Breves channel.

The XINGU, the next large river west of the Tocantins, was first explored by Karl von den Steinen in 1884-87. The river is formed at about 14° S. latitude, on the northern slopes of Brazil's Planalto Central, about 150 mi. northeast of Cuiabá. For most of its length of 1,304 mi. the Xingu is marked by a succession of falls and rapids that are serious obstacles even to canoe navigation.

The TAPAJÓS pours into the Amazon 500 mi. above Belém and is about 807 mi. long. Its headwaters are just to the west of the headwaters of the Xingu at 14° 25' S. latitude. Near this place a number of streams unite to form the Arinos river. The Arinos, the Alto Tapajós and the Tapajós to the last rapid, the Maranhão Grande, is a continuous series of formidable cataracts and rapids; but from the Maranhão Grande to its mouth, about 188 mi., the river can be navigated by large vessels.

The MADEIRA has its junction with the Amazon 870 mi. by river above Belém, and almost rivals it in the volume of its waters. It has a length of 2,013 mi. and is navigable for 807 mi. It rises more than 50 ft. during the rainy season, and the largest ocean steamers may ascend it to the Falls of Santo Antônio, 663 mi. above its mouth; but in the dry months, from June to November, it is navigable for the same distance only by craft drawing from 5 to 6 ft. of water. The Madeira begins where the Beni joins the Mamoré. The major tributary of the Mamoré is the Guaporé. The Guaporé has its headwaters almost in contact with the great Pantanal, probably the largest swamp in South America, which is part of the Paraguay-La Plata river system. Santo Antônio is the first of a formidable series of cataracts and rapids, 19 in number, which, for a river distance of 263 mi., obstruct the upper course of the Madeira until the last rapid, called Guajará Mirim (small pebble), is reached, about 120 mi. below the union of the Guaporé with the Mamoré. The Madeira-Mamoré railroad circumvents these rapids. The Beni and the Mamoré join at the Madeira rapids, a stretch of nearly 5 mi. of reefs, whirlpools and rapids, about 40 mi. below the Guajará Mirim rapids. From the Guaporé, Mamoré and Beni rivers the Madeira receives the drainage from the whole of the eastern and northeastern slopes of the Andes from the southernmost sources of the Rio Grande

(a tributary of the Mamoré) at about 20" S. latitude to the northernmost sources of the Madre de Dios river (tributary of the Beni) at about 12° S. latitude, the whole of the southwestern slope of the Brazilian Mato Grosso, and the northern slope of the Sierra de Chiquitos in the Gran Chaco. All of the upper branches of the Madeira flow across open, almost level plains, which are yearly flooded to an average depth of three feet for a period of from three to four months.

The PURÚS, a very sluggish river of 1,995 mi., enters the Amazon about 230 mi. W. of the Madeira, which it parallels as far as the falls of the latter stream. It is practically a great drainage ditch for the half-submerged, lake-flooded district it traverses. It is one of the most crooked rivers in the world, its length in a straight line being less than half that by its meanders.

The JURUÁ is the next great southern affluent of the Amazon west of the Purús and traverses the same sort of low, half-flooded country as the latter. It rises in the highlands east of the Ucayali which carry the Peru-Brazil boundary and is navigable for a distance of 621 mi. above its junction with the Amazon.

The JAVARÍ (656 mi.), the boundary line between Brazil and Peru, is another Amazon tributary of importance. It is navigable by canoe only from above its mouth to its sources among the Ucayali highlands, but only a fraction has been found suitable for navigation by larger boats. The Brazilian Boundary commission ascended it in 1866 to the junction of the Shino with its Javari branch. The country it traverses in its extremely sinuous course is very level, similar in character to that of the Juruá.

The UCAYALI is among the major tributaries of the Amazon. Its headwaters drain a great section of the Peruvian plateau from the source of the Vilcanota river only 70 mi. N.W. of Lake Titicaca to the sources of the Mantaro west of Cerro de Pasco. The lower 500 mi. of the main channel is bordered by large islands formed by numerous side channels, the whole being very low and flooded in the rainy season. The Ucayali is navigable for light draft launches as far as the Tambo-Urubamba junction. Large steam vessels reach as far as the Peruvian city of Pucallpa (pop about 20,000), which is the terminus of the trans-Andean highway from Lima, and after Iquitos, the largest city in the Peruvian Oriente. South of Pucallpa, on the Pachitea river, a left bank tributary of the Ucayali, lies the Ganzo Azul oil field and the Tournavista agricultural colony, the latter a North American settlement venture.

The HUALLAGA, which joins the Marañón about midway between the Pongo de Manseriche and the mouth of the Ucayali, has its true source in the Yanahuanca river, a stream flowing from a series of glacier-fed lakes northwest of the famous mining centre of Cerro de Pasco. The name Huallaga is applied, however, to a more easterly and much less important headwater tributary which rises a short distance east of Cerro de Pasco. The whole stream is deeply entrenched and from the town of Huánuco to the mouth of the river much of its course is impeded by rapids and gorges.

The MARAÑÓN river rises in Lake Lauricocha, the northernmost of a chain of glacier-fed lakes about 100 mi. N.N.E. of Lima and flows northward in a deeply eroded valley. It is because of this and other deeply entrenched longitudinal valleys, cut by the tributaries of the Amazon, that the erroneous conception of the Peruvian Andes as three separate mountain ranges has arisen. At about 5° 30' S. latitude the river makes a great bend toward the northeast and, after passing through a succession of narrows or *pongos* and no less than 35 formidable rapids, it breaks through the easternmost range of the Andes to the Amazon plain by a great canyon known as the Pongo de Manseriche. This canyon is about 2,000 ft. deep and narrows in places to a width of only 100 ft. Through this dark canyon the Marañón flows, at times, at a rate of over 12 mi. an hour. Beyond the *pongo* the river receives several large tributaries from the north and spreads out into a broad stream with numerous channels and islands.

From the north the Amazon receives many tributaries, but their total volume of water is not nearly so great as that contributed to the parent stream by its affluents from the south. The part of Brazil lying between the Amazon and French, Dutch and British Guiana, and bounded on the west by the Negro, is known as

Brazilian Guiana. It is the southern slope of the Guiana highlands, geologically a part of the larger Brazilian highland which lies south of the Amazon.

The TROMBETAS is the first river of importance on the northern side when ascending the Amazon. Its confluence with the Amazon is just above the town of Óbidos. It has its sources in the Guiana highlands, but its long course is frequently interrupted by violent currents, rocky barriers and rapids. The river is navigable for 149 mi. above its mouth.

The NEGRO, the great northern tributary of the Amazon, has its sources along the watershed between the Orinoco and the Amazon basins, and also receives some of the water from the upper Orinoco by way of the Casiquiare canal. The Negro is navigable in the dry season for 423 mi. above its mouth for vessels of 4-ft. draft, but it has many sandbanks and minor obstructions. In the wet season it overflows its banks, in places to a width of 20 mi. Its lower course is very wide and full of long islands and intricate channels. The main headwater affluent of the Negro is the Uaupés. Its principal affluent from the north is the Branco formed by the union of the Uraricoera and Tacutú which, with their tributaries, drain a large section of the southerly slopes of the Guiana highlands which separate Brazil from Venezuela and British Guiana. The Branco flows nearly straight south for 350 mi. to the Negro which it enters by numerous channels similar to those of the lower course of the latter.

The Casiquiare canal which connects the upper Orinoco, about 18 mi. below the old mission site of Esmeralda, with the Negro, a tributary of the Amazon, near the village of San Carlos, is a natural waterway, the only one of its kind known in the world. The Negro is in the process of capturing the upper Orinoco. According to data obtained by the Rice expedition, which made a survey of the canal in 1919, the length of the canal is 204 mi. Its width at its beginning in the Orinoco is 758 ft.; but this rapidly narrows down to 150 ft. and widens again to 2,150 ft. at its mouth in the Negro. The level of the water at the Orinoco end was found to be 283 ft. and, at the Negro end, 212 ft., giving the canal an average slope toward the Negro of 7.2 in. per mile.

The JAPURÁ or CAQUETÁ. West of the Negro the Amazon receives three imposing streams from the northwest — the Japurá, the Içá or Putumayo and the Napo. The first was formerly known as the Yapurá, but its Brazilian part is now called the Japurá, and its Colombian portion the Caquetá. Jules Crevaux, who descended it, describes it as full of obstacles to navigation, the current very strong and the stream frequently interrupted by rapids and cataracts. It rises in the Colombian Andes, nearly in touch with the sources of the Magdalena.

The IÇÁ or PUTUMAYO rises in the Colombian Andes east of Pasto, flows through the rain forest along the Colombia-Ecuador and Colombia-Peru border to join the Amazon at Santo Antônio do Içá, Braz. Most of its nearly 1,000 mi. length is navigable for shallow-draft vessels.

The NAPO rises among the volcanoes of the eastern border of the Andes in northern Ecuador. Its headwater tributaries in the Ecuadorian Oriente flow through one of the least known areas of the eastern border of the Andes. The Coca, which has its source on the slopes of Cayambe volcano close to the equator, and the Aguarico, an important river with headwaters between Cayambe and the Colombian frontier, join it from the north. The Curaray, transecting an area rich in rubber, joins it from the south about 200 mi. from its mouth. The Napo is navigable for river craft to this point and by canoes to the mouth of the Coca. The Curaray-Coca section of the river is little known.

The NANAY, TIGRE, PASTAZA and MORONA are the major Amazon tributaries between Iquitos and the Pongo de Manseriche. Above the Pongo two important tributaries, the Santiago and the Chinchi, join the Marañón from the north.

THE MAIN RIVER

Physical Characteristics.— The Amazon valley is a great structural depression, a subsidence trough filled with Tertiary sediments, which flares out to its greatest dimension in the upper reaches. It lies between two old and not very high crystalline

plateaus, the rugged Guiana massif on the north and the lower Brazilian massif lying somewhat farther from the main river, on the south. The Amazon valley was occupied by a great fresh-water sea during the Pliocene period. Sometime during the Pleistocene an outlet to the Atlantic was established and the great river and its tributaries became deeply entrenched into the Pliocene surface.

The modern Amazon and its tributaries occupy a great drowned valley. With the rise in sea level that followed the melting of the ice caps the steep-sided canyons that had been eroded into the Pliocene surface during the lower sea stand were flooded. The old lake surface is the soil of the terra firma on which much of the Amazon forest has developed. In the upper part of the valley, in the Peruvian and Bolivian Oriente, more recent outwash from the Andes has covered many of the older surfaces.

At the Obidos narrows, where the river is constricted to a width of a little more than a mile, the average depth of the channel below the mean water level is 300 ft.; in most of the Brazilian part of the river its depth exceeds 150 ft. Yet at the Peruvian border, 2,500 mi. from the Atlantic, the elevation above sea level is less than 300 ft. The maximum free width (without islands) of the river's permanent bed is $8\frac{1}{2}$ mi., upstream from the mouth of the Xingu. During great floods, however, when it completely fills the flood plain, it spreads out in a band 35 mi. wide or more. The average velocity of the Amazon is about one and one-half miles an hour, a speed that increases greatly at flood time.

The great river gradually rises from November to June, and then falls until the end of October. The rise of the Negro branch does not occur at the same time, for the steady rains do not commence in its valley until February or March. By June the Negro is full, and then it begins to fall with the Amazon. The flood levels are in places from 40 to 50 ft. above low river. Taking four roughly equidistant points, the rise at Iquitos is 20 ft., at Tefé 45, near Óbidos 35, and at Belém 12.

The Amazon does not meander in the fashion of the Mississippi but for the most part follows a remarkably straight course. It is still in the process of refilling its broad river-cut valley by its own alluvium, depositing silt into settling basins on a massive scale during each flood season. The size of the flood plain is moderate when compared with the volume of the river. The zone of active alluviation is typically 12–30 mi. wide and is bordered by steep cliffs (*barrancas*), often capped by a horizon of laterite rock (*canga*). Where these cliffs are being undercut by the river they produce the *terras caídas* or "fallen lands" so often referred to by Amazon travelers.

The so-called "black-water" tributaries of the Amazon, the Xingu, Tapajós, Negro, Tefé and Trombetas, carry little or no silt, in part because of the bleached sandy character of the country at their headwaters. The Tapajós and Xingu are in reality a bright emerald-green, for they lack the strong solution of humic matter that characterizes the Negro. Where such streams enter the main river they are blocked off to form true fresh-water lakes and resemble in form, width and depth marine rias.

The first highland met in ascending the river is on the north bank, opposite the mouth of the Xingu, and extends for about 150 mi. up, as far as Monte Alegre. It is a series of steep, table-topped hills, in part of Devonian and Carboniferous Age, interrupted by diabase intrusions. On the south side, above the Xingu, a line of low bluffs extends in a series of gentle curves with hardly any breaks nearly to Santarém. The line is a considerable distance inland, bordering the flood plain, which is many miles wide. Then the bluffs bend to the southwest, and, abutting upon the lower Tapajós, merge into the bluffs which form the terrace margin of that river valley. The next highland on the north side is Óbidos, a bluff 56 ft. above the river, backed by low hills. From Itaquatiara, nearly opposite the river Madeira, to near the mouth of the Negro, the banks are low. Approaching Manaus there are rolling hills; but from the Negro, for 600 mi., as far up as the village of Canaria, at the great bend of the Amazon, only very low land is found, resembling that at the mouth of the river.

On the south side, from the Tapajós to the river Madeira, the banks are usually low, although two or three hills break the general monotony. From the latter river to the Ucayali, a distance

of about 1,500 mi., the forested banks are just out of water, and are inundated long before the river attains its maximum flood line. Thence to the Huallaga the elevation of the land is somewhat greater; but not until this river is passed, and the Pongo de Manseriche approached, does the swelling ground of the Andean foothills raise the country above flood level.

The width of the mouth of the river is usually measured from Cabo Norte to Ponta Tijoca, a distance of 207 statute miles; but this includes the ocean outlet, 40 mi. wide, of the Pará river, which should be deducted, as this stream is only the lower reach of the Tocantins. It also includes the ocean frontage of Marajó, an island about the size of the kingdom of Denmark lying in the mouth of the Amazon. Following the coast, a little to the north of Cabo Norte, and for 100 mi. along its Guiana margin up the Amazon, is a belt of half-submerged islands and shallow sandbanks. There the tidal phenomenon called the bore, or pororoca, occurs, where the soundings are not more than four fathoms. It commences with a roar, constantly increasing, and advances at the rate of from 10 to 15 mi. an hour, with a breaking wall of water from 5 to 12 ft. high. Under such conditions of warfare between the ocean and the river, it is not surprising that the Amazon finds it impossible to build up a delta. Most of the 3,000,000 tons of sediment that the Amazon discharges daily into the sea is carried northward by coastal currents to be deposited along the Guiana coast.

Vegetation. — In diversity of forms and profusion of individuals the plant life of the Amazon river basin is probably the richest on the globe. Within the area drained by this river system, species of practically every ecological type find homes. Most of the idiosyncrasies of the plant kingdom are in evidence, for this enormous territory presents a myriad-faced environment, and each face has its own peculiar complement of plant inhabitants.

The dominant feature of the area is the Amazonian rain forest or selva, one of the most extraordinary vegetation panoramas on earth. It widens from a 200 mi. front on the Atlantic to a belt 1,200 mi. wide where the lowlands meet the Andean foothills, interrupted only by the rivers and, especially below Parintins, by local areas of campos or grassland.

The massiveness and continuity of the great forest, which covers almost the entire geographical area of Amazonia, is above all a reflection of the high rainfall, high humidity and monotonously high temperatures which prevail. Man's imprint on the natural landscape is singularly inconspicuous. The forest itself is, in a sense, a great plant museum, for it is considered by botanists to represent perhaps the oldest vegetation formation on earth, essentially unchanged from Tertiary times.

The most striking characteristics of these vast woods are: the comparative absence of pure stands of any tree species; the paucity of forest giants in large groups; the division of the vertical height of the forest into stories or floors; the multitudes of very different types, both as to form and habit, jumbled together, often in the most tangled confusion; the general absence of seasonal leaf fall and flowering time; the small percentage of soft woods; the number of tree forms with prop roots or buttressed trunks; the long distance between the forest floor and the first branches; the absence of great masses of floral colour and, comparatively speaking, the light colour of the bark.

In the middle latitudes, solid forests of one or a few species are characteristic, so that they are designated under the name of their dominant species, such as oak or pine forests. On an acre of Amazon forest, in most regions, scores of species occur, but only a few individuals of each, although there are considerable areas that might be called laurel forests.

Palms, myrtles, laurels, acacias, bignonias, cedrelas, cecropias, rosewoods, Bombacaceae, Brazil-nuts, rubber trees, figs, purple-hearts and dozens of others often grow on one small area. Within a half-mile square, Louis Agassiz counted 117 different woods. In some regions, particularly rain forest on certain mountain slopes, tree ferns add to the variety. Legumes constitute the most important of all the families as much for their great number of species as for the high economic value of their woods. Conifers are absent.

Seen from the air the equatorial forest looks like an immense and continuous carpet with a spongy surface, uniform and monotonous. The abundant evergreen foliage of its canopy unites the crowns of its tallest trees at approximately the same level, usually from 100 to 150 ft. above the surface of the ground. The forest that grows on the flood-plain lands (*várzea*) of the Amazon and its tributaries and subtributaries can be distinguished from that occurring on the older, higher surfaces, terra firma, that stand above the level of the highest floods.

The *vdrzea* forest is the classical rain forest as described by early Amazon travelers who of necessity restricted their movements largely to the water courses. It has a greater botanical diversity than does that on higher ground, perhaps in part because of the quantity and variety of the seeds carried by the annual floodwaters and deposited on the rich soil of the flood plain. On the flood plain the so-called "white" or soft woods predominate; among them the Pará rubber tree (*Hevea brasiliensis*). One of the more typical trees is the *sumauíma* (*Ceiba*) or kapok whose thick, whitish trunk and tall, spreading crown have led it to be called the "queen of the *vdrzea*." On the upper Amazon and its tributaries, but not on the Negro and other black-water rivers, large areas of the *várzea* are dominated by the tall-plumed cane grass, *cana brava* (*Gynerium*). On the lower river and on Marajó Island the arborescent relative of the calla lily, *Montivichardia arborescens*, is a conspicuous element of the riverine formation. The giant water lily (*Victoria regia*) grows in the shallow back-water lagoons. The lower parts of the *várzea*, which are longest flooded, are the sites of extensive grasslands (*campos de vdrzea*) located along the edges of permanent or seasonal lakes and behind the natural levees, but this is true only from about Parintins downstream to the mouth of the Xingu. On the black-water rivers the *várzea* is usually replaced by overhanging cliffs or, as on the Tocantins, white sand beaches. Small streams of this character are often completely arched by the tangle of high forest and lianas.

The drier Tertiary surfaces above the flood plain typically support species with a higher density that are more valuable as construction timber. These include the *mogno* (*Swietenia mahogani*), *acajú* (*Vouacapoua americana*), *andiroba* (*Carapa guianensis*), *cedro* (*Cedrela*), *massaranduba* (*Mimusops huberi*), *pau rosa* (*Aniba rosaeodora*), *pau d'arco* (*Tecoma*) and an infinity of other species. The *castanheiro* (*Bertholletia excelsa*), source of the Brazil nut of commerce, also makes good construction lumber and is typically found on higher lands, as is the latex-yielding *caucho* (*Castilla*). So are several of the palms that produce nuts of economic value.

The region of the Amazon basin richest in flowers and colour is the little-explored, lichen-choked cloud forest or *ceja de la montaña*, home of the Cinchona, that fringes the tree limit on the eastern flanks of the Andes. Many of the plants recall the middle latitudes, although the species are generally different. Lupines, gentians, barberries, fuchsias, viburnums, lycopodiums, buddleias, raspberries and clematis are typical.

Some of the most valuable economic plants are indigenous to the Amazon valley. In addition to those already cited, the valley contains quinine, cacao, cassava (*Manihot utilissima*) from which tapioca is derived, sarsaparilla, ipecacuanha (the source of ipecac), copaiba, tonka beans for flavouring tobacco, annatto (*Bixa orellana*) for colouring butter and cheese, Pará rubber (*Hevea*), balata, rosewood, snakewood, guava, calabash, coca from which cocaine is derived, *guaraná* (*Paullinia cupana*) and, in the highlands, another long list headed by the white potato.

One of the most noteworthy features of the vegetation of the middle and lower parts of the Amazon valley, and one not fully appreciated until the advent of the airplane, is the considerable extent of scrub brush and short grassland (*campos*) on the higher regions between the main rivers. Palm and leathery-leaved, drought-resistant trees such as the *caimbé* (*Curatella americana*) are typically scattered over the surface of these poorly drained prairies. In most of the lower Amazon below Manaus, though not in the immediate vicinity of Belém, there is a fairly well-marked dry season with bright weather and only occasional thunder-showers from July to September that permits annual burning. The

physical and chemical properties of the soils of these long-weathered surfaces also have had a marked effect on the vegetation in many areas, as on the sandy lower terrace behind Santarém and the plateau of Monte Alegre. The largest continuous areas of campos vegetation are to be found on the north side of the Amazon, especially the Rio Branco and Trombetas drainage, on the coast of Amapá province north of the Amazon mouth, and on Marajó Island.

Fauna.—Although the fauna of the Amazon valley is noteworthy for the variety and number of its genera and species, it is very deficient not only in species of the larger mammals but also in the individuals of these comparatively few species. In contrast with other regions of the world, a large percentage of the mammals are tree dwellers. None of them will attack man unprovoked, under ordinary circumstances. The monkeys are all arboreal and are common below 3,000 ft. altitude. The best known are the red howlers or *guaribas*, which make the great forest resound with their morning and evening choruses. Other common species are the spider, night, saki, marmoset, titi and squirrel monkeys. A scarlet-faced, almost tailless species occurs near Tefé. All forms are hunted and eaten by the aborigines. There are six species of the cat family, among which are the jaguar, puma or cougar, and the ocelot.

This region is particularly rich in rodents. The largest rodent species in the world, the capybara, is indigenous and common along the stream banks. It is said to attain a length of over four feet and a weight of over 50 kg. (100 lb.). Other common rodents are the paca (*Coelogenys*), *cutia* or agouti (*Dasyprocta*), *saúia* or spiny rat, *toro* (*Loncheres*), several species of squirrels, rats and mice, and two species of porcupines. Paca meat is highly esteemed, but the capybara and a number of other animals are also eaten.

The largest animal is the *anta* or tapir, which makes its home in the giant canebrakes along the streams. There are two species of peccary (*Dicotyles*). One of these, the *queixada* or *porco de matto*, lives in bands of 100 or more.

Five species of armadillos or *tatzi* occur, both the giant and the pygmy species being represented. The former reaches a length of three feet. Of the three species of anteaters, two of them are tree-dwelling, while the giant anteater or *Myrmecophaga tridactyla* is generally a savanna animal. The two-toed sloths are both forest forms, and one species lives largely on Cecropia leaves, while the other has a more varied plant diet of foliage and fruit. The flesh of the latter recalls mutton.

Four species of deer are found on the savannas and neighbouring woods, and thousands of hides are exported. The three species of opossums range in size from the *mucura*, as large as a cat, to the mouse-dimensioned *mucura chichica* with large eyes.

Bats by the million fan the Amazon night air, and represent numerous species and genera. Among them are the bloodsucking vampires (*Dysoptes*, *Phyllostoma*), although these are by no means as dangerous as travelers' tales would lead one to believe.

The sea cow or manatee is common in the lakes and is hunted for its meat, which resembles pork. It is one of the most peculiar mammals of the region, with its cowlike face, its small eyes and its two large, well-developed pectoral mammae.

The area is exceedingly rich in bird life. The great valley teems with species, genera and individuals. Vultures, the universal scavengers, are always alert for work. Morning and evening the parrots and macaws, two by two, in brilliant aerial processions, fly to and from their feeding grounds, their gorgeous plumage flashing in the sun, and their raucous voices calling out their presence. Toucans cry at sundown a discordant plaint from some tall, trail-side tree. Through the day the hangnests or caciques quarrel in trees where their nests swing by dozens. Doves of various species dolorously coo through the hot afternoons. Hawks and eagles scream from dead tree stumps. The forest aisles ring with the clear, silvery, metallic notes of the *uirá purú* (*Pachysylvia*). At sundown *perdíiz* or tinamous call out as do the quail. At night the air vibrates with the *correos* of the goatsuckers and whippoorwills. Early morning is full of the clattering music of the pheasantlike Pavos. Hoatzins screech in noisy flocks from streamside brush.

There is always the twittering of legions of small birds, the sound of busy woodpeckers and the guttural noises of various waterbirds. Parakeets fly about in great flocks, more common than sparrows in the United States.

One of the principal food supplies of the valley is the river turtle or tartaruga (*Podocnemis*). In former times millions of turtle eggs were annually gathered from the river sand bars at low water to be dried and rendered into an illuminating and cooking oil. Their numbers are now much reduced. The swamps, sluggish streams and lakes usually contain one or more species of cayman. Lizards of various sizes and colours dart back and forth across the trails. The snakes are not numerous, relatively speaking, but representatives of both poisonous groups occur. The constrictors reach huge proportions, 18 to 20 ft. not being rare. Snakes, however, are not a prominent feature of Amazon life; perhaps the poisonous varieties observed are not more than one in 20 or 30.

The number of fish species of the Amazon has been estimated at about 500 to 2,000, but only a few of them are of economic importance. Of these, the pirarucu is the most sought after. The scales of one species are utilized for making artificial flowers. In the half-covered forest pools, the electric eel is at home. Most of the streams are well stocked with the bloodthirsty piranha (*Serrasalmo*). Giant catfish are common and sting rays are present.

Insects are numerous in the Amazon. Countless multitudes of ants work night and day. Their work varies with the species. Some, like the saubas or leaf cutters, are farmers; others are always on marauding expeditions; while still others live in certain types of trees, and sting as well as bite. Termites, the so-called white ants, abound and cause great destruction to nearly anything of wood. Fireflies with yellow, red and green light make toy fairylands of little brooks, while a host of other insects by various devices, depending on the region, turn a paradise into purgatory. The bees are stingless, but hornets and wasps are plentiful. *Titanus giganteus*, one of the largest beetles known (5 to 6 in. long), is native. The larvae of some of the palm beetles are relished when fried. Cockroaches are everpresent. Part of the afternoon and evening music is furnished by several species of cicadas, one of which sounds like a shrill steam whistle. Centipedes, scorpions, ticks, red bugs and giant spiders are often encountered. Finally, there are the moths and butterflies, hundreds of kinds and thousands of individuals, in marvelous assortments of brilliant colours and patterns. Within an hour's walk of Belém, 700 species have been collected; around Tefé, Henry W. Bates collected 8,000 species of insects, of which 550 were species of butterflies.

Navigation.— On Sept. 6, 1850, the emperor Dom Pedro II sanctioned a law authorizing steam navigation on the Amazon, and confided to an illustrious Brazilian, Barão Mauá (Irineu Evangelista de Sousa), the task of carrying it into effect. He organized the "Companhia de Navegação e Commercio do Amazonas" at Rio de Janeiro in 1852; and in the following year it commenced operations with three small steamers, the "Monarch," the "Marajó" and "Rio Negro." At first the navigation was principally confined to the main river; and even in 1857 a modification of the government contract required the company to provide only monthly service between Belém and Manaus, with steamers of 200 tons cargo capacity, a second line to make six round-trip voyages a year between Manaus and Tabatinga and a third, two trips a month between Belém and Cametá. The government paid the company a subvention of £3,935 monthly. Thus, the first impulse of modern progress was given to the dormant valley. The success of the venture called attention to the unoccupied field; a second company soon opened commerce on the Madeira, Purús and Negro; a third established a line between Belém and Manaus; and a fourth navigated some of the smaller streams. Meanwhile the Amazonas company had largely increased its fine fleet. The latter was bought out in 1874 by an English group and, reorganized as the Amazon Steam Navigation company, continued its increasingly profitable operations as the rubber trade began to expand. The Amazon historically had been closed to foreign traffic. Pressure was strong

from both Washington and London to internationalize it. The visit of Professor Louis Agassiz and the emperor's interest in his work powerfully aided the movement. On Dec. 7, 1866, a decree by Dom Pedro opened the river and certain tributaries to the ships of the world. Peru under an earlier treaty had been granted access to the sea, but now Bolivia, Ecuador and Colombia were similarly relieved from a dependence on trans-Andean trails to reach outside markets.

Rubber.— From 1872 to 1910 the economic life of the Amazon region was focused on the production of rubber from trees growing wild in the forest. Although crude rubber was sent from the Amazon as early as 1827, it was not until Charles Goodyear (*q.v.*) invented the vulcanizing process in 1839 that the annual exportation attained commercial importance. With the remarkable increase in the demand for rubber, prices rose, and gatherers in the forests were sent further afield.

In 1910, however, the increasing competition of low-cost plantation rubber from Malaya and Sumatra brought a disastrous decline of the prices. The whole system of rubber gatherers and traders collapsed, and many families were left stranded in remote places. Many towns were abandoned to the forest.

In 1927 the Ford Motor company established a Brazilian subsidiary to experiment with plantation rubber. Two plantations of 2,500,000 ac. and 600,000 ac., respectively, were established on the Tapajós river. The experiment was not successful because of the scarcity of workers. After World War II the plantations were given to the Brazilian government, which undertook their operation. The original Fordlandia plantation has been abandoned, but at Belterra, where growing conditions are more favourable, some 2,500,000 trees were growing in 1957. Only one out of three was of bearing age.

Trading Spheres.— The vast network of rivers is organized under the control of a hierarchy of traders. Since travel away from the rivers is virtually impossible, the people scattered in small communities along the river banks are dependent for their connections with the outside world on the launch of the trader to whom they are in debt. The largest trading companies are at Belém and Manaus; many smaller traders are controlled by the big companies, each of which occupies a strategic point at a river junction and controls all upstream communications. From many small villages comes a considerable movement of goods downstream, including such products as Brazil nuts, rotenone, cabinet woods, skins and substantial quantities of rubber. In return the traders supply foodstuffs, tools and firearms. The trader acts as purchasing agent for the special needs of his people; through the traders new medicines and drugs, new tools and machines, and even new ideas trickle into the vast region.

Air lines, radio and telegraphy offer connections between the larger towns along the main stream and the world outside. Almost all the towns have small electric light systems, and some are supplied with water from wells. Three railways were in operation in 1957: the Madeira-Mamoré railway, which runs for 226 mi. around the falls of the Madeira (opened in 1912, it never actually was completed to the Bolivian town of Riberalta on the Beni); the railway from Belém to Bragança; and the 126-mi. Amapá railroad completed in 1956 from a new river port near Macapa to the Serra do Navio manganese mine, one of the world's largest.

Exploration.— The unparalleled richness and diversity of the Amazon's fauna and flora and the scantiness of the human population in its unmapped vastness have attracted a steady succession of scientists and explorers. Outstanding among them have been the great naturalists such as C. M. de La Condamine, Alexander Humboldt, Karl von Martius, Robert Schomburgk, Prince Adalbert of Prussia, A. R. Wallace, H. W. Bates, Richard Spruce and Louis Agassiz, all of whom contributed importantly to the scientific knowledge of the area. The expeditions of Lieut. W. L. Herndon of the U.S. army (1851–52) and Lieutenants Henry Lister Maw (1827) and William Smyth (1835) of the British Royal Navy were also important milestones in Amazonian exploration.

Among the later and better-equipped expeditions the one of Theodore Roosevelt and Col. Cândido Rondón, which explored the Amazon, Tapajós and Madeira and their tributaries, was out-

standing. It was initiated on the retirement of Roosevelt from the presidency of the United States in the autumn of 1913 and terminated in Belém in May 1914. The Rice expedition, sponsored by the Harvard Institute of Geographical Exploration, carried on diverse scientific activities from 1910 to 1924. Expeditions have also been sponsored by the American Geographical Society and various United Nations organizations. Brazilian scientists have increasingly concerned themselves with the Amazon region. This is especially true of scientists associated with the Instituto Agronômico do Norte and the Museu Goeldi de História Natural e Etnografia, both located in Belém, the Conselho Nacional de Geografia, and the Instituto Nacional de Pesquisas da Amazônia, established in 1954, in Manaus.

Population. — The dense Indian population reported by Orellana along the river's banks suffered an early and catastrophic decline. Large-scale immigration, chiefly from the drought-stricken northeast (Ceará) area, was especially associated with the rubber bonanza period between 1850 and 1910, but it has continued sporadically to the present. The Amazon *caboclo* population has a large Indian component and the Indian contributed more to the culture of the Amazon region than to any other part of Brazil. Until well into the 19th century the *lingua geral*, a modified form of the Tupi-Guarani tongue, was the most spoken language of the area.

The Amazon basin is one of the great demographic vacuums of the world. The Brazilian government estimated the population of the six federal units making up the Brazilian Amazon to be 2,321,000 in 1960 (1,844,655 by the 1950 census) of which about 320,000 lived in Belém and another 170,000 in Manaus and vicinity. The population of that part of Amazonia falling within Bolivia, Peru, Ecuador, Colombia and Venezuela probably did not exceed 100,000, with 52,000 of these in Iquitos, capital of the Peruvian oriente. The relative emptiness of the Amazon has intrigued people for many years. That the region is unbearably hot is a myth. Temperatures of 100° F. are unknown and temperatures below 60° F. are rare. The humidity, especially near the river, is monotonously high, but this is compensated for on the lower river by a persistent easterly breeze. The increasing effectiveness of malaria control, improved diets and sanitation measures and increased ease in transportation are all making the Amazonian region more attractive for human settlement. Political indifference contributed its share to the cultural and economic stagnation of the basin, which is ruled by six governments. Since World War II, Brazil, Peru and Bolivia have all initiated schemes for the development of the Amazon through programs of public works and agricultural research.

Perhaps the most important lesson learned from the Ford plantation experiment was that workers could live in the Amazon, do hard work, and yet thrive and maintain good health. What is needed is money to provide medical and health services, proper housing and clothing, and the technical skill to provide a properly balanced diet. Yet the region remains empty, and life for the inhabitants of the scattered small villages is not easy. The answer, in part, is that the soils outside the flooded areas are among the poorest in the world; they are heavily leached and contain little humus. Trees grow well enough, but shallow-rooted crops and grasses do not thrive. Most of the agriculture of the region is carried out on soils that are not flooded, for the use of the flood plain would require vast and expensive flood control works. Government-subsidized agricultural colonies have been most successful where they have had access to markets for their produce, as adjacent to the Lima-Pucallpa highway and in the neighbourhood of the Amazonian metropolis of Belém. Japanese colonists since World War II have succeeded in growing jute and black pepper, in both of which Brazil has become self-sufficient. This success encourages the belief that other specialty crops might be found that are similarly adaptable to Amazonian conditions. But the problems of soil fertility on the upland surfaces remain unsolved, as witness the Zona Bragantina along the Belém-Bragança railroad, opened up in 1900 to agricultural settlement and 30 years later largely abandoned to second-growth forest (*capoeira*) because of the deterioration of the soils under permanent tillage. The *várzea*

lands and the foot slopes of the Andes are the most promising for agricultural development. The discovery of small quantities of oil at Ganzo Azul, on the Ucayali near Pucallpa, and at Nova Linda near the mouth of the Madeira river has given new hope to the valley. The large-scale colonization of the leached and poorly drained terra firma surface, however, which comprises 95% of the valley, seems unlikely in the foreseeable future.

(O. E. W.; P. E. J.; Js. J. P.)

AMAZONAS, the extreme northwestern and largest state of Brazil, bounded north by Colombia, Venezuela and the territory of Rio Branco (*q.v.*), east by the state of Pará, south by the state of Mato Grosso, and the territories of Acre and Rondônia (formerly Guaporé), and west by Peru and Colombia. The creation of the territories of Rio Branco and Rondônia in Sept. 1943 reduced the size of the state to 612,537 sq.mi.; pop. (1960 est.) 579,000. Approximately two-thirds of the inhabitants are Indians who are subject only in small part to government control. In the humid tropics, the state occupies an immense plain, densely wooded and traversed by innumerable rivers, whose flood plains are subject to extensive annual inundations.

The principal commercial products are rubber, cacao, jute and nuts; cattle are raised on the grassy plains of the north, west and southwest; curing fish and collecting turtle eggs for their oil give occupation to many people on the rivers. Maize, cassava (manioc), rice and various fruits are produced for domestic needs.

The capital, Manaus, is the only city and port of general commercial importance in the state; it is situated on the Rio Negro, 10 mi. above its junction with the Amazon, about 1,000 mi. from the sea. Manaus became a centre of population during the rubber boom which ended in 1910, and maintained its population in spite of the collapse of the industry. In 1956 the population was estimated to be 164,799 (*município*).

Transportation depends largely upon the Amazon river and its tributaries, the Madeira, the Purús, the Jutai, the Juruá, the Rio Negro and others, a total of about 7,500 mi. of navigable waterways. There is also a local air service.

Up to 1755 all the Portuguese territory on the Amazon formed part of the *capitania* of Pará. The upper districts were then organized into a separate *capitania*, called S. José do Rio Negro, to facilitate administration. When Brazil became independent in 1822, Rio Negro was overlooked in the reorganization into provinces, and reverted, notwithstanding the protests and an attempted revolution (1832) of the people, to a state of dependence upon Pará. In 1850 autonomy was voted by the general assembly at Rio de Janeiro, and on Jan. 1, 1852, the province of Amazonas was formally installed. In 1889 it became a federal state in the Brazilian republic. A governor is chosen by direct election for five years and is ineligible for immediate re-election. A single-chambered legislature of 24 members elected for three years exists. For purposes of internal administration the state is divided into 25 municipalities.

The increased demand for rubber during World War II revived the wild rubber industry of the Amazon basin, and thousands of rubber workers entered the region by way of Belém and Manaus. See also AMAZON; BRAZIL.

(Js. J. P.)

AMAZONAS, a montaña department of northern Perú (pop. (1958 est.) 122,447; area 15,945 sq.mi.), bounded north by Ecuador, west by Cajamarca, south by La Libertad, southeast by San Martín, and northeast by Loreto. The department is composed of alternate mountain and valley; the mountains of the central cordillera are intersected by the deep valleys of the Marañón and its

tributaries. The *Marañón* forms the boundary between Amazonas and Cajamarca for more than half the west side of the department, and then flows in a northeast direction. It is largely a region of equatorial rain forest with considerable rain, heat and humidity, particularly in the lowlands of the north. The main economic resources are forest products: rubber, quinine, hardwoods, nuts and coca. Agricultural products grown in the valleys include cacao, coffee, sugar, tobacco and cotton. Gold mines and placer gold exist there and rock salt is found at Chiliquin. The population, chiefly Indian and mestizo, is mainly in the south. Chachapoyas (pop. [1958 est.] 8,228), capital of the department, lies at 7,600 ft. above sea level on the Rio Utcubamba, a tributary of the *Marañón*. It is the seat of a bishopric and industrial centre of the department; "Panama" hats are the principal manufacture. Chachapoyas may be reached by air and by motor road from Cajamarca. Transportation is otherwise conducted by river, on canoes or rafts or by trail.

(J. L. TR.)

AMAZONAS, a vast territory, 67,857 sq.mi., forming the southernmost part of Venezuela, adjoins the Brazilian state of Amazonas. It lies partly within the drainage basin of the Orinoco and partly within that of the *Río Negro*, mighty northern tributary of the Amazon. The territory contains a maze of intricate water-courses, one 204-mi. stretch, the Casiquiare, links the Orinoco and the *Río Negro*. The Casiquiare is navigable for good-sized launches except at times of lowest water—January to March. Amazonas includes the western outliers of the Guiana highlands. The area has experienced only two periods of comparative prosperity: (1) in the 18th century when the Spaniards established military posts and (2) in the first decade of the 20th century when rubber prices were booming. The 1961 census showed Amazonas with a population of 12,718.

The capital is Puerto Ayacucho on the Orinoco river.

(L. WE.)

AMAZON STONE or **AMAZONITE**, named from the Amazon river, is an attractive bright green mineral sometimes used in jewelry. It is a variety of microcline feldspar obtained from the Ural mountains, U.S.S.R., and at Pikes peak, Colorado, and on the island of Madagascar.

See MICROCLINE; FELDSPAR.

AMB, the smallest of the frontier states that acceded to Pakistan, apart from the tiny khanate of Phulra (former state) in Hazara district, lies along the west bank of the Indus river some 25 mi. N.W. of Abbottabad, West Pakistan. Apart from Amb, the principal township, it contains only a few villages and its estimated population in 1960 was 4,500. Formerly it also included the feudal upper Tanawal across the Indus, but this was merged with Hazara district soon after the establishment of Pakistan in 1947, and after the merger the state was left with an area of 12–15 sq mi. The residence of the ruler (nawab), formerly at Amb, is at Darband, the administrative headquarters. The village of Ashra is the trading centre for the state and adjoining territories.

The land rises to about 4,500 ft. and the main occupation is agriculture, with wheat, barley and maize as the chief subsistence crops. Many sheep and goats are kept and communication routes are restricted to mule tracks and footpaths. There is a small arms factory at Amb where guns, rifles and ammunition are made by hand.

(K. S. AD.)

AMBALA, a city in Punjab state, India, headquarters of Ambala district and division, is situated in the plain 3 mi. E. of the Ghaggar river and 115 mi. N.N.W. of Delhi (124 mi. by rail). Pop. (1951) 52,685. The city has narrow, tortuous streets along which houses are disposed haphazardly. It has four degree-granting colleges affiliated to the Punjab university. Ambala city commands a prosperous agricultural area and has considerable trade in grains and sugar. Its industries include flour milling, glassmaking and papermaking and the manufacture of scientific instruments. Four miles southeast of the city is Ambala cantonment. Pop. (1961) 105,507. Area 14 sq.mi. The cantonment is well laid out and, apart from its military origin, is a commercial centre. It has two Punjab university degree-granting colleges and the administrative offices of the divisional commissioner. Ambala city and cantonment are on the Grand Trunk road and Northern

railway main line between Delhi and Amritsar. Other railway lines link Ambala northward with Kalka and the hill metre-gauge line to Simla, and eastward with Saharanpur. The cantonment has a military airfield.

AMBALA DISTRICT lies between the Sutlej and Jumna rivers and southwest of the Siwalik hills. Immediately below the hills there is a strip of gently sloping land which is badly eroded by the *chos* or turbulent streams rushing down the Siwaliks. The rest of the district is an alluvial plain gradually sloping away from the Siwaliks. Drainage is provided by the numerous *chos* and by the nonperennial Ghaggar, the district's principal stream. The landscape of Ambala district, dotted with olive-green mango trees and with the Himalayan background beyond the Siwaliks, is impressive. The district has sufficient rainfall and only 10% of the cultivated area is irrigated; 65% of the district's area (1,967 sq.mi.) is cultivated. Wheat, sugar cane, maize, gram and peanuts are the main crops. Agriculture is the main occupation of the population, which was 1,372,193 in 1961.

Chandigarh (*q.v.*), (5,294) the Punjab state capital inaugurated in 1953, is in the district, 27 mi. north of Ambala city. Other centres of local trade in the district are Rupar (14,213), Jagadhri (23,943), Jumnanagar (15,684) and Kalka (14,058).

AMBALA DIVISION comprises the districts of Gurgaon, Hissar, Karnal, Rohtak, Simla (*qq.v.*) and Ambala.

(O. P. B.)

AMBARVALIA, an annual religious procession of the ancient Romans, occurring in May, usually on the 29th, the object of which was to secure the growing crops against harm. The priests probably were the Arval brothers (*q.v.*), who conducted the victims—ox, sheep and pig—in procession with prayer to Ceres around the boundaries of the *ager Romanus*. As the extent of Roman land increased, this could no longer be done, and in the *acta* of the Arval brothers, which date from the reign of Augustus, this procession is not mentioned; but in Virgil's *Georgics* and in Cato's *De re rustica* full details and the text of the prayers used by the Latin farmer in thus "lustrating" his own land are given.

The Christian festival that seems to have taken the place of these ceremonies is Rogation or gang week. The perambulation or beating of bounds is probably a survival of the same type of rite. (See BOUNDS, BEATING THE; ROGATION DAYS.)

See W. W. Fowler, *Roman Festivals* (1899).

AMBASSADOR, the highest rank of diplomatic representative sent by one government to another. At the congress of Vienna, 1815, three classes of diplomatic agents were recognized, and a fourth was added by the congress of Aix-la-Chapelle, 1818: (1) ambassadors, including papal legates and nuncios, who are deemed to represent the person and dignity of the sovereign and are entitled to personal access to the sovereign to whom they are accredited; (2) ministers plenipotentiary and envoys extraordinary, including papal internuncios, who are accredited to the head of the state but do not represent the person and dignity of the head of their own state; (3) ministers resident, who are accredited to the head of the state but rank below the previous class; and (4) *chargés d'affaires*, who are accredited by the foreign minister to the foreign minister and may be appointed *ad hoc* (for a specific purpose) or *ad interim* (temporarily).

It was also agreed that agents of the same class should take precedence according to the date of presentation of their credentials, but in Catholic countries (except in France since the abrogation of the concordat) precedence is usually given to the papal legate.

The senior ambassador is the dean of the diplomatic corps and sees that diplomatic privileges and immunities are observed. These rules ended the undignified rivalries between ambassadors that were common in earlier centuries.

Ambassadors were originally accredited only to states enjoying royal honours. Later they were also sent to republics regarded as of equal rank. The United States, however, did not appoint ambassadors until 1893. In 1914 the great powers—Austria-Hungary, France, Germany, Great Britain, Italy, Japan, Russia and the United States—exchanged ambassadors with each other and with Spain and Turkey. The United States exchanged ambassadors with Argentina, Brazil, Chile and Mexico. Between

1919 and 1939 Belgium, China, Poland and Portugal were raised to ambassadorial status, and after 1945 this process was accelerated, especially among the Latin-American states and the new states in Asia. Some representatives to the UN, NATO and the Organization of American States also rank as ambassadors.

The privilege of an ambassador to see the head of the state to whom he was accredited declined in importance as sovereigns became constitutional monarchs or figurehead presidents; in Britain the sovereign is attended by a minister when receiving an ambassador. Before 1914 Emperor William II and Tsar Nicholas II often received ambassadors; so later did Adolf Hitler. In Washington ambassadors present their credentials to the president and thereafter are occasionally received by him on business, with the secretary of state usually present.

Originally ambassadors were entrusted with large, even plenary powers, but after the coming of the telegraph and the telephone they tended to become spokesmen of their foreign offices. Rarely does an ambassador enjoy extensive discretion; his duty is to obey instructions. On the other hand, his personality and prestige may play an important part in making the views of his government understood, and he can always make suggestions to his government. Probably the chief function of an ambassador in modern times is to report about the country to which he has been sent. For the immunities and privileges of ambassadors, see DIPLOMACY; EXTERRITORIALITY.

See Sir E. Satow, *A Guide to Diplomatic Practice*, 4th ed. by Sir Nevile Bland (1957). (B. E. S.)

AMBASSADORS, CONFERENCE OF. This term has been used to denote the sessions or reunions of ambassadors at a certain centre, generally for the period of the execution of a treaty. The best example is perhaps the Ambassadors' conference which sat at Paris and Vienna during 1815-26. After World War I a similar conference meeting at Paris became one of the organs concerned with the execution of the Versailles treaty. It consisted of the representatives of Great Britain, France, Italy and Japan, with the U.S. ambassador attending in the capacity of a spectator after 1921.

The Ambassadors' conference as such had, of course, no special powers and it could only take unanimous decisions previously agreed upon between the respective governments. Such, for instance, was the case when on March 15, 1923, the conference recognized the Polish-Soviet frontier fixed by the treaty of Riga (March 18, 1921).

The most important function performed by the Ambassadors' conference was undoubtedly in Oct. 1921, when the former emperor Charles for the second time returned to Hungary with the intention of regaining his crown. The little entente (Czechoslovakia, Yugoslavia and Rumania) threatened very strong measures against Hungary. But, largely as a result of the ambassadors' intervention, Charles was deposed and extradited, and a law was passed by the Hungarian parliament which abrogated his sovereign rights (Nov. 4). In 1923 the conference was appealed to by the Polish government to settle the Polish-Lithuanian dispute over Vilna and on March 17 the conference awarded title to Poland.

Its action in 1923, in connection with the Corfu incident (see CORFU), brought the conference into some discredit, and shortly after he became prime minister, Ramsay MacDonald announced that its powers would be limited to the execution of the Versailles treaty. It was dissolved in 1931. Its chairman from its inception to the end was Jules Cambon of France.

AMBATO (ASIENTO DE AMBATO), a city in the highlands of Ecuador, capital of the province of Tungurahua, 70 mi. S. of Quito with which it is connected by rail and by the Inter-American highway. Pop. (1959 est.) 44,300. It is located in an intermont basin at an elevation of about 8,400 ft. near the northeast foot of Mt. Chimborazo. The city is the commercial centre of one of the clusters of people in the highlands, and from it a trail passes over the eastern cordillera and descends to El Oriente. In the vicinity are numerous fruit growers, producing strawberries, peaches, apples, pears, grapes and oranges. Nearby are sugar cane plantations and farms that produce maize, wheat, barley and potatoes. In the city there is a variety of manufactures: tanneries, leather works, can-

neries, flour and textile mills, wineries, a rubber goods plant, and factories making furniture, buttons and other small items. The suburb of Miraflores is a favourite resort centre for the wealthy people of Guayaquil. The city has been frequently damaged by volcanic eruptions and earthquakes; about three-fourths of the buildings in the city were destroyed. (P. E. J.)

AMBEDKAR, BHIMRAO RAMJI (1893-1956), untouchable leader, and law minister of the government of India, 1947-51, was born in April 1893, of an untouchable mahar family of western India. His father was a subedar-major in the Indian army, but the boy was humiliated by his high-caste schoolfellows. After he had graduated from Elphinstone college, Bombay, he was awarded a scholarship by the Gaekwar of Baroda, and studied at universities in the United States, Great Britain and Germany. He was awarded doctorates for his *Evolution of Provincial Finance in British India* (1925) and his *Problem of the Rupee* (1923). He then entered the Baroda state service at the Gaekwar's request, but, again ill-treated by his high-caste colleagues, he turned to legal practice and to teaching and examined in economics and law for the University of Bombay. He soon established his leadership among the untouchables (*q.v.*), founded several journals on their behalf and did much to encourage them to improve their position. In his evidence before the Simon commission (1928-29) he demanded separate electorates for the untouchables. When this was conceded Gandhi began a "fast unto death" in protest. Ambedkar reluctantly yielded to this pressure and in the Poona pact (1932) agreed to a compromise whereby a panel of candidates would be chosen by untouchable voters for each untouchable seat, one member of the panel then being elected by a joint constituency of Hindus and untouchables. Ambedkar always contested Gandhi's claim to speak for the untouchables and expressed his views vigorously in *What Congress and Gandhi Have Done to the Untouchables* (1945).

Member for labour in the viceroy's executive council from 1942, Ambedkar became law minister in 1947. He took a leading part in the framing of the Indian constitution and skillfully steered it through the assembly. He resigned in 1951 disappointed at his lack of influence in the government. In Oct. 1956, finally despairing of the elimination of untouchability from Hinduism, he became a Buddhist, together with about 200,000 fellow untouchables, at a ceremony at Nagpur. He died in New Delhi on Dec. 6, 1956.

See Dhananjay Keer, *Dr. Ambedkar: Life and Mission* (1954). (K. E. A. B.)

AMBER, a deserted Indian city 5 mi. N.N.E. of Jaipur, ancient capital of a state in Rajasthan, was reputedly founded by the Minas, an aboriginal tribe. Its name was known to the Greek geographer Ptolemy in the 2nd century A.D. It was held by the Kachwaha Rajputs from 1037 to 1728, when the modern city of Jaipur supplanted it as the royal residence. Amber is celebrated for its scenery — mountain gorge and lake — and for its architecture. A range of hill fortresses defends the palace of Man Singh I (1600), extended in the mid-17th century by Jai Singh I, and comprising, beside the maharaja's apartments, a fine hypostyle *diwān-i ām* (audience-hall), three temples and the *sukh niwās* (pleasure house) with its central water-channel, all grouped around an imposing courtyard. The *diwān-i ām* shows the influence on the Rajput craftsmen of the early Mogul style; the fine palace entrance has closer affinities with the later Mogul buildings at Lahore, except that tempera painting replaces encaustic tilework. The ceilings are inlaid with coloured and mirror glass. (J. B.-P.)

AMBER. True amber is a fossil resin of extinct coniferous trees that flourished along the Baltic coast in Tertiary (Eocene) times, from 60,000,000 to 70,000,000 years ago. The name came from the Spanish *ambar*, a rendering of the Arabic *anbar*. Succinite, the mineralogists' term for amber, was taken from the Latin name *succinum*, from *soccus* ("gum").

According to Greek myth, amber was the congealed tears of Phaethon's sisters, who were turned to trees while weeping for his death. Since Aurignacian times in the Old Stone Age, or about 9000 B.C., amber has been used not only for ornaments but as a cure for countless illnesses such as asthma, rheumatism and internal disorders. Amulets of amber were worn by Roman women

as a protection against witchcraft. Amber has been found in ancient European lake dwellings, at Stonehenge and in Mycenaean tombs. In the Bronze Age and during Greek and Roman times amber was traded regularly across Europe to the Adriatic and Black seas. The history of its trade and acquisition, from crude and dangerous fishing in the sea in early times to modern mining techniques of digging and dredging, is a fascinating study. Equally interesting is the information obtained from the many hundreds of species of fossil insects and plants found as inclusions in amber (*see* PALAEOBOTANY: *Modes of Preservation*).

Amber occurs as irregular nodules, rods or droplike shapes in all shades of yellow to yellowish-brown. Light-coloured opaque material is known as "bone amber." The turbidity of certain kinds of amber is due to the inclusion of great numbers of minute air bubbles. Deeply coloured translucent to transparent amber is prized as a gem material. Though amber and amberlike resins have been found all over the world, true amber, or succinite, characterized by its yield of from 3% to 8% of succinic acid (*q.v.*), comes only from the shores of the Baltic, and in greatest amount from the glauconite sands or "blue earth" of the Samland peninsula in the Leningrad oblast, Russian Soviet Federated Socialist Republic, U.S.S.R. Other ambers contain little or no succinic acid. Simitite is a deep ruby or garnet-red amber from Sicily; some of it is coloured blue or green. The material found near Mt. Etna contains organic sulfur; it is a little softer than succinite. Rumanite, from Rumania, has a wide colour range of yellow, rose-red and dark smoky-gray. It contains many cracks, giving an iridescent effect, and is highly fluorescent. It gives off hydrogen sulfide when heated and has a slightly higher melting point than succinite. Burmite, a deep red amber from Burma, is a little harder than succinite and takes a brilliant polish.

Ornamental carved objects, beads, rosaries, cigarette holders and pipe mouthpieces, are made from amber. Ambroid, or "pressed amber," is obtained by softening fragments or shavings of amber and pressing it into flat sheets, which may be bored or worked into inexpensive articles. Small pieces of amber are used to make a very hard varnish. Synthetic succinic acid has replaced the succinic acid formerly obtained commercially by the distillation of amber. Bakelite, a common synthetic imitation of amber, may be distinguished by its higher refractive index and specific gravity. Celluloid, another synthetic, gives off an odour of camphor when vigorously rubbed.

X-ray investigations by the German crystallographer Friedrich Rinne demonstrated the amorphous, or noncrystalline, structure of amber. Its hardness is only 2.5 and it can be scratched by a copper penny. Though it is easily fractured it is not brittle, and can be carved, worked or bored easily. Its specific gravity ranges between 1.05 and 1.10. Amber will sink in distilled water and will just float in a saturated salt solution. There is variation of the refractive index according to specimen, but the average values are 1.53 and 1.55. Chemically, amber is a mixture of resins and a bituminous substance, approaching the formula $C_{10}H_{16}O$. Finely powdered amber is soluble in cold sulfuric acid; it completely decomposes in hot nitric acid; and is partially soluble in alcohol, ether, chloroform and turpentine. Between 280° and 290° C. amber will melt, throwing off white fumes of oil of amber and succinic acid, which are aromatic but irritating to the throat. A black residue, the bituminous material, is the main ingredient in what is commercially termed amber varnish. Amber is highly resistant to the flow of electricity (*see* INSULATING MATERIAL [ELECTRICAL]). From the Greek name *electron* for this material, an allusion to the sunshine colours of amber and its property of developing a negative electrical charge by friction, evolved the word "electricity." Amber fluoresces dull grayish-white or olive-green to bright yellowish-green in long-wave ultraviolet light. *See also* RESINS.

AMBERG, a town of Germany, which after partition of the

nation following World War II was located in the *Land of Bavaria*, Federal Republic of Germany. It lies on both banks of the Vils, 66 km. (41 mi.) S.E. of Nürnberg, on the railway line from Nürnberg to Furth im Wald, the border station for Czechoslovakia. Pop. (1959 est.) 41,839. It is a medieval walled town with four town gates, and it was the capital (until 1810) and ducal residence (until 1621) of the Upper Palatinate. It is first mentioned in records in 1034. The presence of a mint was recorded from 1274 to the end of the 18th century, and of ore mining from 1326. In the 14th, 15th and 16th centuries it was a court town, with considerable trade (in iron and tinplate) and industry, with many trading and shipping privileges. It was considered to be one of the strongest fortified towns in medieval Germany. Frederick V (*q.v.*) was born in Amberg and lived in the ducal castle for several years with his wife, Elizabeth Stewart. In 1796 the Austrians under Archduke Charles decisively defeated the French under Marshal Jean Baptiste Jourdan there; the battle is recorded on the Arc de Triomphe in Paris. The Gothic town hall is of the 15th century and the ducal castle is now the administrative centre of the rural district. The Jesuits transformed St. George's church from Gothic into baroque in the 18th century; St. Martin's church (begun in 1420) contains pictures by Caspar Crayer and has a tower 300 ft. high; the convent church of the former Salesian sisters is a rococo building; and the former church of the Pauline order is now the Evangelical-Lutheran parish church. The Mariahilfberg (393 ft. high) has been a place of pilgrimage since 1634. The state archives for the whole of the Upper Palatinate as well as the municipal archives are held there, and there is a provincial library, with beautiful ceiling paintings and furniture, founded in 1730. Amberg is a flourishing industrial and commercial centre, with large industries, iron-ore mining, blast furnaces and a foundry; machines are made and there are glass-grinding works, an enamel factory, cold storage plants, breweries, and a brickworks. The surroundings are rural, with cereal crops and potatoes, forestry and pisciculture. In the district there are lignite deposits and open-cast mines of kaolin, with summer skiing facilities on kaolin. Christoph Amberger, the painter and engraver, was born there about 1500 (there is a wooden bust by him in the National gallery, London, Eng.). Martin Merz, the great artillery expert of his time (d. 1501), is buried in Amberg. (R. RE.)

AMBERGRIS is a concretion (whether normal or pathological is still debated) formed in the intestinal tract of the sperm whale. It is believed by some to have its origin in an intestinal irritation caused by the indigestible horny portions of the squid and cuttlefish on which the whale feeds. Fresh ambergris is soft in consistency, black in colour, and has a disagreeable odour. Exposed to sun, air and sea water, the material hardens, its colour fades to a light gray, and it develops a subtle and pleasing fragrance.

Ambergris has been cast up on the shores of China, Japan, India, Africa, Ireland, the Americas and the islands of the tropical seas. The Bahamas have been a particularly rich collecting ground. In addition to this salvage supply from the sea, important amounts have rewarded the labours of the whale hunters. Pieces of ambergris rarely weigh more than a few ounces, but finds weighing up to 100 lb. have been reported.

Known from the days of antiquity, ambergris was long prized in the east as a perfume and a drug. In medieval Europe it was recommended for its fragrance and restorative powers. Its modern usage in the east is chiefly to spice foods and wines, while in the west it is used in the manufacture of perfumes.

The chemical structure of ambergris has not been precisely determined. It is known to contain alkaloids, acids and a fatty substance, ambrein. Ambergris commonly is used in the form of a tincture. It is ground in a mortar and placed in dilute solution with cold alcohol. The tincture is stored for about six months and then filtered. Introduced into fine perfumes, ambergris adds to the scent of essential flower oils its own suave and long-lasting bouquet. *See* PERFUMES; *Animal Perfumes*; SPERM WHALE. (E. L. Y.)

AMBIDEXTERITY, the ability to use both the right and the left hand with equal ease. *See* HANDEDNESS.

AMBLESIDE, a parish and town of Westmorland, Eng.,

nearly a mile north of Waterhead at the head of Lake Windermere and in the centre of the Lake district (*q.v.*) national park. Pop. (1951) 2,392. It is beautifully situated among the bare hills surrounding the richly wooded valley of the Rothay. The hills are Wansfell pike on the east, Loughrigg fell on the west, and Rydal fell and the ridge below Snarker pike (2,096 ft.) to the north. The landing stage of Ambleside is at Waterhead and nearby there are remains of a Roman camp (Borrans Field); in Ambleside is a museum of Roman antiquities. A charter for a market was granted to the town in 1650 and in 1688 James II granted a similar one and power to collect tolls for the poor. During the last weekend of July a rushbearing festival is held. The town was an urban district from 1895 to 1935, when it was combined with Grasmere (*q.v.*) and five parishes to form the Lakes urban district. Catering for tourists is the main industry.

AMBLYGONITE, an important source of lithium, was first discovered in Saxony in 1817, and later at Montebraz, Creuse *département*, France, and at Hebron, Me. It occurs in pegmatite veins with other phosphates and other lithia-bearing minerals, especially spodumene and lepidolite. It is mined commercially near Keystone, S.D., in San Diego county, Calif., at Cáceres, Spain, and at Karibib and Tsumeb, South-West Africa. Canada began exporting small quantities to the U.S. in the 1950s. The mineral is found in cleavable, compact masses, occasionally in indistinct large crystals. It is translucent with a vitreous lustre, usually white, but varies to pale shades of yellow, green, gray or violet. It is readily distinguished from feldspar by its greater specific gravity (3.0) and its chemical properties. It is an aluminum and lithium fluophosphate, $\text{LiAl}(\text{PO}_4)\text{F}$, with part of the lithium replaced by sodium and part of the fluorine by hydroxyl. For uses and methods of extraction see **LITHIUM**.

(Ru. R.; DA. R.)

AMBLYOPIA means dimness of vision of one or of both eyes. It varies in degree and duration and is generally applied to those cases where there is no demonstrable structural defect in the eye itself. Amblyopia may occur suddenly or develop slowly as the result of functional disorders such as hysteria; it also may result from dietary deficiencies and from toxic substances, including various drugs, alcohol, tobacco, wood alcohol, quinine and arsenic. It may also occur as the result of kidney disease in uremic conditions or in the toxemias of pregnancy. The term is also used with reference to colour blindness and night blindness and may result from exposure to brilliant light or to long-continued darkness. It may be transient or permanent and progressive, in which case it may result in blindness. See **BLINDNESS**; **EYE, HUMAN**; **VISION**.

(F. L. A.)

AMBLYPOND, a small hoofed mammal of the extinct order Amblypoda (Pantodonta). Although some of these plant eaters were over eight feet long, most of them were about three to four feet. They lived about 50,000,000 to 70,000,000 years ago. See **UNGULATA**.

AMBO (**OVAMBO**, **AVAMBO**), a southwest African people, many of whom live in southern Angola; the number residing in northern South-West Africa, the former German colony and mandate to South Africa, is estimated at 150,000. Politically they were divided into 13 autonomous units.

There are about 40,000 Ndonga, 17,000 Kwambi, 9,000 Nganjera, 7,000 Kwaluthi, 4,000 Eunda and Nkolonkathi living in South-West Africa. The Kwanyama have about 62,000 in South-West Africa and more in Angola, and the Mbalantu have 10,000 in the former and a small number in the latter. The Esinga, Mbanja, Kashima, Evale and Ehanda are in Angola. The Ndombothola of Angola are sometimes included as a 14th Ambo subgroup.

Formerly these political groups were ruled by kings, who also acted as rain makers, and whose positions were hereditary within exogamous matrilineal lineages. The Ndonga, Kwambi, Nganjera and Kwaluthi are still ruled by hereditary kings, but the others are governed by councils of local headmen under the supervision of European administrators.

Millet and sorghum are raised through shifting hoe agriculture, supplemented by herding, fishing, hunting and gathering. They share the cattle complex with peoples of east Africa. Sculpture

is minimal, but they make pottery and coiled basketry, and smelt and work iron and formerly, copper. Clothing consisted of leather aprons of ox stomach supported by a broad leather belt, with women wearing an additional back covering of ox skin plaited into the hair. The men now wear what European clothes they can afford. Houses are circular with peaked roofs, and are arranged in an intricate circular pattern centred around the meeting place with the hearth for the sacred fire.

The sacred fire cannot be used for cooking, except for the meal of a departing warrior, or for warmth. It is kept alive by the principal wife or daughter of the king or the local chief, and its extinction is an omen of the impending destruction of all his subjects. Local chiefs and headmen light their sacred fires from that of their superiors, and the extinction of the sacred fire is interpreted as warning of impending death for all those subject to a ruler.

(Wt. B.)

AMBO, the reading desk of the early Christian church, was originally small and movable but was afterward made of large proportions and fixed in one place.

By the 6th century the ambo was established as an important and stationary piece of great decorative value. In the Byzantine and early Romanesque periods it was an essential part of church furniture. From the 12th century, and earlier than that outside Italy, the ambo was gradually superseded by the pulpit and lectern. Even in Italy it passed out of liturgical use, except in the Ambrosian rite in Milan.

The position of the ambo was not absolutely uniform; sometimes it was placed in the central point between the sanctuary and the nave, sometimes in the middle of the church and sometimes at one or both sides of the chancel. The normal single ambo consisted of a raised platform in three levels, reached by steps and protected by railings. Each level was consecrated to a special part of the service. The uppermost level was reserved for the deacon who read the Gospel; for promulgating episcopal edicts; for reciting the names inscribed on diptychs (*q.v.*); for announcing fasts, vigils and feasts; for reading ecclesiastical letters or acts of the martyrs celebrated on that day; for announcing new miracles for popular edification, professions by new converts or recantations by heretics; and for preaching sermons by priests and deacons. The middle level was for the deacon who read the Epistle and the lowest for the subordinate clergy who read other parts of Scripture. Later, a separate ambo was built at each side of the church and the various functions divided between them.

Ambos were usually composed as part of the choir screen. In finer churches they were made of marble and frequently decorated with mosaics and carving. A normal type is represented by those in S. Clemente at Rome which date from at least the beginning of the 12th century. Those of Sta Maria in Ara Coeli, Sta. Maria in Cosmedin and S. Lorenzo, all at Rome of the 12th or 13th centuries, are rich with fine-scaled geometric mosaic known as Cosmati work. Fine examples are found in southern Italy, notably at Ravello and Salerno. There it was the rule to have the ambos supported on spiral columns; in Rome the base was usually solid.

In Russian Orthodox usage ambo usually designated the steps leading to the platform in front of the iconostasis (*q.v.*). In the Greek church the ambo retains its earlier form and is placed at one side of the church. In the Greek Catholic Church, the ambo is a table before the doors of the iconostasis.

AMBOINA (**AMBON**, **AMBOYNA**), an important island in the province of the Moluccas, Indonesia, lies southwest of Ceram Island, from 3° 29' to 3° 48' S. latitude and 127° 54' to 128° 25' E. longitude. It is 32 mi. in length and 11 mi. in width; two oblong peninsulas rise parallel from the sea and are united by a narrow alluvial isthmus not more than a mile long. Pop. (1957 est.) 72,679; area 314 sq mi.

The island is subject to damage from earthquakes, as are the neighbouring isles to the east, the Uliasers. Amboina is a Tertiary (Miocene) formation and is traversed by mountain ranges (highest peaks are Salhatu, 3,360 ft. and Wawani, 3,010 ft.) of fine-grained granite, with serpentine, magnesite, etc. The chalk cliffs around

Amboina bay have stalactite caves. The rivers are small and un-navigable, and there are hot springs and *solfataras* but no active volcanoes. The climate of Amboina is comparatively healthful and not unpleasant, the mean maximum temperature being 84.6° F. and the mean minimum 73.4". The hottest time is in February, the wettest in June and July (the east monsoon with very strong winds), and the average yearly rainfall is more than 135 in.

Vegetation and Animal Life.—The profuse vegetation varies on different sides of the island. Damar and copal resins are collected. Amboina wood, very hard and knotty, and of great value for ornamental woodwork, was obtained from Ceram and exported. The indigenous mammals of Amboina are few, but birds include a fine racquet-tailed kingfisher, *Tanysiptera galatea*, described by A. R. Wallace as "the largest and handsomest" of this family. The island also has a crimson lory, *Eos rubra*, and a brush-tongued parrot of vivid crimson colour, and it is rich in insects, particularly Lepidoptera, and in shells. There are 700 varieties of fish in the Bay of Amboina, under which, at the eastern end, are very fine marine gardens.

The People.—The Ambonese (or Amboinese) are mainly of the Melanesian racial type, with dark skin, curly to frizzy hair, flat nose and thick lips. Beside Amboina, they live on the adjacent Uliaser Islands (Saparua, Haruku and Nusa Laut) and the nearby coast of Ceram. Although there are many Muslims, chiefly in the northern part of Amboina, the dominant group is Christian. In 1935 the autonomous Moluccan Protestant church was organized, at which date it had 180,000 members, mainly in Amboina and surrounding islands. The language is a lingua franca Malay with many Portuguese and Dutch words.

The Economy.—Farming is insignificant. Some rice, maize, coffee and root crops are produced, mainly on shifting plots in the forest. The staple food is sago, derived from wild and planted groves, especially on Ceram. Cloves, once important, are still produced, but their export is less than 2% of the world trade. Copra, from the orchards of coconut palms that fringe the coasts, is another export item. Homemade wine, from the aren palm, is a popular drink. Hunting and fishing provide the animal protein in the meagre diet of many. A number of Ambonese, educated in Christian schools, served in the Dutch administration and army, and identified themselves with the colonial power. After independence their social and economic position became precarious.

History.—The clove trade of Amboina led the Portuguese to the island in 1512. They gave the place its name, and founded a settlement in 1521. The Dutch arrived in 1599 and in the next decades succeeded in wresting the monopoly of the spice trade from the Portuguese. In 1615 a British settlement was formed on the other side of the island at Cambello (the Dutch were on the Amboina town site), and the British remained there until 1623, when the Dutch claimed to have discovered British participation in a native revolt in Ceram and in the Bandanese island of Run and massacred the settlers. In 1796 the British captured the island, but it was restored in 1802, retaken in 1810, during the Napoleonic War, and once again restored to the Dutch in 1814.

Japan occupied the former district of Amboina in 1942. When Indonesia gained its independence in Dec. 1949 its structure was agreed to be on the federal principle. Amboina and surrounding islands were one of the constituent autonomous areas. When, a few months later, the central Indonesian government abolished the federation in favour of a unitary, centralized state, the Ambonese seceded and proclaimed an independent South Moluccan republic (April 1950). The movement was suppressed in Ambon by military action of the central government, but guerrilla warfare continued thereafter in Ceram, and a government-in-exile carried on, insisting that the United Nations, which sponsored the independent federated republic of Indonesia, should hear its complaint. In the meantime, a great number of Ambonese found refuge in the Netherlands.

Amboina District and Town.—Amboina was also the name of the former district of the residency of the Moluccas. This is now called Maluku Tengah (central Moluccas), covering an area of 11,438 sq. mi. and including the islands of Amboina; the Uliasers; Buru (capital, Kajeli); Ceram (capital, Kairatu); and the Banda

Isles.

Amboina (or Ambon), the town, and residence of the governor of the province of the Moluccas, is a well-built place with wide streets, often tree-lined, and with many houses and business premises of stone. Ft. Victoria was built in the early 17th century and restored later. A church dating from the earliest settlement, a hospital, barracks (within the fort) and many government buildings were erected there. Most of these were destroyed in World War II.

The town and port is on the eastern side of the bay, a mile short of the narrow entrance to the inner harbour and about 8 mi. from the outer entrance. The depths in the outer bay are great, and anchorages are few but safe. The port, formerly well equipped with wharves and warehouses, served as an auxiliary naval base. It has regular connections with the rest of the archipelago, and is the chief centre for the shipment of Moluccan produce and for the distribution of imports from Europe and America. In 1956 the population was estimated to be 40,477. There are roads sufficient for local needs, a government radio station and a telephone system. G. E. Rumpf (*q.v.*), the naturalist, lived and died in Amboina, and a monument commemorates the fact.

(J. O. M. B.)

AMBOISE, GEORGES D' (1460–1510), French cardinal and chief minister of state under Louis XII, was the son of Pierre d'Amboise, seigneur de Chaumont, chamberlain to Charles VII and Louis XI and ambassador at Rome. Georges received the bishopric of Montauban when only 14 and was appointed an almoner of Louis XI. As a young man under Charles VIII he suffered imprisonment for the cause of the duc d'Orléans (the future Louis XII), but he was elevated to the archbishopric of Narbonne and then to that of Rouen (1493) when Orléans was restored to favour. On the appointment of Orléans as governor of Normandy, Georges became his lieutenant general. When Orléans became king in 1498, Georges was made cardinal and first minister of the crown.

His domestic policy was prudent. He made economies and reduced taxation. By the *ordonnances* of 1499, his most important work, he improved the administration of justice. He was interested, too, in ecclesiastical reform, particularly in that of the monastic orders. Abroad, he sought to increase French power in Italy and supported the campaign begun in 1499 for the conquest of Milan. In 1500 he was named lieutenant general in Italy and charged with the organization of the conquest. On Pope Alexander VI's death (1503) he aspired to the papacy. With French troops, at the gates of Rome he could easily have frightened the conclave into electing him, but he was persuaded to trust to his influence and prestige. The troops were dismissed, and an Italian was elected as Pius III. Again, on the death of Pius within a month, another Italian, Julius II, was chosen. The cardinal d'Amboise received in compensation the title of legate for life in France and in the Comtat Venaissin. He was one of the negotiators of the disastrous treaties of Blois (1504) and of the League of Cambrai against Venice (1508).

The cardinal again accompanied Louis XII into Italy in 1509. On his way home he died at Lyons on May 25, 1510. His body was moved to Rouen, and a magnificent tomb, on which he is represented kneeling in prayer, was erected in the cathedral there.

AMBOISE, a town in the *département* of Indre-et-Loire in central France, is situated on both banks of the Loire 16 mi. by road east of Tours. Pop. (1954) 5,735. Amboise is dominated by the magnificent château built on a rock between the main Loire valley and the side valley of the Amasse. This castle consists of a three-story building with a fine façade, whose top windows are dormer, flanked by two enormous squat towers, the *tour des Minimes* on the Loire side and the *tour Hurtault* on the side of the Amasse. The most important part of the château is the *Logis du Roi*, or King's house, the work of Charles VIII. There is an inclined plane up which horses and carriages may ascend. Straddling the ramparts is the small chapel of St. Hubert. The *hôtel de ville* (early 16th century), with a museum, is on the side of the Loire below the château and nearby is the 15th-century gateway called the *Porte d'Horloge*, which has a carillon. The 12th-century

church of St. Denis to the west contains curious carved capitals to the columns and 16th-century carving representing the burial of Christ. On the Île d'Or in the Loire there is a large camping ground and a public park. Southeast of the town is Le Clos Lucé, formerly called the castle of Cloux, a 15th-century manor where Leonardo da Vinci lived for a short time and died (1519), now a museum. Two miles to the south is the seven-tiered Pagoda of Chanteloup. Amboise is on the main railway line from Paris to Bordeaux. Fishing tackle! shoes, wine presses, caravans, motor bodywork, photographic materials: metalwork, mill wheels, optical instruments, bedding and plastic goods are produced. Wine production is important.

The first mention of the town, then known as Ambatia, was when Alaric, king of the Goths, met Clovis, king of the Franks, between 498 and 506 on the Île St. Jean (now the Île d'Or). In the 11th century Amboise was a lordship under the counts of Anjou and the castle was improved by Fulk Nerra (*q.v.*). United to France in the middle of the 15th century, Amboise became a favourite residence of French kings. The discovery in 1560 of the "conspiracy of Amboise," a plot of the Huguenots to remove Francis II from the influence of the house of Guise, was avenged by the death of many members of that party. In 1563 Amboise gave its name to a royal edict, due to Catherine de Medici and proclaimed by her son, Charles IX, allowing freedom of worship to the Huguenot nobility and gentry. The château was frequently used as a state prison, Abd-el-Kader (*q.v.*) being incarcerated there from 1848 to 1852. In 1872 it was restored by the National assembly to the house of Orléans. Amboise was in German hands for a short time in 1870-71 and in World War II from June 1940 to Aug. 1944.

(R. Go.)

AMBRACIA (modern ARTA in the *nomos* of Arta in north-western Greece), an ancient Corinthian colony in Epirus about 7 mi. inland from the Ambracian gulf (Gulf of Arta), on the navigable Arachthus river in a fertile wooded plain. It was founded between 650 and 625 B.C. by Gorgus, son of the Corinthian tyrant Cypselus. After the expulsion of Periander (*q.v.*) its government developed into a strong democracy. Early features were loyalty to Corinth, a consequent aversion from Corcyra and frontier disputes with Amphilochians and Acarnanians. It took a prominent part in the Peloponnesian War until its defeat by the Amphilochians and Acarnanians, aided by the Athenians, at Idomene (426). In 338 B.C. it surrendered to Philip II of Macedonia.

Ambracia subsequently (294 B.C.) became the capital of Pyrrhus, king of Epirus. It ultimately joined the Aetolian league. The city fell to Rome after a stubborn siege in 189 and never recovered. The foundation by Augustus of Nicopolis Actia (*q.v.*), into which the remaining inhabitants were drafted, left the site desolate. In Byzantine times a new settlement took its place under the name of Arta (*q.v.*).

AMBRIDGE, a borough of Beaver county, Pa., U.S., lies on a wide plain overlooking the Ohio river, 17 mi. N.W. of Pittsburgh. (For comparative population figures see table in PENNSYLVANIA: *Population*.)

An important industrial centre, Ambridge is the home of the largest bridge and structural steel plant in the world. Other products manufactured include wrought iron, cold finished steel, seamless pipe, electrical equipment and building materials.

Within the boundaries of Ambridge is the former village of Economy, founded in 1825 by the Harmony society, under its leader, George Rapp. The Rappites migrated to North America from the kingdom of Württemberg, Ger., at the beginning of the 19th century because of religious persecutions. In 1825 the Rappites, who had settled at Harmony, Pa., and New Harmony, Ind. (*q.v.*), established Economy on a 3,000-ac. tract of land extending five miles along the Ohio river. Under Rapp and his successor, R. L. Raker, Economy prospered for about 50 years and then began to decline because of the practice of celibacy and the lack of fresh converts. In 1906 the society was disbanded. Many of the original buildings were still standing after mid-20th century, including the Great House which was taken over by the state of Pennsylvania in 1919 and maintained as a historical museum.

In 1903 the American Bridge company purchased 2,500 ac. of

land from the Harmony society as a site for the construction of a bridge works and a town. In 1905 the town was incorporated as a borough and named after the American Bridge company. It adopted a council-burgess form of government in 1905.

(M. R. Wo.)

AMBROS, AUGUST WILHELM (1816-1876), Austrian musicologist, best-known for his history of music. Of German-Czech parentage, he was born at Vysoké Myto, near Prague, Nov. 17, 1816. He studied law and entered the civil service in 1840. A keen, well-trained musician, he established himself as a brilliant writer on music, and his pamphlet *Die Grenzen der Poesie und der Musik* (1856), answering E. Hanslick's *Von Musikalischen Schönen*, was an important contribution to a heated aesthetic controversy. In 1869 he became professor of music at Prague and in 1872 professor of musical history at the conservatory in Vienna, where he died. June 28, 1876.

His main work is his comprehensively planned *Geschichte der Musik*. He published three volumes (1862-68); two more were compiled from his notes by C. F. Becker and G. Nottebohm (1878; rev. by H. Leichentritt, 1909), and by Otto Kade (1882), who also enlarged and revised vol. iii (1893). W. Langhans produced a continuation up to the 19th century, 2 vol. (1883-86). (H. GA.)

AMBROSE (AMBROSIVS), **SAINT** (340?-397), bishop of Milan, one of the great doctors of the western church, was born in Trèves of a Roman senatorial family about 340. His father, prefect of Gallia Narbonensis, died while Ambrose was still a youth and the family returned to Rome where Ambrose and his brother Satyrus were educated as young nobles toward government careers. The family was Christian, and during Ambrose's teen years his sister Marcellina received the consecration of a virgin at the hands of Pope Liberius and his mother probably began the life of a dedicated Christian widow, two events which were reflected in his later interest in these forms of life (5 of his extant 35 treatises deal with these topics).

Around 365 Ambrose and his brother went to Sirmium to begin their government careers and were appointed advocates to the praetorian court; in 368 they were appointed to the council. In 370 Ambrose was made governor of Aemilia-Liguria with the seat of government at Milan, which was also the imperial city. He soon won popular favour for the honesty and fairness with which he dispensed justice and preserved the peace of the province.

In 374 the Arian bishop of Milan, Auxentius, died and, since the Catholic bishop had already died in exile, a new bishop had to be chosen. Each party was determined to obtain the bishopric, and it devolved on Ambrose to see that peace was maintained. Addressing the crowd gathered in the cathedral, he was interrupted by the acclamation, "Ambrose, bishop!" He tried every subterfuge to escape the office, but when even the emperor approved the choice he yielded. He was only a catechumen at the time but within a week he received baptism and the various orders, culminating in the episcopacy on Dec. 7. He insisted that he would receive the sacraments only at the hands of a Catholic bishop, thus indicating one of the salient features of his life; he was to be a firm and uncompromising foe of the Arians, although the imperial court favoured them.

As bishop of the imperial city he was thrown into close relationship with the court, and he exerted his influence to the utmost to defend the rights of the Catholics against the attacks of the Arians and the resurgence of paganism under Symmachus. At one time he even barricaded himself and the Catholic community in the cathedral to foil an attempt of the court to seize the church for the Arians. Although his staunch Catholicism earned the undying enmity of the dowager empress Justina, his influence was recognized and he was employed by the court on diplomatic missions on several occasions. Ultimately, he won over the young emperor, Valentinian II, to the Catholic side, but Valentinian died before Ambrose could baptize him.

Despite Ambrose's great political influence, especially in the field of church-state relationships, it is chiefly for his theological contributions that he is remembered. He was not a great speculative theologian, having neither the time nor the interest to develop such a theology. However, he took his episcopal duties

seriously and devoted himself assiduously to the instruction of the people committed to his care. For this task he prepared himself to the best of his ability. He began his episcopal career without any foundation in the theological sciences, and so he devoted the first three years to serious study. Because he had had a good classical education he was fluent in Greek and turned to the writings of the Greek theologians for his training. Among these theologians the most noteworthy influences were found in Origen and Basil of Caesarea, though he was familiar with most of the writings of the great Greek writers of the 3rd and 4th centuries. He made frequent use of the material gleaned from these writers in his own sermons and writings, to such an extent that he has justly been credited with introducing the thought of the east into the Latin church. Perhaps his most important theological contribution to the west was the influence he exerted on the thought of Augustine, particularly in the doctrines of original sin and grace.

The repute in which Ambrose was held as an orator led the rhetorician Augustine to attend the services in Milan. The sermons he heard solved some of the difficulties he found in the Scriptures, and it was only a short time until he was received into the church by Ambrose. (See AUGUSTINE, SAINT.)

Ambrose died at Milan on April 4, 397. His feast day is Dec. 7.

Ambrose's writings cover a wide field. In addition to the treatises on virginity and widowhood mentioned above, he left several exegetical treatises. Most of these deal with the Old Testament: the patriarchs (Hexaemeron, De *paradiso*, etc.), the Psalms and a fragmentary commentary on Isaiah. One work on the New Testament, a commentary on Luke's gospel, is extant. He also left ethical treatises (De Tobia, De *Nabuthe*, etc.), an instruction for the clergy of his diocese (De *officiis*) and many important theological works (De *fide*, De *spiritu* sancto, De *mysteriis*, De *sacramentis*, De *paenitentia*). Most of his writings were first given as sermons to his people, and there remain three funeral orations, in addition to his treatises, from which a good idea of his sermon technique can be derived. The Ambrosian corpus is completed by 91 letters and several hymns, although only a few of the latter can be attributed to him with any certainty.

See also Index references under "Ambrose, Saint" in the Index volume.

See, for the only fairly complete study of Ambrose in the English language, F. Homes Dudden, *The Life and Times of St. Ambrose*, 2 vol. (1935). This work contains a brief but good bibliography of other works. (O. T. W.)

AMBROSE (AMVROSY; in the world ANDREI STEPANOVICH ZERTIS-KAMENSKY) (1708-1771), archbishop of Moscow (1768-71), born on April 17, 1708, in Nezhin, was a typical supporter of the Enlightenment in the Russian hierarchy of the 18th century. He roused the charitable organization of the church to fight poverty in Moscow and did valuable work for church restoration there. During a plague in 1771 the people crowded round a miraculous icon of the Virgin which Ambrose then secretly removed to prevent the spread of infection. On Sept. 16 the enraged mob broke into the monastery where he was living and put him to a cruel death. Ambrose translated the Hebrew Psalter and many of the Greek and Latin Fathers.

See Brockhaus-Efron, *Entsiklopedichesky slovar*, vol. 1, p. 621 (1890). (F. v. L.)

AMBROSE (c. 1190), Norman poet and chronicler of the third crusade, a minstrel who accompanied Richard I of England on that expedition. Nothing more is known of him than that he was probably a native of Evreux and was a noncombatant making the pilgrimage to Jerusalem. His account of the crusade is preserved in the *Estoire de la guerre sainte*, a poem of 12,352 lines extant in an Anglo-Norman manuscript; but the *Estoire* is only an adaptation of Ambrose's work. It was, moreover, the original poem, not the *Estoire*, which was used by Richard, a canon of Holy Trinity, London, as the source for his *Itinerarium regis Ricardi*. The *Estoire* has not much literary merit, but its use of Ambrose's poem makes it a valuable historical source for the events of 1190-92, even though it is biased in favour of Richard.

For the text of the *Estoire* see the critical edition by Gaston

Paris (1897). There are English translations by M. J. Hubert and J. L. La Monte, *The Crusade of Richard Lion-Heart* (1941), in verse, with full bibliography; and by E. N. Stone, *Three Old French Chronicles of the Crusades* (1939), in prose. (J. B. R.)

AMBROSE, ISAAC (1604-1663/64), English Nonconformist minister and a leading figure among those ejected under the Act of Uniformity of 1662, was born in May 1604 at Ormskirk, Lancashire. He was educated at Brasenose college, Oxford, and became vicar of Castleton, Derbyshire, in 1627. He attracted the attention of the duke of Bedford and became one of the king's preachers for Lancashire in 1631 and, by the patronage of Lady Margaret Hoghton, vicar of Preston in 1640. Suffering many vicissitudes during the Civil War, he took part in the subsequent establishment of presbyterianism in Lancashire and Yorkshire. After his ejection from Garstang, to which he had moved in 1654, he retired to Preston, where he died in Jan. 1663/64. His piety and evangelizing zeal won general admiration and his writings show a vivid imaginative power reminiscent of Bunyan. His *Looking Unto Jesus* (1658) was often reprinted. He recommended the keeping of a diary as a pathway to the devout life and fragments of his own are included in his complete works (published 1812).

AMBROSIA AND NECTAR, in Greek mythology, sometimes the food, sometimes the drink, of the immortals. Probably the two terms were not originally distinguished; but usually, both in Homer and in later writers, nectar is the drink and ambrosia the food. On the other hand, in Alcman nectar is the food, and in Sappho and Anaxandrides ambrosia the drink. Each is also used in Homer as a fragrant unguent (*Iliad*, xiv, 170; xix, 38). The word ambrosia has generally been derived from the Greek for "not" and "mortal." A. W. Verrall, however, denied that there is any clear example in which the Greek word ambrosios necessarily means "immortal," and explains it as "fragrant," a sense which is always suitable. If so, the word may be derived from the Semitic *ambar* (ambergris), to which eastern nations attributed miraculous properties. W. H. Roscher thought that both nectar and ambrosia were kinds of honey. The name "ambrosia" was also later applied by Dioscorides and Pliny to certain herbs and has been retained in modern botany for a genus of plants from which it has been extended to the group of dicotyledons called Ambrosiaceae, including *Ambrosia* (ragweed), *Xanthium* and *Iva*, all annual herbaceous plants represented in America. *Ambrosia maritima* and some other species occur also in the Mediterranean regions. (T. V. B.)

AMBROSIAN CHANT is the term for the kind of plainsong (*q.v.*) sung in the diocese of Milan and the churches under its influence, which in the middle ages reached as far as Bavaria. It is still used in Milan and by some churches in Lugano and the Swiss canton of Ticino.

It was introduced probably by Auxentius, a Cappadocian, who was bishop of Milan from 355 to 374, and derived from Antioch. According to St. Augustine (*Confessions*, ix, 7) St. Ambrose (*q.v.*), who succeeded Auxentius, made use of the Syrian practice of singing in alternate choirs, but adapted it in a special way. When he and his followers were besieged in their church by the armies of the Arian empress Justina, he raised their spirits by teaching them to sing psalms "in the oriental manner." From his own account (*Hexameron*, iii, 25) it may be deduced that this meant that the whole congregation joined in the singing of strophic hymns and in responding to each verse of the psalm by a refrain taken from the first line. This way of singing soon spread to all the churches in the west. St. Ambrose was long considered to have introduced the chant which bears his name; though this is no longer thought to be so, he is still accepted as the author of some of the Latin metrical hymns known as "Ambrosian hymns."

Adherence to Ambrosian chant and to the use of the Ambrosian liturgy (see LITURGY) by the churches of Milan was often challenged, notably by Charlemagne, who attempted to discourage, and indeed to destroy, all music and ritual not in conformity with the Roman practice. Many of the chants were, however, gradually adapted to, or replaced by, Gregorian melodies. As no manu-

scripts containing Ambrosian chant written earlier than the 12th century are extant, it is impossible to estimate how much of what survives has the character of the chant in its original form. It may be assumed that the *ambitus*, or range, of the Ambrosian melodies is smaller than that of Gregorian chant proper, that the texture is looser, and that a definite preference for the interval of the fourth (as opposed to the Gregorian fifth) is noticeable. There are, however, some melodia, obviously of a later date, consisting of a number of freely recurring melodic phrases, indicated by roman numerals (e.g., I II III IIII V III IIII V III IIII). Such structure and numbering is a feature of Ambrosian chant. These melodies may either represent forerunners of the sequence melodies or later imitations.

BIBLIOGRAPHY.—The main source for the study of Ambrosian chant are three manuscripts of which the Codex Add. 34209 in the British Museum, London, is published in *Paltographie Musicale*, vol. v (facsimile) and vol. vi (transcription). On the basis of these manuscripts Dom G. M. Suñol re-edited the chants for Mass (1935) and Vespers (1939). See also M. Magistretti, *La Liturgia della chiesa milanese nel secolo IV* (1899); Introduction to *Paléographie musicale*, vol. v (1896); "Fonti e Paleografia del canto Ambrosiano," in *Archivio Ambrosiano*, vii (1956). (E. J. Wz.)

AMBROSIASER, a commentary on St. Paul's epistles, "brief in words but weighty in matter," and valuable for the criticism of the Latin text of the New Testament, long attributed to St. Ambrose. Erasmus in 1527 threw doubt on the accuracy of this ascription, and the author is usually spoken of as Ambrosiaster or pseudo-Ambrose. Owing to the fact that Augustine cites some parts of the commentary on Romans as by "Sanctus Hilarius" it has been ascribed by various critics at different times to almost every known Hilary.

See A. Souter, *The Earliest Latin Commentaries on The Epistles of St. Paul* (1927).

AMEBA: see AMOEBA.

AMEGHINO, FLORENTINO (1854–1911), noted Argentine paleontologist, whose contributions of discovery, description and ordering of sequences of fossil mammals are of major importance to the science, was born Sept. 18, 1854, probably in Luján. Although he was a teacher and administrator, his studies of extinct mammals and the development of man in Argentina were his chief interests. Nearly 200 monographs and memoirs are a monument to his productivity as a scientist.

He began his investigations before he was 20 years old and, except for three years' study spent in Europe, devoted his career to Argentina. From 1902 he was director of the museum of natural history in Buenos Aires.

Ameghino's views of the origin of mammals and especially races of man were radical, and precipitated considerable controversy among his contemporaries. One of his contentions was that all mammals of the world as well as man had their beginnings in Argentina (and other parts of South America). Some of these views, however, were put forward in the face of overwhelming contrary evidence. Severe criticism served to intensify his support of these unorthodox ideas that tended to discredit his extremely valuable, purely factual contributions.

He died at La Plata on Aug. 6, 1911, a controversial figure whose studies, in the light of later evidence, are only now being seriously reappraised by the paleontological world.

His complete works are collected in *Obras Completas y Correspondencia Científica de Florentino Ameghino*, 24 vol. (1913–36). (E. C. O.)

AMEN, an old Hebrew word used in worship by Jews and Christians and to a lesser degree by Muslims. The basic meaning of the Semitic root from which it is derived is "firm," "fixed" or "sure," and the related Hebrew verb also means "to be reliable" and "to be trusted." As a religious term *amen* expresses agreement, confirmation or desire. The Greek Old Testament usually translates *amen* as "so be it" (*genoita*); in the English Bible it may be rendered as "verily" or "truly."

1. In its earliest use the *amen* occurs initially, referring back to the words of another speaker with whom there is agreement. It usually introduces an affirmative statement (I Kings i, 36; Jer. xi, 5; xxviii, 6; cf. Rev. vii, 12). Sometimes the *amen* stands

alone and the expected complementary sentence is suppressed and can be inferred only from the context (Deut. xxvii, 12–26; cj. Rev. v, 14). For emphasis, as in solemn oaths, the *amen* may be repeated (Num. v, 22; Ps. xli, 13; Neh. viii, 6). Such double *amens* are particularly common in the Fourth Gospel (25 times), even in cases in which other Gospel parallels have the singular form (compare, for example, John xiii, 38 and Mark xiv, 30).

Jewish tradition indicates that in temple liturgy the response was not a simple *amen* but an extended formula, such as seems to be preserved in Ps. xli, 13; lxxii, 18–19; lxxxix, 52. But the use of *amen* as a response by the people at the close of a doxology or prayer uttered by a priest seems to have been current as early as the time of the Chronicler; who appends an *amen* to extracts quoted from Ps. xcvi and cvi (I Chron. xvi, 36; cf. Neh. viii, 6). The liturgical use of *amen* developed in the synagogue was adopted by the Christians, as was the Jewish practice of enunciating the *amen* with full power of the voice. Justin (c. A.D. 150) indicates that *amen* was used in the liturgy of the Eucharist in his day; and it was later introduced into the baptismal service.

2. The use of initial *amen* ("verily" or "truly"), single or double in form, to introduce solemn statements of Jesus in the Gospels (52 times in the Synoptic Gospels and 25 times in the Fourth Gospel) has no parallel in Jewish practice. Seldom do such *amens* relate to a preceding speech with which they mark agreement. They rather express the certainty and truthfulness of the statement that follows.

3. A final *amen*, added by the speaker who offers thanksgivings or prayers, public or private, to sum up and confirm what he himself had said, developed naturally from the earlier usage in which others responded with the *amen* (see 1, above). Such use is found in the detached doxologies in Ps. lxxii, 18–19; III Macc. vii, 23; and IV Macc. xvii, 24, and final *amens*, with no change in speaker, are common in the New Testament from the epistles onward. The use of *amen* to conclude prayer was common among Jews in ancient times (Tob. viii, 8); and Christians closed every prayer with it; with the growing popularity of hymns the use of the final *amen* has been extended.

As early as the 1st century A.D. Jews used *amen* in response to a good wish; and in the middle ages they added an *amen* to every possible expression of a desire. Prayers were concluded with such expressions as "and let us say *amen*" or "Amen; may this be the will [of God]." In reaction to Christian usage (c. A.D. 400) Jewish leaders placed restrictions on the use of *amen* in their liturgy; but it is still used in synagogue services.

4. Although *amen* is used as an impersonal substantive in II Cor. i, 20 and the Hebrew text of Isa. lxxvi, 16, the personal use of "the Amen" as a designation of the Christ in Rev. iii, 14 is unique. It is interpreted by the words "the faithful and true witness," added immediately in apposition, which guarantee the certain truth of the revelation given by him.

Although *amen* is but little used among Muslims it is universally employed among them after every recital of the first sura.

AMENDMENT, a change of some document or written or oral statement, by substitution, omission or addition, or by a combination of these methods of change. The change or proposed change may intend improvement or correction by the one proposing the amendment, but improvement or correction are not essential elements.

The word "amendment" is used in many transactions, such as the amendment of federal and state constitutions and statutes, and of municipal ordinances; of bills in the course of their passage by congress or state legislatures; of indictments in criminal cases; of pleadings and records in civil and criminal proceedings and in briefs filed in such cases (see PRACTICE AND PROCEDURE); of trusts, of the charters of private corporations and of numerous other papers representing private transactions; and of oral motions that may be made in meetings of public bodies and private

organizations (see RULES OF ORDER).

It is difficult to generalize about the function of amendments to governmental constitutions or charters. In the 17th century John Locke drafted his "Fundamental Constitutions" intended to "remain the sacred and unalterable form and rule of government of Carolina forever." In the 18th century, this attitude toward immutability was abandoned and the United States constitution of 1789 provided for its own amendment. (See UNITED STATES [OF AMERICA]: Administration and *Social Conditions*.) However, the difficulty of amendment, with other reasons, led to reliance on judicial review (*q.v.*) as the primary means of adjusting the U.S. constitution to new developments. Among democratic nations, no other constitution is so difficult to alter by formal amendment as that of the United States.

Beginning in the 19th century, constitutions provided for somewhat easier amendment procedures. Among U.S. state constitutions, amendment is often so easy as to give the total result the likeness of a statutory code. (See also LEGISLATION; and for motions to amend, RULES OF ORDER.)

Many legislative enactments take the form of amendments to existing law. Thus, in England, for example, the 1949 provision reducing the powers of the house of lords was titled "An Act to amend the Parliament Act of 1911." In the United States: among many examples, Trade Agreements Extension acts are regularly enacted by congress to amend the Tariff act of 1930.

Legislative rules governing amendments vary. Most require that amendments be "germane" or pertinent to the subject of a bill, but this may raise difficult questions of interpretation. An amendment may sometimes be a "substitute motion" introduced in place of pending business, which, if passed, would kill the original measure by supplanting it. Another form of amendment is the "rider"—a provision tacked onto a bill—which its sponsor hopes to get through more easily by including it in other legislation. Riders are also aimed at making the original bill so unattractive as to defeat it. (W. F. D.: C. E. V.)

AMENDOLA, GIOVANNI (1882–1926), Italian journalist who became one of the foremost opponents of fascism, was born in Rome on April 15, 1882. As a young man he contributed articles on philosophical and literary subjects to various reviews and also published several books. He was for a time a lecturer in philosophy at the University of Pisa. Turning to political journalism, he was successively Rome correspondent of the *Resto di Carlino* and of the *Corriere della Sera*. He campaigned for Italy's entry into World War I, in which he fought as a volunteer. After the war he devoted himself entirely to politics as a Democratic Liberal and favoured a policy of *rapprochement* with the Slavs. First elected to parliament in 1919, he was in 1922 minister for the colonies in Luigi Facta's cabinet. After Mussolini's advent to power he became a leader of the opposition and attacked the new regime through the columns of his newspaper *Il Mondo*. After the murder of G. Matteotti he was one of the deputies who withdrew from the chamber in the "Aventine secession" (see ITALY: *History*). In spite of threats against his life during the election campaign of 1924, he declared the fascist electoral law to be unconstitutional. He died at Cannes, France, on April 6, 1926, as a result of injuries received when a gang of fascists attacked him in the Italian spa of Riontecatini.

See G. Carocci, *Giovanni Amendola* (1956); F. Rizzo, *Giovanni Amendola e la crisi della democrazia* (1956).

AMENEMHET (AMUN-EM-WET; Gr. AMMENEMES), the name of four pharaohs of the 12th dynasty of Egypt and several of the 13th. The first three were the most notable.

AMENEMHET I (reigned c. 1991–1962 B.C.), the first pharaoh of the 12th dynasty, is perhaps to be identified with the vizier Amenemhet who held office under the last 11th-dynasty king, Mentuhotep S'ankh-ka-Ra; if so he must have usurped the throne. To him was due the recovery of administrative efficiency and economic prosperity after a long period of civil war, and it was probably he who moved the capital from Thebes to Al Fayyum (oasis), where large irrigation schemes were inaugurated. He secured the northern frontier of Egypt against Asiatic incursions and extended the southern as far as Korusko. A collection of maxims

on wise government, purporting to be addressed by the king to his heir Sensusret I, hints in the preamble at an attempt on his life which may have been successful. He was buried in the north pyramid at Lisht.

AMENEMHET II (NUB-KAU-RA), grandson of Amenemhet I, reigned from c. 1929 to 1895 B.C. Under his administration agriculture was fostered and the Red sea trade with Punt (probably the Somali coast) reopened. He was buried in the "white pyramid" at Dahshur. In the smaller nearby pyramids of his princesses were found some of the finest examples of Middle Kingdom jewelry.

AMENEMHET III reigned from c. 1842 to 1797 B.C. To his long and prosperous reign are attributed large-scale works of drainage and irrigation in Al Fayyum (planned and begun by his predecessors) and the great building known to the Greeks as the Labyrinth, which was probably his mortuary temple. Amenemhet III built two pyramids, one at Dahshur which was abandoned in favour of a larger at Hawara, near the Labyrinth. See EGYPT: *History*.

(M. S. DR.)

AMENHOTEP (AMUN-HOTPE, "Amun is pleased"; Gr., AMENOPHIS or AMENOPHTHIS), the name of four pharaohs of the 18th dynasty and of numerous private persons in ancient Egypt.

AMENHOTEP I (DJESER-KA-RA), was the son of Ahmose I, the Liberator. The length ascribed by Manetho to his reign, namely 20 years and 7 months, is probably correct; it is dated to c. 1546–1526 B.C. by a recorded rising of the star Sothis in his 9th year. He extended Egyptian rule over the Libyan oases and southward beyond the second cataract of the Nile and appointed a viceroy over Nubia. Much of his reign was spent in reorganizing the administration of Egypt and in building temples; he was later worshipped as patron of the Theban metropolis.

AMENHOTEP II (AA-KHEPERU-RA), the son of Thutmose III and Queen Meryt-Ra Hatshepsut, reigned from c. 1450 to c. 1425 B.C. His upbringing was strenuous; he prided himself on his strength and physical prowess, and his monuments refer repeatedly to feats of horsemanship and chariot driving, rowing and archery and to his personal bravery in battle. Succeeding to the throne as a youth he carried on his father's policy of ruthless aggression in Asia and made Napata the boundary of his Nubian empire. Remains of his mortuary temple have been found in west Thebes; his tomb (no. 35) in the valley of the tombs of the kings is well preserved.

AMENHOTEP III (NEB-MA'ET-RA'), sometimes called "the Magnificent," was the son and successor of Thutmose IV. During his largely peaceful reign, c. 1417–1379 B.C., Egypt was at the height of its prosperity, and skilful diplomacy, as the Amarna tablets show, maintained the pharaoh's prestige at the Babylonian, Assyrian, blitannian and Hittite courts. Amenhotep employed his great wealth in the building and embellishment of temples and palaces throughout the land. Of his funerary temple in west Thebes, probably the largest of its kind, virtually nothing is now left but the huge monolithic statues known as the Colossi of Memnon. South of it was the royal palace, or complex of palaces, covering 80 ac, and the vast pleasure lake which he made for his chief wife, Tiy (who appears to have been influential in affairs of state). On the opposite bank of the Nile he greatly enlarged the temples of Karnak and built a temple at Luxor. His mummy and portraits show that his declining years were marred by ill-health.

AMENHOTEP IV, son of Amenhotep III, is better known as Ikhnaton (*q.v.*).

AMENHOTEP, THE SON OF HAPU (Amenhotep the Wise) was chief architect and adviser to the pharaoh Amenhotep III. He was responsible for erecting the colossi mentioned above and other large public works and was awarded the unique privilege of a mortuary temple next to the king's own. In Ptolemaic times he was worshipped as a god in various temples, his father Hapu being identified with Apis (Hapi). See EGYPT: *History*. (M. S. DR.)

AMENORRHEA, the absence of the menstrual flow, is normal before puberty, during pregnancy and lactation, and after the menopause; otherwise not. After conception the first expected period is usually missed, but sometimes a flow, usually light or

only spotting, is noticed at this time. Occasionally, however, there is a flow after conception that is mistaken for a typical menstrual period. In such cases the termination of the pregnancy is calculated from what is really the second month, and consequently labour sets in a month sooner than expected. See MENSTRUATION.

(G. W. B.)

AMERCEMENT (AMERCIAMENT), in English law, an arbitrary pecuniary penalty, inflicted in former days on an offender by the peers or equals of the party amerced. The word has in modern times become practically a poetical synonym for fine or deprivation. But an amercement differed from a fixed fine, prescribed by statute, by reason of its arbitrary nature; it represented a commutation of a sentence of forfeiture of goods, while a fine was originally an arrangement agreed upon between the judge and the prisoner to avoid imprisonment. Articles 20 to 22 of Magna Carta regulated the assessment of amercements. See MAGNA CARTA; ENGLISH LAW.

AMERICA FIRST COMMITTEE, a noninterventionist foreign policy pressure group organized in the United States in Sept. 1940. It opposed Pres. Franklin D. Roosevelt's policy of extending all aid short of war to the victims of Axis aggression. Its leaders feared such aid would involve the United States unnecessarily and unwisely in World War II. The founder and national director of the America First committee was R. Douglas Stuart, Jr., a Yale university law school student. Gen. Robert E. Wood of Sears, Roebuck and company was national chairman. Other spokesmen included Charles A. Lindbergh (*q.v.*), Burton K. Wheeler, Gerald P. Nye and John T. Flynn. The committee enrolled over 800,000 members. It was accused of getting support from Nazi sympathizers, but its leaders tried to bar such persons from membership.

America First battled against passage of the Lend-Lease act, use of the navy for convoys and repeal of provisions of the Neutral-ity act in 1941. It was defeated in its major campaigns and failed to prevent entry of the U.S. into World War II. But the noninter-ventionist strength it represented discouraged President Roosevelt from moving further and faster to aid Great Britain against Nazi Germany. After the Japanese attack on Pearl Harbor on Dec. 7, 1941, the committee dissolved and urged its members to support the war effort.

See Walter Johnson, *The Battle Against Isolation* (1944); Wayne S. Cole, *America First: the Battle Against Intervention, 1940-41* (1953). (W. S. Co.)

AMERICAN ABORIGINAL LANGUAGES. The term "American aboriginal languages" (or, more commonly, "American Indian languages") is a convenient designation for the languages spoken by the original inhabitants of the new world and their modern descendants. It has no other significance. The American Indian languages do not form a single historically interrelated stock (as do the Indo-European languages), nor are there any structural features (in phonetics, grammar or vocabulary) whereby American Indian languages can be distinguished as a whole from languages spoken elsewhere.

Number and Distribution of Languages.—We have no precise knowledge of the number of American Indian languages spoken in the aboriginal period, *i.e.*, before discovery and Euro-pean contact, nor of the size of the population which spoke these languages. Estimates of new world population, based in large part on reports of 16th- and 17th-century contacts between Indians and Europeans, vary widely. The population has been put as low as 8,400,000 and as high as 50,000,000. J. H. Steward in 1949 suggested 15,500,000, an estimate which appeared to meet general agreement. This population probably spoke more than 2,000 lan-guages; the precise number cannot be determined.

During the aboriginal period (before about A.D. 1500), the American Indian languages covered both continents and the islands of the West Indies. There were, however, considerable differences in the distribution of the languages and language groups, and in the size of the populations which spoke these languages.

In America north of Mexico, where the Indian population was thinly spread, there were a number of language groups. *e.g.*, the Eskimoan, Xlgonian, Athabascan and Siouan, which covered large

territories and included a score or more of closely related idioms. Other language groups, however, were smaller and the areas con-taining them correspondingly more diverse in language. In Cali-fornia, for example, more than 20 distinct language groups were represented. These, according to Edward Sapir, exhibited greater and more numerous linguistic extremes than may be found in all of Europe. America north of Mexico, taken as a whole, had about 300 distinct languages, spoken by a population estimated at about 1,500,000.

Mexico and Central America had a much larger Indian popula-tion—estimated at about 5,000,000—which spoke about the same number of languages, 250 to 300, as were spoken north of Mexico. Some of these languages, *e.g.*, of the Aztecs of central Mexico and the Maya of Yucatan and Guatemala, belonged to large and com-plexly organized empires and probably accounted for most of the native population. Others were far more restricted in area and numbers of speakers. The area of greatest linguistic diversity appears to have been in southern Mexico and the region now occu-pied by the Central American republics.

South America, according to J. Alden Mason (1950), had both the largest aboriginal population of the three regions mentioned and the greatest diversity of languages. Here there were probably 9,000,000 people and in excess of 1,400 languages. The bulk of the population was in the Andean region, where there was also a powerful Indian empire, that of the Incas. Their conquests spread the Incas' Quechuan languages far beyond their original homeland in the southern Peruvian highlands and unquestionably resulted in the extinction or reduction of many other Indian tongues. The area of greatest linguistic diversity in South America was in the tropical lowlands of Venezuela, the Guianas and Brazil. Languages of three South American groups spread northward: the Chibchan (centred in Colombia) to parts of Central America, and the Cariban and Arawakan (both mainly in Brazil) to the West Indies.

Indian Languages Still Spoken at Mid-20th Century.—European conquest and colonization ultimately led to the disap-pearance of many American Indian language groups and to radical changes in the lives of the groups which survived. A number of languages became extinct: in the West Indies the aboriginal lan-guages have almost entirely disappeared, and in America north of Mexico, according to C. F. Voegelin (1941), nearly one-half of the aboriginal languages had become extinct. The situation is some-what different in Central and South America. There, although precise figures are not available, fewer languages had disappeared and a greater number were still spoken, some of them by large populations.

Of the American Indian languages still spoken, many by the mid-1950s had only a bare handful of speakers. In America north of Mexico, more than 50% of the surviving languages had fewer than 1,000 speakers each, and of these? more than 70% had less than 500 speakers each (Voegelin, 1941). In communities as small as these, most people were bilingual, and the younger people, educated in English, often had little more than a superficial com-mand of the native idiom. In short, even though the Indian population north of Mexico was actually increasing (1950 census), most of the aboriginal languages were slowly dying out. Only a few languages were flourishing: Navaho, spoken in New Mexico and Arizona by nearly 80,000 people; Ojibwa, in northern United States and southern Canada, by about 32,000; Cherokee, in Okla-homa and North Carolina, by more than 50,000; and Dakota-Assiniboin, in the northern portions of midwestern United States, by more than 42,000. Even in these groups, however, there was a high proportion of bilingualism and it was unlikely that the native languages would long survive in competition with the obvi-ously more useful languages (English and Spanish) of European origin.

In parts of South and Central America there were still a number of widespread and flourishing language groups. Quechuan was one of these: it was estimated that this group of closely related dialects had several million speakers in Ecuador, Peru and parts of Bolivia and Argentina. One of these still-living languages, the dialect of Cuzco, Peru, was the principal language of the Inca empire, con- quered by Pizarro in 1533. The Indians of Mexico and Central

America also still spoke languages which go back to the time of the Spanish conquest (about A.D. 1500): Nahuatlan (or Aztecoid), a group of languages in central and parts of southern Mexico with about 750,000 speakers; the Mayan languages, spoken in Yucatan, Guatemala and adjacent territories by about 500,000 people; and Otomian of central Mexico with about 300,000 speakers. All three of these were languages of Indian empires before 1500, and both the Maya and Aztec peoples had a system of writing similar in kind to (but not derived from) the early Egyptian writing.

One other persistent Indian language group of South America deserves mention. Tupi-Guarani of eastern Brazil and Paraguay. During the aboriginal period, languages of this group were spoken by a large and widespread population. Tupi of Brazil became, after the conquest, the basis of a lingua geral, the medium of communication for Europeans and Indians throughout the Amazonian region. Guarani similarly became a general language medium for much of Paraguay. Tupi was by the mid-20th century gradually being replaced by Portuguese, but Guarani remained an important second language of modern Paraguay, and was even the vehicle of an extensive folk literature.

Classification of Languages.—Linguists classify languages by grouping them into linguistic stocks or families, each of which contains 2 to 20 or more distinct but related tongues. The relationship between languages belonging to the same stock is historical—these languages are derived from a single protolanguage, real or hypothetical, which was spoken at some time in the past. Thus, French, Spanish, Portuguese, Rumanian and a few other so-called Romance languages belong to one stock because of their common derivation from Latin, a protolanguage of which we have actual documentary record. A similar relationship obtains between English, German, Dutch and the Scandinavian languages, which are derived, however, from a hypothetical language called Proto-Germanic. In this case, as in many others, there is no documentary record of the protolanguage; it is assumed on the basis of the many systematic resemblances in sound feature, grammar and vocabulary that exist in the languages belonging to the stock.

To determine whether or not two or more languages belong to the same stock, it is necessary to compare them in some detail. If such comparison reveals the systematic resemblances mentioned above, then the languages are of the same stock. If it does not—that is, if the languages compared reveal only random similarities or similarities which are clearly the result of words and phrases borrowed by one language from another, then the languages are considered to be unrelated, that is, members of different stocks. Close relationships between languages are easy to uncover; it requires, for example, little skill to discover the many resemblances which connect English and German or Spanish and Portuguese. The remoter relationships are more difficult to discover; it is only the expert who can determine the links which unite such diverse tongues as English, Gaelic, Russian, Greek and many others into the large and widespread Indo-European family of languages.

The application of the comparative method to the American Indian languages, and the resultant classification of these languages, presents many difficult problems. For instance, only two American languages were written, and in these (Aztec and Maya) the written records are too few to be of aid to historical studies. Dependence must be placed alone on relatively modern forms (*i.e.*, after 1500) of the languages compared, the records taken by linguists and others since first contact was made with the American aborigines. Some of these records, and in particular those made before 1850, are wholly or in large part inadequate for comparative studies. They were made for more practical reasons, as aids to missionaries and others who had reason to learn to speak and understand the aboriginal languages. Scientifically accurate recordings came for the most part after 1850 and then only for relatively few languages. There were in the mid-1950s a large number of Indian languages, particularly in Latin America, for which there were no adequate recordings at all, to say nothing of the considerable data required for purposes of classification.

As a result, the task of classifying American aboriginal languages is far from complete. Most is known about the languages north

of Mexico, somewhat less of the languages of Mexico and Central America, and very little about the languages of South America and the West Indies. At mid-20th century the linguistic stocks so far established were numerous but tentative; further research would undoubtedly both reduce their number and clarify many remoter relationships which were then obscure. One fact was clear, however: the languages of the Americas are too diverse to be derived from a single source. They belong rather to a large number of stocks, which differ fundamentally from each other in sound features, grammar and vocabulary.

The precise number of linguistic stocks in the Americas was not yet determined. Conservative estimates, however, enumerated about 40 for North and Central America and between 80 and 100 for South America. In North and Central America, where linguistic studies by the late 1950s were further advanced, the latest work suggested a drastic reduction in the total number of stocks, perhaps to as few as 15 or 20. Many of these hypotheses, which consisted of attempts to link smaller language families into larger ones, were debatable; the more remote relationships which had been suggested were not supported by a great deal of evidence. In South America it seemed quite clear that the number of stocks estimated was too large; this number resulted mainly from the fact that too little was known of the South American languages to permit an adequate classification. (For details of the classification of the American Indian languages, see CENTRAL AND NORTH AMERICAN LANGUAGES; SOUTH AMERICAN LANGUAGES.)

Relations Between American Indian Languages and Languages Outside the Americas.—Although there is little doubt that the American Indians came originally from Asia, there is no clear evidence relating the languages of the Americas to those of Asia or elsewhere in the old world. Several such relationships had been proposed by the late 1950s: (1) between the Eskimo-Aleut languages and the proposed Ural-Altaic stock of Asia; (2) between the Nadene languages of North America and the Sino-Tibetan languages of Asia; (3) between the Hokan languages of North and Central America and the Malayo-Polynesian of Oceania; and (4) between the Chonan languages of southern Argentina and the languages of Australia. None of these hypotheses had been verified, and the evidence for all of them was extremely slender. Far more research was needed, on both the American Indian groups concerned and on the language stocks of Asia and Oceania, before any profitable examination of the proposed relationships could be made.

Linguistic Structures of Native America.—A linguistic structure, as the linguist defines it, is made up of two parts: (1) the phonology of the language, which includes not only its distinctive sounds (phonemes) but also the patterns whereby these combine in speech; and (2) the grammar of the language, the meaningful arrangements whereby its words, phrases and sentences are constructed. Each language has also a lexicon, or stock of morphemes. Morphemes are the basic meaningful units of linguistic form: where many words, and all phrases and sentences may be divided into sequences of two or more meaningful units, morphemes may not. Some morphemes function also as words (for example, in English, "cat," "dog," "horse")—these are called free morphemes. Others function only as parts of words: examples are such prefixes as the in- of "in-active" or suffixes like the -er of "farm-er"; these are bound morphemes.

The American Indian tongues exhibit a wide diversity of structure, one so wide that it is quite impossible to speak of the general presence or absence among them of particular structural features. It is also true that structural features evidenced by American Indian languages are only rarely restricted to them. Most of the structural peculiarities found in one or another American language may be paralleled, more or less precisely, in languages outside the Americas.

Finally, it should be noted that there is nothing "primitive" or "undeveloped" about American Indian linguistic structures. All of these structures, whether of the languages of the culturally advanced Maya, Aztec and Quechua peoples, or of the languages of the less advanced Eskimo, Paiute or Ge-speaking peoples, have a fully developed phonology and grammar, as rigidly perfected and

systematized as those of the languages which, like French, English or Spanish, have become the vehicles of a world civilization.

To give some notion of the character and variety of American Indian linguistic structures, we shall describe and illustrate, in the following paragraphs, a few items of phonology and grammar. The languages chosen for illustration are mainly from America north of Mexico, simply because more is known of these languages than of those in Central and South America.

Phonology.—Like languages everywhere else! those of the American Indian vary greatly in phonology, with respect both to the number and kind of the phonemes employed and to the ways in which these may be combined. Some languages have relatively few phonemes: Greenlandic Eskimo has only 17, and Tonkawa, a nearly extinct language of Texas, 25 (as compared with 46 in most English dialects). In Navaho, however, we find 47 phonemes, and the same number is found in Nootka, a language of Vancouver Island.

Some phonemes, particularly consonants; apparently occur more frequently in American Indian languages than in languages elsewhere. One of these is the glottal stop, a sound (often written ') made by closing momentarily the vocal cords in the larynx. This consonant is rather widespread in the Americas, particularly in western North America, but occurs less frequently in the languages of Europe and Asia. In America, too, we find the so-called glottalized consonants, which are formed by making simultaneous closures in the mouth and in the larynx and releasing the two together. The sounds *t* and *k*, and affricates like the *ch* of English "church," are frequently so modified. In Navaho, for example, a clear distinction is made between ordinary *t*, *k* and *ch*, and *t*, *k* and *ch* with accompanying glottal closure. Navaho also modifies continuants, e.g., sounds like *m*, *n* and *y*, by glottalization. This feature occurs elsewhere in the Americas but appears to be rare in other parts of the world.

Other unusual consonantal features found in American Indian languages include: (1) a voiceless and spirantized (fricative) *l* (written *l̥* and similar to the Welsh *ll*), which contrasts with voiced *l* (as in English "light") and, in some languages, with an *l* that is neither voiced nor spirantized; (2) the distinction, in many languages, between aspirated consonants (followed by a puff of air, as in the *p* and *t* of "put" and "take") and consonants which are not aspirated (these are similar to the *p* and *t* of French *père* and *tu*, respectively); (3) the distinction, found in the Eskimo languages, among others, between a palatal *k* (roughly as in English) and one articulated farther back in the throat (the back-velar *k*); and (4) the occurrence, particularly common among the languages of the North Pacific coast, of many consonant clusters; i.e., sequences of two to as many as five consonants without an intervening vowel.

Vowel systems are often quite simple in the languages of the Americas. Greenlandic Eskimo has only three distinctive vowels: *i*, *u* and *a* (compare the relatively complex scheme of most English dialects, which usually have nine distinctive vowels). Other American Indian languages, however, have more complex vowel systems: Navaho has 8 vowels, Tonkawa 10, and an Otomi dialect of Temoaya, Mex., has 12.

Nasalized vowels (similar to those of French) are found in some languages: of the eight Navaho vowels, four are nasalized. In the Otomi dialect mentioned above, the vowels *i*, *a* and *u* contrast with nasalized *i*, *a* and *u*, but the remaining six vowels are all without nasalization. Taos (a language of New Mexico) has 11 vowel phonemes: *a*, *e*, *i*, *o* and *u*, nasalized *a*, *e*, *i*, *o* and *u* and one vowel, phonetically written *a*, which is unnasalized.

In some American Indian languages, as in English, stress accent plays an important role. This is true, for example, of Taos, Delaware (an eastern Algonkian language) and Tunica (a language of Louisiana). Other languages are characterized by pitch accent (rising and falling tones), better known for their occurrence in Chinese, or by complex accentual systems in which both stress and pitch play a part. Navaho is a pitch language (stress plays no role) where each syllable must be either high or low in pitch relative to others in the same utterance. Thus, *bini* means "his nostril" if both syllables are high in pitch, "his face" if both have the

low tone, and "his waist" if the first is low and the second high.

Grammar.—American Indian languages are sometimes called polysynthetic, to indicate that the words of these languages are in general made up of long series of bound morphemes. An example of polysynthesis is found in Tana (a language of northern California), in the word *yābanaumawildjigummaha'nigi*, "let us, each one (of us), move indeed to the west across (the creek)!" This form contains seven bound morphemes: the stem *yā-* "several people move"; formal suffixes of mode (*-ha'* hortatory) and person (*-nigi* "we"); and the modifying suffixes *-banauma* "everybody," *-wil* "across," *-dji* "to the west" and *-gumma* "indeed."

Polysynthesis is not found in all American Indian languages, although it does exist in a number, notably the languages of the Eskimo-Aleut and Algonkian stocks. Other American Indian languages, like Takelma (of southwestern Oregon) and Yokuts (of California), have less complex word structures (much like those of Latin or modern German), and still others (e.g., Coos of the Oregon coast) have even simpler word structures, comparable to those of modern English. In grammar, as in phonology, there is no simple typological category which encompasses all American Indian languages and sets them off from languages spoken elsewhere.

The paragraphs which follow illustrate some aspects of grammar in a few American Indian languages; these, as the reader will note, are by no means general or exclusive to the Americas.

1. Gender, as illustrated by the masculine, feminine and neuter noun categories of many European languages, is rare in the Americas. It is, however, found in the Chinookan languages of the Oregon coast. An equivalent system, which divides nouns into animate and inanimate categories, is fairly widespread in North America, particularly in the languages of the Algonkian stock. Oneida, an Iroquoian language, distinguishes a kind of gender in the third person pronoun. These pronouns are four in number: neuter (for inanimate things and abstract notions), feminine-zoic (in the singular for adult, female persons or general or indefinite reference to any animal; in the dual and plural for groups composed entirely of females, any group of animals, and for inanimate dual and plural objects which are in motion), masculine (in the singular for a male person or animal; in the dual and plural for any group of persons whether these are all males, of mixed sex or their sex is unknown) and feminine indefinite (used in the singular only for a young female or old woman or in reference to an indefinite person or persons in general).

2. Noun cases, analogous to the nominative, accusative, dative and genitive of modern German, are found in some American Indian languages (notably Yokuts and Wintun of California), but a majority of American languages (at least in the region north of Mexico) are as innocent of case distinctions as modern French or English. Greenlandic Eskimo is exceptional in having a complex system of noun inflection for both case and number.

Singular, dual and plural are distinguished for most nouns, as are two purely syntactic cases, absolutive and relative, and six adverbial cases: locative, ablative, allative, perlativ, instrumental and simulative. Details of this system are too complex for inclusion here. (See *Handbook of American Indian Languages*, part I, p. 1010 ff.)

3. Plurality of the noun is often expressed as precisely as in English or French—and sometimes, as noted above for Eskimo, with greater precision. But there are many Indian languages where the noun has the same form in both singular and plural, just as with some English nouns; e.g., "sheep" and "deer." In Navaho, for example, the word *tsé* may mean "stone" or "stones"; the interpretation is made from the context in which the word appears.

In some American languages, verbs may be inherently singular or plural. This is best illustrated by Navaho verbs having reference to movement of one kind or another. There is, for example, no verb which precisely parallels our verb "to go"; there are, instead, three quite distinct forms: *-yá* "one person goes," *-'ààš* "two persons go" and *-kááh* "several persons go." Transitive verbs are frequently altered to reflect the singularity or plurality of the object. Thus, *-γé* "to kill one" but *-γáⁿ* "to kill many" and *-tsèèd* "to slay, slaughter (a great many)."

4. Verb forms, in many American Indian languages, tend to be

far more complex in structure than words belonging to other form classes. In Navaho, for example, nouns have but one paradigm (declension, in nouns, or conjugation, in verbs), the possessive, whereas verbs are generally conjugated in seven. These conjugations do not emphasize tense, as in many European languages, but centre rather on aspect (indicative of the progress of the action) and mode (indicative of the manner of the action). Of the seven Navaho verb conjugations, only one expresses tense—the future. Four are aspectual: the imperfective, which denotes an action moving toward completion, the perfective, one which has been completed, the progressive, one in progress, and the iterative, one which is repeated over and over again. The remaining two conjugations are mainly modal: the customary, which denotes an action performed by reason of habit or custom, and the optative, expressive of a desire that an action be performed.

Tense distinctions are made, however, in some American Indian languages. In Wishram, a Chinookan dialect, we find six tenses: present, future and four preterit tenses which differ from each other in the remoteness of time from the moment of speaking. The Takelma language, on the other hand, distinguishes only two tenses: aoristic or indefinite, which may refer either to the present or the past, and the future.

5. An interesting feature of verb structure, which is found in a number of Indian languages, is noun incorporation, a technique of including noun stems (or some variant form of the stem) within the verb. Noun incorporation has been observed in the Nahuatl languages of Mexico, Southern Paiute (western United States), Yana, Takelma, the Iroquoian languages (of northeastern United States and southeastern Canada) and Pawnee (of the southern plains region of the United States). We list a few examples from Yana: *k'ut-xai-sindja* "I am thirsty" (*k'ut-* "to want, desire"; *-xai-* incorporated form of *xana* "water"); *k'ut-au-sindja* "I want fire" (*k'ut-* "to want, desire"; *-au-* incorporated form of *aura* "fire"); *bui-djalilaihgradu-isiwandja* "he kicks my calf (of leg)" (*bui-* "to kick"; *djalilaihgradu* "calf of leg"); *haik'u-dal-sindja* "I am sick-handed (have a hurt hand)" (*haik'u-* "to be sick"; *-dal-* incorporated form of *dalla* "hand").

6. Personal pronoun systems exhibit a considerable diversity in the Americas. In Navaho we find a relatively simple system, made up of: *ši*, first person singular; *ni*, second person singular; *bi* and *xó*, third person; and *naxi*, first or second person dual. The two third person forms are differentiated as follows: *bi* has reference to persons psychologically close to the speaker, e.g., his friends, relatives or fellow tribesmen; *xó* to persons psychologically remote, e.g., nonrelatives or strangers. Gender distinctions, as in English "he," "she" and "it," are not made in the Navaho pronoun. Note, too, that there is only one plural form, the dual *naxi* which refers to either the first or the second person and is also used in speaking directly to a second person in very formal discourse. No true plural is expressed in the Navaho pronominal system but *bi*, *xó* and *naxi* may take a prefix *dh-*, which defines a distributive plural: *dà-bi*, *dà-xó* "they, each one of them" and *dà-naxi* "we, you (pl.), each one of us, you."

Oneida possesses a far more complicated scheme. Taking into account only the subject pronouns (expressed by prefixes to the verb), we find the following distinctions in the singular (here given only in translation; the actual Oneida forms are too complicated to describe briefly): first person, second person, third person feminine-zoic gender, third person masculine and third person feminine-indefinite. The dual forms are: we two (someone and I), we two (you and I), you two and dual third persons for the feminine-zoic and masculine genders. Plural forms are similarly organized: we (they and I), we (you plural and I), you plural third persons for the feminine-zoic and masculine. The distinction between dual and plural inclusive (you and I, you plural and I) and dual and plural exclusive (someone and I, they and I) is an interesting and rare one, even in the Americas

7. Demonstrative pronouns (like English "this," "that," "these," "those") also reveal wide variation in American languages. In Kwakiutl (of southern British Columbia) the word "that" of the expression "that house" must be translated by one or another of the following six forms (indicated in translation by a phrase;

the native form is a single word): the (house) visible near me, the (house) invisible near me, the (house) visible near thee, the (house) invisible near thee, the (house) visible near him, the (house) invisible near him. All of these are indifferently singular or plural. In contrast, the Navaho system of demonstratives is relatively simple, although it is still very different from that found in English. Here we find five forms: *dii*, which is roughly the same as English "this" or "these" (no distinction is made for number), *'éi* "that nearby (close to the speaker and visible)," *nàγái* "that (near the one spoken to and visible)," *'íléi* "that (away from both speaker and spoken to but visible)" and *'èi* "that (remote and invisible)."

Structural Survey.—Sapir (1929) divided the American Indian languages north of Mexico (and some spoken in Mexico and Central America) into six major groups, and summarized the major structural characteristics of each group. This characterization, although it does not include the many other languages of Central and South America, nonetheless provides the best general survey of American Indian structural types available. (For a detailed statement of the languages included in the six groups, see CENTRAL AND NORTH AMERICAN LANGUAGES; INDIAN, NORTH AMERICAN: *Language*.) (H. HR.)

1. The Eskimo-Aleut languages are polysynthetic and inflective; use suffixes only, never prefixes, reduplication, inner-stem modification or compounding of independent stems; have a great elaboration of the formal aspect of verb structure, particularly as regards mode and person; and make a fundamental distinction between the transitive and intransitive verb, to which corresponds the nominal case distinction of agentive-genitive and absolutive (or objective).

2. The Algonkian-Wakashan languages, too, are polysynthetic and, especially as regards Algonkian, inflective; make use of suffixes, to a much lesser extent, particularly in Algonkian and Ritwan, of prefixes; have important inner-stem modifications, including reduplication; have a weak development of case; and illustrate to a marked degree the process of building up noun and verb themes by suffixing to stems local, instrumental, adverbial and concretely verbalizing elements.

3. The Nadene languages, probably the most specialized of all, are tone languages and, while presenting a superficially polysynthetic aspect, are built up, fundamentally, of monosyllabic elements of prevalingly nominal significance which have fixed order with reference to each other and combine into morphologically loose words; emphasize voice and aspect rather than tense; make a fundamental distinction between active and static verb forms; make abundant use of postpositions after both nouns and verb forms; and compound nominal stems freely. The radical element of these languages is probably always nominal in force and the verb is typically a derivative of a nominal base, which need not be found as such.

4. The Penutian languages are far less cumbersome in structure than the preceding three but are more tightly knit, presenting many analogies to the Indo-European languages; make use of suffixes of formal rather than concrete significance; show many types of inner-stem change; and possess true nominal cases, for the most part. Chinook seems to have developed a secondary polysynthetic form on the basis of a broken-down form of Penutian; while Tsimshian and Maidu have probably been considerably influenced by contact with Mosan and with Shoshonean and Hokan respectively.

5. The Hokan-Siouan languages are prevalingly agglutinative; tend to use prefixes rather than suffixes for the more formal elements, particularly the pronominal elements of the verb; distinguish active and static verbs; and make free use of compounding of stems and of nominal incorporation.

6. The Aztec-Tanoan languages are moderately polysynthetic; suffix many elements of formal significance; make a sharp formal distinction between noun and verb; make free use of reduplication, compounding of stems and nominal incorporation; and possess many postpositions. Pronominal elements, in some cases nouns, have different forms for subject and object but the subject is not differentiated, as in types 1 and 4, for intransitive and transitive constructions. (E. SA.)

Dictionaries and Texts.—American Indian languages probably have smaller vocabularies than the languages, like English, French and Spanish, which are mediums of expression for world-wide civilizations. But Indian vocabularies are not as small as some reports indicate; most of them, if adequately studied, contain thousands, rather than simply hundreds or scores, of words.

It would be a mistake to regard a small dictionary as evidence of a primitive linguistic structure. The vocabulary of a language is geared to the social and cultural requirements of the people who speak it. When a society is small and its culture relatively simple, the vocabulary is shorter than in the larger societies which possess relatively more complex cultures. American Indian groups which have, since European contact, become culturally more advanced, and which have at the same time retained their languages, have increased the native vocabulary to meet the new needs imposed by cultural change. Linguistic structures, wherever found, appear to be capable of such expansion whenever it may be demanded by an altered cultural milieu.

The truly wide differences in both structure and vocabulary which separate Indian languages from those of modern Europe and America result in considerable difficulties when translation is attempted from languages of one group to those of the other. These difficulties are sometimes interpreted as evidence that Indian languages are somehow less expressive, or even incapable of reproducing the finer nuances of meaning commonly employed in the languages of great civilizations.

But this is only a half-truth, at best. The fact is that translation is as difficult when we go from an Indian language to English (or another European tongue) as when we go in the opposite direction. This point may be illustrated by a very simple example: the English phrase "his house" is translated roughly by either of two Navaho expressions: *bi-kin* or *hà-kin*, the former employs the familiar third person possessive *bi-*, the latter the more formal pronoun *&*. But neither *bi-* nor *hà-* adequately translate "his," because this form implies the gender distinction between "his," "her" and "its," and also denotes a single person. But *bi-* and *hà-*, on the other hand, substitute for all nouns: regardless of gender (which is not expressed in Navaho) and may be used of either a singular or a plural referent.

If we now try to translate *bi-kin* into English, we encounter difficulties of the same order, for *bi-* conveys the notion of a possessor psychologically close to the speaker (the familiar third person) and ignores the distinction of gender and number; no English pronoun conveys precisely this meaning. Moreover, the noun *kin* refers to a special kind of house, one made in the modern manner and not necessarily a dwelling. The form which denotes a dwelling or home (modern or in the aboriginal style) is expressed by quite a different word, and the distinction between the two is not paralleled by any two items of the English vocabulary. The inevitable conclusion is that no language response can be separated from the cultural milieu in which it occurs; and that no two languages, providing that the cultures of the people who speak them differ, are precisely translatable one into the other.

Indian languages have of course no literature, as this term is ordinarily understood. But American Indian groups do possess oral folk literatures! the anonymous creations of many generations. These stories and poems or song texts, told and retold by expert raconteurs and sung in frequent rituals, illustrate an artistry of expression comparable to that found in the older European literature, much of which, like the Norse sagas, was derived from an earlier oral tradition. To give only one example—a Navaho song text, which comes from a ritual designed in part to aid the growing crops, and which in translation retains some of the flavour of the original:

Growing things grow with me,
 Growing things grow with me,
 Growing things grow with me,
 Big corn grows with me,
 From beneath its feet, it grows with me,
 At the ends of its leaves, it grows with me,
 The dew of the plants, it grows with me,
 The corn flowers, they grow with me,
 The corn silk, it grows with me,
 The kernels of the corn, they grow with me,

Beautifully, all grows with me
 Growing things grow with me,
 Growing things grow with me,
 Growing things grow with me

The Study of American Indian Languages.—Most, and probably all, American Indian languages are doomed to extinction; it does not seem likely that these languages will ever attain the status and importance of the modern world languages of European and Asiatic origin. One does not therefore study Indian tongues for their practical usefulness, or, since they are un-written, to gain a better understanding of a great literary tradition. But these languages, like all others, are valuable to the science of language, for they present a variety of linguistic structures not to be found elsewhere. They provide, in fact, a laboratory for linguistic science, and it is safe to say that the science of language and general linguistic theory would not be so far advanced as it is were it not for the existence of this laboratory. To understand human language, it is not enough to know only those which are widely used; we must also have evidence from the languages of the more obscure and exotic societies of the world to complete the picture of the whole.

AMERICAN ACADEMY IN ROME, THE, situated on the Janiculum in Rome, Italy, comprises schools of fine arts and classical studies. Founded in 1894 under the leadership of Charles F. McKim, it is administered by a director and staff in Rome, and a president and board of trustees in New York city. The school of fine arts includes departments of architecture, painting, sculpture, landscape architecture, musical composition and creative writing, and the school of classical studies includes departments of classical studies and art history. Mature students of advanced attainment are chosen, through annual competitions, as fellows, for a term of one or more years. Residence and studio are provided in the academy without charge; and stipends are granted to cover the cost of living and travel. There is no formal instruction, but work and travel in classical lands are prescribed, and an excavation is conducted for the benefit of the students in archaeology. Results of research are published in the *Memoirs, Papers* and *Monographs* of the American Academy in Rome. By giving its selected artists and scholars opportunities for intimate association through study and travel in an atmosphere of art and amid the inspiration of masterpieces, the academy aims to contribute toward the elevation of American art and letters.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE was established by scientists in 1848 to further the work of scientists, to improve the effectiveness of science in the promotion of human welfare, and to increase public understanding of the importance and promise of science in human progress. The association includes 70,000 individual members and has as formal affiliates 247 national and regional scientific societies and 47 state and regional academies of science.

All fields of science are included, and the association is divided into 18 sections; e.g., physics, chemistry, geology and geography, zoology, psychology, engineering, medical sciences, etc. The association publishes the weekly magazine *Science* and a series of symposium volumes. A large annual meeting is held during the week following Christmas. Three divisions (Alaska, the Pacific coast, and the southwestern and Rocky Mountain area) also meet

annually. Various special meetings and conferences are held on special topics. Other activities include work on the improvement of science teaching, the distribution of traveling libraries of science books to elementary and secondary schools, and the administration of awards to encourage research in selected areas and to encourage excellence of science reporting in the public press.

AMERICAN BAR ASSOCIATION: *see* LEGAL PROFESSION.

AMERICAN CIVIL WAR, a conflict lasting four years between the United States federal government and 11 southern states that asserted their right to leave the Union. The total population (free and slave) of the southern states that seceded was slightly less than half the population of the northern states that remained in the Union. At the opening of the conflict the seceding states set up an independent government named the Confederate States of America (*q.v.*). The Civil War began when the guns of the South fired on the Federal Ft. Sumter on April 12, 1861; it ended with the surrender of Gen. *Robert E. Lee* at Appomattox Court House, Va., on April 9, 1865, and of Gen. *Joseph E. Johnston* at Durham Station, N.C., on April 26, 1865. (General *Johnston* had signed an armistice on April 18, but its terms were not acceptable to Gen. *Ulysses S. Grant*.) Approximately 4,000,000 troops took part in the war, which has been described as the first "modern" or "total" war—that is, a war in which the industrial potential of the victor determined the outcome. Total casualties exceeded 617,000 dead (North, 359,000; South, 258,000) and 375,000 wounded (North, 275,000; South, 100,000). The war resulted in the preservation of the Union and brought about important alteration in the C.S. constitution, the abolition of slavery and far-reaching social and economic changes.

For the sake of clarity, the names of Confederate statesmen, soldiers and ships are in italics. The article is organized according to the following outline:

- I. The Outbreak of War
 1. Charleston Harbour, 1860–61
 2. The Call to Arms
 3. The Military Outlook
- II. Military Operations, 1861
 1. The Opening Moves
 2. *McClellan* in Supreme Command
 3. Confederate Plans and Problems
 4. War in the West
- III. Military Operations, 1862
 1. The Federal Offensive in the West
 2. *McClellan's* Peninsular Campaign
 3. The Confederate Offensive in the East
 4. The Confederate Offensive in the West
 5. The Federals Resume the Offensive
- IV. Military Operations, 1863
 1. Chancellorsville

 3. Economics of the War
 4. Foreign Affairs

1. THE OUTBREAK OF WAR

1. Charleston Harbour, 1860–61.—During the last months of Pres. James Buchanan's term a succession of events occurred that brought the contending sections to the verge of armed conflict. (For the earlier history of events leading to the Civil War *see* UNITED STATES (OF AMERICA): *History*. *See* also separate entries on battles and leaders and on major topics such as ARMY; ARTILLERY; CONFEDERATE STATES OF AMERICA; CONSCRIPTION; SMALL ARMS, MILITARY.) Soon after the election of Abraham Lincoln in Nov. 1860, the state of South Carolina called a convention that passed an ordinance of secession (Dec. 20, 1860), and Gov. *Francis Pickens* sent commissioners to Washington to claim possession of the forts in Charleston harbour and all other U.S. property in his

state. Maj. Robert Anderson, commanding the Federal garrison at Charleston secretly transferred his two weak companies from Ft. Moultrie, which was untenable against a land attack, to Ft. Sumter in the mouth of the harbour (Dec. 26). *Pickens* seized the arsenal and other forts and began throwing up batteries against Sumter while his commissioners at Washington demanded the recall of the Federal troops from Charleston. This demand Buchanan refused. He had already (Dec. 3) in his message to congress denied the right of secession, but he asserted that the constitution gave him no right to attempt coercion. He hoped for compromise, and a committee of congress considered various proposals for adjustment. A peace conference, called by Virginia, also met in Washington and suggested amendments to the constitution that would satisfy southern grievances. Lincoln and the leaders of the Republican party refused to accept the adjustments that the southerners demanded. Meantime, Buchanan sent an unarmed commercial steamer, "Star of the West," with supplies and reinforcements to Sumter, but it turned back when fired upon in the harbour on Jan. 9, 1861.

Between Jan. 9 and Feb. 1 six other states (Mississippi, Florida, Alabama, Georgia, Louisiana and Texas) followed South Carolina's example. Without attempting negotiation, their governors seized all the forts and arsenals in their respective states except Ft. Pickens in Pensacola harbour. Delegates from the seceding states met at Montgomery, Ala., organized the Confederate States of America and set up a provisional government with *Jefferson Davis* as president. *Davis'* inauguration took place on Feb. 18. The Confederate government then assumed control of the negotiations about Sumter. Neither Buchanan nor *Davis* was eager to precipitate a crisis. The former's fervent desire apparently was to leave the solution of the whole problem to his successor; *Davis* was chiefly concerned to get his own administration in working order. He sent Gen. P. G. T. *Beauregard*, an engineer officer of distinction, to Charleston to complete the defenses of the harbour. The day after *Beauregard* reached Charleston, Lincoln was inaugurated at Washington, D.C. (March 4, 1861).

A difficult problem confronted the new president. Seven slave states had seceded, but eight still remained in the Union. Any attempt at coercion would throw all these states, except Delaware (which practically counted as a northern state), into the arms of the Confederacy. At this stage neither side wanted war; certainly not the North, where a strong feeling was growing in favour of "letting the erring sisters depart in peace"; the South assumed a defensive role, that of a newborn nation asking only to be left alone. Lincoln's inaugural speech was really addressed to the slave states still in the Union; to the Confederate states it sounded like a declaration of war. But they sought to avoid the responsibility of striking the first blow.

The South hoped to force Lincoln's hand over Sumter. Anderson's position there was daily growing more difficult. He would have gladly evacuated the fort to avert a civil war. But his duty as a soldier compelled him to sit with folded hands while the enemy were completing their preparations. His provisions would be exhausted by mid-April. The Confederate batteries had made such progress that he doubted whether it was still possible to relieve the fort unless possession of the whole harbour were secured, and for that purpose he estimated that 20,000 men would be required. The whole U.S. army numbered only about 17,000 men, most of whom were scattered in small posts on the Indian frontier, whence they could not be hastily withdrawn.

Only on March 5 did Lincoln learn that Anderson might be starved into surrender. Gen. Winfield Scott, his chief military adviser, urged evacuation on military grounds. But Lincoln had pledged himself "to hold, occupy and possess the property and places belonging to the Government." It would be fatal to the prestige of his administration to start by going back on his word. Evacuation might seem a virtual recognition of the Confederacy. Against the advice of a majority of his cabinet he determined to send a relief expedition, carrying only food supplies, to Sumter. If the Federal flag should be fired on, that would constitute a *casus belli*, and the responsibility for beginning the war would rest on the Confederates.

Although he did not inform Anderson, Lincoln gave *Pickens* precise information of his intention. He must have foreseen the actual event. By war the Union could be restored and the North, which was not agreed on policy, could be united. *Pickens* promptly informed the Montgomery government, and *Davis* ordered *Beauregard* to reduce Sumter. On Anderson's refusal to evacuate, the batteries opened fire at 4.30 A.M. on April 12. The next afternoon Anderson agreed to surrender and evacuated the fort at noon on the 14th. The Confederate leaders' ready acceptance of Lincoln's challenge may have been due to a fear that without a collision the ardour of the southern people, many of whom had opposed secession, might abate. Neither Lincoln nor *Davis* could have foreseen the dimensions the war would assume.

2. The Call to Arms.—The fall of Sumter "fired the Northern heart." Democrats united with Republicans in denouncing this crowning insult to the national flag. Lincoln called for 75,000 militia for three months' service (April 15)—not that he underrated his task, but he intended to start by treating secession as an act of insurrection. To suppress insurrection was a constitutional function of the militia, but this force could be held only for three months' service outside its own state. The free states enthusiastically responded to the call, but the governors of the seven slave states still in the Union, except Gov. Thomas H. Hicks of Maryland, refused to raise their contingents.

The Virginia convention passed an ordinance of secession on April 17. Gov. *John Letcher* immediately seized the Harpers Ferry arsenal and Norfolk navy yard, and without waiting for popular confirmation of the convention's action entered into a military alliance with the Confederacy. North Carolina, Arkansas and Tennessee took the same course. If they had to choose between fighting for and against the Confederacy, they unhesitatingly threw in their lot with their sister states of the South. But western Virginia beyond the Allegheny mountains, which had its own grievances against the eastern section of the state and belonged geographically to the Ohio valley, repudiated the ordinance of secession and prepared to join the North. In Maryland there was a strong secessionist minority, chiefly concentrated in Baltimore, where a riot occurred (April 19) while the 6th Massachusetts regiment was passing through to Washington. For three weeks Washington was cut off from direct railway communication with the North. But troops were brought around by water to Annapolis, and thence to the capital. No help came to Baltimore from Virginia, and Governor Hicks outmaneuvered the local leaders of insurrection by pretending to yield to their demands until Gen. B. F. Butler with a small force made a sudden dash to the city and occupied it unopposed (May 13).

In Kentucky the parties were fairly equally divided. There was widespread sympathy for the South, but also a genuine devotion to the Union. The governor favoured secession but a small majority in the legislature was opposed to it. His refusal to supply Lincoln with troops met with no protest from the Unionists, who at first concentrated upon keeping the state neutral. But neutrality could not be a permanent attitude. It gave too great an advan-

tage to the Confederates, who drew food supplies from Kentucky and were sheltered from invasion along their western front from the Alleghenies to the Mississippi. Sooner or later the Federal armies must occupy Kentucky as a base for an offensive campaign. But a premature movement would drive Kentucky into secession and to lose Kentucky would be "nearly the same as to lose the whole game," in Lincoln's judgment. Understanding the feeling of his fellow Kentuckians better than any of his counselors at Washington, he handled the critical situation with consummate tact. It was worth sufferingsome temporary disadvantage to win Kentucky in the end. The legislature steadily refused to summon a convention, which might declare for secession. The governor was too good a Kentuckian to overstep the constitutional limits of his office. In August a new legislature was elected with an overwhelming Unionist majority and Kentucky declared for the North in September.

In Missouri, Gov. *Claiborne F. Jackson* was a violent secessionist, eager to take his state out of the Union, and the legislature seemed ready to support him. But when a convention was summoned it proved to be overwhelmingly Unionist. An extreme section of Unionists, led by F. P. Blair, Jr. (whose brother was in Lincoln's cabinet) and largely recruited from the Germans in St. Louis, was ready to meet violence with violence. The St. Louis arsenal, the best equipped in all the slave states, was too rich a prize to be allowed to fall into *Jackson's* hands. But in February Scott had placed in it a sufficient Federal force to secure it against sudden surprise, and in March the convention had adjourned without even discussing secession. A large majority of the people favoured neutrality, and a policy of conciliation would probably have preserved peace within the state, as in Kentucky. But Lincoln allowed himself to be guided by the Blairs. Their agent was the fanatical Capt. Nathaniel Lyon, who broke up (May 10) a militia camp close to St. Louis on the ground that *Jackson* was

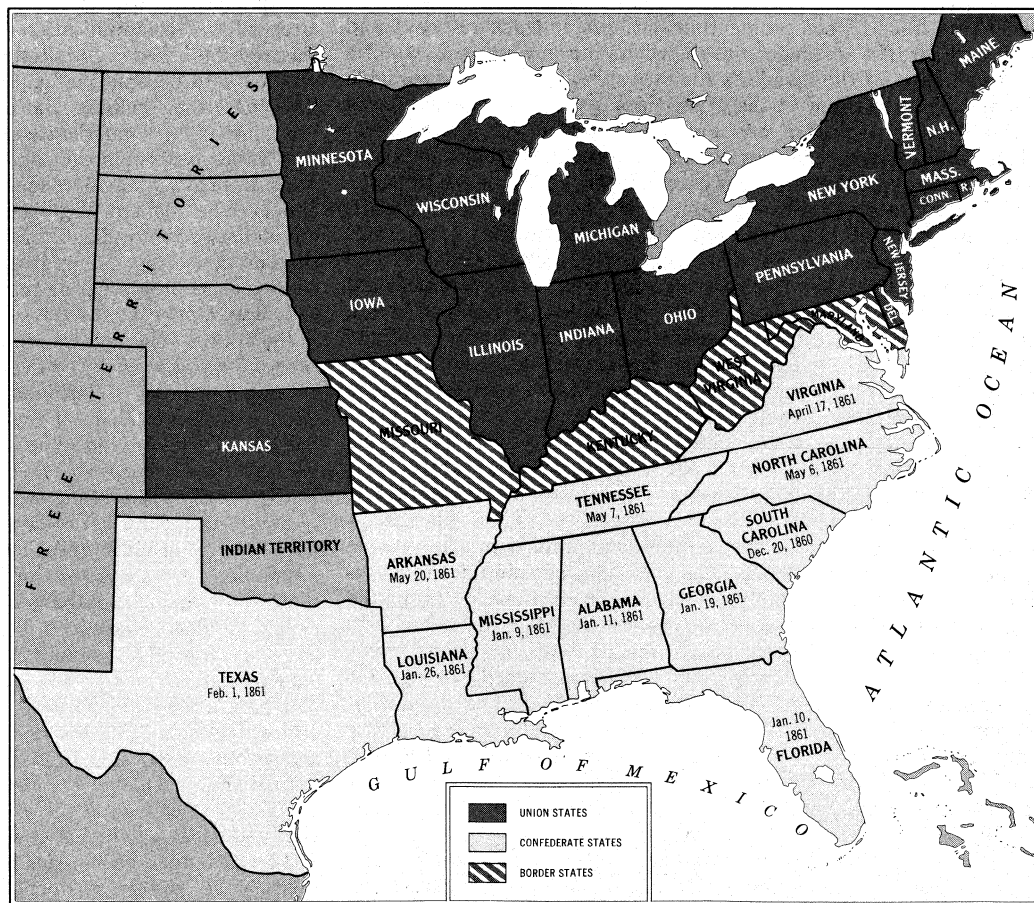

FIG. 1.—THE UNION AND THE CONFEDERACY, 1860-61, SHOWING DATES OF ADOPTION OF ORDINANCES OF SECESSION BY SOUTHERN STATES. BORDER STATES ARE THOSE SLAVE STATES WITH POPULATIONS OF DIVIDED ALLEGIANCE. TWO LOYAL STATES, CALIFORNIA AND OREGON, WERE TOO DISTANT TO BE OF MAJOR IMPORTANCE IN THE CONFLICT

planning an attack on the arsenal. His return to the city with his prisoners caused a riot with considerable loss of life. This premature appeal to force and the use of Federal troops caused a revulsion of feeling in the state. Civil war became inevitable when Lyon was appointed temporary commander of the Missouri department. He promptly ascended the Missouri river with a small force, occupied the state capital, Jefferson City (June 15), and routed a body of secessionist militia at Booneville (June 17). After this defeat *Jackson* fled to the Arkansas border.

3. The Military Outlook.—Twenty-three states (including Kentucky and Missouri) were now arrayed against 11, and the white population of the former (22,000,000) was four times that of the latter (5,500,000). But the 3,500,000 slaves in the South, so far from being a danger to the southern cause, proved of great assistance, supplying the labour required for the production of food and construction of fortifications. Over two-thirds of the officers and all the men of the U.S. army were on the side of the North; so, too, was the navy. In material resources and business capacity the North was overwhelmingly superior. All the manufacturing centres were within its borders, all the shipping in its hands. The South was dependent upon it for practically everything except food. But in spite of these advantages the North was likely to find its strength taxed to the utmost. To restore the Union the South would have to be conquered piecemeal and resistance crushed throughout the whole region, which was "30,000 sq.mi. larger than the combined areas of Austro-Hungary, Germany, France and Italy, with Belgium, Holland and Denmark thrown in." Neither a few victories in the field nor the capture of the Confederate capital would end the struggle, but only the permanent occupation of great stretches of southern territory. The country in which the invading armies must operate was sparsely inhabited, with few cities, poor railways and worse roads. Except in a few favoured districts an army could not find subsistence but would have to carry its supplies with it. Consequently it would be tied to its lines of communication, viz., single-track railways and rivers. East of the Alleghenies the rivers ran down to the Atlantic across the line of the invader's advance and constituted formidable obstacles, but to the west the Mississippi, the Tennessee and Cumberland rivers opened a way into the heart of the Confederacy. Their superiority in mechanical resources enabled the Federals to gain command of these rivers with squadrons of gunboats, to which the Confederates could only oppose a few untrustworthy craft. The possession of the navy similarly secured to the North command of the sea. In a war of attrition the blockade proved to be a potent weapon. The role of the North seeking to reconquer the South was necessarily offensive; that of the South fighting to win its independence mainly defensive. Against such heavy odds the Confederates could not hope to conquer the North, but they expected to make the task of reconquest so costly in life and money that public opinion in the North would demand its abandonment, and in this they nearly succeeded. But at the outset they made a miscalculation. They cherished the delusion that "cotton was king" and that a stoppage of their cotton supply would compel the intervention of Great Britain and France. But in 1861 there happened to be in England, at least, abundant supplies on hand owing to the previous year's record crop, and a glut of manufactured cotton goods. The manufacturers disposing of their accumulated stocks at rising prices had no wish to see the blockade raised. In 1862 and 1863 cotton was exported from Liverpool to New York. The pressure of the "cotton-screw" was not felt until the time for intervention had passed. Yet this groundless belief in foreign intervention infused *Davis'* military policy in the first stage of the war. He hoped that within 12 months at most Britain and France would come to his aid, unless he intensified the prejudice felt against the Confederacy as a slave power by wantonly invading the North.

Both sides had to create their armies before they could fight. Here the South had a distinct advantage. The officers who resigned their commissions contained a disproportionately large number of the ablest men in the old army: the two *Johnstons* and *Lee* had been pre-eminent in their profession. *Davis* was a graduate of West Point, had served seven years in the regular army, had won

distinction as a volunteer in the Mexican War, had been secretary of war in the 1850s and was chairman of the military committee in the senate until just before the outbreak of the Civil War. He could be trusted to appoint the best officers to command his armies and to see that the first steps in military organization were wisely taken. Lincoln lacked military experience, had no knowledge of the professional merits of his officers and personal acquaintance with but a few, including George McClellan, and no business training. His appointments were often made for political reasons. Nathaniel P. Banks, Benjamin F. Butler and John C. Frémont were flagrant instances. Again, the southerners could be more quickly trained as soldiers. There was in the South an aristocracy accustomed to rule, and another class of whites who recognized the aristocracy's claim to leadership. Southerners were accustomed to an open-air life, and were trained to the use of gun and horse. The North, except in the west, did not provide such good fighting material. The Federal armies were uniformly more successful in the west, where the troops on both sides were much of the same class and the North's superior resources turned the scale, whereas in the east townsmen and European immigrants were fighting against country-bred men. But, given time! the northern troops improved and throughout the war the advantage of superior numbers would be theirs. But this advantage was least felt in the first months of the war. The initial problem of both governments was not how to raise men! but how to equip them. There were more volunteers than could be armed. The stocks in the arsenals were quickly exhausted. The South had its fair share of weapons and *Davis* was purchasing arms in England. But the meagreness of his order (10,000 rifles) indicates that he did not anticipate a lengthy war.

II. MILITARY OPERATIONS, 1861

In the first days of the war the city of Washington, shut in between Virginia and Maryland, had been in danger, but by the end of April its defenses had been strengthened and a fortnight later railway communication with the North through Baltimore was re-established. *Lee*, commanding the Virginia state forces, was loath to become the aggressor and refrained from attacking Washington or helping Baltimore. Lincoln had proclaimed a blockade of the Confederate ports (April 19), and called for 42,000 three-year volunteers and 40,000 more men for the regular army and navy (May 3). He was awaiting the result of the referendum to be taken in Virginia on May 23 and scrupulously avoided any violation of Virginian territory, though Federal troops crossed the Potomac (May 24) and without opposition occupied the south bank for the protection of the capital.

1. The Opening Moves.—Gen. Winfield Scott had little faith in the militia. He proposed to use them to defend Washington and recover Harpers Ferry, while he trained the volunteers for an autumn campaign. Washington was served by two railways, the Orange and Alexandria (O. & A.) running southward to Lynchburg and the Baltimore and Ohio (B. & O.) passing through Harpers Ferry. The former was joined at Manassas junction, 30 mi. from Washington, by the Manassas Gap railway from Strasburg in the Shenandoah valley. The Valley (as it was commonly called) between the Blue ridge and the Alleghenies was of great strategic importance, providing the Confederates with a covered line of advance into Maryland and giving them control of a considerable section of the B & O. railway. To the Federals it was of less offensive value, as its direction led away from Richmond, but its possession would enable them to strike at Richmond's direct line of railway communication with the west.

Lee, now acting as *Davis'* military adviser, was gathering two armies, one under *Beauregard* at Manassas junction, the other at Harpers Ferry under *J. E. Johnston*. The latter evacuated his post (June 15) when Gen. Robert Patterson with a larger force threatened attack, and fell back covering the Manassas Gap railway.

The Richmond authorities had vainly attempted to retain their hold on the western section of the state. Having failed to raise recruits from the district itself for its defense, they sent a small force to hold the crests of the Alleghenies; but McClellan crossed the Ohio and overwhelmed it (July 11–13) at Rich mountain and Carrick's ford. Meanwhile a convention at Wheeling had repudi-

ated secession and set up "a restored government of Virginia." West Virginia's defection was a serious blow to the Confederates, losing them the Ohio river, which they intended to make their line of defense, and the western portion of the B. & O. railway.

At Washington there was a demand that *Beauregard* should be attacked before the term of the militia's service expired. "On to Richmond," the new capital of the Confederacy, was the popular cry. On political grounds a plausible case could be made out for overruling Scott's advice. Gen. Irvin McDowell, whom Scott, too old and infirm for service in the field, had appointed commander of the forces south of the Potomac, submitted a plan of operations (June 24). With 30,000 men he proposed to drive *Beauregard's* 20,000 back behind the Rappahannock, provided that Patterson prevented *Johnston* from joining *Beauregard*. The plan was approved and McDowell advanced from Alexandria (July 16) and the next day *Johnston* rushed troops (part of the way by rail) to aid *Beauregard*. The opposing armies met (July 21) at Bull Run (*q.v.*), where after several hours' fighting the Federals left the field. Their retreat became a panic-stricken flight, which carried them back to the Potomac. The Confederates were too disorganized to conduct an immediate pursuit. Presently they advanced to Centreville, where they established their main position and waited for the Federals to make the next move. Washington quickly recovered from its alarm. McClellan was summoned from West Virginia and started to organize a fresh army. The first pitched battle of the war had been an alarming defeat for the North but was barren of decisive results.

In the west a neutral Kentucky interposed a barrier between the combatants, but there was some fierce fighting in southwest Missouri. Lyon pursued *Jackson* as far as Springfield, where he halted to await reinforcements. Ex-governor *Sterling Price*, commanding the state militia, raised a fresh force and being joined by Gen. *Benjamin McCulloch's* troops from Arkansas advanced against Lyon, who, being left unsupported, was defeated and killed at Wilson's creek (Aug. 10). This battle, too, lacked decisive results. *McCulloch*, having entered Missouri without orders from the government, retired after his victory into Arkansas, leaving *Price* to continue the struggle.

2. McClellan in Supreme Command. — The defeat at Bull Run was followed by "the second uprising of the North." Congress authorized the enlistment of 500,000 three-year volunteers. McClellan excelled as an organizer and within three months added 100,000 men to the army of the Potomac, whose discipline and training rapidly improved under his command. But in October public confidence in him began to abate. Confederate batteries on the lower Potomac, which closed its navigation, were left undisturbed, and at Ball's bluff (Oct. 21) four Federal regiments, ferried over the Potomac to make a reconnaissance toward Leesburg, were driven back into the river with the loss of over half their numbers. Nevertheless, on Scott's resignation McClellan, only 34 years of age, was appointed general in chief (Nov. 1). He was expected to open an offensive campaign while the roads in Virginia were still hard and dry. But though his forces were twice as

strong as *Johnston's* at Centreville, he accepted the report of his secret service, which was double *Johnston's* actual numbers. Moreover, in his new post he was engaged, as will be seen, in organizing the military resources in all theatres of war and dispatching expeditions against the Confederate coast. Appreciating the value of sea power he was already contemplating the transfer of his army by water next spring to some point where he would be nearer to Richmond than *Johnston*. But he treated Lincoln with great lack of consideration in keeping his plans a secret from him. In December he contracted typhoid fever and was absent from duty for several weeks.

3. Confederate Plans and Problems. — The Confederate generals at Centreville had been vainly pressing *Davis* for reinforcements that they might enter Maryland. They realized the danger of prolonged inaction, while McClellan's army was daily growing stronger. If *Davis* could reinforce them with 20,000 trained men, they proposed to cross the Potomac and by threatening the communications of Washington force McClellan to risk a pitched battle, before he had time to train his raw levies. *Davis* in conference with his generals (Oct. 1) said that he had no reinforcements to spare; he could not withdraw troops from the coast, which was itself threatened with attack. Though the Confederate coastline extended 3,000 mi, the Federals could make the blockade practically effective by sealing up the few important harbours and getting possession of the North Carolina sounds. The forts guarding Hatteras inlet had been captured (Aug. 29); those protecting the entrance to Port Royal, S.C., fell to another and larger force (Nov. 7); and a third expedition on a still larger scale under Ambrose E. Burnside was being equipped against Roanoke Island, whose capture would complete the conquest of North Carolina's inland waters.

What, however, chiefly decided *Davis* to refuse his generals' request was his determination to stand strictly on the defensive.

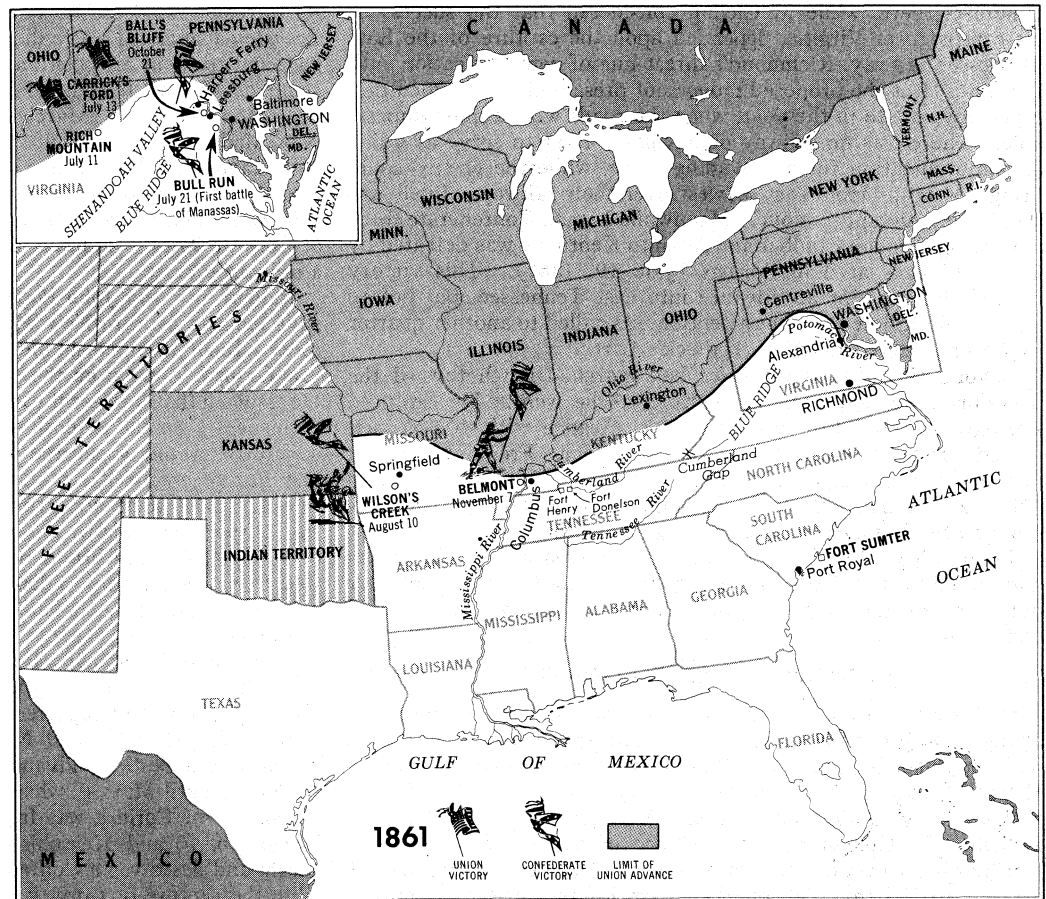

FIG. 2.— MAJOR BATTLES AND APPROXIMATE AREAS UNDER UNION AND CONFEDERATE CONTROL AT THE CLOSE OF MILITARY OPERATIONS FOR THE YEAR 1861. WINNERS OF BATTLES ARE SHOWN BY THEIR RESPECTIVE FLAGS. INSET AT UPPER LEFT SHOWS DETAIL OF MAJOR BATTLES IN VIRGINIA

Even in West Virginia, where William S. Rosecrans, McClellan's successor, was pushing forward into the Kanawha valley, no real counteroffensive was attempted. After Bull Run, *Lee* was sent to co-ordinate the operations of four separate detachments acting independently of each other. But he failed to produce an effective combination, and after his return to Richmond in October the loss of West Virginia was regarded as inevitable.

4. War in the West.—In the west, Confederate encroachments upon Kentucky's territory forced that state into the war. Frémont, commanding in Missouri, was threatening an expedition down the Mississippi, which would involve the occupation of the Kentucky shore. Therefore *Leonidas Polk*, general and bishop, early in September seized Hickman and Columbus, which afforded strong defensive positions on the river, while Grant, one of Frémont's brigadiers, promptly replied by occupying Paducah and Smithland at the mouths of the Tennessee and Cumberland. *Polk's* refusal to withdraw his troops, unless Grant set the example, ended Kentucky's neutrality. A new theatre of war was opened up, the great extent of which offered immense possibilities to either side. McClellan on becoming general in chief set up in the west two military departments, that of the Missouri embracing all Kentucky west of the Cumberland under Henry W. Halleck, and that of the Ohio including the rest of Kentucky under Don Carlos Buell. *Davis* appointed *A. S. Johnston*, one of his ablest generals, to supreme command in the west. *Johnston* advanced into Kentucky and took up a position with his left at Columbus and his right at the important railway junction of Bowling Green, while Forts Henry and Donelson in the centre guarded the approaches up the Tennessee and Cumberland rivers. At the outset the Federals were ill prepared to take the offensive. In Missouri, Frémont had left everything in confusion. The troops from the free states north of the Ohio had been largely diverted to West Virginia or Missouri. Lincoln and McClellan pressed Buell to advance into east Tennessee, Lincoln wishing to send relief to the distressed Gionists there, while McClellan considered that the success of his campaign in Virginia depended upon the capture of the East Tennessee railway, Richmond's direct line of communication with the west. But the proposed movement presented great difficulties, especially so late in the year, when the roads were almost impassable. There was no railway or navigable river to serve as a line of communication for an invading force, while the enemy could bring up troops from east or west over their railway. Buell was therefore reluctant to move. Meanwhile a small Confederate force advancing through Cumberland gap into Kentucky was defeated by G. H. Thomas at Mill Springs (Jan. 19, 1862). This victory cleared the way for an advance into east Tennessee, but before Buell could follow it up, his attention was called to another quarter by an unexpected move on Halleck's part.

Beyond the Mississippi *Price* had marched north toward the Missouri river, gathering up recruits as he went. He captured Lexington (Sept. 20), but Frémont's advance with 40,000 men forced him to retreat to the southwest border. Frémont followed in pursuit to Springfield, where he was relieved of his command (Nov. 2). When *Polk* from Columbus established a post at Belmont on the Missouri bank. Grant descended the river and attacked Belmont (Nov. 7). He was eventually driven back to his boats and forced to re-embark. During the winter Halleck restored order out of chaos and made all preparations for driving *Price* finally out of the state.

III. MILITARY OPERATIONS, 1862

On his return to duty in mid-January 1862 McClellan found two changes, both destined to affect his fortunes adversely. Congress had appointed a joint committee on the conduct of the war, and Edwin M. Stanton had become secretary of war in place of Simon Cameron. McClellan now revealed his new plan of campaign to Lincoln. McClellan offered a choice of three overseas routes, stating his own preference for a movement to be made with great secrecy to Urbana, Va., on the lower Rappahannock, where he would be within 50 mi. of Richmond. He expected by a rapid advance from that base to cut off a Confederate force in the Yorktown peninsula and capture Richmond, before *Johnston* could

intervene. Lincoln did not see how the preparations could be kept secret, and was sure that McClellan would still find *Johnston* between himself and Richmond. He objected to any movement that uncovered Washington and withdrew McClellan from interposing between the capital and *Johnston*. He gave, however (Feb. 27), a grudging assent to an overseas movement without specifying the actual point of disembarkation. Finally he forbade the Urbana plan and left McClellan his choice between landing at Ft. Monroe at the end of the Yorktown peninsula, the route which McClellan considered the worst of the three, and making an overland campaign. McClellan chose the first alternative. Probably the withdrawal (March 9) of *Johnston* behind the Rappahannock reconciled him to the sacrifice of his Urbana plan. Throughout these discussions Lincoln demanded adequate protection for Washington, and McClellan undertook to leave ample forces for the purpose.

1. The Federal Offensive in the West.—The weak point in *A. S. Johnston's* line was at the centre, where the Memphis and Ohio railway, which formed the link between his two wings, crossed the Cumberland and Tennessee so close to Forts Donelson and Henry that the capture of these forts would sever his line of communication with the Mississippi. The Tennessee was navigable as far as Tusculumbia in north Alabama, and the Cumberland up to Nashville. The Confederates had no gunboats on these rivers, and if these forts fell there was nothing to oppose the Federal advance to the Memphis and Charleston (M. & C.) railway, the direct line of communication between east and west. Halleck, without orders from McClellan or arrangement for co-operation with Buell, ordered Grant (Feb. 1.) with 15,000 men and Andrew H. Foote's gunboats to ascend the Tennessee, capture Ft. Henry and destroy the railway bridge. Ft. Henry surrendered to the gunboats (Feb. 6), the garrison escaping to Ft. Donelson. *Johnston* evacuated Bowling Green, sending half his army to Ft. Donelson and retiring with the other half to Nashville. This division of forces proved fatal. The concentration of 18,000 men at Ft. Donelson did not prevent its surrender with the bulk of its garrison to Grant (Feb. 16). *Johnston* abandoned Nashville, which was occupied by Buell (Feb. 24), and took up his position at Murfreesboro, and *Beauregard*, sent from the east to command on the Mississippi under *Johnston*, evacuated Columbus (March 2) after removing its armament to New Madrid and Island No. 10, where he intended to make the next stand against a Federal descent of the river. *Johnston* was thus thrown back to his second line of defense along the M. & C. railway with his wings at Memphis and Chattanooga and his centre at Corinth, Miss. Halleck's unauthorized movement had proved a brilliant success.

Halleck now sent John Pope with 20,000 men down the Mississippi bank to capture New Madrid and Island No. 10, and summoned Buell from Nashville to Savannah on the Tennessee to join Grant encamped on the opposite bank at Pittsburg Landing. He assumed that the recent campaign had thrown the Confederates permanently on the defensive and that the concentration of his own forces would be effected without interruption. But *Johnston* and *Beauregard*, well served with information by local sympathizers, seized their opportunity. By calling up Gen. *Braxton Bragg* from Pensacola with 10,000 men they concentrated an army of nearly 40,000 at Corinth before the end of March. Gen. *Earl Van Dorn* was bringing 15,000 men from Arkansas, but they could not wait for his arrival. The battle of Shiloh (*q.v.*) (April 6–7) was one of the most fiercely contested in the war. *Johnston* was killed the first day and *Beauregard* retreated to Corinth. Halleck joined his armies (April 11) and having been reinforced by Pope (April 21), who had captured with the help of the gunboats the garrison (7,000) of Island No. 10 with all its guns and stores, commenced a cautious advance on Corinth. *Beauregard* held on to Corinth until May 30, when he retreated to Tupelo, Miss. The evacuation of Corinth was followed by that of Ft. Pillow below Island No. 10 and Memphis (June 3). The Federal squadron fought and destroyed a Confederate flotilla at Memphis (June 6). With the capture of Corinth and Memphis the Federal offensive virtually ended. They had cleared Kentucky and west Tennessee of the enemy, established themselves on the M. & C. railway and opened the Mississippi to Vicksburg. But the Confederate army

of the west had escaped and would presently take the offensive.

West of the Mississippi Halleck had scored another success. Price had been driven out of southwest Missouri by Gen. Samuel R. Curtis, who followed him into Arkansas. Van Dorn, commanding in the newly formed trans-Mississippi department, reinforced Price, and their combined forces attacked Curtis at Pea Ridge (or Elkhorn Tavern), Ark., but suffered a severe defeat (March 7-8). Still farther west the Confederates had suffered another reverse. A small expedition under Col. Henry H. Sibley had been sent up the Rio Grande to secure Arizona and New Mexico with a view to bringing California into the Confederacy. Sibley occupied Santa Fe in March, but was forced by Col. E. R. S. Canby in April to make a disastrous retreat to Texas, and the whole of the territory, which he had overrun, was secured permanently by the Federals. But of all the disasters suffered in the west by the Confederates in the spring of 1862 the greatest, because irreparable, was the loss of New Orleans. Flag Officer David G. Farragut with the Gulf squadron ran past the forts guarding the lower Mississippi and appeared next day before the city (April 24-25), which, abandoned by its garrison, surrendered to the fleet, and was formally occupied by Gen. B. F. Butler's troops (May 1).

2. McClellan's Peninsular Campaign.—The sensational ap-

pearance of the ironclad "Merrimack" in Hampton Roads, at the mouth of the James river (March 8), had threatened the collapse of McClellan's oversea campaign, but next day the "Monitor" proved more than her match, and the naval authorities gave a doubtful assurance that they could cover the landing. (See "MONITOR" AND "MERRIMACK," BATTLE OF.) The embarkation began on March 17; McClellan himself reached Ft. Monroe on April 2. On taking command in the field of the army of the Potomac he had been relieved of his duties as general in chief. For the next four months Lincoln and Stanton were responsible for the "higher strategy." McClellan began his advance (April 4), expecting to move rapidly up the peninsula to the neighbourhood of Richmond, where he would fight and win the decisive battle, and capture the Confederate capital. He knew that Yorktown and Gloucester on opposite banks of the York river were fortified, but he counted on the co-operation of the navy to capture Yorktown and intended to land McDowell's corps, which had not yet arrived, on the left bank for the reduction of Gloucester. But the navy could give no help as long as the "Merrimack" was afloat; Lincoln detained McDowell for the protection of Washington on the ground that McClellan had not kept his promise of leaving it absolutely secure. McClellan was held up before Yorktown for a

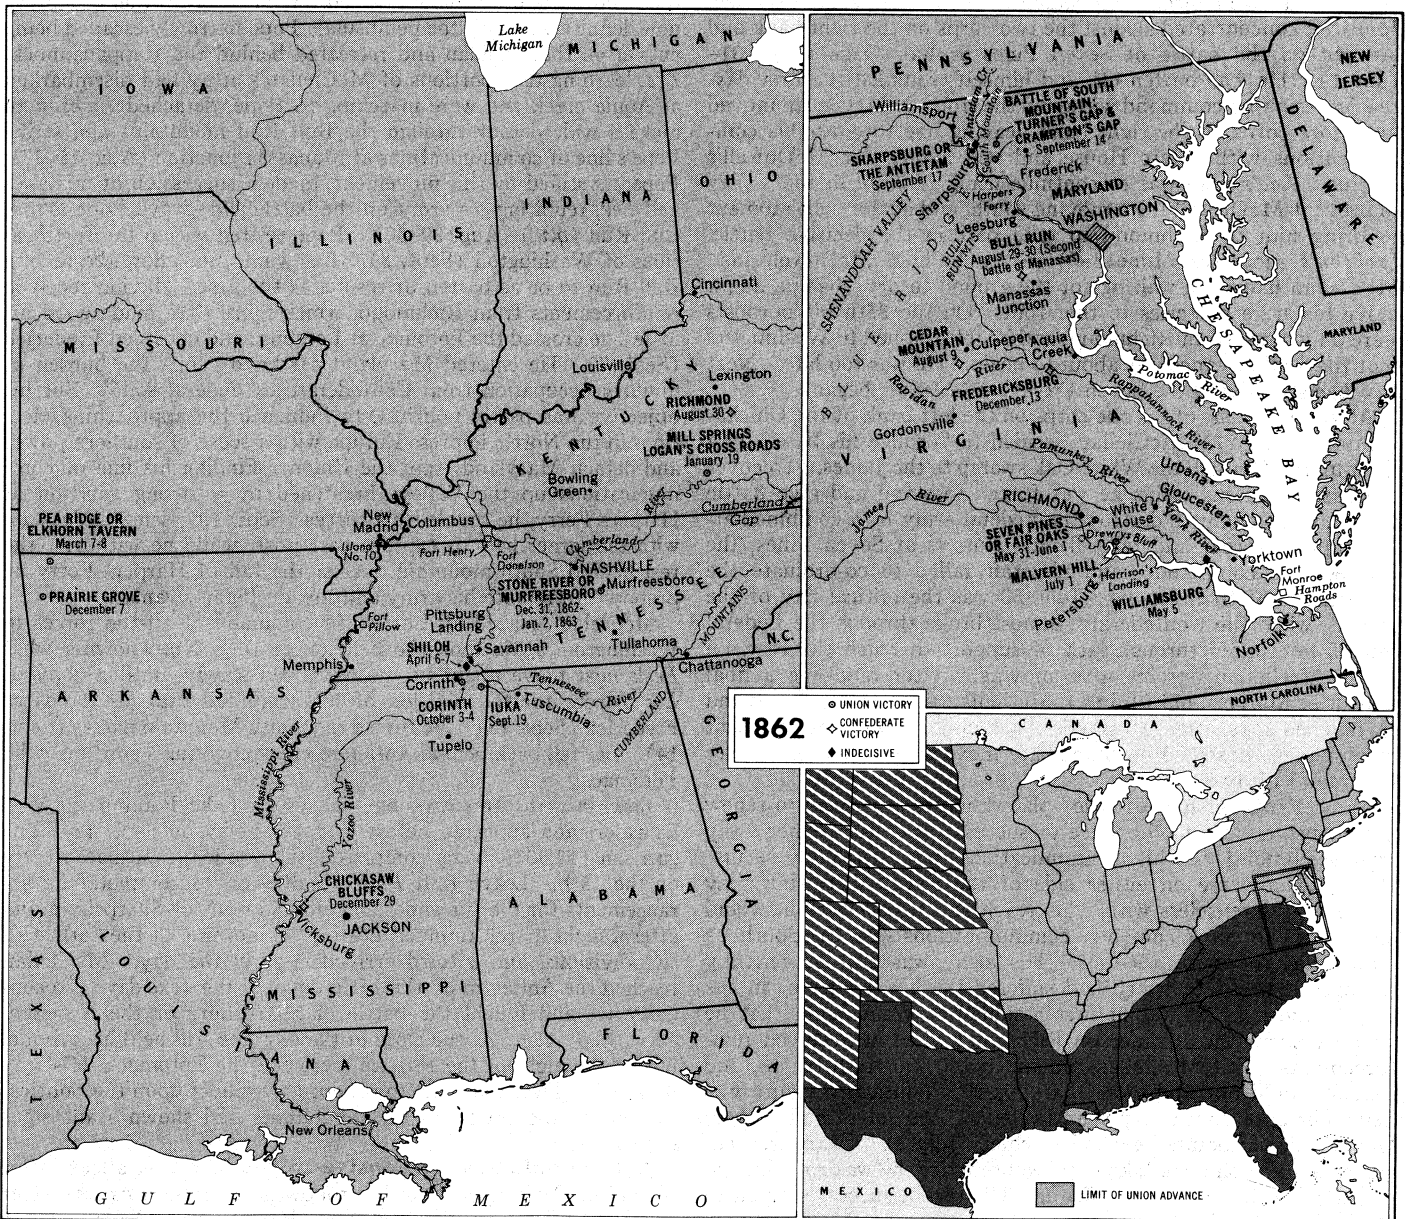

FIG. 3.—MAJOR BATTLES DURING 1862. INSET AT LOWER RIGHT SHOWS APPROXIMATE AREA OF UNION PENETRATION INTO CONFEDERATE TERRITORY

month (April 5–May 3).

J. E. Johnston, who had brought his army to the peninsula and assumed command at Yorktown (April 17), slipped away just as McClellan was about to open fire with his siege batteries. A sharp rearguard action took place at Williamsburg (May 5), and an attempt to intercept *Johnston's* retreat by sending a force up the York river failed. McClellan established his headquarters at White House on the Pamunkey river (May 16). He had succeeded in bringing over 100,000 men (organized into five corps) within striking distance of Richmond, and only 60 mi. away on the Rappahannock opposite Fredericksburg lay McDowell's corps, now under orders to advance on Richmond on May 26. McClellan would have transferred his base from the York to the James, now open to the Federal war vessels as far as Drewrys Bluff, as the Confederates after the evacuation of Yorktown had abandoned Norfolk and destroyed the "*Merrimack*," which was unable to ascend the river. But, informed by Stanton that he was to be reinforced, he advanced to the Chickahominy (May 20) and sent two corps across in preparation for the advance on Richmond, keeping three on the left bank to join hands with McDowell. He retained this position with his wings divided by the Chickahominy, although he learned (May 24) that McDowell's advance was suspended because of "*Stonewall*" *Jackson's* operations in the Valley, hoping that McDowell's movement would shortly be resumed. *Johnston* concentrated against the two corps on the right bank and brought on the battle of Seven Pines or Fair Oaks (May 31–June 1). He was beaten off, and himself wounded the first day. *Lee* on assuming command withdrew the troops. McClellan moved two more corps to the right bank, leaving one to cover his communications with White House and still hoping for McDowell's coming. *Lee's* plan was to continue using *Jackson* in the Valley to prevent McDowell from moving south, and at the right moment to bring him to Richmond to take part in the decisive battle. *Jackson's* successes (June 8–9) served to hold McDowell fast. McClellan had been waiting for the ground to dry, that he might move his siege batteries to the front. On the 25th his outposts were only 4 mi. from Richmond, and he telegraphed to Washington that the final advance was about to begin. He was too late. Next day *Lee* struck and the Seven Days' battle (*q.v.*) began.

After the defeat of his one corps on the left bank of the Chickahominy (June 27), McClellan decided to "change his base" by a flank march through the White Oak swamp to the James. To cover the passage of his trains he was forced to stand and give battle to *Lee*, who sought to destroy the Federal army by a combined attack upon its rear and right flank. But, as at Seven Pines, the Confederate commander and his staff failed to co-ordinate the movements of their troops. June 30 was the critical day of the retreat, when the Confederates almost broke through the Federal centre, but failed through lack of support to reach the road on which McClellan's trains were moving. After repulsing a final assault at Malvern hill (July 1), McClellan reached the James and entrenched a position at Harrison's Landing. *Lee*, finding that his opponent designed no immediate movement, withdrew nearer Richmond (July 8).

McClellan's "change of base" placed him in a position to renew the offensive with good chance of success. He was farther away from Richmond, but his communications were absolutely secure. He could advance on either side of the river. Petersburg lay practically defenseless within his reach and its occupation would enable him to cut Richmond's communications with the South, as Grant was to do in 1864–65. His army was still numerically stronger than *Lee's*, which had suffered the heavier losses in the week's fighting. It was at first assumed at Washington that he would resume the advance on Richmond when he received reinforcements. But McClellan demanded 100,000 fresh troops, and Lincoln could not find more than 20,000. Political pressure was being put upon him to replace McClellan. To solve the problem, Halleck was appointed general in chief (July 11). A retired engineer officer, who had taken up legal practice, he was an acknowledged authority on the art of war. His recent success seemed to mark him out as McClellan's natural successor, but he served only as Lincoln's military adviser. He visited McClellan's army (July

25) and committed his first blunder by ordering the withdrawal of the army of the Potomac to Aquia creek, where it could unite with Pope's army of Virginia on the Rappahannock for an overland advance on Richmond (Aug. 3).

Jackson's Valley campaign is described elsewhere. Here it may be noted that on three separate occasions *Jackson* caused McDowell's corps to be withdrawn from McClellan. His attack at Kernstown (March 23) alarmed Lincoln and was partly the cause of his detaining McDowell in the first instance at Washington. Throughout the campaign *Lee* worked upon Lincoln's anxiety for the safety of Washington to break up the threatened combination against Richmond.

3. The Confederate Offensive in the East.—Pope was summoned (June 26) from the west to command an army composed of the forces on the Rappahannock and in the Valley. *Jackson's* campaign had taught Lincoln that one general is better than three. Pope's immediate task was to lighten the pressure upon McClellan by threatening the Virginia Central railway. *Lee* dispatched (July 13) *Jackson* in time to save Gordonsville from Pope's cavalry. *Jackson* advancing toward Culpeper to prevent the concentration of Pope's scattered forces defeated Banks at Cedar mountain (Aug. 9), but fell back when Banks was reinforced. *Lee*, joining *Jackson* with *James Longstreet's* command (Aug. 15), sought to crush Pope, before he could be reinforced from McClellan's army now definitely leaving the peninsula. Pope narrowly escaped being cut off on the Rapidan and retreated behind the Rappahannock. *Lee*, learning that portions of McClellan's army had disembarked at Aquia creek and were marching to Pope, detached *Jackson* to make a wide detour through the Bull Run mountains and strike Pope's line of communications at Manassas junction (Aug. 25–27). Pope, mystified by this movement, made a succession of mistakes and *Lee*, reuniting his army on the battlefield, drove Pope across Bull Run (*q.v.*) (Aug. 29–30). Pope retired within the fortifications of Washington (Sept. 3). *Lee* would not allow the second Bull Run to be as barren of results as the first. Having received reinforcements from Richmond, which more than made good his losses, he crossed the Potomac at Leesburg and occupied Frederick (Sept. 7). He entered Maryland partly to "shift the burden of military occupation from Confederate to Federal soil." But his objective was partly political, to influence the approaching elections in the North, impress Europe with a sense of southern power and detach Maryland from the Union. Finding his line of communications up the Valley threatened by a strong garrison at Harpers Ferry, he divided his forces (Sept. 10), sending *Jackson* with the larger half to capture that post, while he withdrew the rest behind South mountain. After the fall of Harpers Ferry he proposed to reunite his army and invade Pennsylvania.

McClellan, placed by Lincoln in command of all the forces in Washington, again took the field (Sept. 7). Not knowing what *Lee's* next move might be, he advanced slowly, until a copy of *Lee's* order for the division of his army fell into his hands at Frederick (Sept. 13). He forced the South Mountain passes (Sept. 14). *Lee* fell back behind Antietam creek covering a ford over the Potomac.

Jackson with three divisions had crossed the Potomac at Williamsport and appeared before Harpers Ferry on Sept. 15. The garrison (12,500), being completely surrounded, capitulated early on the 15th. Leaving A. P. *Hill's* division to complete the arrangements for the surrender, *Jackson* started for Sharpsburg and after a night march rejoined *Lee* on the morning of the 16th with two divisions, and a third arrived later in the day. McClellan reached the Antietam on the 15th, devoted the next day to reconnaissance and fought the battle of Sharpsburg or the Antietam (*q.v.*; Sept. 17). At the close of the day *Lee* still held his ground, but on the night of the 18th he recrossed the Potomac. His stay in Maryland was too short to produce any effect upon the political attitude of the state and the inhabitants had shown scant signs of sympathy.

4. The Confederate Offensive in the West.—Halleck, after the fall of Corinth, could either follow up *Beauregard's* retreat or strike at Vicksburg or Chattanooga. Pursuit should have ended in the annihilation of the sole Confederate army in the west; the

capture of Vicksburg would open the Mississippi to its mouth and cut the Confederacy in two; the occupation of Chattanooga would further Lincoln's policy of sending relief to the Unionists in east Tennessee. Halleck limited his offensive to sending Buell's army alone toward Chattanooga, and wasted three weeks by forcing him to use as his line of supply the M. & C. railway, which was exposed to cavalry raids. At the end of June, Buell gained permission to transfer his base to Nashville. As no movement was made toward Tupelo, Bragg, who had succeeded *Beauregard* (June 27), left *Van Dorn* and *Price* to check Grant. On Halleck's appointment as general in chief at Washington, Grant had been left in command of the department of the Tennessee. Bragg sought the co-operation of *Edmund Kirby-Smith*, commanding in east Tennessee, in an advance on Nashville, but yielded to the other's confidence in the political results of an invasion of Kentucky and agreed to march to the Ohio. Buell, whose advance from Nashville on Chattanooga was twice suspended in consequence of cavalry raids upon his communications, took up a defensive position at Murfreesboro covering Nashville.

Kirby-Smith "turned" Cumberland gap, swept aside an extemporized force, which faced him at Richmond, Ky. (Aug. 30), and occupied Lexington (Sept. 2), threatening Louisville and Cincinnati. Bragg, concentrating behind the Cumberland mountains, appeared on Buell's front (Sept. 5). Then ensued a race to Louisville, in which Buell got the worst of the start, as he dared not uncover Nashville, and reached Bowling Green (Sept. 14) to find Bragg planted squarely across the railway between him and Louisville. Buell could not risk an offensive battle with so much at stake: Bragg would only fight on the defensive. He moved out of Buell's path because of lack of supplies (Sept. 21) to make connection with *Kirby-Smith*, who had collected a large depot of stores at Lexington. Buell entered Louisville (Sept. 25) and having reorganized his army marched out (Oct. 1) to find and fight the invaders. Their generals were more occupied with the inauguration of a provisional governor at Frankfort (Oct. 4) than with the need for concentrating their forces. An accidental encounter with indecisive results occurred at Perryville (Oct. 8) between Buell's and Bragg's left wings. Bragg and *Kirby-Smith* now united their armies, but only to retreat through Cumberland gap into east Tennessee. The Confederate invasion of Kentucky was barren of political results. The provisional governor was chased out of his capital immediately after his inauguration.

5. The Federals Resume the Offensive.—After issuance of the Emancipation Proclamation, McClellan was urged to cross the Potomac and force another battle, but he demanded time to reorganize his army. Five weeks passed before he began his advance along the east side of the Blue ridge. Then *Lee*, bringing *Longstreet* to Culpeper, again interposed. McClellan was relieved of his command (Nov. 7), and his successor, Burnside, adopted a new plan of campaign, to transfer his base to Aquia creek, cross the Rappahannock at or below Fredericksburg and march straight on Richmond. But delay in forwarding a pontoon train from Washington prevented his crossing until *Lee* had taken up a position on the Fredericksburg heights. Though the element of surprise was lost, Burnside persisted in crossing the river and, attacking *Lee*, was repulsed with terrible slaughter (Dec. 13).

In the west, Buell was replaced (Oct. 30) by Rosecrans, who as Pope's successor under Grant had gained the credit of defeating *Price* at Iuka (Sept. 19) and *Van Dorn* at Corinth (Oct. 3-4). Before renewing the advance upon Chattanooga he determined to make himself temporarily independent of the railway by accumulating a reserve of 2,000,000 rations at Nashville. The government chafed at the delay. Rosecrans refused to be hurried. He commenced his advance against Bragg (Dec. 26), who since returning from Kentucky had established himself at Murfreesboro, where he expected to pass the winter. The battle of Stone River or Murfreesboro (Dec. 31-Jan. 2) ended with Bragg abandoning the battlefield, evacuating Murfreesboro and falling back to Tullahoma. Rosecrans occupied Murfreesboro and settled down for the winter.

After *Van Dorn's* defeat Grant moved against Vicksburg. Gen. William T. Sherman, starting down the river from Memphis, was

to land his troops at the mouth of the Yazoo, seize the bluffs north of Vicksburg and attack the city from the rear. Meanwhile Grant, who was already advancing along the Mississippi Central railway toward Jackson, Miss., would hold Gen. *John C. Pemberton*, *Van Dorn's* successor, fast and prevent his sending help to Vicksburg. But Grant had to retire when his supply depot was destroyed by a cavalry raid (Dec. 20), and Sherman was forestalled by *Pemberton*, who was kept informed by spies of the Federal movement, and defeated at Chickasaw Bluffs, 6 mi. N. of Vicksburg (Dec. 29). In northwest Arkansas *Thomas C. Hindman* was organizing a fresh invasion of Missouri but was anticipated by James G. Blunt and Francis J. Herron, who crossed the frontier and defeated him at Prairie Grove (Dec. 7).

IV. MILITARY OPERATIONS, 1863

In the east, after "the horror of Fredericksburg" the two armies passed the winter facing each other across the Rappahannock. Gen. Joseph Hooker replaced Burnside (Jan. 26) and quickly restored the shaken morale of his army. *Lee* found great difficulty in feeding his troops, and by direction of the war department *Longstreet* with two divisions was sent to the south bank of the James to collect provisions in the vicinity of Suffolk, which Federal troops occupied. *Longstreet* surrounded Suffolk and at the moment when his divisions were urgently needed on the Rappahannock was engaged in a futile siege 120 mi. away.

1. Chancellorsville.—Both *Lee* and Hooker were eager to take the offensive. *Lee* had been considering with *Jackson* an invasion of Pennsylvania, but in the absence of *Longstreet's* divisions had to resign the initiative to Hooker. The latter aimed at forcing *Lee* out of his entrenchments by a wide turning movement over the upper fords of the Rappahannock above its junction with the Rapidan, and sent his newly organized cavalry corps to destroy the railways in *Lee's* rear and intercept his retreat. He thus deprived himself of "the eyes of his army," and to the absence of his cavalry (except one brigade) was largely attributable the failure of the Chancellorsville campaign.

Hooker, who outnumbered *Lee* by fully two to one, concentrated the larger half of his army about Chancellorsville (April 30), while John Sedgwick crossed the Rappahannock below Fredericksburg. *Lee*, leaving 10,000 men to check Sedgwick, threw Hooker on the defensive (May 1), outflanked and rolled up his right wing with *Jackson's* corps (May 2), drove him out of his entrenchments to a fresh defensive position (May 3), turned on Sedgwick, who had captured the Fredericksburg heights, and forced him back over the river (May 4) and then countermarched to Chancellorsville to strike another blow at Hooker. But the latter retreated across the Rappahannock on the night of May 5. *Lee's* victory was dearly bought at the price of *Jackson's* life (May 10). He now reorganized his army into three corps under *Longstreet*, *Richard S. Ewell* and *A. P. Hill* and prepared to carry out his plan of invading Pennsylvania. (See also WILDERNESS.)

2. Gettysburg.—*Longstreet* had proposed a plan for the relief of Vicksburg, now in dire straits. *Lee* should leave the army that had fought at Chancellorsville to "contain" Hooker on the Rappahannock, and with *Longstreet's* two divisions join Bragg in Tennessee. *Johnston's* troops should be brought from Mississippi and *Simon B. Buckner's* from east Tennessee to the same point. The united forces under *Lee's* command could then take the offensive against Rosecrans, overwhelm him and then invade Kentucky and threaten Louisville and Cincinnati—forcing Grant to raise the siege of Vicksburg. But *Lee* was unwilling to leave Virginia or divide his army.

Lee's objectives in Pennsylvania were much the same as those that had prompted his invasion of Maryland in 1862, and in particular he hoped to levy much-needed supplies of food and clothing from a free state and prevent the sending of reinforcements to Grant before Vicksburg. He commenced his movement on June 3. His plan of campaign was to transfer his army to the Valley, cross the Potomac and march to the Susquehanna. He could count upon Lincoln's anxiety for Washington's safety to keep Hooker from attacking any of his widely separated corps before they were concentrated in Pennsylvania. A cavalry battle at Brandy Station

(June 9) warned Hooker that *Lee* was on the move. Being refused permission to march on Richmond, he began to fall back toward Manassas (June 13). *Hill* marched to the valley covered by *Longstreet*, who advanced east of the Blue ridge. *Ewell* captured Winchester (June 15) and crossed into Maryland, pushing his cavalry forward into Pennsylvania. *Longstreet* passed into the valley in *Hill's* rear and their two corps were crossing the river on June 23-24. Hooker began crossing on June 25 and concentrated at Frederick, threatening *Lee's* line of retreat. *Hill* and *Longstreet* were at Chambersburg, *Ewell* on his way to Harrisburg with two divisions at Carlisle and one at York (June 27). But the absence of "*Jeb*" *Stuart's* cavalry, which was on a raid around the Federal army and did not rejoin until July 2, left *Lee* in ignorance of Hooker's movements. He did not learn until the night of June 28 that Hooker had crossed into Maryland and was threatening his communications. He at once ordered a concentration of all his forces at Cashtown to keep the Federals east of South mountain by threatening Baltimore. Gen. George G. Meade, who had meanwhile replaced Hooker (June 28), was moving his army northward to prevent *Lee* from crossing the Susquehanna. A chance encounter on June 30 at Gettysburg (q v.) brought on the famous battle.

Hill advancing from the nest and *Ewell* coming down from the

north had defeated two Federal corps and occupied Gettysburg (July 1). Neither *Lee* nor Meade expected a battle so soon, but *Lee* could complete his concentration first, and the chance of defeating his opponent in detail urged him to assume the offensive. But he could not get his corps commanders to work together as a team. No attack was delivered (July 2) until 4 P.M., and though the Confederates gained some ground on both flanks and for a moment broke through the Federal centre, at nightfall Meade still held Cemetery ridge and had his whole army concentrated. Lee made his final assault (July 3) with two divisions against the enemy centre, but again concert of action was lacking, and *George E. Pickett's* charge, being unsupported, was a costly failure. *Lee* began his retreat (July 4) through the South Mountain passes. He was held up at Williamsport for a week waiting for the river to run down, but on the night of the 13th withdrew his army and trains into the Valley before Meade, who had appeared on his front the day before, could make up his mind to attack.

Lee gradually fell back behind the Rapidan and Meade followed him across the Rappahannock as far as Culpeper. Both armies were weakened in September by sending heavy detachments to Tennessee. In October and November the two generals engaged in a campaign of maneuver, which had no decisive result and left

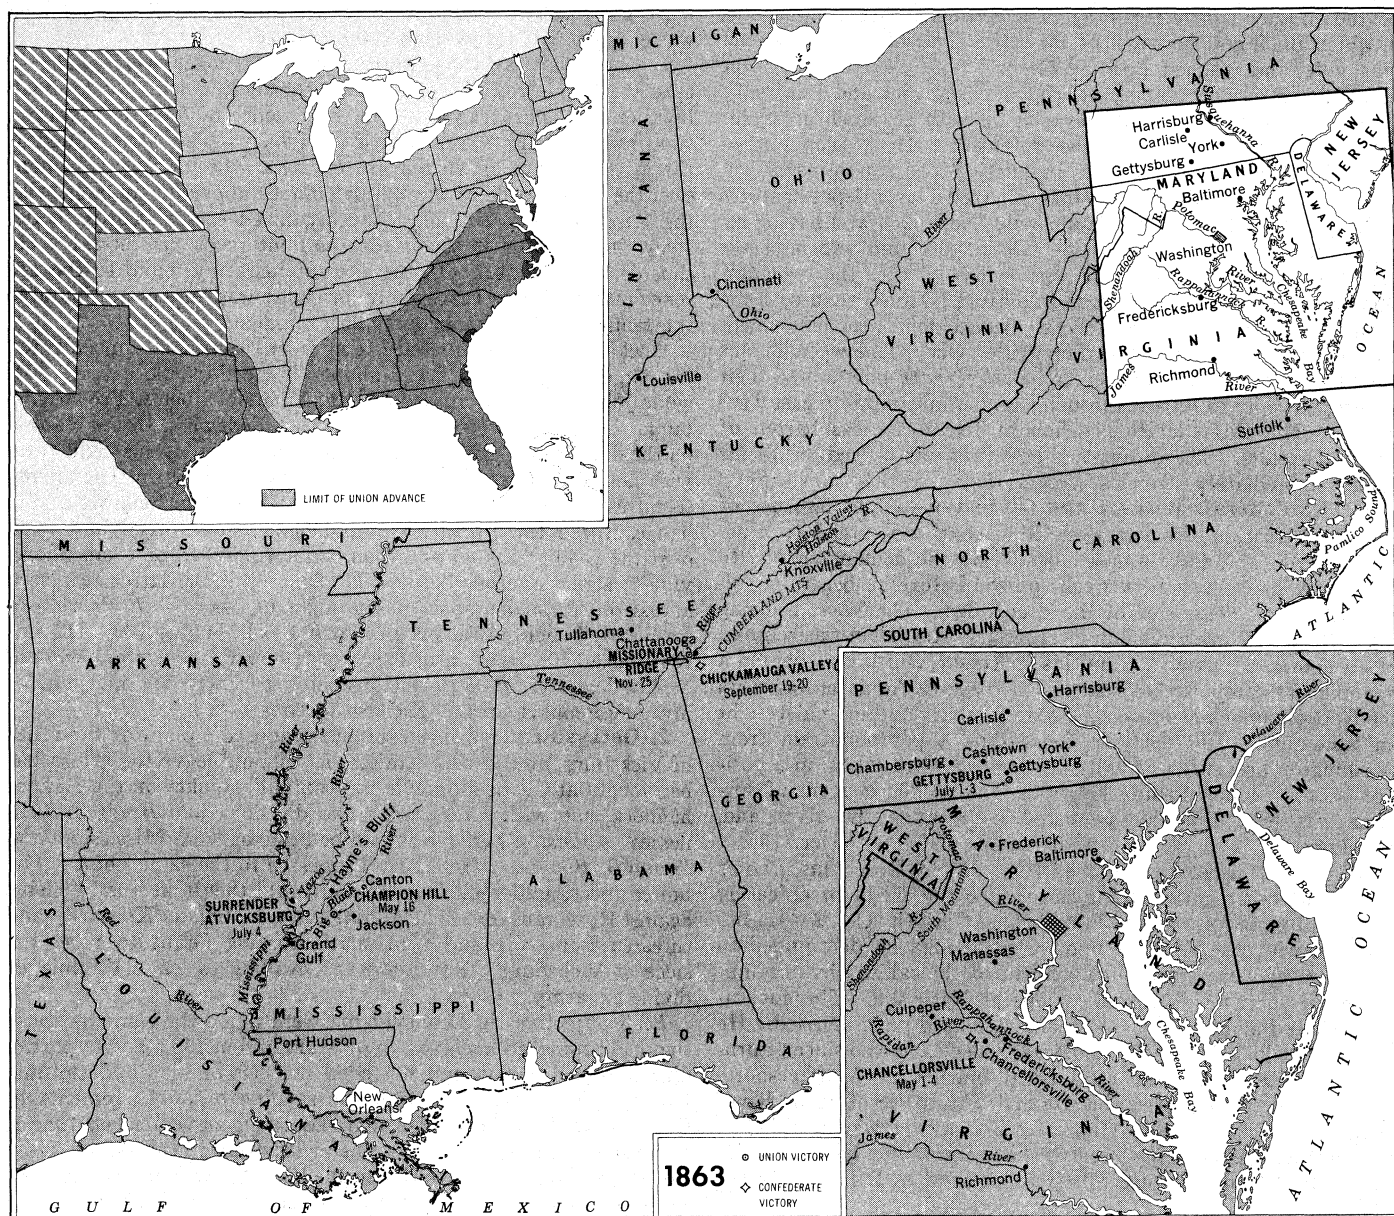

FIG. 4.—MAJOR BATTLES DURING 1863. INSET AT LOWER RIGHT SHOWS DETAIL OF PENNSYLVANIA AND MIDDLE ATLANTIC STATES, INSET AT UPPER LEFT SHOWS APPROXIMATE LIMIT OF UNION ADVANCE

them in their original positions on the Rapidan and Rappahannock respectively.

3. Vicksburg and Chattanooga. — In 1863, as in 1862, it was in the west that decisive results were obtained. By the capture of Yicksburg and Port Hudson the Federals gained complete control of the Mississippi, and in east Tennessee they captured Chattanooga and Knoxville. Grant's Vicksburg (*q.v.*) campaign was one of the most brilliant operations of the war, though he owed much to his opponent's mistakes.

The problem was to transport his army from the right bank of the Mississippi to the high ground in the rear of Vicksburg. After four unsuccessful attempts (Feb.—March) to open up a water route, by which the enemy's flanks might be turned Grant in April, when the winter floods had begun to subside, moved two corps by land to a point below Grand gulf, the extreme left of the Confederate defenses. Part of the Federal fleet had run past the Vicksburg batteries by night (April 16), bringing with them two transports, and five more transports got past six nights later. Grant began crossing the river on April 30 *Pemberton*, who as commander of the department of Mississippi and east Louisiana was responsible for both Vicksburg and Port Hudson, had been so mystified by Grant's demonstrations on the north side of Vicksburg that he had only four brigades available to meet his advance south of the Big Black river. Grant defeated these (May 1) and established a temporary base at Grand gulf. Having been joined by Sherman with further supplies, he advanced (May 7) against the Vicksburg-Jackson railway, on which *Pemberton* depended for supplies and reinforcements. But suspecting after the engagement at Raymond (May 12) that a considerable force was collecting at Jackson, Grant cut loose from his base and marched with his whole army on Jackson, living off the country until he could work around to the north of Vicksburg and establish a new base on the Yazoo. *J. E. Johnston*, commander in chief in the west, had been ordered (May 9) to assume personal command of the troops in Mississippi. He reached Jackson from Tullahoma (May 13) but found only two brigades there. Next day, after fighting a delaying action at Jackson, he retreated up the Mississippi Central railway to Canton. Grant then fell upon *Pemberton's* field force at Champion hill (May 16) and drove it into the fortifications of Vicksburg, occupying Haynes's Bluff two days later. The fate of Vicksburg was now sealed, for *Johnston* was unable to collect a force strong enough to create a diversion, and *Pemberton* capitulated (July 4).

Butler's successor at New Orleans, Gen. N. P. Banks, was equally successful in reducing Port Hudson, 200 mi. below Vicksburg (July 9). Farragut with two warships had run past the Port Hudson batteries (March 14), and by closing the mouth of the Red river deprived the garrison of its main source of supplies. Banks commenced siege operations (May 24), and the Confederates were on the verge of starvation when they surrendered.

In middle Tennessee Rosecrans was urged by the government to take the offensive against *Bragg* to prevent him from sending reinforcements to Mississippi. But Rosecrans maintained that, while he remained on *Bragg's* front, the latter would not risk the loss of middle Tennessee by detaching troops elsewhere. *Bragg* did in fact send some reinforcements to *Johnston*. Rosecrans was really afraid that Grant might be defeated and was unwilling to commit himself to a fresh movement while the issue at Vicksburg remained unsettled. At last he advanced (June 23) and in nine days of incessant rain maneuvered *Bragg* out of two strong positions in succession and forced him to retreat behind the Tennessee river. He resumed his advance (Aug. 16) in co-operation with Burnside, who advanced from Kentucky and occupied Knoxville (Sept. 2). Rosecrans, feinting at *Bragg's* right, as if he intended to cross the Tennessee above Chattanooga and join Burnside, moved the bulk of his army across well below Chattanooga (Sept. 4) and advanced over the mountain ranges south of the river against *Bragg's* line of retreat. This maneuver forced *Bragg* to evacuate Chattanooga (Sept. 8), but he retreated only 25 mi. to Lafayette, where he covered the railway; waiting for a chance to defeat Rosecrans' army in detail. Rosecrans, imagining *Bragg* to be in full retreat, fell into the trap and pressed forward with three columns so widely separated that no two were within supporting distance of

each other. But *Bragg* failed to close the trap. Two chances of overwhelming isolated portions of the Federal army were lost by his lieutenants. Rosecrans reconcentrated his army (Sept. 18), and *Bragg*, having received considerable reinforcements, including five brigades under *Longstreet*, from Virginia, attacked and defeated him (Sept. 19–20) in Chickamauga (*q.v.*) valley and drove him back into Chattanooga, where the Federal army was practically besieged and in danger of starvation. Grant was now appointed to the supreme command in the west and reached Chattanooga (Oct. 23), where Hooker with reinforcements from the army of the Potomac had already arrived. Grant substituted Thomas for Rosecrans in command of the army of the Cumberland and averted all fear of starvation by opening a short line of communication with Bridgeport by way of two ferries over the Tennessee. *Bragg* now weakened himself by sending *Longstreet* with a large detachment against Burnside (Nov. 3). Grant, on the arrival of four divisions of the army of the Tennessee under Sherman, took the offensive and stormed *Bragg's* position on Missionary ridge, which overlooked Chattanooga (*see* CHATTANOOGA, BATTLE OF) (Nov. 25). In his anxiety for Burnside's safety Grant ceased his pursuit of *Bragg's* retreating army (Nov. 28) and dispatched Sherman to Knoxville, where *Longstreet* was besieging Burnside. After failing in an assault upon the Federal works (Nov. 29), *Longstreet* raised the siege (Dec. 4) on Sherman's approach and retreated up the Holston valley. The greater part of east Tennessee was now in Federal hands.

V. MILITARY OPERATIONS, 1864–65

Halleck having failed during 18 months to co-ordinate from Washington the movements of the Federal armies, Grant was commissioned (March 9) lieutenant general, a grade revived by congress, and appointed general in chief to command in the field. Deeming his presence more urgently needed in the east, he attached himself to the army of the Potomac, retaining Meade in actual command. Sherman succeeded him in the west. The presidential election was due in November. The North was war-weary, and Lincoln's chance of re-election would be small unless speedy victory were in sight.

When the Republican or National Union party convention met in Baltimore it renominated Lincoln but found it expedient to add to the ticket a "war Democrat." Andrew Johnson of Tennessee. The Democrats late in the summer nominated General McClellan for president and George H. Pendleton of Ohio for vice-president. The Democratic platform called for immediate cessation of hostilities and the restoration of peace. Although McClellan repudiated this plank, his candidacy gained much from the antiwar sentiment in the North, which was promoted by the "copperheads" (*q.v.*).

1. Grant in the East. — Grant's was a policy of attrition, aiming at the exhaustion of the only two enemy armies of considerable size still in the field, *viz.*, *Lee's* in Virginia and *Johnston's* in Georgia, by concentrating against them all the force available. The objective for Meade's army was not Richmond, but *Lee's* army. Grant planned to force *Lee* out of his entrenchments behind the Rapidan and wear him down by continuous hammering. He could afford to lose two men to *Lee's* one, because southern manpower was nearly exhausted. But he also sought to create a diversion by threatening Richmond and its railway communications on both flanks. Columns were ordered to march on Staunton and Lynchburg, and then unite for a movement against Richmond; the army of the James was to advance up the south bank of the James river. But in allowing Butler to command this army, Grant made a grievous mistake. Butler, a criminal lawyer and influential politician, had shown no military capacity in his various commands, but he was a dangerous man to alienate in a presidential election year.

Grant crossed the Rapidan (May 4). After two days' battle in the Wilderness (*q.v.*) he moved by the left flank to Spotsylvania and continued this side-stepping maneuver until close to Richmond. But in these 40 days he never got *Lee* into the open. On the Po, North Anna and Totopotomoy rivers and at Cold Harbor he found *Lee* entrenched across his path. No diversion came from Butler, who missed the opportunity of capturing Bermuda Hundred

in the first week and was bottled up by *Beauregard* (May 16). The other subsidiary movement was nearly as unsuccessful.

Grant's defeat at Cold Harbor (June 3) cost him about 7,000 casualties to probably less than 1,500 for the Confederates. The three Federal corps (II, VI and XVIII) advanced through devastating frontal and enfilade fire and were stopped within a matter of minutes before reaching their objective. The battle represented one of the worst defeats suffered by the Union forces and is often cited as an example of poor generalship.

After Grant's defeat at Cold Harbor *Lee* detached *Jubal A. Early's* corps to save Lynchburg from David Hunter, who had already captured Staunton. Hunter retreated into West Virginia, leaving the Valley open to *Early*, who marched down it, crossed the Potomac, defeated a small force on the Monocacy (July 9) and appeared before Washington (July 11). Grant sent back one corps for the protection of the capital. But *Early* withdrew (July 12) and retired into the Valley, having given Washington and Baltimore a sudden fright, but without seriously deranging Grant's plans.

Grant's finest achievement was the transfer of his army across the Chickahominy and James rivers unopposed under *Lee's* nose (June 12–15), but he lost the chance of capturing Petersburg (June 15–18), which *Lee* was slow to reinforce (*see* PETERSBURG CAMPAIGN). The ensuing siege of Petersburg was trench warfare and a siege in name only, as *Lee's* army was never invested. Grant's aim was to extend his lines to his left so as to get possession of the railways from the south and southwest to Petersburg and Richmond, while making demonstrations on the north bank of the James and "feeling" the Richmond defenses. The fiasco of the "Burnside mine" (July 30)—when a mine was successfully exploded under a salient in the Confederate lines, but the assaulting troops, because of mismanagement, were repulsed with heavy loss—warned him against frontal attacks on *Lee's* lines around Petersburg. He secured a considerable section of the Weldon and Petersburg railway, but at the end of the year *Lee* still held the Petersburg and Lynchburg and Danville lines. The only Federal successes in the east this year were won by Gen. Philip H. Sheridan in the Shenandoah valley (*see* SHENANDOAH VALLEY CAMPAIGNS). Sent by Grant to drive out *Early*, he won three victories in a month (Sept. 19–Oct. 19) and completely devastated the Valley, which had become the granary of Richmond. Sheridan made excellent use of his cavalry during this campaign and defeated the Confederates in the engagements at Winchester, Fishers Hill and Tom's Brook. These victories, coupled with Sherman's capture of Atlanta (Sept. 2), secured Lincoln his overwhelming triumph over

General McClellan in the election of 1864.

2. Sherman in the West.—Sherman, with three armies under Thomas, James B. McPherson and John Schofield, confronted *Johnston*, who had taken command of *Bragg's* beaten army. The Richmond government had wished *Johnston* to effect a junction with *Longstreet* and invade middle Tennessee, but *Johnston*, finding his army in no condition to take the offensive, remained at Dalton, where he occupied a strong defensive position. Grant's instructions to Sherman were "to move against *Johnston's* army, to break it up and to get into the interior of the enemy's country as far as you can." Atlanta, *Johnston's* base, was at the junction of four important railways. In Sherman's words, it was "full of foundries, arsenals and machine-shops. Its capture would be the death-knell of the Confederacy." Eventually Sherman captured Atlanta but the Confederate army escaped. He had about the same superiority of numbers as Grant had, roughly 100,000 against 60,000, and was as far from Atlanta as Grant was from Richmond. But as compared with Grant he had one great disadvantage. He was practically tied to the railway and could not be continually shifting his base. Grant had intended that Banks should effect a diversion in Sherman's favour by a movement on Mobile in co-operation with Farragut's fleet. But Banks was not available, having previously gone up the Red river on an expedition primarily designed to bring out cotton.

The campaign opened on May 4. *Johnston's* policy was to delay Sherman's advance as much as possible, withdrawing from his successive positions before he could be drawn into a pitched battle except upon his own terms. He was prepared to fall back as far as Atlanta, which he regarded as impregnable, "too strong to be taken by assault and too extensive to be invested." Sherman's general plan of campaign was to keep Thomas' army in the centre to contain *Johnston's* army, for which it was in itself a match, and use the other two to turn his flanks. With McPherson's army he outflanked *Johnston's* left and forced him to evacuate Dalton (May 13) and Resaca (May 15).

In the comparatively open and rolling country between the Oostanula and the Etowah rivers *Johnston* expected to be able to make a stand and give battle, but his corps commanders dissuaded him. Retreating across the Etowah (May 20) he took up a strong position in the mountain pass at Allatoona.

By temporarily cutting loose from the railway and marching on Dallas, Sherman turned the Allatoona pass and by shifting McPherson over to the left flank gradually forced *Johnston* to contract his lines around Marietta (*q.v.*). Wishing to save his troops the fatigue of yet another flank movement over roads rendered

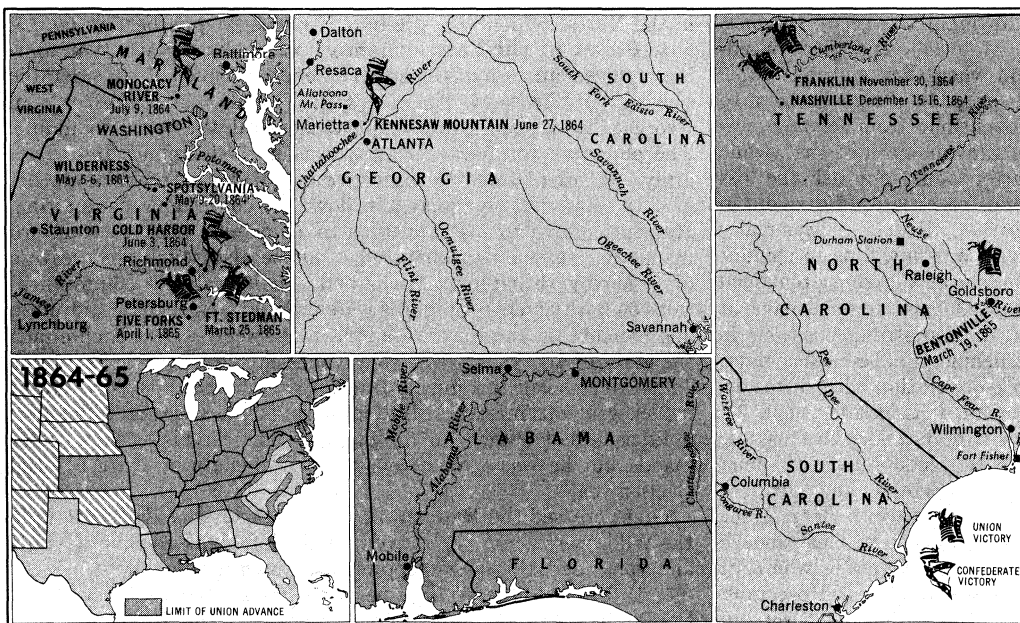

FIG. 5.—MAJOR BATTLES DURING 1864–65; BATTLES WITHOUT VICTORY FLAGS CONSIDERED INDECISIVE. INSET AT LOWER LEFT SHOWS APPROXIMATE AREA UNDER UNION CONTROL AT CLOSE OF THE WAR

almost impassable by continuous rain, Sherman attacked *Johnston's* lines on Kennesaw mountain (June 27), but was repulsed with heavy loss. Resuming the outflanking movement around *Johnston's* left he maneuvered him out of the Marietta position (July 2), and a week later *Johnston* withdrew his whole army behind the Chattahoochee, after Schofield had crossed above his right flank. Though in this protracted duel only the engagement at Kennesaw mountain ranks as a battle, skirmishing never ceased, often developing into hard fighting, especially during the operations around Dallas. During May and June Sherman's casualties amounted to about 17,000, and *Johnston's* were relatively, if not actually, greater. *Johnston* was preparing to fall upon Sherman's columns as they crossed the Peach Tree creek, the only natural obstacle between the Chatta-

GENERALS OF THE CONFEDERATE ARMY

1. R. E. Lee (1807-70), commander-in-chief of Confederate armies, February 1865. 2. James Longstreet (1821-1904), "General Lee's war horse." 3. J. E. Johnston (1807-91), as commander of the army of Tennessee, conducted the campaign against Sherman in Georgia until July 1864. 4. T. J. Jackson (1824-63) "Stonewall Jackson," Lee's chief subordinate. 5. J. B. Hood (1831-79), given command of the army of Tennessee, July 1864. 6. J. E. B. Stuart (1833-64), held a command in the

army of Northern Virginia. 7. J. A. Early (1816-94), in command in the Shenandoah valley, 1864-65. 8. A. S. Johnston (1803-62). (Photograph taken during his service in the United States army previous to the outbreak of the Civil War). 9. B. Bragg (1817-76), the commander of the Western Department, 1862-63. 10. P. G. Beauregard (1818-93), opened the war by bombardment of Fort Sumter

hoochee and Atlanta's northern defenses, when he was superseded by *John B Hood* (July 17).

Davis was tired of *Johnston's* Fabian tactics and believing that he would abandon Atlanta without a battle. put a fighting general in his place. *Hood* promptly fought three battles before the end of July, but was defeated in them all, and evacuated Atlanta (q v) (Sept 2). *Sherman* waited for *Hood's* next move. *Hood* crossed the Chattahoochee (Sept 29) and striking first at *Sherman's* communications marched to Gadsden, Ala, drauing *Sherman* in pursuit more than 100 mi. from Atlanta as far as Gaylesville (Oct. 20). When *Hood* moved still farther west to cross the Tennessee, *Sherman* started back to Atlanta to execute his long-cherished plan of marching through Georgia to the coast. He left *Thomas* to deal with *Hood*. But the force assigned to *Thomas* was barely sufficient for the purpose. In actual numbers superior to *Hood's* army, it was made up of widely separated commands; one corps was still in Missouri, and until its arrival at Nashville (Nov 30) *Thomas* can hardly be said to have had an army at all. *Sherman* could easily have spared another 12,000 men, and this addition to his strength would have made *Thomas's* position absolutely safe.

Hood's plan nas to destroy *Thomas's* forces before they could concentrate, capture Nashville, invade Kentucky, threaten Cincinnati and then march through east Tennessee to join *Lee*. But a three weeks' delay at Florence to collect supplies proved fatal. *Schofield* with 23,000 men had time to take position at Pulaski and delay his advance while *Thomas* was concentrating his other forces at Nashville. Having failed to envelop *Schofield* on the Duck river. *Hood* attacked him furiously but unsuccessfully at Franklin (Nov. 30) and appeared before Nashville (Dec. 2). In spite of the severity of his losses and the fact that he was confronted by an army superior to his own. *Hood* was still bent on retaining the offensive and detached his cavalry against the Federal lines of communication. He remained before Nashville in the vain hope of receiving reinforcements promised from Texas, until *Thomas* marched out and defeated him in one of the most decisive battles of the war (Dec. 15-16). *Hood* escaped over the Tennessee, but his army as a fighting force practically ceased to exist.

Sherman started from Atlanta (Nov. 15) on his 300-mi. march with 60,000 men and without encountering any organized resistance reached the outskirts of Savannah (Dec. 10), feeding his army off the country. His purpose was to demonstrate "the hollowness" of the Confederacy and by ruining the railway system of Georgia, now the granary of the South, prevent food reaching Richmond. Georgia was left undefended except by *Joseph Wheeler's* cavalry and the state militia. *Sherman*, having destroyed 160 mi. of the Georgia Central railway, established communication with the fleet in Ossabaw sound. Savannah was evacuated (Dec. 20). *Sherman* was now free to join *Grant* by sea or land.

Though the Confederates still held Mobile, its value as a port was gone. *Farragut* had forced an entrance into the bay (Xug. 5) and captured the forts guarding the harbour mouth. Only in the trans-Mississippi region had the Confederates gained any success. *Bank's* Red River expedition proved a complete failure and he retreated to New Orleans. But the Federals retained their hold upon northern Arkansas, including Little Rock, the state capital. *Price* made a last raid into Missouri in September and October.

3. Collapse of the Confederacy. — In the early months of 1865 Richmond's fall was near at hand. *Grant's* next advance would plant him on the Petersburg and Lynchburg railway. *Lee* did not have sufficient troops to hold a further extension of his lines. Desertion was thinning his ranks; conscription had broken down. Wilmington, the last Confederate port, was closed by the capture of Ft Fisher (Jan. 15). A peace conference held in Hampton Roads failed (Feb. 3) because *Davis* still insisted on the recognition of southern independence. Congress forced *Davis* to appoint *Lee* (Feb 9) commander in chief of all the Confederate forces. But this step came too late; *Lee* could only appoint *Johnston* to command such troops as could be mustered to meet *Sherman*. For *Grant*, having decided that to the army of the Potomac should fall the honour of capturing Richmond, ordered *Sherman* to march up through the Carolinas. To provide him with a base on the coast,

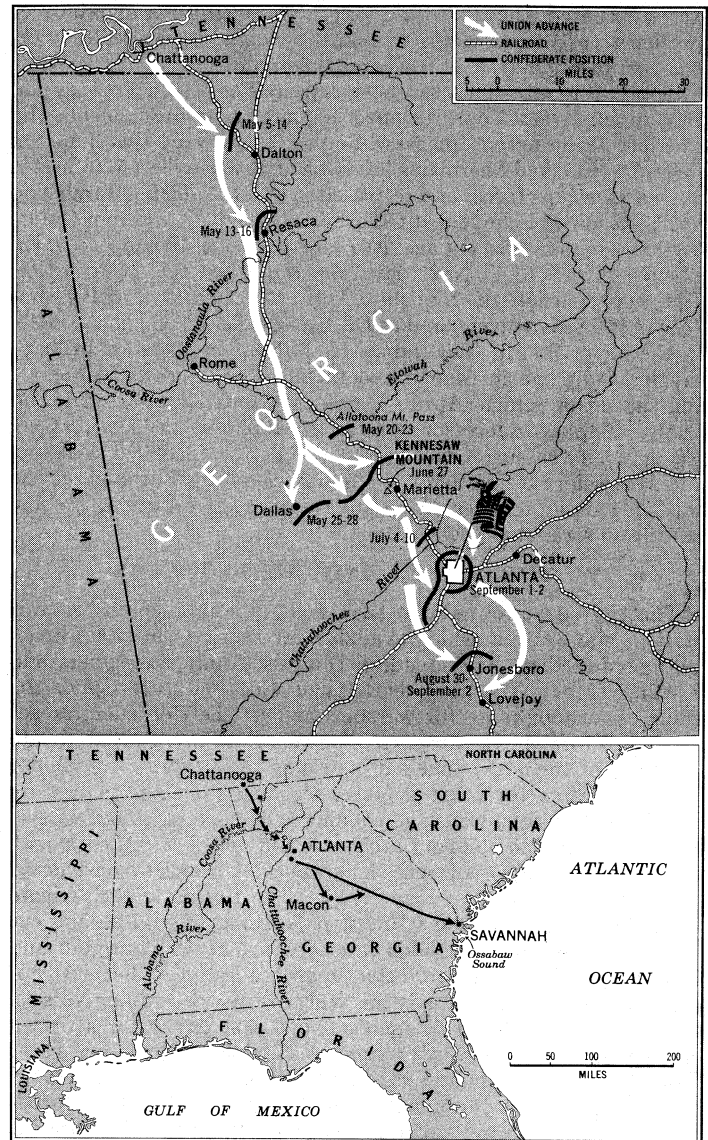

FIG 6.—GENERAL SHERMAN'S INVASION OF GEORGIA 1864 (TOP) UNION ADVANCE ON ATLANTA. SHOWING MAJOR MILITARY ENCOUNTERS, (BOTTOM) GENERAL LINE OF ADVANCE OF ENTIRE GEORGIAN INVASION, SOMETIMES REFERRED TO AS SHERMAN'S "MARCH TO THE SEA"

Grant brought *Schofield* from Nashville to North Carolina to capture Wilmington. *Sheridan* with 10,000 cavalry moved from the Valley to White House (March 19) in time for *Grant's* next advance. *Lee* had determined to withdraw his army to Danville and effect a junction with *Johnston* against *Sherman*. But his artillery horses and transport animals were in no condition for hard work, until the roads improved. To prevent *Grant* extending to the left, *Lee* attempted a diversion by attacking Ft. Stedman (March 25) on the right of the Federal lines. After the repulse of this sortie *Grant* ordered a general advance by the left flank. *Sheridan's* victory at Five Forks (April 1), beyond the extreme right of *Lee's* lines, where with his cavalry and Gouverneur K. Warren's corps he defeated *Pickett's* division and *Fitzhugh Lee's* cavalry, gave the Federals possession of the Petersburg and Lynchburg railway. Next morning *Grant* broke through *Lee's* lines on a broad front, driving him back into the suburbs of Petersburg. That night *Lee* commenced his retreat. Richmond surrendered on April 3. *Lee*, having been forced by *Sheridan* from the Danville road to the north bank of the Appomattox, surrendered on April 9.

Sherman advanced (Feb. 1) and occupied Columbia (Feb. 17). A large area of the city nas burned. whether by Federals or Confederates or by accident has never been determined. Charleston

was evacuated the following day. Although the march over swollen rivers and swamps was most arduous, Fayetteville, N.C., was occupied (March 11), where communication was established with Wilmington, which had been captured on Feb. 22. Sherman now aimed at Goldsboro to effect a junction with Schofield, who had left Wilmington for New Bern. To prevent this junction *Johnston* attacked Sherman's left wing at Bentonville (March 19), but withdrew his forces and retreated to cover Raleigh (March 21). Sherman joined Schofield at Goldsboro (March 23). From Goldsboro Sherman moved out against *Johnston* (April 10) and occupied Raleigh (April 13). Next day *Johnston* asked for an armistice. The assassination of Lincoln (April 14) caused a delay, but *Johnston* finally surrendered at Durham Station, N.C., on April 26. In the lower South, Gen. James H. Wilson conducted a brilliant cavalry campaign in Alabama, defeating Gen. *Nathan B. Forrest* and capturing Selma (April 2), the last Confederate arsenal, and Canby, Banks's successor, captured Mobile (April 12). Gen. *Richard Taylor* surrendered the Confederate forces in Alabama and Mississippi to him (May 4), and *Kirby-Smith* surrendered the trans-Mississippi forces (May 26). *Davis* was captured by some of Wilson's cavalry (May 10).

VI. THE NAVIES AND THE BLOCKADE

The United States navy in 1861 was quite unprepared for war. Half of the 34 steamships available for service were on foreign stations and the home squadron comprised only 7 steamers and 5 sailing ships. The navy department was slow to recognize the value of armour plate for warships and let the Confederates get the start with the "*Merrimack*." *Stephen R. Mallory*, Confederate secretary of the navy, aimed at providing three types of warships: armoured rams for coast defense, seagoing ironclads to destroy the blockading squadrons and commerce destroyers. The last two classes he hoped to build or purchase in Europe. The "*Merrimack*" and the "Monitor" represented the types of ironclad constructed by the two combatants respectively. The former, a U.S. frigate which had been fired and scuttled at Norfolk, was raised and cut down to a ram with a wooden casemate, protected by armour and carrying ten heavy guns, erected upon her hull. At her first appearance in Hampton Roads she sank two wooden sailing vessels, the "Cumberland" and "Congress," but next day, after a drawn battle with the "Monitor," retired to Norfolk. Altogether 12 of these ironclads were constructed, but the weakness of their engines rendered them less formidable than was expected. The Confederates, unable to build engines in their workshops, had to use for their ironclads either the old ones or those they took out of other steamers. The main features of the "Monitor," designed by John Ericsson to counter the "*Merrimack*," were the revolving turret, the low freeboard and the projecting overhang. She drew less water and was more easily handled. The Federals built a large number of monitors, which, though more than a match for the rams, were comparatively ineffective against forts, as was proved by the failure of the naval attack on the Charleston forts (April 7, 1863). The river ironclads, which fought in the waters of the west, were gunboats constructed by James B. Eads with a partially armoured casemate. To the original nine, five more were added in 1863, more heavily armoured and powerfully armed. Three single-turret ironclads of light draught were specially constructed for the Red River expedition.

Two powerful ironclads were built in England for the Confederates, but the British government kept them from sailing. One ironclad built in France passed into southern hands, but reached Havana too late to take part in the war. Three commerce destroyers built or purchased in England did great damage to the Federal mercantile marine. Having auxiliary sail power they could economize on coal. The "*Alabama*," during her 22 months' cruise, never put into a Confederate port. She captured 68 prizes in the Atlantic, Indian ocean and China sea, sank the Hatteras gunboat off Galveston but was herself sunk off Cherbourg, France, by the sloop of war "Kearsarge" (June 19, 1864). The "*Shenandoah's*" objective was the whaling fleet in the North Pacific, which she destroyed (June 1865), having no official news that the war was over. The "*Florida*" raided northern commerce from 1862 to

1864, when she was captured and sunk. The Geneva arbitration (1872) found Great Britain responsible for the losses inflicted by these three cruisers to the amount of \$15,500,000. (See "ALABAMA" ARBITRATION.)

The Federal navy concentrated upon blockading the seven principal southern ports. Lincoln had proclaimed a blockade of the southern coast on April 19, 1861. But for many months it was little more than nominal for lack of ships to enforce it. An attempt to close Charleston harbour by sinking stone-laden hulks in the entrance proved a failure. Not until the middle of 1862 could the blockade be regarded as even moderately effective. Then with the export of cotton at last unrestricted and an increasing demand in the English market, vessels specially adapted for blockade-running were built in the English shipyards, and in spite of the Federal navy blockade-running only ceased to be a profitable speculation when the ports were actually in Federal hands. Savannah had been practically closed since the capture of Ft. Pulaski (Dec. 12, 1862). The loss of Charleston and Wilmington left the Confederacy without an Atlantic port, and reduced the armies of *Lee* and *Johnston* to a state of destitution.

VII. CONCLUDING OBSERVATIONS ON MILITARY ASPECTS

The collapse of the Confederacy was so sudden and complete that it took Europe by surprise. Sherman's "march to the sea" first opened foreign eyes to the probability of southern defeat. But as early as 1863, when *Lee* had suffered defeat at Gettysburg and *Bragg* had finally lost Chattanooga, and the Federals had recovered the Mississippi between Vicksburg and Port Hudson, ultimate defeat stared the Confederacy in the face. The sole remaining hope was that the North, through sheer mar-weariness, might throw away the victory already won. When it appeared that Grant had been fought to a standstill by *Lee* around Richmond in the summer of 1864, and when *Johnston's* army remained still unbeaten between Sherman and Atlanta, the North very nearly reached the limit of its endurance. The Democrats put forward a program, the first article of which pronounced the war a failure. Lincoln despaired of re-election. But the fall of Atlanta and *Sheridan's* triple victory over *Early* in the Valley came in time to turn the scale in favour of the government. Gradually, too, the significance of Grant's position in front of Petersburg came to be realized. *Lee* had lost the power to maneuver when he was shut up in Richmond and Petersburg, and could not force Grant to relax his hold. Yet once more the North was filled with alarm when *Hood* crossed the Tennessee and, with Sherman far away in Georgia, threatened an invasion of Kentucky. Grant himself was on his way to take command at Nashville when he heard the news of Thomas' crowning victory. Sherman could now present Lincoln with Savannah as a Christmas gift, and the one organized army of the Confederacy in the nest was definitely broken up.

The South made a great mistake during the first winter of the war, when the North was organizing its military strength and the Confederates took no countermeasures. Their government, counting on European recognition to be followed by peace, left *A. S. Johnston* in the west with an entirely inadequate force to hold Kentucky and Tennessee. At the first onset the Federals broke through his line of defense; his counterstroke failed; Kentucky and a great part of Tennessee were permanently lost; New Orleans fell; and the Federals gained control of great stretches of the Mississippi. Then the Confederate government awoke from its dream. The first Conscription act (April 1862) retained in service the 148 regiments of one-year volunteers and by encouraging voluntary enlistment enabled *Lee* to save Richmond, but the ground lost in the west was never recovered.

The Confederacy had one inherent weakness. It was composed of sovereign states, which would temporarily sacrifice their "state rights" for the success of their revolution, but demanded that the central government should provide for their protection, and if it failed in that duty, would take their own measures for self-defense. The state governors were always a thorn in *Davis's* side. From the first they required delicate handling and, when things began to go wrong, became refractory. This state patriotism combined

with geographical conditions to isolate the different sections of the country and prevented the Confederates from taking proper advantage of their "interior lines." Only once did troops from the trans-Mississippi region come to the aid of their countrymen on the other side of the river. *Van Dorn* moved from Arkansas to *Beauregard's* aid at Corinth, but his men were very reluctant to cross the river, and it is significant that no attempt was made to bring reinforcements to Vicksburg in 1863 from that department. Only once were considerable reinforcements sent from the east to the west, when *Longstreet* with two divisions was sent to *Bragg's* aid, and the victory of Chickamauga (*q.v.*) was the result.

The west was the really decisive theatre of war. In the east *Lee's* victories did not alter the strategical position. The end of each campaign found the army of the Potomac on the Rappahannock, still menacing Richmond. But the fall of Vicksburg cut the Confederacy in two; the loss of the food supplies, especially cattle, from across the Mississippi was sorely felt, and the capture of Chattanooga and Knoxville not only cut off another section of territory, but opened the way to Georgia, the granary of the South. That *Lee's* and *Johnston's* armies were reduced to starvation was due to the loss of Georgia's supplies. Grant indeed captured Richmond and *See's* army, but had he chosen he might have brought Sherman's army by sea from Savannah to the James, and it could have been there two months before he began his final move.

In final analysis the North's naval superiority must be reckoned a decisive factor. It made possible the conquest of the Mississippi and Sherman's march through Georgia. The capture of New Bern by the Burnside expedition (March 1862) provided the Federal land forces with a base from which they could threaten an advance on Richmond, and caused the permanent retention in North Carolina of a considerable Confederate force which might have been profitably employed elsewhere, notably at the time of *Lee's* invasion of Pennsylvania. The blockade threw the South upon its own resources, which proved inadequate, especially in the matter of munitions of war and medical stores. It was not lack of food, but the difficulty of transport that reduced the Confederate armies to the verge of starvation. The southern railways were not equal to the strain of a four years' war. The rolling stock could not be replaced when worn out or the permanent way kept in working order as a result of the lack of iron rails.

VIII. POLITICS, ECONOMICS AND FOREIGN AFFAIRS

1. Northern Politics. — The military events of the war were played out against a background of political affairs, and politics influenced many military decisions. The Republican party had little internal unity. It was a composite of state parties with varying interests. There were elements of the old Whig party, former Free-Soilers and Liberty party men, Anti-Nebraska Democrats, free-trade nesterners and Pennsylvanians a-ho advocated a high protective tariff. The Democratic party, disrupted by internal dissensions, had still considerable strength in the states and in the federal congress. The firing on Ft. Sumter brought momentary unity to the Republicans, and sharpened division of the Democrats into two groups. War Democrats supported the administration in prosecuting the war, while peace Democrats continued to demand a negotiated peace and opposed conscription, arbitrary arrests, the suspension of habeas corpus and financial measures designed to support the war. Lincoln used patronage to create unity, and gave civil and military appointments to the war Democrats.

Factional divisions soon developed among the Republicans: a moderate group was content to follow Lincoln and prosecute the war in order to restore the Union, while "radical" Republicans enlisting the support of the old abolitionists, were determined to destroy slavery, punish the South, and reorder southern economic life for the benefit of northern industrial and financial interests. A congressional committee on the conduct of the war, dominated by the radicals, investigated and harassed Democratic generals, and became the fountainhead of propaganda demanding vigorous prosecution of the war, complete subjugation of the South, emancipation of slaves and eventually, enfranchisement of the freedmen and punishment of rebels. The committee waged a persistent

warfare against McClellan, a Democrat, and was largely responsible for his eventual removal. Closely allied to the committee were Secretary of the Treasury Salmon P. Chase and Secretary of War Edwin M. Stanton.

From the beginning Lincoln faced problems in handling the government. Congress was not in session when Ft. Sumter was fired on and Lincoln proceeded without immediate congressional sanction to call for troops, to increase the size of the navy and to authorize the enlistment of volunteers. He gave support to the Unionist faction in western Virginia, which was moving toward the creation of a new state; he suspended the writ of habeas corpus in Maryland and other places where dangerous disaffection developed. When congress assembled in July, it approved his actions.

More troublesome were the problems growing out of slavery. Lincoln insisted that he waged the war only for the preservation of the Union, and the day after the battle of Bull Run, congress declared that the federal government had no intention of interfering with slavery. However, fugitive slaves escaping into Union lines constituted a continuing problem for commanders in the field, some of whom returned them to their masters. In Virginia, however, Gen. B. F. Butler declared them "contraband of war" and put them to work on fortifications. In Missouri Gen. J. C. Frémont issued a proclamation confiscating the property of rebel sympathizers, declaring their slaves free. Since Lincoln believed this action would jeopardize the Unionist cause in Kentucky, he rescinded the order and removed Frémont. Radical Republicans denounced Lincoln and demanded an emancipation proclamation, but Lincoln countered with proposals for compensated emancipation in the loyal states. Congress provided for compensated emancipation in the District of Columbia, but not in the border states. In Aug. 1861 and July 1862 acts confiscating the property of rebels provided for freeing the slaves so expropriated. Radicals continued their pressure to make emancipation a war aim, and the movement was strengthened by the desire to use Negro soldiers in the northern armies. Lincoln resisted the pressure. In July 1862 he discussed an emancipation proclamation with his cabinet but determined to wait until a Federal victory furnished a propitious occasion. Late in August he asserted, replying to an editorial in the *New York Tribune*, "My paramount object in this struggle is to save the Union, and is not either to save or to destroy slavery. . . . What I do about slavery and the colored race, I do because I believe it helps save the Union, and what I forbear I forbear because I do not believe it would help save the Union." Within a month of this statement, however, two events hastened the announcement of a preliminary emancipation proclamation. One was the repulse of *Lee* at Antietam, and the other the assembling of northern governors at Altoona, Pa., where they were planning to demand emancipation and the use of Negro soldiers. On the eve of the governors' conference Lincoln issued the proclamation which effectively forestalled the governors' demand but changed the purpose of the war from the preservation of the Union to the emancipation of the slaves. The proclamation itself (issued Sept. 22, 1862, to take effect on Jan. 1, 1863) had no immediate effect, for it applied only to states that were in rebellion and therefore beyond Federal control. Lincoln continued to urge compensation for loyal masters. Slavery was not abolished until congress adopted the 13th amendment to the constitution and sent it to the states to be ratified. It was ratified and proclaimed in Dec. 1865.

The Emancipation Proclamation, arbitrary arrests and limited military success had political reactions, and in the state and congressional elections of 1862 Democrats gained strength. The regular Democrats took courage and began opposing the administration with increasing vigour. Seizing upon the arbitrary acts of the government, the Democrats proclaimed themselves the defenders of liberty and wore copper one-cent pieces which bore "liberty heads" to signify their position. Republicans vigorously denounced the "copperheads" (*q.v.*) and encouraged the formation of Union leagues, which carried on a consistent campaign for the "true" Republican principles of the radicals. In 1863, C. L. Vallandigham (*q.v.*) campaigned for governor of Ohio with copperhead support. General Burnside arrested him and a military

commission sentenced him to imprisonment. Lincoln commuted the sentence to banishment to the Confederacy, but Vallandigham made his way to Canada and continued his campaign. Ohio troops suppressed disorders on election day and Republicans retained control of the state.

By the election of 1864 Lincoln had sufficient strength in his party to secure his renomination. Radicals, however, nominated Frémont, and for a time threatened to split the party. Democrats were seriously divided. They nominated General McClellan, but he repudiated their platform, which declared the war a failure. Negotiations resulted in Frémont's withdrawal and the fall of Atlanta contributed to Republican success. Lincoln won reelection by a vote of 212 to 21 in the electoral college.

2. Confederate Politics.—In the Confederacy, as in the North, there was a constant interaction of civil and military affairs. The Confederate constitution differed little from that of the United States, but there were distinct differences in the organization of political parties. *Davis* was not the choice of a party for the presidency, and there was no organized national party of opposition. There were, however, serious differences of opinion on policy and resulting factionalism. Fundamentally, the conflicts involved the issue of state rights as opposed to southern nationalism. *Davis* attempted to create a national army and administration, but met the opposition of state politicians who represented state interests. The issue became apparent on the question of conscription, which the governors of Georgia and North Carolina, with the support of Vice-Pres. *Alexander H. Stevens*, considered an invasion of state rights. In congress a faction opposing *Davis* questioned his judgment in conducting the war and singled out Secretary of State *Judah P. Benjamin* as the object of repeated attacks. Other matters that caused difficulty were taxation, loans and attempts of the government to fix prices. In 1863 opponents of *Davis* won control of congress and most of the state governments were unco-operative. The result of the declining popularity of *Davis* was lowered morale both in and out of the Confederate armies. Even before the final military campaigns began, the Confederacy, rent by internal divisions, had lost the will to fight.

3. Economics of the War.—In the final analysis, the North's victory was the result of its industrial and financial power. Essentially the conflict was between two different economic societies, and the northern economy proved better able to sustain itself in every way. In actual money the United States spent about \$5,000,000,000, while the Confederacy spent about \$3,000,000,000. On both sides the war effort was financed by taxation, loans and the issue of paper money. Northern customs duties provided revenue, and successive tariff acts raised duties to 47%, the highest in the history of the country. An internal revenue act of 1862 imposed taxes on thousands of items. The income tax was first used in 1861. Loans, however, provided the greater part of the cost, while legal tender notes, inflating the currency, met immediate and pressing expenses. Partly to facilitate the sale of bonds and partly to destroy the confusing system of state banking, the National Bank act of 1863 was passed, creating a new national system of banking. In the Confederacy the government soon exhausted the available credit for its bonds and early resorted to paper money and inflation. When the declining value of currency brought hardship, the government levied a tax in kind to raise supplies.

In the North the financing of the war was accompanied by a series of acts that brought far-reaching economic changes in the nation. The Homestead act of 1862 gave western lands to actual settlers; the Morrill act in the same year made provision for establishing agricultural colleges; extensive grants of bonds and lands were given to aid the construction of railroad lines to the Pacific. Industrial development was stimulated by war contracts, by new sources of raw materials and by the widespread use of agricultural machinery. While the inhabitants of the Confederacy suffered from the exhaustion of their accumulations and severe shortages in supplies of every description, the people of the North generally enjoyed an unprecedented prosperity.

4. Foreign Affairs.—The Confederates, with a weak financial system, placed too much reliance on European aid, which they hoped to influence by controlling cotton. The Confederate govern-

ment expected recognition of its independence, and there was much sympathy for the southern cause in England and France. Early developments, in fact, seemed to presage aid from Europe. The United States was irritated when Queen Victoria, taking advantage of Lincoln's proclamation of a blockade of the southern ports, issued a proclamation recognizing the belligerent status of the Confederacy. A few months later a U.S. warship seized two Confederate emissaries, *James M. Mason* and *John Slidell*, from a British mail ship; the "Trent," and the incident threatened to cause a break in diplomatic relations. The good judgment of President Lincoln and of the Prince consort, Albert, calmed excitement! and the United States eventually surrendered *Mason* and *Slidell*. *Mason* made no headway in England, though he established a newspaper, the *Index*, and furnished aid and encouragement to Confederate sympathizers. The U.S. ambassador, Charles Francis Adams, watched carefully lest England give aid to the Confederates. He was unable to prevent the sailing of commerce destroyers from British ports, but he succeeded in stopping ironclad rams, being built in the Laird shipyards, from putting to sea. In France, *Slidell* was better received by Napoleon III, and a Confederate loan, supported by promises of payment in cotton, was floated on the Paris market. Despite widespread sympathy, however, the French did not recognize the Confederate government and gave it only sporadic, nongovernmental aid. (eds.), *War of the Rebellion: a Compilation of the Official Records of the Union and Confederate Armies*, 130 vol. (1880-1901). (W. B. Wo.; W. B. He.)

AMERICAN COLLEGE OF PHYSICIANS, founded in 1915, is an organization of specialists in internal medicine, including pediatricians, psychiatrists, neurologists, bacteriologists, pathologists, dermatologists, roentgenologists, medical teachers and investigators, tuberculosis and public health specialists. Its purposes are: (1) to maintain and advance standards in medical education, medical practice and clinical research; (2) to perpetuate the history and best tradition of medicine and medical ethics; and (3) to maintain both the dignity and efficiency of internal medicine in its relation to public welfare. Members are elected from all parts of North America.

Activities and functions of the college include the following meetings: an annual session; postgraduate courses held at several different medical schools each year; and approximately 30 regional meetings in as many states each year. The college publishes the *Annals of Internal Medicine*, a scientific journal; the *Bulletin*, a news magazine concerning the members; and a directory of membership. To promote medical education the college sponsors research fellowships, loan funds for young men in training and, in association with the W. K. Kellogg foundation, Latin-American fellowships. In maintaining high standards of medical practice the organization participates with other medical organizations in the Joint Commission on Accreditation of Hospitals and the Joint Commission on Professional and Hospital Activities. Headquarters are in Philadelphia, Pa. (E. R. LD.)

AMERICAN COLLEGE OF SURGEONS was organized in 1913 by leading surgeons of the United States and Canada. It is the largest and most active surgical organization in the world, having by 1960 more than 23,500 fellows in 70 countries. The college is dedicated solely to improvement of the care of the surgical patient, which purpose it fulfills through postgraduate edu-

cation of surgeons, accreditation of various agencies in the field of medical care, financial support of research in surgery, enforcement of ethical principles in the relationship of its fellows with patients and co-operation with other national and international agencies in programs of public welfare.

The college furthers postgraduate education of surgeons by means of scientific meetings, five or six each year, at which programs of the latest developments in surgery are presented; by a library of medical motion pictures which are made available to professional groups; by a program for proper care of injured patients, which includes training of nonmedical persons such as policemen, firemen and ambulance attendants. It is one of four organizations composing the Joint Commission on Accreditation of Hospitals (founded by the college in 1917) which greatly elevated the standard of hospitals in the United States and Canada. The college is the sole agency in the United States which surveys and approves cancer programs which meet certain minimum standards for diagnosis and treatment of cancer. The cancer control program is supported in part by grants from the National Cancer Institute and the American Cancer Society. One of the major efforts of the college is toward the elevation of moral and ethical standards in dealing with surgical patients; it has conducted public campaigns against such practices as buying and selling of patients, unjustified surgical operations, ghost surgery and the charging of exorbitant fees. The college publishes *Surgery, Gynecology and Obstetrics*; the *Bulletin*, devoted to information to the fellowship; and a triennial *Directory of Fellowship*, with supplements in the intervening years. (P. R. Hy.)

AMERICAN COLONIES (U.S.). Thirteen English colonies were established in the area that is now a part of the United States during the 17th and early 18th centuries. They grew both geographically and numerically from the time of their founding to the American Revolution (1776-83). Their settlements had spread far beyond the Appalachians and extended from Maine in the north to the Altamaha river in the south when the Revolution began, and there were at that time about 2,500,000 Americans. Despite the fact that they had been, and still were, much occupied with physical tasks, they had also progressed culturally.

The colonists were remarkably prolific. Economic opportunity, especially in the form of readily available land, encouraged early marriages and large families. Bachelors and spinsters could not live very comfortably, and were relatively few; widows and widowers needed partners to maintain homes and rear children, and so remarried quickly. The social diseases were less common in America than in Europe; divorce was almost unknown; and birth control was seldom practiced. Accordingly, most adults were married, children were numerous and families containing ten or more were common. Despite heavy losses by disease and hardship, the colonists multiplied. Their numbers were also greatly increased by continuing immigration from Great Britain and from that part of Europe west of the Elbe river, for in England and in Europe the colonies were looked upon as a land of promise. Moreover, both the mother country and the colonies encouraged immigration, offering inducements to those who would venture beyond the ocean. They particularly welcomed foreign Protestants. In addition, many were sent to America against their will—convicts, political prisoners and Negroes. The American population doubled every generation.

In the 17th century the principal element in the colonies was English; the second largest was formed by the Negroes. German and Scotch-Irish immigrants arrived in large numbers during the 18th century. Other important contributions to the colonial bloodstock were made by the Netherlands, Scotland and France. New England was almost entirely English; in the southern colonies the English were the most numerous of the settlers of European origin; in the middle colonies the population was much mixed, but even Pennsylvania had more British than German settlers. Except in Dutch and German enclaves, which diminished with the passage of time, the English language was used everywhere and English culture prevailed. The "melting pot" began to boil in the colonial period, so effectively that Gov. William Livingston, three-quarters Dutch and one-quarter Scottish, described himself as an Anglo-

Saxon. As the other elements mingled with the English, they became increasingly like them; however, all tended to become different from the inhabitants of "the old country" and to become American. By 1763 the word "American" was commonly used on both sides of the Atlantic to designate the people of the thirteen colonies.

While life was hard for the early settlers and for all those who made their homes on the frontier, the colonists generally lived in increasing comfort, by the European standards of their time. The log cabins of the middle and southern colonies were gradually replaced by sturdy and attractive homes of wood or brick; clapboard houses superseded the huts of the first settlers in New England; and many mansions appeared before 1776. Food was relatively abundant and varied, the products of tillage being generously supplemented by rich fisheries and plentiful game. Wines, sugar, coffee, tea and spices were eventually imported in quantity. Clothing was substantial, and that of the well-to-do became fine, being imported from England, although common folk continued to wear linsey-woolsey and buckskin. More leisure time became available, notably for wealthy planters, merchants and lawyers.

Social gradations were brought from England and existed in the colonies from the beginning. In 17th-century New England, for example, the gentleman was distinguished from the goodman. During the 18th century there was an American aristocracy based on the possession of land and slaves in the southern colonies, on the ownership of land and success in commerce in the middle and northern colonies. To this aristocracy belonged families such as the Rutledges and Pinckneys of South Carolina, the Randolphs and Lees of Virginia, the Livingstons and Schuylers of New York, and the Saltonstalls and Vassalls of Massachusetts. Hereditary titles were uncommon, and this aristocracy was gentry rather than nobility. Social distinctions became sharper as one moved from north to south, wealth being much more evenly divided in New England than it was in the plantation areas of the Chesapeake bay region and the low country of the Carolinas and Georgia. Most of the American aristocrats were of middle-class origins; few were descended from great English or European families.

The typical American was a landowning farmer. With him in the middle of society were mechanics, artisans, shopkeepers, teachers and other professional folk. The south already had its "poor whites," not yet called so; similar people were not unknown above the Mason and Dixon line. A special group of whites which did not endure was that of the bond servants, persons who contracted to work for a master for a period of years in return for passage money from Europe. Some of them were convicts who had chosen transportation to America in lieu of execution in England. It is likely that a majority of the colonists began their lives in the new world as servants of one sort and another. At the bottom of the social scale were the Negroes, who, in the 18th century, numbered about 20% of the whole; Negroes were most numerous in the southern colonies, forming about 40% of the population of Virginia and about half that of South Carolina. They were principally employed in field labour but some performed household duties. Almost all of them were slaves, although the first Negroes brought to Virginia were technically servants.

The colonists were generally Protestant, either by church affiliation or tradition. Roman Catholics were few, even in Maryland, which was founded in some part as a haven for them. Here and there were Sephardic Jews, notably at New York, where a synagogue was founded as early as 1653. Although scholars frequently say that the percentage of Protestant Church membership in the American population has greatly increased since the colonial time, Protestantism was relatively stronger in America during the colonial period than later. In colonial days it was much more difficult than afterward to secure and to retain church membership, and backwoods people found it hard even to attend services. We may safely assume that tens of thousands whose names were not on church registers were Protestants sufficiently orthodox, and it is clear enough that the clergymen were more influential than afterward, although they had lost much of the power they had exercised in 17th-century New England. As the Revolution approached, the Congregational Church was dominant and was officially established

throughout New England, except in Rhode Island. The Anglican Church was established in all the colonies from Maryland southward, and also in three counties of New York. However, the Anglican Church probably did not have the allegiance of a majority of the people in any colony. Presbyterians were numerous in the middle and southern colonies, and Baptists were to be found everywhere. The Friends (or Quakers) and various sects of German origin were important in Pennsylvania, as was the Dutch Reformed Church in New York and New Jersey.

In the 18th century, the orthodox churches were threatened and weakened in several ways. The Anglican Church, frowning upon "enthusiasm" and not very aggressive, lost attractiveness for many who desired fervour rather than cerebral exercise. The Puritan Churches of New England, with their appeals to Biblical Law and logic, also suffered because they failed to offer a sufficiently emotional type of Christianity. The scholars of the Presbyterian pulpits similarly lost favour. In the Great Awakening of the 1740s and 1750s, in which even the distinguished Rev. Jonathan Edwards (*q.v.*) briefly participated, evangelism and emotional piety flourished, especially in the interior settlements. The orthodox churches were also attacked from a very different quarter, from the world of science. Some intellectuals, considering the universe in the light of Newtonian science, turned toward deism, trying to find the Creator through the laws of Nature rather than the revelations of the Scriptures. Others were satisfied with Unitarianism. The greater prosperity and security which the colonists enjoyed in the 18th century, pushing hardship and death away, lessened the terrors of the afterlife and encouraged doctrinal heresy. Orthodox Congregationalists founded Yale in 1701 because they believed Harvard had become heretical. It should be said, however, that American Christianity was altered rather than vitally weakened. Puritanism, in New England and also in the middle and southern colonies, continued to be a mighty force. On the other hand, the way was opening for the substantial separation of church and state and for a greater religious freedom. Discrimination on the score of religion existed in every colony in greater or lesser degree but was substantially ended during the Revolutionary period.

The rise of more liberal views regarding religion in the colonies was accompanied by and was in some part based upon a wider diffusion of knowledge, achieved principally through schools. It is well known that New England—except for Rhode Island—early took the lead in education and long held it both in quality and quantity. Massachusetts was in the forefront, its general court by a law of 1642 requiring every town to see to it that its children were taught to read. Another more important and famous statute of 1647 ordered every town containing 50 or more families to hire a master to teach children to read and write, or to pay a fine of five pounds. While many towns chose to pay the fine rather than to found a school, elementary instruction became widely available in Massachusetts. In 1647 the general court also called for the establishment of a Latin grammar school, and in the 18th century provided for several academies which gave instruction on the secondary level. Harvard college was founded in 1636, primarily to train clergymen. The example of Massachusetts was substantially followed in Connecticut and New Hampshire. The ability to read and write was fairly common, at least among men, in New England at the close of the colonial period. By that time four colleges had been founded east of the Hudson; in addition to Harvard and Yale, Brown was established as Rhode Island college in 1764, and Dartmouth as a school for Indian and white boys in 1769.

The need for education was recognized also in the middle and southern colonies. The Dutch and the Scotch-Irish, like the Puritans, were fond of learning. The Quakers were at first opposed to education on the grounds that it had a corrupting influence. Although there were public schools in New Ketherland, reliance for elementary instruction in the middle colonies was placed in private schools, which were rather numerous. A few secondary institutions also sprang up, including the Philadelphia academy which later became the University of Pennsylvania. Princeton university appeared as the College of New Jersey in 1746, Columbia as King's

college eight years later and Rutgers university as Queen's college in 1766. Less active in the field of education were the southern colonies, although the College of William and Mary was established in 1693, eight years before Yale. A few public elementary schools appeared, and many private schools. Secondary education was reserved for young men of wealthy families that could afford to hire tutors or to send their sons to public schools in England. Such young men also attended the College of William and Mary, the College of New Jersey, and British and European universities. Illiteracy was somewhat more common in the south than elsewhere. The Negroes were not ordinarily allowed to learn to read and write.

The diffusion of learning was not, to be sure, confined to the achievements of the schools. Newspapers, of which there were 37 by 1776, served to spread information. Almanacs and private libraries served the same purpose. Colonial leaders were often well read in law, the classics and history. Blackstone's *Commentaries* was a favourite.

The colonists, as might be expected, were not so remarkable for their contributions to learning, science and the arts. Benjamin Franklin found England to be crowded with men of genius and talent as the American Revolution approached and the great spaces of America to have relatively few. However, the contributions of Franklin himself to science and literature were major; his autobiography remains a classic. If Jonathan Edwards did not push back intellectual frontiers in philosophy or theology, he was at least a genuinely competent scholar. There are those who claim that Edward Taylor (*q.v.*) of Massachusetts was one of the great metaphysical poets, second only to John Donne, and the most gifted American poet before the 19th century. Since his writings were not published until the 20th century was well under way, his achievements have not been assessed with any certainty. Cotton Mather (*q.v.*) was a fine scholar who presciently declared that disease was caused by animals too small to be seen. The charming sketches of William Byrd II, classicist and frank diarist, retain their attraction. The Bartrams, John and William, of Pennsylvania and Alexander Garden and John Lining of South Carolina were respectable scientists. In New York the royal official, Cadwallader Colden (*q.v.*), not only wrote a history of the Iroquois but delved into mathematics and physics, erroneously conceiving that he could correct Newton. As the colonial period drew to its close, America excelled in political philosophy and produced painters of stature, notably Benjamin West and John Singleton Copley (*qq.v.*). American culture then was clearly more creative and less derivative than it had earlier been. However, American cultural dependence upon England continued after the colonies had become politically independent. See AMERICAN FRONTIER; AMERICAN REVOLUTION; NEW ENGLAND; SOUTH, THE; UNITED STATES (OF AMERICA): *History*; see also Index references under "American Colonies" in the Index volume.

AMERICAN ENGLISH is the English language of the United States as distinguished from that used elsewhere; more narrowly, it pertains to any word or expression that originated in the U.S. Americanisms are of four chief kinds: (1) forms or meanings surviving in current American use though no longer current in British use; (2) foreign loanwords taken into the English language in America; (3) new meanings developed in America for

English words; and (4) new words coined in America. A fifth may be legitimately added: certain pronunciations and spellings are Americanisms in contrast to their standard British counterparts. (See also ENGLISH LANGUAGE; LANGUAGE; LINGUISTICS; GRAMMAR; and SLANG.)

1. **Survivals.**—*Fall*, a local word in England, was displaced by the foreign *autumn*, but in America the old word had a new growth and by 1700 had become the standard term. *Quit* will hardly be encountered in England outside of legal usage; in America it is on everybody's lips—to *quit* work, a game, almost any activity, and its offspring include *quitting time* and the vigorous *quitter*. I guess was the Englishman's comic stereotype for Yankee speech until an English scholar pointed out that Chaucer had used it regularly. So simple a word as the universal American *maybe* was described by *The Oxford English Dictionary* in 1906 as "archaic and dialectal," the English usage being *perhaps*. Americanisms of this first kind, though not numerous, illustrate the conservatism of language in colonies.

2. **Loanwords.**—Speakers of English in America adopted loanwords from all the important languages they met. Indian names for plants and foods include *squash*, *succotash*, *pecan*, *hickory*, *hominy*, *pone* and *tamarack*; for animals and fish: *moose*, *skunk*, *terrapin*, *raccoon*, *opossum* and *muskellunge* (the last three also shortened to *coon*, *possum*, *muskie*); for other things: *moccasin*, *mackinaw*, *toboggan*. All these have long been standard and hardly suggest their origin any more. Some that have not reached this status are *cayuse* (an Indian pony), *Podunk* (symbolic of an out-of-the-way small town) and *hooch*, for what used to be *firewater*. Others retain the association with Indians: *squaw*, *wig-wag*, *tomahawk*, *tepee*, *wampum*. The Indians' ceremonies impressed themselves early upon American political life in such words as *powwow*, *sachem*, *mugwump* and *Tanzmany*.

French loans came in through early exploration; one of the most essentially American words is *prairie*. *Portage*, *butte*, *cache*, *chute*, *levee* and *rapids* are all reminiscent of the vast inland area which the French were the first white men to penetrate. Other Americanisms of the same source are *calumet*, *chowder*, *shivaree* (noisy serenading of a newly married couple), *depot* and *à la mode* (applied to *pie* or other pastry, and meaning "topped with ice cream"). The decimal money terms, *mill*, *cent* and *dinze*, are French.

Though Spanish has contributed more loans than French many are limited to the west; e.g., topographical terms: *canyon*, *mesa*, *arroyo*; names of animals: *alligator*, *coyote*, *cockroach*, *mosquito*, *tuna*; names of plants: *alfalfa*, *marijuana*, *locoweed*; a number associated with cattle herding: *ranch*, *buckaroo*, *rodeo*, *ariat*, *bronco*, *cornl*, *mustang* and the more recent *palomino* horse. Yet others are *pickaninny*, *tornado*, *cafeteria* and the rather slangy *bonanza*, *calaboose*, *hoosegow* and *vamoose*. From Mexico new terms continue to trickle in.

The Dutch of New Amsterdam and the Hudson valley furnished such basic Americanisms as *Yankee* (a nickname meaning John Cheese), *Santa Claus*, *bakery*, *cole slaw* (often naturalized as *cold slaw*, to which has been added the counterpart *hot slaw*), *cookie*, *scow* and *sleigh*, all standard; in addition, the colloquial *boss* (which has gone around the world), *cruller*, *dope*, *stoop* (a small porch), *snoop* (to pry into people's affairs), *spook*, *caboose* and *poppycock*.

To the very large German immigration are due such words as *pretzel*, *delicatessen*, *pinochle*, *sauerkraut*, *wiener* and *hamburger*, as well as the colloquial or slang *dumb* (stupid), *bum* (a tramp, or as a verb, to act the tramp, beg), *loafer*, *dunk*, *hex* and *dingus* (a thingamabob). The 19th-century influence of Germany on American education is reflected in *kindergarten* (becoming naturalized as *kinder-garden*), *seminar*, *semester* and others less commonly used.

Other miscellaneous loanwords fully adopted as Americanisms are the African *voodoo*, *yant*, *okra*, *banjo* and *gumbo*, all standard; the regional *tote* (to carry), *goober* or *pinder* (peanut); and the more recent *juke* joint, with its *jukebox* (a coin-in-the-slot record player). *Tycoon* (a person of power or importance) appears to be the only Americanism from Japanese. *Chop suey* is from Chinese words, though the dish was concocted and given its name in the

U.S. Some slang terms are *shebang*, of Irish origin, and *kosher*, *kibitzer* and *mazuma* of Jewish (Yiddish) origin. Though interesting, foreign loans account for a relatively small number of Americanisms, and the period of their internal adoption virtually ceased with the end of mass immigration.

3. **New Meanings.**—The altered conditions of colonial life, and later those of the new nation, led to the use of English words in countless new senses. In England *lumber* meant rubbish; in America it came to mean timbers and boards; *corn* had included grain in general (wheat, rye, oats), but became specifically Indian corn or maize; a *creek*, at first an inlet from the sea, turned into a small fresh-water stream; a *bug*, still specifically meaning a bed-bug in England, is the general American word for insect. On the other hand the busy *bee* became the symbol of communal activity in America, with *bees* for everything from quilting to spelling. *Pioneer*, after acquiring meanings literal and powerfully metaphorical, has gone back to England. Other words with new American senses are the topographical terms *crotch*, *divide*, *sink* and *bluff*; also *bleachers* (unshaded seats at *ball games* and other spectacles), *gondola* (a type of *freight car*), a *bureau* of government and thousands more, for this is the second commonest kind of Americanism.

4. **Coinages.**—New formations generally follow the established patterns of the English language. There are numerous derivatives such as *auctioneer*, *Americanism* itself and Thomas Jefferson's *belittle*. Compounds, a very large group, include *corn bread*, *cocktail* (of disputed origin), *jackpot*, *hand-me-down*, *grab bag*, *deadwood*, *know-how* (supposed to be extremely American) and *pipeline* (which is acquiring interesting metaphorical uses). Many words have fathered an immense progeny of compounds: *land*, for example, begins about 80 new combinations (*land bank*, *land-hungry*, *land shark*, *land sakes!*) and ends another 150 (*bottom land*, *crawfish land*, *Yankeeland*).

Echoic and sound-symbolic words include *fizzle*, *honk*, *bingo*, *goeey* (sticky) and its noun *gooyunz*, *the jitters* (nervousness) and *jittery*—the latter few still colloquial. Back-formations such as *enthuse* (from *enthusiasm*), *orate* (from *oration*) and some others are traditionally condemned, yet *jell* (from *jelly*) and *peeve* (from *peevish*) have achieved some acceptance. *Donate* was one of the first Americanisms to stir derision in Britain, yet it has long been standard.

New words produced by lopping off either end are common: *gas* (gasoline), *fan* (fanatic), *gym* (gymnasium) and the more recent *copter* (helicopter), which defies etymological division. *Acute* was beheaded to make *cute*, at first in the sense of sharp, clever, even tricky; now it is a counterword, a word with no exact meaning, used to show approval of almost anything and much favoured by women. Words made directly from proper names include *lynch*, *maverick*, *buncombe* (with its expressive shorter form *bunk*) and the immortal *bloomers*. *John Hancock*, the first signature affixed to the Declaration of Independence: means any signature (though it is changing to *John Henry*). Examples of folk etymology are *woodchuck* (from Algonkian *wejack*) and probably *hoecake* (from Narraganset *nokehick*), *carryall*, a light carriage (from French *carriole*), and more recently the Spanish *temblor*, an earthquake, has turned into *trembler*.

Very numerous are functional shifts from one part of speech to another without change of form: to *corner* the market, a *combine* in business or as an agricultural machine, to *feature* or *star* an actor or actress, to *service* machinery. A *mammoth exhibit* illustrates both noun converted to adjective and verb converted to noun (unless *exhibit* is simply a lopped form of *exhibition*). The adjective *real* has become a popular adverb (*real* good, nice, sweet) exactly as *very* did five centuries ago in England. Blend-words may be exemplified by *Amerindian* (American Indian), *motel* (motorist hotel), *smog* (smoke fog) and initial-words by *G.O.P.* (Grand Old Party, at first applied to the Democratic, later to the Republican party), *O.K.* (*q.v.*) and *m.c.* or *emcee* (master of ceremonies). Of the various kinds of Americanisms, new formations are by far the most numerous.

5. **Pronunciations and Spellings.**—A few individual words differ from British use. Examples are *corollary* and *laboratory* (accented on the first syllable in the U.S., the second in England),

trait (the final *t* pronounced in the U.S., silent in England'). In England the noun *slough* rhymes with *now*, in the U.S. with *too*—in fact, it is also spelled *slew* or *slue*. England clings to *plough* and *axe*; America simplifies to *plow* and *ax*. America also simplifies the double consonants of *traveller*, *woollen*, *waggon*, etc. The most regular difference of spelling is in the *color*, *honor*, *labor* group in the U.S., where Britain favours *-our*. British *aluminium* and *speciality* hold to the original French spellings; American *aluminum* and *specialty* are more fully naturalized.

6. Tendencies in Development.—Americanisms have come into being from every sphere of life, but among the most striking are those concerned with establishment of the colonies and later settlement of the continent. The new weather conditions produced *blizzard*, *Indian summer* and *cyclone*. Pioneering and the frontier gave *blockhouse*, *sod fence*, *Conestoga wagon*, *six-shooter*, *batteau* and *corduroy road*; life in the settlements contributed *breaking plow*, *crazy quilt*, *overalls* and *pieplant*. From agriculture and cattle raising have come *corncrib*, *dry farming*, *irrigate*, *share cropping*, *range*, *dogie* and *rustling*.

New religious developments are responsible for *Mormon*, *revivalist*, *Christian Science*, *amen corner* and many more. The widespread education accompanying democracy has been an active source of words: *schoolma'am*, *grade school*, *lyceum*, *campus*, *co-education* (and its colloquial abbreviation *coed*—a girl in a coeducational college), *commencement* and *valedictorian*; the classical element is evident.

Business terms, though numerous, are less original; yet *boom*, *boost*, *merger*, *gilt-edged*, *margin*, *greenback*, *emporium* and *crook* may be mentioned. American inventiveness is illustrated in *baseball*, *bifocals*, *chewing gum*, *cotton gin*, *lightning rod*, *submarine*, *typewriter*, *refrigerator* and many another, the words generally being adopted wherever the inventions themselves go.

Probably the most prolific sphere for new and striking words, however, has been that of government and politics: *democrat*, *caucus* (once thought to be an Indian word, but probably Greek), *congress*, both *gubernatorial* and *governmental*, *abolitionist*, *secession*, *spoils system*, *band wagon* and *Uncle Sam* himself. Later additions to the list include *suffragist*, *antisaloon*, *prohibition*, Teddy Roosevelt's *big stick* and Franklin Roosevelt's *New Deal* (adapted from Mark Twain). Politics produced or gave currency to a number of forms obviously relished for their grotesqueness: the *locofoco* party, the *gerrymander* (like a salamander), *boondoggie* (put effort into useless activity), *globaloney* (which derides internationalism) and *snoilygoster* (a term of insult).

Americanisms have always included words intended to avoid strong language, or embarrassing or unpleasant topics. Some early euphemisms were *darn*, *tarnation*, *doggone*, as mild oaths; *gentleman cow* instead of the sex-suggesting *bull*. A madhouse became a *sanatorium* and a coffin a *casket*. More recently undertakers have become *nzorticians* and their establishments *funeral homes*; the poor have become the *underprivileged* and an *exceptional child*, surprisingly, is one of subnormal intelligence. Closely connected with this is grandiloquence, the application of high-sounding terms to ordinary things, as *sanitary engineer* (plumber), *janitor* or *custodian* (caretaker) and many more. A discharged soldier, no matter how short a time he was in the service, is a *veteran*. To call an automobile "second-hand" is anathema; it is *used*, *reconditioned* or (a triumphant creation) *preowned*.

Like their linguistic ancestors of Elizabethan England, Americans enjoy new words and coin them freely at all levels of usage. This inevitably produces ugly: jargonish and ill-made words along with many very effective ones that win rapid adoption and even world-wide use. Especially characteristic are humorously exaggerated metaphors: *prairie schooner* (pioneer covered wagon), *panhandle* (a strip of land running off from the main body—as in Texas), *bulldozer* (something which intimidates, hence a powerful earth-working machine), *bootlegger* (seller of illicit liquor, who originally carried it in the leg of his boot), to *eat crow* (swallow something unpleasant, hence admit one's mistake), *ghost writer* (one who anonymously writes a speech, or the like, for a well-known person). Many are colloquial or slangy: *crowbar* (worthless meat, usually an old horse)! *eye opener* (something surprising),

rubber check (one which "bounces" because there is no money in the bank to cover it) and the more recent *hot rod* (an old car used for racing) and *wetback* (a Mexican who enters the U.S. illegally by crossing the Rio Grande river).

The taste for novelty leads to many unconventional formations. From *cafeteria* the last syllables are detached and used to form *grocceteria*, *gasateria*, *washateria* and so on for establishments in which, as in a cafeteria, one serves oneself. *Hamburger* is falsely split, *burger* comes to mean a sandwich made with a round bun, then *cheeseburger*, *steakburger*, *snakeburger* and many others follow. The *Ikeburger*, however, is honorific, not cannibalistic. Other unconventional suffixes are *-rama* (detached from *panorama*) as in *motorama*, *aquarama*, *futurama*—all used for exhibitions or elaborate shows; and *-oree* (*-aree*, *-eree*), from the Americanism *jamboree*, as in *fishereee*, *percharee*, *camporee* (contests or celebrations involving fishing, catching perch and camping).

The ordinary *-er* which makes nouns of agent has been much favoured, as in *squatter* (one who settles on a piece of land without legally owning it), *schooner* (a sailing vessel that skims over the water) and *cutter* (a sleigh that moves rapidly and easily). But there is a more characteristic *-er* which suggests the possession of some quality: *carpetbagger* (carrier of a carpetbag, an opportunistic speculator), *forty-niner* (one who approved the 49th parallel as a boundary between the Oregon territory and Canada or who rushed to California for gold in 1849), *fourflusher* (one who pretends to have five cards of the same suit but has only four, a bluffer or deceiver). Many of these creations begin as slang but move up rapidly into colloquial and even written use.

Yet another American predilection is for adding adverbs to verbs, sometimes without clearly affecting the sense—*beat up*, *close up*, *lose out*, *start in*, *test out*—but often with a decided change of meaning—*call down* (scold), *call up* (telephone), *get behind* (be delayed), *lay off* (discharge), *pass up* (fail to take), *put across* (do successfully), *turn down* (refuse).

7. American and English.—Americanisms, looked upon at first as deplorable deviations from the mother speech of England, were much condemned by some and as warmly defended by others (see H. L. Mencken, *The American Language*, ch. 1. and Supplement I, ch. 1). In the course of time attitudes have changed: Americans are less apologetic and Englishmen less disdainful—indeed, in the 20th century borrowing across the Atlantic in both directions is the normal state of affairs. The trade flows, if anything, more actively from west to east, with the influence of American literature, journalism, movies, radio and television making itself strongly felt. The man in the street is hardly aware whether new words are American or English in origin, and even the literary man must examine the evidence closely before he can be sure. The English language is a common possession to which many contribute.

A few examples of Americanisms adopted into standard English usage in the 20th century are: *ballyhoo* (noisy artificial publicity), *blurb* (a piece of overblown praise), *boost* (to "push" commercially or otherwise), *chore* (an unpleasant task), *doodle* (to scribble in a random way when one is abstracted), *hindsight* (the contrary of foresight), *quiz* (a set of questions to test one's knowledge), *routine* (in the sense of normal), the very useful noun *setup* (an arrangement of things) and so seemingly ordinary a term as *executive*.

Down the centuries hundreds of everyday Americanisms have quietly entered English usage—indeed, they have gone wherever the language is used (see H. W. Horwill). Nevertheless, variants persist. A partial list of contrasting terms follows; the American term appears first, followed by its English equivalent.

alumni—old bops (girls)	call up (on the telephone)—
ash can—dust-bin	ring up
ashman—dustman	can (container)—tin
baby carriage—pram	candy—sweets
baggage car—luggage van	car (railroad)—
billboard—hoarding	carriage, van, waggon
brakeman—brakesman, guard	carom (billiards)—cannon
bumper (automobile)—buffer	catalogue (university)—calendar
burial—hessian	checkers (game)—draughts
calendar (court)—cause-list	cheesecloth—butter muslin

chicken yard—fowl-run
 chief of police—chief constable
 collar button—stud
 commencement (university)—
 graduation or degree cere-
 mony
 cookie—small sweet cake, biscuit
 corn—maize, Indian corn
 counterfeiter—coiner
 cowcatcher—fender, plough
 cracker—biscuit
 crystal (watch)—watch-glass
 cuffs (trouser)—turn-ups
 cute—quaint, attractive, dainty
 daylight-saving time—
 summer time
 derby (hat)—bowler
 dime novel—penny dreadful
 dishpan—washing-up bowl
 drugstore—chemist's shop
 dry-goods store—draper's shop
 elevator—lift
 enlisted man—private soldier
 excelsior—wood-wool
 express train—nonstop train
 faucet—tap
 fender (automobile)—
 wing, mud-guard
 firecracker—squib
 fire department—fire brigade
 floorwalker—shop-walker
 fraternal order—friendly society
 freight—goods
 freight car—goods waggon
 gasoline—petrol
 grade (railroad)—
 gradient (railway)
 grain—corn
 grain broker—corn iactor
 hardware dealer—ironmonger
 headliner (stage)—topliner
 hogpen, pigpen—sty, piggery
 hood (automobile)—bonnet
 huckster—
 barrow-boy, costermonger
 hunting—shooting
 installment plan—
 hire-purchase plan
 internal revenue—inland revenue
 janitor—caretaker
 kerosene—paraffin
 laborer—navvy
 legal holiday—bank holiday
 letter box—pillar-box
 locomotive engineer—
 engine driver
 long-distance call—trunk call
 lumber—timber

molasses—treacle
 movie—cinema, film
 orchestra (seats)—stalls
 outbuildings (farm)—offices
 patrolman (police)—constable
 pocketbook—handbag
 poorhouse—workhouse
 postpaid—post-free
 prepaid—carriage paid
 Rhine wine—hock
 roast (of meat)—joint
 roll call (in legislative assembly)—
 division
 round-trip ticket—return ticket
 shoeshine—boot polish
 sidewalk—pavement
 silverware—plate
 sled—sledge
 snoop—pry into others' affairs
 soft drinks—
 minerals and squashes
 sponge (surgical)—wipe
 stockholder—shareholder
 stocks—shares
 store fixtures—shop-fittings
 streetcar—tram
 street railway—tramway
 hubway—tube, underground
 suspenders (men's)—braces
 switch (noun, railroad)—points
 switch (verb)—shunt
 tavern—public house (pub)
 taxes (local)—rates
 tenderloin (beef)—
 undercut, fillet
 tenpins—ninepins
 thumbtack—drawing-pin
 ticket office—booking-office
 tie (railroad)—sleeper
 to run for (congress)—
 to stand for (parliament)
 tansom (door)—fanlight
 transportation—transport
 trolley car—tram
 truck (vehicle)—lorry
 tube (radio)—valve
 tuxedo—dinner jacket
 undershirt—vest
 vest (men's)—waistcoat
 warden (of prison)—governor
 washrag—facecloth
 washstand—wash-hand stand
 wastebasket—
 wastepaper basket
 windshield (automobile)—
 windscreen
 witness stand—witness-box
 wrench (tool)—spanner

Object	Northern	Midland	Southern
container for milk	pail	bucket	bucket
frying pan	spider	skillet	(mixed)
dragonfly	darning needle	snake feeder	mosquito hawk
seesaw	teeter (-board)	seesaw	seesaw
call to a cow	come boss!	sook'	co-n ench!
roller shades	curtains	blinds	mixed
zigzag rail fence	rail fence	norm fence	rail fence
small firewood	kindling	kindling	lightwood
noise a cow makes	moo	moo	low

Numerous subregional and local variants exist for these and thousands of other terms. Pronunciation features are similarly distributed. Most elements of U.S. dialect derive ultimately from the British Isles. See also DIALECT GEOGRAPHY.

BIBLIOGRAPHY.—The principal authorities in the field of American English are *A Dictionary of American English on Historical Principles*, ed. by W. A. Craigie and J. R. Hulbert, 4 vol. (1938-43), and *A Dictionary of Americanisms on Historical Principles*, ed. by M. M. Mathews, 2 vol. (1951). The first is more comprehensive, using "American" inclusively and showing better the continuity of English in the new world; the second gives prominence to those words originally American, has some earlier and later evidence and many helpful illustrations. Both dictionaries, being historical, give dated citations to support every entry. Useful for background material is M. M. Mathews, *The Beginnings of American English* (1951). Rich in miscellaneous human and philological interest is H. L. Mencken, *The American Language*, 4th ed. rev. and enl. (1936) and its two supplements (1945-48), with thorough indexes and useful bibliographies. A short but valuable study is H. W. Horwill, *American Variations*, Society for Pure English Tract, 45 (1936). Two general studies are Thomas Pyles, *Words and Ways of American English* (1952) and A. H. Marckwardt, *American English* (1958). For current treatments of usage and word origins probably the best source is the quarterly magazine *American Speech*. See also "Words and Meanings, New," *Encyclopaedia Britannica Book of the Year* (1944 et seq.).

For studies of American dialects see American Dialect Society, *Dialect Notes* (1890-1939) and *Publications* (1944 et seq.); Hans Kurath, *A Word Geography of the Eastern United States* (1949); Harold Wentworth, *American Dialect Dictionary* (1944); Hans Kurath and Raven I. McDavid, Jr., *The Pronunciation of English in the Atlantic States* (1960). (F. G. Cx.)

AMERICAN FARM BUREAU FEDERATION, largest U.S. farm organization; was an outgrowth of the county farm bureau movement. Shortly before World War I. the idea of using county demonstration agents, agricultural experts or extension workers to provide farmers with the results of scientific study was adopted in a number of areas. In many localities these agents were supported by local groups of farmers who constituted county committees or bureaus. Before the end of the war the county farm bureaus in several states had formed state organizations.

In Nov. 1919 representatives of the state farm bureaus met in Chicago, Ill., and completed plans for the organization of the American Farm Bureau federation. Prior to this meeting, education for better production had been emphasized, but post-World War I conditions were already bringing to the fore the need of a business organization to represent farmers. The purposes of the federation were stated in its constitution: "to promote, protect and represent the business, economic, social and educational interests of the farmers of the nation, and to develop agriculture."

Although the federation grew out of county and state farm bureaus organized to sponsor educational activities, it quickly became active in sponsoring a wide variety of measures to improve farmers' economic welfare. In the early 1920s it supported legislation to strengthen farmer co-operatives and make additional credit available to farmers. Later the federation supported the McNary-Haugen bill to increase prices of the major export crops; the bill was passed by congress in 1927 and 1928, but vetoed each time by Pres. Calvin Coolidge. It continued to press for legislative action for farmers and took a major part in formulating and obtaining passage of the Agricultural Adjustment acts of 1933 and 1938. During World War II the federation opposed price controls and objected to many of the administrative decisions that prevented price ceiling adjustments for farm products. Following World War II the federation supported measures to reduce government participation in economic activities. Through-

8. American Dialects. — The widespread notion that a dialect is a decayed form of a language is false. Historically all standard languages of today began as local dialects but became elevated through their use by a leading class or group to a position of prestige, their sister dialects suffering a corresponding loss of esteem.

In the U.S. there is no one "standard" pronunciation, though the language as printed is consistent in most respects. Standards in the spoken language go by broad regional divisions, whose subordinate variants, when they form localized types, may be called dialects. Since dialect survives only through some kind of isolation, geographic or social, and since there is much mixture, movement and intercommunication of the U.S. population, dialect as distinct from regional speech is virtually limited to coastal strips, mountain areas or those communities within large cities which have remained relatively homogeneous for some time.

Three regional divisions are now recognized: northern (including New England, New York city and the area north of a line drawn through the middle of Ohio, Indiana and Illinois, westward to the Pacific coast); midland (the wedge-shaped area between northern and southern, having Philadelphia at its apex and widening southward and westward to include most of the southwest and south Pacific states); and southern (including the south Atlantic states up to the Blue Ridge, the lowlands of the Gulf states and eastern Texas). A few characteristic terms are:

out the 1950s it advocated measures to reduce government farm price supports and return the direction of the farm economy more largely to commercial markets.

Membership in county and state farm bureaus slumped from between 400,000 and 500,000 in the early 1920s to less than 200,000 in the early 1930s. The more successful state farm bureaus sponsored affiliated co-operatives for the purchase of farm supplies and co-operative insurance companies. The practice of sponsoring affiliated co-operatives spread to most states, and membership in the farm bureau increased rapidly in the late 1930s and early 1940s. Membership exceeded 1,000,000 in the mid-1940s and stabilized a little above 1,500,000 in the second half of the 20th century.

Elected delegates from the county farm bureaus elect the state officers and formulate policies of the state farm bureaus. Delegates from the state farm bureaus elect the officers of the American Farm Bureau federation and formulate the policies of the federation in resolutions which they formulate and adopt annually. See also AGRICULTURAL ORGANIZATIONS.

Kile, *Farm Bureau Through Three Decades* (1948); David E. Lindstrom, *American Farmers' and Rural Organizations*, ed. by Herbert McNee Hamlin (1948). (E. E. Es.; W. W. Wx.)

AMERICAN FEDERATION OF LABOR-CONGRESS OF INDUSTRIAL ORGANIZATIONS, U.S. federation of labour unions formed in 1955 by the merger of the A.F. of L. and C.I.O. The A.F. of L., established in 1886, originally represented the principle of organizing workers in craft unions such as the United Brotherhood of Carpenters and Joiners, though its member unions were never all of this type. The C.I.O., which had broken away from the A.F. of L. between 1936 and 1938, represented the principle of industrial organization, sometimes called vertical organization, including in one union, such as the United Mine Workers of America, all employees in a given industry. Each union retained its autonomy under the new federation and was therefore free to work out its own policies in accordance with its own needs. In general, the new federation followed the policies of the predecessor federations, which are described below. By 1960 the membership of the federation totaled approximately 14,000,000, about 1,000,000 less than the total membership at the time of the merger. (See also TRADE [LABOUR] UNIONS: *United States*.)

Early Moves Toward Federation.—Largely as a result of efforts by the International Typographical union, a conference of labour organizations was called in Terre Haute, Ind., for Aug. 2, 1881. Only 21 delegates from 15 organizations attended. In view of the small attendance, the delegates did not deem it expedient to set up an organization. Instead they decided to call a national labour congress in Pittsburgh, Pa., on Nov. 15, 1881. The call declared the "time has now arrived for a more perfect combination of labor—one that will concentrate our forces so as to more successfully cope with concentrated capital." In addition, the call pointed to the need for the establishment of a legislative committee on the order of the parliamentary committee of the British Trade Union congress to protect the interests of the worker. The meeting was attended by 108 delegates, 50 of whom were members of the Knights of Labor, and the remaining ones from trade unions and central labour councils. The large contingent from the Knights resulted from the desire to prevent the emergence of a rival. After drawing up a preamble, the convention declared its opposition to child labour and Chinese immigration and demanded the establishment of an eight-hour workday and enactment of a mechanic's lien law. A new organization, the Federation of Organized Trades and Labor unions of the United States and Canada was established, and a legislative committee, made up of a secretary, treasurer, president and two vice-presidents, was chosen.

The new federation did little in its first year. It was virtually without funds and appointed no full-time officer. The trade unions which it had sought to rally did not respond, and the skimpy support the federation received never enabled it to do much more than issue an annual statement to its sparsely attended conventions.

It appeared for a time that a federation of trade unions, independent of political and reform parties, would not be established. However, a change in the attitude of many trade unions toward a federation was brought about by the activities of the Knights of Labor which greatly expanded its membership during the 1880s. Devoted to the view that it represented all labour, the Knights of Labor sought to set up organizations competing with many trade unions. These efforts inevitably aroused the resistance of those organizations whose jurisdictions were invaded. Consequently a number of trade unions decided to seek a common defense against these encroachments.

In the spring of 1886 a confidential circular signed by a group of leading trade unionists suggested a meeting of heads of unions to seek to devise a policy for preventing the continued invasion by the Knights of Labor. Twenty unions sent 22 delegates to a conference in Philadelphia on May 17, 1886. In addition, a number of trade unions which failed to send representatives approved the purpose of the meeting. After a two-day conference, a "treaty" was drawn up and submitted to the Knights of Labor. The treaty would have required the Knights of Labor to refrain from organizing trade unions whenever a national or international union was functioning and from admitting those who had been expelled or suspended from a trade union; and to avoid interfering with the activities of trade unions in any manner. In return, the trade unions offered to urge their members to join the Knights of Labor, which was to confine itself to educational work. As the Knights of Labor had just then experienced a great increase in membership and was at the height of its power, it naturally rejected the demands. Thereupon the trade unions called a convention for Dec. 1886, in Columbus, O., which established the American Federation of Labor, with which the Federation of Organized Trades and Labor unions of the United States and Canada merged.

American Federation of Labor.—In contradistinction to the older federation, the A.F. of L. had, from the beginning, the support of many trade unions. It also established a full-time salaried post of president, to which Samuel Gompers (*q.v.*) was elected. In the first years of its existence, the A.F. of L. had to struggle against the opposition of the Knights of Labor and the suspicion of the national and international trade unions that it might encroach upon their authority. As a matter of fact, the A.F. of L. was given no power over the national and international unions. The latter were independent and autonomous, and free to work out their own rules, policies and attitudes toward their members and their employers. Consequently, the A.F. of L. had within its ranks, craft and composite or industrial organizations, conservative and socialist unions, all of which tolerated each other.

By the end of the 1890s, the shrinking Knights of Labor was no longer a serious rival to the A.F. of L., which gradually became the economic spokesman for the U.S. labour movement. In time, virtually all unions, except the brotherhoods, whose members were employed in the service trades on the railroads, affiliated with the A.F. of L.

Throughout its history, the A.F. of L. was forced to develop policies governing the relations of its affiliates to the federation, and of the latter toward government and public issues. By refusing to charter unions whose jurisdiction bordered too closely on that of an affiliate, the federation frequently prevented the growth of narrow craft organizations without an adequate jurisdictional base. The federation also encouraged the amalgamation of closely related unions, so that they would have a broader membership and jurisdiction. Unions were also allowed to expand their jurisdictions so that they would be able to recruit the less skilled, and sometimes even the unskilled, in their industries into their organizations.

Despite the efforts to avoid conflict between labour organizations, jurisdictional disputes developed. Not only did some unions, which preceded the A.F. of L., have overlapping jurisdictions, but changing materials and processes in industry made inevitable conflict over which union would have the authority to organize a specific group of workers. Under the constitutional principles developed by the A.F. of L., every union affiliated with it had the exclusive right to organize the workers in its trade, which con-

stituted its jurisdiction. When jurisdictional disputes first came before the executive council and convention of the A.F. of L., it was hoped that they would not become a serious source of difference and that they would be settled by conference and mutual concession. Instead the number and severity of these disputes increased. In 1900 the A.F. of L. faced a dilemma as a result of a conflict over the jurisdiction of the United Mine Workers of America. That union had, from its inception, organized all workers in and around the coal mines in an industrial union. Several craft unions—machinists, patternmakers, boilermakers, carpenters and others—insisted that the mine workers' union surrender the craftsmen it had recruited, and turn them over to the respective craft unions. As the United Mine Workers refused to agree to such a step, the A.F. of L. faced a serious crisis, which the convention of 1901 met by promulgating the "Scranton Declaration." The declaration recognized the desirability of the coal miners being organized in an industrial union because of the isolation of coal mining communities and the absence of virtually all other industries in coal mining areas. Consequently, it was held necessary, in this instance, to overlook the doctrine of exclusive jurisdiction of a particular union over the workers it had been allowed to organize.

Beginning in 1897, the unions affiliated with the A.F. of L. gained in membership and in influence, and they continued to progress until 1904. Simultaneously they were confronted with an elaborate and well-organized attack from employers so that some unions lost positions they had held for many years. Employer attacks were accompanied by proceedings in the courts against the use of the boycott, which culminated in the Danbury Hatters' suit and the prosecution of leading officers for violation of the restraining order against a boycott of the Buck's Stove and Range Co.

Little progress was made by organized labour between 1904 and 1910, but in the latter year unions were established in the men's and women's clothing industries. With the beginning of World War I in Europe, the unions began their upward march again. Several million members were gained in both the older organized industries and in some of the major unorganized industries such as steel and meat-packing. Union organization was aided by labour shortages and by the more favourable attitude of the federal government. The federal government not only found it desirable to deal with organized labour in the industries which came directly under its influence, but it established the National War Labor board, which in a limited sense protected the right of workers to organize.

Following World War I the A.F. of L. was confronted by attacks both from the right and the left. Steps were taken by employers to reduce the power and influence of labour unions by a concerted open-shop drive which had for its objective the elimination of organized labour from many plants and even industries. Many employers, among them the giant steel companies, refused to deal with unions. Such refusal precipitated strikes, but in the end the unions were usually defeated. On the left, the A.F. of L. faced opposition from elements which had become dissatisfied with its traditional policies. These groups demanded greater militancy on the industrial field and a change in political tactics. The A.F. of L. had followed a program of endorsing political candidates of both parties who supported labour and welfare legislation, a policy epitomized in the slogan "Reward your friends and punish your enemies."

On the other hand, there were always some within the federation who wanted the A.F. of L. to promote independent political activity by supporting a labour party. The leadership of the A.F. of L. modified its position in the campaign of 1924 when it endorsed the independent candidacy of Robert La Follette for the presidency. The step was taken, however, only because of the unacceptability of the candidates of the two major parties. In 1952 the convention endorsed the Democratic candidate, Adlai Stevenson.

After 1924 the A.F. of L. lost a large part of the membership gained during World War I. Even though employment was high during the 1920s, the A.F. of L. failed to gain in strength. With the onset of the depression in 1930 its major strongholds in the

building trades suffered severe losses in membership. While the outlook seemed bleak for the A.F. of L. and its affiliated unions, there was an almost instantaneous change in their fortunes once the first Roosevelt administration took office in 1933. Section 7(a) of the National Industrial Recovery act, which guaranteed to labour the right to organize and bargain collectively through representatives of its own choosing, was of great aid in stimulating workers to join unions. Many organizations of the A.F. of L. greatly expanded during this period, and in some instances, as in bituminous coal mining, re-established themselves on a greater scale than ever. (See also UNITED STATES [OF AMERICA]: *History*.)

Emergence of the C.I.O.—At the same time, the A.F. of L. faced an internal crisis which its leaders could not solve. For the first time in history, there were widespread attempts of the workers in the mass production industries to form unions. These workers had, in the overwhelming majority of cases, never belonged to a labour organization and were not conversant with the constitutional procedures or the laws which governed jurisdictional rights within the A.F. of L. As the majority of the workers in these industries were semiskilled operatives, they sought to establish industrial unions. Such attempts encroached upon the jurisdictional rights of the older A.F. of L. craft unions. Despite the fact that the older unions had virtually no members in the mass production industries, they continued to insist that those who were eligible for membership in their organizations must be transferred from the mass production industrial unions into the craft or semi-craft unions. Several efforts were made to compromise the conflicting claims, but none succeeded. When the resolutions for allowing the mass production industries to organize on an industrial basis were defeated at the A.F. of L. convention of 1935, eight unions organized the Committee for Industrial Organization, soon commonly known as the C.I.O. Under the leadership of John L. Lewis (q.v.), the C.I.O. raised large sums for organizing purposes and succeeded in establishing union recognition in the mass production industries. The success of the C.I.O. forced the A.F. of L. to expand its organizing activities and to recognize that in manufacturing industry the concept of exclusive jurisdiction could not be strictly followed. Once the A.F. of L. began to organize on a large scale, it succeeded in recruiting many more workers to its ranks than the unions of the C.I.O. In the meantime, the latter organization, whose member unions had been expelled (1936) from the A.F. of L., transformed itself into the Congress of Industrial Organizations (1938) and became a permanent rival to the A.F. of L. This step led to the withdrawal of one of its founding unions, the International Ladies' Garment Workers' union from the C.I.O. Eventually that union returned to the A.F. of L.

Reconciliation.—Once the A.F. of L. recognized in fact that unions in manufacturing would have to be allowed to function as industrial unions wherever the needs of the workers and the industry made such structural form necessary, the initial differences that divided the A.F. of L. and the C.I.O. were virtually extinguished. Yet the bitter rivalry and the personal animosity between the two bodies were not easy to overcome. Committees to unify the two organizations were elected a number of times, but their meetings did not lead to fruitful results. One important barrier was the attitude of some leaders of the A.F. of L. who regarded the C.I.O. as an erring offspring and constantly pleaded for a "return home." The presence of several Communist-dominated unions in the C.I.O. was also a complicating factor. These unions were expelled in 1949 and 1950.

The need of a common front before government and the public, especially during wartime, forced the two organizations to cooperate. With the death or retirement of some of the leading participants in the division of the trade unions, an approach to unity was made easier. The United Labor Policy committee which functioned during the Korean war was a first step. This group dissolved in 1951, but labour groups in 1953 appointed a joint A.F. of L.—C.I.O. unity committee to explore the possibilities of organic unity. A first step, the no-raiding agreement, was signed by the presidents and secretary-treasurers of the A.F. of L. and C.I.O. on Dec. 16, 1953. An overwhelming majority of affiliates of both

federations accepted the proposal. This important step helped to eliminate competitive organizing and raiding, which usually led to irritation and promoted antagonisms between unions.

The next step was the working out of a merger agreement under which each national and international union, federal labour union, local industrial union and organizing committee holding a charter or certificate of affiliation from either federation was to retain its place in the merged federation. Each affiliate would retain its integrity and its right to existence and affiliation within the merged federation. Such a policy meant that duplication and overlapping of unions were inevitable. However, wherever such duplication or overlapping existed the affiliates were to be urged to eliminate the possibilities of conflict by agreement, merger or consultation. The merged federation recognized both craft and industrial unions as appropriate and necessary in a trade union federation, and thereby all ideological dissensions arising from differences on the structural question were automatically eliminated. The form of organization thereby became a purely practical problem to be determined by the needs of a particular group of workers.

At the first constitutional convention held in Dec. 1955, and in accordance with the merger agreement reached Feb. 9, 1955, the executive officers of the merging federation, president and secretary-treasurer were initially selected from the A.F. of L. The first president was George Meany and the first secretary-treasurer, William F. Schnitzler. On the other hand, the director of organization was appointed from the ranks of a union affiliated with the C.I.O. An executive council of 27 vice-presidents, with the 2 executive officers, was elected, 17 of the vice-presidents being chosen from A.F. of L. unions and 10 from C.I.O. unions. This council was to meet at least three times each year. An executive committee made up of the two executive officers and six vice-presidents, chosen by the executive council, was to meet bimonthly with the executive council and discuss policy matters. In addition a general board, consisting of the executive council, and a principal officer of each affiliated national and international union was to meet at least once annually and decide all policy questions submitted by the executive officers and executive council. The convention was to remain the seat of all authority, meeting every two years, but subject to special call. National and international unions and organizing committees were to pay a per capita tax, in an amount to be decided by the conventions, for the maintenance of the merged federation.

The merging federation established a department of organization to assist the affiliated unions in planning the federation's organizing work. This department was headed by a director appointed by the president, with the approval of the executive council.

In addition to the above structure a number of standing committees and staff departments were to be appointed by and under the direction of the president, also subject to the authority of the council. Standing committees appointed at the time of merging, as determined by the needs and problems facing the federation, included those on legislation, civil rights, political education, ethical practices, international affairs, education, social security, economic policy, community services! housing, research, public relations, veterans affairs and safety and occupational health.

A.F.L.-C.I.O.—In the first five years of its existence, the new federation (hereafter known as A.F.L.-C.I.O.) launched no major organizing drives, nor did it break any new ground except in the area of ethical practices. At the merger convention of 1955, the protection of the labour movement "from any and all corrupt influences" was declared to be one of the "objects and principles of this Federation." Investigations by the executive council at the request of the president or by any other member of the council were authorized and the committee on ethical practices was given "the duty and responsibility to assist the Executive Council in carrying out the constitutional determination of the Federation to keep the Federation free from any taint of corruption . . ." Codes of ethical practices were later drawn up. In 1956 and 1957 the conduct of six international unions was investigated; all were directed to change some of their policies and practices. Three,

the Allied Industrial Workers of America, the Distillery Rectifying and Wine Workers' International union and the United Textile Workers of America, agreed to introduce the reforms recommended and were placed on probation. Three others, the Laundry Workers' union, the Bakery Workers' union and the Teamsters' union were expelled. Other unions were chartered in place of the Bakery and Laundry organizations, but no steps were taken to challenge the Teamsters' union. The newly established A.F.L.-C.I.O. unions in the bakery and laundry industries made substantial progress, but the outlook for challenging the control of the Teamsters' union leadership was obviously not regarded as favourable.

By the federation's third convention in 1959, it was obvious that the merger was working. Friction appeared at several points in the disputes over jurisdiction between the old X.F. of L. and C.I.O. unions, but differences among affiliates were seldom fatal and had, in fact, usually existed when the A.F. of L. was an independent entity. In 1959 the International Longshoremen's union, which had been expelled by the old A.F. of L. before the merger, was readmitted to the A.F.L.-C.I.O. Several mergers of unions took place, the most important being in the paper manufacturing industry. Several unions of operating railroad workers, including the important Trainmen and Firemen's unions, joined the federation. The A.F.L.-C.I.O. promoted co-operation between the formerly warring seagoing unions but on the whole no significant gains in this area took place.

AMERICAN FRONTIER. The term "frontier" has been defined in various ways and used by historians in even more ways. Webster's *International Dictionary*, in 1890, described it as "that part of a country which fronts or faces another country or an unsettled region; . . . extreme part of a country." The historian Frederick Jackson Turner early noted that, "especially in the United States!" the term referred to "those outlying regions which, at different stages of the country's development," were "but imperfectly settled and constituted the meeting ground of savagery and civilization." To him it referred to that "belt of territory sparsely occupied by Indian traders, hunters, miners, ranchmen, backwoodsmen and adventurers of all sorts" which formed "the temporary boundary of an expanding society at the edge of substantially free lands."

Others have thought of it as "a form of society," "a state of mind." "the edge of the unused." "the first stage in the process of transforming the simplicity of the wilderness into modern social complexity." Some have used the terms "frontier" and "west" interchangeably as referring to an area having geographical location only in relation to a particular period of time and changing constantly as population had advanced. The U.S. census, on the other hand, has considered it a place where the inhabitants number two to the square mile, and on this basis marked the frontier line on a series of maps for each decade.

Yet, amid all this confusion in the use of terms, there remains the simple fact that the history of the United States, up to the beginning of the 20th century, was that of a people moving steadily forward to the occupation of a vast, raw continent. This involved not only recurring physical advances into new geographic basins where life had to be lived on simple, elemental levels for a time, but also constant social evolution from a simple hunting-trading stage to varying degrees of urban complexity and interdependence.

For 300 years this went on. For three centuries some Americans were leaving the older settlements and beginning over again on the frontier. For the same length of time, those who lived in what had become old and established centres were conscious of the fact that there remained an open door to free, unused lands where place and fortune were yet to be won. Thus as a reality for some and as a symbol for others the frontier became a vital factor in

shaping American life and American character.

The First Frontier.—Thus understood, the American colonies along the Atlantic coast were Europe's frontier, and their gradual drift away from European patterns was the first manifestation of frontier influence. They began the conquest of the wilderness; they took the first steps in crossing the continent: they became Americans. This, however, was only the beginning. Scarcely had the colonies themselves become firmly established before the western push began anew. Out from old centres, the dissatisfied, the restless, the adventurous made their way into the back country, there often to crowd the Indian into open resistance but ultimate retreat and to lay the foundations for a new society. Sometimes they moved to secure more room for themselves and their cattle: sometimes they moved because of "the strong bent of their spirits." Well before the American Revolution they had brought a new west into being—in upper New England, in the Mohawk valley, in the great valley of Pennsylvania and above the fall line and out into the ridges and valleys of the south. Already a few had crossed the mountains and opened the way for an even greater west.

This first west differed sharply from the original colonies which had already begun to reproduce the old world social and economic patterns with their class distinctions. It was a "democratic: self-sufficing, primitive agricultural society in which slavery and indentured servants played little part." and in which poverty and toil went along with a scarcity of social accumulations. As population spread and increased, differences between coast and interior became increasingly apparent and strife often developed over taxes, representation, internal improvements and religious matters. Bacon's rebellion, the Regulator movement and soon Shays's rebellion and the Whisky rebellion were all expressions of an east-west conflict produced by expansion.

The Second Period.—The second great westward push carried the frontier across the Alleghenies and deep into the heart of the continent. By 1800 Kentucky and Tennessee had entered the union as states, and Ohio was soon to follow them. The great migration, however, was to come in the years following the War of 1812. A traveler wrote in 1816 that "the Atlantic States seem to have had their day," and that the more active and enterprising, "the people who partake of youth, enterprise and hardihood . . . are looking more and more to the West." A year later another, himself on the road, noted that "Old America seems to be breaking up and moving westward."

The travelers were right. Within their life span (1840) settlement had spread across the lower south along the Gulf to the Mississippi and up the Red river, crowding the Indians out and creating the kingdom of cotton; spread along the Great Lakes into Michigan and Wisconsin, Indiana and Illinois to carry wheat and corn and hogs with it; and out in the centre, from Kentucky and Tennessee, it had crossed the Mississippi and reached the great bend of the Missouri from which the traders and trappers made their way on westward.

Characteristics of the First Frontiers.—Both of these two first frontiers were primarily agricultural in character. Here and there, where timber or minerals were found, lumbering and mining developed, but the main advance was always that of the farmer. Opening the way for him was the lone trapper and trader with the army and the missionary sometimes playing a part in dealing with the Indians. None of these made any great change in the wilderness. That was to come with the pioneers who wanted land and, at least, a temporary home.

The frontier process by which the well-wooded, well-watered regions east of the Mississippi river were settled is described in J. M. Peck's *A New Guide for Emigrants to the West* (1836). He speaks of "three classes, like the waves of the ocean," that had rolled along one after the other. First came the pioneer who lived "largely upon the natural growth of vegetation" and "the proceeds of hunting." He built a crude cabin, cleared a patch of ground by girdling the trees and moved on when "his neighbors' smoke vexed his eyes" and their voices disturbed his sleep.

The second wave of settlers bought these half-developed acres, cleared the roads, bridged the streams, built houses with glass

windows, planted orchards, erected mills, schoolhouses and, as Peck puts it, soon exhibited "the picture and forms of plain, frugal, civilized life."

The final wave was composed of "men with capital and enterprise." They built houses of brick and stone, increased the agricultural surplus well above immediate needs and looked for wider markets in which to sell. They were the permanent settlers who brought the communities to maturity and created the towns with their general stores, their newspapers, their professional men and their politicians. They soon made their influence felt in national affairs.

Early Roads.—Access to the frontier at first was by way of Indian trails and waterways. Trappers and traders followed these in their wanderings and, in time, settlers on their way west pounded the trails into crude roads. Each group of pioneers evidently cleared, for their own passage, bits of whatever road they traveled. Trees were cut and the underbrush cleared away. In low, swampy places logs were placed side by side to form a corduroy road; where streams could not be forded, crude bridges were constructed. Stumps and the larger trees were left standing, and the drainage was so poor that travel was not possible in wet weather. Travelers usually found it best to make their journey when the ground was frozen. Roads to the west were improved only gradually and heavy traffic kept them in bad shape. Yet they tied the regions of unrest to the promised lands and helped to shape the character of both.

In the period before 1812 a system of wagon roads, following the old Indian trails, connected the eastern seaboard with Kentucky, Tennessee, southern Ohio and upper New York. Settlers in Kentucky and Tennessee came largely from the old south and from Pennsylvania. They followed one road that ran south and west from Richmond, Va., and another, known as the Great Valley road, that joined it near Ft. Chissel. From this junction the famous Wilderness road cut by Daniel Boone and his men ran through the Cumberland Gap and across Kentucky to Louisville. A branch road, west of Ft. Chissel, led south and west to Knoxville and on to Nashville. It was joined east of Knoxville by the Jonesboro road that stretched across North Carolina from New Bern on the coast.

Settlers from the middle states had a choice of three roads to the west. They could follow the Great Valley road or make use of one or the other of two military roads built during the French and Indian War—the Forbes road connecting Philadelphia with Pittsburgh, Pa., and Braddock's road running from Baltimore, Md., to Pittsburgh. Both had been recently improved by state action.

New Englanders of this period found a single road running west from Boston. It divided at the Connecticut river and sent one branch northward to join the Mohawk turnpike and the Great Genesee road, which were creeping across northern New York toward Lake Erie, and the other branch southwest to connect with the Catskill road leading to the headwaters of the Susquehanna river.

Afore important than any of these roads was the Cumberland or National road. In the Ohio Enabling act of 1802 a fund from the sale of public lands was set aside for road construction. In 1811 the federal government began work on the first section of a hard-surface (macadamized) road reaching from Cumberland, Md., to Wheeling, Va. (now W. Va.) on the Ohio river. Other sections were completed by 1833 to Columbus, O., at which point the state was forced by the opponents of national internal improvements (as roads and canals were known) to take over the "preservation and repair" of the road within its borders. Tollgates were then set up to provide funds for this purpose and to ensure the extension of the road farther to the west. The National road was not only highly beneficial to western settlement but it also pioneered the building of permanent roads with hard surfaces; it decided the question as to who was to build and maintain the public roads; and it showed the rich possibilities in east-west trade.

The "great migration" that came with peace in 1815 brought a new period of road building, especially along the Great Lakes and into the lower south. In New York the Genesee turnpike reached

Buffalo where new roads followed the south shore of Lake Erie across the Western Reserve and on to Chicago and beyond. From Detroit roads reached the eastern shore of Lake Michigan and a stage coach trail soon rounded the lake into Chicago. The National road had, meanwhile, crossed the new state of Indiana and reached Vandalia in Illinois. All along its course local roads branched out to carry farther inland and to contribute their share to the flood of humanity and goods that filled the main stream. Plank roads as well as roads with crushed rock surfaces were tried here and there, but dirt roads still predominated. Bad weather turned them into quagmires and thus stimulated western efforts at canal and railroad developments.

The opening of cotton lands in the lower south along the Gulf stimulated road building throughout the section. Migrants to the cotton kingdom came largely from the up-country of the old south and from the now mature Kentucky-Tennessee world. Those from the old south took either the Upper road which followed the piedmont from Virginia to Columbus, Ga., or the Fall Line road at the head of tidewater which also reached Columbus. From there the Federal road ran on to Mobile, Ala., and Natchez, Miss. Those who came from Kentucky and Tennessee found a network of roads that linked Lexington, Ky., Nashville and Knoxville with Memphis, Tenn., Natchez, Tuscaloosa and Florence, Ala., and New Orleans, La. None of these roads was first class, but when they were impassable, the abundant southern rivers were filled to overflowing and provided transportation.

Thus by the time the frontier reached the plains, roads were to be found wherever they were necessary. The railroad had reduced the need for roads on long hauls, but the improved road still served local needs and the Conestoga wagon was still an important American institution. See also OREGON TRAIL; PONY EXPRESS; SANTA FE TRAIL.

The Third Period.—The third and last frontier advance carried population across the remaining reaches of the continent to the Pacific and then turned back to fill in the areas passed over in the first forward drive. It began around 1840 and lasted to 1890 and beyond, when the federal census announced the frontier at an end. This is usually referred to as the trans-Mississippi frontier.

The region faced by the American pioneer in this last advance was strangely different in character from anything that he had met before, and the frontiers that emerged were more varied and more colourful than any earlier environments had produced. Beyond the first stretches of prairie lands lay the dry, treeless plains where rainfall was too scant for the accustomed agricultural crops and methods. Its nutritious grasses, however, had supported immense herds of buffaloes, and the settlers, after pushing old crops well beyond their limits, gave way to the cattlemen with their picturesque ranch houses, their cow towns and their carefree cowboys. It was a new kind of frontier, where capital and colour went together to stir the imagination of those whose lives were cast in more prosaic times and places.

Beyond the plains were the Rocky mountain ranges, with inland basins sometimes as large as an eastern state and with fur and mineral riches that brought the trapping frontier and the mining frontier to their fullest development. California and Oregon, on the Pacific coast, with their mines, their trading posts, their missions and their international complications, brought the frontiersman to the end of his journey and turned him back to the half-finished continent.

These last frontiers were unique in many ways. Vast distances and greater physical difficulties to be overcome created problems that the individual alone could not solve. Group action, government aid and outside capital were required to carry forward the necessary irrigation projects, to build the transcontinental railroads and to develop the mines and the timber resources. Everything was on a larger scale; everything was exaggerated. Settlement often came by rushes, not by a slow steady advance. There was more of waste, more of lawlessness, more of colourful incident. Hardships were greater and rewards were in proportion. All that any frontier had meant in the past to American life in terms of optimism, waste, lawlessness, abundance and progress were there magnified at the very time that the physical frontier

was coming to an end.

Significance of the Frontier.—In his famous essay on "The Significance of the Frontier" (1893), Frederick Jackson Turner insisted that "the peculiarity of American institutions is, the fact that they have been compelled to adapt themselves to the changes of an expanding people—to changes involved in crossing a continent, in winning a wilderness, and in developing at each area of this progress out of the primitive economic and political conditions of the frontier into the complexity of city life." It was this unique American experience which reshaped inherited patterns into native ones. It created "a new product that is American." It explains "American development."

The fact that the frontiersman had to look to the national government for his land, often for protection and generally for aid in securing markets and ways to market served as a nationalizing tendency. "On the tide of the father of Waters," says Turner, "North and South met and mingled into a nation."

The part which the frontier played in promoting democracy has been subject to considerable questioning. The difficulty seems to be largely one of emphasis. Turner believed that the necessity of doing things for oneself and standing alone much of the time against difficulties developed a peculiar kind of individualism in the American, and at the same time strengthened his co-operative attitudes toward neighbours who faced the same problems. He saw no contradiction in the fact that a man might think that a fool can put on his own coat better than a wise man can do it for him and, at the same time, always be ready to take his part in the house-raising, the husking bee and the community moves for schools, churches and rapid urban development. This kind of individualism was "antisocial" but it led the new frontier states to grant democratic suffrage and to demand equal representation because their citizens believed in the individual's ability to care for himself. As long as opportunity remained in free lands, competency had its chance and democracy would result. Thus, argued Turner, the peculiar type of American democracy "came out of the American forest"; it was not a European importation.

Critics, however, have insisted that much of democracy came out of the old world and much of it resulted from conditions in American society that had nothing to do either with free lands or the frontier. Opportunity and abundance wherever found created a fluid social-economic condition which produced democracy. There was as much of these in the rising urban-industrial east as on the frontier. And besides, neither the Spanish nor the French frontiers showed democratic tendencies. For these reasons, say the critics, too much has been claimed for the frontier.

On the influence of the frontier in creating certain American intellectual traits there is more agreement. A practical, inventive quality in dealing with material things; an idealism that merges into an incurable belief in progress; a conservative approach that is mixed with a willingness to try new things when the accepted fails—these were frontier traits that have become American traits. With them has gone a rather unusual emphasis on the simple virtues of courage, loyalty, energy and physical strength; a larger respect for women; and a rather marked indifference to things abstract. European travelers, commenting on the American and his ways, have stressed these things and found them more common to the west and the newer regions than to the east.

The Frontier and Politics.—Out of the frontier and the west which it left behind it came a goodly share of the nation's problems and not a few of its most bitter conflicts. The steady advance of population produced a recurring Indian problem. Wars and treaties and ultimate removal of the Indians to reservations were a logical outcome of the frontiersman's determination to possess the whole continent.

The same steady advance kept the land problem alive. From pre-emption and graduation to the passage of the Homestead act and the heavy grants to railroads, the settler had his way against those who would use the public domain for revenue purposes. His insistent demands forced every public man to offer some land policy suitable to the people he represented.

Cheap lands on which to produce a surplus carried with them the demand for internal improvements and aid to markets. The

part which government should play in the building of roads, canals and railroads and its right to pass protective tariffs, in part to create markets, occupied almost as much of congress' time for two generations as did the land policies themselves. All were related to the matter of finances. To migrate to the frontier and to establish a farm in the west was not something which every American could afford to do. It has been estimated that in the mid-19th century it took something like \$1,500 to clear and stock an 80-ac. farm in the new west. Most settlers had to borrow money, and thus a hostility to banks which restricted credit and a general debtor attitude which favoured inflation characterized most frontiers. From Andrew Jackson to William Jennings Bryan such western attitudes played an important part in U.S. politics.

Westward expansion ultimately carried the settler across the border into Texas, and the idea of "manifest destiny," born out of three centuries of forward movement, led through the Mexican War to the acquisition of New Mexico and California. The moves to organize this vast, new territory became tangled with the slavery issue and altered its entire character. Where before the struggle had revolved about the merits of the institution itself, it now broadened into one over the expansion of slavery into the territories. The character of western settlement and the kind of institutions which were to be developed had become a part of a power struggle between the north and the south. The effort to shape the future of a frontier in Kansas brought the "cold war" between the sections to open bloodshed. The settlers at Massachusetts Bay, in Utah and elsewhere had attempted to maintain the unique character of their society but there for the first time rival civilizations fought for frontier control.

In no way did the frontier advance affect American life to a greater degree than in the creation of sections and sectional conflicts. Each forward movement into a new geographic area meant the formation of a new society which might be under the political dominance of some older state or in territories just beginning their careers in national life. In either case, its needs and attitude did not always agree with those of the more mature groups in the state or the nation. The result was conflict: and much of American history, local and national, is made up of the struggles and adjustments which resulted. State capitals have been moved, constitutions rewritten and legislative programs remade to satisfy contending interests, old and new, east and west. One American state has been divided. New western states have been created out of lands once claimed by older parent states. In one case, frontiersmen, who had formed their state of Franklin, had to give way to the demands of North Carolina. One need only recall the part played by the young west in the American Revolution and in the War of 1812 to understand the frontier's part in early national affairs. The dominant role which it played in the economic struggles and in the slavery controversy in the years from 1815 to 1860 has already been noticed. Even more significant as expressions of western as against eastern attitudes were the Granger, Populist and Nonpartisan drives of the late 19th century. Each revealed a marked democratic quality; each showed bitterness against eastern neglect; each bore a debtor flavour; and each tried to say that America stood for something which they represented and which, they thought, was being lost.

The Frontier Role of Women.—Women played an important but not spectacular part on the frontier. They never equaled men in numbers and were seldom found with the trapper and trader and not often in the early mining and lumber camps. Only when the settler came to clear a bit of land and to establish a home did the woman find a permanent place at the pioneer's side. Then she proved her ability to uphold her end of the load even where physical endurance was required. She bore the children, cared for them in sickness and often taught them to read and cipher. She tended her garden, cooked the family's food and preserved what she could for the winter. From the skins of wild animals or from homespun cloth she fashioned clothing for her men and children, and when danger from wild beasts or Indians threatened she proved herself capable in the use of a gun.

Disappearance of the Frontier.—During the final decade of the 19th century the open frontier disappeared from the map.

Scattered areas still remained to be settled, but the building of the continental railroads had given them easy contact and means of communication with the rest of the nation. The physical frontier was at an end. Its influence had not come to an end, however. It was to remain, in picture and in story: as a colourful reminder of the American tradition of individualism, of freedom, of opportunity and of daring.

AMERICANISM CONTROVERSY, centred about the French adaptation of the biography of Isaac Thomas Hecker (*q.v.*) by Walter Elliott in 1897, concerned doctrines ascribed to certain Roman Catholics, chiefly Father Hecker, founder of the Paulist Fathers; Archbishop John Ireland of St. Paul; Bishop John J. Keane, rector of the Catholic university; Monsignor Denis O'Connell in Rome; and Abbé Felix Klein of Paris. Pope Leo XIII in a letter, *Testem Benevolentiae*, Jan. 22, 1899, condemned as "Americanism" certain proposals that the church modify her doctrines to suit modern civilization and grant more freedom to individuals by rejecting external spiritual direction, by extolling natural over supernatural and active over passive virtues, and by eliminating vows in religious life. Ireland and Keane denied that they held the condemned doctrines, but Ireland's critics, Archbishop Michael Corrigan of New York and the German bishops of Wisconsin, thanked the pope for condemning the proposals. (T. T. McA.)

AMERICANIZATION, in its narrowest meaning, describes those activities which are specifically designed to prepare foreign-born residents of the United States for full participation in citizenship. It aims not only at the achievement of naturalization but also at an understanding of and commitment to the fundamental principles of American life.

The analysis of this aim raises basic questions concerning national character and cultural change, and the term "Americanization" therefore broadens out as the discussion of its goal becomes more sophisticated.

The task of assimilating vast numbers of immigrants has not been unique to the United States, but no other nation has had as much experience or has faced the issues more squarely over as long a period of time.

Development of the Movement.—Before the outbreak of World War I in 1914, the American public generally took it for granted that the constant flow of newcomers from abroad brought strength and prosperity to the country. The metaphor of the melting pot had been introduced and enthusiastically accepted to symbolize the mystical potency of the great democracy, whereby people from every corner of the earth were fused into a harmonious and admirable blend. When the war began, however, American reactions to European hostilities revealed to everyone the fact, long known to a few, that the population contained many people who, in spite of long residence in the United States, were still completely foreign in sympathy, loyalty and general social and emotional affiliations. They thought and felt as Germans, Italians, English or Irish. To those who considered themselves true Americans, the sudden awareness of the aliens in their midst produced a profound consternation. If assimilation was not being produced by natural, spontaneous forces, then it must be achieved by deliberate, purposeful means.

The Americanization movement which came into being was primarily a program of education. Committees to promote the work were formed and public authorities at every level of government became active in the development of curriculums and the teaching of classes. The idea won immediate popularity. Throughout the country, Americanization agencies and activities in great variety sprang up, unified only by their common conception of the problem. The logic was simple. These unassimilated foreigners lacked some of the important characteristics of genuine Americans. This was dangerous for the C.S. Therefore they must be taught the

missing qualities. To achieve this end, public schools organized classes, state departments of education formed special divisions, universities and city governments appointed Americanization directors and both private industry and voluntary associations, such as the international institutes of the Young Women's Christian association) established their own activities or lent their support to the public programs. The teaching of foreigners became a favourite form of patriotic service, particularly after the entry of the United States into the war.

In its earliest days, the program was directed toward the correction of the most obvious deficiencies. The core of the curriculum was the English language, American history and the governmental structure of the United States: all necessary for naturalization (see NATURALIZATION LAWS: United States). Those who were interested in teaching other subjects began to capitalize on the popularity of the movement. Soon the offering included courses in millinery, cooking, social amenities and the care of children, all presented, of course, as essential elements of American culture.

Enthusiasm for Americanization persisted throughout World War I and was prolonged into the postwar period. Gradually, however, popular interest diminished. The broad adult education movement began its growth and many of the activities which had formerly been justified on the grounds of Americanization appeared worthy in their own right (see ADULT EDUCATION: United States). Many of the leaders and the programs which had formerly served foreigners broadened their scope of operations to include everyone. Wartime apprehensions subsided and new legislation severely limited the influx of immigrants. Before long Americanization became no more than a fairly obscure but continuing effort to prepare people for naturalization by teaching them English; civics and history, or even English alone. In this latter case, classes often included native illiterates.

During the great depression of the 1930s, there was some recurrence of popular concern with Americanization. Many Americans had come to assume that the foreigners had all been assimilated, but the conditions revealed by the economic crisis soon showed how false was that belief. A new fear of subversion arose and gave impetus to new efforts to inculcate American beliefs. Educational programs were sponsored by the various federal relief agencies, most notably the Works Progress (later Work Projects) Administration (WPA), and a stronger emphasis was placed on education by the various public and private immigration and naturalization services. These latter efforts were intensified in the period of worry about foreign influences which began with the outbreak of World War II in 1939.

Changing Concepts.—Meanwhile, however, there had been a thorough re-examination of the concept of Americanization. The early belief that all foreigners should be transformed into typical Americans began to appear naïve as soon as the tensions of World War I disappeared. Who is the typical American? Are American cultural habits (as defined in any particular curriculum) necessarily better than the way of life with which the foreign resident is familiar? Are there not many truly loyal and thoroughly assimilated Americans who are ignorant of much which the foreigner was required to learn? The United States was built by people who came from many backgrounds; is not the effort to impose conformity itself un-American? These and other questions proved hard to answer in the cynical 1920s. Moreover, even the most enthusiastic workers had found the task of assimilating aliens extraordinarily complex and difficult. The solutions proposed during the war years now seemed far too easy. So deeply did the disillusionment penetrate that within less than a decade after the armistice "Americanization" was a term to be shunned, not used. In the years that followed, it never quite regained its earlier lustre.

Instead of the old idea of supplanting all foreign traits by a standard pattern, there grew up the idea of cultural pluralism. Nationality groups continued to flourish and, particularly in the cities, to possess a political power which had to be reckoned with by the slate makers of every party. It was argued by some that assimilation in its accepted sense was not a desirable goal, but that the United States would reach its highest pinnacle by pre-

serving many separate cultures side by side within its boundaries. Still others contended that this pluralism would gradually disappear over the years, that the American character was still in the process of formation and that as it gradually emerged, it would have been enriched by the harmonious blending of the admirable features of the various foreign nationalities.

The early faith in formal education as the only way to achieve assimilation also disappeared. The process involved represented a prolonged and difficult reaction to a social environment much more vital, involved and inclusive than that of a classroom. Special programs of education for the foreign-born became a permanent part of the work of public-school systems, particularly in the cities, and of many private religious and welfare organizations. English, history and civics remained the central themes, although the development of better methods and materials made possible great improvement in the quality of the teaching. These special classes aided their students to make their primary adjustment to life in the United States, but, both then and later, they were also conditioned by all those forces which mold their fellow citizens, including, of course, the widely available general provisions for adult education.

The problem of loyalty, which created the first interest in Americanization and which caused it to be re-emphasized in the depression and in World War II, still remained. Now, however, the focus was no longer primarily on the foreign-born but on the whole citizenry, and the term "Americanism" was increasingly used by legislative committees, militant associations and others to refer to the protection and inculcation of traditional American values.

BIBLIOGRAPHY.—Virtually all of the discussions about Americanization are presented in terms of the basic issues and problems concerned, such as immigration policy, security clearance, health, welfare, housing and education. On this latter subject, always central to the study of Americanization, one of the most useful publications is "Eight Measures for Evaluating Educational Programs for the Foreign-Born," U.S. Office of Education, Circular 357 (1952). (C. O. H.)

AMERICAN LABOR PARTY, a minor U. S. political party in New York state. It was organized in April 1936 by labour union leaders Sidney Hillman (Amalgamated Clothing Workers of America), David Dubinsky (Ladies' Garment Workers union), G. L. Berry (Pressmen's union), liberal Democrats and old-line Socialists. At first over 200 labour unions were associated with the party and all officers were unionists. It was hoped that the party could hold a balance of power between the Democratic and Republican parties in New York. As a pressure group it endorsed candidates who advocated social legislation. The party opposed Tammany Hall (*q.v.*) but generally endorsed Democrats. It also endorsed a few Republicans and occasionally ran its own candidates, winning five seats on the city council in 1936 and five seats in the assembly in 1937. It polled from 75% to 90% of its vote in New York city and never gained strength outside the city.

The party polled 274,924 votes for Franklin D. Roosevelt in 1936. It helped re-elect Fiorello LaGuardia mayor in 1937 and Herbert H. Lehman governor in 1938. It ran its own candidate, Dean Alfange, for governor in 1942 and endorsed Roosevelt for president in 1940 and 1944. Its largest vote, 509,000, went to Henry A. Wallace in 1918. The party was well organized with old-fashioned clubs and precinct workers.

From the first there were factional fights between the left and right wings. When the Communists failed to qualify on the ballot in 1938 they infiltrated the American Labor party and in the convention of 1940 rioted against the endorsement of Roosevelt. When the Communists gained control of the party in the primary of 1944, Dubinsky and many other founders of the party withdrew and organized the Liberal party (*q.v.*). Support of Wallace in 1948 drove more members from the party. In the election for mayor in 1950 the party's vote dropped to 147,000 votes. Its endorsed candidate for president in 1952, Vincent W. Hallinan, received only 64,000 votes.

After 20 years of stormy history, unable to reconcile the differences in personalities, composition of its membership and conflicting objectives, the state committee voted to dissolve the organization on Oct. 2, 1956. (H. F. Tt.)

AMERICAN LAW. Speaking in a technical sense there is no American law. Except within a field constitutionally restricted, there is no national supreme tribunal to unify legal doctrine. Neither is there a common law of the United States as a sovereign state. Each of the states has its own common law, unrestrained otherwise than by certain provisions of the federal constitution; and none of these necessarily tends to produce unity of law except the clause requiring that "Full Faith and Credit shall be given in each State to the public Acts, Records, and judicial Proceedings of every other State": a provision which does somewhat tend to unify doctrines respecting the conflict of laws.

For a period of nearly a century it was believed that unity would be promoted through the power of the federal courts to develop an independent body of national doctrine in the field of "general commercial law," which the state courts would be inclined, though not bound, to follow. However, the degree of uniformity produced in this way was disappointing, and any remaining hopes for progress along these lines were ended by the supreme court's decision in *Erie R.R. Co. v. Tompkins*, 304 U.S. 64 (1938), requiring the federal courts to apply the laws of the several states. A more significant approach to the ideal of uniformity has been through the uniform acts prepared by the National Conference of Commissioners on Uniform State Laws for adoption by the states. These statutes illustrate the sense in which there does exist an American law—there is a great body of judicial tradition and a vast mass of legislation embodying the rules and standards by which the American people, regardless of state lines, are content to guide their lives; and all this law presents broad features of unity. Indeed, nothing is more astonishing than the rapid spread of statutes, in a few years, into dozens or even scores of states—thus evidencing popular convictions nationally dominant; nothing more certain than the slower spread of a judicial doctrine that is felt to have adjusted justice to new conditions.

Of the civil law that once prevailed in territory subject to France and Spain, little trace remains except in Louisiana and in the variant marital community systems in a few other states.

In the sense just explained, American law is marked by four periods of development: (1) to 1776; (2) 1776–1828; (3) 1828–68; and (4) after 1868.

Colonial Law.—It is a traditional judicial tenet that the colonists brought with them as a birthright, along with English political traditions and precedents, the common law, its concepts of property, liberty and justice and such of its rules as fitted colonial conditions. They did indeed claim the general liberties of Englishmen. They did not claim or desire the common law; they had suffered too much from governmental tyranny which they deemed part and parcel of that system. All of the New England colonies, by practice or explicitly, denied its binding character. Half a dozen of the other colonies endeavoured to follow it from an early date. All the colonies, however, had codes, some notably complete, that covered their essential needs, so that at best the common law was but a subsidiary system; and in several even this position was accorded not to that law but to the Scriptures. Only three colonies gave statutory recognition to the English law in the colonial period.

For these reasons, and because the colonies were isolated and imperial control was slight, the 17th century in particular was a period of experiment and creativeness. The colonists were well aware of the proposals of reform and codification made by Lord Bacon and under the Commonwealth, and some of their codes were prepared in England by men who evidently sympathized with those proposals. Dozens of striking innovations—some of them of singularly modern semblance—were made upon the common law; some persisted into the later law—the most important was perhaps the recording of conveyances.

For two reasons, however, the history of this period, although profoundly interesting in itself, must be regarded as apart from the general legal development of the country. In the first place, its practices were too divergent from the tradition of the common law. There were almost no lawbooks—original, reprinted or imported. In most of the colonies there were extremely few trained lawyers and even the chief justices were rarely lawyers; the highest courts

were legislative or executive. Laymen administered a sort of natural equity. In the second place, most of the valuable innovations were abandoned as soon as a reception of the common law began.

In the 18th century something like an independent judiciary developed. Imperial control became a reality; colonial statutes were disallowed (400 of them) for departures from established law; judicial appeals to England became steadily more numerous. A professional bar—for which there was evidently no place in the preceding century—gradually developed. Many of its leaders studied in the Inns of Court (perhaps 50 before 1760; 111 between 1760 and 1783), and to a very remarkable degree it was composed, otherwise, of graduates of American colleges. When the American Revolution came it was entirely dominant, and this pre-eminence it retained for a century.

This period was one of absorption of the English law, marked by the disappearance of older innovations and the development of few new ones. That it is in the truest sense an integral part of American legal evolution could be illustrated in many ways. Two instances are sufficient. The first, in the field of procedure, is its system of courts, the most characteristic feature of which—the multiplication of local tribunals that brought justice near to every man, instead of a circuit system—persisted (for reasons born of frontier conditions and self-government). The second, in substantive law, is the origin of the American doctrine that in libel truth (subject indeed to commentary for which there is no room) is a defense.

The whole of colonial experience was of course continuous and so the spirit of the earlier century lived on through the later. Demonstrably, various of its positive innovations, clearly adapted to colonial conditions, persisted against the English reception. As for many innovations of omission, doubtless "mere ignorance had freed the colonies of a great mass of antiquated and useless rubbish" (32 N.H. 231), but what was once overlooked in ignorance must later have been excluded in wisdom.

From 1776 to 1828.—Formal adoption of the common law, after the Revolution, as the basis of American law—but in all the states, explicitly or in judicial practice, only so far as suited to American conditions—set an ideal which the next period was reasonably well to realize. The present continued to be essentially one of reception of the English law. This was inevitable. There was still no independent body of American law; the first volume of American reports was published in 1789; less than a dozen volumes were in print in 1800. When James Kent was appointed to the New York bench in 1798 there were no reports of that state. "English authority," he says, "did not stand very high in these early feverish times, and this led me a hundred times to bear down opposition or shame it by exhaustive research and overwhelming authority."

Free from hampering precedents, in his 25 years as judge and chancellor he not only gave form to the entire law of that state but made an unrivaled contribution to the law of the whole country. In this his *Commentaries* (1826–30) played a large part; by universal consent they are worthy of comparison with Blackstone's. He set himself the task of establishing the common law and he succeeded. That he had not a reformer's spirit is shown by his sigh over "the piles of learning," "the profound logic, skilful criticism and refined distinctions" doomed to destruction by the New York statute abolishing the Rule in Shelley's Case. He did, however, reject the doctrine of market overt, extended replevin to any wrongful taking and lauded the establishment of the lien theory in mortgages.

Notable statutes of the period are fairly numerous: permitting grants in fee without mention of heirs; granting powers *in rem* to courts of equity; legitimizing children by subsequent marriage of their parents; abolishing entails and the Rule in Shelley's Case; abolishing primogeniture and establishing inheritance equally by all children; modifying the law of devises in favour of after-born children and the issue of predeceased children; conferring limited liability upon corporations; providing a general law under which corporations might freely organize. Pennsylvania—"the first of civilized countries to do so"—provided in 1776 for a penitentiary, presumably under the influence of the marchese di Beccaria,

whose book had already been published in America and was soon to be found on the remotest frontiers. At the same time Pennsylvania introduced relief for insolvent debtors, and within a generation they were "scheduling out" of jail in remote western territories. New York in 182; made a complete revision of its statute book, altering fundamentally the law of realty and providing a system later adopted by various states. Notable also were reforms due to popular disuse, such as the dying out of feoffments, fines and recoveries, all of which were used in colonial times and were provided for in the statutes of this period. These illustrations sufficiently indicate the experimental spirit of the time. It was not displayed in equal degree by the judiciary. Preferable to Kent's lament was the denunciation of demurrers, by a contemporary farmer-judge, as "an invention of the bar to prevent justice . . . a cursed cheat!"

From 1828 to 1868.—Almost as distinctly as in political history, the triumph of frontier democracy in the elections of 1828 marked the transition to a new era in the law. It was a period great for its critical spirit. Also, although individualism was the dominant notion of the contemporary world in politics and in economics, and though the frontier influence might have been expected to exalt its influence, it was a period remarkable for its social spirit. Both judicial and legislative improvements reveal its originality. What John H. Wigmore said of the law of evidence could be said of other fields of law: "Partly because of the lack of treatises and reports, partly because of the tendency to question important rules and therefore to defend on grounds of principle and policy whatever could be defended, partly because of the moral obligation of the judiciary, in new communities, to vindicate by intellectual effort its right to supremacy over the bar, and partly, also, because of the advent, coincidentally, of the same rationalizing spirit which led to the reformatory legislation—this very necessity of restatement led to a finely reasoned system." Very important in this period, rivaling the influence of Kent in the preceding, was the work of Joseph Story, who in 13 years (1832–45) published nine remarkable textbooks, which in succeeding editions had a profound effect on forming American law.

Thus, in the law of evidence, "the period from 1840 to 1870 saw the enactment, in the various jurisdictions in this country, of most of the reformatory legislation which had been carried or proposed in England," and the promulgation of a body of opinions ("superior ion the whole) to the judgments uttered in the native home of our law."

Notable innovations were the repudiation of the merger of torts in crimes and of postponement of the civil action; repudiation of the doctrine of ancient lights (impossible in a new country); introduction of apportionability of rent; the first decisions permitting suits upon a contract by the beneficiary (now the general doctrine); the first decisions treating divorce as a proceeding in *rem* and recognizing a woman's separate domicile for purpose of divorce: notable decisions—though with precedents "from the first colonization" (Chief Justice Morrison Waite)—upholding the regulation of private business "affected with a public interest"; and the first of many decisions forbidding the malicious use of a landowner's privileges.

Many changes plainly reflect the special conditions of the country. Examples of such were the substitution of navigability for the tidal test of admiralty jurisdiction, thus adapting it to the inland seas and rivers of the country; the introduction of the doctrine of "colour of title" in adverse possession, and other minor changes in that subject due to frontier conditions; fence laws reversing the common-law duties respecting trespass by animals; decisions concerning grain elevators that made novel changes in the law of bailments and confusion of goods. American deeds began to assume forms suitable to the simple description and titles of the country; quitclaim deeds became primary and original conveyances; disseizees acquired the right to make conveyances. Great modifications were made in equitable doctrines of laches and forfeitures in specific performance of contracts for the purchase of land on installments—modifications due to the fact that in America land has always been a subject of commerce: as Kent had pointed out. The amazing persistence of benefit of clergy down

to (and indeed through) this period was certainly due to the illiteracy of even prominent citizens in frontier society. A remarkable adoption of frontier customs in this period (though mainly by statute) was that of the mining and water laws developed in western mining camps.

Even more distinctive than the work of the courts was the legislation of this period. At this time reform by statute became, and remained, the primary characteristic of American government and law. "The establishment of self-government on a new soil realized the idea of the people as the source of political power as it had not been realized in historic times" (Ernst Freund); and on a scale equally unique they proceeded to illustrate the dictum that democracy relies on laws rather than on men. Religious and property qualifications for voting, officeholding and jury services were swept away by the middle of the century. To these triumphs of liberalism a third was added in the creation of a public-school system before the American Civil War.

A prelude to the use of the police power in the following period appears in the elaborate constitutional provisions, beginning before 1850, respecting banks, railroads and canals, and in statutes requiring periodical or cash payments of wages. Income taxes of the modern sense were adopted in the 1830s and 1840s in six states. A great moral movement in the political field—for prohibition, antislavery and women's rights—and an altruistic effort on a vast scale in favour of the poor and defective marked the entire period. Exemption laws (which had come down from colonial times) became general and liberal. Notable was the appearance of the homestead (1836) and its inclusion in the exemption statutes. Save for slight vestiges, imprisonment for debt was everywhere abolished.

The narrow protection in property rights accorded married women by equity was widened by statutes which placed them on an equality with their husbands, although not until 1913 were the disabilities of coverture abolished in the last state. Judicial liberalism supplemented this legislation: *e.g.*, in recognizing a wife's right in the society of her consort. It was recognition of woman's equal participation in the hazards and hardships of frontier life that wrote this entire chapter of the law. Children were protected against parental cruelty by imposing criminal responsibility; reformatories were established for minor delinquents, but their criminal liability was not much altered. In the law of property, rules of inheritance were greatly changed in favour of parents, surviving spouses, the half-blood and illegitimate children. Heirs and next of kin became generally identical. However acquired, and whether from the paternal or maternal side, estates were made to descend in the same manner. All real estate became liable to execution and administration assets for payment of debts with few preferences. The fictions of ejectment disappeared. In this whole field, however, legislative reform was always partial, casual and unsatisfactory. Variations from state to state remained innumerable. The distinctions between realty and personalty and between legal and equitable estates continued to be fundamental. The doctrines of tenure and the devices to evade them that fill the law of future interests remained untouched in most states except by fragmentary tinkering. Entails are still theoretically possible in various states. Shelley's Case continued to have life in about half the states.

Equity, on the other hand, was developed with relative consistency. The erratic state of the property law continued to extend, however, to mortgages, which were hardly the same in any two states, although everywhere the legal incidents tend toward obsolescence. The equitable doctrine of priorities has from colonial days been fundamentally modified by the recording system. For historical reasons the spread of the equity system was delayed in various states, proceeding piecemeal by statutory grant; this was notably true, for example, in Massachusetts and Pennsylvania. The infiltration of equity into law, in such states, was a unique detail of American legal experiment. No American court exercises the full jurisdiction of English courts of chancery, its administrative portions having been given to separate tribunals. The development of probate courts was a noteworthy feature of the period before the Civil War. During it, also, the equitable jurisdiction

was generally entrusted to courts of double jurisdiction (in a few states they continued to remain distinct and some others maintained distinct chancery terms). Under the codes of civil procedure adopted since 1848 in many states the administrative fusion has been complete, the common-law actions and the distinction between law and equity being abolished in the sense that rights and reliefs formerly "legal" or "equitable" are all enforced in one "civil action." This reform was accomplished for the federal courts with the adoption in 1935 of the federal rules of civil procedure, promulgated by the U.S. supreme court under authority of an act of congress. These rules, not only in their complete fusion of law and equity but in their thoroughgoing simplification of practice and procedure, were a major achievement in law reform and constituted a model for the states. The result was not to weaken equitable principles but to give them new vigour and applicability.

The adoption of these codes of civil procedure is the most remarkable feature of the third period and, on the whole, the most ambitious systematic reform yet undertaken in American law. The ideals of these codes were only imperfectly realized. For various reasons (not the least of which was the hostility of the courts when the codes were first created), their construction was once hardly less balefully technical (and perhaps less certain) than the old common-law system. Constant legislative tinkering increased uncertainty and resulted in monstrosities of bulk and complexity. While their fundamental reforms would doubtless never be abandoned, there was, later, a strong agitation for the regulation of strictly procedural matters by rules of court—the principle established in 1938 for the federal courts.

In some ways popular control in this period debased the judiciary. Of particularly evil consequence was a tendency to restrict the power of the trial judge in charging the jury, forbidding more than a bare restatement of the evidence. This remained general practice. Down to 1798 all the judges were appointed by the governor or elected by the legislatures: by 1840 popular election was characteristic, and thereafter it became increasingly predominant. A tendency to shorten the term of tenure sprang from democratic distrust of irresponsible authority. The powers of practically any judge to declare legislation unconstitutional and to issue injunctions kept such distrust alive. Elective terms, however, have always been long as compared with those of other officials, and no frontier state ever made judicial tenure so short and precarious as did two of the oldest states in New England. In the 20th century there has been a decided tendency to re-elect worthy judges and to make their salaries adequate. Few leaders of the bar can be drawn from practice by any feasible salary unless under tenure for good behaviour; but the rising level of judicial ability and the many instances of brilliant men who have already served on the bench justify the belief that judicial competence is obtainable under the elective system. The gravest charge that can be brought against the frontier democracy of the period before the Civil War is that it greatly lowered the standards of admission to the bar.

The bench was both able—in some states, notably in the south, brilliant—and liberal. The legislatures were characterized by rationalism and enlightenment. The bar, whatever its defects, dominated the legislatures and formerly enjoyed in general a social and political prestige that was to diminish in later years. On the whole, the period was one of contradictions but also of substantial accomplishment.

After 1868.—The ultimate protection of private rights rests upon guaranties in the federal constitution. No state may deprive any person "of life, liberty, or property without due process of law." "deny to any person within its jurisdiction the equal protection of the laws" or pass any law "impairing the Obligation of Contracts." The 14th amendment of 1866, containing the first two of these provisions, profoundly altered the relation between the state and federal courts and distinctly marked the beginning of a new period in the legal development of the country. Attempts to define due process and the police power made the federal courts the battleground of the social legislation which stemmed from the complex economic and industrial conditions developed after the Civil War. Many important cases involving corporations (which were for decades parties to approximately half of all litigation)

were also thrown into the same tribunals, for they are "persons" under these clauses and "citizens" for purposes of federal jurisdiction, and their charters are contracts with the state. And as corporations carry on most of the business and own a very large percentage of all the property in the country (Justice Stephen Field of the supreme court estimated it as four-fifths in 1890), the matter has immense social significance.

The establishment of unbridled 19th-century democracy only slightly affected the treatment of industrial property. "For at least 60 years after the adoption of universal suffrage the tendency was all in the other direction—to legislate for the property owner rather than against him; to strengthen the powers of capital rather than diminish them. . . . The small protection given to the rights of man, as compared with that which was accorded to the rights of property, is a salient feature in the early history of every American state—and sometimes of its later history also" (A. T. Hadley).

The explanation of this fact lies undoubtedly in the loose economic framework of society. Cheap land created a people of freeholders without class distinctions, among whom any man who aimed high might rise high. Radicalism, in such a society, could gain no headway. That came with the development of great urban centres and an industrialized society. The rural population was nine-tenths of the total in 1800, and little less in 1850, but considerably less than half by mid-19th century.

Industrial regulation of the modern type began about 1870 with the railroads, and its assertion "shook the foundation of state and national politics for a generation." The subsequent increase of administrative commissions with investigative powers and subject to only limited judicial review is perhaps the most striking phenomenon in modern legislation. There is a tendency to standardize procedure and there is developing in this way a great field of administrative law. Trade regulation began to increase rapidly only in the late 19th century: for example, pure-food laws, later to become universal, began in 1892.

The purely legal status of the American industrial worker is unique. The exemption statutes lessened the effectiveness of the law's remedy of damages; the 13th amendment of the federal constitution, prohibiting "involuntary servitude," makes specific performance impossible, even were equity inclined to try it. Yet these immunities were relatively worthless so long as the worker was unprotected against unfair agreements secured through his economic needs. The tendency was strongly toward increasing restriction upon "freedom" of contract and "right" to labour. As late as 1905 the supreme court held unconstitutional a law regulating the hours of bakers, but the case soon lost its vitality; it was killed by a dissenting epigram of Justice Oliver Wendell Holmes—"the 14th Amendment does not enact Mr. Herbert Spencer's Social Statics." In the field of tort nothing had been done up to 1900 beyond limitations upon the rules of fellow servant, contributory negligence and assumption of risk, sometimes through and sometimes outside of employers' liability laws, thus leaving wholly unprovided for at least half of all industrial accidents. After 1910, however, all the states adopted workmen's compensation acts (first, 1902) entitling the injured employee to compensation without reference to common-law notions of fault.

The range of other social legislation became immense. Much was purely moralistic (against gambling, racing, cigarettes, liquor, sexual sin, etc.). The treatment of women merits, perhaps, special mention. Within the family the married woman was placed in substantial equality with her husband. In industry the attempt to give her special protection was a storm centre of agitation. But generally women came to enjoy such protection and to some extent a favoured position in property and domestic relations. Divorce is allowed in all states: causes run from adultery only to a score and more, including mental cruelty and incompatibility. Such causes are in many instances a cover for mutual consent. In 1942 the supreme court abrogated its former rule on interstate recognition of ex parte divorces (according to which a woman, though lawfully divorced in one state, might be convicted of bigamy in another upon remarriage, and announced that all states must recognize a divorce granted by the state of domicile of either spouse (*Williams v. North Carolina*, 317 U.S. 287)). However, since a

state could still withhold recognition on the basis of a finding that there was no domicile in fact in the divorcing state. "migratory" divorces of this type continued to confer only a somewhat precarious status. Suits for breach of promise to marry and for alienation of affection (both almost exclusively brought by women) are curiosities of American law. Common-law marriage still exists in many states. Desertion of wife or children, a very common offense, is generally a crime and a score of states have adopted a uniform act on this subject prepared by the National conference. There has been considerable eugenic legislation restraining freedom of marriage.

Defects of the System.—Dissatisfaction with the legal profession increased in the first third of the 20th century. The bar lost its onetime leadership because it ceased to lead, to make a social contribution commensurate with its political pre-eminence. In the first three decades of the century the judges, acting with a sense of duty but seldom guided by a liberal appreciation of expanding public interests, invalidated many popular legislative reforms. "Most of the common law has developed in that atmosphere of indifferent neutrality which has enabled courts to be impartial but also keeps them out of touch with vital needs" (Freund). Even the intelligent layman in America rarely knows anything of law except through the newspaper. There he reads only of constitutional questions—seemingly mere matters of policy of which any man may judge and which often seem irrational; of criminal cases which blazon all the vices of criminal procedure: of crowded dockets and delayed justice in spite of judicial work schedules which, at least to the layman, appear leisurely indeed. Hence the discontent which precipitated at one time the demand for the recall of judges and judicial decisions by popular vote and for limitations upon the power of divided courts to invalidate statutes, all of which demands became law in a few states. The administration of justice became a paramount problem in national life. Not only in many cities were the trial dockets filled for two to four years ahead; even in rural jurisdictions the same was sometimes true. General verdicts are the basis for repeated retrials of the facts. The reports of representative states show that at one time appellate decisions turned on pleadings in from 5% to 25% of all cases—and the higher number was much the nearer to the mean. Reversals for all causes are given in a large proportion of all cases appealed. Innumerable reversals are based, even in civil cases, upon errors that could not affect substantial rights, although this came to be statutorily prohibited in about two-thirds of the states. The efforts of reformers were directed toward strengthening the authority of the trial judge; re-establishing the original practice at common law of permitting the appellate court, even on writs of error, to render final judgment on the facts without ordering a new trial, as in appeals in equity; regulating procedure in higher courts by rules of court, as in England, in place of the legislative enactments, sometimes of infinite detail, which had been the almost exclusive system and prolific of delay and appeals; and abolishing appellate reversals for immaterial defects. As regards the last there was a marked improvement in the attitude of appellate judges. A great reform was the declaratory judgment; by the early 1960s more than 35 states had adopted the uniform act drafted by the National conference. Statutes of congress and of various states made arbitration agreements specifically enforceable. Much has also been accomplished in expediting and cheapening the petty litigation of great urban centres by reorganizing them into appropriate branches under a simplified procedure. In a number of cities legal-aid societies were established to dispose of a vast amount of litigation substantially without charge. Regular courts for small claims and poor litigants were also set up.

All the evils of procedure present in civil suits exist in more aggravated form in criminal cases, with many others in addition. Homicides alone are estimated by many authorities as being in the thousands yearly. That many kinds of urban crime are on an organized business basis seems to be unquestionable. That lawyers are essential to, when not part of, this business, prepared with every legal device to delay and evade justice for their criminal clients, is often manifest. Equally alarming is the actual inequality of men, rich or poor, before the law, in consequence of its de-

lays, and of those rich or poor in influence in being brought before it. In 1909 Pres. William Howard Taft declared the administration of the criminal law in all the states, with possibly "one or two exceptions," to be "a disgrace to our civilization." Frequently hundreds, sometimes thousands, of veniremen are examined before a jury is secured; usually days, sometimes months, are thus utilized. Delays in trial are even greater than in civil cases. Indictments are still found deficient in appellate courts, though here there was great improvement, for flaws of unbelievable triviality. The defendant is nowhere compelled to testify. Punishments for the same crime vary amazingly from state to state. In some states the jury has large discretion in fixing the punishment; in many it is judge of both the law and facts. The requirement of unanimous verdicts is universal in criminal cases.

Legislation, however, became extremely active in remedying many of these evils. Some states adopted habitual-criminal acts which, among other things, impose life imprisonment upon a defendant with a record of a small number (usually four) of earlier convictions. Minors were also given greater protection after 1900 by raising the age of criminal responsibility (to 16 or 18) and establishing special courts to deal with the younger delinquents: subjecting these to the state's guardianship somewhat as under the old doctrines of equity. In the field of punishment notable reforms were introduced: suspended and indeterminate sentences, commutations for good behaviour and parole. But even these were perverted. Weak or calculating judges abused the first with a leniency so excessive that it approached immunity; the second appeared plainly to be overgenerous to hardened offenders. The most vicious of criminals were often paroled. The primary cause was probably politics; indubitably so in some states, where every step—whether or not an arrest should be made, the defendant held to the grand jury, the case dismissed, the convict paroled—seemed to be seriously entwined with political corruption.

For these evils, and equally for the evils in trial and appellate courts, in civil and criminal cases, springing from a deep-rooted attitude toward litigation as a mere game of wit, there is no cure except in an increased power and awakened conscience of the bench and a general betterment in the moral tone of the bar. At least as regards intellectual improvement much was accomplished. The university law schools acquired distinguished excellence and a high professional prestige. Higher standards of education were enforced through requirements for admission to the bar—the American Bar association advocating a minimum prelegal education of three years in college and a minimum professional training of three years in law school—but not all states meet these standards. Disbarment is in the hands of the courts and has been sparingly used. A few states incorporated their bars as self-governing bodies with exclusive power over admission and discipline.

Codification.—The process of codification, after the period of activity which began before the Civil War, temporarily ceased, but began again in a new form during the first half of the 20th century. Five codes of penal and of the substantive civil law, 30 codes of civil procedure and about 30 of criminal procedure were mainly the products of the earlier movement. The American Bar association, acting with state commissioners, had prepared more than 90 uniform acts by the early 1960s. Of these, five in the commercial field (on negotiable instruments, warehouse receipts, bills of lading, sales and stock transfers) were adopted in from half to all jurisdictions. An American Law institute, in which teachers of law are dominant, has prepared a restatement of various branches of the substantive law and a model code of criminal procedure, all designed to promote uniformity in essential principles. The "complete" or "revised" statutes existing in every state of course merely supplement the unenacted law, but in many states it would be hazardous to say which of the two is of greater scope. Legislative drafting bureaus (the earliest of 1890) came to exist in practically every state.

The impulse to codification came from the unmanageable bulk of judicial law and the consequent uncertainty of legal knowledge. The number of annual volumes of American reports is in the thousands. The cases cited by the court in any volume run into

hundreds and frequently into thousands, from many jurisdictions. The law is beyond the power of any layman to discover or to comprehend.

Very much has been wisely said on the necessity of guiding legislation and judicial decision by the functional test of social utility, but no efficient instrumentality has existed through which to supply objective evidence of the relative working of substantive legal rules. On the other hand, it was expected that precisely this would be accomplished in the procedural field by the judicial councils created after 1922 in many states for the consistent study and improvement of judicial organization and procedure. Altogether, the immense significance of the new spirit manifest in the profession could not be doubted. Most important of all was the fact that the revolt against unsocial law created by the labour struggle had spread to social workers, social scientists, the law schools and even to the bar. It opened a new epoch in the law of the country.

PUBLIC LAW

The public law of the United States largely revolves around: (1) the federal system; (2) the written constitution; and (3) the judicial construction of written constitutions. These three elements are closely related, for the United States supreme court has from an early day been the final arbiter to determine the respective powers of the United States and of the states under the written constitution of the nation: and the state courts (each within its own territory) are the final arbiters of state governmental power under the written constitutions of the states.

The Federal System.—Plans of colonial federation were several times proposed before the period of the American Revolution. The movement that finally led to independence forced some degree of unity, and the first continental congress assembled in Philadelphia in 1774 was the outward symbol of unity of political action. What political direction there was of the revolutionary movement came through the continuance of such an organization, without any formal written instrument of union, and this system was highly inefficient. It was replaced by the Articles of Confederation in 1781.

The Articles of Confederation established a loose union, with little in the way of a national government and with no power in that government to raise revenue or to enforce its orders by action directed immediately toward the citizens of the United States. The confederation had authority to ask the states to act, but not to compel action either by the state or its citizens. It had power to make treaties but no power to enforce state observance of such treaties. Each state had power to impose restrictions upon trade with other states, and a state with the geographical advantages of New York was in a position to impose and did impose burdensome restrictions upon the commerce of the neighbouring states of New Jersey and Connecticut.

Such conditions could not long continue. They led to the assembling of the federal convention of 1787 and to the framing and adoption of the constitution of the United States, under which the government was instituted in 1789. The constitution was framed with specific reference to the difficulties presenting themselves before its adoption. A governmental organization was set up independent of that in the states, and with power to enforce its commands directly upon the citizens of the states. Large powers were conferred, the most important of which were the powers to control interstate and foreign commerce, to levy taxes and to raise federal revenues independently of the states and the control of foreign relations. Thus a central government was constituted with real authority. The history of the federal system

since 1789 is to a large extent a history of the expansion of the importance and authority of the national government under this constitution. This expansion has been accomplished in several ways: (1) by a broadened construction of the original provisions of the constitution of 1787; (2) by amendment of this constitution; (3) by the development of means of transportation and communication which enormously increased the number of transactions in interstate and foreign commerce, subject to national control; (4) by the increased number of states, the larger portion of which were created out of territory belonging to the national government.

Construction of the National Constitution.—The constitution of the United States has been authoritatively and finally construed by the United States supreme court, an organ of the national government. In substantially all matters this court determines the limits of national power on the one hand and of state power on the other. No matter how impartial such a tribunal may have sought to be, it has almost of necessity tended to favour the government of which it is an organ. Under the chief justiceship of John Marshall (1801-35) it was an essential factor in establishing broad national authority. *McCulloch v. Maryland*, 4 Wheat. 316 (1819), determined that the nation had not only the powers expressly conferred upon its legislative, executive and judicial departments, but also all authority "appropriate" to carry such powers into execution. The constitution uses the words "necessary and proper," but the court held that there was no need to show actual necessity in order to uphold national power.

Under the chief justiceship of Roger Brooke Taney (1836-64) there was an occasional tendency in dicta of the court to regard state power as of greater importance, but no actual reduction of national power took place. In fact, two of the broadest extensions of national power were made under Taney through reversals of views taken under Marshall. In one of these cases admiralty jurisdiction was extended to all navigable waters (*Genesee Chief v. Fitzhugh*, 12 How. 443 [1851]). In the other the federal courts acquired an extensive jurisdiction in corporate matters (*L.C. & C. R.R. Co. v. Letson*, 2 How. 497 [1844]).

Although the powers of the national government under the constitution were expanded, the supreme court at the same time sought to prevent the destruction of state powers by construction. Although in mid-20th century W. W. Crosskey advanced a revolutionary thesis that the powers of the national government were originally intended to be plenary, the orthodox view to the contrary remained settled law, and the national government one of enumerated powers, residual powers being reserved to the states. While the nation's powers were extended, there remained a large sphere of state power upon which the nation may not encroach. No national power exists except as it is found in the terms of the written constitution, and the supreme court can expand such powers only as they may be derived from the terms of the written constitution. The terms of this document are broad and expandible, yet judicial construction of these terms has definite limits.

Amendment of the National Constitution.—By constitutional amendment the terms of the written constitution may be changed. Twenty-three amendments to the constitution of the United States had been adopted through 1961. The first ten of these amendments are limitations upon the national government, but in no material respect do they narrow the powers exercisable by that government. The 11th amendment safeguards the states against suits; the 12th, with reference to the election of the president, does not affect governmental power. The 13th affirmed the judgment of war that slavery should be abolished. As now construed by the courts, the "due process of law" and "equal protection of the laws" clauses of the 14th amendment have transferred the protection of individual rights from the states to the national government. The 15th and 19th amendments, and to some extent the 14th, limit the determination by the state as to who shall have the right to vote. The 17th, by providing for the popular election of senators, somewhat diminishes the importance of the states as units in the federal system. The 18th amendment, until repealed by the 21st, brought the government into closer contact with the lives of citizens. The 16th gave the na-

tional government a new source of revenue and made possible a system of subsidies through which the government gained increased control of state policy. The 20th set the dates for presidential and congressional terms and made provisions for succession in case of death of the president-elect. The 22nd prohibited a third elective presidential term. The 23rd granted residents of the District of Columbia the right to vote in national elections for president and vice-president.

Increased Contacts of a National Character.— In 1789 transactions in interstate commerce were few, and the means of conducting such commerce slow and cumbersome. As new agencies of commerce developed, the federal regulatory power was applied to them. With the transition from the horse and the stagecoach to the steamboat, the railroad, the telegraph, the telephone, the radio, television and the airplane, portions of the country once distant were brought into closer relationship, and the transactions controllable by the national government were infinitely multiplied. These changes necessarily brought increased exercise of national power.

Federal regulation of interstate railroad rates and service came in 1887 and expanded rapidly. The relations between interstate commerce and purely domestic commerce within a single state are necessarily close when both transactions are handled by the same agency. And so by legislation and by judicial decision, the federal government came largely to control the railroad rates for domestic transportation within the states, as an incident to the control of interstate commerce (*Railroad Commission of Wisconsin v. C.B. & Q. R.R.*, 257 U.S. 63 [1922]). In the same manner the nation has come to control safety appliances of railroads in both interstate and domestic commerce (*Southern Ry. Co. v. U. S.*, 222 U.S. 20 [1911]).

Congress began in 1890 the regulation of combinations in restraint of interstate commerce, and in this field largely replaced state action. The commerce power also became the basis of the Labor-Management Relations act, under which the regulation of important labour relations was largely transferred from the states to the national government, acting through the National Labor Relations board. By the expansion of the national banking system and the creation of the federal reserve system, the federal government largely controls the banking business of the country. There is extensive national control of industry, banking, labour, railroads and the protection of individual rights.

These expansions of national authority were natural and to be expected, but they made the national system differ materially from any that could have been thought of in 1787.

Increased Number of States.— The national government was created by a small number of states which were the creators of the nation. States as units in a federal system were naturally more important when their number was 13. The influence of increased numbers becomes more important when it is considered that 23 of the additional states were wholly created out of territory acquired by the nation and were never a part of the original states. These states, forming more than half of the area of the country, are in a very real sense creatures rather than creators of the national government. With the increased importance of interstate relations, state boundaries largely became artificial lines, and national consciousness, greatly strengthened by the Civil War, became politically dominant, since general elections are usually held in all the states upon the same day as national elections.

Yet, though the states came to be less important politically as units in a federal system and lost all political status in international affairs, they came, with increased complexity of social and economic needs, to have a heavier burden of governmental tasks than ever before. For upon them fall the burdens of administering criminal and civil justice in the daily affairs of life and the tasks of more detailed regulation of industry, as well as the conduct of schools, the administration of charities and the protection of persons and property.

The Written Constitution.— The written constitution is an essential element of the federal system in the United States, for there must be some authoritative statement of the respective powers of nation and states. The written constitution is not an

essential device of state government in the United States, but each state has from its beginning had such a constitution.

The national constitution is a relatively brief document, as are a few of the earlier state constitutions. But the typical state constitution came to be a lengthy document that not only organizes and imposes limitations upon the state government, but also contains a great mass of detailed legislation. This legislative detail is frequently altered by state constitutional amendments. In theory the national government has only such powers as are granted to it by the national constitution, and a state government has all powers not denied it by the national constitution and the constitution of the state. This might naturally imply a strict construction against national powers and a liberal construction in favour of state legislative authority. But with long and detailed state constitutions, the opposite results. Under broad constitutional grants of national authority, the United States supreme court has, from the first, been liberal in the construction of national power. Under detailed state constitutions, hedging about the powers of state legislatures, the tendency of state courts has been toward a narrow construction of such powers.

Judicial Construction of Written Constitutions.— Some device is necessary in a federal system to preserve the barriers between federal and state powers. The United States supreme court serves as this agency. In addition it serves as the final agency in other cases for the determination of the powers of congress under the constitution; and the highest court of each state serves as the agency to determine the powers of its state legislature under the written constitution of that state. The courts of both state and nation decline to pass upon certain questions that they term political, but apart from this they construe the written constitutions of state and nation. The power of the courts to determine the constitutionality of legislation was first asserted in *Ken. Jersey* in 1780, and has been generally recognized since the decision of the United States supreme court in *Marbury v. Madison*, 1 Cranch, 13; (1803).

The more detailed the constitutions and the greater the tendency to exercise governmental power to meet new industrial and social needs, the more often are the courts called upon to construe written constitutions. With numerous restrictions imposed on legislative action by constitutional texts, practically every important federal and state legislative enactment comes to the courts for the determination of its validity. This gives to judicial decisions an emphasis proportionately greater than they deserve in the constitutional system of the United States, for in most cases the courts reach results not dissimilar from those in the countries where legislative determinations are final. But in the United States the courts have the last word, and this often leads to an emphasis upon the technical issues of constitutional construction rather than upon the actual merits of legislation. Problems of constitutional construction have become increasingly important in the fields of administrative law and the administration of criminal law.

New economic and social problems necessitated the delegation of wide authority to permanent federal and state boards. National and state constitutions organize governments into three departments, and impliedly forbid the delegation of legislative authority. The courts must answer the questions as to what are the functions of each department and what are legislative powers that may not be delegated. Under pressure of practical need, the courts have found it possible to sustain wide delegations of rule-making power to administrative bodies, and also wide authority in such bodies to make determinations that map appear judicial in character. These results have been obtained through the construction of broad constitutional provisions, and have been wise ones, though the logical devices employed to distinguish later from earlier cases have often been amusing.

In the administration of criminal law the result has not been so satisfactory. Many constitutions contain detailed provisions regarding the grand jury, the jury, bail and the conduct of cases; and a number designate the precise words with which indictments shall terminate. These provisions promote technicality in judicial proceedings and retard progress, and although a number of consti-

tutions are easy to change. others are difficult if not impossible to amend. The courts cannot ignore these constitutional provisions, but must enforce them, though something is accomplished by liberal judicial construction. For example, the constitution of Missouri required that indictments conclude with the words "against the peace and dignity of the State." The Missouri supreme court at first said that the omission of the second "the" was fatal to an indictment, but later took the opposite view (*State v. Campbell*, 210 Mo. 202 [1908]; *Sintc v. Adkins*, 283 Mo. 680 [1920]). But however liberal the courts may be, simplification of criminal procedure is retarded by placing regulations as to such matters in the text of the state constitution.

The problems faced by the courts in constitutional construction are well illustrated by the developments in administrative law and in the administration of criminal law. Constitutional provisions creating three departments of government and providing that each shall exercise separate powers are general and vague in character. A court may and does construe these provisions to permit what the present needs require, even though earlier decisions may have taken a different view. The only harm done by such action, if it is a harm, is the occasional use of bad logic in the effort to harmonize judicial decisions that are obviously not capable of reconciliation. The specific constitutional provisions as to criminal procedure do not give a court as great a latitude of construction, though even where a constitution requires certain precise language the courts may permit some variation of that language.

The year 1937 witnessed a marked change in the attitude and function of the United States supreme court in constitutional litigation, especially as regards the validity of federal and state regulation of economic activities. For several decades prior to the election of Pres. Franklin D. Roosevelt in 1932, the court had generally, but not consistently, adhered to a narrow construction of the powers of congress in important areas. Thus, although the commerce clause was construed as affording a fairly broad basis for the regulation of railroads with respect to rates! safety appliances and injuries to employees, and even of business practices in stockyards, it was not regarded as authorizing the regulation of "production" as distinguished from "commerce"; and congress was denied power to prohibit the interstate shipment of products of child labour. Likewise, a tax on the employment of child labour was held invalid as an attempt to regulate matters reserved to the states and as an illegitimate use of the revenue powers. In the same period the court generally, but again not consistently, took a narrow view of state regulatory powers as restricted by constitutional provisions, notably those of the 14th amendment. Thus, while upholding state laws establishing maximum hours of work for miners and for women, as well as municipal zoning ordinances regulating the use of land, the court held unconstitutional a Pennsylvania statute prohibiting the mining of coal in such a way as to remove support from surface structures, a New York statute limiting hours of work in bakeries, a Kansas statute outlawing yellow-dog contracts (in which an employee agrees as a condition of employment that he will not become or remain a member of a labour union), New York statutes regulating prices charged by enterprises not "affected with a public interest," and a District of Columbia law establishing minimum wages for women and minors. In general, these restrictive attitudes were carried over into the period 1934-37, when state and federal governments alike were attempting to cope with the problems of severe economic depression. There were two notable exceptions: in 1934 the court sustained Minnesota's mortgage moratorium law against the charge that it impaired the obligation of contracts! and, by upholding a New York milk control law, established the general power to regulate prices. But the court again denied the power of government to establish minimum wages, and in a series of cases struck down one important piece of New Deal legislation after another: the National Industrial Recovery act on the ground that it was an unconstitutional delegation of legislative power to the president and an unpermitted regulation of intrastate transactions; the Railroad Retirement act, establishing a pension system for employees of interstate railroads, on the grounds that it denied due process

of law and was not within the commerce power; the Bituminous Coal Conservation act on the ground that it was not authorized by the tax, commerce and general welfare clauses; and the Agricultural Adjustment act on the ground that it was an unauthorized use of the tax and commerce powers. Widespread resentment by the New Deal of these decisions culminated in President Roosevelt's recommendation, shortly after his re-election in 1936, of legislation to reorganize the federal courts. If it had been enacted, this would have authorized increasing the membership of the supreme court from 9 to as many as 15, through appointment of an additional justice for every one who, on reaching retirement age, did not retire. Despite wide dissatisfaction with the court's decisions, this proposal, known as the court-packing plan, encountered strong opposition because of its threat to the independence of the judiciary and its disingenuousness. But within a few weeks the balance of opinion on the court shifted. Overturning its earlier decisions, the court upheld state minimum wage laws, and, despite the restrictive tendency of the precedents, sustained the National Labor Relations act. The reorganization bill, shorn of its defeated and obsolete purpose, was finally passed as a noncontroversial regulation of procedure in constitutional cases. Other New Deal legislation was upheld, notably in decisions which recognized the power of congress, under the commerce clause, to establish national policy with respect to conditions of employment (including child labour) and agricultural production. The Social Security act was sustained as an appropriate exercise of national fiscal power. Rationing and rent- and price-control measures during World War II were sustained without serious question. After 1937 decisions by the supreme court invalidating acts of congress became extremely rare, and decisions invalidating state economic regulation only slightly less so.

This change in attitude was no mere yielding to considerations of expediency, nor was it an abdication of the function of judicial review. It reflected primarily the court's acceptance of a principle of self-restraint which had long been urged upon it by dissenting justices. There was increased awareness of the need for a philosophy of constitutional construction which would not paralyze the agencies of government in their attempts to deal with changing conditions: there was increased tolerance for change and for distasteful economic policy. Above all; there was increased deference to the constitutional function of the legislative branch, a willingness to recognize that the courts are not the sole guardians of the constitution and that they are not the agency best equipped to determine the appropriateness of the means chosen for accomplishment of a legitimate governmental end. Implicit in the new attitude was the conviction that political processes, where available, must constitute the first line of protection against legislative error or excess. The function of the court in constitutional cases nevertheless remained a significant one, involving a considerable degree of independent judgment, especially in cases where political restraints are inadequate, as where the impact of state legislation is upon national interests or upon the interests of minorities.

Thus the court has occasion, from time to time, to protect interstate commerce from undue interference by state regulatory and tax measures. In 1952 it upheld the supremacy of congress in the legislative sphere by holding unconstitutional Pres. Harry S. Truman's seizure of the steel mills to avert a strike. In an important series of decisions it established minimum standards for fair trial in criminal cases, involving such matters as the right of the defendant to representation by counsel and to an impartial jury, the use of forced confessions and the use of illegally obtained evidence. In 1955 it invalidated a section of the Code of Military Justice purporting to authorize military tribunals to try civilians for offenses they had committed while in military status. Another series of decisions strongly reinforced the constitutional guarantees of freedom of speech and religion.

National security legislation was in general upheld after careful scrutiny, but state laws concerning picketing, the use of streets and parks, house-to-house canvassing and the distribution of handbills, motion-picture censorship, compulsory flag salutes and the use of public-school facilities for religious instruction were

frequently found to abridge the rights of free expression and free exercise of religion. The court's decisions dealing with racial discrimination were far-reaching. The right of Negro citizens to vote was made a legal reality; labour unions operating under federal regulation were forbidden by judicial decision to discriminate against Negro members of their crafts; racial restrictive covenants, a device for accomplishing by private action the segregation in housing which the states are forbidden to impose, were held unenforceable, with visible results especially in metropolitan areas. In the field of public education, after years of adherence to its 1896 doctrine that the furnishing of "separate but equal" facilities was a fulfilment of the state's obligation to provide "equal protection of the laws," the court first intimated that separate facilities could hardly be equal in graduate professional schools, and finally declared the inherent inequality of segregation throughout the public-school system.

In American constitutional law there is a tendency to decide the specific case before the court, without affording much guidance as to the law applicable to similar cases in the future. And the constitutional law of the United States is found not so much in the texts of written constitutions as in the judicial decisions construing such constitutions.

Judicial review in America does not amount, as superficial observers have commented, to "government by the judges." The power to declare legislation unconstitutional is, of course, not the same as the power to initiate laws; it is called into play only as the exigencies of adversary litigation require; it does not extend to matters which are purely "political"; and it is appropriately exercised with restraint and deference to legislative judgment. It is, nevertheless, a power of great significance. As Alexis de Tocqueville (*q.v.*) wrote after his mission to America in 1831, "Within these limits the power vested in the American courts of justice of pronouncing a statute to be unconstitutional forms one of the most powerful barriers that have ever been devised against the tyranny of political assemblies." (Alexis de Tocqueville, *Democracy in America*, ed. by Phillips Bradley, vol. i, p. 103, Knopf, 1945.)

AMERICAN LEGION, an organization of U.S. war veterans founded in Paris, France, March 15–17, 1919, by delegates from combat and service units of the American Expeditionary Force assembled in response to a call by a committee headed by Lt. Col. Theodore Roosevelt, Jr. A national charter was granted by congress on Sept. 16, 1919; the charter was amended in 1942 to admit World War II veterans and again in 1950 to include veterans of the Korean war. Nonpolitical and nonsectarian, the American Legion's membership requirement is honourable service and an honourable discharge. Its annual conventions are among the largest volunteer group meetings in the United States. They provide opportunities for airing the organization's special interests in education, labour and industry, and for government officials and candidates for office to express their views.

One of the Legion's major concerns has always been care of disabled and sick veterans; it was instrumental in establishing hospitals and other services for World War I veterans, services which have been expanded to meet the needs of veterans of later wars. During the 1920s the Legion supported proposals for paying a bonus to veterans. It champions compensation and pensions for the disabled and for widows and orphans, but does not favour further federal bonus payments nor all-inclusive general pension legislation. Measures successfully sponsored include many national defense programs, systems of security training for youth and the creation of the U.S. Veterans administration. In 1944 it played

an important role in the enactment of the G.I. Bill of Rights for World War II veterans, and later in supporting similar legislation for Korean war veterans. These measures afforded college or vocational training for more than 10,000,000 veterans, and enabled more than 5,600,000 veterans to purchase homes under the loan provisions of the act.

In its child welfare program the Legion expended more than \$150,000,000 between 1925 and 1960 in emergency aid to needy children of veterans, mostly for food, clothing and medical treatment. The program was financed in part from the income from a \$7,000,000 endowment fund, initiated in 1925. The Legion has helped to raise the standard of juvenile court procedure, child adoption, guardianship and the rights of children through federal and state legislation. The Americanism and youth programs include projects known as "boys' state" and "boys' nation" where groups of young people are given practical instruction in the functions of democratic government. It also includes sponsorship of 4,300 Boy Scout troops, junior baseball leagues with approximately 1,000,000 boys under 17 playing each year, and high school oratorical contests. A continuing program to combat subversive influences is carried on nationally. At the end of the 1950s the total membership of the Legion was 2,800,000 enrolled in 17,000 local posts. The national headquarters is in Indianapolis, Ind.

AMERICAN LITERATURE. Like other national literatures: American literature was shaped by the history of the country which produced it. For almost a century and a half, America was merely a group of colonies scattered along the eastern seaboard of the North American continent—colonies from which a few hardy souls tentatively ventured westward. After a successful rebellion against the motherland, America became the United States, a nation. By the end of the 19th century this nation extended southward to the Gulf of Mexico, northward to the 49th parallel and westward to the Pacific. By the end of the 19th century, too, it had taken its place among the powers of the world—its fortunes so interrelated with those of other nations that inevitably it became involved in two world wars and, following these conflicts: with the problems of Europe and the far east. Meanwhile, the rise of science and industry, as well as changes in ways of thinking and feeling, wrought many modifications in men's lives. All these factors in the development of the United States molded the literature of the country.

17th CENTURY

American literature at first was naturally a colonial literature, by authors who were Englishmen and who thought and wrote as such. An instance is that soldier of fortune, John Smith, who is credited with initiating American literature. His chief books included *A True Relation of such occurrences and accidents . . . as hath hapned in Virginia . . .* (1608); *Description of New England* (1616); and *The Generall Historie of Virginia, New-England, and the Summer Isles* (1624). Although these volumes set forth much in praise of their far from modest author, they were written avowedly to make known to Englishmen colonizing opportunities in the new world. In time, each colony was similarly described in one or more books: John Hammond's *Leah and Rachel* (1656) was subtitled *or, The Two Fruitfull Sisters Virginia and Maryland*; Daniel Denton wrote a *Brief Description of New York* (1670); William Penn, *Some Account of the Province of Pennsylvania* (1681); Thomas Ashe, *Carolina* (1682)—and these were only a few of many works praising America as a land of economic promise for English colonists.

Such early writers tacitly acknowledged British allegiance. Others, however, wrote works which stressed some of the differences of opinion which spurred the colonists to leave their homeland—works which attacked certain doctrines of opposing sects and defended doctrines of their own. More important (according to modern thought, at least), they argued the questions of government, ordinarily questions which involved the relationships

between church and state. The attitude which most of the authors attacked was jauntily set forth by Nathaniel Ward of Massachusetts Bay in a quaint book, *The Simple Cobbler of Aggawam in America* (1647). Here Ward amusingly defended the *status quo* and railed at colonists who sponsored newfangled notions. He was, for instance, against tolerance. "He," wrote Ward, "that is willing to tolerate any unsound opinion, that his own may also be tolerated, will for a need hang God's Bible at the Devil's girdle." A variety of counterarguments to such a conservative view were published. Stern John Winthrop's *Journal*, covering the years 1630 to 1649, told sympathetically of the attempt of Massachusetts Bay colony to form a theocracy—a state with God at its head and with its laws based upon the Bible. A theocracy, Winthrop thought, was "a mixed aristocracy"; a democracy, he believed, was "the meanest and worst form of government." Later defenders of the theocratic ideal were Increase Mather (1639–1723) and his son Cotton (1663–1728). William Bradford, in *The History of Plymouth Plantation*, told the story to 1646, of another colony. His history revealed that, unlike Winthrop's Puritan group, who merely wished to purify the Anglican Church, Bradford's Pilgrim companions—Separatists—broke completely with Anglicanism. More radical than the Puritans, they conceived of their government as a covenant, as evidenced by the Mayflower compact in which the Pilgrims agreed to "covenant and combine ourselves together into a civil body politic . . . and by virtue hereof to enact . . . such just and equal laws . . . as shall be thought most meet and convenient for the general good of the Colony, unto which we promise all due submission and obedience." Even more radical than Bradford was Roger Williams who left the Separatists to become a Baptist, the Baptists to become a Seeker. Williams, in a series of controversial pamphlets (1643–52) advocated concepts such as the separation of church and state, the vesting of power in the people and the tolerance of different religious beliefs. Although Williams' writings made very dull reading they contained important ideas, many of which were put into practice in the colony which he founded—Rhode Island, the first democratic commonwealth in America.

The factual or utilitarian writings of the 17th century included many sorts—not only promotion tracts, controversial works and autobiographies, but also biographies, treatises, accounts of voyages and sermons—and there were many works of each of these kinds. In this practical period of strenuous colonizing, belles-lettres loomed small. Yet there were some achievements in this field—not in drama or fiction, since there was a deep and widespread prejudice against these forms which Cotton Mather and others held were shelved in "the library of the powers of darkness," but rather, in the field of poetry. There was some very bad poetry in such works as the famous *Bay Psalm Book* (1640) which literally translated the psalms, and in Michael Wigglesworth's popular summary in doggerel verse of Calvinistic belief, *The Day of Doom* (1662). But there was some poetry, at least, of a higher order. Anne Bradstreet of Ipswich and North Andover, Mass., wrote some lyrics, published in her book, *The Tenth Muse*, (1650), which movingly conveyed her feelings concerning religion and her family. Engaging though some of her poems were, modern critics rank above her a poet whose works were not discovered and published until 1937. This shy poet was Edward Taylor (1644?–1729), an English-born minister and physician who lived in Boston and Westfield, Mass. Less touched by gloom than the typical Puritan, Taylor wrote conceited lyrics which showed his delight in Christian belief and experience—poems which still have power to charm the reader.

All 17th-century writings, not surprisingly, are in the manner of British writings of the same—or even an earlier—period. John Smith wrote in the tradition of the geographical literature of the day; Bradford echoed the cadences of the King James Bible; the Mathers and Roger Williams, dissimilar as they were in their beliefs, wrote bejeweled prose typical of the day. Anne Bradstreet's poetic style derived from a long line of British poets, among them Spenser, Sidney, Quarles and Sylvester. Taylor was in the tradition of such metaphysical poets as Herbert, Donne

and Crashaw; and he seems clearly to have been influenced by at least the first of these British poets. Both the content and form of the literature of this 1st century in America were thus markedly English.

18th CENTURY

In the early years of the 18th century, some writers carried on the older traditions. Cotton Mather, for instance, produced his huge *Magnalia Christi Americana* in 1702, his vigorous *Manuductio ad Ministerium* in 1726. Both these learned books were defenses of old beliefs, reiterations of ancient Puritan convictions. More effective as an advocate for old attitudes was Jonathan Edwards, born in Connecticut in 1703 and educated at Yale—an influential preacher in Massachusetts. Though a frail and intellectual man, Edwards was feverishly active as a religionist. He initiated the Great Awakening, a revival which stirred the eastern seacoast for many years. And he wrote much in behalf of his burning belief in Calvinistic doctrine—of the concept that man, born totally depraved, could attain virtue and salvation only through God's grace. Supporting this old belief, he wrote some truly great philosophical treatises, notably the one on *The Freedom of the Will* (1754). This philosopher's philosopher supported his claims by relating them to a complex and poetic metaphysical system, by reasoning brilliantly and by stating his thoughts in clear and often beautiful prose.

But Mather and Edwards were defending a doomed cause. Such liberal New England ministers as John Wise (1652–1725) and Jonathan Mayhew (1720–66) showed in their writings a movement away from the older beliefs and toward a less rigid religion. In other ways, Samuel Sewall (1652–1730), a magistrate and merchant of Boston, heralded a change in his famous and amusing *Diary* which covered the years 1673–1729. Sincerely religious though Sewall was, he showed in his daily records how life in commercial New England led him to love the more worldly things—to modify rigid Puritanism into what Parrington has called a "tradesman's conception of religion." Again, there was the *Journal* of another Bostonian, Mme Sarah Knight, comically detailing a journey she took to New York in 1704. Mme Knight, a woman with a keen eye for life and character along the way, wrote vividly of what she saw and commented upon it from the standpoint of an orthodox believer. But there was a quality of levity in her witty writings—even when some jocose impieties were involved—which showed that she was much less fervent than the Pilgrim founders had been.

In the south, a short time afterward, William Byrd II of Westover plantation, Va., showed how aristocratic plantation living had wrought to create an urbane and witty author who contrasted sharply with gloomier predecessors. His record of a surveying trip in 1728, *The History of the Dividing Line*, and his account of a visit to his frontier properties in 1733, *A Journey to the Land of Eden*, were his chief works. That this American's years in England, on the continent and among the social gentry of the south had created gaiety and grace of expression is evident in these sparkling journals. Although a sincerely devout Anglican, Byrd was far from being obsessed by religion; on the contrary, he was as playful as the Restoration wits whose works he clearly admired.

The wrench of the American Revolution emphasized differences which had been growing, perhaps without being voiced, between American and British political concepts. As the colonists moved to the belief that rebellion was inevitable, as they fought the bitter war and as they worked to found the new nation's government, their thoughts, feelings and actions were influenced by a number of very effective political writers.

Important in the early stages of the war were such authors as Samuel Adams (1722–1803) of Boston, Mass., John Dickinson (1732–1808) of Philadelphia, Pa., both of whom favoured the colonists—and Loyalist Joseph Galloway (1731–1803) of Philadelphia. But two figures loomed above these—Benjamin Franklin and Thomas Paine.

Franklin, born in Boston in 1706, had started to publish his writings in his brother's newspaper as early as 1722. This news-

paper, the *Sew England Courant*, which championed the cause of the Leather Apron man and the farmer, had attempted to appeal by using easily understood language and by using practical arguments. The style of writing probably had wielded its influence from the first upon this Yankee who took naturally to the idea that practical common sense was a good guide. The influence at any rate had been clear in the popular *Poor Richard's Almanack*, which Franklin edited between 1733 and 1758, annually filled with prudent and witty aphorisms purportedly written by uneducated but experienced Richard Saunders. The influence had been clear also in the author's *Autobiography*, written between 1771 and 1788, a record of his rise from humble circumstances which offered his descendants worldly-wise suggestions for future success.

Franklin had been molded by other family and social forces, and he had been a wide reader. His culture, though self-attained, was deep and wide, and it gave substance and skill to the varied articles, pamphlets and reports which he wrote concerning the dispute with Great Britain and which were extremely effective in stating and shaping the colonists' cause.

Thomas Paine, an Englishman, was a failure when he sought out Franklin in London to propound a scientific question. "Impressed," as Franklin explained, "by those wonderful eyes of his," Franklin persuaded Paine to try his fortunes in the new world. Paine went to Philadelphia, became a magazine editor and then, about 14 months later, the most effective propagandist for the colonial cause. His pamphlet, *Common Sense* (Jan. 1776), probably did more than any other agency to influence the colonists to declare their independence. His series, the *Crisis* papers (Dec. 1776–April 1783) spurred Americans to fight on through the blackest years of the war. One reason for the effectiveness of both works was the fact that the papers, based upon the simple deistic beliefs of Paine, showed the conflict as a stirring melodrama in which the angelic colonists arrayed themselves against the forces of evil. Such white and black picturings here, as often before, were highly effective as propaganda. Another reason for his success was the fact that Paine's poetic fervour found expression in impassioned words and phrases, many of which were long to be remembered and quoted.

An author of the war period who did not engage actively in the controversy was French-born Michel Guillaume Jean de Crèvecoeur. After serving in the French army in Canada, settling in New York and becoming a farmer and a naturalized citizen, Crèvecoeur wrote and published *Letters From an American Farmer* (1782). These commentaries picture the lives of Americans, at times idyllically, and at other times voice many of the advanced ideas afloat in tumultuous days of change.

The New Nation.—When the postwar period came, some of these eloquent men were no longer able to win a hearing. Thomas Paine and Samuel Adams, for instance, lacked constructive ideas which appealed to those interested in forming a new government. Others fared better, for example Franklin, whose tolerance and common sense showed themselves in addresses to the constitutional convention. A different group of authors, however, became leaders in the new period—the talented writers of the *Federalist* papers and Thomas Jefferson.

The Federalist was a series of 85 essays, published in 1787 and 1788, urging the virtues of the new constitution. They were written by Alexander Hamilton (1755–1804), James Madison (1751–1836) and John Jay (1745–1829). More distinguished for their insight into problems of government and for their cool logic than for their eloquence, these works became a classic statement of American governmental theory. At the time they were highly effective in influencing legislators who voted on the new constitution. Hamilton, who wrote the bulk of the series (perhaps as many as 51 essays), became, with John Adams (1735–1826), a leader of the Federalist party. A series of messages which Hamilton wrote as first secretary of the treasury (1789–95) were influential in increasing the power of national government at the expense of the state governments.

Thomas Jefferson, like Franklin, was a writer on politics who was influential both during the war and the postwar period.

The merits of his great summary, the Declaration of Independence, consisted, as Madison pointed out, "in a lucid communication of human rights, a condensed enumeration of the reasons for such an exercise of them, and in a style and tone appropriate to the great occasion, and to the spirit of the American people." After the war this philosophic statesman—probably the most cultured of the 18th-century American political thinkers—formulated in more detail the exact tenets of his faith. In various papers, but most richly in his letters and his inaugural addresses, he stated a belief at odds with that of Hamilton. Where Hamilton urged strong federal government, Jefferson urged individual freedom and local autonomy—decentralization. Thus far his life upon the frontier shaped his creed. Yet, being a Virginian, he had faith in aristocrats as leaders, and he thought that "a natural aristocracy" with "virtue and talents" should be trusted with high governmental positions. Though he held that all men are created equal, Jefferson did not hold that all are equally qualified as leaders. Jeffersonian democracy was a transitional stage between aristocratic belief and Jacksonian democracy.

Poets and Poetry.—Poetry became a weapon during the American Revolution, with both Loyalists and Continentals urging their forces on, stating their arguments and celebrating their heroes in verse. Some of the songs of wartime, such as "Yankee Doodle," "Nathan Hale" and "The Epilogue," are lively pieces, and most have more polish, say, than *The Bay Psalm Book* or "The Battle of the Kegs." Most, however, were set to popular British melodies of the time, and were in manner like the British poems of the period.

The period also was productive of a school of poets, a group centred in Hartford, Conn., and called the Hartford Wits. Most famed were John Trumbull (1750–1831), Timothy Dwight (1752–1817) and Joel Barlow (1754–1812). Most were Federalists in politics, and all tended to be as conservative in their methods of poetic composition. They wrote many satires, mock heroic poems and several dull epics. In general the poems show that these authors, adept though they were, were nothing more than skilled imitators of their contemporaries in England. One poet in the group, on one occasion, did better than the rest. This was Joel Barlow, who in 1793 composed "Hasty Pudding." Though this was a mock heroic poem in Popeian couplets and hence in general form like other imitative poems, it contained lively and vivid descriptions of rural New England scenes which gave it a momentary native flavour if not a completely native quality.

The most memorable poet of the period was Philip Freneau (1752–1832), a native New Yorker of Huguenot ancestry who became interested in writing while a student at Princeton. His first well-known poems were Revolutionary War satires which were effective propaganda, but later he turned to various aspects of the American scene. Although he wrote much in the stilted manner of the neoclassicists, such poems of his as "The Wild Honey Suckle," "To a Caty-did" and "On a Honey Bee" were romantic lyrics of real grace and feeling which were forerunners of a literary movement which was to be important in the 19th century.

Drama and the Novel.—In the years toward the close of the 18th century, both dramas and novels of at least some historical importance were produced. Despite the fact that theatrical groups had long been active in America, the first American comedy presented professionally was Royall Tyler's *The Contrast* (1787). This drama was full of echoes of Goldsmith and Sheridan, but it contained a Yankee character (the predecessor of many such in years to follow) who brought something native onto the stage. Tyler wrote only this one important play, but William Dunlap (1766–1839) wrote many dramas and encouraged other dramatists to try their skill.

William Hill Brown wrote the first American novel, *The Power of Sympathy* (1789), which showed authors how to overcome ancient prejudices against this form by following the preachy, sentimental novel form which had been invented by Samuel Richardson. A flood of sentimental novels followed, down to the end of the 19th century. Shortly H. H. Brackenridge followed other models—Cervantes and Fielding—with some popular suc-

ness, in *Modern Chivalry* (1792-1815), amusing because of its satire on democracy and interesting for its portrayal of frontier life. Gothic thrillers were nationalized to some extent at least in Charles Brockden Brown's *Wieland* (1798), *Arthur Mervyn* (1799-1800) and *Edgar Huntly* (1799). But all such works were more interesting as beginnings rather than as outstanding artistic achievements.

EARLY 19th CENTURY

In a commencement poem at Princeton in 1771, young Philip Freneau, celebrating "The Rising Glory of America," urged his compatriots to create a literature of their own. The prologue to *The Contrast*, in 1787, boasted that the play was one which the people of the nation "might fairly call their own." After the American Revolution, and increasingly after the War of 1812, writers were exhorted to produce a literature which was truly national. Although the most ambitious dramas were Elizabethan in form (if not in excellence), some dramas began to depict native characters. But this was not to be a great period in the American theatre. Nevertheless, to satisfy the demand for national writing, four authors of very respectable stature appeared: William Cullen Bryant, Washington Irving, James Fenimore Cooper and Edgar Allan Poe initiated a great half century of literary development.

Bryant (1794-1878), a New Englander by birth, attracted attention in his 23rd year when the first version of his poem "Thanatopsis" appeared. This early poem showed, as later ones did, that his first training had been in the 18th-century school of poetry. Later, under the influence of Wordsworth and other romantics, he wrote nature lyrics which vividly represented the New England scene. In such poems as "To a Waterfowl," "A Forest Hymn," "Robert of Lincoln" and "The Prairies," he achieved truly impressive expressions of thought and feeling. Turning to journalism, he had a long career as the fighting liberal editor of the *Evening Post*. As a member of the so-called Knickerbocker Group Bryant overshadowed such earlier poets as Joseph Rodman Drake (1795-1820) and Fitz-Greene Halleck (1790-1867). He himself was overshadowed, in renown at least, by a native-born New Yorker, Washington Irving.

Irving, the youngest member of a prosperous merchant family, joined with some of the other gay young leaders of the town in producing *Salmagundi* papers (1807-1808) which took off on the foibles of Manhattan's citizenry. This was followed by *A History of New York* by "Diedrich Knickerbocker" (1809), a burlesque history which mocked pedantic scholarship and sniped at the old Dutch families. Irving's models in these works were obviously such neoclassical Englishmen as Addison, Steele, Goldsmith and Swift, from whom he had learned to write in a polished, bright style. When the family business was in dire straits in 1811, Irving went abroad to do what he could to save it. The business failed but Irving, having met Scott and having become acquainted with some of the imaginative German literature, introduced a new romantic note in *The Sketch Book* (1819-20), *Bracebridge Hall* (1822) and other works. He was at his best in essaylike narratives wherein his fancy and his charming personality were gracefully set forth. Irving was the first American writer to win the ungrudging (if somewhat surprised) respect of the British critics.

James Fenimore Cooper, born six years after Irving, won even wider fame. The son of a prosperous squire, he lived as a boy on Otsego lake in New York, then attended Yale briefly, went to sea briefly and settled down to be a country squire himself. Almost by accident he turned to the writing of fiction. Following the pattern of the Waverley novels, he did his best work in the Leatherstocking tales (1823-41) a five-volume series celebrating the career of the great frontiersman Natty Bumppo. His skill in weaving history into inventive plots and in characterizing his compatriots brought his acclaim not only in America and England but on the continent as well. He also wrote novels of the American Revolution, of life upon the sea and several novels of social purpose which embodied his vigorous social and political beliefs.

Edgar Allan Poe, reared in the south, lived and worked as an author and editor in Baltimore, Md., Philadelphia, Richmond, Va., and New York city. A neurotic and somewhat theatrical

personality, he was the sort of figure about whom legends naturally tended to develop; his poems and stories, many of them weird and strange, were associated by many with his unhappy career. His work instead was shaped largely by his analytical skill which showed clearly in his role as an editor: time after time he gauged the tastes of readers so accurately that the circulation figures of the magazines under his direction soared impressively. It showed itself in his critical articles, wherein he lucidly explained and logically applied his criteria. His Gothic tales of terror were written in accordance with his findings when he studied the most popular magazines of the day. Moreover, his masterpieces of terror—"The Fall of the House of Usher" (1839), "The Masque of the Red Death" (1842) and "The Cask of Amontillado" (1846) and others—were written according to a carefully worked out psychological method. So were his detective stories such as "The Murders in the Rue Morgue" (1841) which historians credit as the earliest of the genre. As a poet, too, Poe wrote with a careful artistry—and at least some of his songs had melody and suggestive imagery of a high order. In general his methods and effects were too obviously contrived, but in his rather limited sphere he was an impressive craftsman.

Two southern novelists were also outstanding in this period: John Pendleton Kennedy and William Gilmore Simms. Kennedy, a citizen of Maryland, came to know Virginia when he visited his mother's family there. He wrote delightfully—if somewhat idyllically—of life on the plantations in *Swallow Barn* (1832); and in *Horse-Shoe Robinson* (1835) he told an interesting story of Virginia and the Carolinas during the Revolution. William Gilmore Simms of Charleston started his career in fiction with a melodramatic novel in 1833, then in 1834 he found his real bent. His forte was the writing of historical novels, like those of Scott and Cooper, which treated the history of the frontier and South Carolina. *The Yemassee* (1835) and a series of Revolutionary romances (1835-56) shined him at his best—particularly when he portrayed (usually in minor roles) a group of amusing rogues.

AMERICAN RENAISSANCE (1829-70)

The lives of the authors just discussed overlapped those of others who came into prominence in the 1830s and were active until about the end of the Civil War. But the new group—the humorists, the classic New Englanders, Herman Melville, Walt Whitman and others—were of a new breed. In various ways they were influenced, as their predecessors had been, by the literature of other lands. But they did their work in a new spirit and their achievements were of a new sort. Partly this was because all of them in one way or another were influenced by the broadening democratic concepts which in 1829 triumphed in Jackson's inauguration as president. Partly it was because, in this romantic period of emphasis upon native scenes and characters in many literatures, they put much of America into their books.

Particularly full of vivid touches were the writings of two groups of American humorists whose works appeared between 1830 and 1867. One group created several down-east Yankees who used common-sense arguments to comment upon the political and social scene. The most important included Seba Smith (1792-1868), whose chief figure was Jack Downing; James Russell Lowell (1819-91) who quoted the rhymed remarks of pious Hosea Biglow and rascally Birdofredum Sawin; and Benjamin P. Shillaber (1814-60), creator of Mrs. Partington and her nephew Ike. Despite their concern with preachments, these authors caught the talk, the characters, the ways of living in New England at the time as no one else did. In the old southwest, meanwhile, such writers as Davy Crockett (1786-1836), Augustus Baldwin Longstreet (1790-1870), Johnson J. Hooper (1815-62), Thomas Bangs Thorpe (1815-78), Joseph G. Baldwin (1815-64) and George W. Harris (1814-69) drew lively pictures of the people of the ebullient frontier. Though less interested in preachments than their New England counterparts, and though rather more boisterous and masculine, these authors accomplished the same sort of realistic sectional portrayal. All showed the kind of interest in the common man which was a part of Jacksonian democracy.

New England Brahmins.—Although one of their members, Lowell, for a time joined the writers of a native humour, the group of New England writers who were associated with Harvard and Cambridge in this period—the Brahmins, as they came to be called—were at an opposite extreme. Henry Wadsworth Longfellow (1807–82), Oliver Wendell Holmes (1809–94) and Lowell were all aristocrats, all steeped in foreign culture, all active as professors at Harvard. They wrote genteel literature which was at times touched by pedantry, at other times too close to foreign models. Yet each, through his travels and study and his interest in the American scene, had valuable gifts for his countrymen. Longfellow adapted European methods of storytelling and versifying to narrative poems dealing with American history, and a few of his less didactic lyrics perfectly married technique and subject matter. Holmes, in his occasional poems and his Breakfast Table series (1858–91) brought touches of urbanity and jocosity to a perhaps oversober polite literature. And Lowell in poems descriptive of the out-of-doors in America and in his *Biglow Papers* (1848, 1867) put much of his homeland into verse. His odes—particularly the "Commemoration Ode" (1865)—gave fine expression to noble sentiments. His chief importations from abroad were a set of critical standards and a method of criticism which made him one of America's most readable as well as incisive critics.

The Transcendentalists.—Concord, Mass., a village not far from Cambridge, was the home of the leaders of another important New England group. The way for this group had been prepared by the rise of a theological system. Unitarianism, which early in the 19th century had replaced Calvinism as the faith of a large share of the New Englanders. Ralph Waldo Emerson, the most famous of the Concord philosophers, started as a Unitarian minister but found even that liberal doctrine too confining for his broad beliefs. He became a Transcendentalist who, like other ancient and modern Platonists, trusted to insights transcending logic and experience for the revelations of the deepest truths. He was not, however, a perpetual dweller in cloudland for, as Lowell pointed out, if he had a "Greek head," it was set on "right Yankee shoulders." His scheme of things ranged all the way from the lowest objects and the most practical chores to soaring flights of imagination and inspired beliefs. He had theories too of writing which helped him phrase his thoughts in simple and concrete words, so that his prose was dotted with aphorisms. His *Essays* (1841, 1844), *Representative Men* (1850) and *English Traits* (1876) were thoughtful and poetic explanations of his beliefs; and his roughhewn lyrics, packed with thought and feeling, were as close to 17th-century metaphysical poems as any produced in his period.

An associate of Emerson with a salty personality of his own and an individual way of thinking was Henry David Thoreau. A sometime surveyor, labourer and naturalist, Thoreau was closer to the earthy and the practical than even Emerson was. He also was more of a humorist—a dry Yankee commentator with a flair for paradoxical phrases and sentences. Finally, he was a learned man, widely read in the western classics and the books of the orient. These qualities gave distinction to *A Week on the Concord and Merrimac Rivers* (1849) and to *Walden* (1854). The latter was a record of his experiences and ponderings during the time he lived in a hut by Walden pond—a defense of his belief that modern man should simplify his demands if need be to "suck out all the marrow of life." In his essay, "Civil Disobedience" (1849), Thoreau expounded his anarchistic views of government, insisting that if an injustice of government is "of such a nature that it requires injustice to another [you should] break the law [and] let your life be a counter friction to stop the machine." The concept of American individualism here reached one of its climaxes.

Associated with these two major figures were such minor Transcendentalists as dreamy Amos Bronson Alcott (1799–1888), George Ripley (1802–80), Orestes Brownson (1803–76), Margaret Fuller (1810–50) and Jones Very (1813–80). Margaret Fuller, a brilliant bluestocking, was for a time the editor of the organ of the movement, the *Dial* (published 1840–44) wherein

some of the best writings by minor Transcendentalists appeared. Her *Woman in the Nineteenth Century* (1845) was historically important in the feminist movement.

New England Reformers and Historians.—The world-wide movement for change which exploded in the revolutions of 1848 naturally attracted numerous Americans. Reform was in the air, particularly in New England, and even the aloof Brahmins at times were drawn into the controversies raging during the period. Several Transcendentalists allied themselves with workers for change: not only Thoreau but also Alcott (at Fruitlands) and Ripley (at Brook Farm) experimented with anarchistic, socialistic or communistic schemes for living. Suffrage for women, better conditions for workers, temperance for all and even modifications of dress and diet all had their fiery defenders. And the advocates of the abolition of slavery made their mark upon U.S. history.

William Lloyd Garrison (1805–79), ascetic and fanatical, was the moving spirit in the fight against slavery; his weekly newspaper, *The Liberator* (1831–65), despite its rather small circulation, was its most influential organ. A contributor to the newspaper (who was more famous, however, as an eloquent lecturer) was aristocratic Wendell Phillips (1811–84). Still another contributor—probably the greatest writer associated with the movement—was John Greenleaf Whittier. His simple but emotional poems in behalf of abolition were collected in such volumes as *Poems Written During the Progress of the Abolition Question . . .* (1837), *Voices of Freedom* (1846) and *Songs of Labor* (1850). These had the melodramatic quality of rhetoric and therefore lacked excellence as poetry; his less controversial poems, some of them written after the war, were to have a more lasting appeal. The outstanding novelist of the movement—so far as effect was concerned—was Harriet Beecher Stowe. Her *Uncle Tom's Cabin* (1852) combined the elements of contemporary humour and sentimental fiction to dramatize the plight of the Negro. Probably no other American literary work, in that period or later, had so widespread an effect.

One other group of writers—and one great novelist—contributed to the literature of New England in this period of its greatest glory. The group consisted of several historians who combined scholarly methods learned abroad with vivid and dramatic methods of narration. These included George Bancroft, author of an impressive (though somewhat overpious) *History of the United States* (completed in 10 vol. in 1875), and John Lothrop Motley, who traced the history of the Dutch republic and the United Netherlands in nine fascinating volumes (1856–74). The greatest member of the group was Francis Parkman, descendant of a prominent Boston family who, in a series of books (1851–92), wrote as a historian of the fierce contests between France and England which marked the advance of the American frontier. His record of his own westward journey, *The Oregon Trail* (1849), is an absorbing picture of life along the trail and of a sojourn among the Sioux.

Hawthorne.—History also figured in the tales and romances of the leading New England fictionist of the period, Nathaniel Hawthorne. He was convinced, as he said, that such a writer as he succeeded best if he located his fictions in "a neutral territory . . . where the Actual and the Imaginary may meet, and each imbue itself with the nature of the other." Therefore many of his tales and longer works; e.g., his masterpiece, *The Scarlet Letter* (1850), and "The Minister's Black Veil" were set against the background of colonial America with emphasis upon their distance from 19th-century New England. Others; e.g., *The House of the Seven Gables* (1851), dealt with the past as well as the present. Still others, e.g., "The Birthmark," "Rappaccini's Daughter" and *The Marble Faun* (1860), were set in distant countries. Remote though these narratives were at times from what Hawthorne called "the light of common day," they showed deep psychological insight and probed into complex ethical problems. Weaving allegory and symbolism firmly into the texture of his poetic fables, Hawthorne made them rich commentaries upon such subjects as the nature of sin and the relationship between the individual and his fellow men.

Melville and Whitman.—Another great fiction writer, for a time a neighbour and associate of Hawthorne, was New York-born

Herman Melville. After relatively little schooling, Melville went to sea; a whaling ship, as he put it, was his "Yale College and his Harvard." His first books were fiction in the guise of factual writing based upon his experiences as a sailor—*Typee* (1846) and *Omoo* (1847); so were such later works as *Redburn* (1849) and *White Jacket* (1850). Between 1846 and 1851, however, Melville's reading in philosophy and the literary classics, as well as in the writings of Hawthorne, gave him new literary interests and ambitions. The first sign of this interest was *Mardi* (1849), an uneven and disjointed transitional book which used allegory after the model of Rabelais to comment upon all sorts of ideas afloat in the period—nations, politics, institutions, literature and religion. The new interest came to its finest fruition in *Moby Dick*; or *The White Whale* (1851), a richly symbolic work, complex but brilliantly integrated, which gave the pursuit of the white whale by mad Ahab and his crew significant philosophical meanings. Only in short stories; "Benito Cereno"—a masterpiece of its genre—and others, in the psychological novel. *Pierre* (1852), and in the novelette. *Billy Budd* (1890?) was Melville again to show sporadic flashes of the genius which created *Moby Dick*.

Another New Yorker and one of the most ardent singers of the praise of Manhattan. Walt Whitman saw much less of the dark side of life than Melville did. He was a great optimist, and hence a voice for a period of general hopefulness. He was, in addition, a believer in Jacksonian democracy, in the splendour of the common man. Inspired by the romantic concept of the poet as prophet and also by the Transcendental philosophy of Emerson, Whitman in 1855 published the first edition of *Leaves of Grass*. As the years passed, nine other editions of this singular work were published, always with the revision of old poems and the adding of new ones. This autobiography in verse was intended to show the ideas, beliefs, emotions and experiences of the common man in this great period of American individualism. Whitman had a hard time winning a following, because he was frank and unconventional in his Transcendental thinking, because he used free verse rather than rhymed or regularly metred verse and because his poems were not conventionally organized. Nevertheless (assisted somewhat by enthusiastic friends), this poet steadily gained the approval of the critics and in time came to be recognized as one of the great poets of America. Modern critics see form where some of Whitman's contemporaries saw only chaos—in such fine poems as "Crossing Brooklyn Ferry," "Out of the Cradle Endlessly Rocking," "When Lilacs Last in the Dooryard Bloom'd" and "Passage to India." With the passage of time, too, readers came to be less shocked by Whitman's frankness, his thought, his strange diction and his irregular rhythms.

Southern Poets and Orators.—In the south, meanwhile: the authors tended to be overshadowed by their New England neighbours. The humorists of the southwest, to be sure, were unsurpassed, and Poe (who considered the south his home) wrote within certain limits important stories, poems and critical works. But, with one exception, other southern writers of significance were quantitatively and qualitatively surpassed. Henry Timrod (1828–67) and Paul Hamilton Hayne (1830–86) were the best of the poets. The former, in particular, achieved memorable expressions in behalf of the south in poems such as "Ethnogenesis," "Ode" and "The Cotton Boll." The south's best answer in poetry to the abolitionist songs of Whittier was William J. Grayson's "The Hiring and the Slave" (1854) wherein, in heroic couplets often very well turned, the author stated the case for slavery.

More noteworthy in a period of great oratory, were the orators of the south. New England, of course, had as its spokesman the "godlike" Daniel Webster whose eloquence many considered unsurpassed. But the southerners held with some reason that they had finer representation in the halls of congress than the north had managed to produce. John Randolph of Roanoke (1773–1833), a picturesque aristocrat, found the best expression for his flamboyant personality in his stirring addresses. Henry Clay (1777–1852), who was born in Virginia but represented Kentucky in Washington, D.C., was at the time esteemed as the greatest of the orators; doubtless his speeches did much to bring about the adop-

tion of his various proposals for compromise. More to the taste of later readers (and admired at the time) was John C. Calhoun (1782–1850) of South Carolina. His simplicity of style, his grasp of history and his sharp logic made the most impressive case possible for his beloved south.

Abraham Lincoln.—Kentucky and Illinois produced the one orator, Abraham Lincoln, who managed to speak to future generations in utterances which rose above the bitterness of wartime. His prewar speeches, including the famous debates with Stephen Douglas in 1858, were more effective upon the immediate audience than upon later readers. There were speeches even after his nomination for the presidency which, though historically important, were ephemeral in thought and form. But at least four of his speeches—"Farewell to Springfield" (1861), "First Inaugural Address" (1861), "The Gettysburg Address" (1863) and "Second Inaugural Address" (1865)—whether or not one agrees with their interpretation of history, were great utterances. Lincoln was able thus to stir listeners beyond his own times because he was at this stage in his career a sincere believer in democracy and a man profoundly aware of the sorrow and the suffering of war. He was also a devoted reader of two literary classics which molded his simple but eloquent style—Shakespeare and the King James version of the Bible. He was, finally, a man of real poetic ability who took great pains to seek out the words, the images and the rhythms which best expressed his thought and emotion.

THE CIVIL WAR TO 1914

Like the Revolution and the election of Andrew Jackson, the Civil War marked a turning point in U.S. history. To some degree a result of certain changes under way in the prewar decades, to some extent an accelerator of those changes, the Civil War marked the beginning of new ways of living. Industry became increasingly important as factories rose and cities grew and agrarian pre-eminence declined. Science contributed to the growth of industry, influenced men's thinking about philosophical problems and wrought great changes in everyone's life. The frontier, which always before had been an important factor in the economic scheme, moved steadily westward, and toward the end of the 19th century vanished. All these changes brought modifications in the ethical and political beliefs of many Americans. The rise of modern America was accompanied, naturally, by important mutations in literature.

Literary Comedians.—American humour, the type of writing which appealed most directly perhaps to popular taste, shortly embodied important changes. Although they continued to employ some of the devices of the older humorists, the group of comic writers which now rose to prominence was different in important ways from the older group. Charles Farrar Browne (1834–67), David Ross Locke (1833–88), Charles Henry Smith (1826–1903), Henry Wheeler Shaw (1818–85) and Edgar W. Nye (1850–96), wrote, respectively, as Xrtemus Ward, Petroleum V. (for Vesuvius) Nasby, Bill Arp, Josh Billings and Bill Nye. Appealing to a national audience, these authors forsook the sectional characterizations of earlier humorists and assumed the roles of literary comedians. This meant that the characters they pretended to be became blurred or unlocalized—that instead of writing in the roles, say, of Yankee farmers, Georgia planters or Tennessee mountaineers, they wrote (to use Samuel Clemens' phrase) as "genial idiots" whose characteristics were not particularized. In such guises they could often comment obliquely and amusingly upon current affairs. In such guises, too, they could use all sorts of verbal devices—slang, bad spelling, poor grammar and anticlimactic sentences, incongruously combined with learned allusions and Latinate words for humorous effects. The nature of the humour thus shifted from that of character portrayal to that of diction. Most that they wrote wore badly, but thousands of Americans in their time and some in later times found these authors vastly amusing.

Fiction and Local Colourists.—Since the achievements of short-story writers and novelists were to be both historically important and aesthetically appealing the pre-eminent form in this period was destined to be fiction. The first group of fiction

writers to become popular—the local colourists—took over to some extent the task of portraying sectional groups which had been abandoned by writers of the nen humour. Bret Harte, the first of these writers to achieve great success, admitted indebtedness to the prewar sectional humorists, as did some others; and all showed resemblances to the earlier group. Some, it is probable, went to school to more respectable poets and novelists of the early 19th century. Whittier, for instance, before the war had written much poetry which authentically pictured New England life, and now was to write more including his masterpiece "Snow-Bound" (1866). Too, Cooper and innumerable other writers in the tradition of Scott had before the war pictured hundreds of characters with clearly displayed sectional traits.

Whoever their antecedents were, the local colourists quickly became pre-eminent. Within a brief period, books by pioneers in the movement appeared—Harriet Beecher Stowe's *Oldtown Folks* (1869) and *Sam Lawson's Oldtown Fireside Stories* (1871), delightful vignettes of New England; Bret Harte's *The Luck of Roaring Camp and Other Sketclzes* (1870), humorous and sentimental tales of California mining camp life; and Edward Eggleston's *Tlze Hoosier Schoolmaster* (1871), a novel of the early days of the settlement of Indiana. Down into the 20th century, short stories (and a relatively small number of novels) in patterns set by these three appeared. In time, practically every corner of the country had been portrayed in local colour fiction. Additional important writings were the depictions of Louisiana creoles by George Washington Cable (1844–1925), of Virginia Negroes by Thomas Nelson Page (1853–1922), of Georgia Negroes by Joel Chandler Harris (1848–1908), of Tennessee mountaineers by Mary Noailles Murfree (1850–1922), of tight-lipped folk of New England by Sarah Orne Jewett (1849–1909) and by Mary E. Wilkins Freeman (1852–1930), of the people of New York city by Henry Cuyler Bunner (1855–1896) and by William Sydney Porter ("O. Henry") (1862–1910). The avowed aim of some of these writers was to portray realistically the lives of various sections and thus to promote understanding in a united nation. The stories as a rule were only partially realistic, though, because: (1) the authors often set their narratives in the past or, if they showed the contemporary scene, winnowed out the less glamorous aspects of life in their section; (2) they were often too much coloured by sentiment or humour, or (typically) by both; (3) they exploited the picturesque or the quaint rather than the typical. Some have suggested that the authors tended to re-visit the past instead of portraying their own time, because of their nostalgia for an America which had disappeared. Touched by romance though they were, these fictional works were transitional to realism, for they did portray common folk sympathetically; they did concern themselves with dialect and mores; and some at least avoided the older sentimental or romantic formulas.

Mark Twain.—Samuel L. Clemens (Mark Twain) was allied with the literary comedians and the local colourists. As a printer's apprentice on his brother's newspaper in Hannibal, Mo., he knew and emulated the prewar sectional humorists. He rose to prominence in the days when Artemus Ward, Bret Harte and their followers were the idols of the public. His first books, *The Innocents Abroad* (1869) and *Roughing It* (1872), like several of later periods, were travel books in which the affiliations with the postwar professional humorists were clearest. *The Adventures of Torn Sawyer* (1876), *Life on the Mississippi* (1883) and *The Adventures of Huckleberry Finn* (1884), his best works, which recreated the life of the Mississippi valley in the past, were closest to the work of the older humorists and the local colourists. Even in his best work, however, he succumbed now and then to the temptation to play the buffoon or sink into burlesque.

Despite his flaws, Mark Twain was one of America's greatest writers. He had more skill than his teachers in selecting rich details of the life in his section; he had a genius for creating character; he had unusual inventive powers and he was master of a poetic and masculine style.

William Dean Howells.—The local colourists and Mark Twain thought of themselves as portrayers of life as it really was, although they frequently let a nostalgic haze blur actuality.

Nearer to the later concept of realism were some of the books of a long neglected New Englander, John William De Forest—*Miss Ravenel's Conversion Front Secession to Loyalty* (1867) which told truths about the Civil War and which portrayed some very lifelike characters! and *Honest John Vane* (1875), a novel whose theme was the Crédit Mobilier scandal. Even nearer to the later concept were three novels produced in the middle west in the 1880s—E. W. Howe's *The Story of a Country Town* (1883), which showed the pinched life of a midwestern village, and Joseph Kirkland's *Zury, the Meanest Man in Spring County* (1887), a rather grim picture of the Illinois frontier. Howe was unaware that he was influenced by anybody; but Kirkland gladly acknowledged his indebtedness to the English realist, Thomas Hardy. A greater writer and a more conscious realist than any of these was another midwesterner, born and raised in Ohio, William Dean Howells.

Howells went abroad for consular service, then returned to live in the east. An avid reader from childhood, he apparently became enthusiastic about realistic writing when, in Italy, he encountered the plays of 18th-century Carlo Goldoni; but as the years passed he learned lessons from other authors as well. And as an influential editor and as an author, he was the most effective advocate of the new mode of fiction writing.

At the start, Howells conceived of realism as the truthful portrayal of ordinary facets of life—with some limitations; he preferred comedy to tragedy, and he tended to be reticent to the point of prudishness. The formula was displayed at its best in *Their Wedding Journey* (1872), *A Modern Instance* (1882) and *The Rise of Silas Lapham* (1885). Howells preferred later novels written after he had encountered Tolstoi's writings, and had been persuaded by them, as he said, to "set art forever below humanity." In such later novels as *Annie Kilburn* (1889), *A Hazard of New Fortunes* (1890) and *The World of Chance* (1893), he chose his characters not only because they were commonplace but also because the stories he told about them were commentaries upon society, government and economics.

The Naturalists.—Other writers toward the close of the 19th century moved toward naturalism, a more advanced stage of realism. Hamlin Garland was one whose writings marked some aspects of this development. When this young midwesterner called on Howells for the first time in 1885, his views were much like those of the older writer. In his short stories and novels, however, he departed from the practices of the Howells of the pre-Tolstoi period: he made his narratives vehicles for philosophical and social preachments; and he was franker than Howells in treating some aspects of life—the harsher details of the farmer's struggles and the subject of sex. His *Main-Travelled Roads* (1891) and *Rose of Dutcher's Coolly* (1895) displayed Garland's particular talents. These and his critical manifesto for the new fiction, *Crumbling Idols* (1894), were his effective contributions to the developing movement. He was to live well into the 20th century and to produce, in a new period, fine autobiographical works, notably *Son of the Middle Border* (1917) and *A Daughter of the Middle Border* (1921).

Garland thought of himself as a "veritist." Other authors of the same period or slightly later were avowed followers of the group of French naturalists led by Émile Zola (1840–1902). Theodore Dreiser, for instance, treated subjects which had seemed too daring to the earlier realists and, like other naturalists, illustrated his own beliefs by his depictions of characters and his unfolding of plots. Holding that men's deeds were "chemical compulsions," he showed characters unable to direct their actions. Holding, also, that "the race was to the swift and the battle to the strong," he showed characters defeated by stronger and more ruthless opponents. His important books included *Sister Carrie* (1900), *Jennie Gerhardt* (1911), *Tlze Financier* (1912), *The Titan* (1914) and—much later—*An American Tragedy* (1925).

Dreiser did not bother with—or did not care for—some of the niceties of style such as were found in some French naturalistic works. Frank Norris and Stephen Crane were more concerned with such matters. As a result, they embodied many symbolic details in their writings. In his short novels *Maggie: A Girl*

of the Streets (1893) and *The Red Badge of Courage* (1895) and in some of his short stories. Crane was an impressionist who made his details and his setting forth of them embody his conception of man overwhelmed by circumstance and environment. Frank Norris, who admired Crane's "aptitude for making phrases—sparks that cast a momentary gleam upon whole phases of life," himself tried to make phrases, scenes and whole narratives cast such gleams in *McTeague* (1899), *The Octopus* (1901) and *The Pit* (1903). Both Norris and Crane died young, their full abilities undeveloped, but their experiments foreshadowed later achievements in the 20th-century novel.

Henry James.—In the books of Henry James, born in New York but later an expatriate in England, fiction took a different pathway. Like the realists and naturalists of his time, he thought that fiction should reproduce reality. He saw reality as fiction presented it, however, as twice translated: (1) through the author's peculiar experiencing of it; and (2) through his depicting of it. Deep insight and thorough experience were no more important, in his thinking, than the highly complicated and delicate task of the artist. His *The Art of Fiction* (1884), his essays on novelists and his brilliant prefaces to his collected works showed him struggling very thoroughly and consciously with the problems of his craft. Together, they formed an important body of discussion of fictional artistry.

Excellent as a short-story writer, James nevertheless was chiefly important for novels in which his doctrines found concrete embodiment. Outstanding were *The American* (1877), *The Portrait of a Lady* (1881), *The Spoils of Poynton* (1897), *What Maisie Knew* (1897), *The Wings of the Dove* (1902), *The Ambassadors* (1903) and *The Golden Bowl* (1904). The earliest of these were international novels wherein conflicts arose from the relationships between Americans and Europeans—each group with its own characteristics and morals. As time passed, he became increasingly interested in the psychological processes of his characters and in the rendering of their limited insights, their perceptions, their emotions, in subtle and complex but interesting and true narratives. His later novels, in particular, fascinated the readers and critics who, beginning in the 1930s, gave James a higher place in U.S. fictional history than he had achieved during his lifetime.

Critics of the Gilded Age.—Writers of many types of works contributed to a great body of literature which flourished between the Civil War and 1914—literature of social revolt. Novels attacked the growing power of business, the growing corruption of government and some novelists outlined utopias. In 1873 Mark Twain and Charles Dudley Warner produced a chaotic novel, *The Gilded Age*, which featured the growth of corruption in government. The same theme, as well as political inefficiency, figured in Henry Adams' novel *Democracy* (1880). Edward Bellamy's *Looking Backward* (1888) was both an indictment of the capitalistic system and an imaginative picturing of a utopia achieved by a collectivist society in the year 2000. Howells' *A Traveler From Altruria* (1894) pleaded for an equalitarian state in which the government regimented men's lives. The year 1906 saw the publication of Upton Sinclair's *The Jungle*, the first of a library of novels and treatises by that author which criticized U.S. economic and political life and which urged socialism as the remedy.

Two poets became famous for the criticisms which they embodied in songs. Edwin Markham, a California schoolteacher, in 1899 published "The Man With the Hoe," protesting against the exploitation of labour and vaguely threatening revolution; it immediately stimulated nation-wide interest. A year later William Vaughan Moody's "An Ode in Time of Hesitation" denounced growing U. S. imperialism as a desertion of earlier principles. "On a Soldier Fallen in the Philippines" (1901) even more effectively developed the same theme.

With the rise of the journalistic magazines, a group of journalists became important as critics of America—the group dubbed "the muckrakers" by Theodore Roosevelt. Ida M. Tarbell's *History of the Standard Oil Company* (1904) and Lincoln Steffens' *The Shame of the Cities* (1904) were typical contributions by two members of a large group of journalistic crusaders.

Henry Adams.—One of the most devastating as well as one of

the most literate of the attacks on modern life was the autobiography of a scion of an ancient New England family, the Adamsons. Educated at Harvard and abroad, Henry Adams was a great teacher and a great historian (*History of the United States* [1889–91] and *Mont Saint-Michel and Chartres* [1904]). His *The Education of Henry Adams* (1906), however, complained that his lifelong hunt for some sort of order in the world, some sort of faith for man, in the end left him completely baffled. The quiet, urbane style served well to underline, in an ironic way, the message of this pessimistic book.

Poetry.—The latter 19th century and the early years of the 20th century were a poor period for poetry; yet (in addition to Moody) two poets of distinction wrote songs which survived long after scores of minor poets had been forgotten. One was southern-born Sidney Lanier, a talented musician who utilized the rhythms of music and the thematic developments of symphonies in such fine songs as "Corn" (1874), "The Symphony" (1875) and "The Marshes of Glynn" (1878). Distressed, like many of his contemporaries, by the changes in U.S. life, he wove his doubts, fears and suggestions into his richest poems.

The other poet was a New Englander, Emily Dickinson, probably the outstanding U.S. woman poet. A shy, playful, odd personality, Miss Dickinson allowed practically none of her writings to be published during her lifetime. Not until 1890, four years after her death, was the first book of her poems published, to be followed at intervals by other collections. Later poets were to be influenced by her individual techniques—the use of imperfect or eye rhymes, the avoidance of regular rhythms, the tendency to pack her brief stanzas with cryptic meanings. Like Lanier, she rediscovered the value of conceits for setting forth her thought and feeling. Such poems as "The Snake," "I Like to See It Lap the Miles," "The Chariot," "Farther in Summer than the Birds" and "There's a Certain Slant of Light" represented her unusual talent at its best.

FROM 1914 TO 1945

Looking back after several years, literary historians could see that modern movements in drama, poetry, fiction and criticism took form in the years before, during and after World War I. The eventful period which followed left its imprint upon books of all kinds, for it was a time when writers were much concerned with the life about them. World War I, the peace that followed it, the prosperous 1920s, the depression beginning in 1929, the New Deal, the drift to World War II, and World War II itself all shaped literary expression.

The literary forms of the period were extraordinarily varied, but one thing was true of every genre: in drama, poetry and fiction the leading authors tended to experiment with radical innovations in technique. So many deviations from older techniques occurred that some members of the reading public found the new literature: at first, beyond their comprehension. In time, however, the most startling innovations tended to disappear, and readers tended to approve of some of the changes.

Experiments in Drama.—U.S. drama in the 19th century had not been a pre-eminent form. During the American Renaissance the outstanding dramas had been grandiloquent blank verse tragedies such as Robert Montgomery Bird's *The Gladiator* (1831) and George Henry Boker's *Francesca da Rimini* (1855). The extraordinarily popular dramatizations of *Uncle Tom's Cabin* (1852) and Dion Boucicault's melodramas; e.g., *The Octoroon* (1859), dated even more obviously. Nor did the post-Civil War stage fare much better. James A. Herne's *Hearts of Oak* (1878), *Margaret Fleming* (1890) and *Shore Acres* (1892) were praised as realistic plays, but were more stagey than lifelike. Bronson Howard (1842–1908), Augustus Thomas (1857–1934) and Clyde Fitch (1865–1909) were successful playwrights each of whom was, in his day, much admired. The works of these writers, however, in retrospect appear to have been rather shallow, good theatre rather than good drama.

So type of writing embodied wider experimentation than the new drama which arose as a result of a rebellion against the glib commercial stage. In the early years of the 20th century many

young Americans, traveling abroad, found a vital theatre flourishing in Europe. Returning to their homeland, these young men and women became active in founding a little theatre movement in every corner of the country, experimenting with dramatic forms and methods of production free from commercial limitations. In time the movement supplied producers, actors and playwrights trained in community playhouses and college classrooms. And some little theatre groups became important commercial producers; e.g., the Washington Square Players, founded in 1915, became the Theatre Guild in 1919. The drama which resulted was marked by a spirit of experimentation and by a new seriousness and a new maturity.

Eugene O'Neill, by general consent America's greatest dramatist in the period, was a product of the movement. Having been trained in George Baker's drama class at Harvard university, he worked with the Provincetown Players before his plays were commercially produced. His dramas showed a remarkable range of experimentation. Some, such as *Beyond the Horizon* (1920), *Anna Christie* (1922), *Desire Under the Elms* (1924) and *The Iceman Cometh* (1946), were naturalistic. Some used expressionistic techniques; e.g., *The Emperor Jones* (1921) and *The Hairy Ape* (1922). He made use of a stream-of-consciousness dramatic form in *Strange Interlude* (1928) and of psychological analysis in *Mourning Becomes Electra* (1931). All his best plays, however, set forth O'Neill's tragic view of life in words of real poetic power.

Although no other dramatist was as generally praised as O'Neill, many others wrote plays—often in the same experimental spirit—which were of a high order. Marc Connelly collaborated with George S. Kaufman in writing the expressionistic *Beggar on Horseback* (1924) and himself wrote touching fantasy in a Negro folk Biblical play. *The Green Pastures* (1930). Elmer Rice wrote *The Adding Machine* (1923), an expressionistic drama, and the naturalistic *Street Scene* (1929). Maxwell Anderson began as a realist, then turned to poetic dramas such as *Elizabeth the Queen* (1930) and *Winterset* (1935), then to a musical comedy satire, *Knickerbocker Holiday* (1938). Robert Sherwood wrote distinguished plays in the forms of comedy; e.g., *Reunion in Vienna* (1931); melodrama. *The Petrified Forest* (1935); historical chronicle, *Abe Lincoln in Illinois* (1938); and tragedy. *There Shall Be No Night* (1940). Clifford Odets, in *Waiting for Lefty* (1935), a plea for labour unionism, utilized the auditorium as well as the stage for action, and in *Awake and Sing* (1935) wrote in the vein of naturalism. Thornton Wilder used stylized settings and poetic dialogue in *Our Town* (1938) and turned to fantasy in *The Skin of Our Teeth* (1942). These dramatists and others were thus alike in their catholicity of form and their eagerness to make their plays, of whatever sort, convey significant commentaries.

The New. Poetry.—Robinson and Frost.—In form, poetry ranged between older sorts of versification and sorts which departed greatly from the older procedures. Two New England poets who did not diverge from Victorian methods of writing won both critical and popular acclaim in the new period. Edwin Arlington Robinson, whose first book had appeared in 1896, found sonnets, ballad stanzas and blank verse satisfactory to set forth his thought; yet, in the 1920s, he won three Pulitzer prizes—for his *Collected Poems* (1922), *The Man Who Died Twice* (1925) and *Tristram* (1928). Like Robinson, Robert Frost used established stanzas and blank verse. His first book, *A Boy's Will* (1913), was followed by such volumes as *North of Boston* (1914), *Mountain Interval* (1916), *New Hampshire* (1923), *A Further Range* (1936) and *Masque of Reason* (1945). Both Robinson and Frost were admired because their concepts and emotions chimed with those of the time. Both saw tragic aspects of life, both commented upon the complexities of human existence and both were skeptical about pat solutions.

Midwestern Poets.—Just as modern U.S. drama had its beginnings in little theatres, modern U.S. poetry took form in little magazines. Particularly important was *Poetry: a Magazine of Verse* founded by Harriet Monroe (1860–1936) in Chicago in 1912. The region around Chicago—the midwest—soon became

prominent as the home of three poets. One was Vachel Lindsay, born and reared in Springfield, Ill. Adapting legendary lore and native oratory to irregular odelike forms, Lindsay wrote poetry in a style well adapted to oral presentation. His lively reading on lecture tours contributed to the success of such books as *General William Booth Enters Into Heaven, and Other Poems* (1913) and *The Congo, and Other Poems* (1914). Carl Sandburg of Galesburg, Ill., wrote Whitmanesque free verse about life on the prairies and in the cities, which appeared in such volumes as *Chicago Poems* (1916), *Cornhuskers* (1918), *Sntoke and Steel* (1920) and *The People, Yes* (1936). Edgar Lee Masters, a native Kansan, was in Chicago when he wrote his very popular *Spoon River Anthology* (1915), free verse monologues of the village men and women most of whom spoke bitterly of their frustrated lives. All these poets experimented with new forms; all commented upon the ironic or bitter aspects of life; all were concerned in one way or another with the changes wrought by the rise of science and industry.

Changing Forms, Changing Ideas.—Modern readers, it soon developed, were hospitable to poets who experimented with new forms, or who expressed new attitudes, or who did both. Sara Teasdale (1884–1933) and Edna St. Vincent Millay (1892–1950) wrote traditional sonnets and brief, personal lyrics which were unusually frank (according to old standards) for women poets. Three fine Negro poets—James Weldon Johnson (1871–1938), Langston Hughes (1902–) and Countee Cullen (1903–46) told of the problems of their race in poetic forms which were only on rare occasions radically experimental. These typified a number of poets who found old molds satisfactory for new ideas.

Other poets tried a great range of experiments. Amy Lowell (1874–1925) was spokesman for the Imagists, a group with radical theories about the diction, the rhythms and the imagery (though not the subject matter) of poetry. Conrad Aiken (1889–) experimented with poetical imitations of symphonic forms often mingled with stream-of-consciousness techniques. Marianne Moore (1887–) invented and employed brilliantly a different kind of free verse. E. E. Cummings (1894–) abolished capital letters, used unusual punctuation and divided his lines in a novel fashion to produce poems which often had surprisingly fresh impacts. Stephen Vincent Benét (1898–1943), though ordinarily a rather conventional poet, ranged through many forms, from the ballad stanza to free verse: many of these he wove into his stirring novel in verse. *John Brown's Body* (1928). Robinson Jeffers (1887–) used violent imagery and interestingly modified Whitmanesque and blank verse lines to express what were perhaps the most bitter views of any major poet writing in the period.

The Metaphysicals.—The most complex modern poets proved to be a varied group who were strongly influenced by the 17th-century British poets, especially John Donne. Like Donne, these poets used unusual figures—conceits—and freighted their lines with philosophical thought, often of an obscure sort. Their ideas and emotions were unusual for poetry, and their lines often harshly departed from romantic rhythms and melodies. Lovers of poetry found them difficult to read, but often agreed that an understanding was worth the trouble.

The giant of the group and the acknowledged master of many of its members was T. S. Eliot. Eliot, himself, was much indebted to an unstable genius, Ezra Pound (1885–), whose critical ideas and fragmentary poetical works provided a great stimulus to Eliot and others. But, beginning with *The Waste Land* (1922) Eliot rapidly progressed in general esteem; and such volumes as *Ash-Wednesday* (1930), *The Rock* (1934) and *Four Quartets* (1943)—as well as his brilliant critical studies—led to the greatest respect. Not only was his style rich and complex; his thoughts and feelings were shared by many who, like him, moved from complete despair in a world that seemed chaotic to a faith of some sort.

The influence of Eliot was very clear in the writings of Archibald MacLeish (1892–); his earlier poems were similar both in manner and thought to *The Waste Land*, and in later poems he

Stephen Vincent Benét (1898-1943). 12. Ernest Hemingway (1899-1961). 13. Thomas Clayton Wolfe (1900-38). 14. John Steinbeck (1902-). 15. James Thomas Farrell (1904-)

voiced a positive belief—a belief, however, in social advance rather than in the religious attitude advocated by Eliot. A number of southern poets showed affiliations, though not so clearly—John Crowe Ransom (1888–), Donald Davidson (1893–) and Allen Tate (1899–); their poems were particularly concerned with the south—its past and its problems. Hart Crane (1899–1932) was similar in manner but had matter of his own. Others of the metaphysicals with individual qualities of thought and method were Louise Bogan (1897–), Léonie Adams (1899–), Muriel Rukeyser (1913–), Delmore Schwartz (1913–) and Karl Shapiro (1913–).

Fiction.—The little magazines which helped the growth of poetry were also influential in the growth of modern U.S. fiction. Not only did they print short stories which diverged from the older patterns; they also published attacks upon the established writers and stressed the merits of unconventional fiction. The *Dial* (1880–1929), the *Little Review* (1914–1929), the *Seven Arts* (1916–1917) and others encouraged rebellion (see LITTLE MAGAZINE). More potent than any of these were two magazines edited by that ferocious but humorous journalist-critic, H. L. Mencken (1880–1956)—*Smart Set*, which he edited from 1914 to 1923, and *American Mercury*, under his charge from 1924 to 1933. Mencken published short stories in the new manner, attacked established U.S. beliefs and institutions and praised fiction writers who were unconventional in thought and manner. A powerful influence, he helped launch the new fiction.

The trend was indicated by one of Mencken's favourites, James Branch Cabell. Cabell, who had been writing since 1905, sprang to fame with *Jurgen* (1919)—a novel which attacked America's orthodoxies and institutions by telling a cynical story full of Freudian symbolism. Other authors whom Mencken favoured launched "a revolt against the village," pointing out the narrow, frustrated qualities of life in rural communities; e.g., Zona Gale (1874–1938) and Ruth Suckow (1892–1960). The most famous of the village writers was Sherwood Anderson. His *Winesburg, Ohio* (1919) and *Triumph of the Egg* (1921) were collections of short stories which showed villagers suffering from all sorts of phobias and suppressions. Anderson in time wrote several novels of superior quality, the best being *Poor White* (1920), which treated both a frustrated character and the impact of industry upon American living.

In 1920, critics noticed that a new school of fiction had risen to prominence with the success of books such as F. Scott Fitzgerald's *This Side of Paradise* and Sinclair Lewis' *Main Street*. Thereafter, fiction took on new qualities related to the modern period. Writers tended toward realism and naturalism—frank portrayals of contemporary life. There was a trend, however, from completely documented realism toward the selection of detail. The novelists' portrayal of characters and motives, and even their selection of detail, consistently were much influenced by the psychology of Freud and others.

And the novel tended to be particularly concerned with problems of the day. In the decades which followed, fiction voiced reactions to changing times: novels of the 1920s voiced disillusionment and protest against established institutions and ideologies. Some of those of the 1930s protested against the economic and political system; others advocated remedies of some sort—told of new-found hope and faith. The drift toward World War II and the war itself led many novelists to see qualities of excellence in American life not before realized, to voice patriotic enthusiasm. Some authors wrote works which fell into one or two of these periods; others ran the gamut from disillusion to the acquisition of a new faith. The number of competent—even superior—novelists was huge, so large that the following study can discuss only a few of those who generally were felt to be outstanding.

Critics of Society.—F. Scott Fitzgerald's *This Side of Paradise* (1920) showed the disillusionment, the moral disintegration of post-World War I America. The book initiated a career of great promise which found its finest fruition in *The Great Gatsby* (1925), a more poignant and more unified development of the same theme. These two books of criticism of American society were destined to be Fitzgerald's best achievements. Like Fitzgerald, Sinclair

Lewis was best as a social critic. His onslaught against the "village virus," *Main Street* (1920); against average businessmen, *Babbitt* (1922); against materialistic scientists, *Arrowsmith* (1925); and against the racially prejudiced, *Kingsblood Royal* (1947) were satirically sharp and thoroughly documented. Similar careful documentation, though little satire, characterized James T. Farrell's naturalistic *Studs Lonchan* trilogy (1932–35), all of which indignantly underlined social inequalities. Similar in pattern were Richard Wright's books which protested against the position of the Negro—*Uncle Tom's Children* (1938) and *Native Son* (1940). A number of authors wrote proletarian novels attacking capitalistic exploitation; e.g., Albert Halper wrote *The Foundry* (1934) and *The Chute* (1937). Satire, directed against some of the aristocratic New England groups, featured the rather lighter indictments of J. P. Marquand, *The Late George Apley* (1937) and *Wickford Point* (1939).

Particularly admired as a novelist of protest was John Dos Passos, who first attracted attention with an anti-World War I novel, *Three Soldiers* (1921). His most sweeping indictments of the modern social and economic system, *Manhattan Transfer* (1925) and the U.S.A. trilogy (*42nd Parallel* [1930]; *1919* [1932]; *The Big Money* [1936]), used various distinctive devices; e.g., "The Camera Eye" and "Newsreel," to attack from the left. Later, after he had undergone changes in belief, he wrote *Adventures of a Young Man* (1939), *Number One* (1943), and *Mid-century* (1961), attacks upon the leftists.

Hemingway, Faulkner, Steinbeck.—Three authors whose writings showed the shift from disillusionment were Ernest Hemingway, William Faulkner and John Steinbeck. Hemingway's early short stories and his first novels, *The Sun Also Rises* (1926) and *A Farewell to Arms* (1929), were full of the disillusionments of the lost generation concerning both war and peace. The Spanish war, however, led him to believe in the possibility of collective action to solve social problems, and his novels *To Have and Have Not* (1937), *For Whom the Bell Tolls* (1940) and *The Old Man and the Sea* (1952) embodied the new belief. At his best, Hemingway showed a power to select and arrange details and to write simple, hard-hitting prose which critics found most effective.

Less controlled but equally distinctive, at its best, was the prose of William Faulkner. His handling of point of view, his use of stream-of-consciousness techniques and even some of his descriptions of backgrounds and actions all at times led to the puzzlement of the reader. But such novels as *The Sound and the Fury* (1929), *As I Lay Dying* (1930), *Light in August* (1932) and *The Hamlet* (1940) overcame handicaps of occasional obscurity. Many of his short stories and novels were parts of the unfolding of a history of Yoknapatawpha county, a mythical Mississippi community, which showed his convictions about the decadence of the south. The picture as a whole was grim and dark, but Faulkner had convictions about the solutions to the problem which became increasingly clear. These were set forth most clearly and explicitly in *Intruder in the Dust* (1948).

Steinbeck's career—marked by uneven achievements—began with a historical novel, *Cup of Gold* (1929), wherein he voiced the distrust of society, the glorification of the anarchistic individualist typical of the rebellious 1920s. Later, however, he appeared to move toward a belief in the possibilities of collectivist action as a pathway to man's salvation. Such, at least, was the implication of *In Dubious Battle* (1936) and *The Grapes of Wrath* (1939), generally considered to be his best books. The latter was a narrative, interrupted by prose poem interludes, of the migration of a dust bowl family to California. Their great discovery, symbolically set forth, was the necessity for co-operation between the poor and downtrodden for the betterment of the lot of men.

Lyric Fictionists.—One of the interesting developments in fiction was a movement in the direction of poetry. The increased tendency to select details and to endow them with symbolic meaning, the tendency to set down the thought processes and emotions of the characters and the tendency to make use of rhythmical prose gave fiction more of a lyrical quality than it had had. In varied ways, Crane, Norris, Cabell, Dos Passos,

Hemingway, Steinbeck and Faulkner all showed the trend—in passages, in short stories, even in entire novels. Faulkner showed the trend at its worst in *A Fable* (1954) which, ironically, won a Pulitzer prize.

Lyricism bulked increasingly in the writings of Willa Cather. *O Pioneers* (1913), *The Song of the Lark* (1915) and *My Antonia* (1918) contained poetic passages about the disappearing frontier and the creative efforts of frontier folk. *A Lost Lady* (1923) was elegiac in form, and *Death Comes for the Archbishop* (1927) was an exaltation of the past and of spiritual pioneering. Katherine Anne Porter, whose works took the form of novelettes: wrote more in the style of the metaphysical poets. Her use of the stream-of-consciousness method in *Flowering Judas* (1930) and *Pale Horse, Pale Rider* (1939) had the complexity, the irony and the symbolic sophistication characteristic of this group.

Another leading poetic fictionist was Thomas Wolfe, the author of four large novels which in effect were one long lyrical recording of the author's life—of his strivings, his thoughts and his feelings turned into fiction. *Look Homeward, Angel* (1929), *Of Time and the River* (1935), *The Web and the Rock* (1939) and *You Can't Go Home Again* (1940) dealt with a figure much like Wolfe—his youth in the south, his young manhood in the north and his eternal search to fulfill a vision. The memories of the author of details of his past and his contemplations upon the significances and meanings of his experiences were set forth in prose reminiscent of Walt Whitman's poetry. The books, despite their chaotic qualities (or perhaps because of them) were essentially lyrical achievements.

Criticism.—Some historians, looking back over the first half of the 20th century, were inclined to think that it was particularly noteworthy for its achievements in literary criticism. Beyond doubt, it was true that criticism thrived as it had not for several generations, that it was an important influence on the shaping of literature and that it quickened the perceptions of readers.

The period began with a battle between a group who called themselves the Humanists—a group which stood for the older values in judging literature—and a group who urged that old standards be overthrown and new ones adopted. The Humanists, allied in some ways with the earlier Brahmin critics of New England, were led by Irving Babbitt, Harvard university professor, whose scholarly books included *The New Laokoön* (1910), *Rousseau and Romanticism* (1919), *Democracy and Leadership* (1923) and *On Being Creative* (1932). In these books and in vigorous essays Babbitt preached his belief that man has a tendency toward the good, the true and the beautiful and a contrary tendency toward evil. The application of this scheme was that modern writers with their tendency toward naturalism—the haste in man's nature—were a vicious influence. Such associates of Babbitt as Paul Elmer More (1864–1937), Korman Foerster (1887–) and Stuart Sherman (1881–1926) upheld this claim. The leader of the opposition was the pugnacious H. L. Mencken, who doubted that the values of the Humanists existed and who claimed that regardless, the duty of writers was to present "the unvarnished truth" about life. His magazine articles and books of *Prejudices* (1919–27) shouted this claim, as did the writings of his associates, a number of figures of lesser fame. In the end, the results were the liberation of literature from a number of ancient restrictions and the progress of naturalism.

Socio-Literary Critics.—In this period of social change, it was natural for a number of critics to consider literature in its relationships to society and to politics. Their study took many forms, but consistently this group judged books: (1) as reflections of society; or (2) as expressions of social truth. Van Wyck Brooks and V. L. Parrington illustrated the two chief approaches. Brooks, who wrote numerous studies which embodied such an interest: in *America's Coming of Age* (1915) and *The Ordeal of Mark Twain* (1920) scolded the U.S. public for making it all but impossible for an author to realize his genius fully. Later books by him presented rather different pictures, but developed from similar interests: *The Flowering of New England* (1936), *New England: Indian Summer* (1940), *The World of Washington Irving* (1944), *The Times of Melville and Whitman* (1947) and

The Confident Years (1952) showed how in the past many authors expressed their time and their locality. Parrington, in *Main Currents in American Thought* (1927–30) re-evaluated American literature in terms of its adherence to the tenets of Jeffersonian democracy.

The growth of Marxian influence upon thinking in the 1920s and 1930s was shown in several books. V. F. Calverton set forth the general principles of Marxian evaluations of literature in *The Newer Spirit* (1925), and in *The Liberation of American Literature* (1932) he judged literary figures on the basis of their representation of life and their implementation of the rise of the proletariat. Granville Hicks's *The Great Tradition* (1933) applied similar yardsticks. Many writers for a time followed the same lines of thinking, but beginning in 1939, as enthusiasm for communism waned, many (including Hicks) renounced the dogmas of the party. Some critics, however, found that some Marxian suggestions for critical procedures could be adapted and amended so as to be of service. Two outstanding critics in this group were Edmund Wilson (1895–) and Kenneth Burke (1897–).

Moral-Aesthetic Critics.—But Wilson and Burke, like many critics of the time, were interested in other matters than the relationships between literature and society; they were interested in both analyzing and evaluating literary creations. In a sense, they, like other moral-aesthetic critics, were eager to see in detail how a literary work was constructed; but they were equally eager to assess the sensitivity which the literary work embodied. Morton D. Zabel (1901–), himself a leading critic and scholar of modern criticism, suggested that Henry James had aptly formulated the aim of this group when he said, "The critic's judgment, being in the best analysis an estimate of the artist's quality of mind, is at once moral and aesthetic." The group was distinguished, as a result, for its close attention to the creative process involved in a work and also for its care in ranking the work.

As in poetry, T. S. Eliot here proved a leader. In essays and books; e.g., *The Use of Poetry and the Use of Criticism* (1933), he subjected writings and writers to careful analyses, and developed the thesis that "the 'greatness' of literature cannot be determined solely by literary standards; though we must remember that whether it is literature or not can be determined only by literary standards." Others used various ways of discussing relationships between form and value—R. P. Blackmur in *The Double Agent* (1935), Allen Tate in *Reactionary Essays on Poetry and Ideas* (1936), John Crowe Ransom in *The World's Body* (1938), Yvor Winters in *Maule's Curse* (1938) and Cleanth Brooks in *The Well Wrought Urn* (1947). This new school greatly advanced ways of discussing literary structure; it also distinguished and applied contrasting methods of evaluation. Like other groups: it therefore did much to advance the understanding and appreciation of literature.

POST-WORLD WAR II

Following World War II, readers expected a literary Renaissance like that following World War I. Despite predictions, however, a similar emergence of writers new in outlooks and techniques and also tremendously popular did not occur. Several older writers continued to loom large or won deferred recognition. Robert Frost, T. S. Eliot, William Carlos Williams, Ezra Pound and Robinson Jeffers, all born before 1890, and E. E. Cummings were admired "elder statesmen" among the poets. Archibald MacLeish, who had won a Pulitzer prize in 1933, repeated in 1953 and 1959; such prizes tardily went to Marianne Moore in 1952 and to Wallace Stevens (1879–1955) in 1955. The fiction of F. Scott Fitzgerald was read with revived appreciation; Hemingway and Faulkner between 1949 and 1955 won both Pulitzer and Nobel prizes. No new figures achieved fame and acclaim comparable to those of such older writers. Nevertheless there were interesting developments.

The Drama.—Perhaps because of ever-increasing costs of production and the tendency of only "smash hits" to prosper, most dramatic writings were unexperimental and inferior. Sympto-

matic were Pulitzer awards in 1950 and 1960 to musical comedies and in 1958 and 1961 to dramatizations of novels. Critics agreed that two playwrights, both at times successful at the box office, had well-deserved reputations: Tennessee Williams (1913–) continued the wartime experimentation of *The Glass Menagerie* (1944), which utilized a narrator, unorthodox settings and poetic dialogue, in *A Streetcar Named Desire* (1947), *Cat on a Hot Tin Roof* (1955), *Orpheus Descending* (1957) and *Suddenly Last Summer* (1958), all of which employed unrealistic settings and modern techniques. Arthur Miller (1915–) was experimental in a variety of ways in *All My Sons* (1947), *Death of a Salesman* (1949), *The Crucible* (1953) and *A View From the Bridge* (1955). The unconventional materials and the dialogue of both playwrights—often very frank, often poetic—shocked audiences into attention. Several young dramatists showed enough promise in initial works to justify hope that they might round out noteworthy careers—among others William Inge, William Gibson, Frank O'Hara, Lionel Abel, Jack Gelber, Jack Richardson, Edward Xlbee and Lorraine Hansberry. These dramatists and workers in "off Broadway" theatres and in lively little theatres throughout the U.S. offered some promise that American drama might again reach the heights from which it had fallen.

Poetry.—Although they greatly respected their predecessors of the early 20th century, poets of the new generation in many instances moved in a different direction. They tended to forsake the obscurantism, the surrealism, the free forms of previous decades. They sought instead dramatic or dialectical organization; some cultivated the epigram, the poetry of wit; they tended to be more rigid in versification, even in the use of rhyme. Poets who had anticipated such developments came into their own: Stanley Kunitz (1905–), "indeed one of the masters" in the words of one critic, was the recipient of a Pulitzer prize in 1959 for *Selected Poems 1928–1958*; Theodore Roethke (1908–) in 1954 received the Pulitzer prize and in 1958–59 received the Bollingen prize, the National Book award, the Edna St. Vincent Millay award of the Poetry Society of America and a Ford grant. Among younger poets Karl Shapiro (1913–) was a Pulitzer prize poet for *V-Letter and Other Poems* in 1945; Robert Lowell (1917–) for *Lord Weary's Castle* in 1947; Richard Wilbur (1921–) for *Things of This World* in 1957; W. D. Snodgrass (1926–) for *Heart's Needle* in 1960. "Beat" poets—a group more successful in producing headlines than in creating literature—were in the less disciplined tradition; but one of their best, Donald Duncan, wrote in the newer manner, even on occasion using archaic diction.

Robert Lonell's *Life Studies* (1959) gave Kunitz "the sense . . . of witnessing a preliminary breakthrough into the poetry of the next decade" since it "recaptured a good portion of the territory that poetry has for so long yielded to the novel" (*Harper's Magazine*, 129.177 [Oct. 1959]). Extraordinarily personal and autobiographical narrative poetry, this shoed a loosening of form and was filled with prosaic details more often found in fiction than in poetry. To some degree such poetry had been predicted by Gwendolyn Brooks (1917–) in *Annie Allen*, Pulitzer prize poem of 1950, a versified novel largely autobiographical, recounting a Negro girl's life from childhood to maturity. Robert Penn Warren (1905–) had experimented with the versified novel in *Brother to Dragons* in 1953. As the 1960s began such young poets as Anne Sexton and Snodgrass were publishing fictionlike verse narratives. Whether this genre would loom as important in retrospect as Kunitz predicted remained to be seen.

Fiction.—The reading public continued to be more interested in fiction than in any other literary form. Increasingly important were paperback editions of fictional works both old and new, some of which had phenomenal sales. Especially prominent among the best-sellers were those whose materials were sensational. Examples were books exploiting sex—older works such as Erskine Caldwell's *Tobacco Road* (1932) and *God's Little Acre* (1933); never productions such as Mickey Spillane's series of murder stories; and Grace Metalious' *Peyton Place* (1956). Exposé in fictional form—both hard- and paperback—often attracted many readers, as did, for instance, Sloan Wilson, *The Man in the Gray Flannel*

Suit (1955), concerning the business world; J. D. Voelker (pseudonym, Robert Traver), *Anatomy of a Murder* (1958), dealing with lawyers and courts; W. J. Lederer and E. L. Burdick, *The Ugly American* (1958), an attack on U.S. diplomatic practices; Allen Drury, *Advise and Consent* (1959), which peered behind the Washington, D.C., governmental scene. The appeal of such books was a phenomenon more interesting to sociologists than to literary critics, however, since few of them had much artistic merit or seemed destined to have more than temporary fame.

Occasionally a writer of fiction which critics took more seriously managed to attract the mass audience; but if he did so it was because his novel happened to have material with a wide appeal. James Gould Cozzens (1903–), whose quiet craftsmanship had long been admired and whose *Guard of Honor* (1948) had won a Pulitzer prize in 1949, caught the popular fancy with *By Love Possessed* in 1957 largely because its theme demanded unusual frankness. Vladimir Nabokov (1899–), after writing several admirable books which attracted little attention, had sensational success with *Lolita* (1955), because it was threatened with censorship. For the most part, though, novelists whose works were of interest to critics and historians of literature had to be content with smaller audiences.

Their more limited appeal resulted in part from their chief concern, which Herbert Gold, in his introduction to *Fiction of the Fifties* (1959), characterized in the statement that "Writers of fiction have been taking on the role traditionally played by religious leaders, philosophers, metaphysicians." "Most of the interesting novels of the 50s," as Granville Hicks says, "are concerned with the problems of the individual rather than the problems of society, with problems of identity and relationship, problems we can think of as philosophical or ethical."

Critics and young intellectuals probably admired above all other post-1945 novels J. D. Salinger's *The Catcher in the Rye* (1951) and Saul Bellow's *The Adventures of Augie March* (1953). Both are "spiritual picaresques." In Salinger's novel, written in the first person, 16-year-old Holden Caulfield tells his adventures during his last day in the preparatory school from which he is being expelled and the two following days spent in wandering about New York city. His story of his varied encounters and his comments upon them reveal the boy's deep discontent, his disillusionment, his desperate search for values, for identity. Bellow's book, also in the first person, traces Augie's development from boyhood to maturity against a great variety of settings in America and elsewhere; it also details a search for values ending with the narrator's better understanding of himself and others.

Robert Penn Warren's review of *The Adventures of Augie March* contrasted the novel with the author's earlier *Dangling Man* (1944) and *The Victim* (1947), "finely-wrought novels of . . . the Flaubert-James tradition" characterized by economy, tight structure, careful ordering and interrelating of episodes. Both Salinger and Bellow, in moving toward a more episodic or picaresque—a more thematic—form, marked the direction of much contemporary fiction. In it, as in these two novels, the central figures—often those through whose eyes the action is viewed—are marginal figures in modern society: children, adolescents, outcasts, artists, intellectuals. Often such characters, unhappy and bewildered, are searching for philosophical or ethical insights. The novels of Salinger and Bellow are typical also in combining serious purpose with much humour: a trend toward comedy, even fantastic comedy, was noteworthy. Salinger and Bellow likewise represent a trend toward an ebullient vernacular style employed with painstaking precision.

Outstanding fictional works—some novels, some collections of stories—showing one or more often several of these tendencies included: Robert Penn Warren, *All the King's Men* (1946); Carson McCullers, *The Member of the Wedding* (1936); Norman Mailer, *The Naked and the Dead* (1948); Nelson Algren, *The Man With the Golden Arm* (1949); Ralph Ellison, *Invisible Man* (1952); Howard Nemerov, *Federigo* (1954); Flannery O'Connor, *A Good Man Is Hard to Find, and Other Stories* (1955); Herbert Gold, *The Man Who Was Not With It* (1956); Wright Morris, *Love Among the Cannibals* (1957); James Agee, *A Death in the*

Family (1957); Jack Kerouac, *On the Road* (1957); Bernard Malamud, *The Magic Barrel* (1958); Philip Roth, *Goodbye, Columbus, and Five Short Stories* (1959); James Purdy, *Malcolm* (1959); Saul Bellow, *Henderson the Rain King* (1959); Grace Paley, *The Little Disturbances of Man* (1959); Richard G. Stern, *Golk* (1960); Harper Lee, *To Kill a Mockingbird* (1960); and William Styron, *Set This House on Fire* (1960).

Hoffman, *The Modern Novel in America, 1900–1950* (1951); Louise Bogan, *Achievement in American Poetry, 1900–1950* (1951); Morton D. Zabel (ed.), *Literary Opinion in America* (1951). (W. BL.)

AMERICAN MEDICAL ASSOCIATION. The American Medical association was founded on May 5, 1847, when 250 delegates representing more than 40 medical societies and 28 colleges met in the hall of the Academy of Natural Sciences in Philadelphia, Pa. The objective of the association is the promotion of the science and art of medicine and the betterment of public health. It is a physicians' organization existing to serve the public and its physician members and their interests.

The association's first president was Nathaniel Chapman of Pennsylvania. Each year a new president succeeds to office, a position which he holds without pay and to which he is elected by the members of the house of delegates. This body consists of delegates mainly from state medical associations. Each state medical association is permitted a delegate for each 1,000 physician members of the A.M.A. or fraction thereof. This body meets twice each year to consider and determine the basic policies by which the association shall operate. Between meetings of the house the affairs of the association are governed by a board of trustees, the members of which are elected by the house for five-year terms of office.

Headquarters are at Chicago, Ill. In Washington, D.C., is another office which serves as a point of information for those seeking data on problems of interest to doctors, their patients and their national association. In the headquarters office are various departments concerned with a wide variety of medical topics, including geriatrics, maternal and child care, hospital facilities, medical education, nutrition, drugs, insurance plans, scientific exhibits, health in rural areas, medical films, medical books and journals, mental health, cost of medical care and health of industrial workers. There are other offices of similar importance which aid in the work of the association. Also located at the headquarters are chemical laboratories and laboratories for testing physical devices.

Much of the work is done under the guidance of committees and councils, the membership of which is either elected by the house of delegates or appointed by the board of trustees. Other work is undertaken in departments. All offices have executive heads who are responsible for administrative activities. The council on medical education and hospitals was created in 1904, the council on pharmacy and chemistry (after 1957 the council on drugs) in 1905, the bureau of investigation (which looks into harmful health practices) in 1906, the chemical laboratory in 1906, and the

bureau of health education in 1910.

Publications of the association include the *Journal of the American Medical Association* (weekly); nine journals issued monthly and devoted to medical specialties such as surgery and diseases of children; *Today's Health* (formerly *Hygeia*), a monthly magazine for the general public; and books relating to drugs, uniform nomenclature for illnesses and operations and other special medical subjects.

The American Medical association aids in the development of standards for the improvement of medical care. It does not develop or enforce laws; it has no legal power. Its effects, far reaching in many aspects of medical care, are possible because of the desire of its members and others to follow standards or worthwhile suggestions. Thus any improvements in drug therapy, insurance coverage, medical education standards, medical care in rural areas, or other act on which the A.M.A. may have had an effect stems from moral persuasion and not from legal enforcement. (A. E. SH.)

AMERICAN REVOLUTION (1775–1781), known also as the American War of Independence. This war, by which the British colonies along the Atlantic seaboard definitely separated themselves from the mother country, began with the skirmish at Lexington in Massachusetts, on April 19, 1775, and was virtually ended by the capitulation of Cornwallis at Yorktown, Va., on Oct. 19, 1781. In this article the progress of the war itself is alone considered; its other aspects are treated under UNITED STATES (OF AMERICA): *History* and related articles such as DECLARATION OF INDEPENDENCE; WASHINGTON, GEORGE. From a military standpoint it was a conspicuous and instructive conflict. It was conspicuous as being the most famous struggle in history where colonial dependencies defeated their mighty parent state, though the powerful aid of France, Spain and Holland must never be forgotten. It was instructive as presenting exceptional conditions and consequent errors in the attempt to put down the revolt. The reasons for Great Britain's failure appear in the progress of the war, which assumed two distinct stages: operations in the north, followed by operations in the south. In point of time and energy, military activity was about equally divided between these two fields. As the naval operations in connection with the war have a European interest as well, they are dealt with in a separate section.

LAND CAMPAIGNS

To strike at the rebellion first in the north was a natural move. To King George and his ministry, Massachusetts was the hotbed of disloyalty, the head and front of opposition to their colonial policy, and there coercion should begin. It was also a convenient point for a prompt display of authority, as the town of Boston was the headquarters of Gen. Thomas Gage, recently appointed royal governor of Massachusetts and commander of the king's troops in North America. He had with him four regiments of regulars, the initial force with which to overawe the restless and defiant population in his vicinity.

Lexington and Concord.—While Gage is to be credited with advising his government that not less than 20,000 men would be necessary for the work in hand, he proceeded after some delay to suppress warlike preparations near Boston. His first determined effort brought about the skirmish of April 19, 1775 (see LEXINGTON), in which a detachment sent to seize some military stores collected at Concord suffered heavily at Lexington, Concord and other places, at the hands of the surrounding militia. This encounter roused the New England colonies, and in a few days about 16,000 of their townsmen marched in small bands upon Boston to protest against and resist further incursions; and in this irregular body we have the nucleus of the colonial forces which carried the war through. A noteworthy incident of the Lexington affair, and characteristic of the attitude which the provincials had maintained and continued to maintain for another year, was the official representation to the king that the regulars were the first to fire, and that the colonials returned the fire and fought through the day in strict defense of their rights as Englishmen. Who actually fired the first shot immortalized as "the shot heard round the world,"

"THE LANDING OF THE BRITISH FORCES IN THE JERSEYS," UNDER GENERAL CORNWALLIS. NOV. 20, 1776. DRAWING ATTRIBUTED TO LORD RAWDON, BRITISH OFFICER, A MEMBER OF THE LANDING PARTY

no man knows. The colonists repeated their professions of loyalty to his majesty and the principles of the English constitution. Conscious, nevertheless, that a struggle impended, they instantly sent word to all the other colonies, whose Whig elements sympathetically responded to the alarm. The war had opened.

Siege of Boston.—The home government extended its precautions and preparations. Gen. Sir William Howe, who succeeded Gage in the chief command in October, and Gen. Sir Henry Clinton and Gen. John Burgoyne were sent out at once with reinforcements. Cornwallis followed later. These four generals were identified with the conduct of the principal operations on the side of the British. The force at Boston was increased. The continental congress at Philadelphia, acting for the 13 colonies, voted general defensive measures, called out troops and appointed George Washington of Virginia commander in chief. Before he reached the camp forming around Boston, a second and more important collision took place. On June 17, 1775, occurred the battle of Bunker hill (*q.v.*), in which, although victorious, the British suffered heavily, losing one-third of their force in storming the hastily constructed lines of the rebels. In moral effect the battle proved anything but a defeat to the Americans, who drew a cordon of works around Boston, hemming Howe's army in a contracted, and, as it proved, untenable, position. On July 3, Washington took command of the American forces at Cambridge, Mass., and attempted to train and organize them on a sound basis. He also proceeded with what is known as the siege of Boston, which was marked by no special incident, and closed with the American seizure of Dorchester heights and the evacuation of the town by the British on March 17, 1776, Howe sailing to Halifax, Nova Scotia.

Ticonderoga and Quebec.—While the main interest centred at this point, the year 1775 was marked by two enterprises else-

where. Fort Ticonderoga, the key to the passage of Lakes George and Champlain to Canada, was surprised and taken on May 10 by a small band under Col. Ethan Allen, yielding a valuable supply of cannon. Col. Benedict Arnold headed an expedition through the Maine woods to effect the capture of Quebec, where Sir Guy Carleton commanded. Arnold joined Gen. Richard Montgomery, who was already near the city, and the combined force assaulted Quebec on Dec 31, only to meet with complete defeat. Montgomery was killed and many of his men taken prisoners. Demonstrations against Canada were soon discontinued, and Arnold drew off the remnant of his army in May 1776.

Campaign of 1776.—The events of 1775, though partly favourable to America, were but a prelude to the real struggle to come. For the campaign of 1776 both sides made extensive preparations. To the home government the purely military problem, although assuming larger dimensions and more difficulties, still seemed to admit of a simple solution, namely, to strike hard where the rebellion was most active and capable of the longest resistance. Defeated there, it would quickly dissipate in all quarters. As more than one-half of the population and resources of the colonists lay north of Chesapeake Bay—New England alone having an estimated population of over 700,000 persons—it was only a question as to what point in this area should be made the future base of operations. Largely upon the representations of Howe, Burgoyne and others, it was determined to shift the field from Boston to New York city, from there to hold the line of the Hudson river in co-operation with a force to move down from Canada under Carleton and Burgoyne, and thus effectually to isolate New England.

Upon this plan the new campaign opened in June 1776. Howe, heavily reinforced from home, sailed on June 10 from Halifax to New York and on July 5 encamped on Staten Island. Washington,

anticipating this move, had already marched from Boston and fortified the city. His left flank was thrown across the East river beyond the village of Brooklyn, while his front and right on the harbour and North or Hudson river were open to a combined naval and military attack. The position was untenable since the British absolutely dominated the waters about Manhattan. Howe drove Washington out of New York, and forced the abandonment of the whole of Manhattan Island by three well-directed movements upon the American left. On Aug. 22 he crossed the narrows to the Long Island shore with 15,000 troops, increasing the number to 20,000 on the 25th, and on the 27th surprised the Americans, driving them into their Brooklyn works and inflicting a loss of about 1,400 men. (See LONG ISLAND.) Howe has been criticized, rightly or wrongly, for failing to make full use of his victory. Washington skilfully evacuated his Brooklyn lines on the night of the 29th, and in a measure relieved the depression which the defeat had produced in his army. On Sept. 15, Howe crossed the East river above the city, captured 300 of the militia defending the lines and occupied the city. Washington had withdrawn his main army to the upper part of the island. A skirmish, fought the next day, opposite the west front of the present Columbia university, and known as the affair of Harlem heights, cost the British a loss of 70 of their light infantry. Delaying until Oct. 12, Howe again moved forward by water into Westchester county, and marching toward White Plains forced another retreat on Washington. In the fight on Chatterton hill at White Plains, on Oct. 28, an American brigade was defeated. Instead of pressing Washington further, Howe then returned to Manhattan Island, and, Nov. 16, captured Fort Washington with nearly 3,000 prisoners. This was the heaviest blow to the Americans throughout the war in the north. The British then pushed down through New Jersey with designs on Philadelphia. Washington, still retreating with a constantly diminishing force, suddenly turned upon Lieut. Col. Johann Rall's advanced corps of Hessians at Trenton on Dec. 26, and captured nearly 1,000 prisoners. This brilliant exploit was followed by another on Jan. 3, when Washington, again crossing the Delaware, outmarched Cornwallis at Trenton, and marching to his rear defeated three British regiments and three companies of light cavalry at Princeton, N.J. Marching on to Morristown, Washington encamped there on the flank of the British advance in New Jersey, thus ending the first campaign fought on the new issue of American independence, which had been declared on July 4, 1776.

The Decisive Year of 1777.—While these closing successes inspired the Americans, it was undeniable that the campaign had gone heavily against them. Having raised a permanent force called the Continental line, they awaited further operations of the enemy. Following up the occupation of New York, Howe proceeded in 1777 to capture Philadelphia. Complete success again crowned his movements. Taking his army by sea from New York to the head of the Chesapeake, he marched up into Pennsylvania, where Washington had repaired to watch him, and on Sept. 26 entered the city. The Americans attempted to check the advance of the British at the Brandywine river, where an action occurred on the 11th resulting in their defeat (see BRANDYWINE, BATTLE OF); and on Oct. 4, Washington directed a well-planned attack upon the enemy's camp at Germantown on the outskirts of the city, but failed of success. (See GERMANTOWN.)

Howe's victorious progress in Pennsylvania was neutralized by disasters farther north. Indeed his whole expedition to seize "the enemy's capital" was nothing less than an abandonment of an expedition from the north with which he was expected to co-operate. Clinton, whom he left at New York, protested against this folly to the last. Lord George Germain in England was only in part to blame. Burgoyne marched from Canada in June 1777, with a strong expeditionary force, to occupy Albany and put himself in touch with Howe who was expected to come up the Hudson. Driving the Americans under Gen. Arthur St. Clair out of Ticonderoga, and making his way through the deep woods with difficulty, he reached the Hudson at Fort Edward on July 30. Gen. Philip Schuyler, commanding the Americans in that quarter, retreated to Stillwater, 30 mi. above Albany, barricading the roads and impeding Burgoyne's progress. Unjustified dissatisfaction with his con-

duct led congress to replace Philip Schuyler by Gen. Horatio Gates. On Aug. 13, Burgoyne dispatched a force to Bennington, Vt., under the German colonel, Friedrich Baum, to capture stores and overawe the country. On the 16th Baum was attacked by Gen. John Stark with the militia from the surrounding country, and was overwhelmed. Colonel Breyman, marching to his relief, was also routed. The misfortune cost the British 1,000 men. Equally unfortunate was the fate of an expedition sent under Col. Barry St. Leger to co-operate with Burgoyne by way of the Mohawk valley. On Aug. 16 he was met at Oriskany by Gen. Nicholas Herkimer and forced to retreat. Despite these disasters Burgoyne pushed south to Stillwater, where he was defeated by Gates's improvised army of continentals and militia in two battles on Sept. 10 (Freeman's farm) and Oct. 7 (Bemis's height). On the 17th he was forced to surrender. (See SARATOGA, BATTLES OF.) This disaster was followed by the alliance between America and France in 1778, and later by the addition of Spain and Holland to England's enemies—events of far-reaching importance.

Northern Campaigns, 1778–80.—A noteworthy movement, in 1778–79, was the expedition of George Rogers Clark, under the authority of the state of Virginia, against the British posts in the northwest. With a company of volunteers Clark captured Kaskaskia, the chief post in the Illinois country, on July 4, 1778, and later secured the submission of Vincennes, which, however, was recaptured by Gen. Henry Hamilton, the British commander at Detroit. In the spring of 1779 Clark raised another force, and recaptured Vincennes from Hamilton. This expedition did much to free the frontier from Indian raids, gave the Americans a hold upon the northwest, of which their diplomats probably took advantage in the peace negotiations, and later, by giving the states a community of interest in the western lands, greatly promoted the idea of union.

In 1778 Sir Henry Clinton succeeded Howe in the chief command in America. With fewer resources than his predecessor, he could accomplish practically nothing in the north. In June 1778, he evacuated Philadelphia, with the intention of concentrating his force at New York. Washington, who had passed the winter at Valley Forge, overtook him at Monmouth, N.J., and in an action on June 28 both armies suffered about equal loss. Thereafter (except in the winter of 1779, at Morristown) Washington made West Point on the Hudson the headquarters of his army, but Clinton avowed himself too weak to attack him there. In 1779 he attempted to draw Washington out of the highlands, with the result that in the maneuvers he lost the garrison at Stony Point, 700 strong, the position being stormed by Gen. Anthony Wayne with the American light infantry on July 16. During the summer Gen. John Sullivan marched with a large force against the Indians (all the Iroquois tribes except the Oneidas and part of the Tuscaroras siding with the British during the war) and against the Loyalists of western New York, who had been committing great depredations along the frontier; and on Aug. 29 he inflicted a crushing defeat upon them at Newtown, on the site of the present Elmira. In addition several Indian villages and the crops of the Indians were destroyed in the lake region of western New York.

Meanwhile the co-operation of the French became active. In July Comte de Rochambeau arrived at Newport, R. I., occupied by the British from 1776 to the close of 1779. An unsuccessful attempt was made to drive them out in 1778 by the Americans assisted by the French admiral Charles Hector d'Estaing and a French corps. The year 1780 is also marked by the treason of Gen. Benedict Arnold (*q.v.*), and the consequent execution of Maj. John André (*q.v.*). Minor battles and skirmishes occurred until in Aug. 1781 Washington undertook the project of a combined American-French attack on Cornwallis at Yorktown, Va., the success of which was decisive of the war.

Campaign in Georgia.—The inadequate results of the British campaigns against the northern colonies in 1776 and 1777 led the home government to turn its attention to the weaker colonies in the south. Operations in the north were not to cease, but a powerful diversion was now to be undertaken in the south with a view to the complete conquest of that section. Success there would facilitate further movements in the north. An isolated attack on

Charleston, S.C., had been made by Sir Henry Clinton and Sir Peter Parker as early as June 1776, but this was foiled by the spirited resistance of Gen. William Moultrie; after 1778 the southern attempts, stimulated in part by the activity of the French in the West Indies, were vigorously sustained. On Dec. 29 of the same year Col. Archibald Campbell with an expeditionary corps of 3,500 men from Clinton's army in New York, captured Savannah, Ga., defeating the American force under Gen. Robert Howe. In the following month he pushed into the interior and occupied Augusta.

Gen. Benjamin Lincoln, succeeding Howe, undertook to drive the British out of Georgia, but Gen. Augustine Prevost, who had commanded in Florida, moved up and compelled Lincoln to retire to Charleston. Prevost, making Savannah his headquarters, controlled Georgia. In Sept. 1779 he was besieged by Lincoln in conjunction with a French naval and military force under Admiral d'Estaing, but successfully repelled an assault (Oct. 9), and Lincoln again fell back to Charleston. In this assault Count Casimir Pulaski, on the American side, was mortally wounded.

The prestige thus won by the British in the south in 1779 was immensely increased in the following year, when they victoriously swept up through South and North Carolina. Failing to achieve any advantage in the north in 1779, Sir Henry Clinton, under instructions from his government, himself headed a combined military and naval expedition southward. He evacuated Newport, R.I. (Oct. 25), left New York in command of the German general Wilhelm von Knyphausen, and in December sailed with 8,500 men to join Prevost of Savannah. Cornwallis accompanied him, and later Lord Rawdon joined him with an additional force. Marching upon Charleston, Clinton cut off the city from relief, and after a brief siege compelled Lincoln to surrender on May 12. (See CHARLESTON.)

The loss of this place and of the 5,000 troops included in the surrender was a serious blow to the American cause. The apparent submission of South Carolina followed. In June Clinton returned to New York, leaving Cornwallis in command, with instructions to reduce North Carolina also. Meanwhile an active and bitter partisan warfare opened. The British advance had been marked by more than the usual destruction of war; the Loyalists

rose to arms; the Whig population scattered and without much organization formed groups of riflemen and mounted troopers to harass the enemy. Little mercy was shown on either side. The dashing rider, Col. Banastre Tarleton, cut to pieces (April 14, 1780) a detachment of Lincoln's cavalry, and followed it up by practically destroying Buford's Virginia regiment near the North Carolina border.

On the other hand, daring and skilful leaders such as Francis Marion and Thomas Sumter kept the spirit of resistance alive by their sudden attacks and surprises of British outposts. Hanging Rock, Ninety-Six, Rocky Mount and other affairs brought their prowess and devotion into notice. By the month of Aug. 1780, with the main British force encamped near the North Carolina line, the field seemed clear for the next advance.

The threatening situation in the Carolinas alarmed congress and Washington and measures were taken to protect the distressed section. Before Cornwallis could be brought to bay he was faced successively by four antagonists, the generals Gates, Nathaniel Greene, La Fayette and Washington. They found in him the most capable and dangerous opponent of the war. Greene called him "the modern Hannibal." With Lincoln's surrender of nearly all the Continental soldiers in the south, a new force had to be supplied to meet the British veterans. Two thousand men, mainly the Maryland line, were hurried down from Washington's camp under Johann de Kalb; Virginia and North Carolina put new men into the field; and the entire force was placed under command of General Gates. Gates marched towards Camden, S.C., and on Aug. 16 encountered Cornwallis near that place. Each army by a night march attempted to surprise the other, but the British tactics prevailed, and Gates was utterly routed. The reputation he had won at Saratoga was ruined on the occasion by overconfidence and incompetence; De Kalb was killed in the action. Gen. Greene, standing next to Washington as the ablest and most trusted officer of the Revolution, succeeded Gates. Cornwallis marched leisurely into North Carolina, but before meeting Greene some months later he suffered the loss of two detachments sent at intervals to disperse various partisan corps of the Americans. On Oct. 7, 1780, a force of 1,100 men under Major Patrick Ferguson was surrounded at King's Mountain, S.C., near the North Carolina line,

by bands of riflemen under Col. Isaac Shelby, Col. James Williams, Col. William Campbell and others, and after a desperate fight on the wooded and rocky slopes, surrendered. Ferguson himself was killed.

On Jan. 17, 1781, Gen. Daniel Morgan was attacked at Cowpens, southwest of King's Mountain, by Colonel Tarleton with his legion. Both were leaders of repute, and a most stirring action occurred in which Morgan, with Col. William Washington leading his cavalry, practically destroyed Tarleton's corps. Despite the weakening his army suffered by these losses, Cornwallis marched rapidly through North Carolina, giving Greene a hard chase nearly to the Virginia line. On March 15 the two armies met at Guilford courthouse (near the present Greensboro, N.C.) and a virtually drawn battle was fought. The British, by holding their ground with their accustomed tenacity when engaged with superior numbers, were tactically victors, but were further weakened by a loss of nearly 600 men. Greene, cautiously avoiding another Camden, retreated with his forces intact. With his small army, less than 2,000 strong, Cornwallis declined to follow Greene into the back country, and retiring to Hillsborough, N.C., raised the royal standard, offered protection to the inhabitants, and for the moment appeared to be master of Georgia and the two Carolinas. In a few weeks, however, he abandoned the heart of the state and marched to the coast at Wilmington, N.C., to recruit and refit his command.

At Wilmington the British general faced a serious problem, the solution of which upon his own responsibility unexpectedly led to the close of the war within seven months. Instead of remaining in Carolina he determined to march into Virginia, justifying the move on the ground that until Virginia was reduced he could not firmly hold the more southern states he had just overrun. This decision was subsequently sharply criticized by Clinton as un-military, and as having been made contrary to his instructions. To Cornwallis he wrote in May: "Had you intimated the probability of your intention, I should certainly have endeavoured to stop you, as I did then as well as now consider such a move likely to be dangerous to our interests in the Southern Colonies." The danger lay in the suddenly changed situation in that direction; as Gen. Greene, instead of following Cornwallis to the coast, boldly pushed down towards Camden and Charleston, S.C., with a view to drawing his antagonist after him to the points where he was the year before, as well as to driving back Lord Rawdon, whom Cornwallis had left in that field. In his main object, the recovery of the southern states, Greene succeeded by the close of the year; but not without hard fighting and repeated reverses. "We fight, get beaten, and fight again," were his words. On April 25, 1781, he was surprised in his camp at Hobkirk's hill, near Camden, by Lord Rawdon and defeated, both sides suffering about an equal loss. On May 22 he attempted to storm the strong British post at Ninety-Six but was repulsed; and finally on Sept. 8 he fought the last battle of the war in the lower southern states at Eutaw Springs, S.C. In the first part of the action Greene was successful after a desperate conflict; in the pursuit, however, the Americans failed to dislodge the British from a stone house which they held, and their severe loss in both engagements was over 500 men. The British lost about 1,000, one-half of whom were prisoners. Better success attended the American partisan operations directed by Greene and conducted by Marion, Sumter, Andrew Pickens, Henry Lee and William Washington. They fell upon isolated British posts established to protect the Loyalist population, and generally captured or broke them up. Rawdon found himself unable with his diminishing force to cover the country beyond Charleston; and he fell back to that place, leaving the situation in the south as it had been in the early part of 1780. On the American side, Greene was hailed as the deliverer of that section.

Virginia Campaign. — Cornwallis, meantime, pursued his Virginia project. Leaving Wilmington, N.C., on April 25, 1781, he reached Petersburg on May 20. There he found British detachments, 2,000 strong, composed of troops whom Clinton had sent down separately under Gen. Benedict Arnold and Gen. William Phillips to establish a base on the Chesapeake, as a diversion in favour of the operations of Cornwallis in the Carolinas. Virginia at

the moment presented a clear field to the British, and they overran the state as far north as Fredericksburg and west to Charlottesville. At the latter place Jefferson, governor of the state, barely escaped capture by Tarleton's men. A small American force under La Fayette, whom Wayne reinforced during the summer, partially checked the enemy. At Green Spring, near Jamestown Island, La Fayette boldly attacked his antagonist on July 6, but had to save himself by a hasty retreat. Early in August Cornwallis retired to Yorktown to rest and await developments. There he fortified himself, and remained until the American-French military and naval combination appeared and compelled his surrender on Oct. 19. (See YORKTOWN.)

With this event war operations ceased. Preliminary articles of peace, signed on Nov. 30, 1782, were followed by a definitive treaty concluded on Sept. 3, 1783. Charleston, S.C., was evacuated late in 1782; New York on Nov. 25, 1783. The reasons of Great Britain's misfortunes and failure may be summarized as follows: Misconception by the home government of the temper and reserve strength of her colonists, a population mainly of good English blood and instincts; disbelief at the outset in the probability of a protracted struggle covering the immense territory in America; consequent failure to dispatch sufficient forces to the field; the safe and Fabian generalship of Washington; and finally, most decisive of all, the French alliance and European combination by which at the close of the conflict Britain was without a friend or ally on the continent. (H. P. J.; C. H. VAN T.)

THE WAR AT SEA

The American Revolution took on a prominently maritime aspect in its early phases. Heavily in debt from recent wars, England was also faced with a constantly increasing demand for overseas markets and marine expansion, because of the industrial revolution through which she was then passing. Beginning in 1764 parliament passed a series of laws to raise revenue through taxing the sea-borne imports of the colonies, and to favour English maritime trade by discriminations against colonial shipping. Laws looking solely to the latter object had been in existence for many years, but custom had given them little attention. A large and prosperous colonial merchant marine had grown up on a technically illegal trade and had become an important element in the economic life of the colonies. Consequently the enforcement of these Navigation acts was the cause of much hardship and resentment in America. As early as 1764 a British schooner so engaged was fired on in Rhode Island waters. In 1769 the sloop "Liberty," similarly employed, was seized and burned at Newport. Such incidents became more common as British coercive measures increased, and when war finally broke there was a popular uprising on the sea quite comparable to that on land.

The onset of the Revolution found the colonies with no naval forces whatever but with a large maritime population and many merchant vessels employed in domestic and foreign trade. This merchant service was familiar not only with the sea, but also with warfare. Colonial ships and seamen had taken a prominent part in the large naval expeditions against Cartagena and Louisburg, had engaged in privateering during the more recent French war, and even during peace had habitually gone armed as a protection against pirates. In 1775 it was therefore natural that considerable numbers of colonial merchant vessels should turn to privateering. This practice was continued on a large scale until the close of the war under legal authorization of individual colonies and of the continental congress. Records are incomplete but indicate that well over 2,000 private armed vessels were so employed during the course of the war, carrying more than 18,000 guns and 70,000 men. In addition, several of the colonies organized state

navies which also engaged in preying upon hostile commerce. These operations were on such a scale that they must be regarded as a primary American military effort of the war. Together with the operations of a few continental vessels they constituted the only sustained offensive pressure brought to bear by the Americans which materially affected the attitude of the British people towards peace. Such injury was done British commerce as to increase insurance rates to unprecedented figures, to seriously reduce available sources of revenue and to alarm the seacoast population.

In its military-naval aspect the war followed two distinct phases, the first ending when France allied herself with the colonies in 1778, until which time Britain had no foreign enemy, and was free to concentrate her whole strength against the Americans. In the second phase England ultimately had to contend against the fleets of France, Spain and Holland, and her consequent inability to meet the naval necessities in American waters was a major influence in the final and decisive campaign ending at Yorktown. With the large navy available during the first three years of the Revolution it was repeatedly urged by Viscount Barrington, the British secretary of war, that: "Conquest [of the colonies] by land is unnecessary when the country can be reduced first by distress, and then to obedience by our marine totally interrupting all commerce and fishery, and even seizing all ships in the ports with very little expense and less bloodshed." Instead of adopting such strategy the British naval forces were used primarily in direct support of army operations and in the protection of their own maritime commerce.

The pressing lack of munitions for the colonial army was the chief impulse in the creation of regular American naval forces. This need caused Benedict Arnold, formerly a sea captain, to march from the siege of Boston, and in association with Ethan Allen to make a surprise capture of the well-stocked stronghold of Ft. Ticonderoga on Lake Champlain, May 10, 1775. This seemingly minor event had far-reaching results. Not only were munitions obtained, but the prompt seizure of all lake watercraft also gave to the colonies control of the only practicable line of communications from the St. Lawrence river to the Hudson valley. A few weeks after he took command of the Continental army besieging Boston, Washington organized a naval force to prey upon the British water communications of that port, and in this way essential munitions were obtained. In Oct 1775 congress voted funds for the first units of a small fleet of eight vessels which sailed from the Delaware on Feb. 17, 1776, under Com. Esek Hopkins (*q.v.*). The objective was Nassau in the Bahama Islands, where a quantity of powder was stored. This was captured on March 3, and the valuable munitions taken in to New London. Meantime the British army under Howe had evacuated Boston and gone by sea to Halifax. Correctly estimating the future probabilities, Washington marched to New York and also provided for the defense of Lake Champlain. For the campaign of 1776 the British plan was to isolate New England by capturing and holding the line of the Hudson river. With this end in view, Howe, heavily reinforced, sailed in June for New York, while other forces undertook an advance via Lake Champlain. Here Arnold had retreated after an unsuccessful attack on Quebec, and had begun the construction of a fleet to retain control of the lake

During the summer a British army of nearly 13,000 men ad-

vanced from Quebec to the lake but was compelled to halt until a sufficient naval force could be constructed to cope with Arnold's rapidly growing fleet. This they were able to do after some months through the assistance of artisans from their ships in the St. Lawrence river, and by reassembling on the lake a large vessel whose dismantled parts had been transported in small boats from Quebec. In a series of naval actions on Oct. 11, 12 and 13, Arnold's fleet of 15 vessels was destroyed. Meantime Howe had gained possession of the lower Hudson, but the season was now so late that the British command on Lake Champlain decided to abandon further operations until spring, and retreated into Canada. When in June 1777 Burgoyne renewed the advance from the north, Howe had shifted his operations by sea for the vicinity of Philadelphia, and Burgoyne was forced to surrender at Saratoga (Oct. 17, 1777) from lack of support. Thus had Arnold's fleet, by delaying the British army for nearly a year, contributed largely to the decisive battle of Saratoga which proved to be a turning point in the war.

Impressed by the evidence of American strength given at Saratoga, and wishing to recover her losses to England in previous wars, France entered into a treaty of alliance with the United States in Feb 1778. The event marked the beginning of an entirely new phase in the war. Henceforth naval power was to be employed on a great scale and to vitally affect military operations in America, as well as the course of European history, and the fate of valuable possessions from the West Indies to the East Indies.

A French fleet under Admiral d'Estaing sailed from Toulon in April 1778, bound for America. Advance news of its coming caused a hasty evacuation of the Delaware by the British fleet then acting in support of the army occupying Philadelphia. Fearing to risk the loss of the army in the event of meeting a superior French fleet at sea, the British command decided to march the troops, bereft of their line of supply, by land to New York, where a junction with the fleet was again made. D'Estaing appeared off the port a few days later, but having missed the opportunity of a decisive victory in the Delaware, he sailed for Newport in accordance with an understanding made with Washington. While preparations were in progress at Newport for a joint attack by Americans and French upon the British garrison of 6,000 troops, the British fleet approached, having been reinforced from England. D'Estaing hastily abandoned the land operations and put to sea to meet them. A partial engagement ensued, followed by a gale which so damaged the ships as to persuade the French admiral to

go to Boston for extensive repairs (Aug. 1778). Because of this the American army before Newport was withdrawn. Meantime a second and more powerful French fleet had been fitted out at Brest with the object of indirectly assisting their overseas naval forces by holding the main strength of the British navy to its home waters. In July 1778 a large but indecisive fleet action was fought off Ushant. Under cover of these major operations Capt. John Paul Jones (*q.v.*) of the Continental navy with a small squadron based on French ports, carried on a series of raids against British coastal shipping.

At this period of history considerations of weather during the winter season usually caused the transfer of naval operations from the western hemisphere to the West Indies, which held the further attraction of being the richest of the world's commercial regions in value of products. Therefore when D'Estaing sailed from Boston in Nov. 1778 his destination was the Caribbean sea, for which locality most of the British fleet in America also sailed on the same day. The latter took 5,000 troops with them, thus greatly reducing the land forces opposed to the Continental army. During the next four years the West Indies were the scene of a large-scale naval war, the forces on each side being often augmented from home, and in the case of the French fleet, by Spanish reinforcements.

Meantime in the autumn of 1778 the British had sent a small expedition from New York, under naval convoy, to Savannah, which place was taken. These operations were extended to the neighbourhood of Charleston during the following year, and attracted the attention of D'Estaing. Arriving off Savannah from the West Indies with his whole fleet in Aug. 1779, he failed in an attempt to retake the place. Nevertheless, upon receiving news of the Savannah affair, General Clinton at New York was so concerned over the safety of his diminished army in the north that he abandoned Newport in order to concentrate his forces against possible French attack.

The summer of 1779 also saw the ill-starred Penobscot expedition. A British military-naval force having occupied what is now Castine, Me., the Massachusetts government undertook to dislodge it. A fleet of 40 vessels including three of the Continental navy and 20 transports, in all carrying 200 guns and 3,000 men, sailed from Boston and began its attack on the British position on July 25. Fighting continued afloat and ashore until Aug. 13, when a superior British naval squadron arrived from New York

and put Americans to rout.

John Paul Jones, operating from French bases with a small squadron, made a cruise around the British Isles from Aug. to Oct. 1779. Many prizes were taken and the British frigate "Serapis" was captured after a memorable duel with the American flagship "Bon Homme Richard." The success of these operations was greatly aided by the fact of the absence in distant waters of practically the whole naval strength of Great Britain, and by the operations in the English channel of a large combined French and Spanish fleet in support of a threatened invasion of England from France.

On the American coast the year 1780 saw the inception of the British policy of conquering the Carolinas which involved such a division of forces as to bring about the ultimate loss of the war. An army detachment escorted by naval forces was sent from New York and captured

Charleston in May. These operations were placed in some jeopardy by the arrival of a French squadron with 6,000 troops at Newport in July, but this was offset by British naval reinforcements reaching New York.

Not meeting with the success which had been anticipated, Cornwallis, commanding the southern British army in America, decided upon a movement into Virginia where naval support could be utilized to better advantage. Meantime on the James river, Benedict Arnold (then under British allegiance) had been ravaging the country, and at the request of Washington the French squadron at Newport had proceeded to the Chesapeake; but after an indecisive action with a British squadron (March 1781), had returned to Newport. Cornwallis joined Arnold on March 20, at Petersburg, with the intention of undertaking vigorous offensive operations in Virginia. But the commander in chief, General Clinton, who was at New York, felt that the forces available were insufficient for such an undertaking, and ordered Cornwallis to intrench himself in a strong position which would control a fleet anchorage. Cornwallis complied by moving to Yorktown, where he arrived on Aug. 22 with 7,000 troops.

After the alliance with France the most important development on the American side was the emergence of General Washington as a master of military-naval strategy. The astonishing evacuation of Philadelphia by the British in great haste (1778) merely because of the probable arrival of a superior French fleet made a profound impression upon Washington. Thereafter he undertook only minor land operations for nearly three years, holding his army in readiness for joint action with a fleet, which he constantly sought. When D'Estaing attempted the capture of Savannah (Sept.-Oct. 1779), Washington vainly urged him to come north and attack New York jointly with the American army. Upon arrival of the handsome reinforcement of Rochambeau's army, July 1780, he held it inactive for nearly a year until De Grasse's fleet was expected. Summing up his operations for the year 1780 Washington wrote Franklin in Paris, "Disappointed . . . especially in the expected naval superiority, which was the pivot upon which everything turned, we have been compelled to spend an inactive campaign, after flattering prospects at the opening of it."

Washington finally got a fleet through sending his aide to Paris. When Adm. François de Grasse sailed from France for the West Indies he had orders to co-operate with Washington's armies in a joint operation. Exchanging messages by fast frigate, the gen-

eral and admiral concerted a plan for a junction of fleet and armies for action against the British in lower Chesapeake bay. Later Cornwallis entrenched at Yorktown to facilitate receiving critically needed logistic aid from the British fleet. Thus Yorktown became the primary objective of the Franco-American military-naval forces upon their arrival in that locality.

In conformity with the agreed plan Rochambeau's army joined Washington north of New York and the two marched for northern Chesapeake bay down which they were to go principally by water transport, under cover of French naval vessels upon their arrival. Concurrently De Grasse sailed from his Haitian base, wisely deferring the dispatch of a large merchant convoy in order to take north his full force of 28 ships-of-the-line and 3,300 troops. Meanwhile, Adm. Samuel Hood of the British West Indies fleet became concerned for the security of New York. Although not aware of De Grasse's departure for the north, fearing such a move Hood started north five days after De Grasse, with 14 ships-of-the-line.

With faster ships following a more direct route, Hood was the first to reach the Chesapeake. Finding no sign of French ships he hastened to the protection of New York, where he was joined by five ships-of-the-line under Adm. Thomas Graves. The latter being senior took command of the whole force. Soon information was received of the sailing from Newport of eight ships-of-the-line under Admiral De Barras. Correctly assuming that this Newport squadron was bound for Chesapeake bay, Graves sailed with his 19 capital ships in ample time to intercept it. When Graves reached the Chesapeake entrance De Barras had not yet arrived, but a startling sight greeted him,—the forest of masts of the great fleet of De Grasse from the West Indies, at anchor just inside Cape Henry. The French admiral was equally astonished as he had not been aware of Hood's presence in northern waters.

This mutual surprise, Sept. 5, 1781, seems to have shaken the judgment of both admirals. De Grasse hastily got underway and stood out to sea in a long column, thus exposing his fleet to piecemeal destruction as it emerged from the harbour. Instead of exploiting such a golden opportunity, Graves deliberately awaited the exit of the French, outnumbering him 24 to 19, before attacking from his advantageous "weather gauge." The poorly executed British attack resulted only in leading squadrons of the two fleets being engaged in the late afternoon. For three days the two fleets were becalmed, and, within sight of each other, drifted nearly 100 mi. southward. One damaged British ship was abandoned and sunk by her crew. When a breeze sprang up the French got it first and hastened back to the Chesapeake where De Barras had arrived meanwhile. With this French reinforcement, the British were decisively outnumbered and Graves sealed the fate of Cornwallis by sailing for New York. In the opinion of the British naval historian, Sir William M. James, this was "the decisive battle of the war."

Washington's armies, aided by water transportation down Chesapeake bay under French naval protection, did not arrive before Yorktown until Sept. 28. Within a few days Cornwallis received a message from General Clinton in New York, stating that a reinforced British fleet of 26 ships-of-the-line and 5,000 troops would sail from New York about Oct. 5 for his relief. With hopes thus buoyed, Cornwallis continued resistance. On Oct. 13 he tried a retreat across the York river, hoping to reach a position more favourable to a relieving fleet for supplying him. Failing in the attempted retreat and in urgent need of supplies, he surrendered on Oct. 19, it being apparent that Clinton had been overly optimistic and that the indispensable relief by water could not possibly reach him in time.

In retrospect the American Revolution is seen to have developed from small beginnings into one of the greatest naval wars in history. During its progress the early issues of colonial maritime rights and independence became subordinated in European eyes to that of the control of the then commercially very valuable West Indies, and other objects. The fleet operations which in a few weeks decided the fate of Yorktown, and of the American cause, were merely incidental to the vast naval campaign carried on over a period of five years in Caribbean, European and Indian waters.

AMERICAN'S CREED, a U.S. patriotic document, written in 1917 by William Tyler Page, clerk of the U.S. house of representatives. The document was adjudged to be the best brief summary of the political faith of the United States of America from among the several thousand entries submitted in a national citizens' creed contest. On April 3, 1918, the U.S. commissioner of education read the American's Creed in public for the first time before a session of the house of representatives, where it was formally accepted in the name of the U.S. government. The creed reads as follows:

"I believe in the United States of America as a Government of the people, by the people, for the people; whose just powers are derived from the consent of the governed; a democracy in a republic; a sovereign Nation of many sovereign States; a perfect Union, one and inseparable; established upon those principles of freedom, equality, justice and humanity for which American patriots sacrificed their lives and fortunes.

"I therefore believe it is my duty to my country to love it; to support its Constitution; to obey its laws; to respect its flag; and to defend it against all enemies."

AMERICANS FOR DEMOCRATIC ACTION, a liberal independent political organization operating on national, state and city levels in the United States. A.D.A. was formed in Jan. 1947 by labour leaders, civic leaders, representatives of the national congress and state legislatures, intellectuals and academicians who were liberal in national affairs, international in world outlook and anticommunist by conviction. It is devoted to the propagation of liberal ideas, the election of liberal public officials and the passage of liberal legislation. The headquarters of the organization are in Washington, D.C., and the membership numbers about 50,000.

The organization has been vigorously attacked by both the extreme right and the extreme left for some positions it has taken, among them the successful fight led by A.D.A. for a strong civil rights platform in the 1948 Democratic convention, A.D.A.'s exposure of the communist domination of the Progressive party, and A.D.A.'s vanguard battle against Sen. Joseph R. McCarthy and various right-wing movements residual from McCarthyism. With the election of John F. Kennedy as president of the United States in 1960, many A.D.A. leaders and members were appointed to key positions in the new administration. Americans for Democratic Action believes that planned, reasoned processes of government can be used to bring about necessary social and economic changes and at the same time to protect individual rights and liberties. It seeks to focus attention on the paramount issues of the day and to bring them from the discussion stage into the arena of practical political decision and action. (R. R. N.)

AMERICAN STATES, ORGANIZATION OF. On April 30, 1948, the 21 republics of the western hemisphere at the ninth conference of American states at Bogotá, Colombia, signed the charter of their new organization, replacing the Union of American Republics (*see* PAN-AMERICAN CONFERENCES). Ratification of the charter by the 14th state took place on Dec. 13, 1951, giving formal legal validity to the treaty which had been in practical effect since its signature.

Like the charter of the United Nations, the charter of the Organization of American States begins by stating the general nature and purposes of the organization, which do not differ substantially from the traditional objectives of the Union of American Republics. The two succeeding chapters of the charter set forth the principles of the organization and the fundamental rights and duties of member states, constituting a valuable summary of the basic law of the inter-American regional system, supplemented by pro-

visions for the pacific settlement of disputes and for collective security in accordance with the provisions of the treaty of reciprocal assistance signed at Rio de Janeiro in 1947.

The charter next sets forth the organs of the organization. The International Conference of American States, described as the Inter-American conference, was made the supreme organ of the organization, functioning on the basis of the legal equality of the members, and holding its meetings every five years. Supplementing the conference, and equal in authority to it, is the meeting of consultation of foreign ministers, to be held to consider problems of an urgent nature and of common interest to the American republics. The meeting of foreign ministers was given the further duty of serving as the organ of consultation in the event of an armed attack or an act of aggression within the territory of an American republic, bringing into effect the provisions of the treaty of reciprocal assistance. The third organ, in permanent session, is the council, successor of the former governing board of the Pan American Union, composed of one representative of ambassadorial rank from each member state, and acting as a sort of executive committee of the organization, supervising the activities of its central permanent secretariat, the Pan American Union (which name had hitherto been used popularly for the larger Union of American Republics), and having at its service three advisory councils, dealing respectively with economic and social juridical and cultural matters. In addition the council of the organization supervises the work of the specialized conferences called from time to time to deal with special technical matters and of the various specialized organizations of a permanent character.

While the charter described the Organization of American States as a regional agency within the United Nations, in actual fact the organization was completely independent, merely subordinating its measures of enforcement to the obligations of its members as members also of the United Nations. Close co-operation, however, was maintained between the two organizations, particularly in respect to the work of their technical organs.

The collective security provisions of the treaty of reciprocal assistance represented the general acceptance by the American states of the principle underlying the Monroe Doctrine (*q.v.*), that an attack upon an American state by a non-American state would be considered as an attack upon all, each state being obligated to assist in meeting the attack while awaiting measures of collective action by the whole group. The "continentalization" of the Monroe Doctrine, as it has been called, thus created obligations for the other American states without restricting the right of the United States to take immediate action in self-defense.

The adoption of the charter in 1948 gave a stimulus to concerted measures looking to the promotion of the economic and social welfare of the American states, the creation of greater mutual understanding through the exchange of teachers and students and the diffusion of educational material. The program of technical assistance was a significant feature of the measures of economic co-operation.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY, THE. The first telephone company was formed in 1876 when Alexander Graham Bell (*q.v.*) assigned his first two telephone patents to the Bell Patent association. On July 9, 1877, this association was succeeded by the Bell Telephone company, first as a trusteeship, and later as an incorporation.

The Bell Telephone company was succeeded in 1879 by the National Bell Telephone company, and later by the American Bell Telephone company, organized March 20, 1880. On Dec. 30, 1899, all assets of the latter company were transferred to the already existing American Telephone and Telegraph company by an exchange of stock.

The American Telephone and Telegraph company thus became the central organization of the Bell system. Through 20 principal telephone subsidiaries it provides the bulk of the telephone service in the United States. Revenues from telephone service make

up more than 90% of the total operating revenues of the company and its principal associated companies. The company operates a network of wire and radio circuits and related equipment for intercommunication between and through territories of subsidiary companies and other telephone companies, and for interconnection between U.S. telephone systems and those in many other parts of the world.

In 1882 the Western Electric company was acquired as the system's manufacturing and supply unit. In 1921 the Bell Telephone laboratories was established as the system's research and development organization. It is owned jointly by Western Electric and American Telephone and Telegraph company.

There is close collaboration between the research, manufacturing and operating units of the Bell system in the development, design and manufacture of new and improved communications facilities. Standardization of equipment and methods throughout the system has been emphasized.

In 1915 the first transcontinental telephone line was opened between New York and San Francisco. In 1927 New York and London were linked by radiotelephone. Three decades later, more than 120 countries and territories could be reached from the United States by radio and underocean telephone cable. The first undersea telephone cable was opened across the North Atlantic in 1956. Other cables subsequently linked the U.S. mainland with Alaska and Hawaii.

Various communication services furnished by the Bell system have been expanded over the years. Teletypewriter exchange service, a written form of public message communication, and private line systems are used extensively by industry, finance, the press and government. Radio network service, started in the 1920s, grew greatly in the following years. In the 1940s, development of coaxial cable and radio relay made practical the transmission of intercity television programs.

During World War II, the telephone industry contributed greatly to the war effort, particularly in electronic developments such as radar. More than 1,200 military projects were completed. From 1942 through 1945, Western Electric company supplied over \$2,000,000,000 worth of specialized equipment to the government.

The Bell system's most extensive construction and expansion program followed World War II. Billions of dollars were invested in new buildings and equipment, to meet the demand for service.

The Bell system continued, primarily through Western Electric, to contribute to the nation's defense after the war. Bell laboratories' inventions such as the transistor (*q.v.*) found ready use in both military and civilian capacities. For continental defense, the Bell system developed and produced the U.S. Army's "Nike" guided missile. In the far north, the DEW (Distant Early Warning) line of radar stations was constructed for the U.S. Air Force. Related military communications facilities were installed in Alaska. Western Electric played a major role in the construction of the U.S. Air Force's air warning and control system, known as the SAGE (Semi-Automatic Ground Environment) system. This included handling the project's engineering and administrative work, and designing and supervising construction of key buildings. Bell and independent telephone companies provide interconnecting communication facilities for this air warning system.

(F. R. K.)

AMERICAS, THE. America, or the Americas, is the term by which the two continents of the western hemisphere are known. Its two chief parts, North and South America, resemble each other in outline and topography. Both are roughly triangular, with their apexes pointing to the south, and both are rimmed on the west by ranges of high mountains of recent origin that slope gently eastward to broad river valleys.

Differences between the two are marked, however, because of their relation to the earth's equator. The broad northern portion of North America has a subarctic climate, its mountains in the northwest bear huge glaciers, and much of the rest is covered with ice. In contrast, the northern part of South America, crossed by the equator, lies wholly within the tropics and has a torrid flora and fauna, while its southern end reaches a narrow point at Cape Horn and is characterized by cold waters and glaciers.

The two continents reach their narrowest link at the Isthmus of Panama, where they are separated by the Panama canal. Linguistic and cultural divisions, however, do not correspond with the geographical. In these respects, there are two Americas: Latin America, which, broadly defined, includes Mexico, Central America, most of the West Indies, and all of South America; and Anglo-America; *i.e.*, the United States and Canada. The term Middle America is sometimes used to designate Mexico, Central America and the West Indies, collectively.

Christopher Columbus inaugurated the "Age of Discovery" by his epochal voyage of 1492 when he sailed westward and landed on what has been generally identified as Watlings (or Watling) Island in the Bahamas, on Oct. 12, 1492. The Indians called it Guanahani, but Columbus changed this to San Salvador (Holy Saviour). Norse explorers touched the North American mainland before this time, but their discoveries had no permanent results.

On his great voyage, Columbus was searching for and thought he had found a new route to India—and had thus reached the fabled orient, which Marco Polo had described for Europeans. Hence he spoke of the lands he had discovered as "the Indies," which long continued to be Spain's official name for her American possessions.

The name "America" is derived from that of the early explorer and friend of Columbus, Amerigo Vespucci (*q.v.*), who made several voyages to the new world and, perhaps just as important, described his travels in letters to friends in Italy. One of these letters, published in 1504, used the term *Mundus Novus* ("New World") in referring to South America. The letter circulated from hand to hand; the eye-catching title of *Mundus Novus* excited popular fancy. When a copy reached Martin Waldseemüller in Germany, he (apparently unaware of Columbus' voyage of 1498

during which he discovered the continent of South America) included some of Vespucci's writings in his *Cosmographiae Introductio* (1507).

Waldseemüller observed that "Another fourth part (of the inhabited earth) had been discovered by Americus Vespucci . . .," and he suggested that the new land be called America. Waldseemüller's book was a best seller, and in time his proposal became universally accepted.

For further historical and geographical material see COLUMBUS, CHRISTOPHER and LATIN AMERICA; also, CENTRAL AMERICA; MIDDLE AMERICA; NORTH AMERICA, SOUTH AMERICA; WEST INDIES; GREENLAND; ICELAND; and articles on other regions and countries of the western hemisphere.

(G. P. Hd.)

AMERICIUM. The synthetic chemical element americium has the symbol Am and the atomic number 95. An account of its discovery is given in the article TRANSURANUM ELEMENTS. Americium occupies a position in the periodic system of the elements as the sixth member of a rare-earthlike transition series, the actinide series, which includes the heaviest known elements in which an inner electronic shell (the 5f shell) is being filled.

Production.—Americium can be prepared in gram amounts through the intense neutron bombardment of Pu²³⁹. The isotope Pu²⁴¹ results from the capture of two neutrons and this undergoes beta decay, with a 13-year half life, to Am²⁴¹. This element is entirely synthetic in origin, and the amount which might be present in nature is too small to make its detection likely.

Since the isotopic composition of any given sample of americium

BY COURTESY OF THE BANCROFT LIBRARY, UNIVERSITY OF CALIFORNIA

"AMERICA OR THE NEW WORLD. A NEW DESCRIPTION." FROM THEATRUM ORBIS TERRARUM, 1570, BY ABRAHAM ORTELIUS

depends on its source, the concept of atomic weight has no meaning in the ordinary sense. Because the isotope Am^{241} can be prepared in relatively pure form by extraction as a decay product, over a period of years, from strongly neutron-bombarded plutonium containing Pu^{241} , and because this has been a practical source of americium for many chemical investigations, it may be convenient to use 241 (more precisely 241.07) as the atomic weight (on the chemical scale). The isotope Am^{243} has proved more convenient for chemical investigations in view of its longer half life (7,950 years as compared with 458 years for Am^{241}) and should assume greater importance as it becomes more available.

The specific alpha activity of Am^{241} , about 70,000,000,000 alpha disintegrations per minute per milligram, makes it necessary to conduct investigations using this isotope with special precautions, using special techniques for handling this very highly alpha-active material.

A mixture of the isotopes Am^{241} , Am^{242} and Am^{243} can be prepared by intense neutron irradiation of Am^{241} . Nearly isotopically pure Am^{243} can be prepared by a sequence of neutron bombardments and chemical separations as follows: the bombardment of Am^{241} with neutrons yields Pu^{242} ; after chemical separation, the Pu^{242} is irradiated with neutrons to produce Pu^{243} which decays with the emission of a negative beta particle to form Am^{243} . The Am^{243} can be chemically separated.

Fairly pure Pu^{242} for this purpose can be prepared more simply by intense neutron irradiation of Pu^{239} as the result of successive neutron capture reactions.

Isotopes of Americium

Isotope*	Half life	Type† and energy of radiation (Mev)
Am^{237}	~1.3 hr.	EC α (0.005%) 6.01
Am^{238}	1.9 hr.	EC
Am^{239}	12 hr.	EC α ($4 \times 10^{-3}\%$) 5.78
Am^{240}	50 hr.	EC
Am^{241}	458 yr	α 5.534 (0.35%) 5.500 (0.23%) 5.477 (85%) 5.435 (12.6%) 5.378 (1.7%)
Am^{242m}	16.0 hr.	β^- (81%) 0.625, 0.667 EC (19%) IT ($\leq 6\%$)
Am^{242}	—100 yr.	β^- (90%) 0.59 EC (10%)
Am^{243}	7,950 yr.	α 5.339 (0.17%) 5.308 (0.16%) 5.266 (87%) 5.224 (11.3%) 5.169 (1.1%)
Am^{244}	26 min.	β^- 1.5 EC ($3.9 \times 10^{-2}\%$)
Am^{245}	1.98 hr.	β^- 0.91
Am^{246}	25 min.	β^- 2.10, 1.60, 1.31

*The symbol ^m placed after the mass number refers to an isomeric form of isotope.
†EC=electron capture; α =alpha particle; β^- =negative beta particle; IT=isomeric transition.

Chemical Properties.—Americium is a basic element like the other actinide elements, and the reduction to the metal can be effected only with powerful reducing agents. The metal can be prepared by the reduction of americium trifluoride with barium at a temperature of 1,000° to 1,200° C. The metal produced in this manner is silvery white and appears to be more malleable than uranium and neptunium prepared in the same manner. It tarnishes slowly in dry air at room temperature. The experimentally measured density is 11.7 ± 0.3 g./c.c., and the melting point appears to be about 1,000° C.

Much early chemical investigation of americium was done by use of the tracer technique, using the isotope Am^{241} . This demonstrated that the (III) oxidation state is very stable in aqueous solution, in line with the tendency toward the stabilization of the lower oxidation states in going from uranium to plutonium. The most important information has been obtained by work with weighable amounts, much of it using the isotope Am^{241} . This work shows that this element exists in acidic aqueous solution in the (III), (V) and (VI) oxidation states with the ionic species probably corresponding to Am^{+3} , AmO_2^+ and AmO_2^{+2} . The oxidation potentials in acidic aqueous solution are summarized in the following diagram.

The potentials are in volts relative to the hydrogen-hydrogen ion couple as zero.

As the potentials indicate, americium can be oxidized to the (V) or (VI) state only with strong oxidizing agents, and this can be used to separate it from the other actinide elements. Adsorption and elution from columns packed with ion exchange resins are also used to separate americium from the other tripositive actinide elements. A common method of separating it from the rare-earth elements is by the use of such columns and elution with concentrated hydrochloric acid. The hydrochloric acid forms complex ions with the actinide elements which are much more stable than the corresponding ones formed with the rare-earth elements. Americium may be more readily oxidized in alkaline solution.

Americium (V) can be precipitated readily in the form of an insoluble compound by oxidizing americium (III) in carbonate solution using sodium hypochlorite. This compound has been shown to have the composition $\text{RbAmO}_2\text{CO}_3$ when the only cation present is rubidium, and the oxidant is ozone or peroxydisulfate. The absorption lines of solid americium compounds at low temperatures are extremely sharp, of the order of 1–10 Å wide, which is a width comparable to the sharpest rare-earth spectra, and some compounds exhibit fluorescence under certain conditions.

In its precipitation reactions americium (III) is very similar to the other tripositive actinide elements and to the rare-earth elements. Thus, the fluoride and the oxalate are insoluble and the phosphate and iodate are only moderately soluble in acid solution, while the nitrates, halides, sulfates, sulfides and perchlorates are all soluble.

When americium is precipitated as the insoluble hydroxide from aqueous solution and heated in air, a black oxide is formed which corresponds almost exactly to the formula Am_2O_3 . This may be reduced to Am_2O_3 through the action of hydrogen at elevated temperatures. The Am_2O_3 has the fluorite type structure, isostructural with UO_2 , NpO_2 and PuO_2 . The orange-red Am_2O_3 has both the hexagonal and the cubic sesquioxide structure typical of early members of the rare-earth series. As in the case of the preceding actinide elements, oxides of variable composition between $\text{AmO}_{1.5}$ and AmO_2 are formed depending upon the conditions.

All four of the trihalides of americium have been prepared and identified. These are prepared by methods which are similar to those used in the preparation of the halides of other actinide elements. In addition it has been found that AmF_4 (and its double salt KAmF_5) can be prepared by the reaction of fluorine gas at 500° C. with Am(III) , Am(IV) or Am(V) compounds.

See G. T. Seaborg and J. J. Katz (eds.), *The Actinide Elements*, "National Nuclear Energy Series," vol. iv-14A (1934); and G. T. Seaborg, J. J. Katz and W. M. Manning (eds.), *The Transuranium Elements*, "National Nuclear Energy Series," vol. iv-14B (1949); J. J. Katz and G. T. Seaborg, *The Chemistry of the Actinide Elements*, (1957); G. T. Seaborg, *The Transuranium Elements* (1958).
(G. T. Se.)

AMERIND or **AMERINDIAN**, a word coined by J. W. Powell, director of the Bureau of American Ethnology, to designate the aboriginal inhabitants of the American continent. The term "American Indian" was frequently abbreviated to "Indian," thereby leading to confusion with the inhabitants of India.

See **INDIAN, NORTH AMERICAN**.

AMERSFOORT, a town in the province of Utrecht, Neth., lies 12 mi. E.N.E. of Utrecht, on the Eem river. Area 9.9 sq.mi. Pop. (1957 est.) 66,403 (mun.). The walled centre of the city has a street pattern dating from the middle ages with two water gates and 15th- to 16th-century wall houses, built in the city walls. St. George's church (12th-16th century) has mural paintings and an organ loft and tombs by Jacob van Campen; the Gothic tower of Our Lady (c. 1450), 295 ft. high, was the bell tower of a church destroyed in 1787. Amersfoort has a regional museum, a government archaeological research station and a school for bell ringers. There was rapid development of light industry, chiefly metals,

chemicals and foodstuffs, after World War II, with a corresponding increase in population.

AMERSHAM, a town in Buckinghamshire. Eng., 26 mi. N.W. of London by road, lies at the foot of the Chiltern hills, there thickly wooded, where the river Misbourne emerges from its valley. Pop. (1951) 10,894. The wide high street of the old town, with its inns, timbered buildings and 13th-century town hall, is very attractive. The parish church of St. Mary dates from the 13th century. Market gardening, turkey and pheasant raising, woodworking, light engineering and the manufacture of instruments, bricks and cosmetics are carried on in the district. In the newer part of the town there is a centre for the distribution of radioactive isotopes. Amersham and Chesham Bois railway station lies on the main line from London through Aylesbury to the north. Amersham, formerly a borough by prescription, returned two members to parliament from 1624 to 1832, when it lost its privileges. The fair has taken place annually since 1200. Amersham forms part of the Chiltern Hundreds (*q.v.*).

AMERY, LEOPOLD CHARLES MAURICE STENNETT (1873–1955), British politician who was a persistent advocate of imperial preference and tariff reform; and did much to promote the constitutional advance of colonial territories, is chiefly remembered for his part in bringing about the fall of the Chamberlain government in 1940. He was born at Gorakhpur, India, on Nov. 22, 1873, and educated at Harrow school and Balliol college, Oxford. He was elected a fellow of All Souls college, Oxford, in 1897. In 1899–1900 he was chief correspondent of the *Times* from the South African War and remained on the staff of that paper until 1909, editing *The Times History of the South African War*, 7 vol. (1900–09). He entered parliament in 1911 as Unionist member for the South (later Sparkbrook) division of Birmingham and held this seat until 1945. During World War I, he served abroad with the British army in 1914–16, but from 1917 he was on the staff of the war cabinet in London and of the inter-Allied war council at Versailles. He became undersecretary of state for the colonies in 1919 and was moved to a junior post at the admiralty in 1921. During this period he was a leader of the "undersecretaries' revolt" which contributed to the fall of the Lloyd George coalition government in 1922 and to the Conservatives' return to power.

He was made a privy councillor in 1922 and thereafter, apart from a term as first lord of the admiralty (1922–24), he spent the rest of his career as a minister in imperial departments. He was secretary of state for the colonies (1924–29) and also for the dominions (1925–29), and created in 1925 the dominions office which later became the commonwealth relations office. He was excluded from office by the national government (1931–40) and was a sharp critic of the Munich agreement with Hitler and Mussolini. Despite his industry, integrity and passionate advocacy of his own causes, he never dominated the house of commons, but in 1940 his voice was influential in breaking the Chamberlain government to which he applied Cromwell's injunction to the Long parliament: "In the name of God, go!" From 1940 to 1945 he was secretary of state for India and Burma. In 1935 he was made a companion of honour. He died in London on Sept. 16, 1955.

Amery's works include *Thoughts on the Constitution* (1947) and *My Political Life*, 3 vol. (1953–55). (J. F. B.)

AMES, FISHER (1758–1808), U. S. congressman, orator and essayist, was born at Dedham, Mass., on April 9, 1758, and entered Harvard college at the age of 13. After graduation in 1774 he remained at home, gaining more maturity through reading and studying, until 1781 when he began a successful law practice. Convicted by Shays's rebellion that stern measures must be taken to deter attacks upon property and authority, he turned to politics (*see SHAYS, DANIEL*). As a member of the Massachusetts convention that ratified the federal constitution in Feb. 1788, he argued strongly in favour of the clause in the constitution (art. 1, sec. 2) providing for biennial rather than annual elections for the house of representatives. Ames was a Federalist member of the house during Washington's administration (1789–97). On April 28, 1796, he overcame Republican opposition by his spellbinding oratory and secured passage of the appropriation bill for Jay's

treaty.

Ames agreed with Hamilton's vision of a vigorous federal government guided by men of means and virtue. Although not in congress during the Adams and Jefferson administrations, Ames shared the view of the Essex junto—a group of New England Federalists who urged a friendly policy toward Britain and a strong campaign against France. He hoped the Sedition act of 1798 would control the French revolutionary doctrines. After retirement from congress Ames continued to state his views in more than 25 essays and numerous letters. He died at Dedham on July 4, 1808.

(H. I. BE.)

AMES, JAMES BARR (1846–1910), C.S. legal historian, teacher and writer, was born in Boston: Mass. on June 22, 1846, and taught at Harvard law school from the year of his graduation in 1872 until his death in Wilton, N.H., on Jan. 8, 1910. From 1895 to 1910 he was also dean of the law school. He published many casebooks for student use and wrote extensively in legal periodicals, primarily in history, equity and torts; but his *Lectures on Legal History*, collected after his death and published in 1913, constitute his enduring contribution to legal scholarship and jurisprudence. (A. DM.)

AMES, JOSEPH (1689–1759), English bibliographer and antiquary, whose *Typographical Antiquities* (1749) is a valuable account of printing in England from 1471 to 1600. Later editions were published with added information by William Herbert (1785–90) and T. F. Dibdin (1810–19). Ames is variously described by contemporaries as a ship chandler, a patten maker, a plane-iron-maker, and an ironmonger. He led a prosperous life at Wapping, and amassed valuable collections of antiquities. He died on Oct. 7, 1759. His other works are catalogues of English printers: of the collection of coins which belonged to the earl of Pembroke; of about 2,000 English portraits; and *Parentalia* (1750), a memoir of the Wrens, undertaken with Sir Christopher Wren's grandson, Stephen Wren.

AMES, OAKES (1804–1873), U.S. industrialist and congressman, one of the builders of the first transcontinental railroad and key figure in the Credit Mobilier scandal of 1872–73, was born Jan. 10, 1804, in Easton, Mass. He went to work as a youth in his father's shovel factory and helped develop a business valued at \$4,000,000 on the eve of the American Civil War. Ames, a Republican, was elected in 1862 to the first of five consecutive terms in the national house of representatives. In 1865 he and his brother Oliver (1807–77) became associated with the Union Pacific railroad. Ames also obtained control of the Credit Mobilier of America, a company organized by promoters of the Union Pacific for the purpose of securing to themselves the enormous profits expected from the building of the road. Through Credit Mobilier, Ames arranged the necessary contracts and pushed construction to its completion in 1869. Meanwhile, in order to insure the friendship of certain members of congress, he had begun to sell them Credit Mobilier stock at a price well below its actual value. The dramatic exposure of these transactions during the campaign of 1872 led to congressional investigations. A committee report early in 1873 recommended expulsion of Ames, but the house of representatives contented itself with a resolution censuring his conduct. Guilty of impropriety, but hardly of outright dishonesty, Ames thus became something of a scapegoat for the sins of a railroad-building generation, which, in condemning him, convicted itself. He died while his disgrace was still fresh, on May 8, 1873, at North Easton, Mass.

See CRÉDIT MOBILIER OF AMERICA.

(D. E. F.)

AMES, WILLIAM (known as AMESIUS) (1576–1633), English Puritan theologian and controversialist: a champion of Calvinism as opposed to Arminianism during the Remonstrant controversies, was born at Ipswich, Suffolk, in 1576. Xmes was educated at Christ's college, Cambridge, and became a fellow there. In 1609, following a sermon in which he denounced the heathenish debauchery attending the feast of St. Thomas, he was obliged to leave England and spent the rest of his life in the Netherlands. He was aided in leaving England by wealthy English merchants who wished him to convert the supporters of the English church in Leiden. At Rotterdam, wearing the fisherman's habit donned for

the passage, he opposed Grevinchovius (Nicholas Grevinckhoven, d. 1632), minister of the Arminian or Remonstrant church, in a debate. (See ARMINIANISM.) The fisherman-controversialist made a considerable stir and became known throughout the Low Countries. Subsequently Ames entered into a controversy in print with Grevinchovius on universal redemption and election and cognate problems. His views were brought together in his *Coronis ad collationem hagiensem*, prepared for the synod of Dort (q.v.), 1618–19, a book which figured largely in Dutch church history.

He was for a short time chaplain to Sir Horatio Vere in Holland, then professor of theology at Franeker, Friesland, from 1622 to 1633. In the latter year he moved to Rotterdam where he undertook pastoral work. Ames did not long survive this move and died in Rotterdam in Nov. 1633. His *Fresh Suit Against Ceremonies*—the book which is said to have made Richard Baxter (q.v.) a Non-conformist—was published posthumously. His other works include *Medulla theologiae*, a manual of Calvinistic doctrine for his students; *De conscientia eius iure et casibus*; and Latin commentaries on the Psalms and the Epistle of St. Peter.

See the *Life* by M. Nethcnus, prefixed to the collected edition of his Latin works (1658).

AMES, WINTHROP (1871–1937), U.S. theatrical producer, was born in North Easton, Mass., on Nov. 25, 1871. He graduated from Harvard in 1895 and spent the following year in special study at the university. For eight years he edited and published art and architectural works in Boston, Mass., followed by a year abroad, where he studied the continental drama. In 1905 he became manager, in association with Lorin F. Deland, of the Castle theatre, Boston, where for three years they conducted a very notable stock company. In 1908 Ames became director of the New theatre (later the Century) in New York city, where he made an attempt to establish a repertory theatre. With the passing of the New theatre, he began, in 1912, independent production and management, erecting two theatres, the Little and the Booth. He contributed a wide variety of productions, among them *Snow White*, the first play given in New York city especially for children. He also produced the Gilbert and Sullivan operas.

Ames died in Boston on Nov. 3, 1937.

AMES, a city of Story county, central Iowa, U.S., 33 mi. N. of Des Moines. Ames was laid out in 1864, and named after Oakes Ames (q.v.), a railroad promoter; it was incorporated in 1870, and adopted a council-manager form of government in 1920. (For comparative population figures see table in IOWA: *Population*.)

Ames is the seat of the Iowa State University of Science and Technology (formerly the Iowa State College of Agriculture and Mechanic Arts) established in 1858 as a "state agricultural college and model farm." The central campus of 781 ac. is a beautiful park. An inner plaza of 20 ac., containing a campanile with a chime of 36 bells cast in Loughborough, Eng., is surrounded by stately buildings of white Bedford stone. The university's college of veterinary medicine, founded in 1879, is the oldest in the United States and the U.S. department of agriculture's animal disease research laboratory is located in Ames. The Institute for Atomic Research, established at the university in 1945, became one of the major research centres of the U.S. Atomic Energy commission.

Toys, water purifiers and electronic and chemical instruments are manufactured in Ames. (J. T. Sc.)

AMESBURY, a town in Wiltshire, Eng., lies in the rich and well-wooded valley of the Avon amid the chalk downs of Salisbury plain, 8 mi. N. of Salisbury. Pop. (1931) 4,235. The immediate neighbourhood is rich in remains of prehistoric man, among which Stonehenge (q.v.), 1½ mi. W., is the greatest surviving megalithic structure in the British Isles. On a hill overlooking the town is a large earthwork, the Ramparts, which perhaps marks an earlier settlement. At Amesbury (Ambresberia, Aumbresbery) a witenagemot (Anglo-Saxon national council or parliament) was held in 932, and about 980 Aelfthryth, queen dowager of Edgar, erected a nunnery there in expiation of the murder of her stepson. At the time of Domesday (1086), Amesbury was a royal manor. From the 12th century the nunnery was attached to the abbey of Fontevrault in Anjou, France, and was enriched by royal charters and

private gifts. A weekly market (no longer held) and fair were granted in 1317. The church of St. Mary is largely Early English, with richly decorated windows. Pipe clay abounds in the neighbourhood and in the 17th century Amesbury was famous for its pipes. Its interests are largely agricultural, frequent sheep fairs being held. The town profits from the permanent army camps in the vicinity (particularly from Larkhill) and from the tourist traffic visiting Stonehenge and other objects of interest on the plain. Amesbury lies on one of the two main roads between London and Exeter and is served by a branch railway line for freight traffic.

AMESBURY, a town of Essex county, in northeast Massachusetts, U.S., on the Merrimack river, 43 mi. N. of Boston, at the New Hampshire border. (For comparative population figures see table in MASSACHUSETTS: *Population*.)

Amesbury was first settled in 1642 as part of Salisbury. It became practically independent in 1654 although not legally a township until 1666. In 1667 it was named for the English town in Wiltshire. The witchcraft hysteria swept the town in 1693. Quaker settlers came in 1701. Josiah Bartlett (1729–95), a signer of the Declaration of Independence, was born there.

The early agriculture was soon supplemented by shipbuilding and the making of barrel staves. Amesbury was an important shipbuilding centre until the decline of wooden sailing vessels. Other early industries included the manufacture of iron: begun in 1710; hats, 1769; nails! 1796; and carriages, 1800. The water power of the Merrimack and Powow rivers attracted the textile industry in 1812.

Modern manufacturing is varied in nature and provides the largest source of employment in the industrial area. Amesbury was the home of John Greenleaf Whittier from 1836 to 1876 and many of his poems describe the surrounding country and the life of the community. (CA. M. C.)

AMETHYST, a violet or purple variety of quartz (q.v.) used as an ornamental or gem stone (see also GEM). The name is generally said to be derived from the Greek for "not intoxicating," expressing the old belief that the stone protected its owner from strong drink. It was held that wine drunk out of a cup of amethyst would not intoxicate. The colour of amethyst is usually attributed to the presence of manganese, but as it is capable of being much altered and even discharged by heat it has been referred by some authorities to an organic source. On exposure to heat, amethyst generally becomes yellow, and much of the cairngorm or yellow quartz used in jewelry is heat-treated amethyst.

The amethyst was used as a gem stone by the ancient Egyptians, and was largely employed in antiquity for intaglios. It later was used for episcopal rings. It is a very widely distributed mineral, but fine, clear specimens fit for cutting as ornamental stones are confined to comparatively few localities. Such crystals occur either in cavities in mineral veins and in granitic rocks, or as a lining in hollow agate nodules or geodes. Many of the hollow agates of Brazil and Uruguay contain a crop of amethyst crystals in the interior. Much fine amethyst comes from the U.S.S.R., especially the Sverdlovsk area.

AMETROPIA, any departure from the normal refractive condition of the eye (emmetropia). Like a camera, the eye is provided with a lens and light-sensitive membrane, the retina. The cornea and the transparent substances that fill the eyeball aid the refractive power of the lens. In an ideal eye at rest, parallel rays come to a clear focus on the retina. Although only about 2% of properly examined eyes exactly meet this standard, the majority of normal eyes closely approach it. When, however, due to defects in the refractive mechanism, parallel rays do not come to a clear focus on the retina of a resting eye, the condition is called ametropia. Such defects may be abnormalities in length of the eyeball or irregularities in the curvature of the cornea or lens, and the resulting varieties of ametropia are called myopia (shortsightedness), hyperopia (farsightedness) and astigmatism. See ASTIGMATISM; EYE, HUMAN; VISION.

AMHARA, the name of one of the former central provinces of Ethiopia, stretching roughly from the river Abbai or Abay (Blue Nile) on the west to Lake Hayk in the east, but later including

Begamedr (Begemdir) and Lake Tana. It has ceased to be an administrative unit, having been replaced by Shoa (Shewa) to the south. Amhara in early times was a kingdom ruled, under the king of Ethiopia, by a subking whose title was tsahafalam. This title first appears in documented history in the reign of King Amda Tseyon (1312–42), but appears to have lapsed by 1520, when the Portuguese embassy which included the chaplain Francisco Alvares came to Ethiopia. As late as 1689, however, the governor of Amhara was eighth in the official order of precedence. In 1646 Manoel de Almeida described Amhara as the most mountainous part of Ethiopia and as very fertile. From Amhara is derived the name of the modern official and literary language of Ethiopia, Amharic, spoken by 3,000,000 to 5,000,000 people over central Ethiopia almost from the eastern to the western border, though not as a lingua franca. It has developed from Ge'ez; the earliest known specimens belong to the 14th century A.D. See also ETHIOPIA: History.

BIBLIOGRAPHY.—C. F. Beckingham and G. W. B. Huntingford, *Some Records of Ethiopia, 1593–1646* (1954; for Almeida's description of 1646), *The Prester John of the Indies* (1961; for F. Alvares' descriptions of 1540); C. H. Walker, *The Abyssinian at Home* (1933); E. Ullendorff, *The Ethiopians* (1960). (G. W. B. H.)

AMHARIC, the national language of Ethiopia probably since the 12th century, originally was spoken in the province of Amhara, hence its name; it is the language of the central and southern highlands of Ethiopia. The oldest Amharic documents are songs from the 14th century. In the late 16th and early 17th centuries, Jesuits used Amharic against the Monophysite Ethiopians. Amharic is one of the Semitic languages (*q.v.*), but has been greatly modified by Cushitic influence. Amharic uses the Ethiopic syllabary with additional signs; it has 33 characters. Each character has seven forms representing a consonant followed by different vowels.

In relation to proto-Ethiopic the features of Amharic are the following: In phonology the loss of the laryngeals and the palatalization of the dentals and sibilants are notable. In morphology the characteristic features are: the loss of *-t* as feminine marker; the disappearance of the mark *-a* of the accusative and of the construct state; and the usage of the external plural (*-oč*) with elimination of the internal plural. The verb developed derived stems for actions not found in proto-Ethiopic. Syntax and vocabulary are strongly influenced by Cushitic, especially by Galla and Sidamo.

BIBLIOGRAPHY.—F. Praetorius, *Die amharische Sprache* (1879); C. H. Armbruster, *Initia Amharica. An Introduction to Spoken Amharic, part 1: Grammar* (1908); I. Guidi, *Grammatica elementare della lingua amarīnā*, 4th ed. (1935); M. Cohen, *Traité de langue amharique* (1936). (W. L. U.)

AMHERST, JEFFREY AMHERST, BARON (1717–1797), British soldier, who was commander of the army which captured Canada between 1758 and 1760, was born at Sevenoaks, Kent, on Jan. 29, 1717. He received a commission in the foot guards in 1731 and was selected as aide-de-camp first by Lord Ligonier and then by the duke of Cumberland. Pitt and Ligonier selected him for the Canadian command in 1758. With a force of 14,000 men he besieged and captured Louisburg, and was promoted to chief command in America. He then drew up a plan for a concentric advance on Montreal by three columns, one moving westward up the St. Lawrence river and capturing Quebec, the second northward from Albany by Ticonderoga and Crown Point, and the third westward from Fort Niagara. The first under James Wolfe captured Quebec late in 1759 and the final offensive was launched in 1760, when Montreal surrendered and Canada passed into British hands. Amherst remained in Canada as governor general till 1763, quelling the Indian rising under Pontiac in 1761. He acted as commander in chief of the British army almost continuously from 1772 to 1795, but though he suppressed the Gordon riots in 1780, his tenure of office was not a successful one, being marred by failure in the war with the American colonies and by the growth of serious abuses in the army.

He was created a baron in 1776, a field marshal in 1796, and died at Sevenoaks, Kent, on Aug. 3, 1797.

See Amherst, J. A., *Journal*, ed. by J. C. Webster (1931); J. C. Long, *Lord Jeffery Amherst* (1933). (E. W. SH.)

AMHERST, WILLIAM PITT AMHERST, EARL (1773–1857), British diplomat whose tenure of the governor generalship of India (1823–28) was notable mainly for the conduct of the first Burmese War. He was born at Bath on Jan. 14, 1773, the nephew of Jeffrey, Baron Amherst (*q.v.*), to whose title he succeeded in 1797. Amherst served from 1809 to 1811 as British envoy at the court of Naples, where he acquired some reputation as a diplomatist. In 1815 he was sent to China to conduct negotiations on commercial questions, but achieved nothing because of his refusal to perform the kowtow ceremony or accept inferior diplomatic status. On his return journey he visited Napoleon at St. Helena (1817). In London he received more credit for his firmness than censure for the failure of his mission. On the resignation of Lord Hastings, Amherst was appointed governor general of India in 1823, against the rival candidacy of Lord William Bentinck. George Canning, who managed the appointment, called it, in a letter to William Huskisson, "as good a barren choice as could have been made."

So in fact it proved. Within a month of his arrival Amherst was confronted by aggression from Burma, which precipitated the first Burmese War (1824–26). Despite some mismanagement (including the dispatch of Indian troops by sea, which caused the Barrackpore mutiny in 1824), the war was brought to a conclusion with the annexation of the jungle coastal strips of Arakan and Tenasserim to Great Britain in 1826. For his services during the Burmese War, Amherst received an earldom in 1826. He died on March 13, 1857.

See A. T. Ritchie and R. Evans, *Earl Amherst* (1894). (T. G. P. S.)

AMHERST, one of the four districts of the Tenasserim division of Burma. After the creation of the Karen state (*q.v.*) it was reduced to a narrow coastal strip, mainly of forested hills, running southward along the Gulf of Martaban from the mouth of the Salween. Its headquarters are at Moulmein (*q.v.*), an important town and port, but it takes its name from the town of Amherst, named in honour of a viceroy of India and planned as an outpost of Moulmein, though it failed to develop as such.

(L. D. S.)

AMHERST, a town of Hampshire county, Mass., U.S., in the central part of the state. (For comparative population figures see table in MASSACHUSETTS: Population.) The town was settled as a precinct of Hadley about 1730, and recognized as a district under the name of Amherst in 1759; it was named for Jeffrey Amherst (*q.v.*), a British general in the French and Indian War. It was incorporated as a town in 1775. Originally an agricultural area, it became an industrial village in the 18th century and for more than a century produced carriages, bricks, textiles, paper, tools and hats. In the 19th century industry gave way to farming: large dairy herds and apple orchards, some poultry and tobacco.

Amherst is, however, pre-eminently an academic town. Prior to the establishment of public high schools (1861) Amherst academy and other private schools provided training for young people, many from out-of-town. Amherst college, a men's college affiliated with the Congregationalist church, was founded in 1821; before 1871 more than 40% of its graduates entered the ministry. Its annual enrollment is approximately 1,000. Among its founders were Noah Webster, the lexicographer, and Samuel F. Dickinson, grandfather of the poet, Emily Dickinson.

Academic facilities include, in addition to classrooms and laboratories, Converse library, the Mead Art centre (with a distinguished collection of early American paintings), Kirby theatre, Pratt Museum of Natural History, an observatory and a special laboratory for radioactive research. The college administers the Merrill Center for Economics at Southampton, N.Y., and the Folger Shakespeare Memorial library in Washington, D.C. The University of Massachusetts (originally the Massachusetts Agricultural college and later Massachusetts State college) was incorporated in 1863 and admitted its first students in 1867. The campus comprises 700 ac. about 1 mi. N. of the village centre, and a demonstration forest of 755 ac. 6 mi. farther north. Helen Hunt Jackson and Emily Dickinson were born in Amherst, and Noah Webster lived in the village (1812–22) while working on his dictionary. (F. P. Ra.)

AMHURST, NICHOLAS (1697–1742), English satirical poet and editor of the *Craftsman*, was born at Marden, Kent, on Oct. 16, 1697. He was expelled from St. John's college, Oxford, in 1719, probably because of his outspoken Whig principles and because of the satire against the university in his poems.

Amhurst settled in London, and in 1721 began a series of satirical papers called *Terrae Filius*. He became prominent among the pamphleteers hostile to Sir Robert Walpole's government, and edited the famous *Craftsman*, the Whig paper which Lord Bolingbroke and William Pulteney had founded and to which they contributed. The paper had unprecedented popularity for a political journal, and published articles by Tory as well as Whig writers. In 1737 it printed a letter, supposedly from Colley Cibber, attacking the new act for licensing plays, and for this suspected libel both Amhurst and the printer, Richard Francklin, were imprisoned for a short time.

When Pulteney and his political friends came to terms with the government after Walpole's downfall, Amhurst was forgotten, and the end of his life was apparently spent in poverty and obscurity. He died at Twickenham, Middlesex, on April 12, 1742.

AMICABLE NUMBERS (also known as AMIABLE NUMBERS or, less commonly, as AGREEABLE NUMBERS), two integers each of which is equal to the sum of the aliquot parts (exact divisors) of the other. For example, 220 and 284 are amicable numbers, for the aliquot parts of 220 are 1, 2, 4, 5, 10, 11, 20, 22, 44, 55 and 110, the sum of which numbers is 284.

Similarly, the sum of the aliquot parts of 284 (that is, of 1, 2, 4, 71 and 142) is 220. These two numbers are mentioned by the Greek arithmetician Iamblichus (c. 325). Mathematicians have discovered 389 other pairs.

See E. B. Escott, "Amicable Numbers," *Scripta Mathematica*, vol. 12, pp. 61–72 (1946).

AMICI, GIOVANNI BATTISTA (1786–1863), Italian astronomer and microscopist, was born March 25, 1786, at Modena and died at Florence, April 10, 1863.

His name is best known for the improvements he effected in the mirrors of reflecting telescopes and in the development and construction of the microscope.

AMICUS CURIAE, a term used primarily in law, means, literally, "a friend of the court." An amicus curiae is a stranger to a law suit who assists the court by furnishing information or advice regarding questions of law or fact. He differs from an intervenor in that the latter has a direct interest in the outcome of the law suit and therefore is permitted to intervene as a party.

An amicus curiae normally may not participate except by leave of the court, and most courts seldom permit persons to appear as amicus curiae. However, the supreme court of the United States permits federal, state and local governments to submit their views in any case without obtaining the consent of either the court or the parties. Private persons may appear as amicus curiae in the supreme court either if both parties consent or if the court grants permission.

(J. R. B.)

AMIDES (ACID AMIDES), chemical compounds which may be considered as derived from ammonia by replacement of one or more of its hydrogen atoms with acyl residues. (An acyl residue is the characteristic group of an acid, from which it may be derived by removal of the acidic hydroxyl group or groups.) Certain amides of the sulfonic acids, or derivatives of them, comprise the "sulfa drugs," of great importance in medicine. Sulfanilamide was the first of these drugs to be widely used; it may be considered the parent substance from which the remaining drugs are derived by structural modifications. (See SULFONAMIDES.)

A few amides of inorganic acids are known, such as nitramide, $H_2N.NO_2$ (from nitric acid), and sulfamic acid, $H_2N.SO_3H$ (from sulfuric acid), but the great majority are derived from organic acids. Of these latter compounds, the amides of the type $R.CO.NH_2$, which are derived from the carboxylic acids, are the most important, the group $.CO.NH_2$ being called the amido group. They may be prepared by the dry distillation of the ammonium salts of the acids (A. W. von Hofmann), by the partial hydrolysis of the nitriles, by the action of ammonia or ammonium car-

bonate on acid chlorides or anhydrides, or by heating the esters (*q.v.*) with ammonia. They are solid crystalline compounds (formamide excepted); the lower members of the series are soluble in water, the solubility, however, decreasing as the carbon content of the molecules increases. They are easily hydrolyzed, breaking up into organic acids and ammonia when boiled with acids or alkalies. Nitrous acid decomposes them, with elimination of nitrogen and the formation of the corresponding acid:

When distilled with phosphoric anhydride they yield nitriles. By the action of sodium hydroxide and either bromine or chlorine on the amides, they are converted into amines containing one carbon atom less than the original amide:

This reaction possesses great theoretical importance (A. W. von Hofmann), and is also of industrial interest in the Badische synthesis of indigo (*q.v.*), for in accordance with Hofmann's reaction phthalimide is converted by alkali hypochlorite into anthranilic acid.

Formamide, $H.CONH_2$, is a liquid readily soluble in water, boiling at about $195^\circ C.$ with partial decomposition. Acetamide, $CH_3.CONH_2$, a white deliquescent crystalline solid, which melts at $82-83^\circ C.$ and boils at $222^\circ C.$, is usually prepared by distilling ammonium acetate. Benzamide, $C_6H_5.CONH_2$, crystallizes in leaflets which melt at $130^\circ C.$

The amides of the sulfonic acids are only slightly less important than those of the carboxylic acids discussed above. They may be prepared by the action of ammonia upon the corresponding sulfonyl chlorides:

Among the important derivatives of the amides are those in which one or more of the hydrogen atoms attached to nitrogen have been replaced by alkyl or aryl groups.

AMIEL, HENRI FRÉDÉRIC (1821–1881), Swiss writer whose *Journal intime* is a masterpiece of self-analysis, was born at Geneva on Sept. 27, 1821. After studying for seven years in Italy, France, Belgium and Germany, he was appointed professor of aesthetics in 1849 and of moral philosophy in 1854 at the academy in Geneva. Disappointments in his youth, followed by what he felt to be failure at the academy and as a poet—only his "Roulez, tambours" achieved success, becoming the national anthem of the French-speaking part of Switzerland—drove him into himself. He found his real life in the diary which he kept from 1847 until his death in Geneva on May 11, 1881. Parts of the 16,900 pages of this *Journal intime* were published during 1883–84. It gained a European reputation and was translated into English, Russian, German and other languages. It remains a fascinating document of a sensitive, rich mind desperately struggling for values in an age of growing scepticism and pessimism.

BIBLIOGRAPHY.—*Fragments d'un journal intime*, ed. by B. Bouvier, 3 vol. (1923) and by L. Bopp (1939–); B. Bouvier, *La jeunesse d'H.-F. Amiel* (1935); A. Thibaudet, *Amiel ou la part du rêve* (1929); E. Merian-Genast, "H.-F. Amiel im Spiegel der europäischen Kritik, 1881–1931," in *Neuere Sprachen* (1931); Van Wyck Brooks, *The Malady of the Ideal* (1913). (A. Bx.)

AMIENS, principal city of Picardy (region of northern France) and capital of the Somme *département*, lies in the marshy valley of the Somme river below its confluence with the Avre, 81 mi. N. of Paris by road. Pop. (1954) 87,126. It is the seat of a bishop.

The town is dominated by the cathedral of Notre Dame, one of the finest Gothic churches in France. Begun in 1220 on the plans of Robert de Luzarches it was finished about 1270; though the lateral chapels, the towers on each side of the façade and the rose window were added later. It is 469 ft. long by 216 ft. wide, the nave being nearly 140 ft. in height. There are aisles, a transept with aisles and a choir (with deambulatory) ending in an apse surrounded by chapels. The façade, flanked by two towers of unequal height added in the 14th and 15th centuries respectively, has three decorated portals. The central one has a 13th-

century statue of Christ, while the right hand one contains a figure of the Virgin and other statuary and the left is devoted to St. Firmin. The portals are surmounted by two galleries, the upper one containing 22 statues of the kings of Judah in its arcades, and by a fine rose window. A slender spire rises above the crossing. The interior of the cathedral contains beautifully carved stalls and a flamboyant choir screen, and is remarkable for the high nave and the boldness of the columns supporting the vaulting.

The busy part of the city, largely reconstructed after extensive damage in the two world wars, lies between the railway to the south and the Somme on the north. The old quarter straddles the seven branches of the river and the new parts spread out to the north. The line of the former ramparts is followed by a series of boulevards, and there is another ring of boulevards beyond. Opposite the railway station is the 30-story Perret tower, 341 ft. high, built by Auguste Perret, architect of the station, after World War II. The town hall, built in the 17th century and almost entirely rebuilt in the 19th, stands in the centre of the old town. To the north is the 15th-century church of St. Germain, to the south the Picardy museum with collections of archaeological finds: paintings and sculpture and to the east the Louis XVI façade of the ancient theatre.

Amiens is on the main railway from Paris to Calais, and other main lines run northeastward to Dunkerque and Lille and southeastward to Laon, Reims and Switzerland. Secondary lines run to Rouen, Beauvais, Compiègne and St. Pol. There is an important railway marshalling yard at Longueau (1 mi. E.). The textile industry, famous since the middle ages, includes velvet, cotton, wool, silk, hemp and flax spinning, hosiery and a variety of mixed fabrics. Manufactures of machinery, chemicals and tires, and printing and dyeing are also carried on. Amiens is a market for the produce of the allotments and small market gardens (*hortillonnages*) in the fertile land between the many branches of the Somme and Avre, which cover a considerable area mainly to the east of the city. Amiens also trades in grain, sugar, wool, oilseeds, and in the duck pasties and macaroons for which it is renowned. The vegetable market is held on board the many small boats which bring the produce from the *hortillonnages*, and a fair for all types of merchandise is held every year.

In pre-Roman days Amiens was known as Samarobriua, capital of the Ambiani, from which it derives its modern name. Settled by the Romans at the beginning of the Christian era, Christianity was brought there in the 4th century by St. Firmin, its first bishop. Its territory became the medieval countship of Amienois and early in the 12th century the citizens gained a charter, profiting from the rivalry between count and bishop. The fief became a dependency of the French crown in 1185. By the treaty of Arras it went to the dukes of Burgundy in 1435 and remained theirs until 1477. Surprised by the Spaniards in 1597, the city was recaptured from them by Henry IV after a long siege. Until 1790 it was the capital of the government of Picardy. The treaty between Great Britain, France, Spain and Holland which made a short pause in the Napoleonic War was signed there in 1802. During the Franco-German War Amiens fell to the Prussians on Nov. 28, 1870, after a battle to the east of the city. During World War I the city was captured by the Germans on Aug. 30, 1914, but after a few days they withdrew when the front was established about 20 mi. to the east, where it remained until 1918, when, during their final offensive, the Germans advanced to within 8 mi. of the city. In World War II Amiens was occupied by the Germans on May 21, 1940, and recaptured on Aug. 31, 1944.

See also Index references under "Amiens" in the Index volume. (BE. Bo.)

AMIENS, BATTLE OF, the name commonly given to the opening stage of operations in Picardy in 1918, Germany's last bid for victory on the western front in World War I (*q.v.*). (For the Allied offensive of Aug. 1918, sometimes called the battle of Amiens, see ST. QUENTIN, BATTLE OF.)

Encouraged by the collapse of Russia, the German general Erich Ludendorff planned an offensive with the initial object of capturing the important communication centre of Amiens and thereby

of separating the British and French armies. The main attack started early on March 21, 1918, on a front of 60 mi. between Arras and Laon, held by British forces. The 71 German divisions were opposed by 29 British. Helped by fog, the attackers advanced rapidly, mainly on the front held by the British 5th army (Gen. Sir H. Gough). On March 26, however, when the French general Ferdinand Foch assumed control of all Allied forces. French reinforcements began moving up. By April 5 the Germans had advanced about 25 mi. and were within 10 mi. of Amiens, but the attack had spent its force. Amiens remained in Allied hands. British casualties amounted to 163,493, French to about 77,000, Germans to about 250,000. Later German attacks on other parts of the front were without any solid success.

See Sir James E. Edmonds, the official British History of the *Great War*, vol. i and ii (1935 and 1937). (C. N. B.)

AMIN AL-HUSAPNI (1893–), mufti of Jerusalem from 1921 to 1937, outstanding for his anti-British role in Arab politics. A Palestinian Sunni Muslim, he was educated in Jerusalem, at al-Azhar university, Cairo, and in Istanbul and was commissioned in the Turkish artillery (1910). He began recruiting for the Arabs of the Hejaz in their rising against Turkey in 1917, became persona grata in Arab nationalist circles and—after a brief imprisonment for anti-Zionist agitation—was made mufti of Jerusalem by the high commissioner, Sir Herbert Samuel, in 1921. He became president of the supreme Muslim council in 1922. As head of the important Palestine Arab party and later of the militant Arab Higher committee, he was an Arab nationalist party leader, the most extreme and least scrupulous spokesman and organizer of anti-Zionist activities in Palestine. He moved to Lebanon in 1937 and to Iraq (where he exercised considerable anti-British influence) in 1939. Fleeing from Iraq on the failure of Rashid Ali's movement (1941), he took refuge in Iran and then in Berlin: where from 1942 to 1944 he acted as wholehearted Nazi propagandist. From Germany he proceeded to France in 1945 and then in 1946 to Egypt, where he was received by King Faruk and re-elected as president of the Higher Arab committee for Palestine. From 1947 onward he lived at Heliopolis, outside Cairo, paying more than one visit to Pakistan as member, or president, of Muslim conventions. His titular position as head of the "government of all-Palestine" was meaningless after the partition of that country between Israel and Jordan (1947–49). Despite his wide pretensions, he had few followers in the 1950s. (S. H. Lo.)

AMINES, in chemistry, derivatives of ammonia (*q.v.*) in which one or more of the three hydrogen atoms are replaced by alkyl or aryl groups. The replacement of one hydrogen atom by one alkyl or aryl group gives rise to primary amines; of two hydrogen atoms by two groups to secondary amines; of three hydrogen atoms by three groups to tertiary amines. The tertiary amines possess the power of combining with one molecular proportion of an alkyl iodide to form quaternary ammonium salts.

The structural relations of these compounds may be shown thus:

Aliphatic Amines.—An amine is said to be an aliphatic one if each carbon atom that is joined directly to the amino nitrogen atom is saturated. This is true even if aromatic rings are present in more distant parts of the molecule. (Cf. benzylamine, below.) The compounds of this type possess properties very similar to those of ammonia. The lowest members of the series are combustible gases and are readily soluble in water. The next higher members of the series are liquids of low boiling point and are also readily soluble in water, the solubility and volatility, however, decreasing with the increasing carbon content of the molecule. The highest members of the series are odourless solids of high

boiling point and are insoluble in water. They are all moderately strong bases, readily forming salts with the mineral acids. They are ionized in aqueous solution to a somewhat greater extent than ammonia. The quaternary ammonium bases, NR_4OH , as distinct from the amines, are solids that are soluble in water; they are much more strongly basic than ammonia or any of the amines, and, in fact, are comparable in strength with sodium and potassium hydroxides.

Many methods have been devised for the preparation of primary amines. Methylamine was isolated in 1849 by A. Wurtz on boiling methyl isocyanate with potassium hydroxide, $\text{CH}_3\text{NCO} + 2\text{KOH} = \text{CH}_3\text{NH}_2 + \text{K}_2\text{CO}_3$. Further methods of preparation include the reduction of nitriles with alcohol and sodium; the hydrolysis of the alkyl phthalimides (S. Gabriel, 1887); and the action of bromine or chlorine and a strong base on the amides of carboxylic acids (A. W. Hofmann, 1885).

The secondary amines are prepared, together with the primary and tertiary, by the action of ammonia on the alkyl iodides (see below) and also in numerous other ways.

By the action of ammonia on the alkyl iodides a complex mixture of primary, secondary and tertiary amines, along with a quaternary ammonium salt, is obtained, the separation of which is difficult. A method was worked out by Hofmann in 1850 for the ethylamines but has not been widely extended. A more general method devised by O. Hinsberg (1890) consists in treating the mixed bases with benzene sulfonyl chloride (or *p*-toluene sulfonyl chloride). The primary base gives an acidic derivative, $\text{C}_6\text{H}_5\text{SO}_2\text{NHR}$, soluble in aqueous alkali, the secondary base furnishes the compound $\text{C}_6\text{H}_5\text{SO}_2\text{NR}_2$, insoluble in alkali, whereas the tertiary base does not react. The process is applicable to both aliphatic and aromatic amines.

The primary, secondary and tertiary amines may be distinguished by their behaviour with various reagents. Primary amines when heated with alcoholic sodium hydroxide and chloroform yield isonitriles, which are readily detected by their offensive odour. The secondary and tertiary amines do not give this reaction. With nitrous acid, the primary amines yield alcohols (usually accompanied by olefines), the secondary amines yield nitrosamines and the tertiary amines do not react. The condensation with benzene sulfonyl chloride in the presence of alkali also furnishes a method of diagnosis (see above).

Methylamine, CH_3NH_2 , occurring in the herb *Mercurialis perennis*, in bone oil and herring brine, is also a decomposition product of many alkaloids. At ordinary temperatures it is a gas with a strong ammoniacal smell, burns readily and is exceedingly soluble in water. Dimethylamine, $(\text{CH}_3)_2\text{NH}$, found in Peruvian guano, is a heavy vapour which liquefies at 7°C . and has a strong fishlike smell. Trimethylamine, $(\text{CH}_3)_3\text{N}$, is a vapour very similar to dimethylamine, but liquefies at $3.2^\circ\text{--}3.8^\circ\text{C}$. It is usually obtained from vinasse, the residue from the distillation of beet sugar alcohol. The three methylamines can be obtained from ammonia and formaldehyde solution and a suitable separation for each of the three was devised by E. Werner (1917).

Tetramethylammonium iodide, $\text{N}(\text{CH}_3)_4\text{I}$, the final product obtained by the action of methyl iodide on ammonia (Hofmann), crystallizes in quadratic prisms and has a bitter taste. By warming its aqueous solution with an excess of silver oxide it is converted into tetramethylammonium hydroxide $\text{N}(\text{CH}_3)_4\text{OH}$, which crystallizes in hygroscopic needles, and has a very alkaline reaction. On dry distillation it is decomposed into trimethylamine and methyl alcohol. If the nitrogen atom in a quaternary ammonium salt is in combination with four different groups, then the molecule is dissymmetric, and the salt can be resolved into optically active enantiomorphous isomerides (W. J. Pope and S. J. Peachey, 1899 [see STEREOCHEMISTRY]).

Benzylamine, $\text{C}_6\text{H}_5\text{CH}_2\text{NH}_2$, although it contains the phenyl group C_6H_5 , is a typical aliphatic primary amine (see above). It can be obtained together with di- and tribenzylamines by the action of ammonia on benzyl chloride (S. Cannizzaro, 1865) and in other ways. It is a liquid which boils at 183°C ., has an alkaline reaction and is miscible in all proportions with water, alcohol and ether.

Diamines.—The diamines contain two amino groups. Two of them are identical with the so-called ptomaines, which are produced by the putrefactive action of bacteria on albumen and other related substances. Tetramethylenediamine (putrescine), $\text{NH}_2(\text{CH}_2)_4\text{NH}_2$, is prepared also by reducing ethylene dicyanide (succinonitrile) with sodium in absolute alcoholic solution (A. Ladenburg, 1886). It melts at 27°C . and is easily soluble in water. Pentamethylenediamine (cadaverine), $\text{NH}_2(\text{CH}_2)_5\text{NH}_2$, is prepared by reducing trimethylene cyanide in ether solution by zinc and hydrochloric acid (Ladenburg, 1883). Cadaverine is a sirup at ordinary temperatures and boils at $178^\circ\text{--}179^\circ\text{C}$. It is readily soluble in water and alcohol, but only slightly soluble in ether.

Aromatic Amines.—The aromatic amines are those in which the amino nitrogen atom is joined directly to at least one aromatic ring. These substances in some respects resemble the aliphatic amines, since they form salts with acids and also distill without decomposition. On the other hand, they are much weaker bases than the aliphatic amines, their salts undergoing extensive hydrolysis in aqueous solution. The primary aromatic amines may be prepared by the reduction of the nitro-hydrocarbons, the reducing agents used being frequently tin and hydrochloric acid, or on the manufacturing scale iron and water acidified by hydrochloric acid. They may also be obtained by the action of sodium hydroxide and either chlorine or bromine upon the amides of aromatic carboxylic acids, and on the manufacturing scale by treatment of aryl chlorides with ammonia at high temperatures and pressures in the presence of a catalyst.

The primary aromatic amines are colourless liquids or crystalline solids which are sparingly soluble in water but readily soluble in the common organic solvents. When heated with alkyl or aryl iodides they are converted into secondary and tertiary amines. When heated with concentrated sulfuric acid they become sulfonated. They form condensation products with aldehydes, and they form anilides when heated with organic acids. They give the isonitrile reaction (see above) when warmed with chloroform and a caustic alkali. When warmed with a solution of nitrous acid, they are converted into phenols; if, however, nitrous acid be added to an ice-cold solution of a primary amine in excess of mineral acid, a diazonium salt is formed (see ANILINE; AZO COMPOUND; DIAZO COMPOUNDS).

The secondary amines may be of two types—namely, the purely aromatic amines and the mixed secondary amines, which contain an aromatic residue and an alkyl group. The purely aromatic amines are obtained by heating the primary amines with their hydrochlorides and, in some cases, by heating a phenol with a primary aromatic amine and a catalyst (anhydrous zinc chloride or 1% of iodine). The mixed secondary amines are prepared by the action of alkyl iodides on the primary amines, or by heating salts of the primary amine with alcohols under pressure. (See ANILINE.) The mixed secondary amines have basic properties, but the purely aromatic secondary amines are only very feeble bases.

The tertiary amines may also be of two types, the purely aromatic and the mixed type. The mixed tertiary amines are produced by the action of alkyl halides on the primary amines. The simplest aromatic tertiary amine, triphenylamine, is prepared by the action of bromobenzene on sodium diphenylamine (C. Heydrich, 1885). Purely aromatic quaternary ammonium compounds are not known. The mixed quaternary hydroxides, such as trimethylanilinium hydroxide, $\text{C}_6\text{H}_5\text{N}(\text{CH}_3)_3\text{OH}$, are as strong bases as their purely aliphatic analogues.

Diphenylamine, $(\text{C}_6\text{H}_5)_2\text{NH}$, the simplest representative of the true aromatic secondary amines, crystallizes in white plates, which melt at 45°C ., and it boils at 302°C .

Aromatic Diamines.—The simplest aromatic diamines are prepared by reducing the three nitranilines. Ortho-phenylenediamine, $\text{C}_6\text{H}_4(\text{NH}_2)_2$, crystallizes from water in plates, which melt at $102^\circ\text{--}103^\circ\text{C}$. and it boils at $256^\circ\text{--}258^\circ\text{C}$.

The three classes of aromatic diamines may be distinguished by their behaviour toward nitrous acid. The ortho compounds are transformed into benzotriazoles, the meta compounds yield azo

dyestuffs and the para compounds yield bis-diazo compounds of the type $XN_2.C_6H_4.N_2X$. See DIAZO COMPOUNDS; see also Index references under "Amines" in the Index volume.

AMINO ACIDS, a class of organic acids containing the amino ($-NH_2$) group and forming the chief constituent of proteins. See PROTEINS; see also Index references under "Amino Acids" in the Index volume.

AMIOT (AMYOT), JEAN JOSEPH MARIE (1718–1793), French Jesuit missionary who provided a key to the thought and life of the far east by his *Dictionnaire tartare-mantchoufrançais*, was born at Toulon in Feb. 1718. He entered the Society of Jesus in 1737 and was sent in 1750 as a missionary to China. He soon won the confidence of the emperor Ch'ien Lung and spent the remainder of his life at Peking, where he died Oct. 9, 1793. Other than the *Dictionnaire* (1789), his writings are to be found chiefly in the *Mémoires concernant l'histoire, les sciences et les arts de Chinois* (1776–91). The *Vie de Confucius*, the 12th volume of that collection, is complete and accurate.

See, for full bibliography, C. Sommervogel, *Bibliothèque de la Compagnie de Jésus*, i, pp. 294–303 (1890–1932); for his works on Chinese music see F. J. Fetis, *Biographie universelle des musiciens* (1837–44).

AMIR, also spelled EMIR, a title common in the Muslim east (Arabic *amr*, "commander," from the root 'mr, "command").

The word originally signified any military commander but was subsequently applied to governors of provinces and other high military officers. The title of *amir al-mu'minin*, "commander of the faithful," was assumed by the second caliph, Omar, and was adopted in later times by most of the various dynasties that claimed the caliphate (*q.v.*). In the 10th century the commander of the caliph's armies at Baghdad was styled *amir al-umara*, which is translated "supreme commander" or "generalissimo." In later use *amir* was applied as a title of dignity to the descendants of the Prophet.

Amir was also used in combination with other terms, to denote office (as in *amir al-hajj*, "leader of the pilgrimage"). It was adopted also by the rulers of several independent states in central Asia, notably those of Bukhara and Afghanistan. As applied to naval commanders it is the origin (through medieval Greek and Italian) of the English "admiral."

AMIR ALI, SEYYID (1849–1928), Indian-Muslim jurist, leader and thinker, was born at Cuttack in Orissa on April 6, 1849. He traced his descent from the eighth Shi'ite imam, Ali al-Riza. After graduating in Calcutta, he came to England and was called to the bar of the Inner Temple in 1873. Thereafter he began to practise law in Calcutta. A member of the Bengal legislative council in 1878, chief presidency magistrate in 1879, a legislative member of the governor general's council, he became a judge of the Calcutta high court in 1890. Permanently resident in England from 1904, he was appointed to the judicial committee of the privy council in 1909. He died in Sussex on Aug. 3, 1928.

A founder of the National Mohammedan association (1877) which was intended to give Indian Muslims experience in western political techniques and to protect their interests, Amir Ali supported British rule in India, believing that the alternative was Hindu domination masquerading as Indian nationalism. In 1909 he helped to secure communal electorates for Muslims under the Rlorley-Minto proposals (see INDIA: History). He sought also to reinterpret Islam in and to the modern world and his *Spirit of Islam* (1891) remains a modernist Muslim classic.

See "The Memoirs of the Late Rt. Hon'ble Syed Ameer Ali" in *Islamic Culture* (Oct 1931 and Oct. 1932). (P. H.)

AMIR KHUSRAU (1253–1325), Persian poet and historian, known as "the parrot of India," and regarded as the greatest writer in Persian to be born outside the motherland, was born in 1253 at Patiala in northwest India. He was the son of a Turkish officer, who had joined the service of Itutmish, sultan of Delhi. He shined a precocious gift for poetry, and was encouraged by Balban, sultan of Delhi during 1266–86, and his son Mohammed

Khan of Multan. In 1287 he was in Delhi when Bughra Khan advanced to expel his son the sultan Kai-Qubad; he witnessed their reconciliation, which provided him with the theme of his first historical epic, *Qiran al-sa'dain* ("Conjunction of the Two Stars"). Enjoying the patronage of Kai-Qubad and his successors, he composed a further series of epic poems celebrating the military exploits of his royal masters: ending with the *Tughlak-nama* on Ghiyas ud-Din Tughlak's victory in 1320 over the usurper Khusrau Khan. In the short span 1298–1301 he wrote a group of five long idylls in emulation of the *Khamse'* ("Five") of Nizami (*q.v.*). In addition he published no fewer than five collections of odes and lyrics, from *Tulzfah al-sighar* ("The Present of Youth") in 1272 to *Nihayat al-kamal* ("Ultimate Perfection") in 1325. In prose too he composed abundantly: a history of sultan Ala ud-Din Khilji's victories, a biography of the saint Nizam ud-Din Auliya whose disciple he was, and the *I'jaz-i Khusravi*, a massive collection of elegant compositions and model letters.

See Mohammed Wahid Mirza, *Life and Works of Amir Khusrau* (1935); A. J. Arberry, *Classical Persian Literature*, pp. 273–282 (1998). (A. J. AR.)

AMIS ET AMILES, an Old French epic written about 1200, concerns two men predestined to eternal friendship. When Amis is smitten with leprosy, Amiles kills his children so that his friend can be healed by bathing in their blood. The children are miraculously restored to life after the cure of Amis. The poem, written in assonanced decasyllabic verse, is stylistically one of the finest Carolingian epics. There were probably two earlier Old French epics on this subject; if they existed, both are lost. There are later versions in most European literatures.

See J. Bédier, *Les Légendes Épiques*, 4 vol., 2nd ed. (1914–21); J. A. Asher, *Amis et Amiles* (1952). (J. A. AR.)

AMISH, OLD ORDER, a conservative body of Mennonites characterized particularly by their distinctive dress and by their nonconformed way of life. Numbering about 17,500, they are found chiefly in Lancaster county, Pa.; Holmes county, O.; and Lorange and Elkhart counties! Ind. See MENNONITES.

AMITABHA (Jap. AMIDA, "immeasurable light," or AMITAYUS, "immeasurable life"), the hero of the Sukhavativyuha Sutra (the fundamental scripture of the Pure Land, or Pure Realm, Buddhist faith), also host of the Pure Land. Besides the historical Buddha, Mahayana Buddhists conceived many Buddhas as their ideals, the most attractive figure among these being Amitabha. According to the sutra, long ago a monk named Dharmakara made a series of vows, the 18th of which reads: "If, after my obtaining Buddhahood, all beings in the ten quarters, who desire in sincerity to be born into my Buddha country, cannot be born thereto by only adoring me ten times, may I not take the enlightenment." His vows have been accomplished, he has become a Buddha and now lives in the Pure Land. This very Buddha is Amitabha. He acquired many followers in India and the far east, especially Japan, where the majority of Buddhists believe that by adoring Amida they will be born into the Pure Land. See also BUDDHISM; MAHAYANA.

AMMAN, JOST (1539–1591), Swiss painter and print maker, was one of the most prolific book illustrators of the 16th century. Born at Ziirich on June 13, 1539, and educated there, he worked for a short time in Basel, where he designed glass paintings for prominent families. About 1560–61 he moved to Nurnberg, but retained his citizenship of Zurich until 1577. No paintings by Amman are known, but in his numerous drawings, such as the "Entry of Maximilian II Into Niirnberg in 1570," he reveals himself as a brilliant and witty recorder of contemporary events. His etchings include historical portraits, such as those of the kings of France, heraldic designs, title pages, scenes of warfare, hunting and pageantry. Most of his energy was consumed in the production of thousands of woodcut illustrations for the publisher Feirabend of Frankfurt. Most popular were those for the Bible, *Reynard the Fox*, *The Art of Riding* and the *Book of Animals*.

See Adam Bartsch, *Le Peintre graveur*, vol. ix, pp. 351–383 (1866). (H. JM.)

AMMAN, the capital and administrative centre of the Hashemite Kingdom of Jordan, lies about 47 mi. E. of the Jordan river at an altitude of 2,400 ft. Amman district includes the subdistrict of Zerka (Az Zarqa'), and has an area of about 927 sq.mi. Pop. (1959 est.) city 133,201, district 291,971.

The city is built on a series of hills and in their valleys, in one of which is the source of the Wadi Zerka (Jabbok). It almost trebled in size in the 15 years after 1945. Extending westward in the direction of Wadi Syr and eastward to the airport, it contains the royal palaces and many fine government and administrative buildings, law courts, hospitals, parliament building, etc. On the ancient citadel is the archaeological museum, displaying artifacts of all periods of the country's ancient history. A few miles to the southeast are quarries of coloured marble, which is used extensively for floors, dadoes, tables and other decorative purposes. Most buildings are constructed of local white limestone, a beautiful building material.

Amman is connected by railway with Damascus and Beirut in the north and Ma'an in the south; there is a modern airport with connections with all other middle eastern countries. It is the commercial heart of the country and provides a shopping centre; there is also a small market which caters to the needs of the desert dwellers and peasants. The chief exports include phosphates, building stone, vegetables, fruits and other vegetable products; imports include vehicles of all kinds, liquid fuels, sugar, flour, fabrics, etc.

Amman is the site of the biblical Rabbath Ammon, though apart from some tombs excavated in the vicinity there are practically no remains of the ancient town. It was at the gate of Rabbath Ammon that Uriah the Hittite was placed in the forefront of the battle by order of David to meet his death. In Hellenistic times Ptolemy Philadelphus (283–246 B.C.) captured and rebuilt the city, renaming it Philadelphia, by which name it was known in Roman and Byzantine times. It was one of the cities of the Decapolis (*q.v.*). After the collapse of Byzantium in the 7th century A.D. the old name returned to use again. It became the capital of Transjordan when the amir Abdullah (later King Abdullah) established his government there soon after World War I.

There are many remains of the Roman city, in particular a fine theatre seating about 6,000, a much ruined nymphaeum on the river bank, and remains of a temple (probably of Hercules) on the citadel. Also on the citadel is a small square building attributed to either the Ghassanids or the Omayyads (6th or 8th century A.D.). (G. W. L. H.)

AMMANATI, BARTOLOMEO (1511–1592), Florentine sculptor and architect, one of the most competent artists of the generation after Michelangelo, was born in Settignano on June 18, 1511. He executed works in Venice, Padua and Lucca as well as papal commissions in Rome and many designs for the archdukes of Tuscany in Florence.

Ammanati is distinguished for the precision, control and elegance of such structures as the bridge over the Arno known as the Ponte della Trinita (destroyed 1944, rebuilt 1957) and the Palazzo Giugni, both in Florence, and for the sober dignity of such portraits as those of the Del Monte tomb, S. Pietro in Montorio, Rome. His talents and limitations are clearly revealed in the Neptune fountain, Piazza della Signoria, Florence. The colossal central figure of Neptune seems a constrained and flaccid imitation of Michelangelo's heroic figures but the accompanying bronze figures of nymphs, satyrs and sea creatures are superbly wrought; a lively, inventive sequence executed with the ease and skill justly esteemed by Ammanati's aristocratic patrons. He died in Florence on April 22, 1592. (E. D. B.)

AMMETER: see INSTRUMENTS, ELECTRICAL MEASURING: Indicating Instruments.

AMMIANUS MARCELLINUS (c. 330–after 391), the author of a history of the later Roman empire from 353 to 378, was born into a Greek noble family at Antioch. Entering the army at an early age he served under Ursicinus, the magister equitum of Constantius II, first in the east against the Persians (353), then in Gaul against the Franks, and again in the east, where he barely escaped from the capture of Amida (now

Diarbekr) by the Persian king Shapur II in 359. Ammianus may have shared in Ursicinus' loss of favour with Constantius, but under Julian, Constantius' successor, he fought against the Persians, and on Julian's death (363) he took part in the retreat of his successor Jovian as far as Antioch, where he was living in 371. He visited Egypt and Greece. Eventually he settled in Rome, where at an advanced age he wrote (in Latin) a history of the Roman empire from the accession of Nerva to the death of Valens (96–378), thus continuing the work of Tacitus.

This history, *Rerum gestarum libri*, was originally in 31 books, of which the last 18 only have survived, covering the period from 353 to 378. It is a clear, comprehensive and honest account of events by a contemporary of soldierly qualities, independent judgment and wide reading. Roman history no longer turned on the city of Rome but was played out in the various theatres of imperial policy from west to east, and Ammianus made full use of his own experience. He gives excellent pictures of the social and economic problems of the empire, which go far to explain subsequent developments.

A pagan and religiously tolerant, he took an impartial view of the intellectual trends of his day. His judgment in political matters was limited only by his own straightforward attitude. In his literary composition he used the regular techniques of later Roman historiography: rhetoric in his speeches, ethnographical digressions, biographical conventions in character sketches, along with a fondness for literary allusion. Above all, he wrote with dramatic power in conscious imitation of Tacitus. His style is unequal and often overloaded with metaphor and ornament, but the effect is vivid and striking.

BIBLIOGRAPHY.—*Rerum gestarum libri*, ed. by C. U. Clark, 2 vol. (1910–15) and by J. C. Rolfe in the "Loeb Series" with Eng. trans., 3 vol. (1935–39). Eng. trans. by Philemon Holland (1609). Thompson, *The Historical Work of Ammianus Marcellinus* (1947). (A. H. McD.)

AMMINES, in chemistry, compounds resulting from the addition of ammonia, NH₃, to metallic salts or other chemical compounds. The term is applied in a broader sense to compounds containing organic amines in place of part or all of the ammonia. It should not be confused with amines (*q.v.*). See CO-ORDINATION COMPOUNDS.

AMMONIA is a colourless alkaline gas, lighter than air, with a characteristic pungent odour. Ammonia and its salts have a wide range of applications in commercial products and processes, including use as fertilizer; in the manufacture of explosives; in refrigerating and air-conditioning equipment; in the manufacture of synthetic fibres and dyes; in the synthesizing of sulfa drugs; and (in conjunction with chlorine) in the purifying of water supplies.

The chemical formula of ammonia is NH₃.

In 1902 Wilhelm Ostwald, seeking to make Germany independent of Chilean nitrates, patented his process for producing nitric acid from ammonia. Much of the world's supply of nitrates is now derived from ammonia.

The ammonia clock, the first atomic timekeeping device, was developed in 1948 at the U.S. bureau of standards. Its design is based on the oscillation of the nitrogen atom in the ammonia molecule. It was the most accurate of all clocks until the development of another atomic timekeeper, the cesium clock.

Sal ammoniac (ammonium chloride) was an article of commerce in antiquity, and is mentioned by Pliny. It was first derived from organic material containing nitrogen by heating either camel's dung or a mixture of salt and urine. During the middle ages ammonia was obtained in aqueous solution by distilling the horns and hoofs of oxen; thus, its alchemical designation as "spirits of harts-horn."

Joseph Priestley (1774) prepared ammonia gas, which he called "alkaline air," by heating sal ammoniac with lime. Karl Wilhelm Scheele (1777) showed that ammonia contained nitrogen, but it remained for C. L. Berthollet (1785) to ascertain its exact composition.

Occurrence and Preparation.—Ammonia is found in small

traces in the atmosphere and in rain water, usually as the carbonate. It is formed when nitrogenous animal and vegetable matter undergoes putrefaction. It is found in humus-rich soils, in sea water and in plant and animal liquids (such as urine). It also occurs in variable but limited quantities in the vapours of lavas and in other volcanic effusions, in crater gases and is occasionally concentrated in the form of ammonium salts in the mineral incrustations adjoining fumaroles.

Ammonia is present to the extent of about 0.1% in the vapours of the *soffioni* (natural steam vents) at Larderello (province of Tuscany), Italy, and is actually recovered on a commercial scale from this source.

The more important laboratory methods for the preparation of ammonia include: (1) the action of alkaline hydroxides upon ammonium salts (usually the chloride or the sulfate), $\text{NH}_4\text{Cl} + \text{NaOH} = \text{NaCl} + \text{NH}_3 + \text{H}_2\text{O}$; and (2) the hydrolysis (decomposition by water) of nitrides such as magnesium nitride, $\text{Mg}_3\text{N}_2 + 6\text{H}_2\text{O} = 3\text{Mg}(\text{OH})_2 + 2\text{NH}_3$. Large tonnages of ammonia and of ammonium sulfate are obtained as by-products in the manufacture of coke and gas from coal.

For many purposes, however, synthetic ammonia is preferred. The latter is made directly from the elements by the Haber process, or a modification thereof, involving use of high pressures ranging from 200 to 1,000 atm., temperatures between 400° and 500° C. and a variety of catalysts (see NITROGEN, FIXATION OF). The synthetic ammonia process is one of the most important industrial chemical processes now in operation and accounts for more than 85% of the total of ammonia production. An older process based upon the hydrolysis of calcium cyanamide is now used only to a limited extent.

Properties.—The density of air being taken as 1, the relative density of ammonia is 0.589. It is easily liquefied either by cooling to the normal boiling point, -33.42°C . or by compression. The most important physical properties of ammonia are given in Table I.

TABLE I.—Physical Properties of Ammonia

Melting point	195.36° K. (-77.74°C .)
Boiling point	239.68° K. (-33.42°C .)
Density of liquid	0.735 g./ml.
at triple point	0.682 "
at boiling point	0.234 "
at critical temperature	0.81 "
Density of solid at triple point	45.58 mm.
Vapour pressure at triple point	538.3 "
at -40°C	3,221.0 "
at 0°C	8,749.0 "
at 30°C	172.3 atm.
at critical temperature	406.0° K. (132.9°C .)
Critical temperature	1.07 cal./g.
Specific heat at boiling point	1.05 "
at freezing point	1,352 cal./mol.
Heat of fusion	5,581 cal./mol.
Heat of vaporization (at boiling point)	0.34 "
Ebullioscopic constant (observed)	9.97 "
Cryoscopic " (observed)	26.7 "
Dielectric constant at -60°C	18.94 "
at -5°C	16.26 "
at 25°C	1.325 "
Refractive index, $\lambda = 0.589\mu$ at 16°C	

The ammonia molecule has been shown to possess a pyramidal structure with the nitrogen atom resonating between two equally stable positions at a distance of 0.360 Å (Å, angstrom unit = 10^{-8} cm.) above and below the plane occupied by the three hydrogen atoms. Its electronic structure is represented by three normal covalent bonds between the three hydrogen atoms and the nitrogen atom, leaving the latter with an unshared pair of electrons. This structure accounts for many of the properties of ammonia (and of its derivatives), such as its tendency to act as a proton (hydrogen ion) acceptor to form the ammonium ion,

and its ability to form co-ordination compounds, such as the metal amines, also designated as ammoniates; *i.e.*, compounds containing ammonia of crystallization. The latter vary widely in stability, some, such as $\text{AgCl} \cdot 3\text{NH}_3$, losing ammonia readily on

heating, while others such as the cobalt and chromium amines—*e.g.*, $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$ and $[\text{Cr}(\text{NH}_3)_6](\text{NO}_3)_3$ —being stable (see CO-ORDINATION COMPOUNDS). It is of interest to note that Michael Faraday liquefied ammonia for the first time (1823) by heating the compound $\text{AgCl} \cdot 3\text{NH}_3$ in a sealed, two legged-tube, one leg of which was cooled in an ice-salt mixture to effect more ready condensation of ammonia vapour.

Ammonia undergoes thermal dissociation in the presence of certain catalysts to give nitrogen and hydrogen. Ammonia is therefore used as a convenient means for transporting hydrogen in the combined form since the gaseous mixture obtained by its decomposition contains 75% by volume of hydrogen and 25% by volume of nitrogen. Decomposition into the elements can also be effected by photochemical means and by passing a silent electrical discharge through the gas. Traces of hydrazine are obtained when such decomposition is brought about at low pressures, or when a highly heated tungsten filament is immersed in liquid ammonia.

Oxidation.—Ammonia does not support combustion, but it will burn when mixed with oxygen to give a variety of products, principally nitrogen and water with some oxides of nitrogen. Ammonia has been prominently mentioned as a constituent of various types of fuels, both for internal-combustion engines and for jet propulsion. A liquid mixture consisting of a solution of ammonium nitrate in liquid ammonia is stated to be a self-sustaining fuel combination requiring no addition of an oxidant, such as air.

The controlled oxidation of ammonia by air using platinum gauze as the catalyst is a technical process of great importance since it results in the formation of nitric oxide, this being the first step in the manufacture of synthetic nitric acid by the Ostwald process (see NITRIC ACID AND NITRATES). Mixtures of nitrous oxide and ammonia, especially in the volume ratio of 3:2, can be made to detonate with violence, yielding nitrogen and water as the reaction products: $3\text{N}_2\text{O} + 2\text{NH}_3 = 4\text{N}_2 + 3\text{H}_2\text{O}$. Ammonia reacts at higher temperatures with some metallic oxides, such as cupric oxide, to effect their reduction to the metals; in other cases, nitrides are formed. The hydrogen atoms of ammonia may be partially or completely replaced by metals to give either amides or nitrides. When ammonia is bubbled through molten sodium or potassium there are formed sodium amide, NaNH_2 , and potassium amide, KNH_2 , respectively; magnesium, on the other hand, is transformed into the nitride, Mg_3N_2 .

Chemical oxidation of ammonia in aqueous solution usually causes formation of nitrogen gas. Chlorine reacts with ammonia (in excess) to give ammonium chloride and either nitrogen or chloramine, NH_2Cl . If chlorine is used in excess, the highly explosive nitrogen trichloride, NCl_3 , is also produced. Iodine yields a violently explosive substance commonly referred to as nitrogen triiodide. This black crystalline product was shown by D. Chattaway and by O. Silberrad to have the composition $\text{NI}_3 \cdot \text{NH}_3$. The commercial procedure for the manufacture of hydrazine is based upon the oxidation of aqueous ammonia by sodium hypochlorite solution, a process which appears to be successful only if a large excess of ammonia is employed together with certain catalytic materials which inhibit the decomposition of hydrazine: $2\text{NH}_3 + \text{NaClO} = \text{N}_2\text{H}_4 + \text{NaCl} + \text{H}_2\text{O}$. (See HYDRAZINE.)

Ionization.—The phase diagram of the system, ammonia-water, reveals the existence of two solid hydrates, $\text{NH}_3 \cdot \text{H}_2\text{O}$ and $2\text{NH}_3 \cdot \text{H}_2\text{O}$, both melting at approximately -79°C . It is doubtful if either one of these is capable of existing at room temperature, even though the solubility of ammonia in water is high. At 20°C . and normal pressures about 700 vol. of ammonia gas dissolve per volume of water. Ammonia gas may be expelled completely from the aqueous solution by boiling.

Since ammonia is a proton acceptor (combines with the hydrogen ion), that is, acts as a base, it undergoes reaction with water in accordance with the following equation: $\text{NH}_3 + \text{H}_2\text{O} \rightleftharpoons \text{NH}_4^+ + \text{OH}^-$. It is highly improbable that any appreciable concentration of molecular ammonium hydroxide, NH_4OH , exists in aqueous solution, even though water solutions of ammonia are generally referred to as "ammonium hydroxide." Ammonia is a weak base and therefore reacts with the solvent water only to a limited ex-

tent to produce ammonium and hydroxide ions. A decinormal solution of ammonia (0.17% NH_3) in water reacts only to the extent of about 1% to form NH_4^+ and OH^- ions, the dissociation constant, K_b , for aqueous ammonia as a base being $K = 1.65 \times 10^{-5}$ at 25°C .

The ammonium ion, NH_4^+ , is a univalent radical resembling the alkali metal ions. Ammonium salts, for instance, are crystallographically similar to the corresponding potassium and rubidium salts. The ammonium radical may take the place of the alkali metals in such double salts as those represented by the type formula $\text{CuSO}_4 \cdot \text{M}_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ and in the alums $\text{MAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$, where M represents NH_4 or some alkali metal. Many attempts have been made to prepare the free ammonium radical, but the evidence for its existence is at best circumstantial. H. H. Schlubach and F. Ballouf allowed potassium and ammonium chloride to interact in liquid ammonia at -70°C . and obtained only one-third of the theoretical quantity of hydrogen. They therefore assumed the existence of free ammonium in such a solution; at -40°C . the remainder of the hydrogen was evolved. The addition of sodium amalgam to a cold concentrated aqueous solution of ammonium chloride gives a spongy mass which resembles the amalgams of the alkali metals in some respects but not in others; this product decomposes readily into ammonia and hydrogen.

Ammonium Salts.—Preparation of ammonium salts is by direct combination of gaseous or aqueous ammonia with the desired acids; thus, combination of ammonia with hydrochloric acid yields ammonium chloride (sal ammoniac), with nitric acid, ammonium nitrate. Ammonium salts of practically all acids, both inorganic and organic, have been isolated and characterized. The ammonium salts of strong acids dissolve in water to give an acid reaction, hydrolysis being caused by the fact that the following equilibrium is established: $\text{NH}_4^+ + \text{H}_2\text{O} \rightleftharpoons \text{NH}_3 + \text{H}_3\text{O}^+$. Rise in temperature shifts this equilibrium to the right as is evidenced by the fact that some ammonia is lost when solutions of ammonium salts are heated to boiling. Some ammonium salts, such as ammonium chloride, do not melt on heating but dissociate into their components in accordance with the equation: $\text{NH}_4\text{X} = \text{NH}_3 + \text{HX}$; others, such as ammonium nitrate and ammonium sulfamate, have definite melting points and are stable at the melting point.

Ammonium salts have been shown by L. F. Audrieth and co-workers to behave as acids at higher temperatures. Ammonium chloride has long been used as a fluxing agent for removal of oxide films from metal surfaces prior to soldering; ammonium sulfate has been employed in the "opening up" of ores; fused ammonium nitrate reacts directly with many metallic oxides to give the corresponding nitrates. Characterization of ammonium salts as acids, per se, is accounted for by the fact that the ammonium ion is capable of releasing the proton; i. e., can in accordance with the modern concept of acidity behave as an acid. Ammonium salts behave as acids when dissolved in liquid ammonia.

Ammonium salts have found wide application technically, but only the most important ones will be mentioned here.

Ammonium chloride, NH_4Cl , also long known under the trade name sal ammoniac, is made commercially by the neutralization of hydrochloric acid with aqueous or gaseous ammonia. It is purified by sublimation. It is extensively used as a constituent of galvanizing, tinning and soldering fluxes, since it reacts readily at higher temperatures with metal corrosion products, thus serving as a metal cleaner. In galvanizing operations a double salt with zinc chloride, either $\text{ZnCl}_2 \cdot 2\text{NH}_4\text{Cl}$ or $\text{ZnCl}_2 \cdot 3\text{NH}_4\text{Cl}$, is usually employed to serve first as a liquid protective layer over molten zinc; second, as a metal cleaner for the material to be coated with zinc; and third, to dry and preheat the work (sheet or article) which is to be coated with zinc. As a soldering flux it is employed either by itself or in aqueous solution or in admixture with rosin, paraffin waxes or oils, organic surface active agents and/or other acids. Ammonium chloride also finds use (1) as a pharmaceutical, being a common constituent of many proprietary cold and cough medicines; (2) in dry cells; (3) in the manufacture of a number of dyes and as a weakly acid constituent of dyeing baths; and (4) in the manufacture of iron cements and other ammonium salts.

Ammonium nitrate, NH_4NO_3 , is the most important nitrogenous fertilizer. The commercially available "fertilizer grade" (FGAN) contains 33% available nitrogen. Due to its hygroscopicity (tendency to pick up moisture) it is manufactured in the form of pellets or balls ("prills") covered by a small amount of claylike conditioning material. When properly bagged and stored, it reaches the farmer in a form satisfactory for application to the soil with customary farm machinery. Mixed ammonium nitrate fertilizers are also produced commercially containing calcium phosphate, limestone, dolomite, ammonium sulfate or soluble potassium and phosphate ingredients. Ammonium nitrate is capable of explosive decomposition, especially in the confined state, and acts as a powerful oxidizing agent since it will support combustion in a fire with combustible material even in the absence of air. Because of these potential hazards special shipment and storage precautions have been imposed by government regulation to prevent disastrous explosions, such as those that occurred at Oppau, Ger. (1921), and Texas City, Tex. (1947), with attendant loss of life and destruction of property. Ammonium nitrate also finds widespread technical application as a constituent of various military high-explosive and propellant compositions, in dynamites and blasting explosives and as a source of nitrous oxide, since it decomposes on heating in accordance with the equation $\text{NH}_4\text{NO}_3 = \text{N}_2\text{O} + 2\text{H}_2\text{O}$.

Other Ammonium Salts.—Ammonium sulfate, $(\text{NH}_4)_2\text{SO}_4$, is produced in large amounts as a by-product in the manufacture of coke and gas from coal. It is one of the more important nitrogenous fertilizers, but also finds use in fireproofing fabrics and to a limited extent as a medicinal. Ammonium thiocyanate, NH_4SCN , can be obtained from carbon disulfide and ammonia. It isomerizes to thiourea on heating; if fused in the presence of desulfurizing agents such as lead oxide, PbO , it can be converted into a guanidine compound:

Both thiourea and guanidine are valuable industrial raw materials in the manufacture of rubber accelerators, plastics and medicinals.

Three ammonium phosphates, known respectively as the mono-, di- and triammonium phosphates, or as the monobasic, dibasic and tribasic salts, are obtainable by interaction of phosphoric acid with the requisite quantities of ammonia. The solid triammonium phosphate, $(\text{NH}_4)_3\text{PO}_4$, loses ammonia quite readily to go over into the diammonium salt, $(\text{NH}_4)_2\text{HPO}_4$. The monoammonium phosphate, $\text{NH}_4\text{H}_2\text{PO}_4$, is an important ingredient of baking powders. Both the monobasic and dibasic salts are used extensively in flameproofing of paper, wood and textiles, in the formulation of nutrient solutions and in the production of special fertilizer mixtures as, for instance, for use in the practice of hydroponics (soilless agriculture).

Ammonia and carbon dioxide react to give ammonium carbamate, $\text{NH}_2\text{COOH} \cdot \text{NH}_3$, which is formed as an intermediate product in the high-pressure synthesis of urea, $\text{CO}(\text{NH}_2)_2$. Ammonium carbamate hydrolyzes in water solution to form ammonium hydrogen carbonate, NH_4HCO_3 . Commercial ammonium carbonate, $(\text{NH}_4)_2\text{CO}_3$, is usually a mixture of the normal carbonate and the hydrogen carbonate. Ammonium perchlorate, NH_4ClO_4 , is of interest chiefly because it can be made to react with concentrated nitric acid to give nitrous oxide and perchloric acid. It is one of the less soluble ammonium salts. The ammonium salts of high molecular weight fatty acids, such as ammonium stearate, $\text{RCOOH} \cdot \text{NH}_3$, find use as detergents, emulsifying agents, textile assistants and as surface active agents of the anionic type.

The Ammonia System of Compounds.—Particular reference is made to the fact that ammonia resembles water in many of its physical properties. This similarity is even more striking when consideration is given to the fact that ammonia occupies an anomalous position with respect to the other hydrogen compounds of the fifth group of the periodic system just as water is different from the remaining hydrides of the sixth group. Its boiling point, dielectric constant and heat of vaporization are abnormally high, as compared with phosphine, arsine and bismuth hydride, indicat-

ing that liquid ammonia consists of molecular aggregates, rather than of simple NH₃ molecules. Like water, liquid ammonia is not only an excellent solvent for many inorganic and organic compounds, but has been found to serve as a useful medium for carrying out a wide variety of chemical reactions.

Related to its interesting properties as a solvent is the fact that ammonia may be looked upon as the parent substance of the "ammonia" or "nitrogen" system of compounds. Nitrogen compounds, both inorganic and organic, can be regarded as derivatives of ammonia much as the oxygen compounds may be considered as derivatives of water. The prefix "ammono" has been applied to these nitrogen compounds to distinguish them from the analogous "aquo" compounds derived from water as the parent substance. This concept has not only been helpful in classifying nitrogen compounds but has received experimental confirmation by the study of behaviour of nitrogen compounds in liquid ammonia and other non-aqueous solvents. Typical ammono compounds are listed in Table II together with the analogous aquo compounds. The relationship of these to the corresponding oxygen compounds is evident from a consideration of related groups derived from each parent solvent.

From water: HOH OH- O²⁻
From ammonia: HNH₂ NH₂⁻ NH₂²⁻ and N³⁻

Compounds containing the -NH₂ group have been shown to behave in ammonia as solvent in the same way that substances containing the OH group react in water.

The true character of many nitrogen compounds becomes self-evident from this point of view. Such mercury compounds as HgNH₂Cl and HgCl₂·2NH₃, known as the "infusible" and "fusible white precipitates," represent an ammono basic compound and a compound containing co-ordinated ammonia, respectively (see MERCURY). Sulfamic acid, H₂NSO₃H, and sulfamide, SO₂(NH₂)₂, are both analogues of sulfuric acid as becomes obvious from the following structural relationship:

Sulfamic acid is now a commercially available chemical and has found widespread use as a nonhygroscopic, crystalline compound which in solution behaves as a strong acid. Ammonium sulfamate, NH₄SO₃NH₂, is an effective flame retardant and an outstanding herbicide. Sulfamide resembles urea and like the latter is used technically for the production of thermosetting polymers. Potassium nitridotrisulfate, N(SO₃K)₃·2H₂O, and the imidodisulfate, HN(SO₃K)₂, are salts of acids derived from sulfamic acid. They undergo hydrolysis in boiling water to give the sulfamate, KSO₃NH₂. Reaction of sulfur trioxide with ammonia gives mixtures of the ammonium salts of imidodisulfuric and nitridotrisulfuric acids.

TABLE II.—Ammono Compounds

Formula	Name	Character	Aquo analogue
KNH ₂	potassium amide	ammono base	KOH
Hg ₂ N ₂	mercuric nitride	anammonide	HgO
K ₂ Zn(NH) ₂	potassiumammonozincate	amphoterie amide	K ₂ ZnO ₂
SO ₂ (NH ₂) ₂	sulfamide	ammono sulfuric acid	SO ₂ (OH) ₂
C(NH)(NH ₂) ₂	guanidine	ammono carbonic acid	CO(OH) ₂
CO(NH ₂) ₂	urea	ammono carbonic acid	CO(OH) ₂
H ₂ NCN	cyanamide	ammono carbonic acid	CO(OH) ₂
CH ₃ NH ₂	methylamine	ammono alcohol	CH ₃ OH
(CH ₃) ₂ N	trimethylamine	ammono ether	(CH ₃) ₂ O
CH ₃ CONH ₂	acetamide	ammono acetic acid	CH ₃ COOH
CH ₃ CONHNa	sodium acetamide	salt of ammono acetic acid	CH ₃ COONa
CH ₃ CONHCH ₃	N-methylacetamide	ammono ester	CH ₃ COOCH ₃
CaCl ₂ ·8NH ₃	calcium chloride-8-ammonia	compound containing ammonia of crystallization	CaCl ₂ ·6H ₂ O

Reactions With Halogen Compounds.—Ammonia is capable of converting active halogen compounds, such as the nonmetallic halides, thiohalides and oxyhalides, into the corresponding nitro-

gen compounds. These reactions of "ammonolysis" are similar to those effected by water (reactions of hydrolysis) as the following parallel equations demonstrate:

The nitrogen content of products obtained by these reactions depends upon conditions, particularly the temperature. While phosphorus (III) triamide, P(NH₂)₃, is obtained and appears to be stable at -33° C., the product loses ammonia at room temperature to yield diphosphorus (III) triimide, P₂(NH)₃, and undergoes complete deammonation (analogous to dehydration) at 550° C. to give phosphorus (III) nitride

Table III gives a list of compounds obtained when specific non-metallic halides react with ammonia.

TABLE III.—Reaction Products of Nonmetallic Halides With Ammonia

Compound treated with ammonia	Substance formed and conditions
BCl ₃	B(NH ₂) ₃ (-23°, 0° C.)
BBr ₃	B ₂ (NH) ₃ (-10°, +20° C.)
SiCl ₄	Si(NH ₂) ₄ (-50° to 0° C.)
	Si(NH) ₂ (20° C.)
	[Si(NH)NH ₂] ₂ (low temperatures)
SiSCl ₂	
Si ₂ Cl ₆	
GeCl ₄	Ge(NH ₂) ₂ (-80° C.)
SnCl ₄	2Sn(NH ₂) ₂ ·Cl·NH ₄ Cl (0° C.)
TiBr ₄	TiNBr _x ·xNH ₃
PCl ₅	PN(NH ₂) ₂ (-70° C.)

Attention is directed to the fact that only partial replacement of halogen is effected in the case of the halides of tin, titanium and vanadium under the given reaction conditions. The reaction between phosphorus pentachloride and ammonia can also be made to stop at an intermediate stage, especially when ammonium chloride is used to effect ammonolysis. Here again parallel equations may be given to show the similarity between reactions of ammonia and water

Partial replacement of halogen in phosphorus pentachloride results in the formation of the phosphonitric chlorides, (PNCl₂)_x, where x=3, 4, 5, 6, 8 and n. The lower members of this series undergo polymerization on heating to the "inorganic rubber" (PNCl₂)_n, a substance which resembles the better known natural and synthetic elastomers in its physical properties.

Hydrolysis of the phosphonitric chlorides yields the corresponding phosphonitric acids, also known as the metaphosphimic acids; as represented by the type equation:

These ammono-phosphoric acids are related to amido- and diamido-phosphoric acids, (HO)₂PONH₂ and HOPO(NH₂)₂, which were first isolated by H. N. Stokes. They constitute the simplest members of a large and interesting group of nitrogen derivatives of phosphoric acid.

Organic Derivatives of Ammonia.—Ammonia finds wide application in organic chemistry as a synthetic agent. It reacts with the alkylhalides to form the alkylamines, RNH₂ (primary), R₂NH (secondary), R₃N (tertiary); with ethylene dihalide to yield ethylenediamine, H₂NCH₂CH₂NH₂, diethylene triamine, H₂NCH₂CH₂NHCH₂CH₂NH₂, together with the higher members of this series; with ethylene oxide or ethylene chlorohydrin to give the mono-, di- and triethanolamines, H₂NC₂H₄OH, HN(C₂H₄OH)₂ and N(C₂H₄OH)₃. Under special conditions alcohols can be caused to react with ammonia in the presence of dehydrating catalysts such as activated alumina to yield the corresponding primary, secondary or tertiary amines, depending upon the ratios of the reactants and upon the temperature. The

amines are basic in character and form salts which in many respects resemble the corresponding ammonium salts. Tertiary amines, R_3N , combine with alkylhalides to form the quaternary or tetraalkylammonium salts: $R_3N + RX = R_4NX$. These compounds resemble the alkali metal salts even more strongly than do the ammonium salts.

The tetraalkylammonium hydroxides are almost completely ionized and behave as strong bases in aqueous solution. The relative stability of the quaternary ammonium radical is further illustrated by the fact that the corresponding amalgams are much more stable than that of ammonium. H. N. McCoy and W. C. Moore obtained a tetramethylammonium amalgam which did not decompose below $10^\circ C$. Electrolysis of tetramethylammonium iodide in liquid ammonia results in the formation of a blue coloration in the cathode region. Since the alkali and alkaline earth metals produce this coloration in ammonia, it seems highly probable that the tetramethylammonium radical is actually discharged and thus capable of existence for a limited time. When all four alkyl groups of a quaternary ammonium salt are different, the compound can be resolved into optical isomerides.

Esters and acid chlorides react with ammonia to form amides:

At high temperatures and in the presence of dehydrating catalysts it is possible to convert the fatty acids of high molecular weight, such as those derived from fats and oils, into the corresponding nitriles:

The nitriles can be converted by various indirect procedures into the amidines, involving essentially addition of ammonia:

Of great technical importance is the high-pressure synthesis of urea from carbon dioxide and ammonia. Urea is, in fact, a carbonic acid derivative of ammonia and is related to such compounds as guanidine, cyanamide, cyanic acid and carbamic acid as indicated in the accompanying schematic diagram.

Some ammonia derivatives of carbonic acid. The compounds cyanic acid and cyanamide are desolvation products, whereas cyanuric acid and melamine are polymerization products of simpler units.

Hydronitrogens.—Ammonia is the simplest hydronitrogen, the latter being defined as one of a series of compounds containing only hydrogen and nitrogen. The hydronitrogens, like the hydrocarbons, may be divided into several homologous series, but unlike their carbon analogues only a few (ammonia, hydrazine and diazoic acid) have actually been isolated in the free state. Most of them are known only in the form of their organic derivatives, but these constitute a large and variegated group of compounds. (See also AMIDES; ANILINE; CYANAMIDE, CALCIUM; DIAZO COMPOUNDS; GUANIDINE; HYDRAZINE; UREA; URETHAN.)

Detection and Estimation.—Solutions of ammonia and ammonium salts, even if dilute, give a distinct yellow or yellowish-

brown coloration with Nessler's solution, because of the formation of a complex iodide, $\text{NH}_2\text{I}\cdot\text{H}_2\text{O}$, which is obtained as a precipitate from stronger solutions; this is also the basis of a colorimetric method for estimating minute traces of ammonia in drinking water. Larger quantities of ammonia or its salts can be detected by evolution of the characteristic smell of free ammonia on heating with caustic alkalis or lime. Quantitative estimation may be effected by (1) distillation of salts or ammoniacal liquors with sodium or potassium hydroxide and absorption of the liberated ammonia in an excess of standard sulfuric acid, the excess being titrated by alkali; (2) by absorption of ammonia in hydrochloric acid and precipitation as the chloroplatinate, $(\text{NH}_4)_2\text{PtCl}_6$; or (3) by the addition of neutral formaldehyde to a neutral solution of an ammonium salt, whereby hexamethylenetetramine is formed and the acid originally in combination with the ammonia is set free and may be titrated: $4\text{NH}_4\text{Cl} + 6\text{CH}_2\text{O} = (\text{CH}_2)_6\text{N}_4 + 4\text{HCl} + 6\text{H}_2\text{O}$.

AMMONIACUM or GUM AMMONIAC, a gum resin (*q.v.*) exuded from the stem of the perennial herb *Dorema ammoniacum* growing in Iran. Upon incision or injury, the plant oozes a milky juice which hardens to what is called in commerce tears or mass. This substance was formerly used medicinally as a stimulant, carminative and laxative. (R. H. DH.)

AMMONITE, any member of a group of extinct Mollusca belonging to the class Cephalopoda. They possessed an external shell that was coiled in a flat spiral and divided into chambers very similar to that of the modern nautilus. Many reached a

great size, the largest, *Pachydiscus seppenradensis*, from the Cretaceous of Westphalia, having a shell six feet eight inches in diameter.

The Ammonites appeared in the Carboniferous period (285,000,-000 to 235,000,000 years ago) and became extinct at the end of the Cretaceous (about 70,000,000 years ago).

AMMONITES, a Semitic people of ancient Transjordan. Their land was north of Moab, and their chief city, Rabbath Ammon (later Philadelphia, the modern Amman, capital of the Hashemite Kingdom of Jordan), stood on the banks of a tributary of the Jabbok. In the Old Testament they are almost always referred to as "the sons of Ammon."

The Ammonite kingdom was not established until the 13th century B.C.; before then Transjordan was inhabited by wandering nomads. The original Ammonite kingdom apparently lay in a small strip east of the Jabbok river where it flows from south to north, extending to the desert. At times they spread westward to the Jordan river. Their civilization flourished from the 13th to the 6th century B.C., being very similar to that of Moab and Edom (*qq.v.*), and oriented to Syria and Arabia as well as Israel.

The Ammonites were defeated by the judge Jephthah and by Saul, and were subdued by David. They had regained their independence by the time of Shalmaneser III, who records that they furnished soldiers for the battle of Karkar in 853 B.C. (See AHAB.) Several Assyrian kings from Tiglath-Pileser III through Ashurbanipal received tribute from kings of Bit-Ammanu, "the House of Ammon." Ammonites were allied with bands of Chaldeans, Syrians and others in an attack on Judah in the reign of Jehoiakim, but later, in the time of Zedekiah, were involved in plans for rebellion against Babylonia (Jer. xxvii). They may have taken some Judean territory at the time of the Babylonian capture of Jerusalem, as the Edomites did. Several Hebrew prophets denounced them at various times (Amos i, 13-15; Jer. xlix, 1-6; Ezek. xxv, 1-7; Zeph. ii, 8-11). The Judean governor, Gedaliah, was assassinated at the instigation of a king of Ammon. When Nehemiah attempted to restore the purity of the Judean community, a bitter opponent was Tobiah the Ammonite. The Ammonites were defeated by Judas Maccabaeus (IMacc. v, 6-8). They still formed a community in the days of Justin Martyr.

Little is known of the religion and culture of the Ammonites. One of their gods was Milcom. They combined pastoral life with the limited amount of agriculture that is possible in the region east of the Jordan. Archaeology has shown that they had several fortified towns in the period from the 13th to the 6th century B.C. (J. P. Hy.)

AMMONIUM is a positive univalent ion, NH_4^+ , whose salts resemble those of potassium and univalent thallium in solubility and crystalline form. The free ammonium radical has been prepared as an amalgam. See AMMONIA.

AMMONIUS HERMIAE (*i.e.*, Ammonius son of Hermias) (fl. 5th century A.D.), Greek philosopher, who was one of the most influential of commentators on Aristotle. He studied under Proclus at Athens and later was appointed head of the Alexandrian school.

He was a sober, unprejudiced expositor, free from mysticism and well informed in the science of his day. The commentaries which survive are concerned with logical subjects. In the Berlin Academy's *Commentaria in Aristotelem Graeca* are to be found his commentaries on Porphyry's *Isagoge*, on the *Categories* and on the *De Interpretatione* (ed. by A. Busse, 1891) and also his commentary on the *Prior Analytics I* (ed. by M. Wallies, 1899). These works were much studied down to the time of the Renaissance and were printed in Latin versions.

The literary activity of Ammonius was more extensive than this. Expositions both of the *Organon* and of the physical treatises of Aristotle seem, from coincidences evidently pointing to a common source, to contain much that is derived from him. From internal evidence it appears that he did not himself prepare his commentaries for publication. A life of Aristotle which is ascribed to him in some manuscripts is full of errors and is evidently not his work. (D. J. A.)

AMMONIUS SACCAS (*c.* A.D. 175-242), the teacher of Plotinus, was a self-taught Alexandrian philosopher who, according to Porphyry as reported by Eusebius, had been brought up a Christian and later became a pagan. His pupils, besides Plotinus, included the rhetorician and philosopher Longinus, the pagan philosopher Origen and perhaps also the Christian Origen. He left no writings, and his pupils were pledged to secrecy about his teaching; consequently next to nothing is known about his doctrines, the allusions to them in Nemesius and in Photius' extract from Hierocles giving no clear or reliable information. All that is certain is that he deeply influenced Plotinus, though there seems no way of establishing with certainty how much in the latter comes from Ammonius and how much is original. (A. H. AG.)

See the article "Plotinus" in Pauly-Wissowa, *Real-Encyclopadie der classischen Altertumswissenschaft* vol. xxi, pp. 477-481.

AMMUNITION, ARTILLERY, a term that includes projectiles, fuzes and propelling charges for guns, howitzers, mortars and recoilless rifles. Bombs, grenades, mines, rockets and guided missiles are also sometimes placed in this category, but are not included here as they are discussed in separate articles (see BOMB; GRENADES; ROCKETS).

There is no hard and fast line separating artillery ammunition from small-arms ammunition but, in general, cartridges with projectile elements one inch or more in diameter are classified as artillery and the smaller sizes as small arms. In practice, ammunition of calibre .60 ($\frac{6.0}{100}$ in. in diameter) has usually been considered the largest of the small-arms types.

With small-arms ammunition, all the components of a single round are normally assembled into a compact unit which includes a metal (usually brass) case containing the propellant (often called smokeless powder or gunpowder), a projectile or bullet affixed to one end of the case and a primer inserted in the other end. The smaller calibres of artillery ammunition are assembled in the same manner and are known as fixed ammunition. Semifixed ammunition differs from fixed ammunition in that its projectile may be detached from the case to permit increasing or decreasing the propelling charge and thus adjusting the range. In the third type, known as separated ammunition, the projectile is separated from the case, but the case is sealed so that no adjustment can be made in its propelling charge. A fourth type, known as separate-loading ammunition, is employed for pieces of medium or large bore and permits adjustment of the propelling charge. As the name suggests, with this type of ammunition each element—projectile, propellant and primer—is loaded into the weapon separately. First the projectile, usually very heavy, is rammed into the chamber, then the desired number of bags of propellant are put in place (without a cartridge case) and the primer is separately inserted into its seat in the breechblock. No matter what its form (fixed, semifixed, separated or separate-loading), the combination of one full set of the elements (propellant, projectile and primer) necessary for a single firing of a piece is known as a complete round of ammunition.

is referred to as the ogive. It usually contains a fuze of one type or another, though with armour-piercing (AP) rounds the fuze may be at the base of the shell. Wherever placed, its function is to set off at the proper moment the explosive charge carried within the steel walls of the projectile. The *bourrelet* is an accurately machined section of the shell body, at the point where the body begins to taper. Slightly greater in diameter than the body of the projectile, it rides smoothly on the lands of the rifling and centres the forward end of the projectile as the rotating band centres the back end. The rotating band (or driving band) is a ring of comparatively soft material, such as gilding metal, pressed firmly into a groove near the base of the projectile.

When the weapon is fired and the projectile moves down the tube, the rotating band engages the lands of the bore and causes the projectile to rotate. As the rotating band is cut into, or engraved, by the lands it fills the grooves of the rifling and prevents escape of propellant gases. The part of the projectile back of the rotating band may be tapered somewhat to improve its flight characteristics and is then described as boat tailed. If not tapered, the shell is said to be square based. HE shells have their bases securely protected by a steel disk, known as a base plate or base plug, designed to keep powder gases from finding their way into the cavity containing the explosive through possible defects in the base of the shell.

The metal container for the propelling charge of fixed, semifixed or separated ammunition is the cartridge case, formerly made of brass but now commonly made of steel. Within the cartridge case is a metal tube known as a primer or artillery primer that contains a small quantity of sensitive explosive needed to bring about complete ignition of the propellant. The primer runs through the centre of the propellant charge and when fired spreads flame evenly throughout the charge. A common type, the percussion primer, is fired when struck by the weapon's firing pin. The electric primer is fired by heat generated when an electric current passes through a resistance wire. Still another type is fired by friction.

Within the typical HE shell is a high-explosive filler such as T.N.T. (trinitrotoluene) or RDX (cyclonite), and a booster containing a small quantity of some high explosive such as tetryl that is more readily detonated than the main charge. The latter, for reasons of safety in manufacture and handling, is always composed of a material that is insensitive to any but the most violent activators. In addition to the booster there is a primer, sometimes called the fuze primer to distinguish it from the primer that initiates the propellant. It is extremely sensitive but not very powerful. Next to the primer is the detonator which, when acted upon by the primer, amplifies the weak primer flash and transmits it to the booster. The whole arrangement, from fuze primer to detonator to booster to explosive charge, is known as the explosive train, and its functioning may be compared to the act of lighting a coal fire. First comes the striking of the match, which compares to the striking of the primer, but as the match will not itself set fire to a lump of coal it is applied first to crumpled paper or other readily inflammable material in much the same way that the primer is applied to the detonator. The burning paper in turn causes the wood kindling to take fire, just as the detonator ignites the booster; and the steady burning of the wood eventually ignites the coal in, the same way that the booster sets off the explosive charge of the shell. The act of lighting a coal fire is slow, of course, while the explosive train of a shell acts with lightning speed and shattering effect. (H. C. T.)

II. HISTORY OF AMMUNITION

1. Early Ordnance Projectiles.—The introduction of instruments employing gunpowder to project missiles dates from early in the 14th century (see ARTILLERY). The necessary propellant (black powder) had been described a full half century earlier by the English friar Roger Bacon, but he apparently remained unaware of its manifold military applications. The first ordnance projectiles were obviously adaptations of those already used in contemporary weapons (crossbow and longbow), being nothing more nor less than iron darts "feathered" with brass, their shafts wrapped with stuffings of leather to lessen leakage of powder gases. These projectiles could hardly have been large or heavy, for ancient records quoted by Napoleon III in his famous work on artillery, *Études sur . . . l'artillerie*, disclose the fact that there existed at the royal arsenal at Rouen in 1338 a *pot-defer* (cannon) the weight of a dart for which he estimates at not over 6½ oz., the propelling charge therefore being about ¾ oz. of black powder. But some accounts speak of bolts weighing 200 lb.

2. Round Shot.—Though the dart was ballistically unsound, it and similar missiles continued occasionally to be discharged from firearms for centuries. As inventive minds cast about for something better they soon fastened on the sphere, a form of ammunition destined to rule supreme until the general introduction of rifled

weapons in the 19th century. Stone was selected as the material for spherical projectiles because it was readily available and had been used in engines of war (*q.v.*) for ages past. References to stone spheres are found in France in 1346, in Italy in 1364 and in England in 1378. But because stone shot tended to break when it struck a stone wall, other materials were adopted to assure penetration. Thus iron shot is mentioned as early as 1350, though it apparently did not come into general use until the reign of Charles VIII of France (1483-98). Iron shot was designed originally for use in hand and shoulder weapons but it was soon applied to artillery.

Two ancient texts of the period 1400-50 recommend that small-arms balls be heated red hot when fired against troops sheltered in wooden structures. Hot shot is said to have been used in cannon as early as the siege of Cherbourg in 1418. It is probable that it would have been employed earlier but for the lack of adequate insurance against the propelling charge being set off ahead of time by the heat of the projectile. That problem was partially solved for artillery pieces by interposing a thick wad of moist clay, wet straw or other insulating agent between powder and shot. Naval hot shot became obsolete in the 19th century when navies adopted armour plate and when improved incendiary shells appeared.

Bronze shot enjoys an antiquity equal to that of the stone projectile, for it is mentioned by Petrarch (1344 or earlier) as in use among the Italians of his day. The same is true of leaden missiles, for Napoleon III quotes from 14th-century records to show that these were in use in France in 1345. For a period, metal shot of all three types just mentioned (iron, bronze, lead) appears to have been used indiscriminately. Thus the Venetians employed some of each in their action against the French at the battle of Taro (1491). Strange as it may appear, the material which survived most successfully the many field tests to which cannon missiles of the time were being subjected was stone. Such a choice was based on two very good reasons, viz., stone balls, even though their method of fabrication was painfully slow (gradual chipping into spherical form, with hammer and chisel, from rough blocks), were still cheaper than those of metal, for human labour commanded pitifully small recompense, and stone missiles, being lighter than metal ones of equal size, were started up the bore of a piece with smaller charges of powder, hence with less strain upon the fragile cannon of the period. Under the circumstances, it is easy to see that the life of one of the contemporary cannon, rudely fashioned as it was, was very likely to be more prolonged when balls of stone were fired from it than when those of metal were employed.

The same held for the crews that served them. The bursting of guns was a not unusual occurrence, as evidenced by a contemporary manuscript which says that: "A cannoneer must always love and serve God, for every time he fires a gun or makes powder, he may be killed." Each master gunner was then his own powder mixer, the art of incorporating the ingredients of this compound in such a manner that they would not separate on handling not having been developed. In separating, the heaviest ingredient, sulphur, settled to the bottom, while the lightest, carbon (charcoal), rose to the top, the result being a marked reduction in the potency of the product which, at best, was feeble and uncertain in action. Hence it became the practice to convey the components to the battlefield in separate containers and stir them together on the spot. And the danger undergone by him who undertook this was far from remote, for the glowing matches of any musketeers who happened about offered ready means for igniting the deadly brew before it could be gotten from mixing bowl to gun chamber.

3. Canister.—Round (spherical) shot proved satisfactory for battering walls and buildings and, in the smaller sizes, as used in hand and shoulder weapons, against personnel. But a single cannon ball, no matter how large, was of limited effectiveness against troops, because only those directly in its path were endangered. Hence, as the use of ordnance became more general, attention was directed toward devising means whereby a considerable number of small projectiles rather than a single large one could be fired simultaneously into hostile ranks. This end had already been

attained in a measure by the introduction and rather wide use of ribaudequins, which consisted in effect of a large number of shoulder pieces, or sometimes just the barrels, mounted like so many organ pipes on a cart and discharged simultaneously or in sizable numbers at the enemy. But such contrivances were clumsy and slow in operation and, once all the barrels had been emptied, practically impossible to reload and fire again before the fate of the day had been decided. Hence the early development of canister or case shot for great guns, consisting of a cylindrical metal container of bore diameter, filled with small projectiles of whatever nature happened to be handy—not infrequently simple pebbles of stone. The container burst and released its deadly burden shortly after leaving the muzzle.

The use of such projectiles is reliably reported as early as 1410 and they figured prominently in the siege of Belgrade three decades later. The ribaudequin slowly disappeared from the scene, though the idea persisted through the ages and took new life during the U.S. Civil War in the Billingham and Requa "machine gun," which, in the last analysis, was nothing more than a row of musket barrels mounted on a wheeled carriage.

4. Explosive Shell.—The next development in artillery ammunition was, quite logically, the shell, originally—and for centuries thereafter—a simple, hollow sphere of cast iron, filled with explosive (black powder), with a hole drilled through its wall into the explosive cavity and, fitted into this hole, a fuze of some sort to ignite the powder. W. W. Greener in *The Gun and Its Development* ascribes this invention to the Netherlands. Other authors state that the Venetians (1376) antedated the Hollanders in the employment of shell in cannon, and assert that the invention would have come still earlier had means for preparing satisfactory fuzes been available. After its introduction, the shell soon came into wide use for land operations among all great nations and eventually became and has remained, with certain periodic fluctuations in the degree of favour enjoyed, the most important projectile available to the artilleryist.

On the sea, however, the firing of explosive or incendiary missiles was long held too dangerous (to the user) to be considered. But one captain, a Frenchman named Deschiens, appears to have defied convention and employed shells horizontally from his long guns. (Practice on land countenanced their use only for high-angle fire from mortars.) The efficacy of this tactic was attested in an engagement in 1690 wherein his vessel was beset by four British ships. Employing shells of his own contrivance he readily dispersed the British, and in a later exchange with two Dutch ships he sank one and disabled the other. But apparently he was far ahead of his time, for none undertook to follow the precedent he established. Toward the close of the 18th and the commencement of the 19th centuries, however, all nations began to realize that something must be done to make naval ordnance more effective. One incident which drove this fact keenly home was the battle of Trafalgar—in which not a single vessel was sunk by gunfire. Naval authorities began to look about for a remedy. They had not far to seek, for an excellent example lay before them.

In 1788 an Englishman, Sir Samuel Bentham, who had risen to high places in the naval service of the tsar of Russia, had fitted out a flotilla of longboats, mounting brass cannon and amply supplied with shell, carcasses (incendiary projectiles) and solid shot. Attacking with these minuscule vessels a very considerable Turkish squadron, he gained a notable victory. His shell not only tore gaping holes in the sides of the enemy ships but started conflagrations which resulted in the destruction of the entire Turkish fleet. As not infrequently happens, however, Bentham's countrymen studiously ignored the lesson thus delivered. So it fell to France to exploit the new agency, or rather the new adaptation of an old one. This it did assiduously over several decades, its efforts culminating in the development by Gen. Henri Paixhans (1822) of a comprehensive system of naval armament based upon a fleet of steam vessels especially designed to mount shell guns of high muzzle velocity and considerable range. Thenceforward the place of the shell in naval operations was assured.

The latter part of the 18th century also witnessed the adoption of the shell for horizontal fire in land operations, tests in England

toward that end having been conducted as early as 1760 but discontinued when a number of the projectiles exploded in the bore. But the idea would not down, and was revived during the siege of Gibraltar (1779-83) when the British fired mortar shell from long 24-pounders into the Spanish lines. At about the same time Lieut. (later Gen.) Henry Shrapnel was making the first official demonstrations of the spherical case shot of his invention, adopted by the British army in 1803. This differed from ordinary case in that it was fuzeed and filled with musket balls plus a small charge of black powder just sufficient to disrupt the container. When the fuze acted, the sphere was cleft open, and the balls continued forward in an ever-widening sheaf, laying low all enemy personnel in their path. As originally designed, no additional velocity was acquired by the musket balls when they left the shell beyond that possessed by the sphere at the instant of rupture. In later forms of shrapnel an elongated shell was used and an added velocity of about 350 ft. per second was imparted by the powder charge embodied in the missile.

5. Miscellaneous Types.—Other types of projectile once widely used (but now long obsolete) include the carcass, grape, bar shot, chain shot, etc. The first-named was an iron shell filled with inflammable materials which, ignited by the flash of the propelling charge, served to set afire wooden buildings or other vulnerable objects within enemy lines. Easier to manipulate than hot shot (which had to be heated to redness in a special furnace), it was handier to use and to transport (being naturally lighter than solid shot of equal diameter) but, by the same token, less far ranging.

A round of grape comprised a number of iron spheres, usually twice or more the diameter of the conventional musket ball as found in canister and shrapnel, and commonly arranged in three layers separated by metal plates. This composite projectile fell apart shortly after leaving the muzzle and was fearfully effective when fired at short ranges against assaulting troops, constituting, as it were, a sort of oversize canister.

Bar shot was employed in naval operations, and consisted of two spheres or two hemispheres of cast iron connected by a bar of the same material. Fired into the rigging of hostile vessels, they flew crazily through the air and caused great damage—provided they found their targets.

Chain shot, designed for a similar purpose, embodied two hollow hemispheres linked by a section of stout chain, the two portions of the globe being fitted together before firing, with the chain nested into the cavity so formed. Shortly after leaving the muzzle the hemispheres flew apart to the length of the connecting chain. As may be imagined, the effect on the spars, ropes and sails of an enemy vessel was considerable.

6. Early Fuzes.—The shell had in the first half of the 19th century come into its own, as had shrapnel. Neither of these, however, could attain full stature until the crude time fuzes of the period had undergone material improvement, and until the detonating powder developed by Alexander Forsyth in 1807 and the years immediately following, harnessed in percussion caps and other devices, permitted the construction of a missile that would explode on the shock of striking its target; *i.e.*, the concussion or percussion shell. The time fuze was no novelty, for it required little ingenuity to pack a train of slow-burning powder into a wooden or metal tube and, knowing the distance traveled over varying periods of time by the shell in which this was to be used, and the burning rate of the powder train, to mark the tube surface with graduations corresponding to different ranges.

This device was now driven into a fuze hole in the shell, first having been cut off, or otherwise set, for the range at which firing was to take place. If all went well, the missile burst at the point intended. When the projectile was rammed home, the fuze faced toward the muzzle of the piece, being situated on the side of the shell opposite that which rested on the propelling charge. It was nevertheless ignited by the flash from the propellant, for the projectile was always sufficiently smaller in diameter than the bore of the gun firing it to permit a considerable portion of the incandescent-powder gases to escape past it and perform this important function. Obviously this clearance between projectile and

bore resulted in the waste of a large percentage of the gases generated and a consequent reduction in the energy expended on propelling the missile. But this was considered a necessary evil and no serious steps were taken to remedy it until rifled pieces came upon the scene. This latter development, which was beginning to take place in the mid-19th century, had long been awaited, indeed foreseen. But the same difficulties that beset the infantryman in his search for a suitable rifled weapon operated in the case of artillery.

7. Rifled Guns.—A projectile small enough to pass readily down the bore of a piece to its seat in the chamber was, by the same token, not large enough to expand into and acquire a motion of rotation from a set of rifling grooves leading from that point to the muzzle. Further, such rotation increased the effectiveness of a round missile so little that it hardly justified the expense and trouble involved. It did increase enormously the range and accuracy of an elongated (cylindroogival) bolt; indeed, projectiles of this form could not be made to function properly save in a rifled piece. Elongated projectiles were obviously much heavier than spherical shot of equal diameter and called for greatly increased powder charges, which the older types of cannon were unable to withstand.

During the fourth, fifth and sixth decades of the 19th century, however, improvements in black powder and the materials and methods of gun construction made possible the building of ordnance capable of handling these charges. Coincidentally, inventors in widely separated parts of the world were developing systems of rifling and projectiles adapted to them which, while not at once wholly successful, presaged the early introduction of a new era. Among these systems may be mentioned that of Charles Lancaster, which involved the use of a projectile, oval in section, fired from a gun similarly bored (the oval spiraling from breech to muzzle); of Joseph Whitworth, who used a six-sided missile delivered from a tube the bore of which was a hexagon twisted upon itself (both of these designs were British); and the French system in which a series of studs that engaged the rifling grooves of the gun were screwed into the surface of the projectile. Another variation, which perhaps reached its highest degree of perfection in the U.S. Sawyer projectile, involved casting on the surface of the shell a series of longitudinal ribs or flanges, corresponding in number, position, angle and dimensions to the grooves of the gun bore.

All of these devices suffered from one of the chief faults of the smoothbore system: clearance between the surfaces of bore and missile was so considerable (and necessary, to permit easy loading) that much of the force of the powder charge was wasted in the gas that escaped past the projectile. To remedy this, scores of devices were employed, the commonest being a disk of some soft metal attached to the base of the shell, its edge curving slightly backward (toward the powder charge) all around its perimeter, exactly as though a pie pan had been nailed to the bottom of the missile. When the powder was ignited, the free edge of this disk was forced forward and outward by the pressure of the burning gases, sealing the bore more or less effectively. But at best these were makeshift solutions, and it required the perfection of the breech-loading gun to provide a really satisfactory answer to the problem of gas leakage.

This type of piece was as old as artillery itself, but had never proved practicable, not because of gas escape along the bore, but at the breech. However: during the 19th century breech-loading systems, each slightly better than its predecessor, followed one another in rapid succession; *e.g.*, those of G. Cavalli (Sardinia), Baron Wahrendorff (Sweden), W. Armstrong (England), A. Krupp (Germany), R. de Bange (France), etc. It now became possible to introduce, at the breech of a piece, a projectile part or all of which was of "groove diameter"; *i.e.*, equal in over-all thickness to the distance measured from the bottom of one groove to the bottom of that facing it on the opposite side of the bore. This meant that the lands, or elevated surfaces between the grooves, bit deeply into the outermost layer of the missile: forcing it to follow the spiral of the rifling. To avoid needless friction and unnecessary wear, those portions of the projectile which were machined to groove (maximum) diameter were fabricated of some relatively soft material. The Armstrong shell, for instance, was shrouded

in a lead envelope. The body of the missile never measured more on its transverse axis than the distance across the lands; *i.e.*, from the top of one land to the top of that opposite—technically known as bore diameter as contrasted with the groove diameter described above. It was soon found, however, that satisfactory rotation could be effected by encircling the projectile near its base with a single narrow band, rather than a full-length envelope, of ductile metal (copper), of groove diameter. The surface of the shell (which was of bore diameter) rode, as it were, the tops of the lands, while the latter cut into the copper rotating band to a depth equal to that of the grooves adjacent. Thus was finally evolved the basic form of projectile thenceforward to find employment in ordnance of every size and type.

8. Confusion in Nomenclature.—With the general adoption of rifled cannon and elongated projectiles, there occurred a confusion in nomenclature that was for a time quite disconcerting. During the centuries in which the round (cast-iron) sphere seemed best, guns had been classified according to the weights of the balls they carried. And since the specific gravity of the metal remained a constant, everyone knew that a 6-pounder was a gun with a bore of about 3.67 in., since a cast-iron shot weighing 6 lb. had a diameter of 3.55 in., and it was customary to make the bore of a gun slightly larger than the missile it was designed to project. Similarly a 12-pounder had a bore of 4.62 in.; an 18-pounder, 5.3 in.; a 24-pounder, 5.82 in.; a 32-pounder, 6.4 in.; and a 42-pounder, 7 in. But with the advent of the cylindroogival missile, a 10-lb. shell (as in the Parrott rifle) came to be fired from a 3-in. gun, whereas had it been a solid sphere it would have required a bore diameter of at least 43 in. to handle it. A 12-in. cast-iron shot weighed about 229½ lb., while the solid elongated projectile fired in the U.S. 12-in. rifle, model 1874, weighed 700 lb. Obviously, to describe this piece as a "700-pounder" came far from giving an idea of its actual dimensions, for only the ordnance expert knew the length and shape of the missile it fired. (Had this been spherical, it would have called for a bore of more than 17 in.) The result was that designations in pounds, after struggling hard for survival, finally went by the board, being replaced by others wherein the calibre of the piece was indicated by its bore diameter in inches or millimetres.

9. Improved Fuzes.—As artillery ammunition improved in range and effectiveness, the old wooden and metal tubes stuffed with slow-burning black powder, which had served so long as fuzes, gave way to more efficient, if more elaborate and more complicated, types wherein the rate of burning and the instant of explosion could be more accurately controlled. It had long been recognized that any fuze containing black powder as a component was likely to be erratic in action by just so much as this ingredient might be affected by external influences (moisture content of the air, barometric pressure, etc.). Under ordinary conditions, these factors played insignificant parts, but in World War I, when antiaircraft artillery came to be developed and widely used, it was discovered that the rate of burning of the powder train varied markedly with the altitude to which a shell was fired, thus adding just one more correction to those the gunner had to make. This discovery stimulated interest in a mechanical time fuze, the operation of which would obviously be independent of altitude effects, and such fuzes were developed and adopted, although their complexity and cost of manufacture placed them distinctly in the luxury category among war munitions.

The era of rifled ordnance resulted, as has been seen, in the introduction of tight-fitting, cylindroogival projectiles, the rotating bands of which sealed the bore so perfectly that almost none of the burning-powder gases escaped past them. But this set up a new problem for the ammunition maker, as it meant that the fuze was no longer inflamed by the flash of discharge, and that some other means to effect this must be contrived. The solution was simple. A striker was located in a hole drilled in the long axis of the fuze body which capped the shell. At the base of this hole was a percussion cap and below this a powder train. On firing, the cap was carried forward with the mass of the shell to impact against the striker which, floating freely in the drill hole, tended to remain stationary while the shell about it gathered momentum. The re-

sulting flash ignited the powder train. This mechanism, technically known as setback, has been widely employed in fuzes of many types. As originally designed, it lacked safety factors, for if the shell were accidentally dropped, detonation of the cap was likely to result. To correct this defect, devices were later installed which interposed a block between striker and cap until disengaged by the centrifugal force developed from rotation of the missile in the bore. Such fuzes are known as bore safe, a number of rotations being required to arm the fuze, *i.e.*, put it in a position to function, so that the missile has traveled an appreciable distance from the muzzle before the fuze is free to act. Some such safety mechanism is of necessity embodied in all types of shell.

10. Improved Shells.—As rifled pieces increased in power and range and suitable breech-loading mechanisms were perfected, the materials used in the fabrication of both guns and ammunition underwent corresponding changes. Solid and hollow missiles of cast iron began to give way to other types such as the Armstrong segment shell. This shell consisted of a thin outer casing of cast iron surrounding six layers, of seven segments each, of the same material, these in turn bordering a central cavity containing an explosive charge of black powder. This shell, in addition to incorporating a time fuze, was fitted with one of the percussion type. In this a detonating cap at the forward end of an axially located tube received the impact, when the shell was suddenly arrested in its flight, of a striker at the rear, which slid forward as the mass about it came to a stop—the action reversing that of setback described above. This arrangement, like the setback, later figured quite generally in shell design. Such a shell was found most effective when used against personnel, but was obviously impotent against fixed fortifications or armoured vessels, which used wrought-iron plates of increasing thickness as early as the 1850s. In order to render cast-iron projectiles effective against these, the shell was cast in a mold, as before, but the nose (point) cooled rapidly through contact with a cast-iron chill, the body proper radiating its heat more slowly in a bed of sand. This cooling resulted in greatly increased hardness and crushing strength at the point without otherwise modifying the characteristics of the projectile, and such bolts proved highly successful. But the defense now countered with the substitution of steel for wrought iron—a measure which would have been adopted sooner had the means for producing this material of good quality and at reasonable price been available earlier. Against steel, the cast-iron shell proved unavailing, and the offense was forced to steel missiles before it could make further headway. Thus projectiles of forged steel were already in common use by the late 1880s. Projectiles of cast steel had been experimented with, but not successfully.

As the shell body improved, so did its bursting charge and its propellant. The explosive properties of guncotton and of picric acid and certain of its salts had long been known, and such substances were the subject of numberless experiments attempting to produce them in forms suitable for use as shell fillers. Until the mid-1880s, however, none of these was attended with much success. But by 1886 the French had managed to control picric acid to a point where they commenced to employ it (under the name of melinite) in this capacity. The British followed with lyddite, the Japanese with shimose—all different names for the same substance. From this time, black powder saw less and less use as an explosive agency in shells, though it retained its place for this purpose in shrapnel. The only thing now lacking to bring artillery ammunition to the state of technical development which it enjoyed when World War I engulfed an amazed civilization was a smokeless propellant. This came about coincidentally with the introduction of high explosives as bursting charges and was largely the work of the French chemist P. Vieille (1884). Ballistite, a smokeless powder made of nitrocellulose and nitroglycerin, was introduced by Alfred Nobel (*q.v.*) in 1888. At the same time the British government adopted a similar compound known as cordite.

Some time elapsed, however, after smokeless powders were functioning satisfactorily in small arms before suitable types could be developed for heavy ordnance. Indeed, the Spanish-American War of 1898 was fought, so far as artillery matériel was concerned, chiefly with black powder, but this was the last major conflict in

which it played an important part. (C. Gd.; H. C. T.)

11. Ammunition in World War I.—In World War I, artillery played an important role and, along with machine guns, reached a high point of development. Thunderous barrages were fired from hundreds of guns to demoralize the enemy, hamper his communications, destroy barbed wire and prepare the way for advancing infantry. The rate of fire of Allied field guns in 1918 ranged from 30 to 35 rounds per gun per day as compared with about 4 rounds per gun per day in the U.S. Civil War and the Russo-Japanese War. To seek protection from such concentrated fire, armies were forced to go underground, and a condition of stalemate resulted.

The main types of artillery ammunition employed in this conflict were explosive shell, shrapnel and canister, all of which have been previously discussed. Some shells were of the low-explosive type, filled with black powder; others were high-explosive, filled with T.N.T., amatol (a mixture of T.N.T. and ammonium nitrate), explosive D (ammonium picrate) or picric acid, widely used by the French. In the ordinary HE shell the weight of the explosive

was about 10% that of the shell, but in armour-piercing varieties it amounted to only about 2%, for armour penetration called for projectiles with thick walls. Shell bodies were normally made of common steel, forged and machined to shape, though semisteel (practically a high grade of cast iron) was successfully used as a substitute. Chemicals of various types figured prominently as shell fillers, both for the purpose of producing screening effects (smokes) and producing casualties. Other special-purpose types of ammunition included incendiary shells filled with Thermit or phosphorus, plus a bursting charge just large enough to rupture the containing walls; illuminating or star shells for night operations; and tracer shells which marked their path by the emission of smoke or flame, thus enabling the gunner to alter his aim if incorrect.

A new use for artillery appeared during World War I—firing on hostile aircraft—but the

BY COURTESY OF U.S. DEPT. OF DEFENSE
Fig. 2.—75-MM. SHRAPNEL

development of special antiaircraft (AA) guns and ammunition was barely begun. At the same time, shrapnel was passing from the scene.

World War I was the last major conflict in which shrapnel was used, but the term continued in popular writing, erroneously applied to shell fragments. Shrapnel had proved useful against large infantry units in the open but of less value against dispersed and protected troops.

Whatever the design of a projectile, the problem of shooting it from the gun tube depends primarily upon the nature of the propellant, the modern term that is applied to chemical compositions that have taken the place of the earlier types of gunpowder or black powder. As noted above, so-called smokeless powder had first been introduced in the latter part of the 19th century and was generally adopted by the time of World War I. Oddly enough, smokeless powder was neither entirely smokeless nor a powder, but the term, nevertheless, gained wide currency. The two main types were single base, of nitrocellulose alone; and double base, nitrocellulose plus nitroglycerin. The U.S. forces favoured the former and British forces the latter, giving it the name cordite. Charges for fixed ammunition were loaded loose into the cartridge case while those for other types were prepared in silk bags that could be placed loose in the gun or in cartridge cases at the time of firing.

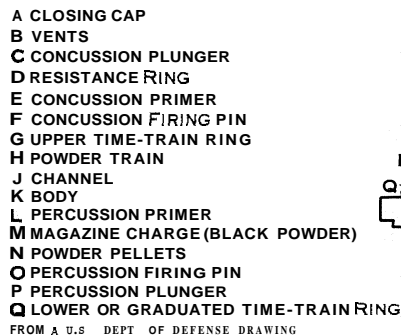

Fig. 3.—21-SEC. COMBINATION FUZE

Raw silk was chosen as the material for the bags because it was almost entirely consumed on firing and left no smouldering remains in the bore.

III. ARTILLERY AMMUNITION AFTER WORLD WAR I

During the quarter century following World War I, artillery ammunition went through a period of rapid development, with improvements being made in all elements—fuzes, explosives, shell bodies, propellants and methods of manufacture. These developments were stimulated chiefly by the appearance in World War I of two new classes of weapon, the tank and the airplane, and they were aided by technological advances in metallurgy, chemistry and electronics. In turn, the development of new and improved ammunition types had an influence on military tactics, making World War II a far different type of conflict from its predecessor. World War II was a war of movement with the two standard elements, mobility and firepower, combined to an unprecedented degree. The HE shell continued to play a leading role on the battlefield, though for certain purposes aerial bombs were more effective. Anglo-American forces expended vast quantities of artillery ammunition to prepare the way for the advance of ground troops or to break up an enemy attack. Conventional HE ammunition was supplemented by hypervelocity armour-piercing (HVAP) ammunition for attacking armoured vehicles, fortifications or ships. A wide variety of chemical shells appeared, some yielding clouds of smoke to blind the enemy and others containing white phosphorus that burned the enemy as it gave off smoke.

Pyrotechnics were widely used for illumination or signaling, and the familiar canister was occasionally employed against personnel. Rockets and shells containing a new type of shaped-charge explosive proved exceptionally valuable for penetrating tank armour. For antiaircraft fire, and for attacking troops in the open, the VT or proximity fuze that detonated its explosive when the shell came within range of its target was a revolutionary new device.

By mid-20th century, before the possibilities for full employment of nuclear weapons had been realized, conventional artillery ammunition—that fired from guns, howitzers, mortars or recoilless rifles—held a commanding position in warfare. "The artillery projectile," wrote one U.S. officer in World War II, "has been the great instrument which has spread death and destruction among the enemy forces." It was the settled doctrine of U.S. and British commanders to pre-

BY COURTESY OF U.S. DEPT. OF DEFENSE
Fig. 4.—ASSEMBLED ROUND OF 75-MM. AMMUNITION

pare the way for the advance of infantry troops by lavish expenditure of artillery ammunition. In the European theatre, U.S. forces fired, during the single month of Dec. 1944, over 3,000,000 rounds of 105-mm. howitzer ammunition. In Korea, where United Nations forces were outnumbered by the enemy, artillery ammunition was fired at previously unheard-of rates to hold back the enemy or break up his attacks.

1. HE Shells.—The typical HE shell of World War II and the Korean war was of the familiar cylindrogogival shape and was made of forged steel with comparatively thin walls. The shell carried a large bursting charge of T.N.T., amatol, explosive D, RDX or other high explosive. It was equipped with a fuze designed to cause detonation of the explosive at the proper time, whether upon impact with the target, upon approaching the target or after a certain lapse of time. The standard HE shell came in a wide range of calibres, from the smallest to the largest guns, and was used against personnel, vehicles, buildings, bridges or fortifications. It achieved its end in part by the blast effect of the explosion and in part by filling the air with flying steel fragments.

The most widely used U.S. HE shell in World War II was that for the 105-mm. howitzer. Its projectile weighed about 33 lb. and had a maximum range of 12,500 yd. The armour-piercing round for the 155-mm. gun was far heavier, its projectile weighing 100 lb. and its range exceeding 25,000 yd. The still larger 8-in. howitzer fired a 200-lb. projectile containing over 35 lb. of T.N.T. The huge 240-mm. howitzer threw a 360-lb. shell containing 54 lb. of T.N.T. to a range of 25,250 yd.

2. Chemical Shells.—These were similar to HE shells in general construction but contained a military chemical rather than a high-explosive charge. One of the best-known types was the smoke shell containing white phosphorus. As noted above, it not only concealed troop movements and blinded the enemy but also served as an antipersonnel round by scattering pieces of burning phosphorus. Various types of poison-gas shells were available to the warring nations but were not used in combat. One type of chemi-

Data on Representative Ammunition Types of World War II

Calibre of weapon	Approx. weight of projectile in lb.	Approx. maximum range in yds.
37-mm. gun (U.S.)	1½	9,500
60-mm. mortar (U.S.)	3	2,000
75-mm. pack howitzer (U.S.)	14	9,760
2½-pounder gun-howitzer (British)	24	13,400
105-mm. howitzer (U.S.)	33	12,500
150-mm. gun (German)	95	27,000
155-mm. gun (U.S.)	95	25,700
170-mm. gun (German)	140	32,000
7.2-in. howitzer (British)	200	16,900
8-in. howitzer (U.S.)	200	18,100
210-mm. howitzer (German)	249	18,260
240-mm. howitzer (U.S.)	360	25,250

cal shell contained a narrow burster tube filled with tetryl that served to rupture the shell and allow the chemical filler to escape without excess dispersion. Another type ejected its smoke canisters through the base of the shell while another emitted smoke from a hole in the base.

3. Armour-Piercing Projectiles.—This type of ammunition, long employed in the naval service; made great strides during World War II as designers of tanks and designers of antitank ammunition competed with each other. As tanks were built with thicker and tougher armour, ammunition makers were forced to devise new means of penetrating such armour—or "defeating" it, to use the language of the ordnance engineer. The term AP shot described a solid steel projectile—not a shell—without an explosive charge or a fuze. It was made of high-carbon alloy steel specially heat-treated to penetrate armour. A pointed nose or windshield of steel or aluminum was usually added to improve its ballistic performance. A similar type, fired at high velocity and known as HVAP, contained an extremely hard core of tungsten carbide. The U.S. army's 80-mm. HVAP round could penetrate many inches of homogeneous armour. The term AP projectile described a somewhat similar type that had a small cavity holding an explosive charge and a base-detonating fuze; *i.e.*, a fuze that exploded the shell after it had penetrated the tank armour. For attacking face-hardened armour, the blunt nose of this type of shot or projectile

was sometimes enclosed in a cap of forged alloy steel, heat-treated so that it had a hard face and a comparatively soft core. On impact, the hardened face of the cap penetrated the hardened surface of the armour while the softer portion protected the core for further penetration. This type was known as armour-piercing-capped or APC ammunition, and sometimes also had a thin-walled windshield.

The most significant new type of antitank ammunition to appear in World War II was the so-called HEAT (high-explosive anti-tank) round based on the shaped-charge principle. An explosive such as pentolite, formed around a thin metal cone, with the base forward, achieved remarkable armour penetration by focusing the explosive effect on one spot, as a magnifying glass focuses the sun's rays. This type of ammunition was based on the so-called Munroe effect noted by the U.S. chemist Charles E. Munroe in the 1880s. Munroe had discovered that a cavity in the side of a block of explosive facing the plate to be penetrated increased the degree of penetration. Demolition engineers had applied the principle for years, and it is said that safe-crackers had long been familiar with it. Shaped-charge or HEAT ammunition differed from other types of AP ammunition in one important respect—its power of penetration was not a function of its velocity. For this reason it was first introduced in rifle grenades and in rocket launchers such as the bazooka (*q.v.*), both of which had a low velocity. In addition, the shaped-charge projectile lost some of its effectiveness when rotated as were other rounds fired from guns or howitzers. It was therefore necessary to devise special HEAT rounds that did not rotate, or rotated very slowly, and were stabilized by metal fins rather than by their rotation—fin stabilized rather than spin stabilized. Such ammunition was capable of penetrating the thickest armour known to be used on tanks in World War II and the Korean war. It was also effective against log bunkers and concrete fortifications.

When the HEAT round struck its target, the shaped charge directed a jet of metallic particles from the cone liner against the target at very high velocity, on the order of 30,000 ft. per second, higher even than the detonation velocity of the explosive. This jet stream was followed by a slug formed of the remaining bits of the cone. Two requirements had to be met before the shaped charge achieved its full effect: the explosive charge had to be detonated from the rear, and it had to be detonated at a certain distance from the target, known as stand-off. (See also MINES, LAND.)

4. Mortar Ammunition.—This type differs from other forms of artillery ammunition in that it is ordinarily designed to be fired from smoothbore pieces, though rifled mortars are by no means unknown. Mortars are relatively light, simply constructed weapons that can easily be carried by front-line troops and quickly set up in firing position. Because they are usually smooth-bore weapons, mortars fire fin-stabilized projectiles. The typical mortar round has either a teardrop or cylindrical shape with a fuze in the nose and metal fins in the tail, the latter to keep it from tumbling end over end in flight. The propelling charge is placed within the fin assembly and may be adjusted in the field to yield the proper range. A mortar round is fired by dropping it, fins first, into the muzzle of the weapon, whereupon its ignition charge strikes the firing pin and inflames the propellant. Mortar ammunition is characterized

FROM A U.S. DEPT. OF DEFENSE DRAWING

FIG. 6.—SHAPED CHARGE AND TARGET

by its low muzzle velocity, high trajectory and short range. The most common types in World War II, and in the years that followed, were the 60-mm. and 81-mm. ranges extending from 200 yd. up to 2,000 or 3,000 yd. Larger rounds were developed for 105-mm. and 155-mm. pieces, with correspondingly greater ranges. The 4.2-in. chemical mortar differed from other types in that it was rifled. Developed at first to project smoke shells, it was later adapted for HE ammunition as well.

5. Recoilless Rifle Ammunition.— This special new type of ammunition, and weapons to fire it, appeared during the closing months of World War II. It was one of the most interesting new ammunition developments of the 1940s. The U.S. army produced two weapons of artillery calibre, 57 mm. and 75 mm., designed to eliminate all "kick" or recoil, and other nations developed similar types. They achieved recoillessness by permitting a portion of the propellant gases to escape rearward through vents in the breech, thus equalizing the forward and backward forces acting on the weapon. For this purpose, cartridge cases were perforated and the chamber of the piece was made larger than the cartridge case to allow room for escape of the gases to the rear. The perforated cartridge case, lined with paper to retain the propellant, was the most obvious distinguishing feature of recoilless rifle ammunition. Another was the pre-engraved rotating band. To eliminate the pressure required to force the copper rotating band against the rifling, the band was notched or pre-engraved so that, when properly aligned in the weapon, it moved easily through the tube, acquiring a spin as it went.

Recoilless ammunition was produced in a variety of types, such as HE antipersonnel, white phosphorus and HE antitank. Recoilless ammunition was fired from lightweight rifles (about 100 lb. for the 75 mm.), yet possessed the explosive power of light artillery ammunition. It was highly effective against tanks and pillboxes at comparatively short range. When designed to fire shaped-charge projectiles, for which spin is undesirable, recoilless ammunition was fin stabilized.

6. Canister.— Though an old type, canister proved valuable in the wars of the mid-20th century, particularly for use against troops concealed in the foliage of jungle areas. It consisted of a quantity of lead or steel balls embedded in a resinous matrix, the whole encased in a cylindrical metal container. The number of balls in each case varied from less than 50 to several hundred, depending upon the model and calibre. The canister round contained neither fuze nor explosive but burst automatically soon after leaving the muzzle. It was most effective at comparatively short ranges.

7. Pyrotechnics.— Under this heading are classed those forms

DRAWN FROM A U.S. ARMY PHOTOGRAPH

FIG. 7.—HYPERVELOCITY ARMOUR-PIERCING SHOT WITH TUNGSTEN CARBIDE CORE

of military ammunition used for producing light for illuminating enemy positions or smokes and lights for signaling. They consist mainly of flares, signals, photoflash cartridges and illuminating shells. Only the latter type clearly falls within the category of artillery ammunition. The standard illuminating shell of the U.S. army in the 1950s had an exterior design similar to that of standard HE shells, but its body enclosed a different set of elements. Most important of these elements was the illuminant, sometimes called the candle, consisting of powdered aluminum or magnesium along with an oxidizing material. Attached to the candle was a parachute that opened when the expelling charge of black powder forced it out through the base of the shell. The usual burning time for the larger types was about 60 sec. and the light was sufficient to illuminate a circle 400 yd. in diameter.

8. Cartridge Cases.— One of the most significant technological advances in ammunition during the 1940s was the development of cartridge cases made of steel rather than brass. The limited supply of copper, and the great demand for copper for other purposes, forced this development during World War II. But it was attended by many difficulties. Brass was an excellent material for cartridge cases because it could be easily worked, did not rust and had the necessary elasticity to expand at the moment of firing and instantly contract for easy extraction from the gun. Limited quantities of steel artillery cases were produced in the United States during World War II, and by the time of the Korean war they were in quantity production.

Meanwhile an entirely new approach to the cartridge-case problem was made by ordnance researchers working toward the production of combustible cases. Made of material that would burn rapidly and completely, leaving no residue in the chamber, combustible cases were seen to offer significant advantages for tank and aircraft guns because they would eliminate the need to dispose of fired cases.

9. Fuzes.— During World War II the U.S. army employed about 150 different types and sizes of fuzes, the three main classifications being point-detonating, base-detonating and time. As its name implies, the point-detonating fuze functioned when the point of the projectile, wherein the fuze was inserted, struck its target. It was commonly shipped separately from the projectile and inserted just before the shell was loaded into the gun. It came in several forms such as superquick, which caused instantaneous detonation; short delay, which held off the detonation for .05 sec.; and long delay, which held it off for .15 sec. Base-detonating fuzes were normally used in shells designed for penetrating armour or concrete against which a point fuze might have been crushed and rendered inoperative on impact. Time fuzes were used chiefly in antiaircraft shells and could be set to explode a shell in flight after it had reached the estimated altitude of the enemy plane. Time fuzes, as noted above, were of two types: the 21-sec. powder-train type or the mechanical time fuze with clockwork mechanism.

By far the most revolutionary development in fuzes in modern times came with the appearance of the VT or proximity fuze in World War II. This electronic marvel contained a miniature radio transmitting and receiving oscillator which, while the projectile was in flight, sent forth a continuous radio signal. When this signal was reflected back to the fuze by a solid object, whether airplane, ship or ground, the fuze detonated the projectile. The fuze was set with such precision that the shell would explode only when it was within lethal range of its target. Proximity to the target was the key to its functioning.

One of the most highly prized Allied secrets in World War II, the VT fuze was not at first used on land for fear the enemy would recover a specimen, learn the secret of its construction and turn similar ammunition against the fleets of Allied bombers that were pounding German and Japanese cities. Its first use was at sea in antiaircraft fire from the U.S. cruiser "Helena" in Jan. 1943. From that time on it was regularly employed by the British and U.S. navies and helped greatly to provide naval vessels with an effective means of defense against air attacks, which became particularly menacing as the Allied fleets closed in on the Japanese home islands.

The first land use of the proximity fuze for antiaircraft fire was

in the defense of London against the German "buzz bombs" in 1944. Late in the autumn of 1944 the Allied high command released the VT fuze for unrestricted use by field artillery and it played a part in repulsing the German counteroffensive of Dec. 1944. It was very effective against troops in the open or in trenches and against truck convoys on the road, for it caused shells to explode in the air. Aerial bombs equipped with VT fuzes were dropped on the island of Iao Jima in early Feb. 1945. In aircraft rockets or cannon it greatly increased the effectiveness of plane-to-plane fire and air-to-ground attacks.

10. Propellants and Explosives.—In the years following World War I much attention was devoted to two problems: (1) development of a propellant that would be as flashless as possible and would thus not reveal the location of guns employing it, particularly during night operations; and (2) development of non-

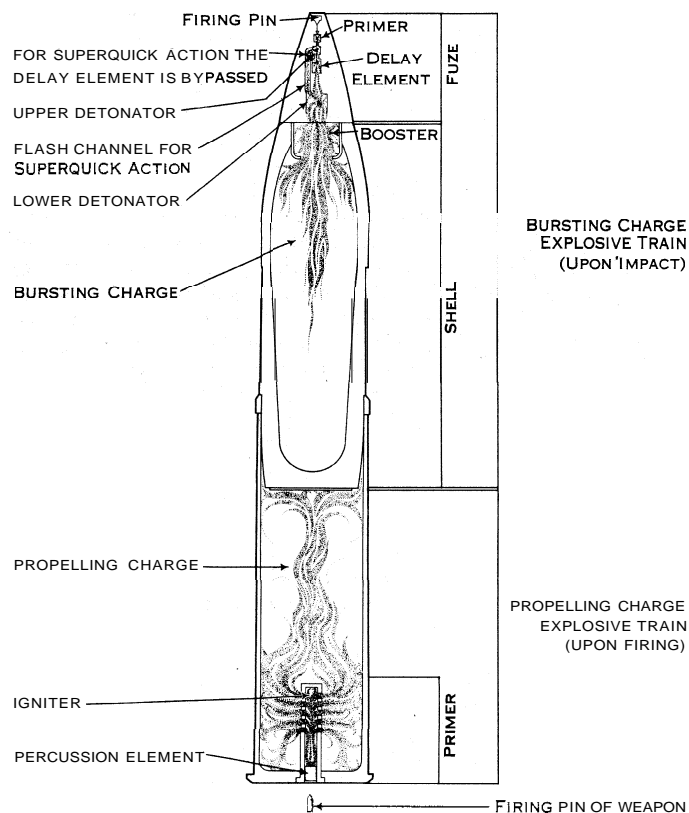

FIG. 8.—FUNCTIONING OF A TYPICAL ROUND OF AMMUNITION

hygroscopic propellants; *i.e.*, without a tendency to absorb moisture. Considerable success attended these efforts and so-called flashless nonhygroscopic (FNH) propellants came into use. But achievement of all the desired characteristics in one propellant proved impossible. Reduction of smoke usually caused increased flash, and vice versa. The propellants in general use had a nitrocellulose base and were commonly known as smokeless powder. Their usual form was that of small cylindrical pellets, perforated to improve their combustion.

The standard explosive filler for HE shells during the first half of the 20th century was either T.N.T. or amatol. T.N.T. was a particularly satisfactory military explosive because it was sufficiently insensitive to withstand both the shock of setback when the projectile was fired and the shock of impact at the target. It was cheap, easy to manufacture and safe to handle—all very important practical considerations. And, unlike picric acid, it did not corrode metals or form dangerous compounds.

Ordnance scientists, however, continued to seek improved explosives, particularly those with greater brisance or shattering effect. Tetryl was more brisant than T.N.T. but was also more sensitive, so it was most often employed as a booster to detonate T.N.T. Another explosive, sometimes called cyclonite by the U.S.

and RDX by the British, gained wide acceptance in World War II though it was so sensitive it had to be mixed with oils, waxes or other explosives to form a usable composition. Another new explosive was ethylenedinitramine, shorted to EDNA, developed largely by a U.S. chemist, George C. Hale, for whom it was named haleite. A fourth was PETN, the shortened name for pentaerythritol tetranitrate, and its derivative, pentolite (half T.N.T. and half PETN), which became the standard filler for high explosive anti-tank rounds. These and others were combined in many ways in a never-ending search for an ideal shell filler.

Military explosive charges are made in many different shapes and sizes to form a special class of ammunition known as demolition materials. Their main purpose is to destroy fortifications, railroads, bridges, dams or buildings, or to clear mine fields. Common forms are dynamite sticks, blocks of T.N.T., ammonium nitrate or nitrostarch and shaped-charge devices. The shaped-charge device used to blast holes in steel or concrete usually consists of a cylindrical block of high explosive with a conical cavity in its lower end and a blasting cap in the top end. The whole block rests upon metal legs that provide the necessary standoff for maximum effect. Small explosive charges may be connected to doors or windows so that they will explode when the doors or windows are opened or closed; others may be wired to attractive items to form booby traps that explode when the item is picked up. The bangalore torpedo is another type of explosive device used to clear a narrow path through mine fields or wire entanglements. It consists of lengths of explosive-filled steel tubes that may be used singly or joined together.

During World War II the appearance of the shaped charge, described above, helped solve the armour-penetration problem, and after the war an entirely new and infinitely more powerful element came into the picture, the atomic shell.

11. Atomic Shells.—The most spectacular development in artillery ammunition came in the decade following World War II with announcement by the U.S. army that it had produced a 280-mm. atomic shell. The first firing of this devastating new shell (about 11 in. in diameter) took place at the Atomic Energy commission's proving ground near Las Vegas, Nev., on May 2 j, 1953. Its range was announced as being approximately 20 mi. As the 280-mm. gun was a huge 8j-ton weapon with limited mobility, work went forward in compressing atomic explosives into rounds of smaller calibre and by 1957 the existence of an 8-in. shell was announced by the U.S. army. Whether employed in artillery shells, bombs, demolition charges, rockets or guided missiles, nuclear energy held a dominant position in the military realm. See MISILES.

AMNESIA is a hysterical symptom, classified as a dissociative reaction, characterized by disturbances of memory. Amnesia may be general, in which case all functions of memory are involved; or partial, in which case only certain groups of ideas, proper names, the meanings of words, events and their associations, and the like are screened from memory. See HYSTERIA.

AMNESTY (oblivion of injuries), which may be declared by treaty or national authority, manifests a determination to forget past wrongs and animosities; to restore conditions of amity and to refrain from prosecuting persons guilty of political offenses. Generally cited as the first historical example of amnesty is the act by which Thrasylbulus of Athens proclaimed an amnesty in 403 B.C., expressly excluding the 30 tyrants and a few others from its operation. In Roman law, the principle of *restitutio in integrum* amounted in practice to an amnesty.

In modern treaties an amnesty clause implies an obligation of the parties to regard their enmity as terminated and to renounce it as a pretext for a new war. The treaty of Osnabriick between

the emperor on the one hand and Sweden and the Protestant states of Germany on the other (1648), and that of Oliva between the emperor, Sweden, Poland and the elector of Brandenburg (1660) provided not only that mutual wrongs should be consigned to oblivion but that property should be restored to all persons who had been dispossessed during the war. The final act of the congress of Vienna in 1815 extended amnesty to Poles and Swedes, and the treaty of Frankfurt between France and Germany in 1871 limited amnesty provisions to the inhabitants of the territory ceded by France to Germany, though this was subsequently extended by special negotiations. The treaty of San Stefano, between Russia and Turkey in 1878, contained the unusual provision requiring Turkey to extend amnesty to its own subjects compromised during the war. The peace of Vereeniging ending the Boer War in 1902 provided amnesty for Boers who accepted British nationality with exception of a list of Boer officers who were to be tried for violations of the law of war. Some peace treaties have not included an amnesty clause, but amnesty is said to be implied except in so far as express provision is made to the contrary.

National amnesties following civil strife are regarded as acts of grace by the sovereign. That proclaimed by Charles II on his restoration in 1660 excluded persons who had taken part in the execution of his father. The last British amnesty was that of 1747 extending to participants in the second Jacobite rebellion. Napoleon's amnesty of March 13, 1815, excluded Talleyrand and a dozen other eminent persons. Pres. Andrew Johnson issued a proclamation on May 29, 1865, which granted full pardon to all former Confederates (except certain leaders) who took an unqualified oath of allegiance to the United States; these provisions were modified in subsequent proclamations issued in 1867 and 1868.

The treaties ending the two world wars of the 20th century did not contain general amnesty clauses, but in some cases provided for the waiver of claims of certain types beyond those specified in the treaty. These treaties discriminated between the victorious allies and their enemies in respect to the restoration of sequestered property. They provided explicitly for the return of prisoners of war and interned civilians, except those of enemy nationality subject to trial for war crimes or other offenses. France, Germany, the Netherlands, Norway, Belgium and Japan have declared amnesties for persons engaged in compromising activities during World War II, in the case of Japan including 1,300,000 persons. After prosecuting thousands of war criminals, the western Allies declared in 1949 that they would hold no further war crimes trials in either Europe or the far east. Opinion in Germany and Japan demanded clemency for convicted war criminals and, after the Japanese peace treaty went into effect in 1952, a clemency board was set up and large numbers of war criminals were paroled. In Germany a large proportion of war criminals held by the western powers had been released by 1953, but the Soviet Union still retained custody of an unknown number of prisoners of war and war criminals estimated at over 100,000. Some of these subsequently were released. (Q. W.)

AMOEBA, the genus as well as the common name given to certain microscopic unicellular animals characterized by the ability to form temporary extensions of the body, called pseudopodia or false feet. The well-known amoeba of fresh-water ponds and streams, *Amoeba proteus*, is a fascinating object of study which may be found on decaying bottom vegetation. Each amoeba is a small mass of jellylike material, slightly grayish in appearance. Although apparently simple in gross structure, it carries on many of the vital functions of higher animals—metabolism, growth, reproduction, locomotion and response to stimuli.

The protoplasm of an amoeba is differentiated into a thin outer plasma membrane; a layer of stiff, clear ectoplasm just beneath the plasma membrane; and the central granular endoplasm. Located in the endoplasm are a granular nucleus, a clear contractile vacuole and numerous food vacuoles.

Amoeboid movement, characterized by the formation of pseudopodia, is considered to be the most primitive type of animal locomotion. This type of locomotion is also exhibited by certain cells

ADAPTED FROM DELLINGER IN "JOURNAL OF EXPERIMENTAL ZOOLOGY" (WISTAR)

FIG. 1. — COMMON AMOEBA MAGNIFIED 260 TIMES

The extensions of the body are pseudopodia. The nucleus is large and granular; the contractile vacuole is a clear spherical structure and the other large inclusions are food vacuoles

chief function is to remove excess water from the amoeba. Reproduction in the common amoeba is asexual, by binary fission. In this process the amoeba rounds up, the nucleus divides and then the cytoplasm divides forming two daughter amoebae, each with a nucleus. That the nucleus functions in connection with processes, other than reproduction may be demonstrated by cutting the animal into two pieces, one with and the other without the nucleus. The piece with the nucleus feeds and grows like an ordinary amoeba and eventually reproduces. The piece without the nucleus moves about for a time but it cannot feed or digest food and it dies after the reserve food in its protoplasm has been used up.

During periods of adversity many kinds of amoebae are able to survive by encysting. In this process the amoeba rounds up, gives off a large amount of its water content and secretes a protective envelope or cyst membrane. Such cysts may be dispersed by air currents or other agencies; if they fall into a suitable environment, the envelope ruptures and the contained amoeba emerges.

ADAPTED FROM DOFLIN
FIG. 2. — DYSENTERIC AMOEBA MAGNIFIED 2,250 TIMES

The dark circles are red blood corpuscles; the other circle with a beaded periphery is the nucleus

of higher animals, for example, white blood corpuscles. By watching the movements of the granular endoplasm one can see some of the factors involved in amoeboid movement. The outer, more viscous region of the ectoplasm is called the plasmagel, whereas the inner more fluid region is known as the plasmasol. A pseudopodium starts to form at a point where the outer gelled region of the amoeba liquefies, thus presenting a weakened region through which the adjacent plasmasol flows. As the plasmasol flows "forward," it turns back and becomes part of the plasmagel. At the temporary posterior of the amoeba, plasmagel changes into plasmasol. It is assumed that the outer gelled region contracts and forces the fluid plasmasol forward into the pseudopodium where the plasmagel is thinnest. If the tip of an advancing pseudopodium is touched, the plasmagel thickens at this point and the direction of movement is changed.

There is no mouth or anus; food may be taken in and the undigested remains cast out at any point on the surface. In feeding on algae and other protozoa, extensions of the body flow out around the food organism and finally coalesce, resulting in the formation of a food vacuole. Digestion occurs in the vacuole through the action of enzymes secreted into it. Oxygen for respiration diffuses in from the surrounding water and wastes of metabolism diffuse from the amoeba to the surrounding water.

The contractile vacuole opens to the surface by a pore through which the contents are expelled. This structure is absent in most marine and parasitic species, and its chief function is to remove excess water from the amoeba. Reproduction in the common amoeba is asexual, by binary fission. In this process the amoeba rounds up, the nucleus divides and then the cytoplasm divides forming two daughter amoebae, each with a nucleus. That the nucleus functions in connection with processes, other than reproduction may be demonstrated by cutting the animal into two pieces, one with and the other without the nucleus. The piece with the nucleus feeds and grows like an ordinary amoeba and eventually reproduces. The piece without the nucleus moves about for a time but it cannot feed or digest food and it dies after the reserve food in its protoplasm has been used up.

During periods of adversity many kinds of amoebae are able to survive by encysting. In this process the amoeba rounds up, gives off a large amount of its water content and secretes a protective envelope or cyst membrane. Such cysts may be dispersed by air currents or other agencies; if they fall into a suitable environment, the envelope ruptures and the contained amoeba emerges.

There are numerous species of parasitic amoebae. Of the six species of amoeba that may live in man's alimentary tract, one, *Entamoeba histolytica*, is pathogenic, causing amoebic dysentery. *E. histolytica* can penetrate the lining of the intestine and produce a characteristic ulceration in the intestinal wall. In some cases they are carried in the blood to the liver where they produce abscesses. This amoeba ingests red blood corpuscles. Transmission is by the cyst stage and numerous cysts may be present in the feces of infected individuals. Infection occurs through the drinking of contaminated water or the eating of un-

cooked contaminated food. Excystment, or emergence from the cyst, occurs in the intestine of man. The obvious control of *E. histolytica* is proper sanitation.

Amoebae, widely studied in zoological laboratories as examples of protoplasm, have also been used extensively in cell research in determining the relative functions and interactions of nucleus and cytoplasm.

See PROTOZOA. For more details on amoebic dysentery see DYSENTERY: *Amoebic Dysentery*. (W. H. J.)

AMOEBIASIS (AMEBIASIS), in general, means any infection with amoebae, but the term is most commonly used to describe infection with *Entamoeba histolytica*, including amoebic dysentery, amoebic liver abscess, etc. See PARASITIC DISEASES; AMOEBA; DYSENTERY.

AMON (AMUN, AMANA; Gr. AMMON), Egyptian god, was originally one of eight gods (the ogdoad) of Khmun (Lat. Hermopolis Magna, mod. El Ashmunein) in middle Egypt, where they personified the mysterious invisibility of the primeval ocean. In circumstances unknown his cult reached Thebes shortly after that town became the capital of the united country (c. 2100 B.C.). There he assumed features of other gods, especially of the fertility god Min of Coptos, and was identified with the Heliopolitan sun-god Ra (RE) as Amon-Ra (Amon-RE). His priesthood claimed for him the titles of "king of the gods" and "lord of the thrones of the two lands" (*i.e.*, of upper and lower Egypt), and two local deities were associated with him, the goddess Mut and the moon-god Khons. Under the 18th dynasty (from 1580 B.C.) Amon was believed to have granted to the pharaohs the victories leading to the formation of their empire in Asia. At the same time his cult was introduced into Napata in Nubia, and a little later to the new royal residence at Pi-Ramesse and into the oases. The religious revolution of King Ikhnaton (*q.v.*) was chiefly directed against Amon and his priests, but after Tutankhamen's reaction (c. 1350 B.C.) his two Theban temples at Karnak and Luxor greatly increased in wealth; under the 21st dynasty (c. 1100 B.C.) Amon's high priest headed a sacerdotal state at Thebes. This soon began to decline, and the Assyrian sack of Thebes about 663 B.C. reduced Amon to mere local importance. His famous oracle at Oasis Siwa in the Libyan desert remained, however, to welcome Alexander the Great as the son of a god. Amon was represented in human form, sometimes with a ram's head; his sacred animals were the ram and the Nile goose. The Greeks identified him with Zeus. See also Index references under "Amon" in the Index volume. (J. Cy.)

AMONTONS, GUILLAUME (1663–1705), French physicist, best known for his work in friction and in thermometry, was born in Paris on Aug. 31, 1663. In 1687 he presented to the Academy of Sciences a hygrometer of his own invention, and in 1695 he published his *Remarques et expériences physiques sur la construction d'une nouvelle clepsydre, sur les baromètres, thermomètres et hygromètres*. He also published some investigations on friction (1699) and several other papers on physical and mechanical subjects, the most notable being two papers on thermometry in 1702–03. He died in Paris on Oct. 11, 1705.

AMORA (meaning literally "speaker" or "interpreter"; pl. amoraim), one of four different types of Jewish postbiblical teachers, the others being Sofer, Tanna and Gaon (*q.v.*). The amoraim, working at academies in Palestine and in Babylonia, beginning about A.D. 200, were authors of the Gemara section of the Talmud, in the main a legal interpretation of and commentary on the Mishnah. Their work was completed with the compilation of the Babylonian Talmud about A.D. 500. See TALMUD.

AMORGOS, an island of the Cyclades (*q.v.*), Greece, is long and narrow—about 20 mi. from southeast to northwest. Area 45 sq.mi. Pop. (1951) 2,505. It is very mountainous but supports a dwindling agricultural community, notably in the Catapola plain, where there is the only good anchorage. Amorgos was a great centre in the Early Bronze Age, but in classical times had only three cities, Arcesine, Minoa and Aegiale. An important industry in antiquity was the production of *amorgina*: fine, transparent fabrics made from locally grown flax or cotton. The Romans used the island as a place of banishment. Visitors land at Catapola

on the west coast, four hours traveling from Amorgos, the principal village. (J. Bo.)

AMORITES. The term Amorite, referring to a people of the ancient near east, encompasses the manifold aspects of race, language, territories occupied and even social status. Considered in the light of changes in historical conditions and semantic range during a period of more than 2,000 years, this subject is one of the most debatable in the history of the near east. The Amorites are known from cuneiform sources and from the Old Testament; these sources are here dealt with separately.

Generally speaking, the name Amurru or Amorite is, on the one hand, connected with northern Arabia and, on the other hand, with a Semitic group called Canaanites. At about 1600 B.C., the term Amorite lost all connection with Arabia and became instead the geographic term used to designate the land of the west; at the same time, the term Amorite lost all value for denoting a language.

Cuneiform Sources.—Period I: c. 2400–2000 B.C.—It is only a hypothesis that the earliest Amorites spoke the same language as the Akkadians. Some centuries later, when personal names and a few of their tribe names appear in the sources, at least a part of the Martu (the Sumerian equivalent of Amorite) spoke a language different from Akkadian, one that was perhaps between Akkadian and the language of the west Semitic group discussed below (Period II). From the oldest sources, the Martu, or Amurru as the Akkadians called them, were equated with the west wind and the west, though their true place of origin was most likely in Arabia, not Syria. In the Ur III period, three kinds of Martu were distinguished: (1) those dwelling in Arabia proper who made contacts with the kings of Ur (*e.g.*, King Ipiq-reum of Yamat, a region which later sources identify with Aḫlamu, meaning Arabia); (2) those tribes that crossed the two rivers to the eastern hills; (3) those Martu who were dispersed among the Sumero-Akkadian population as labourers but who perhaps still maintained their tribal organization; they were called Martu/Amurru and were distinct from the rest of the population.

The Martu of this period was described as one who ate raw meat, who knew no house, who was not buried when he died. They came down from the mountains, probably east of the Tigris, to encroach upon the civilized; they were one of the causes of the downfall of the Ur III empire. In this entire period, no Martu/Amurru is attested for the mid-Euphrates region or for Syria.

Period II: c. 2000–1600 B.C.—About a century after the end of period I, a large-scale migration of great tribal federations from Arabia resulted in the occupation of Babylonia proper, the mid-Euphrates region and Syria-Palestine. The language of these tribes was a dialect of the family of Semitic languages called Canaanite, best known from the Hebrew dialect. Because of this obvious affinity with Canaanite, some scholars apply the name Eastern Canaanite, or Canaanite, to the population that invaded Babylonia and the mid-Euphrates; other scholars name this distinct wave of population Amorites, thereby denying the basic difference between this stock and the people treated in period I above.

Although the local kings in Babylonia belonged to this stock almost without exception, they quickly assimilated to the basic population. Some tribes maintained their old sheikh system but recognized the local kings as chieftains. The same situation prevailed in the mid-Euphrates, well documented by the archives of Mari (Tall al Hariri). Farther west, the political centre of these Canaanites was the city of Ḥalab (Xleppo); in this area, as well as in Palestine, they were thoroughly mixed with the Hurrians (*q.v.*). The tribal federation to which the rulers of Mari and Aleppo belonged was that of the Haneans. There existed also other main tribe groups (*e.g.*, the "Sons of the North" and the "Sons of the South") whose relationship with the Haneans remains obscure. Clearly distinct from these "civilized nomads" were the wild nomads of Arabia and the Syrian desert, the Suteans. The region then called Xmurru was northern Palestine with the centre at Hasor, and the neighbouring Syrian desert comprised of four independent kingdoms. This region was a centre of horse breeding whence both horses and personnel were brought.

Three great conquerors of this period bore Canaanite names:

Hammurabi of Babylon, Shamshi-Adad of the mid-Euphrates and Yarim-lim of Aleppo. In the Old Assyrian documents the term Amurru apparently covered a wider range of meaning than it did elsewhere, but why or to what extent has not been determined.

Period III: c. 1600-1100 B.C.—In the dark age that followed period II, the term Amurru as well as the Canaanite language disappeared completely from Babylonia and the mid-Euphrates, while it became dominant in Syria and Palestine. In the Amarna letters (c. ± 1360; see TEL EL-AMARNA) the term Amurru is relegated to a tiny state that extended from the port of Arvad to the Lebanon; it was first under Egyptian, then Hittite control. At the same time, the bedouins, now called Ahhlameans, were still emigrating from Arabia. (See CANAAN; PHOENICIA.)

Period IV: 1100-500 B.C.—In the Assyrian inscriptions from 1100 on, the use of the by then purely literary term Amurru (*i.e.*, no Amorite kingdom, region or population still existed) was meant to designate part of Syria and the whole of Phoenicia and Palestine. Though Palmyra (Tadmor) still belonged to Amurru, the Arabian peninsula is no longer so called. In addition, the name Hatti came to be used almost synonymously with Amurru; this shift of meaning for these two historical terms is paralleled by the use of the terms Emori and Hitti in the Old Testament.

Old Testament.—The pentateuchal source called the Elohist (dating perhaps from the 8th century B.C.) named as Amorites the population (spread out in many small kingdoms) that was conquered by the Israelites. The Jahvistic source (c. 900 B.C.) applied instead the term Canaanites, so that the two terms must have been synonymous. But the table of nations in Gen. x (which is not assigned to either of the above-mentioned sources) lists Emori as one of the 11 sons (cities or tribes) of Canaan. The passage Judg. i, 29-36, in dealing with the remnants of the old population not conquered by the Israelites, distinguishes between Canaanites in the south and Amorites in the north of Palestine. A further historical reminiscence which may contain a sound tradition is found in Num. xxi, where Sihon the "king of the Amorites" is said to have dwelt at Heshbon, in a kingdom situated east of the Jordan between the Arnon and Jabok rivers, in the country later known as Moab. The semimythical reference to the Amorites as a race of giants in Deut. iii, 11, Amos ii, 9 may be noted. See also SEMITIC LANGUAGES: Amorite.

AMORTIZATION. In finance, amortization means the systematic repayment of a debt; in accounting, it means the systematic writing off of some account over a period of years. An example of the first meaning is a mortgage on a home that may be repaid in monthly installments that include interest and a gradual reduction of the principal obligation. Another is a bond issue of a business corporation or a governmental body that may be amortized by annual or semiannual payments. These payments may be used to repurchase bonds or held in a sinking fund to retire the debt at some date in the future or the bond issue may have serial maturities so that a portion of the issue comes due and requires repayment each year. Systematic annual reduction increases the safety factor for the investor by imposing a small annual burden rather than a single large final obligation that might be a threat to the solvency of the debtor. There is also the logic of repayment during a period not greater than the useful life of the property financed by the given debt.

In the second, or accounting sense, the amortization, or writing off, of an asset, such as a building, a machine or a mine, over its estimated life has the effect of reducing its balance sheet valuation and charging its cost into the expenses of operation. Such expense is called depreciation or, for exhaustible natural resources, depletion. In some instances the asset to be amortized may, like

good will or organization expenses, be regarded as having an indeterminate life. Management often prefers to eliminate such intangible assets as a matter of conservatism but wishes the process to be gradual. Some items, like property that is abandoned or lost in some catastrophe, may continue to be carried among the firm's assets until its extinction is achieved by gradual amortization.

A corporation selling its own bonds at a price other than the face amount will nevertheless show the bond liability at the face, or par, value. Any excess proceeds over par will appear among the liabilities as "premium on bonds"; any deficiency, on the asset side as "discount on bonds." These two accounts are amortized over the life of the debt, unless prior repayment requires earlier extinction. The annual amortization of discount becomes an addition to the current interest payments as a part of the cost of the borrowed funds; premium amortization serves as a reduction of the interest costs. Investors, on the other hand, ordinarily enter such bonds in their accounts at their cost rather than at par value and treat the premium or discount as capital loss or gain when the bond is paid at par. A few investors, however, like life insurance companies, amortize the difference between cost and par over the life of the bond and are said to carry bonds at "amortized value" in their balance sheet. Some commercial banks carry discount bonds at cost until maturity or resale but charge off all premiums paid at the time of purchase as a matter of conservatism.

Taxation.—During World War II, business concerns in the United States were permitted to amortize the cost of defense facilities over a five-year period for income tax purposes when proper certificates had been issued. Any unamortized balance could be written off in the last year of the war. After the war, this principle of accelerated amortization was extended to encourage business to expand productive facilities which would serve the national defense. Because such plant and equipment would normally be acquired only if it had some peacetime use as well, the American Institute of Certified Public Accountants recommended that in published statements, "normal depreciation" should be employed rather than the accelerated amortization used in income tax returns. But such normalization of depreciation, if reported along with the reduced income taxes, would give an appearance of unusually high earnings during the five-year period of accelerated amortization followed by depressed earnings in the succeeding years when income taxes would appear above normal because of the absence of any deduction for depreciation or amortization. A recommendation was therefore made that with "normalized depreciation" should go a "normalized income tax expense" and that any amount of the income tax not being paid currently should be set up as a deferred income tax liability. At the end of the period of accelerated amortization, when income tax payments rise, the excess over normal is charged against this liability account so that the tax expense account shows only the same amount as in the preceding years. This normalization runs counter to the accounting theory which opposes introducing speculative figures into the accounts. The procedure assumes that future income tax rates will be like those of the present. On the other hand, the argument for normalization is that it improves the income statement as a basis for judging earning power and recognizes that income tax accounting does not always constitute the best measure of financial performance.

The advantage of accelerated amortization for tax purposes does not lie in any reduction of taxes paid but in their deferment. The drain of income taxes is reduced for the business during the early years when amortization is accelerated. It thus releases more funds for the repayment of any obligations incurred in financing the property. The financial problem arises in the subsequent years when, in addition to paying the normal income taxes, the business must earn enough to pay the additional income tax resulting from the absence of any deduction for depreciation.

Some public utility and railroad commissions have required companies subject to their rule to report normal depreciation rather than accelerated amortization but to report income taxes in the amounts currently being paid without any normalization. The

income statements in these fields consequently require special analysis to ascertain the basis employed and the significance of the figures as measuring earning power on some uniformly comparable basis. (H. G. Gn.)

AMORY, THOMAS (1691?–1788), British writer of Irish descent known for his autobiographical *John Buncl*. It is believed that he lived in Dublin where he knew Swift. Later he lived at Westminster and also Hounslow. He was a staunch Unitarian and a student of medicine, geology and antiquities. He published two books, the *Memoirs* (1755) dealing with the life of an imaginary lady, Mrs. Marinda Benlow, and *The Life of John Buncl*, *Esq.*, 2 vol. (1756 and 1766), written in the form of an extravagant autobiography. The hero, "an odd compound of a man," marries seven wives in succession, each embodying one of his ideals of womanhood. Something of the spirit of Rabelais and of Dickens informs Amory's eccentric works. He died Nov. 25, 1788.

See J. C. Walters, *John Buncl*, a *Curio of Literature* (1919).

AMOS, BOOK OF, one of the books in the collection of 12 prophets (or minor prophets) in the Old Testament. In the original Hebrew text and in the Vulgate it is placed third, in the Septuagint second, but chronologically it is the earliest of the twelve.

Contents. — Amos was a pattern for later prophetic books. It contains: (1) oracles, often very short, which were gathered into groups by the prophet himself or by the traditionists; (2) short passages giving features from the life of the prophet, related by himself or by disciples or by later "historians"; and (3) later additions by disciples or traditionists. These three groups also can be found in other prophetic books of the Old Testament. It is not known whether Amos' oracles of doom were also patterns for contemporary and later prophets, or if this reaction from the prophets was a spontaneous one during this period.

The nine chapters of the book of Amos, which are mainly written in poetry, begin with an introductory prose verse indicating the period of the prophet, his profession and his habitat. His profession is given as that of a herdsman or shepherd, but his stylistic ability and his knowledge of the ancient traditions of his people show that he was no ordinary one. The second verse is a superscription and motto, while i, 3–ii. 16 is a composite composition, consisting of oracles against neighbouring peoples, Judah and Israel. The other oracles are built in the same way, and they are grouped together according to ancient near eastern patterns. It is probable that the prophet himself was responsible for the arrangement; for any compiler not only must have possessed great rhetorical and stylistic ability but also must have reshaped some of the oracles. The two first chapters and ix, 7 indicate clearly that God in the eyes of Amos was not nationally limited; here are glimpses of universalism like those found later in Deutero-Isaiah.

In ch. iii–vi the prophet pronounces a series of oracles against Israel: with arguments to show why the doom of Israel was necessary. It is here that he speaks of the day of the Lord as a day of lamentation, darkness and destruction (v, 16–20). The people of Israel had forgotten their ancient social solidarity: they suppressed the poor and put their trust in elaborate worship in the temple of Bethel and Gilgal (v, 4 ff). Therefore the doom had to come. In vii, 1–9, 10 several visions of the prophet are declared, interrupted by the narrative of the incident when the priest Amaziah turned Amos out of the king's sanctuary in Bethel (vii, 10–17). The two first visions, of locusts and of fire, in vii, 1–6 are supposed by some scholars to be from an early stage in the preaching of Amos, because in them Yahweh holds his doom back. There are, however, no suggestions in the text to support this theory. The last part of the book (ix, 11–15), which speaks about the restoration of the Davidic kingdom and the return of the exiles, is considered by many scholars to be an addition to the original text, but opinions diverge on this point.

Amos v, 25 is quoted by Stephen (Acts vii, 42), and Amos ix, 11–12 (the passage at the end about the rebuilding of the fallen booth of David) is quoted by James at the Council of Jerusalem (Acts xv, 16–18), but in neither case is Amos named. In later ages Amos was remembered for his prophecies of doom and for the oracle of the rebuilding of the house of David. In the eyes of the church

fathers all his prophecies had been confirmed. Modern interpreters have first and foremost seen Amos as the first prophet of doom, who showed a way for his contemporaries and for later prophets.

Authorship and Date. — The book contains the words of the prophet Amos, who in the introductory verse is said to have had his visions two years before the earthquake, in the days of Uzziah, king of Judah, and of Jeroboam II, the son of Joash, king of Israel. King Uzziah, also called Azariah, reigned from c. 783 to c. 742 B.C. and Jeroboam II from c. 786 to c. 745 B.C. It is generally supposed that Amos acted as a prophet only for a short period, most probably beginning c. 760 B.C. From many of his words and especially from ch. vii it can be seen that he worked in Israel, the northern kingdom, although he had previously lived at Tekoa near Bethlehem, in the southern kingdom of Judah.

Amos' words were preserved by temple circles in Jerusalem, and thus reached their established place in the Old Testament. His oracles were most probably not written down as soon as they were uttered, nor were they ever written by the prophet himself, although he may have been able to write. Oral transmission was the usual one for oracles like his. Several features in the book indicate this, one of them being the way in which the narrative about the visit of Amos to the temple of Bethel has been inserted among the visions in ch. vii. Probably before the northern kingdom was destroyed by the Assyrians in 722 B.C. it was found necessary to have the oral traditions written, and thus the words of Amos were conveyed to Judah.

AMOSITE: see ASBESTOS.

AMOY (OR HSIA-MEN), formerly also Ssu-ming, one-time treaty port in the province of Fukien (*q.v.*), on the highly indented southeast coast of China (24° 27' N., 118° 05' E.). Amoy's population (1953 of 224,330 made it the second largest city in Fukien. The city is on the southwest arm of hilly Amoy Island, about 45 sq.mi. in area, at the head of a wide bay at the mouth of the Chiu-lung river. Its deepwater anchorage is well protected from late summer typhoons and is one of the finest on the coast. The city's natural hinterland was long confined to southeast Fukien where tea for Europe attracted British and Dutch traders in the 18th century, and from whence Chinese traders and overseas settlers set out for T'aiwan (Formosa), the Philippines and Malaya. By the treaty of Nanking, 1842 (see CHINA: *History*), Amoy was opened as one of the five original treaty ports, with westerners residing in the international settlement on Kulangsu Island, one-half mile to the west; in 1943 both the United States and Great Britain relinquished their special privileges. With the decline of tea exports in the late 19th century, Amoy stagnated commercially except for shipments of native paper, fishing nets, pottery ware, canned fruits and sea foods to the Chinese in southeast Asia. Remittances from Chinese living abroad have been locally important, as have been such activities as the founding of Amoy university by K. K. Tan, an Amoy man in Malaya, and the planning of the modern municipal water reservoir by Homer Ling of Manila.

During the 1950s the area became increasingly important in the economic and military planning of the government of the Chinese People's Republic. On Dec. 9, 1956, the first train steamed into Amoy city, marking the completion of a 433-mi. railway from Ying-t'an, northern Kiangsi, and requiring 3.1 mi. of filled causeway from Chi-mei on the north. A branch to Foochow joined at Nan-p'ing, Fukien. This line provided a means for tapping the interior resources such as coal, iron, lumber and sugar; it also had military value because of its proximity to the Nationalist-held islands of Quemoy (Chin-men) and T'aiwan. (TE. H.)

AMPELOPSIS, a genus of about 20 species of woody, climbing, tendrill-bearing vines of the grape family, Vitaceae. Strongly resembling the grapevine in habit, native to Asia and North America, some of them are cultivated as ornamental climbers. They

have inconspicuous flowers, but showy, coloured berrylike fruits. The pepper vine (*A. arborea*), somewhat shrubby, with pinnate leaves is found in the southern United States and Mexico. The simple-leaved ampelopsis (*A. cordata*) occurs in the southern United States. The ampelopses are of easy cultivation in a variety of soils, but as they lack the sucking disks of the Virginia creeper, these vines need tying to their supports. All are hardy in England and the United States.

The Virginia creeper (*q.v.*) and the Boston or Japanese ivy were once placed in this genus but are now considered as belonging to *Parthenocissus*. (N. Tr.)

AMPÈRE, ANDRE MARIE (1775–1836), French physicist, who pioneered in electromagnetism, was born at Polémieux, near Lyons, Jan. 22, 1775. From about 1796 he gave private lessons at Lyons in mathematics, chemistry and languages; and in 1801 he removed to Bourg, as professor of physics and chemistry, leaving his ailing wife and infant son at Lyons. His wife died in 1804 and he never recovered from the blow. In 1809 he became professor of mathematics at the École Polytechnique in Paris. There he continued his scientific researches and multifarious studies with unabated diligence. He was admitted to the Institut National in 1814.

It is on the service that he rendered to science in establishing the relation between electricity and magnetism and in developing the science of electromagnetism, or, as he called it, electro-dynamics, that Ampère's fame mainly rests. On Sept. 11, 1820, he heard of H. C. Oersted's discovery that a magnetic needle is acted on by a voltaic current. On the 18th of the same month he presented a paper to the Académie des Sciences, containing a far more complete exposition of that and kindred phenomena.

The whole field thus opened up Ampère explored with characteristic industry and care, and developed a mathematical theory which not only explained the electromagnetic phenomena already observed but also predicted new ones. Late in life he prepared a remarkable *Essai sur la philosophie des sciences*, and wrote many scientific papers, including two on the integration of partial differential equations (*Jour. École Polytechn.*, x, xi). He died at Marseille on June 10, 1836. See also **MAGNETISM: History**.

AMPÈRE, JEAN JACQUES ANTOINE (1800–1864), French critic, scholar and traveler who introduced works of foreign literature to France. The son of André Marie Ampère (*q.v.*), he was born at Lyons on Aug. 12, 1800. His life was largely dominated by his platonic love for Mme Recamier with whom he long corresponded. On his first journey to Germany, in 1826, he was greatly esteemed by Goethe, as later he was in France by Sainte-Beuve. In his wide knowledge of foreign civilizations, on which he lectured, as well as in his theories of the environmental influences on history, he was a precursor of H. A. Taine. He was a professor at the Sorbonne, at the Collège de France, and in 1848 he was elected to the French academy. Later, in the company of Prosper Mérimée, he traveled to the near east, and in 1852 to the United States and Mexico where he predicted the cutting of the Panama canal.

Among Ampère's works of research are his *Histoire littéraire de la France avant le 12^e siècle*, 3 vol. (1839–40) and his *Histoire de la formation de la langue française* (1841). His major historical work is *L'Histoire romaine à Rome*, 4 vol. (1861–64). He died at Pau on the night of March 26/27, 1864.

(1875); L. de Launay, *Un amoureux de Mme. Recamier* (1927); P. Mérimée, *Portraits historiques et littéraires* (1928); H. E. F. Haufe, *Jean-Jacques Ampère. Ein Kritiker der Frühromantik* (1935); L. Mallez, *Le Roman d'amour de Jean-Jacques Ampère* (1937).

AMPÈRE METER or **AMMETER**, an instrument for measuring electric currents. Ammeters used for the measurement of direct current are moving iron or moving coil low resistance galvanometers. For measuring alternating current, the instrument is, in general, a form of dynamometer, measuring the current flowing through two sets of coils which are connected in series. See **INSTRUMENTS, ELECTRICAL MEASURING**.

AMPERSAND, the name of the sign, & or &, which is a

combination of the letters *e*, *t*, of the Lat. *et*, and; a corruption of the mixed English and Latin phrase, "and *per se* and," of which dialect forms are, "ampussyand," or "ampersand."

AMPHETAMINE, introduced commercially as **BENZEDRINE**, is one of a series of synthetic drugs with pronounced stimulatory actions on the central nervous system. It is a colourless, mobile, slowly volatile liquid, with an acrid taste and a slight odour of geranium leaves. The most widely used preparation of the drug is amphetamine sulfate, a white, odourless powder with a slightly bitter numbing taste. Other members of this series include dextro-amphetamine (Dexedrine) and methamphetamine (Desoxyn).

In adequate doses, these drugs partially overcome the effects of anesthetics, narcotics, hypnotics and alcohol. All cause profound psychic effects, including wakefulness and mental alertness, increased initiative and elevation in mood, enhanced confidence, euphoria or elation, lessened sense of fatigue, talkativeness and increased ability to concentrate.

The stimulating effects of amphetamine make it useful for the symptomatic treatment of certain mild nervous depressions and, to a lesser extent, the more severe depressions accompanying some forms of mental disorder. In chronic alcoholism, the drug is of value as an aid to psychological suggestion in helping patients abstain. It is also useful for the management of narcolepsy, a condition marked by an uncontrollable desire for sleep. In that form of Parkinson's disease (shaking palsy) occurring after brain inflammation, the administration of amphetamine in conjunction with other therapeutic agents may relieve muscle rigidity. Amphetamine effectively dulls the appetite when taken before meals, and therefore is widely used as an adjunct to dietary restriction in a weight reduction.

Amphetamine can produce undesirable effects, the commonest of which is overstimulation with restlessness, inability to sleep, tremor, tenseness and irritability. Abdominal cramping with nausea, vomiting and diarrhea also may occur. Large doses, sometimes taken with suicidal intent, can produce loss of consciousness, collapse and death.

Indiscriminate use of amphetamine to overcome fatigue and sleepiness or to provide increased energy and alertness is common, particularly among truck drivers, athletes and students. The council on drugs of the American Medical Association in *New and Nonofficial Drugs, 1958*, pp. 189–190 (J. B. Lippincott Co., Philadelphia) has commented as follows regarding the use of the drug in normal persons:

The use of amphetamine to alleviate sleepiness and fatigue by persons not under medical control is to be condemned. The dangers lie in the elimination of the warning signal of fatigue in individuals who are overdoing, the possibility of habit formation on continued use, and undesirable circulatory effects. Collapse has occurred in some such cases. Except when administered under the strict supervision of the physician, its use is not recommended for developing a sense of exhilaration, increased energy and capacity for work; nor as a "pick-me-up" following temporary alcoholic overindulgence.

Although amphetamine can be obtained legally in the United States, as in Great Britain and most other countries, only on the prescription of a physician, illicit sale and distribution is common and constitutes one of the major grounds for prosecution under the Federal Food and Drug laws.

Because of its vasoconstrictive action, which is similar to that of epinephrine (adrenaline), amphetamine has been used by inhalation to produce shrinkage of the nasal mucous membrane in hay fever, asthma, acute sinusitis and similar conditions. Excessive improper use of Benzedrine inhalers has given rise to serious toxic effects, and U.S. and British manufacturers no longer make inhalers containing amphetamine.

Addiction to amphetamine can occur after prolonged use, but this is much milder in form than is addiction to narcotic drugs. The severe abstinence syndrome characteristic of the morphinelike drugs does not develop when amphetamine is withdrawn abruptly, although tremor, depression, weakness and gastrointestinal symptoms have been observed. Except in Japan, where amphetamine addiction became fairly common after World War II, the number of amphetamine addicts is probably small, certainly far smaller than the number of narcotic drug addicts. Despite its relative un-

commonness and mildness, however, amphetamine addiction is a serious problem to the person concerned, since profound personality defects always underlie the tendency to drug abuse. In the United States, amphetamine addiction frequently is associated with similar abuse of barbiturates or alcohol. (J. C. BN.)

AMPHIARAUS, a celebrated seer and prince of Argos, son of Oicles (or Apollo) and Hypermetra. He took part in the voyage of the Argonauts and in the chase of the Calydonian boar. He foresaw the disastrous issue of the war against Thebes and at first refused to share in it, but his wife, Eriphyle, bribed by Poly-nices with the fatal necklace of Harmonia, persuaded him to set out on the expedition. Knowing his doom, he bade his sons, Alcmaeon and Amphiloehus, avenge his death upon their mother.

On the defeat of the Seven, Amphiarus, pursued by Periclyme-nus, would have been slain had not Zeus opened a chasm into which the seer, with his chariot and horses, disappeared. Thereafter he was numbered with the immortals and worshied as a god. Near Oropus, on the supposed site of his passing, his sanctu-ary arose, with healing springs and an oracle famous for its interpretation of dreams. There was another temple dedicated to him on the road from Thebes to Potniae, and here was the oracle of Amphiarus consulted by Croesus and Mardonius.

AMPHIBIA, a class of backboneed animals sometimes known as the Batrachia. In the general classification of the animal king-dom, Amphibia are placed between the fish and reptiles. Living Amphibia include the frogs, toads, salamanders and caecilians, all of which have a smooth or rough but not scaly skin. Like the fish and reptiles, they are cold-blooded (poikilothermic or ectothermic); *i.e.*, their body temperature is related to the temperature of their environment.

Most Amphibia have four legs and live on land, but unlike other tetrapods they respire largely through their skin. Most of them lay their eggs in water; as the young develop they pass through a larval aquatic stage in which breathing is accomplished by external gills; the gills are lost during metamorphosis into the adult stage. The egg, even when laid on land, is without a shell and does not develop the amnion or allantois (egg membranes) of reptiles, birds and mammals.

Modern Amphibia are readily distinguished from reptiles by many skeletal differences, but the fossil forms were so similar that no sharp distinction can be made between them. Fossil remains have also tended to bridge the gap between Amphibia and fishes.

The living groups of Amphibia are a small remnant of what was once a larger and more successful class; the fossil and extinct types of Amphibia outnumber the living types. The ancestors of the amphibians were the internal nared fishes of the Devonian pe-riod. From the ancestral amphibians arose a great diversity of fossil forms. These forms survived until the Triassic period. From these ancestral fossil amphibians the living orders of frogs, salamanders and caecilians are descended. (For chart showing geological eras see GEOLOGY: *Historical Geology*.)

KINDS OF LIVING AMPHIBIANS

Frogs.—Among the living Amphibia the frogs, or Salientia, are the best known. Members of this group are also called toads, tree frogs, tree toads and spring peepers. Characteristically, they are modified for jumping by having enlarged hind legs, shortened fore-legs and no tail.

From the eggs, which usually are laid in water, develop larvae commonly known as tadpoles, or polliwogs. The tadpoles are usually herbivorous whereas the adults are usually insectivorous or carnivorous. The duration of the tadpole stage varies according to the adaptations of the species and environmental conditions. After the larval development there is a period of metamorphosis during which gills are abandoned, lungs become functional and limb development is completed. Many frogs have modified this pattern by eliminating the free-swimming tadpole stage.

The approximately 2,000 species of frogs are widely distributed on all continents, although more than 80% of the species are found in the tropics. In Europe, one species is found as far north as 71° latitude, and in North America one species gets just above the Arctic circle. Frogs are known from the southern limits of Africa,

UNITED PRESS INTERNATIONAL

FIG. 1.—(LEFT) BULLFROG (*RANA CATESBEIANA*) AND (RIGHT) NORTHERN LEOPARD FROG (*RANA PIIPIENS PIIPIENS*)

Tasmania, Australia, New Zealand and South America.

The ancestors of the frogs appeared in the Triassic period about 200,000,000 years ago, but the modern frogs appeared in the Jurassic period about 160,000,000 years ago.

Salamanders.—The second best-known group of Amphibia are the salamanders, also known as newts, efts, spring lizards, water dogs, mud-puppies, hellbenders, tritons, congo eels and sirens. These amphibians characteristically have four legs and a tail, but some, for example the congo eels and sirens, have lost or reduced their appendages.

Many salamanders lay their eggs in water; from the eggs develop gilled larvae that later metamorphose into lung-breathing and/or skin-breathing adults. Some salamanders have evolved special types of eggs in which the larval stage develops; in others, the eggs are retained within the female, who gives birth to living young.

The approximately 200 species are found in Europe, North America, northern South America and eastern Asia. There are no salamanders in Australia, Central and South Africa, central and southern Asia, the Indo-Australian archipelago or the islands of the Pacific.

Salamanders date from the Upper Jurassic period (about 140,000,000 years ago).

Caecilians.—The caecilians, or Apoda, are the least known of the living Amphibia. They are tropical, burrowing, wormlike creatures that lack legs. They are always found in moist places and usually lay their eggs near or in water. Some are ovoviviparous (*i.e.*, the eggs develop and hatch inside the female) with reduced larval stages; some have gilled larval stages of long duration. About 75 species are known from tropical Central and South America, Africa, Asia and the tropical Asian islands.

EVOLUTION

Descended From Fishes.—The first Amphibia made their appearance about 350,000,000 years ago, but their ancestry lies among the early internal-nared fishes belonging to the rhipidistian branch of the Crossopterygii, or lobe-fin fishes. These fishes lived in the large, continental fresh-water swamps and seas of the Devonian

ISABELLE HUNT CONANT

FIG. 2.—FIRE SALAMANDER (*S. SALAMANDRA TAENIATA*)

and Carboniferous periods. They were fusiform fish covered with an armour of cosmoid scales, with lobe fins and a heterocercal tail. These fish had functional lungs and an internal narial system that was probably complemented by gill breathing. The paired pectoral and pelvic fins had bony elements similar to elements in the primitive amphibian limb. The teeth were of the labyrinthodont type.

FROM F. AND P. SARASIN

FIG. 3.—CAECILIAN (ICHTHYOPHIS GLUTINOSUS) IN BURROW GUARDING EGGS

In the transition from rhipidistian fish to primitive amphibian many major anatomical and physiological changes had to take place. Probably due to the desiccation of the great fresh-water swamps, natural selection favoured those fishes that were best adapted to traversing short areas of dry land in order to get to the next pond, lake or other water body. The rhipidistian fish gave rise to the earliest amphibian fossils known—those belonging to the Ichthyostegalia.

These first amphibians had many skull features similar to the ancestral fish, but the opercular bones and probably the gill apparatus were reduced in the adult. The olfactory area in the anterior portion of the skull was enlarged and the posterior part was reduced, a reversal of the condition in the ancestral fish. The vertebral elements were only slightly better developed than in the ancestral fish with a slight increase in bony elements and a decrease in notochordal elements. In general the vertebral plan foreshadows the type found in the Rhachitomi. The pectoral and pelvic girdles and probably the limbs were well developed. The primitive amphibian probably carried his body well off the ground. A fishlike tail was retained with some dermal rays.

Early Adaptations.—The transition from crossopterygian fish to ichthyostegian amphibian enforced stringent selection on the early land vertebrate populations. Accommodation had to be made to the new environment. The buoyancy of the water no longer supported the body, and the vertebral column and the limbs had to support the body against gravity. The ancestral amphibian was no longer bathed continuously by water, and as a consequence the water conservation mechanisms in the skin and kidneys slowly evolved with increasing terrestriality. The return to the water for fertilization and egg-laying by the ancestral amphibian was a return to his ancestral habitat. Here external fertilization took place and the larval gill forms (the branchiosaurs) underwent their metamorphosis, as evidenced by the fossilized remains of

these larval forms.

Among the earliest derivatives of the Ichthyostegalia are the Embolomeri that appeared in the Carboniferous period. These were still aquatic or partially aquatic forms with a vertebral column strengthened by well-developed interlocking articulations (zygapophyses) and two equally developed central bony elements (pleurocentrum and intercentrum) over which rode the neural arch. The skull was relatively broad and flat with the orbits placed dorsolaterally. The skull was highly ossified but the limbs relatively weak. This line of amphibians was definitely tending toward terrestrial life although still highly aquatic. A closely related order, the Seymouriamorpha, has been placed sometimes among the reptiles and sometimes among the Amphibia. Many features of the skull of seymouriamorphs, such as the skull roof, clearly indicate relationship with the embolomeres. By the Permian period the embolomeres became extinct.

Rhachitomi and Stereospondyli.—An early and most successful derivative of the first amphibians were the Rhachitomi. These amphibians appeared in the Carboniferous and became extinct by Triassic times. These relatively terrestrial amphibians had a well-developed vertebral column with two bony elements—a large intercentrum and a smaller pleurocentrum—in the vertebrae. (This condition bears a distinct resemblance to the Ichthyostegalia.) The skull was very broad and flattened with orbits turned dorsad. The limbs were developed. Some of these rhachitomes grew to a length of at least six feet and had the general appearance of a modern crocodile.

By the end of the Permian or beginning of the Triassic, another group, the Stereospondyli, evolved from the Rhachitomi. These were secondarily aquatic amphibians with reduced ossification in the skull, weak limbs and a weak vertebral column. The skull became very flat and the vertebral centra became reduced to a single intercentral element. By the Triassic period this group was the dominant group of amphibians but became extinct shortly thereafter.

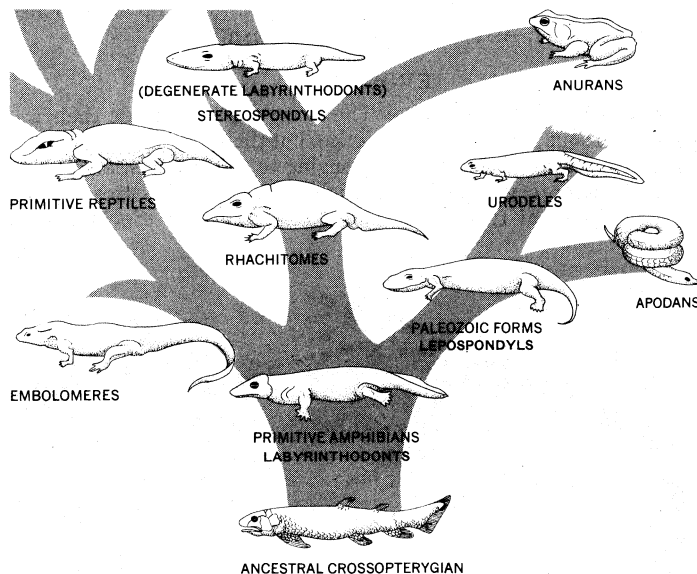

Lepospondyli.—By the early Carboniferous (Mississippian) period there appeared another major group of amphibians, the subclass Lepospondyli. Although not as abundant as the before-mentioned groups of the Apsidospondyli, they still present an abundant fossil record in some cases. This group is characterized by the development of vertebrae as a bony cylinder around the notochord. It is the apparent similarity of the vertebrae of the Aistopoda, Nectridia and Microsauria with that of the Crodela and Apoda that places these groups in the same subclass. The Aistopoda were small snakelike forms with many vertebrae. The Nectridia were snakelike or peculiar aquatic forms with hornlike extensions of the skull and relatively weak bodies. The Microsauria were relatively unmodified in general appearance and build.

Frog Ancestry.—Among the living Amphibia the most successful group are the frogs. Their primary adaptation is the one for jumping, which involves loss of the tail, reduction of the vertebral column, elaboration of the pelvic girdle and enlargement of the pelvic limbs with shortening of the forelimbs. The jumping mechanism may have developed because it enabled the frog to escape from his enemies by outjumping them on land and outswimming them in the water.

The ancestry of the frogs is not yet clearly understood, but it most probably lies either among the Rhachitomi or the primitive Embolomeri. *Protobatrachus* of the Proanura has a froglike skull but little else indicating the major frog adaptation. There is no evidence of the frog's ancestry between the above Triassic form and the first frog remains from the Upper Jurassic (about 140,000,000 years ago). It is plain that by the Cpper Jurassic the frogs had developed their primary adaptation, the jumping mechanism, as is evidenced by the pelvic girdle.

The fossil history of the modern frogs is still fragmentary. Those families (Montsechobatrachidae, Notobatrachidae, Leiopelmididae) that are provided with nine or more presacral vertebrae, ribs, amphicoelous vertebral articulation and a supposedly primitive, weakly joined, pectoral girdle are considered primitive.

The modern frogs appeared in the Cretaceous and were probably first represented by a leptodactylid type. From this type most

FROM ALFRED S. ROMER, "THE VERTEBRATE STORY": © THE UNIVERSITY OF CHICAGO

FIG. 4.—FAMILY TREE OF THE AMPHIBIA. THE THREE SURVIVING GROUPS ARE SHOWN AT UPPER RIGHT

of the advanced families are descended.

Caecilian Ancestry.—The caecilians and salamanders are believed to be related most closely to the other lepospondylous groups of Amphibia. This belief is based primarily on the development of the vertebral centra. There are many students of this problem, however, who believe that the very definite anatomical resemblance between salamanders and frogs may indicate a closer relationship.

On the basis of skull anatomy the caecilians are believed most closely related to a lepospondylous form such as *Lysorophus*. Since there is no fossil record for the caecilians the comparisons must be made between the living forms and their fossil relatives. Caecilians are characterized by a wormlike body that is divided into many external segments. These are primarily burrowing forms that feed on small invertebrates. Embedded in their skin are small dermal plates homologous to the dermal armour of ancient fossil Amphibia. All the living genera are placed in a single family that is circumtropical in distribution.

Salamander Ancestry.—The ancestry of the salamanders is poorly understood, although parts of the salamander fossil record are complete. The first salamanders are known from the Lower Cretaceous of Europe and North America and the Upper Jurassic

FIG. 5.—RESTORATION DRAWING OF A LABYRINTHODONT. ONE OF THE PRIMITIVE AMPHIBIANS. FROM THE LATE DEVONIAN OF EASTERN GREENLAND

of North America.

It is generally believed that the most primitive living salamanders are the Hynobiidae of Asia and eastern Europe. These salamanders are characterized by their method of external fertilization. The Cryptobranchidae, which developed from the primitive hynobiidlike ancestral type, are represented by two living genera, *Cryptobranchus* of the eastern United States and *Megalobatrachus* of China and Japan. These are essentially gill-breathing, giant derivatives of the hynobiids and are probably examples of a type of neoteny (the development of sexual maturity in the gilled larval stage). The Cryptobranchidae are like the Hynobiidae in having external fertilization. The fossil record for the genus *Megalobatrachus* is rather complete and is represented in the Tertiary period (about 70,000,000 to 1,000,000 years ago) of Europe by the genus *Andrias*.

From this basal group have evolved the higher salamanders, all of which have an internal fertilizing mechanism whereby the female picks up the sperm from the spermatophore produced by the male. In North America there is the family Ambystomidae with four or five living genera. In this family the development of neotenic forms is quite common. Another large family is the Salamandridae, with similar reproductive adaptations. This family, now found both in the new world (two genera) and in the old world, had already appeared by the beginning of the Tertiary and probably will be known from Cretaceous deposits; they probably gave rise to several other groups. The Amphiumidae or congo eels, a group of large eellike salamanders with reduced limbs, are restricted to the swamps of southeastern United States.

The Proteidae (sometimes regarded as two separate families, the Necturidae and Proteidae) is a family of two neotenic genera, *Proteus* and *Necturus*. The ancestry of *Proteus* is known to be

from a Middle Eocene form, *Palaeoproteus*, of Germany. The relatively reduced skeleton and musculature is due to neoteny and the general similarity to larvae of salamanders in general. The family Plethodontidae is one of the successful derivatives of the salamandroid complex and is characterized by the loss of lungs and related parts of the pulmonary circulation. These losses probably represented an early adaptation to mountain-stream life with later diversification into more aquatic and terrestrial habitats. The family has been reported from the beginning of the Tertiary era. It is found today primarily in the new world with one species, *Hydromantes italicus*, from France and Italy. Many genera still inhabit the primitive mountain-stream habitats but others have become terrestrial and have invaded the leaf mold of the forest floor. Others have become aquatic through neoteny, reaching such extreme cases as shown in the genera *Typhlomolge* and *Haideotriton*. Members of a section of this family have invaded the moist cool forest of Central America and are the only salamanders that now inhabit the tropics. These salamanders breathe primarily by cutaneous respiration and like all salamanders are restricted to moist terrestrial conditions. In general this group is more sensitive to water loss and heat than the equally successful Salamandridae.

The family Sirenidae is one of the most isolated of the salamander families. Studies based on blood serum and anatomy indicate it is only distantly related to the other salamandroid salamanders. Its fossil record is rather well known and apparently goes back to the Early Cretaceous (130,000,000 years ago). Its known past and present distribution is completely within North America. Today these gill-equipped salamanders are restricted to the swamps of the eastern United States and range in length from several inches to two or three feet.

MODERN AMPHIBIANS

Habitat.—**Physiological Limitations.**—The living members of the class Amphibia have reached all the continents, continental islands and most of the oceanic islands. They have achieved this in spite of limitations inherent in their physiology.

One major limitation is the ease with which they lose water, either as a result of simple desiccation or by being placed in salt water. Few amphibians ever live under true desert conditions, and those that do are able to survive only because they associate themselves closely with whatever water is available. The amphibians (usually frogs and not salamanders) that occur under such situations made their way into the desert under more pluvial conditions or were introduced by humans.

Many frogs have shown great ability to colonize oceanic islands, despite their inability to tolerate salt water. Experimental studies have shown frogs are unable to survive in water whose salt content is equal to that of sea water. Yet many anurans have successfully colonized such oceanic islands as those of the Antilles, Polynesia and Micronesia. This they have done by floating on or in logs or fallen trees that are carried in currents or by storms. It is possible that during and immediately after tropical storms enough fresh water is present on the surface of the sea to reduce the effect of the salt water on the frogs. Salamanders, by way of comparison, have been completely unsuccessful in this type of colonization.

Introduction by Humans.—Some amphibians have been distributed through human agency. The common marine toad, *Bufo marinus*, has been used as an enemy of various types of insects such as those in the sugar fields. This species has been introduced into the West Indies, Bermuda, Hawaiian Islands, tropical Australia, New Guinea, the Solomons and other Pacific islands. It is native only in tropical America. The American bullfrog, *Rana catesbeiana*, and the European edible frog, *Rana esculenta*, have been introduced for food.

Natural Range.—Frogs generally occur farther north than salamanders. *Rana temporaria* reaches 71° N. in Scandinavia and probably farther north in Asia. *Rana sylvatica*, the wood frog, gets above the Arctic circle in northwestern North America. *Hynobius keyserlingii* gets above the Arctic circle in Siberia, but no other salamanders approach this elsewhere. The salamanders of north-

ern Europe (*Salamandra* and *Triturus*) do not get farther north than 63°. In North America the genus *Plethodon* reaches 55° N. in eastern Canada and the genus *Ambystoma* reaches 59° N. in Alaska. In the southern hemisphere, only frogs reach the tips of the southern continents.

Salamanders are found only on continental islands, such as the British Isles, Japan, the Ryukyus and Formosa. Caecilians mainly inhabit only the continental tropics but get to such continental islands as Ceylon, Sumatra: Java and Trinidad, and to such isolated islands as the Philippines. Frogs are on all continental islands and get to such isolated oceanic islands as the Seychelles, Madagascar, New Zealand, the Indo-Australian archipelago, the Philippines, the Solomons, Palau, the Fiji Islands and the Rest Indies.

The frogs are the most versatile of the living Amphibia in ability to adjust to climate. The caecilians are almost completely tropical, barely entering the edges of the temperate zone in Australia and South America. Salamanders are practically restricted to the north-temperate zone. The Salamandridae barely gets into the Asiatic tropics, whereas the Xmbystomidae ranges into the tropical zones of Mexico but at high altitudes. The Thorinae, one branch of the lungless salamanders (Plethodontidae), has invaded the tropics in Central America and northern South America. Such genera as *Bolitoglossa*, *Chiropetrotriton*, *Magnadigitata*, *Oedopina* and *Pseudoeurycea* have invaded the tropics but primarily in special, localized cool habitats.

In peculiar habitats such as caverns, caves and isolated water holes many salamanders and frogs manage to survive by becoming specialized, although frogs rarely invade deep into caves because their visual equipment prevents them from passing beyond semi-darkness. Salamanders often adapt to cave life by losing their pigmentation and eyes, as in *Typhlotriton*, *Typhlomolge*, *Proteus* and *Haideotriton*. Salamanders that become associated with deep underground waters often become sexually mature in a larval stage, as in *Typhlomolge*, *Haideotriton* and *Proteus*. Under severe aridity or other conditions that make land surface uninhabitable, many other species of salamanders also become neotenic. Such is the case in western North America, where the genera *Ambystoma* and *Eurycea* have many isolated populations that are neotenic, probably because of reduced flow of thyroxine, the hormone produced by the thyroid gland. The metamorphosis steps seen in *Ambystoma* and *Eurycea* probably represent equivalent stages in the evolution of the perennibranch (permanent gills) salamanders, such as *Necturus*, *Proteus*, *Typhlomolge*, *Haideotriton* and *Siredon*.

Life History.—Most Amphibia lay their eggs in water; where they hatch into larvae or tadpoles destined to spend a more or less extended period in this element before metamorphosing into terrestrial adults similar to their parents. The larval state seems to be an inheritance from their crossopterygian fish ancestors. Even primitive Amphibia underwent a metamorphosis, as is proved by fossil remains of larval labyrinthodonts.

Metamorphosis represents a period of tremendous change in both the morphology and physiology of Amphibia. It is marked by such external changes in salamanders as the reduction of the external gills, the loss of the tail fin, the shedding of the larval skin, the formation of eyelids, etc. Fundamental changes in skull form and throat musculature also take place. In frogs metamorphosis is indicated by a freeing of the forelimbs by autolysis of local areas in the operculum, by radical changes in the shape and structure of the head and by absorption of the tail.

Certain groups of salamanders, as mentioned previously, fail to metamorphose. This phenomenon appears as a variation in the life history of many of the salamanders that normally metamorphose, particularly in species that pass their larval period in deep, cold water. Neoteny in the latter case is due to the failure of the thyroid to function, but the causes of arrested development in the case of groups unknown as metamorphosed individuals is more complex. Neoteny is not a new development in the Amphibia. It is found even in the Permian *Dvinosaurus*.

Some salamanders and many tropical frogs produce large yolked eggs which they lay on land, although a few retain them within the oviducts until the young are born, more or less fully developed. Only one genus of frogs is ovoviviparous; it includes two

FIG. 6.—TWO AMPHIBIAN LARVAL TYPES. (ABOVE) FROG TADPOLE HAS GILLS COVERED BY FLAP OF SKIN; (BELOW) SALAMANDER LARVA HAS FEATHERY EXTERNAL GILLS

African species (*Nectophrynooides tornieri* and *N. vivipara*). The breeding habits of the Amphibia are often elaborate and one may trace within the group a gradual evolution in many of the instincts associated with courtship and egg-laying.

Longevity.—Knowledge about the longevity of Amphibia is based on observations made of Amphibia in captivity. A European toad (*Bufo*) was kept in captivity for 36 years and a midwife toad (*Bombina*) for 29 years. Salamanders have been known to live longer. The large aquatic giant salamander of Japan has lived up to 60 years in captivity. The American spotted salamander and tiger salamander have been kept alive for 25 and 28 years, respectively. The small salamander of Japan, *Triturus pyrrhogaster*, lived for 32 years. Various European salamanders have been known to live 10 to 20 years.

Sense Organs.—Behaviour in Amphibia depends on the sensations received by the receptor organs. The primary receptor organs are the lateral line system, the olfactory organs, the eye, organs of taste, the ear and the skin. The lateral line system is located, as in the fish, in deep pits in the skin along either side of the head and body. These pits, lined by sensory cells with nerve connections, respond primarily to changes in pressure and to vibrations in water. The lateral line is found in the aquatic larval stages of most Amphibia and in most aquatic adult salamanders and some aquatic adult frogs. The organs of olfaction are poorly developed in most Amphibia but are fairly well developed in the salamanders. Some can use the sense of smell to locate their prey. Caecilians possess a tentacle on either side of the snout that is a tactile as well as an olfactory organ. The sensation of taste is primarily centred in the mouth region. Isolated groups of taste buds are distributed over the palate, jaws and tongue.

Frogs and salamanders are visually oriented animals and can perceive colours. They are extremely sensitive to movement within their visual field but have only slight ability to distinguish shape and size. The eye in caecilians is small and lies under a transparent patch of skin. It is sensitive to light intensity and direction, a response that is associated with the caecilians burrowing mode of existence. In general the eyes become reduced in cave dwelling and burrowing forms. Light-sensitive cells are present in the skin of all Amphibia, and frogs may react to light after the eyes are removed.

The sense of hearing is best developed in the frogs, due in large part to the well-developed tympanum. Frogs can hear sounds over a range of 50 to 10,000 vibrations per second. Some females are extremely sensitive to the call of the male of their species and can distinguish their call from the calls of males of related species. Hearing is poorly developed in salamanders and caecilians. Sounds from the water or ground are transmitted to the inner ear through the soft tissues and bones.

Tactile sensations are perceived principally through the skin. The skin is also a chemoreceptor and is sensitive to heat, cold and moisture. For example, the skin on the soles of the feet of toads is highly sensitive to differences in moisture content of the

substratum.

Behaviour.—The behaviour of Amphibia is more stereotyped than that of higher vertebrates. Their response to environment depends on the ability of their sense organs to perceive sensations. As a result frogs and toads are more visually oriented than salamanders and caecilians. Frogs and toads have a strong sense of location and have a homing reaction. They can learn and find their way out of mazes and can remember this for as long as a month. The home territory of frogs and toads is greater than that of salamanders, who may spend their entire lives within a few square yards. Complex breeding migrations are made by many frogs and salamanders. In most of these the males precede the females to a body of water that may be a pond, spring or stream. Complex prenuptial behaviour patterns occur in many salamanders.

Voice.—During the breeding season, which usually occurs at the end of winter hibernation, frogs congregate in ponds and pools. Here the males call until the females come to the water to mate and lay their eggs. In some species there is only one median balloonlike vocal sac under the lower jaw. In others there are two, one on each side.

Salamanders have very rudimentary vocal powers. Occasionally they emit a gargling sound or a small cry probably associated with defense, not with reproduction.

Each species of frog has a distinct call, ranging from the high-pitched "peep" of the spring peeper to the deep-throated croak of the bullfrog. To produce the sound, the frog forces air out of the lungs, past the vocal cords and into vocal sacs. The mouth is kept closed and the air is sent back and forth between the vocal sacs and the lungs, producing sound each time it passes over the vocal cords.

Enemies.—Amphibia have many enemies, including man, fish, birds, mammals and invertebrates. The enemies may eat the larvae, the eggs or the adults. Some invertebrates parasitize Amphibia; molds and bacteria also may attack them.

Economic Value.—Toads, because they feed indiscriminately on insect life, are of great use to farmers. During insect plagues toads feed on the dominant insect and tend to restore the balance of nature. Frogs and toads are used for food in many parts of the world, but successful frog farms are rare. Frogs require from two to five years to reach maturity, and large quantities of living insect food are needed during this period. Hence, in America almost the entire frog crop is obtained in the wild state.

Dried frogs and salamanders are used for medicinal purposes in various parts of the world, particularly in the orient. Their value as a cure is chiefly psychological. Probably the greatest use of Amphibia to humanity is their martyrdom to science. Frogs and salamanders, both in adult and young stages, have long been recognized as ideal laboratory animals. Some of our most fundamental discoveries in experimental embryology, endocrinology and general physiology have been made with amphibian material.

GENERAL MORPHOLOGY

Integument.—The skin of modern Amphibia may be rough and dry or smooth and moist, but it is never covered with scales as in nearly all reptiles. Many caecilians, however, have rings of minute scales hidden in the transverse folds of their skin. Aquatic or fossorial Amphibia, which rely to a large extent on their skin for respiration, usually have a thinner and smoother integument than terrestrial forms, but many exceptions to this rule occur, particularly in the Pipidae and Bufonidae. The fossil labyrinthodonts and lepospondyls were frequently well armoured with scales, especially on the ventral surface where these scutes of varying shapes and sizes were arranged, for the most part, in orderly rows converging toward the mid-line. In a few salamandrids and many tropical Salientia a secondary deposit of bone forms in the deeper dermal tissues and may produce encrustations ankylosed to the underlying bones. The bizarre casques of *Pternohyala*, *Triprion*, *Diaglena*, etc., are of this character. Less conspicuous bony covers on the skull appear in the spadefoot toads and various hylids, particularly the marsupial frogs. Similar bony growths extend to the skin of the back in various Salientia and in rare instances (*Brachycephalus*) may be ankylosed to the vertebrae. The epider-

mis covering warts or spines may be more or less cornified (horny) in various Urodela (*Desmognathus*, *Necturus*, etc.). In a few hynobiids thick horny pads occur on the palms and soles, while in the larvae of others the epidermis of the digits is extended into pointed claws. Similar horny claws occur on the three inner toes of the African pipids and may have been found on all the digits of some extinct Amphibia, for in one of the most primitive labyrinthodonts the terminal phalanges have the form of curved claws.

The integument of modern Amphibia is further distinguished from that of reptiles in being highly glandular. There are two main types of glands: the granular and the mucous. The granular may be broadly distributed over the dorsal surfaces or massed in folds or warts on the sides of the body. Its secretion is creamy, very irritating to mucous membranes and poisonous when taken internally. The mucous glands are more uniformly distributed over the body. They produce a slime less irritating to the nasal passages and conjunctiva but, nevertheless, toxic when injected into lower animals. Amphibia differ enormously in both the quantity and kind of integumentary secretion. Some species, such as the toads, secrete only when mistreated, while others, such as *Dendrobates*, *Bombina* and particularly the American *Plethodon glutinosus*, produce a copious irritating or sticky secretion when handled. Closely related species may differ considerably in their secretions. The South American *Ceratophrys americana* has a virulent poison while the much larger and more brightly coloured *C. dorsata* possesses an innocuous skin secretion. Frequently the secretions are odorous, certain closely related forms of *Rana*, *Bufo* and *Hyla* being readily distinguished by their odour alone.

The skin of the larva differs from that of the adult in that the glands are unicellular and the epidermis consists of only two layers of cells. Larvae approaching metamorphosis and most perenni-branches have a thicker epidermis equipped with multicellular glands. The superficial layer of epidermis is periodically shed by the adults, usually in one piece. The first shedding of the entire epidermis occurs normally at metamorphosis.

Pigmentation.—The coloration of Amphibia is due in part to a diffuse pigment distributed throughout the integument but chiefly to a number of cellular elements of which three main types may be recognized: first, white cells that owe their colour to a dense deposit of guanine (a pigment allied to the urates); secondly, the yellow cells that contain droplets of oil; and thirdly, the dark brown cells filled with melanin.

White cells are often clumped together in small areas under the epidermis, producing the white flecks on the backs of many salamanders or the white spots in some tree frogs. Other guanine-filled cells lie closely associated with the yellow and brown cells directly under broad areas of the epidermis and give the characteristic ground colour of these regions. Green is a mixed colour due to the blue rays of light reflected from the small guanine or "turbid cells" mixing with the yellow tone in the overlying yellow cells to produce a green. The blue reflections of the turbid cells are swamped by the white reflections of the subjacent tissues when the melanophores or dark cells are contracted. Brown is produced by the complete enclosure of the turbid cells by the expanded melanophores. The latter expand to surround the turbid cells when stimulated by cold, moisture and rough surfaces, or by hormones produced by the pars intermedia of the pituitary gland. The colour tone of a frog or toad at any one time may be due to either stimulations received through the skin or eyes or to the emotional state of the individual toad or frog.

Organs of Nutrition, Circulation and Reproduction.—Larval Amphibia suck on plant material with cornified papillae situated around the mouth.

As the larvae develop, teeth are formed. But not all Amphibia have teeth. Frogs have teeth only in the upper jaw. Some salamanders and caecilians have teeth on several bones of the jaws. Normally the teeth are used only to catch and hold the prey, not to chew.

The tongue may be attached to the front, rear or floor of the mouth. In some Amphibia the tongue secretes a sticky substance that helps hold the prey. In others the tongue is prehensile with an identical effect.

Adult Amphibia eat all kinds of animals: insects and their larvae, myriapods, mollusks, worms, small crustacea, arachnids, fish, other Amphibia, small reptiles, birds and even small mammals. They can be voracious eaters. An American toad kept in captivity ate 9,936 different insects in a three-month period. A marine toad ate 52 mosquitoes in one minute. Some Amphibia are discriminating in their choice of food and will feed only on one kind of insect, such as ants or termites.

Although the Amphibia have not evolved from the dipnoans, they show many similarities in their venous and arterial systems. The hearts of salamanders show various modifications according to the extent the lungs are used in respiration.

Fertilization in the Amphibia may be external or internal. Most female salamanders, except in the Hynobiidae and Cryptobranchidae, are equipped with a spermatheca, a series of tubules in the roof of the cloaca where the sperm remain after copulation until the time of fertilization. In these salamanders the sperm mass is emitted by the males in the form of spermatophores, small tufts of sperm attached to a gelatinous base. Courtship in the salamanders is primarily directed toward exciting the female sufficiently to ensure her picking up the spermatophore with the cloacal lips. The sperm then make their way into the spermatheca by their own efforts. The Apoda are equipped with a protrusible cloaca that is used as an intromittent organ. The male American leopelmid frog, *Ascaphus*, has a movable extension of the cloaca. In these forms, as well as in certain little-known African frogs that have no special apparatus for transmitting sperm, fertilization is internal. The gonads are variously modified in different groups to permit a greater freedom of the seminal ducts from the kidneys.

Skeleton.—Once vertebrate life was established on land it reverted not once but many times to the aquatic habitat long before the modern Amphibia appeared. Despite the frequent change of habitat the skeletal organization of the first Amphibia continued to evolve steadily in definite directions with time. In recent Amphibia, too, the fundamental structure has changed slowly while the various groups may show the widest adaptations. Ranids may be arboreal, aquatic or fossorial; plethodontids may be the same.

Skull.—The first tetrapods inherited a skull very similar to that of their fish ancestors. It consisted of a cartilaginous box, or chondrocranium, covered completely above by dermal bones and internally strengthened by bones that replaced the cartilage in part. This skull, the prototype of all tetrapod skulls, differed remarkably from that of modern Amphibia by the far greater number of skull elements it contained, by the greater ossification of the chondrocranium and by its reptilelike form.

The skull of the primitive Labyrinthodont agreed in most details with that of the osteolepid fishes. The skull roofs were similar except for a cluster of small bones in the nasal region in osteolepids. The distribution of the lateral line canals in both skulls facilitates the identification of lachrymal, prefrontal, jugal, postorbital, postfrontal, supra- and intertemporals. The spiracular notch of *Osteolepis* has become the otic notch and the elements bordering this and the orbit may be readily homologized. The palates agree remarkably in the small size of the interpterygoid vacuities and the almost identical position of the palatal and jaw bones. The distribution and replacement of the large teeth are identical in fish and tetrapod. An internal naris is present in all osteolepids and is identical in position, size and borders with that of primitive Amphibia.

The lower jaw of the first tetrapods differed greatly from that of modern Amphibia in the far greater number of elements it contained. It was, however, identical with that of the osteolepid jaw. The brain cases of osteolepids and primitive Amphibia were very similar but not identical.

Once this highly ossified and complex skull of the ancestral fish became established in land forms, it underwent enormous specialization. Very soon there began a progressive fenestration, the bones tending to segregate along lines of greatest stress. The solid domelike skull roof progressively lost various dermal elements until in the modern frogs only the premaxillary, maxillary, nasal, quadratojugal, squamosal, frontal and parietal are left. The more primitive salamanders still retain a lachrymal and prefrontal in

addition to the frog's equipment. The quadratojugal, although appearing as a separate element during ontogeny in the Urodela, later fuses with the quadrate. This loss of elements was perhaps largely due to a shortening of the skull. The second great change that developed as the tetrapod series evolved was the gradual flattening of skull. The third fundamental change was a progressive weakening of the bony organization of the skull with the result that the brain case became progressively less well ossified.

The most reduced part of the modern amphibian skull is the lower jaw. The primitive Amphibia inherited a complex mandible of many pieces. In primitive salamanders the only sections left were a dentary, a prearticular and articular and an angular. Coronoids are present in the larvae of most salamanders. The angular is fused with the prearticular in all members of this group above the Cryptobranchioidea. In caecilians a very early fusion of the jaw elements occurs in most genera, but the resulting element probably contains a coronoid as well as the dentary, articular and prearticular; two rows of teeth are present in many forms. In the Salientia the reduction is carried to an extreme, for only the dentary and prearticular are recognizable. The articular ossifies in very few Salientia and is then fused to the prearticular. The anterior end of Meckel's cartilage ossifies as a pair of distinct elements in some Ranidae, Hylidae and Bufonidae.

The osteolepid ancestors of the Amphibia had five branchial arches, while the modern Amphibia have at most four. The latter possess, however, a pair of laryngeal cartilages that may or may not represent the fifth branchial arch. The gill arches in the adult salamander or frog are modified by reduction and fusion.

Vertebrae.—The vertebrae of the Amphibia are often used as the basis for classifying the different subclasses, orders and suborders. Their history can be traced from the ancestral crossopterygian fish through the different groups of Amphibia and on to the amniote classes of vertebrates.

In the earliest amphibians and their ancestors, three separate elements can be recognized in the adult vertebrae: the neural arch, the pleurocentrum and the hypocentrum with its associated ventral arch and rib. In the rhipidistian ancestors of the early Amphibia the vertebrae are weaker in construction than in the Amphibia because the primary element, particularly in the centre of the vertebral column, was the notochord, although two thin, weak, bony elements, the pleurocentrum and hypocentrum, lie alongside the notochord under each neural arch. Such an arrangement gave little strength to the vertebral column, but this was efficient enough for an aquatic organism in which buoyancy was an important factor. These bony structures did not hinder the functioning of the axial skeleton as a flexible rod, which is so important in the more or less sinuous movement of the fish.

In the Ichthyostegalia the condition was intermediate between the rhipidistian fish and the earliest amphibian. In all later Amphibia the notochord is at least partially destroyed but may remain as an intervertebral element. The Ichthyostegalia have a modified rhipidistian plan with expanded hypocentrum (the larger centrum element) and pleurocentrum, plus erect large neural spines and zygapophyses. The pleurocentrum and hypocentrum of the rhipidistian fish have increased in thickness and compressed the notochord until it is but a narrow channel running through the middle of the vertebrae.

The Rhachitomi have taken this plan and elaborated it by developing a double centrum made up of two interlocking wedges, the intercentrum and pleurocentrum.

The Stereospondyli further developed the rhachitomous plan by reducing the size of the pleurocentrum (or eliminating it) so that in effect a single central element became the main supporting element of the vertebra. The Embolomeri have developed a double centrum with two equally developed elements, the hypocentrum (intercentrum of others) and pleurocentrum. Probably this primitive type of vertebra gave rise to the dominant, pleurocentrum type of vertebra of the seymouriamorphs and the amniotes.

The lepospondyls appear abruptly in the fossil record, and the intermediate condition is not known. But from a study of living forms it appears that the vertebra has a single spoollike centrum developed directly from bone, although on the basis of embryo-

logical evidence this centrum would be in the position of the pleurocentrum.

The origin of frog vertebrae is not yet clear, but they apparently can be derived from embolomerous, prerhachitinous or rhachitinous types of vertebra. Since the hypocentral elements are reduced in the frogs, there seem to be five basic types of centra in the Amphibia: (1) ichthyostegalian and rhachitinous; (2) embolomerous; (3) stereospondylous; (4) lepospondylous; and (5) anuran.

Ribs.—The ribs of primitive amphibians and reptiles articulate with all vertebrae, at least as far back as the middle of the tail. In phylogeny the sacral ribs become fused to the vertebrae first, then the caudals, next the lumbar, the cervical and finally the thoracic. In elongate salamanders the ribs have become reduced in number. *Siren* and *Amphiuma* have only the anterior thoracic vertebrae still retaining the ribs. In frogs the reductions have reached an extreme. Discoglossids retain three, leiopelmid retain only two ribs in the adult. The pipids have two ossified ribs in the larva, but these fuse later to the diapophyses. The bits of cartilage on the ends of the diapophyses of the higher frogs have been considered homologues of the ribs. This is perhaps a matter of definition. No ossified ribs appear as the distinct elements in the development of any Salientia above the Pipidae.

The ribs are shortest in the frogs and the long-bodied perennibranchs, longest in the primitive salamandrids. In *Tylotriton* and its close relative *Triturus walhi* the tips of the ribs may be long, pointed and actually protruding through the skin.

Pectoral Girdle.—The pectoral girdle of the first tetrapod was similar to that of the primitive bony fish except that a new dermal element, the interclavicle, had been added to its ventral surface in the mid-line.

The Salientia have retained the pectoral girdle of the more terrestrial primitive Amphibia. The interclavicle has been lost and a new structure, the omosternum, has arisen. The broadened ventral ends of scapulocoracoid bars have become fenestrated. The posterior rim ossifies as a separate centre, the coracoid, while the mesial and anterior part usually remains cartilaginous. The anterior rim is called the procoracoid, and the mesial part is called the coracoid cartilage. The sternum was possibly cartilaginous in the labyrinthodonts and branchiosaurs, although it is never found fossil in these groups.

The Urodela are specialized in the complete loss of the dermal elements. As if in compensation for this loss the coracoid cartilages are usually broadly dilated. The salamanders are primitive in that the scapulocoracoid usually ossifies as a single piece.

Pelvic Girdle.—The pelvic girdle of the first tetrapods has advanced beyond the conditions found in fishes in that a pubis, ischium and ilium are present, meeting in the acetabulum in a triradiate suture. The ilium, however, was not firmly attached to the sacral ribs. The ilium soon gained a firmer support to the sacral ribs.

Modern Amphibia have inherited the platelike pelvis of the primitive labyrinthodonts. The pubis is usually unossified, as in the higher labyrinthodonts. In a few Salientia the pubis region is ossified, but it rarely forms a separate bone. The pubis cartilage is of variable extent in the different families of Urodela, being more extensive in aquatic than in terrestrial forms.

Many salamanders exhibit at the anterior end of the pubis a Y-shaped cartilage called an epipubis or an ypsiloid apparatus; this structure serves to assist in controlling the shape of the lungs in those forms that use this structure as a hydrostatic organ. It seems to be a neomorph in the salamander group.

Limbs.—The Amphibia arose from some generalized crossopterygian. The skeletons of the paddles of only two of these primitive types of fishes are known. These fin bones are leglike in that they consist of a proximal element or humerus subtending two distal elements, a radius and ulna. The outer row of elements, however, are more numerous than the supporting elements in the hands or feet of tetrapods. The fundamental plan of single-proximal, double-median and multiple-distal elements was already well established in the fish ancestors of the tetrapods.

The chief problem in establishing the origin of the typical mod-

ern vertebrate limb concerns the distal segment. How many digits were present on the limbs of the first land vertebrates, and how many carpal and tarsal elements formed their support? *Diplovertebron* had five well-developed digits, as in the case of the oldest reptiles.

All modern Amphibia had only four digits in the hand. *Eryops* apparently had a stout prepollex (early form of thumb), a rudiment of the fifth finger (postminimus) and a cartilaginous block representing a sixth. In modern Salientia the prepollex is almost universally present and often hypertrophied in the male to ensure a better grip in amplexus. In Urodela, even in forms that are not known to practise amplexus, the prepollex is sometimes present and even bony. The modern Amphibia inherited a prepollex, four digits and a rudiment of a fifth digit in the hand.

In the foot of modern Amphibia there are five digits, as in *Diplovertebron*, but in most Salientia there is also a prehallux (early form of first toe); and in some primitive Urodela there are both a cartilaginous prehallux and a postminimus. In burrowing Salientia the prehallux is greatly enlarged to form the core of a "spade."

Numerous fusions and losses have occurred in the carpus and tarsus of modern forms. The Hynobiidae, Ambystomidae and Cryptobranchidae approach most closely the primitive condition. Salamanders with a reduced number of digits have suffered the greatest number of fusions. The Salientia have also diverged considerably from the primitive type. The tarsus of the Salientia is peculiar in the great elongation of the two proximal elements (astragalus and calcaneum) and in the loss or fusion of all the other elements except three or four that articulate with the bones of the "toes." This elongation of the proximal series gives the frog's hind leg the appearance of having three long segments instead of the usual two. Such a specialization is undoubtedly an adaptation to jumping, although various species living today have given up that habit.

CLASSIFICATION

The great array of living and fossil forms of Amphibia are classified below, with the living groups placed in their approximate phylogenetic position in relation to the fossil forms. The classification of the living forms is taken down to families to show the general diversity in these groups.

Subordinal groups are not included under the orders Anura and Urodela because of the general lack of agreement regarding this level of classification.

Subclass Apsidospondyli (amphibians with vertebrae preformed in cartilage and later changed to bone)

Superorder Labyrinthodontia (ancestral and fossil amphibians with generally heavy, low, depressed skulls, relatively primitive limbs and labyrinthine teeth; began their history in the late Paleozoic era)

Order Ichthyostegalia (among the most primitive amphibians, being intermediate between the ancestral lobe-fin fishes, the Crossopterygii, and the more advanced Amphibia; known from the Devonian to the Pennsylvanian periods)

Order Rhachitomi (fossil amphibians with rhachitinous vertebrae; appeared in the Mississippian period and became very abundant during the Permian period)

Order Stereospondyli (fossil group of primarily aquatic amphibians derived from the Rhachitomi; originated in the Early Triassic and became extinct by the earliest Jurassic period)

Order Embolomeri (fossil amphibian group that appeared in the Pennsylvanian and continued into the Permian period; members of this group are intermediate between the primitive amphibians and the first reptiles)

Superorder Salientia (frogs and their relatives)

Order Proanura (ancestral type with froglike skull but with limbs not modified for jumping; known from the Triassic period)

Order Anura (frogs and their relatives with hind limbs and pelvic girdle modified for jumping)

Families of frogs:

Montsechobatrachidae (primitive fossil frogs from the Jurassic of Europe and North America)

Notobatrachidae (primitive fossil frogs of South America)

Leiopelmididae (primitive living frogs from New Zealand and western North America)

- Discoglossidae (the midwife toad, the fire-bellied toad or unken, the ribbed frog of Europe, Asia, North Africa and the Philippine Islands)
- Pipidae (aquatic frogs lacking tongues; Surinam toads of South America and the clawed frog of Africa)
- Rhinophrynidae (small burrowing frog of Central America and Mexico)
- Pelobatidae (fossorial or partially fossorial spadefoot toads of North America and Eurasia)
- Pelodytidae (group of frogs similar to the preceding but lacking spadefoot and called "mud divers"; known from Eurasia)
- Palaeobatrachidae (modern type of fossil frog known from the Miocene of Europe)
- Leptodactylidae (modern type of frog found abundantly in South America, Central America, West Indies, Australia; known in the United States as the white-lipped frog, barking frog, robber frog and cave frog)
- Bufoidea (group similar to the above but lacking teeth on the upper jaw; commonly known as toads. Many species in North America; two species, the common toad and natterjack, in the British Isles; group occurs all over the world, partially by human introduction)
- Dendrobatidae (brightly coloured poisonous tree frogs of South America)
- Atelopodidae (brightly coloured tree frogs of Central America)
- Pseudidae (paradox frogs of South America)
- Hylidae (commonly known as the true tree frogs, usually with adhesive discs at the end of the digits that aid in climbing; usually arboreal but not always; practically a cosmopolitan group with many species in North America but unsuccessfully introduced into the British Isles)
- Ranidae (commonly known as the true frogs of the old and new worlds; the green frogs, gopher frogs, meadow frogs, wood frogs, river frogs of North America and the common frog of Great Britain; found all over the world; common laboratory frog in United States and Great Britain)
- Hyperolidae (Asiatic and African frogs and tree frogs closely related and similar to the preceding family)
- Microhylidae (the narrow-mouth toads of the Americas, Africa, southern and eastern Asia, Indo-Australian archipelago and Australia)
- Phrynomeridae (a single genus of frogs similar to the above family; found in Africa south of the Sahara)
- Heleophrynidae (a single genus of toadlike frogs limited to South Africa)

Subclass Lepospondyli (amphibians with vertebrae not preformed in cartilage)

- Order Aistopoda (group of late Paleozoic amphibians that are snakelike in form)
- Order Nectridia (generally elongate or snakelike aquatic or subaquatic amphibians of the late Paleozoic era)
- Order Microsauria (elongate, weak-limbed amphibians of the late Paleozoic era)
- Order Urodela (salamanders or living tailed amphibians with appendages)

Families of salamanders:

- Hynobiidae (Asiatic land salamanders with external fertilization; eastern Europe, and western and central Asia)
- Cryptobranchidae (hellbender of the eastern United States and giant salamanders of Japan and China; aquatic forms with external fertilization)
- Ambystomidae (tiger, spotted and burrowing salamanders of North America with internal fertilization)
- Salamandridae (newts, efts and salamanders of Europe, Asia and North America with internal fertilization)
- Amphiumidae (large snakelike salamanders with reduced limbs; called congo eels in the southeastern United States; with internal fertilization)
- Plethodontidae (lungless salamanders of the new world and Europe; with internal fertilization)
- Proteidae (the olm of Yugoslavia and the mud puppies of eastern North America; external gilled salamanders with internal fertilization)
- Sirenidae (dwarf sirens, mud sirens and great sirens of the southeastern United States; with internal fertilization)

Order Apoda (wormlike amphibians of a single circumtropical family, Caeciliidae)

AMPHIBIAN PLANE: see SEAPLANE.

AMPHIBIOUS WARFARE, a term applied to military operations characterized by attacks launched from the sea by naval and landing forces against hostile shores. The principal form is the amphibious assault which may be conducted for any of several purposes. It may be a prelude to further combat operations ashore, it may be to seize a site required as an advanced naval or air base, or it may be to deny the use of the site or area to the enemy.

The Allied counteroffensive in World War II (with the exception of the Russian front) was predicated upon a series of amphibious operations required to give re-entry into Axis-held territory. In the European theatre these operations were generally called invasions because they were carried out against large land masses and were followed by extensive land campaigns. In the Pacific theatre, because of the insular nature and limited land area of most of the Allied objectives, particularly in the central Pacific, the term seizure was commoner. Tarawa, Eniwetok, Kwajalein, Peleliu and Iwo Jima are classic examples of amphibious seizures. On the other hand, operations against the larger islands, such as the Solomons, New Guinea, the Marianas, the Philippines and Okinawa, shared many of the characteristics of an amphibious invasion of a large land mass. (See KOREAN WAR; TACTICS: *World War II*; WORLD WAR II.)

Other forms of amphibious warfare, which differ from the amphibious assault in that they do not require the firm establishment ashore of the landing force, are the amphibious withdrawal, the amphibious demonstration and the amphibious raid.

An amphibious withdrawal is the evacuation of forces from a hostile shore by sea. The evacuation of the British expeditionary force from Dunkirk, France, in 1940 and of the United Nations force from Hungnam, Korea, in 1950 were both large-scale amphibious withdrawals.

An amphibious demonstration is a show of amphibious force for the purpose of deceiving the enemy. For example, such a demon-

Green tree frog (*Hyla cinerea*) found in swampland and on the edges of lakes and streams in southeastern U.S.

Bullfrog (*Rana catesbeiana*), largest frog of the U.S., found throughout the eastern states and in most of the south. Grows to a length of six inches

A young Great Plains toad (*Bufo cognatus*), found chiefly in the north central plains states and in the southwestern U.S.

Southern leopard frog (*Rana pipiens sphenoccephala*). Together with the northern and Rio Grande leopard frogs, also a subspecies of *R. pipiens*, this is the most widely distributed true frog in North America

Two pictures taken less than one minute apart, showing the ability of the Couch spadefoot toad (*Scaphiopus couchi*) to bury itself by digging a burrow in the soil. Found in the southwestern U.S.

COMMON FROGS AND TOADS

Midwife toads (*Alytes obstetricans*), a small species—about 2 in. long—common to most of central Europe. After the eggs are laid, the male (left) carries them attached to his legs until they are ready to hatch

Colorado river toad (*Bufo alvarius*), found in the southwestern US and northern Mexico. It is noted for the strong poison it secretes from glands behind the eyes and along the legs when approached by a predaceous enemy

Small-mouthed salamander (*Ambystoma texanum*), a mole salamander found in the middle western and south central mostly underground

Sedge frog (*Hyperolius* species), an inch-long, multi-coloured rhacophorid found in tropical Africa

REPRESENTATIVE AMPHIBIANS AND THEIR HABITS

Eggs of the spotted salamander (*Ambystoma maculatum*), nearly ready to hatch. Like most other amphibians, these salamanders hatch as larvae and later undergo metamorphosis

An American toad (*Bufo terrestris americanus*) about to capture a mealworm with a thrust of its long, sticky tongue. All adult amphibians are carnivorous

Bell's ceratophrys (*Ceratophrys ornata*), a South American horned frog. The genus is toothed and predaceous, often feeding on other small frogs

Broken-striped newt (*Diemictylus viridescens dorsalis*), a salamander that, after spending about two years on land, returns permanently to the water as an adult

Red-eyed tree frog (*Agalychnis callidryas*), found in Mexico and Central America, lays its eggs in a foam and leaf nest that it builds on a branch above the water

American toad with its vocal sac enlarged as it prepares to sing. Although frogs and toads use their voices chiefly at mating time, they may also cry out in fear or in warning

São-Tomé caecilian (*Schistometopum thomense*). Caecilians are primitive limbless amphibians found in tropical climates

Two-lined salamander (*Eurycea bislineata*), lives in small brooks and streams of eastern US.

Tiger salamander (*Ambystoma tigrinum*). This is one of the mole salamanders, so-named because most members of this genus are found underground except during breeding season

Slimy salamander (*Plethodon glutinosus*), a large woodland salamander found in ravines or on hillsides in most of the eastern and southern US.

Spotted salamander (*Ambystoma maculatum*), a common and widely distributed species which breeds in woodland ponds in the early spring

A CAECILIAN AND FOUR COMMON SALAMANDERS

station was made against the southern beaches of Okinawa on April 1, 1945, to mislead the Japanese as to the site of the true landings.

An amphibious raid is a landing from the sea involving the temporary occupancy of the objective area. It is unique in that it ordinarily includes a planned withdrawal. Amphibious raids historically have had a variety of uses: to inflict loss or damage upon the enemy; to secure information; to create a diversion; or even for reasons of morale and training. Dieppe and Makin Island are noteworthy examples of World War II amphibious raids.

Early Historical Development. — The hydrography and geography of the Mediterranean have been particularly conducive to the conduct of amphibious operations, a fact which throughout recorded history is periodically reaffirmed. The battle of Marathon (490 B.C.), for instance, can be considered a successful counterattack by the Greeks against the beachhead established by the invading Persian host. The distinction between invasion and raiding was established very early. The requirement for specially trained troops was also soon perceived. The Romans, as early as the Punic Wars, employed specially trained legionnaires as marines. Julius Caesar, in particular, demonstrated his grasp of this form of warfare in his Mediterranean campaigns as well as in his two invasions of Britain.

The dark ages, following the decline of the Roman empire, are interesting from the viewpoint of amphibious warfare chiefly because they repeatedly demonstrated the vulnerability of western Europe and of Britain to the amphibious incursions of the barbarians from the north. These Norse amphibious techniques were combined successfully with French chivalry in William the Conqueror's invasion of England in A.D. 1066.

The middle ages, with warfare dominated by the armoured knight and the fortified castle, and with military thinking circumscribed completely by the laws of feudalism and the rules of chivalry, generated little in the way of amphibious innovations. An exception to this generalization can be found in certain of the waterborne crusades. For example, in Louis IX's crusade against Egypt (1249) the Genoese shipbuilders, going back perhaps to Roman designs, developed ramped galleys which could carry and launch through stern doors three or four smaller landing craft.

The Hundred Years' War (1338–1453), although marked by the repeated invasion of the Low Countries and France by the English, contributed little to amphibious knowledge. In almost every case the English had conveniently friendly territory in which to land so that there was no necessity to plan or execute an amphibious assault.

The maritime wars between the Dutch and the English in the 17th century are of amphibious interest in that both sides saw fit to establish permanent corps of marines. The duke of York and Albany's maritime regiment of foot was formed in 1664 and although there were subsequent reorganizations and interruptions in service this date is accepted as that of the founding of the present day royal marines. The Netherlands marine corps, with a similar history, was organized in 1665 by Adm. Michael de Ruyter. (See MARINES.)

The 18th century with its wars of colonial expansion paid considerable attention to conjunct operations and littoral warfare, as amphibious operations had come to be called. However, in practice, 18th-century amphibious warfare was more notable for its reverses than for its successes. Adm. Edward Vernon in his Caribbean venture, for instance, failed with 12,000 troops to take Cartagena in 1741 and later in the same year failed again at Santiago de Cuba. The capture of Quebec in 1759 by Gen. James Wolfe (*q.v.*) was one of the most striking successes of the Seven Years' War, illustrating the importance of combining surprise with strong ground and water-borne forces.

Napoleonic Era. — Napoleon's failure to carry out an invasion of England is cited frequently as a classic example of the inability of a strong continental force lacking in sea power to project its strength over even the narrowest of seas. Napoleon's preparations for the invasion reached a peak in 1805 when he had 100,000 troops encamped at Boulogne and over 500 transports at his disposal. But his crossing required that he control the Channel, and this

control his admirals could not give him. When Villeneuve was destroyed by Nelson at Trafalgar all chance of a successful invasion of England by the French disappeared. (See NAPOLEONIC CAMPAIGNS: Naval Operations.)

The outstanding amphibious success of the Napoleonic Wars was probably the landing of Sir Ralph Abercromby on March 8, 1801, near Aboukir, Egy. Careful preparation and co-ordination enabled Sir John Moore, the landing force commander, to land 5,500 troops almost simultaneously. The remainder of the British troops were put ashore the same day, losses were only 600 killed and wounded, and the expedition successfully moved to the capture of Alexandria.

This success can be contrasted with the failure of Lord Chatham at Walcheren in 1809. Chatham, with 400 ships and 40,000 troops, the largest expedition to put out from England up to that time, landed successfully on the miasmatic Lowlands island but ultimately foundered because of lack of strategic purpose, inertia and malaria, which alone caused 4,000 deaths.

19th-Century Amphibious Experience. — Amphibious doctrine of the 19th-century, as it had evolved from 18th-century and Napoleonic era successes and failures, was simple, direct and, within its limitations, effective.

Gen. Winfield Scott's capture of Veracruz during the Mexican War is typical. Avoiding the defenses of the city itself, he put his 12,000 soldiers and marines ashore in an unopposed landing on an open beach three miles south of the city. Then through a co-ordinated effort of the fleet and the army, the city was brought under siege, subjected to 500,000 lb. of shot and shell, and on March 29, 1847, capitulated.

Amphibious operations in the American Civil War are obscured by the more sanguinary campaigns fought in Virginia and the west, but by the end of the war the Federal forces had a well-developed amphibious capability as was demonstrated at Ft. Fisher. This fort was the key Confederate defensive position guarding the seaward approaches to Wilmington, N.C., which, by mid-1864, was the last Atlantic port accessible to blockade-runners. The conjoint attack aimed at its reduction had as its naval leader, Adm. David D. Porter, and, initially, as its expeditionary force commander, Maj. Gen. Benjamin F. Butler.

In the first attack against the fort, Porter landed Butler with 6,500 men on Christmas day, 1864. The Confederate scheme of defense was classic. Light defense of the landing beaches, stubborn defense of the key feature (Ft. Fisher itself), and a strong mobile reserve (Hoke's division). After two days' ineffective maneuvering, Butler ordered his troops re-embarked. He was replaced by Maj. Gen. Alfred H. Terry, who on Jan. 13, 1865, landed with 8,000 men. Two days later a co-ordinated assault was made and Ft. Fisher was successfully taken.

The amphibious lessons of the Civil War had to be in large part relearned in the Spanish-American War of 1898. Adm. George Dewey, after his decisive defeat of the Spanish fleet in Manila bay, had no landing force at his disposal with which to exploit his victory and the eventual occupation of the city had to be delayed three months. On the other hand, Adm. William T. Sampson, in his operations in Cuban waters, was able to land a battalion of marines at Guantánamo bay and thus seize a base which contributed materially to the blockade of the Cuban north coast and the eventual destruction of the Spanish fleet at Santiago.

World Wars I and II. — Gallipoli, or the Dardanelles campaign, was the principal amphibious experiment of World War I. (See DARDANELLES CAMPAIGN.) Fostered by Winston Churchill, then first lord of the admiralty, the campaign had as its purpose the turning of the strategic flank of the central powers by knocking Turkey out of the war and reopening the Black sea route to tsarist Russia. The first naval attack began on March 18, 1915; the final evacuation took place on the night of Jan. 8, 1916. Of the 410,000 British and 79,000 French who were engaged, 252,000 became casualties.

After this disaster, world military opinion was almost universal in dismissing the future of amphibious operations, at least so far as the large-scale, daylight assault on a well-defended position was concerned. An exception to this thinking was to be found in a

WIDE WORLD
FRENCH EXPEDITIONARY FORCES LOADING TANK INTO U.S. LST (LANDING SHIP, TANK) IN NORTH AFRICA DURING WORLD WAR II

small group of U.S. marine and naval officers who, in a series of theoretical studies carried out primarily at Quantico, Va., dissected the Gallipoli landings and concluded that future amphibious assaults were feasible if certain conditions were met. These conditions included the requirements for a specially trained landing force; an integrated naval and landing force command; adequate ship-to-shore communications; adequate air cover; suitable amphibious transports, landing craft and amphibian vehicles; and many contributory techniques such as the combat loading of amphibious shipping and workable shore-based control of naval gunfire and close support aircraft.

As a result of these studies and the fleet exercises which tested their findings; the United States entered World War II with a well-developed amphibious theory and doctrine that was eventually adopted by all the major Allied powers. Conversely, the failure of Germany to develop an adequate amphibious doctrine or capability was a major contributory cause of Hitler's ultimate defeat. Hitler's unexpectedly swift victory over France in 1940 and Britain's decision to continue the war alone found the Germans unprepared for an invasion of England. In this respect, the similarity between Napoleon's position in 1805 and Hitler's in 1940 is obvious.

Korean War.—The outstanding example of amphibious warfare in the Korean war (1950–53) was the landing at Inchon on the west coast of Korea in Sept. 1950. A difficult and daring operation, it achieved complete success and resulted in the destruction of the North Korean army with a loss of more than 100,000 prisoners. This operation illustrated the point that under modern conditions amphibious landings can be made successfully only when the attacker has command of both sea and air, and only when the element of surprise is employed effectively. (See KOREAN WAR.)

Current Amphibious Doctrine.—Modern amphibious warfare integrates virtually all forms of land, sea and air operations. An amphibious operation's greatest advantage rests in its mobility and flexibility; concentrations of strength can be applied with great selectivity against the enemy's shore line; surprise is of great importance. An amphibious operation's greatest limitation is that the attacker must build up his strength ashore from an initial zero. The tactics and techniques by which the amphibious operation's advantages are exploited and its disadvantages overcome make this one of the most complicated and sophisticated forms of modern warfare. An amphibious operation; from its inception until its completion, usually passes through six recognizable phases: planning, embarkation, rehearsal, movement to the objective area,

assault and termination.

Planning begins with the decision that the landing be made and continues until the termination of the operation. Some of the factors which complicate amphibious planning are the necessity to co-ordinate naval and landing forces; the special problems of amphibious logistic support, the unique command relationships, and the requirement for precise timing in air, naval gunfire and artillery support.

Before detailed planning can proceed certain basic decisions must be made. Climatic and seasonal conditions as well as the strategic and tactical situation are factors in the determination of the date and time of landing. Similarly, geographic and hydrographic conditions, as well as the concept for operations ashore, affect the place of landing.

In the embarkation phase men and matériel are assembled and embarked in a manner designed to support the scheme of maneuver ashore. The key technique is combat loading of the amphibious shipping. Combat loading, which includes several methods of stowage and cargo handling, is designed to facilitate the rapid and selective unloading of troops, equipment and supplies.

World War II saw the development of a highly specialized family of amphibious ships. In the U.S. service, the principal types at mid-20th century were the AGC or amphibious force flagship, the AKA or attack cargo ship, the LSD or landing ship dock and the APD or high-speed transport, usually a converted destroyer type. Some use has also been made of transport submarines, for example, in the marine raid against Japanese-held Makin Island (1942).

An even more specialized form of amphibious shipping were the landing ships, based for the most part upon an amalgamation of American and British designs. These ships were unique in that they had a beaching capability. Best known and most versatile was probably the LST or tank landing ship. Other landing ships developed during World War II include the LSM or medium landing ship, the LSIL or infantry landing ship large, and the LSSL or support landing ship large.

Post-World War II developments in amphibious ship construction were directed at faster! more versatile ships, including a capability of operating helicopters. The LPH or amphibious assault ship, for example, combined many of the characteristics of an aircraft carrier with those of an assault transport.

The rehearsal phase includes the conduct of one or more exercises, under conditions approximating the impending operation. To test the planning, the timing, the communications and the combat readiness of the forces involved.

The movement to the objective area embraces the departure of the ships from the loading points (sortie), the passage at sea and the arrival in the objective area (entry).

The assault phase is distinguished by the ship-to-shore movement of the landing force. Much of the Allied amphibious success in World War II depended upon the development and large-scale production of landing craft and amphibious vehicles. The most widely used ramp-bowed landing craft were the 36-ft. LCVP (landing craft vehicle, personnel) and the 50-ft. LCM (landing craft, mechanized). Both were based on designs developed by Andrew

WIDE WORLD
AMPHIBIOUS ASSAULT FROM LCVP (LANDING CRAFT VEHICLE, PERSONNEL) BY U.S. TROOPS; NORMANDY, FRANCE. JUNE 1944

Higgins, a New Orleans boatbuilder. Two distinct types of amphibious vehicles appeared during World War II: the LVT or amphibian tractor developed for the marine corps and the army-sponsored duck (DUKW) or amphibious truck. The LVT, a track-laying vehicle which superficially resembled a tank, was based on the "alligator" invented by Donald Roebling of Florida. The duck, on the other hand, moved on rubber tires while ashore and was propeller-driven afloat.

At mid-20th century military opinion recognized that the great concentrations of shipping and the congested beachheads of World War II would be suicidal against a nuclear-equipped enemy. To eliminate this congestion, helicopters and other vertical-rising or short-take-off aircraft were replacing the slow landing craft and amphibian vehicles of the past. Helicopters, operating from high-speed amphibious assault transports such as the LPH, were to converge on the objective area from many miles at sea. At the same time they were to avoid the beach defenses by flying inland. See also COAST DEFENSE.

Isely and Philip A. Crowl, *The U.S. Marines and Amphibious War* (1951); Alan Moorehead, *Gallipoli* (1956); Frank O. Hough, Verle E. Ludwig and Henry I. Shaw, Jr., *Pearl Harbor to Guadalcanal* (1958). (E. H. Si.)

AMPHIBOLE, a large and important group of common rock-forming minerals. Most of the amphiboles are darkly coloured with various shades of green, brown and black predominating. Generally, the darker the colour, the higher the iron content. Magnesium-rich amphiboles can be nearly colourless. Sodium-rich amphiboles can have a distinct bluish colour if it is not masked by a high iron content.

The amphiboles are metasilicates (inosilicates). They are characterized by two planes of well-developed prismatic cleavages which intersect at angles of about 124° and 56°. Many of the amphiboles develop elongate crystals, some becoming needlelike and fibrous. Other members of the group form short, stubby crystals and thus, all gradations can occur. Crystal faces, or traces of them, are commonly present on the individual grains, especially those faces which parallel the cleavage directions.

Amphiboles, as a group, form over most of the temperature range observed in the earth's crust. For example, amphiboles can be present in volcanic rocks, metamorphic rocks and as overgrowths on detrital grains in slightly metamorphosed sediments. Amphiboles can be found in most of the igneous rocks as minor and major constituents and form the major constituent in many metamorphic gneisses and schists. Hornblende schist, anthophyllite schist and cummingtonite schist are the commonest. Amphiboles form gangue (waste) minerals in certain ore deposits, and contact metamorphic deposits often include some of the amphiboles.

Some of the fibrous forms of the amphiboles, tremolite, anthophyllite and riebeckite, are often used in commercial asbestos. Some of the jade used in carvings and jewelry is a variety of tremolite called nephrite.

Composition and Classification.—The amphiboles are characterized by a large variation in composition including sodium (Na), calcium (Ca), magnesium (Mg), iron (Fe), aluminum (Al), silicon (Si), oxygen (O), hydrogen (H) and fluorine (F); the general formula is:

Potassium is the only abundant element in the earth's crust that is not included as a major constituent. In mineral groups of such variable composition, species names are generally applied to idealized pure compositions called end members. These end members are capable of mixing with other end members to form single homogeneous solid solutions. Consequently, most of the natural minerals can be considered as being composed of various mixtures of these end members.

Mineral names are also given to ranges of compositional variation. In general, the amphiboles form two distinct groups: (1) those crystallizing in the orthorhombic system; and (2) those crystallizing in the monoclinic system. The more important end

members are listed below.

	<i>Orthorhombic amphiboles</i>
Anthophyllite	(Mg, Fe) ₇ Si ₈ O ₂₂ (OH) ₂
Gedrite	(Mg, Fe) ₅ Al ₂ (Si ₆ Al ₂)O ₂₂ (OH) ₂
	<i>Monoclinic amphiboles</i>
Cummingtonite	(Fe, Mg) ₇ Si ₈ O ₂₂ (OH) ₂
Tremolite	Ca ₂ Mg ₅ Si ₈ O ₂₂ (OH) ₂
Tschermakite	Ca ₂ Mg ₃ Al ₂ (Si ₆ Al ₂)(OH) ₂
Edenite	NaCa ₂ Mg ₅ (Si ₇ Al)O ₂₂ (OH) ₂
Glaucophane	Na ₂ (Mg ₃ Al ₂)Si ₈ O ₂₂ (OH) ₂
Riebeckite	Na ₂ (Fe ₃ ²⁺ Fe ₂ ³⁺)Si ₈ O ₂₂ (OH) ₂

The calcium-containing amphiboles listed above have iron equivalents: for these, the mineral name is prefixed with ferro-, as, ferrotremolite. If the iron content in the orthorhombic series exceeds a certain amount, the mineral becomes monoclinic; and also, magnesium-rich cummingtonite is unknown. It is apparent that the amphibole group can accommodate a wide variety of compositions and concentrations. It is also obvious that a chemical analysis is needed to identify the individual species. For this reason, the noncommittal name hornblende is generally applied to all of the calcium-rich amphiboles. Microscopic work is required to distinguish the orthorhombic amphiboles and cummingtonite from hornblende. At high temperatures such as occur in lava flows, hydrogen can be driven off and the ferrous iron oxidized to ferric iron, resulting in the oxyhornblendes.

The variation in composition allowed in the amphiboles is best explained by the following diagram. Instead of single chains for the form of the silicate anions (negative ions) as in the pyroxenes (*q.v.*), endless double chains occur:

These double chain groups are parallel to the elongated direction of the crystal and are bonded to parallel adjacent double chains by the Na, Ca and Mg, Fe²⁺, Fe³⁺, Al ions of the crystal. There are only small differences between the ionic sizes of Mg, Fe²⁺, Fe³⁺ and Al so that those positions in the crystal which are occupied by Mg can also be occupied by these similarly sized ions; i.e., they can substitute for each other. The ionic sizes of Ca and Na are similar enough that they can substitute for each other. The ionic size of Al is also close enough to the size of Si that a limited Al substitution for Si occurs. Thus, any combination of the one, two, three and four valent metal cations (positive ions)

and any mixtures of similarly charged cations that will satisfy the remaining charge demands on the oxygen anions (plus the two OH [hydroxyl] groups) and at the same time will be accommodated in the seven atomic positions for the one, two and three valent cations and the eight atomic positions for the Si and Al cations (per 24 O's, as indicated in the diagram) can form an amphibole. (G. W. DeV.)

AMPHIBOLITE, a rock composed of one of the amphibole (*q.v.*) minerals. Technically, amphibolite means that only amphiboles are present, but rocks composed of only one mineral are rare and it is customary to include rocks that are predominantly composed of amphiboles in the term amphibolite. The term is restricted to rocks of metamorphic origin, but this is not a complicating restriction inasmuch as amphibole-rich rocks are nearly always metamorphic. A planar or sheetlike structure or foliation is commonly present in such rocks and its presence is denoted by the term schist added to the rock name. Hornblende schist forms one of the commoner amphibolite rock types in metamorphic terrains. Anthophyllite schists, cummingtonite schists and glaucophane schists can also be important rock types in such an area.

The mineralogy of the amphibolites is relatively simple. Plagioclase feldspar of about andesine composition and quartz are

the commonest minerals present with the amphiboles in amphibolite. Other minerals such as garnet, biotite, pyroxene and epidote may or may not be present. Except for the tremolite and anthophyllite schists which are often light coloured, the amphibolites are usually dark green or black. The elongate amphibole crystals are often oriented parallel to each other in the schistose rocks, but sometimes are intertwined together in non-schistose rocks.

The origin of the amphibolites and amphibole schists and the manner in which they are formed is not clearly understood. Classically, a large variety of different rocks which have chemical compositions similar to the amphibolites such as graywackes, shales, impure limestones, certain volcanic ash beds, basaltic lava flows, diabases and gabbros have been considered to be altered and recrystallized to form the amphibolites; *i.e.*, the chemical composition of the original rock is preserved in the resulting metamorphic rock.

In addition to simple recrystallization, amphibolites can be formed if material of amphibolite composition is introduced into rocks not of amphibole composition. Such material can be introduced by a diffusion mechanism or solution transfer. The introduced material, by reacting with the material present in pre-existing minerals to form amphiboles or by dissolving the pre-existing minerals and simultaneously precipitating amphiboles, could transform the original rock into an amphibolite or amphibolite schist. The criteria to distinguish these two methods of formation are not clear-cut or even generally accepted. Because intermediate stages of transformation are often absent, it is sometimes impossible to determine the character of the original rock and the manner of formation of the amphibolite schist. The amphibolite schists are more abundant in the intermediate grades of metamorphism (*q.v.*) and form one of the characteristic rock types in the epidote-amphibolite facies and amphibolite facies.

Although the amphibolites and amphibole schists are not commonly associated with ore deposits, gold-bearing quartz veins are occasionally found. (G. W. DEY.)

AMPHIBOLOGY (AMPHIBOLY), in logic, a verbal fallacy arising from ambiguity in the grammatical structure of a sentence. It occurs frequently in poetry, because of the alteration for metrical reasons of the natural order of words; as an example, the line from Shakespeare, Henry VI, is often quoted: "The duke yet lives that Henry shall depose." The success of ancient oracles was largely due to skill in amphibology.

AMPHICTYONY (AMPHICTYONY), in ancient Greece, meant an association of neighbouring states (from Gr. *amphictiones*, "dwellers around"), holding festivals accompanied by fairs. The term is restricted to associations based on a religious centre and is not used of political alliances. The most important such associations in the Greek world were the Delian and Delphic amphictyonies and, in the archaic period, the Calaurian (comprising states around the Saronic gulf).

The Delian amphictyony reached the height of its splendour early in the 7th century B.C. A hymn to the Delian Apollo composed about that time celebrates the gathering of the Ionians at the shrine of their god on the island of Delos, to worship him with music, dancing and gymnastic contests. Pisistratus, carrying out a purification of Delos in the 6th century to win the favour of Apollo, seems to have used the sanctuary as a means of extending his political influence; but the fall of the Athenian tyrants, the decline of Ionia and the growing danger from Persia led to the abandonment of the festival. When, after the Persian Wars, the Aegean cities united in a league they chose as its centre the temple of the Delian Apollo and the league's council met at Delos. The removal of the treasury to Athens in 454 B.C. deprived Delos of political importance, but Athenian commissioners controlled the treasury of Apollo, and in 426 the Athenians revived the festival and added horse racing. At the end of the Peloponnesian War Athens was deprived of Delos, but it appears to have regained control after the victory of the Persian fleet over the Spartans at Cnidus (394 B.C.). The affairs of the temple were managed by a board of five Athenian amphictyons, accompanied for a short period by five Andrians and assisted by some Delian officials. At

this time the amphictyony is known to have embraced both the Athenians and the inhabitants of the Cyclades; but a strong Delian party bitterly opposed Athenian rule! which came to an end with the supremacy of Macedonia. The dissolution of the amphictyony soon followed.

Far more famous is the Delphic amphictyony. It was originally composed of 12 tribes dwelling round Thermopylae—the Thesalians, Boeotians, Dorians, Ionians, Perrhaebians, Magnetes, Locrians, Oetaeans, Phthiotes, Malians, Phocians and Dolopians. The name of the council (*pulāia*) and of one set of deputies (*pulagorai*), together with the importance of the temple of Demeter at Anthela, near Thermopylae, suggests that this shrine was the original centre of the association. How and when Delphi became the centre is uncertain. The council of the league included deputies of two different kinds—*pulagorai* and hieromnemes. The latter were 24 in number, two from each tribe. Originally made up of neighbours, the league in time admitted the Dorians of the Peloponnese and the Athenians. After the Sacred War of 355–346 B.C. Macedonia took the place of the Phocians, and the Delphians partially displaced the Perrhaebians and Dolopians.

In the following century the Aetolians gained such dominance in the amphictyony as to convert the council into an organ of their league. They were never formally admitted to membership but maintained their supremacy in the council by controlling the votes of their allies. They made no material change in its composition, which, accordingly, after the dissolution of their league by the Romans is found to be nearly as it was after the Sacred War of 355–346. A few minor changes were introduced under the supremacy of the Roman republic. The emperor Augustus increased the number of votes to 30 and distributed them according to his pleasure. In the age of the Antonines the association was still in existence.

The hieromnemes of the Thesalians, who held the presidency, were elected, but the office was ordinarily, as at Athens, filled by lot. As a rule they were renewed annually. Each hieromnemon was accompanied by two *pulagorai*, elected semiannually. The hieromnemes were formally superior but, being usually mediocrities, readily became the tools of the *pulagorai*, who were orators and statesmen. The latter are rightly given credit for the acts of the council and had a right to propose measures and to take part in the deliberations. The hieromnemon, however, cast the vote of his community, though in the record his two *pulagorai* were made equally responsible for it. The council decided all questions which fell within its competence. Matters of greater importance, as the levy of an extraordinary fine on a state or the declaration of a sacred war! it presented in the form of a resolution to an assembly, composed of the deputies, the amphictyonic priests and any other citizens of the league who chanced to be present. This assembly was relatively unimportant, however.

The amphictyons met both in the spring and in the autumn at Delphi and at Thermopylae. The meeting at Thermopylae followed that at Delphi. The primary function of the council was to administer the temporal affairs of the two shrines. The duty of the hieromnemes was to inspect periodically the sacred lands, to punish those who encroached and to see that the tenants rendered their quota of produce; and the council held the states responsible for the performance of such duties by their deputies. Another task of the council was to supervise the treasury, to protect it from thieves, to increase the capital by investment and to control the expenditure. It contracted for the rebuilding of the Delphic temple after it had been destroyed by the fire of 548 and there are mentions of its adorning the interior with statues and pictures, inscribing the proverbs of the Seven Sages on the walls, bestowing crowns on benefactors of the god, preparing for the Pythian games, awarding the prizes and issuing coins. One law imposed an oath upon the members of the league not to destroy an amphictyonic city or to cut it off from running water in war or peace and enjoined them to wage war upon those who transgressed this ordinance and punish any others who sought to injure the god. In this regulation can be seen one of the origins of Greek interstate law. It was also unlawful to levy tolls on pilgrims to the shrines. Other regulations were made to secure peace at the time

of the festival, and occasionally the council was called upon to arbitrate in a dispute, but no provision was made to compel arbitration.

The council furthermore had judicial power. As jurors the deputies took an oath to decide according to law or, in cases not covered by law, according to their best judgment. The earliest known penalty inflicted was the destruction of Crisa for having levied tolls on pilgrims. This offense was the cause of the first Sacred War (c. 590 B.C.); the Sacred Wars of 355-346 and 339-338 were declared by the amphictyons against the Phocians and the Amphisseaens respectively for trespassing on the sacred lands.

The judgments of the council were sometimes considered unfair, and were successfully defied by the states affected. The inability of the council to enforce its resolutions was chiefly due to its composition; the majority of the communities represented were even in combination no match for individual cities like Athens, Sparta or Thebes; the support of the great powers was necessary if more than moral influence was to be employed.

See W. A. Laidlaw, *A History of Delos* (1933); H. W. Parke and D. E. W. Wormell, *The Delphic Oracle* (1956).

AMPHILOCHUS, in Greek legend, a famous seer, son of Amphiaraus and Eriphyle and brother of Alcmaeon. According to some, he assisted in the murder of Eriphyle, which, according to others, was carried out by Alcmaeon alone. He took part in the expedition of the Epigoni against Thebes and in the Trojan War. After the fall of Troy he founded, in conjunction with Mopsus, another famous seer, the oracle of Mallos in Cilicia. The two seers afterward fought for its possession, and both were slain in the combat. Amphilocheus is also said to have been killed by Apollo.

According to another story, he returned to Argos from Troy, but, being dissatisfied, left it for Acarnania, where he founded Amphilocheian Argos on the Ambracian gulf. He was worshiped at Oropus, Athens and Sparta.

AMPHINEURA, a class of marine mollusks (phylum Mollusca) comprising two subclasses, the Aplacophora, wormlike animals without shell plates, and the Polyplacophora, flattened elliptical forms having eight shell plates on the dorsal surface. The Amphineura are world-wide in distribution, ranging from the intertidal zone to great depths. This article will deal only with the Polyplacophora, or chitons; for a discussion of the Xplacophora see MOLLUSCA.

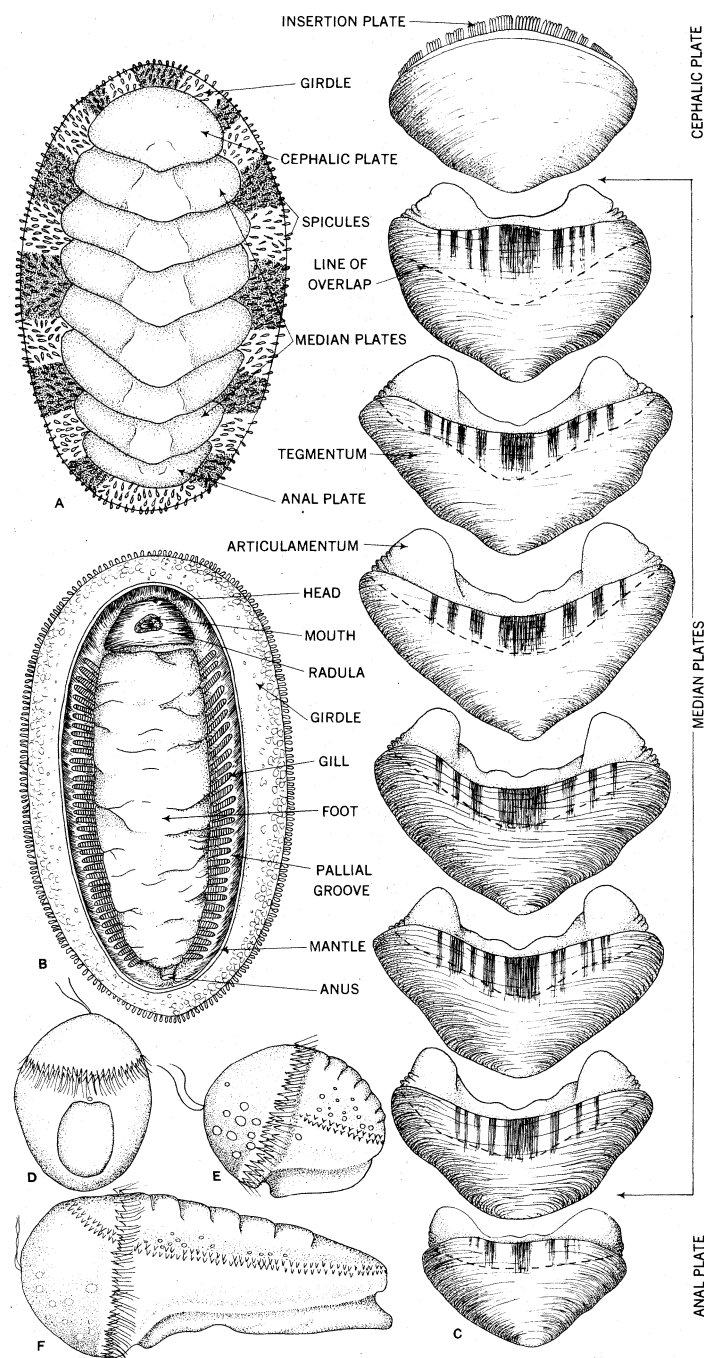

The Polyplacophora, also known as Loricata, Crepidoda or, more commonly, chitons, range in length from a fraction of an inch to 12 to 14 in. In most forms the shell plates are held together in part by a girdle which surrounds the edges of the plates. In others the plates may be completely imbedded in the tissue, as in the adult but not the young of *Cryptochiton*, or partially imbedded, as in *Cryptoplax*. The girdle may be smooth, scaly or armed with limy spicules or tufts of chitinlike hairs. On the ventral surface is a large, flat foot which is developed for creeping and for adhering by suction to the surface of rocks. The gills are located in a groove, the pallial or mantle groove, on either side of the foot between the foot and the mantle. The number of gill filaments varies greatly in the different groups. There may be only a few, near the posterior end of the animal, or many, extending nearly to the head.

The mantle covers the dorsal side of the animal, producing the shell plates dorsally and the covering of the muscular girdle at its margin. The overlapping plates and the many muscles attached to them give a chiton a great deal of flexibility which allows it to fit snugly into the irregularities of the substratum or to curl up into a ball as a pill bug, or wood louse (*q.v.*), when removed from the rocks. Because of the habit of curling, chitons are known as sea curbs in the Bahama Islands. They can adhere so firmly to a rock surface that it is usually necessary to use a knife or other tool to pry them loose.

Chitons feed by scraping off the surface film on rocks or other surfaces on which they might be living. They feed mainly on algae, diatoms, small hydroids, decaying seaweeds and the like. Most species feed only at night, wandering a short distance during the process but returning to their "home site" in the morning. Although some species remain on exposed rocks during the day,

most of them retreat to the underside of rocks or into crevices when exposed to sunlight.

Although world-wide in distribution, chitons are very much more abundant, both as to numbers of species and individuals, in tropical and warm temperate waters. Most species, particularly in warm areas, are found in shallow water, often in the intertidal zone, whereas in colder areas the proportionate number of species occurring in deeper water increases. A few species are found at great depths, some having been taken from over 2,000 fathoms. Fourteen species are listed for New England, only two of which, both small, may be collected in the intertidal zone, the remainder being obtained only by dredging. The eastern Pacific is rich in species and it is there that *Cryptochiton stelleri*, the largest known species (reaching a length of about 14 in) is found; it ranges

FIG. 1.— REPRESENTATIVE CHITON (*ACANTHOPLEURA GRANULATA*) (A) Dorsal view; (B) ventral view; (C) disarticulated shell; (D) trochophore larva; (E, F) intermediate stages in development

from Alaska to California. The most varied and most beautiful chiton fauna is found in Australian and New Zealand waters. In this region, isolated plates of chiton shells, because of their shape, sculpture and beautiful colouring, are often referred to as butterfly, sunset or toenail shells.

The shell plates of a chiton are composed of two layers. The outer layer, or tegmentum, is porous and composed largely of conchilin with a relatively small amount of calcium carbonate. It may be smooth or highly sculptured with ridges and nodules. In many species these plates are penetrated by the "shell-eyes" (*see* below). The inner layer, or articulamentum, is a hard, compact layer that in most forms projects anteriorly beyond the tegmentum. It is this portion of the plate to which the muscles are attached. The extension of the articulamentum on the anterior edge of the head plate, the posterior edge of the anal plate and the lateral margins of the median plates are known as insertion plates. These are imbedded in the girdle. The characteristics of these plates are very important in the classification of the various genera.

The anatomy of the Polyplacophora is relatively simple. They are bilaterally symmetrical animals with an anterior mouth and a posterior anus. The poorly developed head region can only be seen by turning the animal over; it is separated from the foot by a narrow groove. A short snout with a mouth at its end is evident, but there are no eyes or tentacles. Within the mouth is the long rasping tongue-like radula that is armed with many rows of teeth; some of the teeth are very large and powerful. The esophagus is short and opens into a large, thin-walled stomach that is surrounded by a large "liver," or digestive gland. The long, coiled intestine, characteristic of all plant feeders (herbivores), is imbedded in the digestive gland. It opens on a short nipple into the pallial groove, which is at the posterior end of the animal.

The nervous system consists of a ring around the esophagus (the circumesophageal ring) with nerves running forward to the head region and two pairs of nerve cords running the length of the body, two running ventrally (the pedal cords) and the other two running laterally (the pallial cords). The ventral nerve trunks are connected in a ladderlike fashion by numerous connecting nerves. From the main nerve trunks small nerves are given off to innervate the various organs.

Many groups of chitons have "shell-eyes," or aesthetes, on the dorsal surface. These eyes are supplied with nerves that penetrate the shell plates. In some groups the eyes have a definite crystalline lens.

The heart, which is located at the posterior end of the animal, is composed of a long median ventricle with elongate auricles on either side. The dorsal blood vessel carries the blood from the ventricle forward to the various organs. Lateral blood vessels carry the blood from the gills back to the heart.

The elongate reproductive organ, or gonad, is located in the medial dorsal area just under the shell plates. Sexes are separate; the male organ is usually reddish in colour, the female greenish. Paired gonoducts, which carry sperm or eggs to the outside, open into the pallial groove near the posterior end of the body. The eggs may be produced singly, in jellied masses or in strings. In most species the eggs develop into free-swimming trochophore larvae, but in some species they are held within the pallial groove until development is well along. In *C. viviparus* the developing eggs are held within the gonoducts of the female, and there is no free-swimming stage. A very large number of eggs may be produced by a single female, the estimate being as high as 200,000 in some species. As is true throughout the animal kingdom where

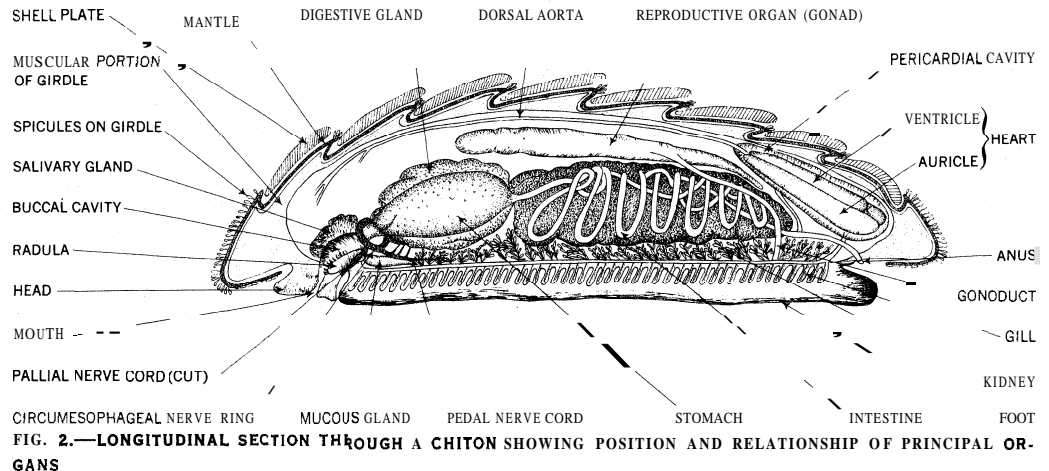

FIG. 2.—LONGITUDINAL SECTION THROUGH A CHITON SHOWING POSITION AND RELATIONSHIP OF PRINCIPAL ORGANS

such large numbers of eggs are produced very few ever reach maturity.

Chitons are not an economically important group. Although they may have been eaten by poorer classes of people at an earlier time, it was not a common practice. In the Bahama Islands chitons along with a variety of other mollusks not generally eaten may be gathered and made into a stew if food becomes scarce. Chitons are a source of food, however, for some carnivorous snails, and the tremendous numbers of free-swimming young released during the breeding season are an important element in the plankton on which many marine animals feed.

CLASSIFICATION

The classification of living Polyplacophora is based on whether or not insertion plates are present. There are two orders in this subclass: the Paleoloricata, which are fossil forms known only from the Upper Cambrian to the Upper Cretaceous; and the Neoloricata, which are known from the Upper Cambrian to the Recent. There are three main suborders in the Neoloricata. The suborder Lepidopleurina contains three families that usually lack insertion plates, but if plates are present, they are simple and without slits. The suborders Ischnochitonina with nine families and the Acanthochitonina with one family have insertion plates with slits. The numerous genera and more than 600 species belonging to these groups are classified mainly on the characteristics of the girdle and insertion plates, the sculpturing of the shell and the gill arrangement.

The fossil record for chitons is poor; about 100 species have been described. Unfortunately almost all of them have been based on isolated plates. Chitons are known to have occurred as far back as the Upper Cambrian (over 400,000,000 years ago).

AMPHION and **ZETHUS**, in Greek mythology, the twin sons of Zeus by Antiope. When children, they were exposed on Mt. Cithaeron, but were found and brought up by a shepherd. Amphion became a great singer and musician, Zethus a hunter and herdsman. After punishing Lycus and Dirce for cruel treatment of Antiope (*q.v.*), they built and fortified Thebes, huge blocks of stone forming themselves into walls at the sound of Amphion's lyre. Amphion married Niobe, and killed himself after the loss of his wife and children.

AMPHIOXUS (LANCELET), the common name for small marine somewhat eel-like animals (genera *Branchiostoma* and *Asymmetron*) of great interest to zoologists because of their primitive chordate characteristics (*see* CHORDATE). The term *Amphioxus* was formerly the accepted genus name of *Branchiostoma*.

Amphioxus lives in clean sand and moderately shallow water where there is a good flow of current. It ranges throughout the temperate and tropical regions and is especially abundant at the Straits of Messina (off the toe of Italy) and also off the China coast near Amoy, where the only amphioxus fishery in the world has existed for hundreds of years.

Its biological significance arises from its structure, which is clearly related to that of vertebrates in spite of the fact that it lacks a true head and backbone. Any theory concerning the origin of the vertebrate class as a whole, and therefore by inclusion man's own ancient origins, must rest heavily upon the nature of amphioxus, even though this animal is still a living contemporary and may or may not have changed since its origin.

General Structure. — Amphioxus is a slender, pinkish-white translucent creature about two inches long, pointed at both ends and flattened from side to side. It lives normally in the sand with its mouth more or less flush with the surface and its body almost completely buried, feeding upon minute particles filtered from the surrounding water. This method of feeding is associated with a sedentary existence. It is capable of quickly wiggling backward into the sand when disturbed and is further equipped with the basic locomotory apparatus characteristic of a fish, even though it lacks such control mechanisms as a brain and sense organs. Thus the whole organism is somewhat paradoxical, and in this combination of a sedentary filter-feeder mechanism, fishlike musculature and support, and virtual headlessness, its fascination and mystery lie.

The adult amphioxus has what every embryo, from fish to man, has to start with: a supporting rod of turgid cells known as the notochord. In vertebrates the vertebral column is built around the notochord, but in amphioxus the notochord persists alone. Above the notochord lies the nerve cord in the form of a hollow tube, the spinal cord, again similar to that of vertebrates. Along each side of these axial structures lie the long series of segmental muscle bands, arranged like chevrons on a sergeant's sleeve. These

muscles, supplied by segmental nerves from the spinal cord, give rise by successive contraction to the quick undulating swimming movements that this animal can perform. This basic supporting structure and neuromuscular organization is the fundamental plan of vertebrates as well.

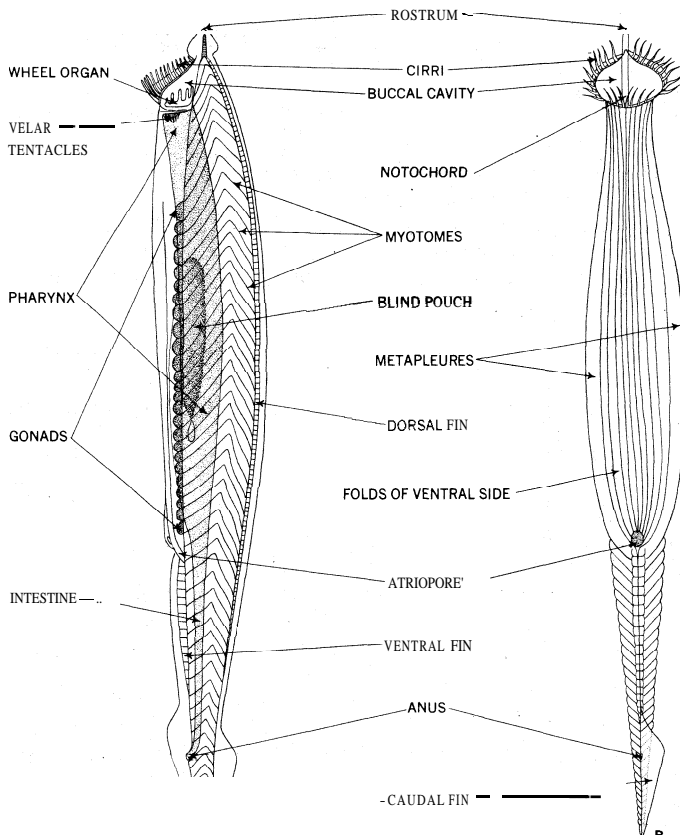

Amphioxus also possesses a cuticular vertical fin extending the length of the body, like an upper keel, and a ribbed underside, like rows of small bilge keels, all serving to stabilize movement through water. It is consequently remarkable that the spinal cord fails to expand in front to form any kind of brain and that there are no discernible organs for sight and balance, or even smell. Everything that is necessary to swim like a fish is present; there is, however, no guidance system, which suggests that in this sense amphioxus may be degenerate. As a swimming chordate animal, however, amphioxus is in other ways primitive rather than degenerate, for example, in the absence of paired fins.

Feeding Mechanism. — Amphioxus feeds by means of a highly elaborate and delicate mechanism, the endostylar feeding apparatus, which is almost identical with that of tunicates (see TUNICATA) and is also remarkably similar to that of the ammocoete larva of the lamprey, a true vertebrate. There is every reason therefore to regard this apparatus not only as an interesting mechanism in itself but as the primitive feeding mechanism for the chordate group as a whole, a mechanism which vertebrates in general discarded when they evolved jaws and became predators.

The mechanism is primarily a filtration system whereby minute food particles are filtered out of relatively large quantities of water taken in through the mouth. The digestive canal itself is a straight tube running from mouth to anus, but in the throat region it dilates as an extensive gill system. There is no liver or obvious digestive glands, except for a blind pouch where a liver or pancreas might be expected. The entire side walls of the throat, or pharynx, however, are pierced by a paired series of long narrow gill slits lined with powerful lashing cilia, or protoplasmic hairs. The combined action of these cilia is to draw water in through the mouth and to pass it out again to the exterior so that the large quantity of water taken in does not enter the digestive region of the intestine. The flow of water emerging through the gill slits on each side of the body does not however escape directly to the exterior; it enters an enclosed space known as the atrial cavity, or atrium, the outer enclosing wall of which serves to protect the delicate gill structure and to increase the efficiency of the outgoing water current. The atrium, which extends far back along the body, opens to the exterior only at the small atriopore situated a short distance in front of the anus. All the water drawn into the capacious pharynx is forcibly propelled out as a jet near the hind end of the body. This alone could serve as a means of gentle locomotion if the animal left the protection of the sand for a more hazardous existence in the sea above, which is actually the case during the night for at least one species. Otherwise the jet serves to flush the surrounding sand.

In amphioxus, as in the tunicates, water enters the front end into a vestibule, or buccal cavity. What part of it actually constitutes the mouth is a question of opinion. The outer opening is fringed by stiff processes, or cirri, which can bend outward to open the buccal cavity or can bend inward to form a protective grating to keep out sand and mud. Inside the cavity lies a second circlet, consisting of highly sensitive tentacles. These operate in such a way that only food or other particles below a certain minute size actually enter the pharynx behind the mouth. Within the pharynx lies the food-trapping mechanism which consists of a ventral groove or endostyle, diverging in front to pass up each side of the mouth to the dorsal side. The tissue lining the grooves secretes mucus that moves as a thin sheet forward and upward and backward, and on to which the fine food particles adhere. At the dorsal side of the pharynx the mucus sheet with its contained particles is passed along another groove and into the intestine. This extraordinarily efficient and intricate filter system is essentially the same in tunicates and the larval stage of lampreys.

It is remarkable, from a purely human standpoint, that in the lamprey larva part of the endostyle groove transforms at the time of metamorphosis into the thyroid gland of the adult; and in some-

FIG. 2 — ORGANIZATION OF DIGESTIVE TUBE IN ANTERIOR REGION OF *B. LANCEOLATUM*. ARROWS INDICATE MOVEMENT OF FOOD AND WATER

what like manner in the human embryo, as in all other vertebrates, the gland originates from a pocket in the floor of the pharynx. Similarly, the pituitary gland of vertebrates can be traced to a small structure, the wheel organ in amphioxus and tunicates, lying just behind the mouth and just below the floor of the nerve cord.

From the viewpoint of later evolution, this unique feeding system has led to the large, complex gills of fishes and to their derivatives in higher vertebrates, the middle ear cavity of all land-living forms, including humans, and the two most important hormone-producing glands in the vertebrate body.

Reproduction and Development. — The sexes are separate in amphioxus, unlike the hermaphroditic condition in tunicates, and in both male and female the reproductive glands (gonads) are present as a paired series corresponding to the series of muscle segments of the middle part of the body. Each small gland, whether ovary or testis, bursts when ripe into the atrial cavity, and the released eggs or sperm pass to the exterior through the atrial pore, fertilization taking place in the water. The minute, transparent eggs develop in a manner essentially like that of many vertebrates. In particular a flat plate of the outer embryonic layer folds inward to form a tube which in amphioxus becomes the spinal cord but in vertebrates becomes both cord and brain.

Amphioxus larvae hatch shortly after fertilization and spend many subsequent weeks, and perhaps months, drifting with the ocean currents. Surprisingly, they do not swim horizontally like a fish but drift head up and tail down as though they were already imbedded in the sand on the sea floor. Finally they do sink to the sea floor: at which time they transform from curiously asymmetric larva into symmetrical adults.

Classification. — Two genera are commonly recognized: *Branchiostoma* (*Amphioxus*), which has a series of gonads along each side of the body; and *Asymmetron*, which has a series of gonads on one side only, recalling somewhat the asymmetrical nature of the larval type. Species of both genera are widely distributed. These genera constitute the nonvertebrate subphylum Cephalochordata of the phylum Chordata.

AMPHIPOLIS (mod. AMFIPOLIS in the province of Macedonia), an ancient city of Macedonia, lies on the east bank of the Strymon (Strimon) river, about 3 mi. from the Aegean sea. Originally a Thracian town, known as *Ennea Hodoi* ("Nine Roads"), it was colonized by Athenians with other Greeks under Hagnon in 436 B.C., previous attempts — in 497, 476 and 465 — having been unsuccessful. In 424 it surrendered to the Spartan Brasidas without resistance; Thucydides, the historian, who was with the fleet at Thasos, was too late in coming to the rescue. In 422 Cleon led an unsuccessful expedition to recover it; both he and Brasidas were slain. It was to have been restored to Athens by the peace of Nicias (421) but remained long independent. In 357 Philip II of Macedonia occupied it in spite of Athenian opposition. The importance of Amphipolis was due to its command of the bridge over the Strymon and the route from northern Greece to the Hellespont; it was a depot for the gold and silver mines of Pangaeus and for ship timber. Under the early Roman empire it became the headquarters of the governor of Macedonia, though itself a free city. Many inscriptions, coins, etc., have been found there, and traces of ancient fortifications and a Roman aqueduct are visible.

AMBHISBAENA, the genus name for one of the ("worm lizards") (*Amphisbaenidae*), a family of elongate forms included among the lizards, though there is some doubt as to their actual kinship. The group is represented in Florida and Lower California, Mexico, Spain, north Africa and southwestern Asia, but most of its members are found in tropical America and Africa.

In these "lizards" the body is of nearly the same thickness throughout, the tail being very short. The various species range from about six inches to two feet in length. The head (in which the eyes are beneath the scales of the head) is blunt like the tail, and it is this superficial resemblance between the head and tail that leads the Brazilians to call it the snake with two heads and to the belief that it can move equally well backward and forward.

The wormlike body-form is correlated with burrowing habits.

Worm lizards feed on termites, ants and other small subterranean animals. The majority of worm lizards are egg layers, only one, an African species, bearing live young. Underground nests of termites and ants are used as incubators for the eggs and as a storehouse of food for the developing young.

The majority of forms of the family being wholly limbless, it is remarkable to find a genus (*Bipes*) in western Mexico and Lower California with short forelimbs that appear to sprout from the neck like a small pair of hands. See LIZARD. (K. P. S.; X.)

AMPHITHEATRE, a freestanding building of round or oval shape with a central arena and seats concentrically placed around it. The word is Greek, meaning "theatre with seats on all sides." but as an architectural form it is of Italic, or rather Etrusco-Campanian origin, and answers well the requirements of the specific form of entertainment which these people cherished; i.e., the gladiatorial games. Originally such games took place in the forum and wooden stands were erected from time to time to accommodate the spectators. The earliest permanent amphitheatre in Rome, built by T. Statilius Taurus in 29 B.C., was also mainly a wooden structure, but at that time provincial towns in the Roman world had long had amphitheatres of permanent building material. The oldest that has come down to us is that of Pompeii (c. 80 B.C.) where the arena is sunk into the natural ground, so that the upright part of the structure is low. It is built in rubble-faced concrete.

The earliest great amphitheatre in Rome is the Colosseum (*Amphitheatrum Flavium*), erected by the emperors Vespasian

NEW YORK ZOOLOGICAL SOCIETY

RHINEURA FLORIDIANA, THE ONLY SPECIES OF AMPHISBAENA NATIVE TO THE UNITED STATES, ATTAINS AN AVERAGE LENGTH OF 12 IN. AND CLOSELY RESEMBLES AN EARTHWORM

and Titus (A.D. 69–81) on the site of Nero's Golden House. The Colosseum, named after the colossal statue of Nero which stood close to it, shows some repairs of the 3rd century but is, as it now stands, mainly a Flavian structure. It was seriously damaged by earthquakes in late antiquity and during the middle ages. It measured in over-all dimensions 620 by 513 ft., the arena was 287 by 180 ft., and its capacity is estimated at about 50,000.

Other great examples of the ancient amphitheatre are: the Amphitheatre Castrense in Rome, built of brick-faced concrete, probably during the reign of Lucius Septimius Severus; those at Capua, Minturno, Verona and Pozzuoli, the latter particularly famous for the perfect preservation of its stage arrangements; and, outside of Italy, those at Nîmes and Arles in France; Pola in Istria (Yugoslavia); and Thysdrus (El Djem) in Africa. The arenas were from about 200 to 300 ft. long and about 115 to 200 ft. wide. Besides these, fragmentary remains are found widely scattered throughout the western provinces of the Roman empire. In England, at Silchester in Hampshire, there is an example in which the seats were placed largely on banked up earth.

In the typical Roman amphitheatre the arena was usually raised above an elaborate structure containing cells for wild beasts, storage rooms, connecting passages and rooms for gladiators, all ingeniously arranged to connect by means of many trap doors with the arena above. Around this arena, and separated from it by a high wall, arose the seats of the spectators. These were divided by passageways running around the amphitheatre into several sections (maeniana): the lowest, known as the podium, for state officials; the next reserved for the wealthy or the nobles; and those above for the rest of the populace. Each of these was divided into wedge-shaped sections (cunei) by radial walks and from them many exits (vomitoria) led down to the passages below the seats and so to the street.

The seats were supported on walls running radially to the exterior between which the exit stairs were most ingeniously arranged so that the enormous crowds were distributed evenly to the exit arches which surrounded the ground story. Awnings sheltered the spectators from the sun. In addition, vaulted corridors ran elliptically around the outside, connecting the various radial elements; the arcaded exterior was, therefore, a necessary and logical expression of the construction.

In modern usage the word amphitheatre is sometimes used for a theatre or concert hall whose seats surround the central area, as, for example, the Albert hall, London, and both the new and the old Madison Square Garden in New York.

Modern open amphitheatres also exist, particularly in connection with the sports. See STADIUM. (E.K. S.)

AMPHITRITE, in mythology of ancient Greece, a sea-goddess daughter of Nereus (or Oceanus) and wife of Poseidon. It was said that Poseidon saw Amphitrite first dancing at Naxos among the other Nereids, and carried her off. She then fled from him over the sea, but was found by the dolphin of Poseidon, which was afterward set among the stars.

In works of art she is represented either enthroned beside him or driving with him in a chariot drawn by sea horses or other fabulous creatures of the deep, and attended by Tritons and Nereids.

AMPHITRYON, in Greek mythology, son of Alcaeus, king of Tiryns. Having accidentally killed his uncle Electryon, king of Mycenae: Amphitryon was driven out by another uncle, Sthenelus. He fled with Alcmena, Electryon's daughter, to Thebes, where he was cleansed from the guilt of blood by Creon, his maternal uncle, king of Thebes. Alcmena, who had been betrothed to Amphitryon by her father, refused to marry him until he had avenged the death of her brothers, all of whom except one had fallen in battle against the Taphians. Amphitryon accordingly took the field against the Taphians, accompanied by Creon, who had agreed to assist him on condition that he slay the Teumessian vixen, which had been sent by Dionysus to ravage the country. The Taphians, however, remained invincible until Comaetho, the king's daughter, out of love for Amphitryon, cut off her father's golden hair, the possession of which rendered him immortal (cf., the story of Scylla and Nisus [*q.v.*]). Having defeated the enemy, Amphitryon put

Comaetho to death and handed over the kingdom of the Taphians to Cephalus. On his return to Thebes he married Alcmena.

The more famous portion of the myth of Amphitryon concerns his wife. When Amphitryon was once absent at war, Alcmena became pregnant by Zeus, who, disguised as her husband, visited her during a long night (contrived by Apollo); she became pregnant again by her real husband on his return. Of these unions were born twin boys, of whom Iphicles was the son of Amphitryon, Heracles the son of Zeus.

The stories of the absolutely faithful wife deceived by a disguise, and of the hapless husband displaced by a paramour bearing his own name and form, have obvious dramatic possibilities. A number of ancient dramatists presented the theme, notably Plautus, whose comedy *Amphitruo* still survives (cf., the sophisticated *Amphitryon* 38 of Giraudoux).

The modern use of Amphitryon in the sense of a generous host is derived from Molière's comedy on the subject.

(T. V. B.)

AMPLIFICATION, the process by which the strength (current, voltage or power) of an electrical signal is increased. This process is accomplished by a device called an amplifier. Amplifying action can be provided by electromechanical devices such as transformers and generators, feed-back circuits, vacuum tubes and transistors (see AMPLIFIER, ELECTRONIC; AMPLIFIER, MAGNETIC; TRANSISTOR).

The ratio of the output (current, voltage or power) to the input, where both are expressed in the same units, is a measure of the amplification and is termed the gain. The term amplification factor, inherent where vacuum tube amplifiers are concerned and usually applied to a single tube, is defined as the ratio of a change in the plate voltage to a change in grid voltage that will produce no change in plate current. Both the gain and the amplification factor are pure numbers since they express ratios of similar quantities (see ELECTRON TUBE: *Grid Control of Electron Streams in High Vacuum*).

A single amplifier employed to perform an amplifying task is called a stage of amplification. The amplification resulting from a single stage is often insufficient to raise the output to the desired level. In such cases the output of the first stage is fed into a second stage, whose output is fed to a third stage, and so on, until the output level is satisfactory. The result is cascade, or multi-stage amplification. Long-distance telephone, radio, television, electronic control and measuring instruments, radar and countless other devices all depend on this basic process of amplification. The over-all amplification of a multistage amplifier is the product of the gains of the individual stages.

There are various schemes for coupling of cascading electronic amplifiers depending upon the nature of the signal involved in the amplification process. If the output of one stage is directly coupled to the input of a second stage, the term direct-coupled is applied. Such coupling is used, for example, where zero frequency (that is D.C.) signals are to be amplified. When a capacitor is used as the coupling device (a resistor is also necessary) between stages, the term R-C coupled is used. Should a transformer be used between stages, the amplifiers are said to be transformer coupled. The method of coupling employed is one scheme of amplifier classification.

An important aspect of the amplification process is the ability of an electronic amplifier to produce a magnified output signal, identical in every respect to the input signal. This is linear operation. If the output is altered in shape after passing through the amplifier, amplitude distortion exists. This type of distortion is usually measured by the percentage of harmonic content of the amplified signal in relation to the applied signal. If the amplifier does not amplify equally at all frequencies, frequency distortion or discrimination results. When the phases of some frequencies are shifted more than those of other frequencies, phase distortion exists. Frequency distortion usually results in phase distortion.

When the power level required from the output of the amplifier is so large as to preclude the use of electronic devices, dynamoelectric and magnetic amplifiers find wide application.

(A. L. SY.)

AMPLIFIER, ELECTRONIC, a device designed to take a small signal (voltage, current or power) from some source and produce a much larger output signal that contains the essential wave-form features of the input signal. The output signal may be proportional to the input signal, or input and output may be related in quadratic, logarithmic or other nonlinear fashion when the amplifier is performing a function other than the simple multiplication of the original signal in amplitude (see **AMPLIFICATION**).

Amplifier action can be utilized in electronic circuits in a number of ways, depending upon the results desired. The purpose for which the amplifier is used is responsible for a scheme of classifications for amplifiers descriptive of their properties and operation.

Amplifiers are classified as power, current or voltage amplifiers if they are designed to develop maximum power, current or voltage at the output. They are further classified with regard to the frequency range over which they are designed to operate. Direct-current amplifiers, audio-frequency amplifiers, radio-frequency amplifiers, video-frequency amplifiers, ultrahigh-frequency amplifiers and very high-frequency amplifiers are standard classifications.

Direct-current amplifiers amplify D.C. and low-frequency A.C. signals. Audio-frequency amplifiers respond to frequencies of about 20 to 20,000 cycles per second. Video-frequency amplifiers cover a range from well down in the audio range up to 5 megacycles and higher. Amplifiers designed to operate in and amplify any frequency range above the audio range are classified as radio-frequency, ultrahigh-frequency or very high-frequency amplifiers depending on the actual range of frequencies covered.

Four classes of electronic amplifier operation, applied particularly to power amplifiers, are class A, class AB, class B and class C. This scheme of classification is based primarily on the fraction of the input cycle during which plate current is expected to flow under full-load conditions. These terms are defined as follows (in American Standard Definitions of *Electrical Terms*, American Institute of Electrical Engineers [1941]):

Class A.—A class A amplifier is an amplifier in which the grid bias and alternating grid voltages are such that plate current in a specific tube flows at all times.

Class AB.—A class AB amplifier is an amplifier in which the grid bias and alternating grid voltages are such that plate current in a specific tube flows for appreciably more than half but less than the entire electrical cycle.

Class B.—A class B amplifier is an amplifier in which the grid bias is approximately equal to the cut-off value so that the plate current is approximately zero when no exciting grid voltage is applied, and so that plate current in a specific tube flows for approximately one-half of each cycle when an alternating grid voltage is applied.

Class C.—A class C amplifier is an amplifier in which the grid bias is appreciably greater than the cut-off value so that plate current in each tube is zero when no alternating grid voltage is applied, and so that plate current flows in a specific tube for appreciably less than one-half of each cycle when an alternating grid voltage is applied.

In all four classifications, the subscript 1 may be added to the letter or letters of the class identification to denote that grid current does not flow during any part of the input cycle. The subscript 2 is used to denote that grid current flows during some part of the cycle.

Other miscellaneous amplifier classifications such as wide band, narrow band, tuned and untuned are also sometimes used.

Electronic amplifier design requires consideration of the following factors: (1) amount of amplification required; (2) type of input signal; (3) desired frequency range; (4) impedance of source or pickup device connected to the amplifier input; (5) impedance of the load; (6) requirements for stability; (7) possible selectivity of amplification of certain frequencies; (8) type of coupling where several stages are used; (9) phase relation of output signal to input signal; and (10) power supply available

In general, when the signal of interest is very small, or involves rapid changes or high frequencies, thermionic tube amplifiers are used almost exclusively. In cases where the power level required is so large as to preclude the use of electronic devices, dynamoelectric and magnetic amplifiers are used (see **AMPLIFIER, MAGNETIC**)

Direct-current generators may be considered to be power amplifiers in that small changes in the value of the excitation can produce relatively large changes in the power output. Also, in a sense, voltage and current amplification is performed by the step-up transformer, but, in contrast to electronic and dynamoelectric amplifiers which draw power from a source other than the input signal, the transformer demands an even greater input power than it produces at the output.

For many high-power applications, particularly in the control of heavy machinery, specially constructed rotating electrical machines such as the amplidyne (essentially a two-stage amplifier) can be used as amplifiers; these have the advantage of simplicity and high power amplification. Frequently, electromechanical amplifiers of this type are used in conjunction with thermionic tube amplifiers.

(A. L. SY.)

AMPLIFIER, MAGNETIC, a device using saturable reactors to secure amplification and control in alternating-current circuits (see **MAGNETISM: General Description of Magnetism**). Fig. 1(A) shows schematically a simple saturable reactor consisting of an iron core linked by two windings. With no signal applied, the magnetic core flux alternates about zero over a range of high permeabilities; in these conditions the load winding has a high reactance and the load current is small. The direct-current signal shifts the centre of the flux alternations from zero; low permeabilities prevail at some time in the cycle, and the load current becomes larger. Undesirable voltages are induced by transformer action in the control circuit of fig. 1(A); these voltages are repressed in the two-core reactor of fig. 1(B).

Among the earliest developments in electric control! saturable reactors were employed, for instance, to vary the brightness of lights in theatres. The electric power spent in the control circuit is much smaller than the power supplied to the bank of lamps; in other words, power amplification is obtained. E. F. W. Alexanderson used saturable reactors as amplitude modulators in transoceanic radiotelephony before the invention of suitable electron tubes.

The technological importance of magnetic amplifiers in modern automation and instrumentation is due largely to the development of core materials with sharp saturation characteristics; in these materials the differential permeability $\mu = \frac{dB}{dH}$ is extremely high when the magnitude of the induction is within a certain range, and drops abruptly, almost to zero, beyond this range (see **MAGNETISM: The Magnetization Curve**).

The introduction of rectifying elements in the circuit is a further development resulting in higher amplifications. Fig. 2 shows an elementary amplifier of the so-called self-saturating type. At the beginning of a positive half-cycle of the alternating supply voltage the core flux is at a certain ϕ_0 . In the initial part of the half-cycle the supply voltage is balanced by the rate of change

FIG. 1.—SCHEMATIC DRAWING OF SATURABLE REACTORS SHOWING (A) SINGLE-CORE REACTOR (BURGESS AND FRANKENFIELD, 1901); AND (B) TWO-CORE REACTOR (ALEXANDERSON, 1912)

FIG. 2. — SELF-SATURATING MAGNETIC AMPLIFIER SHOWING (A) HALF-WAVE AMPLIFIER CIRCUIT; (B) HYSTERESIS LOOP OF THE CORE. FOR A CERTAIN VALUE OF SIGNAL; (C) LOAD CURRENT VERSUS TIME

of the rising core flux, and only a small current flows through the load. This unsaturated interval terminates when the magnetic induction reaches the saturation value, and then, for the remaining part of the half-cycle, the supply voltage appears transferred directly at the load terminals. In negative half-cycles the rectifier blocks the supply voltage and the flux is reset, from saturation to the level ϕ_0 , under the influence of the signal. Essentially the duration of the unsaturated interval depends on the value of ϕ_0 and, in turn, ϕ_0 is dictated by the signal. Combinations of two or more of these half-wave components are used in more complex amplifiers, single-phase or polyphase, single-ended or in push-pull. Multistage amplification is possible, and positive or negative feedbacks can be introduced. A proper amount of positive feedback leads to a bi-stable type of operation in which the amplifier behaves like an on-off relay, without moving contacts. Amplifiers that detect signal powers of 10^{-10} w., and even less, are in industrial usage under severe environmental conditions. On the other hand, an application is known in which an output power of 1.7 megawatts is controlled by magnetic amplifiers, at 60 cycles per second. Smaller weights, as well as higher performance, result from the use of higher supply frequencies (400 to 10,000 cycles per second or higher).

The basic phenomena described can be exploited for many other purposes where power amplification is not the primary aim. Magnetic amplifier components are used to perform analytical and logic operations in analogue and digital computers. Signal integrators, pulse counters, timers, static frequency multipliers and dividers, modulators and choppers converting direct-current signals into alternating current, constant-current references and regulated power supplies, are further examples of the versatility of these magnetic devices. Structural simplicity, reliability and ruggedness are the essential advantages of the magnetic amplifier. Some disadvantages are seen in the peculiar wave forms of output voltage and in certain unavoidable delays, of one or more half-cycles, that occur between a change of signal and the corresponding readjustment of output.

See also AMPLIFIER, ELECTRONIC.

Engrs.*, vol. 77, pt. i, pp. 613-627 (1958); "1957 Magnetic Amplifier Bibliography," A.I.E.E. Committee Report, *Trans. Amer. Inst. Elect. Engrs.*, vol. 77, pt. i, pp. 1051-1057 (1958). (L. A. F.)

AMPTHILL, ODO WILLIAM LEOPOLD RUSSELL, 1ST BARON (1829-1884), British diplomat, who was outstandingly successful as the first British ambassador in Berlin after the creation of the German empire. The third son of Maj. Gen. Lord George William Russell and of Elizabeth Anne, daughter of the Hon. John Rawden, he was born in Florence, Italy, on Feb. 20, 1829. His eldest brother, Hastings, became 9th duke of Bedford, and his brother Arthur represented Tavistock in parliament for many years. His mother held original views on education, and

Odo's linguistic talent, fully developed by private tuition and wide travel, made him a master of French, German and Italian. At the age of 20 he became attache at Vienna: with his genial temper, integrity of mind and social gifts, he was assured of success in a diplomatic career. A period in the foreign office and experience in Paris, Constantinople and Florence was followed by special service in Rome from 1858 to 1870; there, in 1868, he married Lady Emily Theresa Villiers, third daughter of Lord Clarendon. In 1869-70, during the Vatican council (*q.v.*), the pope, appreciating Russell's discretion, granted Cardinal Manning a special dispensation to disclose secret information to him so that his government might be kept authoritatively informed. Recalled to become assistant undersecretary for foreign affairs, he was soon assigned another diplomatic mission, this time to Versailles. The Franco-German war was raging, and his appointment to the German headquarters, where he conferred with Bismarck on the critical situation created by Russia's denunciation of the Black sea clauses of the 1856 treaty of Paris, had important consequences. Though Gladstone feared he went beyond his instructions by threatening that Great Britain would be forced to go to war "with or without allies" if Russia persisted, Lord Granville reminded the prime minister that war had been a possibility after the last British note. The direct result of Russell's mission was a peaceful solution of the immediate problem through the London conference in Jan. 1871 and indirectly it led to his appointment to Berlin (Oct. 1871).

As ambassador, Russell worked wholeheartedly for good relations. Where internal policy was concerned he was prudent. His private conviction that the *Kulturkampf* must fail did not influence the objectivity of his reports, nor was his constant kindness to friends who incurred Bismarck's displeasure ever tainted by any suspicion of intrigue. While the crown princess found in the embassy a second home, and Count von Arnim (*q.v.*) learned that his disgrace did not affect Odo Russell's attitude, the cordial relations established with Bismarck at Versailles remained unimpaired.

Called to the privy council in 1872, Russell was made a knight grand cross of the Bath on Gladstone's resignation in 1874. During the near eastern crisis of 1875-76, he avoided adding to the excitement, acting with prompt tact upon his instructions. His appointment as third British plenipotentiary at the Berlin congress in 1878 was recognition of his patient services behind the scenes. Following that, he alone represented the government on the conference delimiting the Greek frontier. His creation as knight grand cross of St. Michael and St. George in 1879 was followed by elevation to the peerage in 1881, after Gladstone's return to power, Germany's colonial policy now began to create new problems, and Lord Amthill's untimely death at Potsdam on Aug. 25, 1884, was a calamity for both countries. In Bismarck's own words, "England might give a successor to the ambassador that she had lost, but could not expect to replace him."

His eldest son, ARTHUR OLIVER VILLIERS RUSSELL (1869-1935), succeeded him as 2nd baron. After being private secretary to Joseph Chamberlain, he was governor of Madras, 1899-1906, acting as viceroy of India during Lord Curzon's absence in 1904.

See P. Knaplund, *Letters From the Berlin Embassy 1871-1874, 1880-1885* (1944); W. A. Taffs, *Ambassador to Bismarck* (1938). (W. A. T.)

AMPUTATION means removal of any part of the body, but commonly the term is restricted to mean surgical removal of a part of or an entire limb, either upper or lower extremity. The reasons for surgical amputation in general are injury, infection, tumour, diabetes or insufficient blood supply (arteriosclerosis); occasionally surgical amputation is performed on nonfunctioning or grotesquely deformed limbs. Persons born without a limb or limbs are said to have suffered congenital amputation. Surgical amputation may be a lifesaving measure in the severely injured patient, suffering from both loss of blood and infection; in patients with diabetic or arteriosclerotic gangrene, in whom amputation may be the only method of preventing spread of the gangrene; and in patients suffering from malignant tumours of soft tissue or bone.

Modern reconstructive surgery makes possible the rehabilitation of many badly damaged limbs without amputation, and experience

gained in World War II of early and thorough treatment of the severely injured, particularly the use of blood and plasma, has saved many extremities. Furthermore, modern prostheses, particularly for amputations in the lower extremity, have reduced the handicap to the amputee.

The congenital amputee seldom requires any corrective surgery but is benefited by prosthetic replacement. There is no definitely known causative factor for congenital amputation, but it probably is not a hereditary deformity. (C. N. L.)

AMRAM BEN SHESHNA (d. 875), a famous Gaon (*q.v.*) or head of the Jewish academy of Sura, Persia, whose prayer book, *Siddur Rab Amram*, was the foundation of most of the extant rites in use among the Jews. He was author of many responses, (*i.e.*, interpretations of talmudic law), but his chief work was liturgical. He was the first to arrange a complete liturgy for the synagogue. The *Siddur* was published in Warsaw in two parts (1865).

AMRAVATI (formerly **AMRAOTI**), a town and district in Maharashtra state, India. The town, 85 mi. W.S.W. of Nagpur, is an important cotton-processing and marketing centre. Pop. (1951) 87,099. It is the seat of six colleges associated with Nagpur university. It is also the headquarters of the Shri Shivaji rural university and there is a fine government polytechnic built of basalt. It is the terminus of a branch line from Badnera on the Central railway's Nagpur-Bombay main line.

AMRAVATI DISTRICT (area 4,723 sq.mi.; pop. [1951] 1,031,160) is an undulating lava tract on the Berar plain. The average elevation is 1,000 ft. above sea level, except in the northwest where the Gawilgarh hills, a long spur of the Mahadeo (east-central Satpura) hills, intrude southwestward. These hills rise to 3,000 ft. between the Tapti river and its tributary the Purna to the south. The basaltic nature of the district's terrain yields rich black cotton soil; the main crops are cotton and jowar, grown in rotation. In Melghat subdivision on the Tapti, the shallow red soils are cultivated for grains by the Korkus. These aboriginal tribespeople speak one of the Munda languages (*q.v.*), but most inhabitants now speak the regional language, Marathi. Their main occupations are forestry and stock raising.

After Amravati the most important town is Achalpur (Ellichpur) a cotton-weaving centre with a population of 35,712, on another Central railway branch. Captured from the Hindu Yadava king Ramachandra in 1296 by 'Ala ud-Din Khalji (later usurping emperor of Delhi), it remained an important Muslim regional capital until the decline of the Moguls in the 18th century. A relic of this past is the stately *idgah* or prayer hall (1347) of Imadul-Mulk, nephew of the Delhi emperor Mohammed Tughluq. In the Gawilgarh hills are Gawilgarh fort, one of whose governors, Fathullah, proclaimed an independent Berar sultanate (1484-c.1574), and the beautiful hill resort of Chikhaldia.

(D. G. NA.)

AMRELI (ancient **AMARAVALLI**), a town and district in Gujarat state, India. The town is in the Kathiawar (Saurashtra) peninsula, 125 mi. S.W. of the state capital, Ahmedabad (153 mi. by Western railway metre-gauge). Urban area 25.1 sq.mi.; pop. (1951) 27,826. The chief industries are oil crushing and the manufacture of *khadi* (coarse cotton cloth). There is an airfield but no regular service. Amreli has a children's museum built in 1955.

AMRELI DISTRICT comprises the Kathiawar possessions of the former Baroda state (acceded to India in 1949) and Gogho mahal (subdivision), formerly in Ahmedabad district, with (from Aug. 1, 1959) the addition of seven mahals from adjacent districts and the exclusion of Okhamandal on the western tip of the peninsula. The 1959 reorganization was to help obviate the former scattered nature of the district. The chief crops are millet, peanuts, cotton, wheat and pulses. (V. A. M. J.)

AMR IBN AL-AS (d. A.D. 664), the Arab conqueror of Egypt, was born in Mecca, possibly c. A.D. 580. He belonged to the tribe of Quraish (Koreish) in Mecca and was an opponent of Mohammed until his conversion in 629. Soon after becoming a Muslim and going to Medina he was given a series of military commands. In 633 the caliph Abu Bakr put him in charge of

one of three forces invading Palestine. Amr's initiative brought about the movements of Arab expansion from Palestine into Egypt and North Africa (see **CALIPHATE**). His expedition of 639 into Egypt opened the way to a rapid conquest, Alexandria surrendering in 642 and Tripoli falling in 643. He founded the garrison-city of Fostat (Fustat), the forerunner of Cairo. He was removed from the Egyptian command by the caliph Othman, but later supported Mu'awiya I against Ali, reconquered Egypt, represented Mu'awiya in the "arbitration" and was rewarded with the governorship of Egypt until his death at Fostat in 664.

(W. M. WT.)

'AMR IBN KULTHUM (6th century A.D.), Arab poet, was the author of one of the poems in the *Mu'allaqat* (*q.v.*). Nothing is known of his life except that he was a member of the tribe of Taghlib in Mesopotamia and that he killed the Arab king of Hira, 'Amr ibn Hind, who is violently attacked in his poem, for an insult offered to his mother.

AMRITSAR, a municipal city and district of Punjab, India. The city is about 16 mi. from Wagah, the outpost of the India-Pakistan border on the main road from Delhi to Lahore. It is the largest and most important city in Punjab, and in 1961 had a population of 375,542. It is the centre of Sikhism and the site of the Sikh's principal place of worship, the Golden temple. On a site granted by the emperor Akbar, the city was founded by Ramdas, the fourth Guru, who also ordered excavation of the sacred tank or Amrita Saras ("pool of nectar") from which the city derives its name. In the middle of this tank on a small island, the fifth Guru, Arjun Dev, built a temple. During the reign of Ranjit Singh (1780-1839) the upper part of the temple was decorated with a gold-foil-covered copper dome and since then it has been known as the Golden temple, alternately called the *Darbar Sahib* ("court divine") by the Sikhs.

Nearby is an octagonal seven-story tower (150 ft. high) in memory of Baba Atal Rai, son of Har Govind, the sixth Guru. About two furlongs from the Golden temple is a spacious park, the famous Jallianwala Bagh where, in 1919, government troops fired on the participants of a political meeting, killing several hundred persons. The site of this massacre was declared a national monument after the country became independent.

Hall bazaar is the main shopping centre, while Guru bazaar is the centre for articles of jewelry. Bazaar Mai Sewan is famous for books and pictures of the Sikh religion. Near the Lohgarh gate is the Durgiana temple, built in recent times by Hindus. Just outside the city is Rambagh, a large well-kept park which contains the summer palace of Maharaja Ranjit Singh. Khalsa college (established 1899), a Sikh institution 3 mi. west of the city, Glancy medical college, a separate dental college and four other colleges are all connected with the Punjab university. The city is a centre for the textile and chemical industries and for the manufacture of electric fans, rolling mills and cycle parts. Other items of manufacture include carpets, silk, embroidery and brocade.

AMRITSAR DISTRICT (area 1,940 sq.mi.) is an almost level plain sloping slightly from northeast to southwest and drained by the Ravi and the Beas rivers that flow for some distance along its western and eastern boundaries respectively. In 1961 it had a population of 1,547,241. Towns other than Amritsar are Taran Taran (16,344), Patti (14,297), Jandiala (12,704), Chheharta (10,367), Majitha (7,368), Khemkaran (7,069), Sur Singh (6,506) and Sultanwind (5,059).

The district depends on agriculture and owes its prosperity to irrigation, mainly from the Upper Bari Doab canal (constructed in 1859). The main crops are wheat, pulses and maize with some cotton, sugar cane and oilseeds. There are cotton ginning and pressing factories. The Northern railway and Grand Trunk road cross the district from west to east. (S. S. BH.)

AMROHA, a municipal town and *tehsil* (subdivision) of Moradabad district, Rohilkhand division, Uttar Pradesh, India, lies about 81 mi. E. of Delhi on the Delhi-Moradabad section of the Northern railway. Pop. (1951) 59,105. It is on the left bank of the Sot river, on a low site among mango groves, and is noteworthy for the shrine of Sheikh Saddu, a Muslim saint. Three in-

intermediate colleges are connected with Agra university. Carpet weaving and ornamental pottery making are its chief industries, and there is a sugar mill.

AMROHA TEHSIL has an area of 383 sq.mi. and a population (1951) of 293,198. (s. S. BH.)

AMSDORF, NIKOLAUS VON (1483–1565), German Protestant reformer who was one of Luther's most determined and active supporters, was born at Torgau on Dec. 3, 1483. He was educated at Leipzig and then at Wittenberg, where he became a professor of theology in 1511. With Luther he attended the Leipzig conference (1519) and the diet of Worms (1521), and was in the secret of Luther's Wartburg retreat. He assisted the first efforts of the Reformation at Magdeburg (1524), where he became superintendent, Goslar (1531), Einbeck (1534) and the Schmalkalden debates (1537). In 1539 he opposed Luther by speaking out strongly against the intended bigamous marriage of Philip (*q.v.*), landgrave of Hesse. In 1542 he was made evangelical bishop of Naumburg by John Frederick I, elector of Saxony, and Luther, in opposition to the chapter. His position was a painful one, but under Luther's persuasion he remained until he had to yield place to the Roman Catholic bishop, J. Pflug, in 1547.

After 1547, as an exile at Magdeburg and (1550) a counselor of the Saxon dukes at Eisenach, he superintended the Jena edition of Luther's works and continued to fight for the purity of his doctrine. He opposed the Augsburg Interim, urged the separation of the High Lutheran party from Melancthon and got the Saxon dukes to oppose the Frankfurt Recess (1558). Many of his letters and other short works are extant. He died at Eisenach on May 14, 1565. He became famous through his opinion on good works, which he held to be dangerous for faith. An inflexible character and a faithful Lutheran, he was more the type of an orthodox theologian than a representative of Luther's theological school.

(E. B.)

AMSTERDAM, the capital of the Netherlands, and one of its chief ports, which also gives access from the Rhine waterways to the sea, is situated in the province of North Holland, at the mouth and on the south side of the Y or IJ, an inland arm of the Zuider Zee (called, since it has been largely drained, the IJsselmeer), and connected by canal with the North sea. Founded among swamps and stretches of water, the city has always been built on piles and methodically planned. Called by Luigi Guicciardini "the Venice of the North," its architectural style has inspired the planning of other cities, notably St. Petersburg (Leningrad), U.S.S.R., and Recife, Brazil. It is divided by the canalized river Amstel into two main sections, joined by a sluice dam (hence its name; originally Amstelredam or Amstel Dam), and subdivided by 50 mi. of canals into 70 islands, connected by 500 bridges.

The old part of the town owes its charm to its 17th- and 18th-century red brick houses, with high, pointed step-gables, and to the elm and linden trees that border the canals. The development of a distinctive modern style of architecture (the Amsterdam school) has ensured, however, that the newer districts are as beautiful as the old, and as characteristically Dutch. Pop. (1957 est.) 871,188 (mun.).

Plan and Development.—The medieval town, which had developed on both sides of the Amstel, is situated at the centre of the city, around the dam, in an area enclosed by the semicircular Singel (ditch or moat), outside which are the three main canals, constructed when the town's first big planned development took place in the 17th century: the Heren-, Keizers- and Prinsengracht. Within this area are two smaller canals running north-south; two others were filled in at the end of the 19th century. Two towers of the old fortifications are still standing: the Schreierstoren and the Sint Anthonieswaag (St. Anthony's weighing-house), now a historical and medical museum.

In this old part of the city are many ancient buildings. The

A. F. KERSTING

THE OUDE ZIJDS VOORBURG WAL, ONE OF THE OLDEST CANALS IN AMSTERDAM. IN THE BACKGROUND IS THE DOME OF ST. NICOLAS CHURCH, 1300

Oude Kerk (Old church) of St. Nicolas (1300) contains good 16th- and 17th-century glass; the Nieuwe Kerk (New church, 1408; rebuilt 1645), a fine building in which the sovereign of the Netherlands is invested during a session of the general assembly of the states general, stands near the dam. Next to it is the royal palace, built in classical Palladian style as a town hall by Jacob van Campen, 1648–55, and used as a palace after 1808, outside which stands the monument to those who died in World War II. Other notable old buildings are the Munttoren (Mint tower), the upper part of which was superimposed by Hendrik de Keyser in 1618 on to the remains of a medieval gate; the Zuiderkerk (1611), also by Hendrik de Keyser, in which is a permanent town-planning exhibition; the Trippenhuis (1662), originally the home of the patrician Trip family, now the Royal Academy of Science; the Westerkerk (1631), with the highest tower in Amsterdam (282 ft.), where Rembrandt is buried, which stands on the edge of the Jordaan, an old working-class district with a distinctive character; and the main building of the municipal university, the Oudemanhuispoort (Oldman's house gate). There are also good later buildings in this area: the Sint Nicolaas-Kerk (1886), the Centraal station (1889), the Exchange building (by H. P. Berlage, 1903) and the Shipping house, a good example of the Amsterdam school of architecture (1916). From early times the Jewish population has been concentrated in the east of the old town. The famous Portuguese synagogue (1670) and the house where Rembrandt lived and worked, now a museum containing many of his drawings and etchings, are located there. The three main squares of the old town are the Dam; the Leidseplein, where the Stadschouwburg (city theatre) and the artists' café, the American stand; and the Rembrandtsplein containing many cinemas and restaurants. The canals are lined with fine 17th- and 18th-century patrician houses.

The 17th-century development of the city (began in 1612, completed in 1658, 1700) saw the enclosure of the town with the three canals, which were ringed by the Buitensingel, a moat with 26 bastions, now the Nassaukade, Stadhouderskade and Mauritskade. Building outside the Buitensingel began in the last quarter of the 19th century, when further extension was made necessary by rapid economic expansion, especially after the unification of Germany in 1871. Notable buildings in this area are the Rijksmuseum (1876–85); the Concertgebouw (concert hall, 1888), home of the famous Concertgebouw orchestra; and the municipal and shipping

museums (1895 and 1922). Development at this stage was somewhat haphazard and a new systematic plan was adopted in 1907. After World War I the need for new houses became acute and a plan to increase the municipal territory fourfold was put into operation in 1921; this led to the development of the Amsterdam school of architecture, building mainly in brick. Several garden cities on the outskirts, in which low buildings predominate, belong to this period. The plan of 1928–34 laid down the main lines of the city's development to the year 2,000, envisaging the growth of population to approximately 1,000,000. Public buildings finished before World War II included the Royal Tropical institute (1916–26); the Olympic stadium, with 60,000 seats (1928); the nine-story State Insurance bank (1939); and the Amstel station (1939). Post-World War II buildings included a telephone exchange, a tax office 136 ft. high, the highest building in Amsterdam, and several interesting modern churches in the suburbs. Urban development took place chiefly toward the west.

There are several parks in the old part of the town, of which the best known is Vondelpark, named after the poet Joost van den Vondel. Between the Olympic stadium and the airport is the Amsterdamse Bos (the Forest park, 2,000 ac.). Started in 1928 it is 12 ft. below sea level and drained by 180 mi. of pipes. It contains a 2,200-m. rowing course used for international championships.

Amsterdam is the commercial, financial and cultural centre of the Netherlands and its stock exchange (*Beurs*) has achieved considerable importance. It is the seat of the Bank of the Netherlands, of the University of Amsterdam (1632) and of the Free Reformed university (1880). It is also the home of many scientific and learned societies, and of the state theatre and a national opera company. The city council awards annual prizes in literature, music, architecture, etc.

Communications, Shipping and Trade.—From Amsterdam communications radiate over the Netherlands and western Europe: roads connect it with The Hague, Rotterdam, Haarlem and North Holland; electric railways carry internal and transcontinental express traffic; the airport at Schiphol, 4½ mi. from the town, rebuilt after complete destruction in World War II, is one of the most modern in Europe. Amsterdam is also a centre of inland navigation, and the starting point of 245 truck-transport services and of 30 internal and trans-European bus services.

For centuries Amsterdam has been one of the chief outlets for the Rhine. At first the maritime route crossed the Zuider Zee, but as the entrance to the harbour gradually silted up, a 50-mi. canal through North Holland was opened (1824). In 1876 more direct communication with the North sea was established with the building of the 15-mi. North sea canal. At the sea end at IJmuiden there are huge locks. A new canal, the Merwede, was begun in 1892 and enlarged in 1952. It has one of the biggest inland sluices in Europe. After World War II new harbour installations for wood and oil developed west of the town and a power station, built in 1953, formed the centre of a growing industrial area.

Amsterdam had always been a piece-goods port, importing and processing goods from the east (tobacco, tea, rubber, cacao, spices). Industrial development between and after World Wars I and II brought changes, and in postwar traffic, greater in the late 1950s than in the 1930s, bulk goods played an important part. Annual traffic in the port averaged 7,000 ships.

The principal industries, employing more than 150,000 in the 1950s, of whom 25% were women, are those relating to metal, clothing, building, foodstuffs and beverages, chemicals, printing, leathernare, timber, paper and diamonds.

History.—Amsterdam originated in the 13th century as a small fishing village, held in fee by the lords of Amstel from the bishops of Utrecht. Its development began with the building of a dam to keep out the sea by Gisbertus III and it is first mentioned as a town in 1275, when a charter of Floris IV, count of Holland, exempted it from certain taxes. In 1296 it passed out of the hands of the lords of Amstel, because of the part played by Gisbertus IV in the murder of Count Floris V, and was bestowed by Count John (d. 1304) on his brother, Guy of Hainaut, who granted its first charter in 1300. In 1343 more extensive privileges were granted

by Count William IV. It was walled in 1482.

During the 15th century Amsterdam developed into one of the most important trading centres of northern Europe. In 1367 it had joined the Confederation of Cologne, and its position as port for the Rhineland towns ensured its prosperity. In the religious wars of the 16th century it benefited from the influx of refugees from Antwerp and Brabant; because of its trading interests, it did not join the other towns in their revolt against Spain until 1578. However: its adherence to the nationalist Protestant side (against Catholic Spain) did not adversely affect its prosperity; it gained from the fact that Antwerp, another great trading centre, remained in Spanish hands. The Dutch voyages of discovery, and the founding (1602) of the Dutch East India company, enlarged its sphere of influence, and the policy of religious toleration in the northern Netherlands brought in new waves of refugees with their special skills—Jews from Spain and Portugal, merchants from Flanders, Huguenots from France. This led to a fourfold extension of the city at the beginning of the 17th century. In the 17th and 18th centuries it played a leading part in Dutch policy and this led to conflicts with the government, which had its seat at The Hague, although Amsterdam was the commercial capital. In 1650 it withstood attack by William II of Orange and in 1672 was defended by Stadtholder William III when attacked by Louis XIV, but in 1787 it was occupied by the Prussians and in 1795 the French commander Charles Pichegru was able to capture it because the exceptional cold froze the surrounding water into ice. It was then made capital of the Batavian republic, and in 1806 became capital of the kingdom of Holland established by Napoleon under the rule of his brother Louis. In 1810, when Holland was incorporated into the French empire, Amsterdam was designated its third city, after Paris and Rome. It became capital of the kingdom of the Netherlands when independence was proclaimed in 1813, sharing the status with Brussels until the separation of Holland and Belgium in 1830. During World War II, from 1940 to 1945, it was occupied by the Germans, and almost all the Jewish population (10% of the total) was deported. After the war Queen Wilhelmina granted it the use of the motto *Heldhaftig, Vastberaden, Barmhartig* ("Heroic, Resolute, Merciful") under its coat of arms, in recognition of the conduct of its people during the occupation.

(P. J. M.)

AMSTERDAM, city of Montgomery county, in eastern New York, U.S., lies on the north and south shores of the Mohawk river, about 31 mi. N.W. of Albany.

Amsterdam was settled by Albert Veeder of Schenectady in 1783 although other settlers were reported there as early as 1775. It was called Veedersburg until 1804, when its present name was adopted. It was incorporated as a village in 1830 and chartered as a city in 1885. Amsterdam grew in importance after the opening of the Erie canal in 1825 and the coming of the first railroad in 1836. A principal factor in its growth was its location on the low-level Mohawk river route through the Appalachian mountains. Through this natural corridor passed settlers headed west, many of whom stayed in the area. Once an important centre for the manufacture of rugs, carpets and other textiles, beginning with establishment of the carpet industry in 1838, the city began to shift to the manufacture of other goods in the 1950s. These included plastics, automotive, electronic and communications equipment, textiles and leather goods. For comparative population figures see table in NEW YORK: Population. (P. F. W.)

AMU-DARYA (ancient OXUS; Arabic JAYHUN) is the largest river of Soviet Central Asia, exceeding its nearest competitor, the Syr-Darpa (*q.v.*) by about two to three times in volume of flow. The headwaters rise in the lofty mountain ranges of Soviet Tadzhikistan and northern Afghanistan at elevations of up to 16,000 ft. In its upper, mountain-girt basin the Amu-Darya follows a westerly course and, together with its upstream extensions, the Pyandzh (Panj) and the Pamir, constitutes the international frontier between the U.S.S.R. and Afghanistan. The river receives the

name Amu-Darya only below the confluence of the Pyandzh river with the Vakhsh, a tributary feeding into the main stream from the north. After leaving the highland zone, the Amu-Darya veers to the northwest and crosses the desert expanses of the Turanian lowland to its mouth on the Aral sea. In the lowland zone it forms the boundary between the Kara-Kum desert to the west and the Kyzyl-Kum desert to the east.

The upper, or ancient, delta begins at a point 240 mi. from the river's mouth, and the lower, or contemporary, delta 100 mi. from the mouth. In the lower delta the Amu-Darya branches into a number of distributaries. Total length of the river from source to mouth is about 1,578 mi., of which almost one-half is in the mountain zone. Approximate area of the Amu-Darya's basin is 180,000 sq.mi.

In ancient times the Amu-Darya flowed into the Sary-Kamysh depression, a large dry basin to the west of the upper delta, rather than into the Aral sea as at present. Part of the water in the Sary-Kamysh depression followed the channel of the Uzboy westward and discharged into the Caspian sea near Krasnovodsk. The Uzboy dried up 2,000–3,000 yr. ago. The Turkmen Canal scheme, authorized in 1950 but subsequently abandoned, envisaged the diversion of water once more along this route for the irrigation of large acreages in western Turkmenistan.

Hydrologically, as well as physiographically, the Amu-Darya's basin consists of two units: the mountainous zone of nourishment and the lowland zone of depletion. In the upper basin, tributary streams flowing off the mountain slopes swell the main river as it wends its way westward along the international frontier. Major tributaries entering the river from the north, or Soviet portion of the basin, are the Gunt, Bartang, Kyzyl-Su, Vakhsh, Kafirnigan and Surkhan-Darya. The two main tributaries from the south, or Afghan portion of the basin, are the Kokcha and Kunduz. Although 40% of the zone of nourishment lies within Afghanistan, a smaller share, not likely exceeding 25%, of the Amu-Darya's runoff originates in that country. In its middle and lower courses across the Turanian lowland no tributaries enter the river and it is rapidly depleted through irrigation, seepage and evaporation. The total average annual discharge of the river at Nukus, at the head of the lower delta, is about 38,000,000 ac.ft. (52,500 cu.ft. a second); at Kerki, 500 mi. upstream, the mean annual discharge is 52,500,000 ac.ft.

About 60% of the Amu-Darya's runoff is concentrated in the four-month period from May to August. The river is fed to a large extent by meltwater from high perennial snow fields and alpine glaciers, and flows remain at a high level throughout the entire summer, peak discharges being recorded in July. In its lower course the Amu-Darya is ice-covered for a period of two to two and one-half months; farther to the south, in its middle reaches, it rarely freezes. It is navigable up to the mouth of its tributary the Kokcha, or for a distance of almost 900 mi.

Irrigation has been practised in the basin of the Amu-Darya since ancient times. The irrigated acreage of field crops in the Soviet portion of the basin expanded from about 1,000,000 ac. in the late 1920s to an estimated 1,500,000 ac. by the mid-1950s. About 65% of the irrigated land is in the delta region, 15% along the west bank of the middle course (between the Soviet-Afghan frontier and the delta) and 20% in the upper basin, primarily in the valleys of the Vakhsh, Surkhan-Darya and Kafirnigan. Cotton is the principal crop.

Several schemes have been proposed for diverting water westward to irrigate vast tracts between the Amu-Darya and Caspian sea. Construction of the Kara-Kum canal along the southern edge of the Kara-Kum desert was begun in the late 1940s and, after an interruption of several years, resumed in 1954. The scheme ultimately envisages a canal 550 mi. in length from the Amu-Darya to a point west of Ashkhabad, irrigating an area of up to 1,100,000 ac. The abandoned Turkmen Canal scheme was planned to skirt the northern edge of the Kara-Kum desert.

Only a minor fraction of the Amu-Darya's water resource is yet utilized for irrigation. It represents the last major source of surface water which can be tapped for irrigation expansion in Soviet Central Asia.

Hydroelectric development is confined to a few installations, of small to medium capacity, on upstream tributaries. (N. C. F.)

AMULET, an object, whether natural or made by man, believed to be endowed with special powers of protection or of bringing good fortune. In the latter capacity an amulet may also be called a talisman, or in modern usage a charm or mascot (though mascot is a wider term which can also include animals). Amulets are carried on the person or kept in the place which is

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

ANCIENT GEM AMULETS. (LEFT) AGATE AND (RIGHT) GREEN PORPHYRY FROM LATE MINOAN AND MYCENAEAN PERIODS; (CENTRE) BABYLONIAN GLAZED FAIENCE

the desired sphere of influence, for example, on a roof or in a field.

Natural amulets can be of many kinds: precious stones, metals, teeth and claws of animals, plants, etc. Man-made amulets are equally varied: for instance, small models of animals or of objects,

medallions bearing religious pictures or inscriptions (such as invocations to deities, the tetragrammaton, texts from the Bible or the Koran), and lockets containing such inscriptions on paper or metal.

Amulets have been and are widely used by both primitive and civilized people, though as receptacles of superstitious belief and magical properties they have always incurred the disapproval of the Christian church.

Amulets are thought to derive power from their connection with natural forces, from religious associations (as for instance of a holy image or inscription) or from being made in a ritual manner at a time of favourable planetary influence out of material and in a shape suiting the purpose. An Indian advertisement in 1943 gave a list of 12 purposes (with three degrees of effective power

CARL G. DIEHL

AMUNDSEN, ROALD (1872–1928), Norwegian explorer who must be regarded as one of the greatest in the field of polar exploration, discoverer of the south pole, was born at Borge, on July 16, 1872, a few miles south of Oslo. He studied medicine for a while and then took to the sea. In 1897 he joined a Belgian expedition as mate. The ship, the "Belgica," was the first to winter in the antarctic and Amundsen, with the American physician-explorer F. A. Cook, was largely responsible for bringing the crew

through severe attacks of scurvy. In 1903 he made plans for conquering the northwest passage in a sloop of 47 tons named the "Gjøa." With a crew of six he sailed secretly to escape creditors. He was the first man to take a ship through the passage, and it focused his attention on the spectacular in polar exploration. His next plan, to drift across the north pole in F. Nansen's old ship, the "Fram," was affected by the news that Robert E. Peary, the American explorer, had reached the pole in 1909, but he continued his preparations. When he left Norway in June 1910 no one but his brother knew that he was heading for the south pole instead of the north. He sailed the ship direct from the Madeira Islands to Ross sea and there set up a base 60 mi. nearer the pole than Captain R. F. Scott, the English explorer. It was vital that he should be first at the pole and this he did in an amazing journey by dog sledge with four companions. With funds from this dramatic journey he successfully took up the shipping business and then built a new ship, the "Maud," with which to carry out his original plan. He left port in 1918, again secretly, so as to avoid German submarines and made the northeast passage to Bering strait. There things went wrong and he abandoned his plan in favour of trying to reach the north pole by air. In 1925 he made an adventurous journey with the American explorer Lincoln Ellsworth and got to within 170 mi. of it. In 1926 he tried once more. In the dirigible "Norge," and succeeded, jointly with Umberto Nobile of Italy, crossing from Spitsbergen to Alaska. Disputes arising over who should be credited with this flight embittered his later years.

Amundsen was lost over the arctic seas when on June 18, 1928, he joined in the attempt to rescue Nobile who had crashed in the dirigible "Italia." No trace of Amundsen's airplane was found.

(F. DE.)

AMUR, an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., was formed in 1932 from Khabarovsk *krai*; its present boundaries were established in 1948, giving it an area of 140,425 sq.mi. The *oblast* occupies the basins of the middle Amur and its tributary the Zeya, extending up to the crest of the Stanovoi range. The southern part is the fertile black-earth lowland of the Zeya-Bureya plain, which until the advent of the plow was covered by a steppe-like vegetation. The higher north and east is almost all forest-covered.

The population was 717,000 in 1959, most of which was of Russian or Ukrainian stock. The largest of the 16 indigenous groups are the Yakuts and Evenki of the north. The chief town and administrative centre is Blagoveshchensk (*q.v.*).

Agriculture is concentrated in the lowland and where virgin land has been plowed. Grain, chiefly spring wheat, occupies nearly three-quarters of the cultivated area, and maize has also been introduced. Soybeans and sunflowers are the main industrial crops. Opencast coal of low quality is mined at Raichikhinsk. In the north gold is mined.

Timber production for matches, telegraph poles and pit props is important but not fully developed. The main arteries of communication are the navigable Amur and the Trans-Siberian railway, which has feeders to the Amur river at Blagoveshchensk and elsewhere.

Russians first reached this area in the 17th century, but by the 1689 treaty of Nerchinsk yielded it to the Chinese. In the 19th century Russian colonization recommenced and in 1858 the area was incorporated in Russia.

(R. A. F.)

AMUR (Chinese HEI-LUNG CHIANG), a river of eastern Asia, forming part of the Soviet-Chinese frontier. The Amur is formed by the confluence of the Shilka and the Argun. The Shilka, in turn, is formed by the junction of the Ingoda, rising near Mt. Sokhondo in Soviet Transbaikalia, and the Onon, which flows from Outer Mongolia. The Argun, known as the Hailar in its upper course, rises on the western slopes of the Khingan mountains and is connected by an intermittent channel with the lake Dalai Nor (Hu-lun ch'ih), which receives the Kerulen river from Outer Mongolia. The Amur river flows to Amur bay of the Tatar strait, which separates the island of Sakhalin from the Siberian mainland and connects the Sea of Okhotsk with the Sea of Japan. Counting the Shilka-Onon system, the Amur river has a length of 2,703 mi.; the Amur proper, from the Argun-Shilka confluence, is 1,767 mi.

long.

The Chinese name Hei-lung Chiang means Black Dragon river; another Chinese name is Hei Ho (Black river). The origin of the name Amur is disputed. Some authorities link it to Mamu, a name given to the river in its lower reaches by local tribes; others derive the name Amur from Khara-muren (Black river), a Mongol-Tungus designation of the river. The Amur river flows past the cities of Blagoveshchensk, centre of the Zeya-Bureya agricultural plain, and Khabarovsk and Komsomolsk, Soviet industrial centres, and the fishing port of Nikolayevsk. The principal tributaries are the Zeya and Bureya rivers on the left and the Sungari and Ussuri (also a Soviet-Chinese border stream) on the right. The Amur proper is navigable in its entire length during the ice-free season, which lasts from May to October. During this season the Amur reaches its high-water stage due to summer monsoon rains. The river carries grain, salt and manufactured goods downstream, and crude and refined oil, fish and timber upstream. The Soviet bank of the Amur, which is paralleled by the Trans-Siberian railroad and is relatively well developed economically, contrasts sharply with the sparsely settled Chinese bank.

The Russians first appeared on the banks of the Amur in 1644, when Vasily Poyarkov's Cossacks reached the river from Yakutsk. Another Russian, Yerofey Khabarov, explored the Amur valley in 1649-51. By the treaty of Nerchinsk (1689), the Argun became part of the Russian-Chinese boundary and the Chinese retained both banks of the Amur. By the treaty of Aigun (1858), confirmed by the treaty of Peking (1860), the Chinese ceded all lands north of the Amur and east of the Ussuri to the Russians. In 1956 Soviet and Chinese experts began to formulate long-range plans for joint utilization of the hydroelectric, transportation and economic potential of the Amur river basin.

(T. SD.)

AMUSEMENT TAX. By the early 1960s the U.S. federal government, over two-thirds of the states and a number of localities imposed amusement taxes or taxes on admissions. All but a few of the state taxes were either applications of general sales taxes to admissions or special levies on admissions to racing and other sporting events. State rates varied in the 2% to 5% range, but most were 3%. Local taxes, confined to about one-fourth of the states, were usually 5% or less. The federal tax, after 27 years at 10%, was raised to 20% in 1944 and then cut to 10% in 1954 except for admissions to cabarets. By 1960 admissions costing less than \$1 were exempt from the federal tax. Most of the yield came from admissions to motion-picture showings.

Events sponsored by or for religious, educational, governmental, charitable, symphony, opera and other nonprofit organizations had become widely exempted, but details varied. Federal taxes such as those on club dues and bowling alleys; and state and local licence taxes or charges on theatres or places of amusement are not strictly admissions taxes. The pure amusement tax is almost always quoted separately and presumably shifted to the buyer of the ticket.

The common justification for singling out this form of consumption for special taxation is that entertainment is not a necessity and that spending on recreation evidences somewhat more than ordinary taxpaying ability. Such views, however, seem to many economists and others to be far removed from modern notions of psychology, the sources of mental health and the economics of consumption above the most elemental level.

(C. L. H.; X.)

Great Britain.—The entertainment duty, which was introduced by the Finance (New Duties) act of 1916 and amended by subsequent finance acts before its repeal by the Finance act of 1960, was chargeable on all payments for admission to any exhibition, performance, amusement, game or sport in which the person being admitted was a spectator and not a participant; for instance, no duty was chargeable for admission to a whist drive. There were three scales of duty: (1) on performances in which the performers were actually present and their words or actions constituted the entertainment (*e.g.*, a play, concert, lecture or circus); (2) on entertainment including racing, games or exhibitions; (3) on entertainment which consisted of reproductions of words or actions of performers not actually present (*e.g.*, a film show).

Duty was generally paid by tickets of admission which had to be stamped to show that the duty had been paid. In certain cases admission through a barrier or turnstile was authorized. In some cases also the proprietor of the entertainment, who was responsible for payment of the duty, furnished returns of payments for admission.

Certain entertainments were entirely or partially exempt from duty, and these exemptions were gradually extended by successive finance acts in the 1950s. In 1955 a number of entertainments received exemption, including wholly educational entertainments, indoor entertainments in rural areas or in buildings holding not more than 400 persons, and a wide range of entertainments given by charitable or nonprofitmaking organizations. In 1957 the Finance act provided that entertainments duty should not be chargeable except in respect of entertainments consisting wholly or partly of a motion-picture or television show.

In 1958 the Entertainments Duty act consolidated the previous enactments on this subject. Finally this act itself was repealed, and any entertainments duty unpaid at the passing of the Finance act in 1960 and chargeable on a payment for admission to an entertainment given after April 9 of that year was remitted, by virtue of section 4 of the act. The duty was thus abolished.

(W. T. Ws.)

AMYL ACETATE, the collective term applied to the acetic acid esters of any amyl alcohol or mixture of amyl alcohols. All of the amyl acetates are colourless, neutral, mobile liquids having pleasant fruitlike odours, hence the use of certain amyl acetates as essences in perfumery and cosmetics. Of the eight possible isomeric amyl acetates (empirical chemical formula $\text{C}_7\text{H}_{14}\text{O}_2$), six are produced in commercial quantities. Amyl acetate is also known as banana oil.

The amyl acetates are powerful solvents, and with the exception of the small amounts used by the perfume and pharmaceutical industries, their commercial importance depends upon this quality. Production of amyl acetates in the U.S. declined rapidly after the peak years of 1944 and 1945.

(D. G. Z.; N. C. S.; X)

AMYL ALCOHOLS. There are eight of these alcohols theoretically possible. All are known, and the most important is iso-butyl carbinol (or isoamyl alcohol), the chief constituent of fermentation amyl alcohol and consequently present in fusel oil (*qv*). It can be extracted from fusel oil by shaking this with strong brine, discarding the brine layer and collecting the portion boiling between 125° and 140° C. By shaking this product with hot aqueous calcium hydroxide, separating the oily layer, drying it with calcium chloride and collecting the fraction boiling between 128° and 132° C., a further degree of purification may be effected. A mixture of amyl alcohols that is used as a solvent for pyroxylin lacquers is manufactured by the chlorination of pentanes from petroleum and subsequent hydrolysis of the resulting amyl chlorides.

All eight amyl alcohols have the general formula $\text{C}_5\text{H}_{11}\text{OH}$, the differences being caused by the different ways in which the carbon atoms are linked together and by the different positions of the hydroxyl groups (OH). All have been obtained synthetically by the standard methods of organic chemistry.

AMYL NITRITE (ISOAMYL NITRITE), a liquid which finds application in medicine, since it dilates the blood vessels and gives quick relief from attacks of angina pectoris. It is used also to some extent in the preparation of diazonium and isonitroso compounds. It is prepared by passing nitrous fumes (from starch and concentrated nitric acid) into warm isoamyl alcohol; or by distilling a mixture of 26 parts of potassium nitrite in 1 j parts of water with 30 parts of isoamyl alcohol in 30 parts of sulfuric acid. It is a yellow-coloured liquid of specific gravity 0.877, boiling at about 95° – 96° C., of characteristic penetrating odour and having the composition $\text{C}_5\text{H}_{11}\text{ONO}$. It is insoluble in water, but dissolves readily in alcohol, ether, glacial acetic acid, chloroform or benzene. It is easily reduced by metal-acid combinations, with the formation of ammonia and isoamyl alcohol; and on hydrolysis with potassium hydroxide it forms potassium nitrite and isoamyl alcohol. When the liquid is dropped on fused potassium hydroxide, it forms potassium valerate.

(F. L. A.)

AMYMONE, in ancient Greek legend, daughter of Danaus. With her sisters, she had been sent to look for water, the district of Argos being then parched through the anger of Poseidon. Amymone, having thrown her spear at a stag, missed it, but hit a satyr asleep in the brake. The satyr pursued her, and she called for help from Poseidon, who threw his trident at the satyr. Where it fell a spring arose, which received her name. Aeschylus wrote a satyric drama on the subject. By the god Amymone became the mother of Nauplius, the wrecker. Her meeting with Poseidon at the spring is frequently represented on ancient coins and gems.

AMYNTAS II or III (d. 370 B.C.), king of Macedonia from c. 393 to 370 B.C., came to the throne at a time of confusion and disorder which had persisted since the death of the strong king Archelaus in 399. Externally he was beset by the Illyrians and by the Chalcidian league of Greek cities; the threat from the latter was removed when Sparta's intervention led to the league's being disbanded (379). Later he entered into alliances with Athens and with Jason of Pherae, the ruler of Thessaly, and played a minor role in Greek international politics. Philip II, who first made Macedonia a great power, was the youngest of his three sons.

See F. Geyer, "Makedonien bis zur Thronbesteigung Philipps II," *Historische Zeitschrift*, Beiheft xix (1930). (R. H. St.)

AMYOT, JACQUES (1513–1593), French bishop and classical scholar, famous for his translation of Plutarch's *Lives* (*Vies des hommes illustres*), was born at Melun, near Paris, on Oct. 30, 1513. He was educated at Paris university and at Bourges, where he became professor of Greek and Latin and translated Heliodorus' *Aethiopia*, the romance of Theagenes and Chariclea. For this Francis I gave him the abbey of Bellocane. Amyot then went to Italy to study the Vatican text of Plutarch, on the translation of whose *Lives* (1559; 1565 ff.) he had been engaged for some time. He also undertook a mission to the Council of Trent. On his return to France he was appointed tutor to the sons of Henry II. Both favoured him on accession, Charles IX making him grand almoner in 1560. Amyot was made bishop of Auxerre in 1570, and spent the rest of his life there, troubled by insubordinate clergy but continuing to perfect his translations. He died at Auxerre on Feb. 6, 1593.

Amyot translated seven books of the historian Diodorus Siculus (1554), the *Daphnis et Chloé* of Longus (1559) and the *Opera Moralia* of Plutarch (1572), as well as the *Lives*. Idiomatic and lively in style, so that it reads like an original work, the *Vies des hommes illustres* was translated into English by Sir Thomas North (1579), and supplied Shakespeare with material for his Roman plays. The personal method of Plutarch appealed to a generation fond of memoirs, so that Amyot's book won immense popularity and exercised great influence upon several generations of French writers. Amyot took great pains to find out and to interpret correctly the best authorities, but the appeal of his translations lies in the simplicity and purity of language.

See A. de Balignières, *Essai sur Amyot et les traducteurs français au XVI^e siècle* (1851); *Vies des hommes illustres* (1914).

AMYOTROPHIC LATERAL SCLEROSIS. Progressive muscular atrophy (PMA), amyotrophic lateral sclerosis (ALS) and progressive bulbar palsy (PBP) are all variations of a single disease process often referred to as "motor system disease." The outstanding feature is a progressive paralysis caused by an unexplained degeneration of the motor neurones in the spinal cord (PMA), spinal cord and cerebral cortex (ALS) and medulla oblongata (PBP).

The first symptom may be a weakness of a few of the muscles in the hand or arm or of the tongue, pharynx and larynx, the latter presenting itself as a difficulty in speech or swallowing. Twitching of parts of muscles (fasciculations) and cramps are common. Later other muscles are involved. The limbs become either stiff with overly active reflexes or slack with reduced reflexes, depending on whether cortical or spinal motor neurones are predominantly affected. The senses are unimpaired and the intellect remains sound.

The onset is insidious, usually occurring in the fifth and sixth decades of life, and the course is usually progressive to a fatal

termination in two to six years. The disease is rare and, as a rule, nonfamilial. The cause is unknown and there is no effective treatment.

(R. D. 4.)

ANABAPTISTS, called among themselves more commonly "Christian Brethren," constituted the massive radical or left wing of the Reformation. Their most distinctive tenet was adult baptism. In the first generations of the movement converts exposed themselves to the charge of submitting to a second baptism and were liable to capital punishment according to provisions against rebaptism in the Theodosian and Justinianic codes which were revived to cope with them.

The Anabaptists themselves, of course, denied that they were rebaptizers, for they repudiated their own baptism in infancy as a blasphemous formality. They considered their entry into "the covenant of a good conscience with God" in the public avowal of sin and faith, sealed by adult baptism, as the only proper implementation of the apostolic ordinance. They refused to consider the baptism of children, practised by classical Protestants in continuation of Catholic usage, as containing any of the essential elements of the true ordinance such as repentance, experiential faith and a responsible pledge to lead a Christian life. In their insistence on personal faith and accountability ("the Christian life is not child's play"), the Anabaptists held that the Protestant equation of circumcision under the Old Covenant and infant baptism under the New was a monstrous distortion of the gospel. Likewise they repudiated the interrelated doctrines of original sin and predestination on which this postulate of equivalence was theologically grounded (*e.g.*, by Zwingli). They held instead that Christ's atoning work had wiped out the consequences of Adam's fall for all mankind and that therefore infants were henceforth not punishable for sin until an awareness of good and evil emerged within them, whereupon by the exercise of their own free will (as against Luther's conception of the bondage of the will in respect to one's decision for salvation) they might appropriate the remedy instituted by Christ for the burden of personally committed sins, namely, the rite of believers' repentance and baptism.

In keeping with their distinction between circumcision and baptism, between the Old Testament and the New, the Anabaptists also on principle separated the church, which to them was the community of the redeemed, from the state, which for them was ordained solely for the punishment of sinners. This principle they defended with their lives in thousands of fiery, bloody or watery martyrdoms, thereby testifying to their conviction that no magistrate, whether a reforming Protestant or, a defender of the Catholic order, had competence in the sphere of Christian regeneration nor any right to use coercion in the mysterious realm of faith and conscience. Most Anabaptists, indeed, opposed the use of the sword by Christians alike in the maintenance of social order and in the conduct of a just war, even in the defense of Christendom against the Turks. In their strict compliance to the laws of Christ they also refused to swear the civil oath.

Unlike the classical or magisterial Protestants, who on principle made use of the magistrate to implement their Reformation, the Anabaptists were not aiming at reform of the medieval church. They were determined instead to restore the institutions and the spirit of the primitive church in their utter confidence that they were living at the end of all ages. Hence they readily recognized in their leaders divinely summoned prophets and apostles. Hence also all converts, including women, the peers of men, stood ready to give a full account of their faith before the magistrates. In their restorationist urge, they identified their suffering with that of the martyrs and confessors of the first three Christian centuries.

Northwestern Europe.—Anabaptism was first organized in separate conventicles in the canton of Zurich in Jan. 1525 under the leadership of the young patrician Conrad Grebel (*q.v.*), erst-while associate of Zwingli. The first to receive rebaptism was the former priest George Blaurock of Grisons. This radical evangelical movement spread rapidly like a revival with itinerant evangelists into the other cantons and thence into south Germany, there winning a notable convert in Baltbasar Hubmaier, the reformer of Waldshut. The Swiss movement formulated some of its more distinctive convictions in the seven articles of the Con-

fession of Schleitheim drawn up in 1527 under the leadership of Michael Sattler.

A second and apparently independent hearth of Anabaptism was Augsburg, where Hans Denck, formerly of Nürnberg, rebaptized Hans Hut, who had once been a follower of the radical spiritualist Thomas Müntzer (*q.v.*). Denck, more contemplatively inclined than Hut and inspired by the mysticism of Johann Tauler (*q.v.*), by young Luther's spiritualism and by Müntzer's passion for social justice, stressed the redemptive importance of imitating Christ's suffering in patient abandon to the will of God (*Gelassenheit*) and the attendant purification of the will in preparation for the acceptance of the baptismal "covenant of a good conscience." Denck's disciple Hut carried over from Müntzer more of the sense of the imminence of the Latter Days and the judgment of God and became the main apostle of Anabaptism in the upper valley of the Danube.

In Austria and the Tyrol and particularly in Moravia (which, under tolerant lords eager for enterprising colonists, quickly became an asylum for the persecuted Anabaptists from all parts), a third type of Anabaptism emerged which stressed the community of goods on the model of the primitive church in Jerusalem and under the influence also of an epistle (IV Clement) wrongly attributed to Clement I of Rome. Under the leadership of the charismatic Tyrolean Jakob Hutter, who imposed his will with the authority of a latter-day apostle, the burgeoning communistic colonies assumed his name. Hutterites survive to this day, mostly in the western states and provinces of the United States and Canada.

A fourth major regional variant of Anabaptism arose under the leadership of the former Lutheran evangelist turned radical apocalypticist, the furrier-prophet Melchior Hoffman (*q.v.*). In Strasbourg, where he was converted to Anabaptism, he came to espouse the view, shared in one form or another also by Kaspar von Schwenckfeld and Michael Servetus (*qq.v.*), that Jesus Christ's human nature derived not from the substance of Mary his mother but from God the Father and was brought with him from heaven, a celestial flesh identical with the manna which sustained the children of Israel in the desert. The doctrine was thus not only christological but also eucharistic and was the theological basis for a perfectionist conception of the church, to which the convert was admitted by believers' baptism, in which he was sustained by progressive incorporation into the eucharistic body, and from which, by a communally exercised ban, he could be excluded at the slightest infraction of the stern code of the disciples of Christ. Melchior Hoffman was the apostle of the lower Rhine and the Netherlands, beginning in 1530.

Hoffman was himself imprisoned on a return journey to Strasbourg in 1533. His eschatological fervour was misappropriated by the Dutchmen Jan Mathijs and later John of Leiden (Jan Beuckelson), who converted the radical reformation of Münster under Bernard Rothmann, a former Lutheran, into a communist, polygamous, Maccabean theocracy (1534–35). Over this community John ruled as the Anabaptist king with pretensions to global sway in preparation for the second coming of Christ and the Fifth Monarchy (the millennium).

The excesses of the bellicose Munsterites confirmed the evil reputation of all Anabaptists in the eyes of the classical Protestants and the Catholics. Both Protestants and Catholics henceforth, with little discrimination between the belligerent minority centred in Münster and the pacifistic majority elsewhere, intensified throughout central Europe the mandates and judicial procedures against what seemed to be an omnipresent conspiracy, at once seditious and blasphemous, on the part of the lower classes. The pacifistic Netherlands and north German Anabaptists now rallied under the leadership of the former priest Menno Simons (*q.v.*) and his lieutenant Derck Philips. They have survived in large numbers to the present day under the name of Mennonites (*q.v.*).

With the collapse of the Münsterite kingdom, Anabaptism extended as a movement of the people from Hull to Danzig, from Brussels to Venice.

Italy and Eastern Europe.—In the Po valley and particularly

in Venetia and the Italian-speaking valleys within the jurisdiction of the relatively tolerant confederation of the Three Leagues of Raetia (Graubunden or Grisons), another regional variant developed under the influence of Servetus, an immersionist, and particularly of Camillo Renato. The distinctive features of Italian Anabaptism were a distrust of the Nicene formulation of the doctrine of the Trinity; a stress on the doctrine of election for salvation which attenuated the covenantal and ecclesiological significance of believers' baptism; and a widespread adherence to psychopannychism (the belief that the soul at death sleeps or even perishes altogether, to be resurrected with the body for the last judgment and eternal life with Christ). A large synod at Venice in 1550 articulated these views along with an adoptionist Christology which went much further than Servetus in the abandonment of the dogma of the Trinity.

Anabaptism in Poland and the grand duchy of Lithuania—though originally Mennonite, Silesian and Moravian and centred in the Dutch colonies in the marshy delta of the Vistula and related areas in ducal Prussia—at length transcended the language barrier, working within the radical sector of the Reformed Church to emerge as an important regional variant of the movement. Here its distinctive features were tritheism changing into ditheism and then unitarianism. Baptism was by immersion (instead of by pouring as with most other Anabaptists). Many members of the Polish gentry on becoming converts renounced the use of the sword and freed their serfs. Petrus Gonesius in 1558 was the first Pole to avow his adhesion to the Hutterite-Servetian version of Anabaptism before a duly convoked Reformed synod. Martin Czechowic and Gregor Pauli were other leaders. Vilna (Vilnius) in Lithuania (1563–66), Lublin, Cracow, Pinczow and the communistic colony at Rakow in Little Poland, beginning in 1569, were notable centres. Under the leadership of Faustus Socinus (see SOCINUS), a decade later, the Polish and Lithuanian Brethren were gradually converted to Socinianism, in which most of the typical Anabaptist characteristics, except for pacifism and adult baptism, were attenuated.

On their flight from Poland in the next century the Socinians introduced into Holland their practice of baptism by immersion, which was adopted by the Arminian Collegiants and by such liberal Mennonites as the Waterland *Doopsgezinden* (baptism-minded). In turn the practice of immersion was taken over by the English General Baptists exiled in their midst. English (Calvinistic) Baptists, however, were only indirectly connected with the Melchiorite (Hoffmanite) Anabaptists in England under Henry VIII and Elizabeth I, though the name Anabaptist with its Munsterite connotations was used of the Baptists by their foes in both old and New England into the 18th century.

Relationship with Baptists and Other Protestants.—Modern scholarship—still divided in assessing the genetic and theological relationship of 16th-century Anabaptism to normative or magisterial Protestantism on the one hand and, on the other, to the demimonde of late medieval piety and speculation—has variously characterized the movement as, at one extreme, a radical variant of authentic Protestantism, at the other as a Protestantized version of medieval conventicular dissent (Waldensianism, Hussitism, Sacramentism). Anabaptism was surely in one sense a radical sectarian version of the earlier Netherlands, Saxon and Swiss sacramentarian movement, represented by Cornelis Hoen, Karlstadt (*q.v.*) and Zwingli. It assimilated also and carried through, unambiguously or undialectically, such central Protestant affirmations as salvation by faith alone and the pre-eminence of the Bible over tradition, creed and canon law.

Precisely because of their evangelical fervour and biblicism, the Anabaptists were a continuous challenge to the more sensitive or conscientious leaders of classical Protestantism. Thus extended public disputations were as much a part of the 16th-century history of the movement as judicial hearings and persecutions. The most notable disputations, synodal and epistolary, within the radical Reformation itself were the Nikolsburg disputation in 1526 between Hubmaier and Hut over the legitimacy of using the sword; the debate in 1542 between the spiritualizer Kaspar Schwenckfeld and Pilgram Marpeck, the latter by then

the principal organizer of south German Anabaptism; and the synod in Strasbourg in 1555 between the Netherlanders and the upper Germans over excommunication and Christology. The most notable confrontations with the classical Reformers, including Zwingli, Heinrich Bullinger (*q.v.*), Martin Bucer (*q.v.*) and Jan Laski (see LASKI), were the disputations of Zurich in 1525, Zofingen in 1532, Strasbourg in 1533, Berne in 1538, Worms in 1557, Frankenthal in 1571 and Emden in 1578.

More than was realized at the time on either side, the testimony and the stubbornness of the Anabaptists helped to build up the institutions and theology of classical Protestantism. Modern Protestantism, moreover, has in the perspective of the years come to see the Munsterite episode as an aberration of a movement some of the principles of which Protestantism has unconsciously assimilated or indeed openly espoused, notably the principle of the separation of church and state and the voluntary basis of church membership.

ANACARDIACEAE, the cashew family containing about 70 genera and 600 species of dicotyledonous trees and shrubs of both hemispheres, chiefly tropical. In North America *Rhus* and *Toxicodendron* (combined as one genus, *Rhus*, by some authors) are widely distributed and represented by about 20 indigenous species known as sumac, poison oak and poison ivy. Two other native genera *Metopium* and *Cotinus* are represented by the poison tree (*Metopium toxiciferum*) of Florida and the smoke tree (*Cotinus americanus*) found from Tennessee to Texas.

The family is important for the edible nuts of the cashew (*Anacardium occidentale*) and pistachio (*Pistacia vera*); for the fruit of the mango (*Mangifera indica*), mombin (*Spondias* species) and Kafir plum (*Harpephyllum caffrum*); for resins, oils and lacquers obtained from the varnish tree (*Toxicodendron vernicifluum*) and the mastic tree (*Pistacia lentiscus*); for a few ornamentals (*Rhus* and *Cotinus* species); and for much of the commercial supply of tannic acid, obtained from the wood of the quebracho (*Schinopsis* species). See CASHEW; MANGO; MASTIC; POISON IVY; SUMAC; VARNISH TREE.

ANACHARSIS (? early 6th century B.C.), a legendary Scythian prince included in some ancient lists as one of the Seven Wise Men and extolled as a type of primitive virtue. Herodotus (iv, 76–77) describes how, after extensive travels abroad in quest of knowledge or as an ambassador, Anacharsis returned home and was killed by the Scyths either because he wanted to introduce the cult of the Great Mother of the Gods or because of his attachment to Greek customs. Later authors, however, offer more details, crediting Anacharsis with numerous aphorisms and citing an interview between him and Solon (see the "life" by Diogenes Laertius, i, 101–105; also Lucian, *Scythe*). The Cynic philosophers represented Anacharsis as a "noble savage," to be contrasted with the degenerate Greeks. Ten letters anciently ascribed to him are obviously not authentic.

ANACHRONISM, a neglect or falsification, whether intentional or otherwise, of chronological relation (Gr. *ana*, "back," and *chronos*, "time"). Its commonest use is in the antedating of events, circumstances or customs; *i.e.*, in the introduction, especially in works of imagination that rest on a historical basis, of details borrowed from a later age. Anachronisms originate in disregard of the different modes of life and thought that characterize different periods, or in ignorance of the progress of the arts and sciences and other varying facts of history. Only since the close of the 18th century has this kind of misrepresentation jarred the general intelligence.

Anachronisms abounded in the works of Raphael and Shakespeare. Artists tended to represent characters in terms of their own nationality and time. The Virgin was pictured both as an Italian peasant and as a Flemish housewife; Alexander the Great appeared on the French stage in the full costume of Louis XIV

down to the time of Voltaire. Modern realism, the progress of archaeological research and the scientific approach to history came to make an unconscious anachronism an offense. On the other hand, anachronisms may be introduced deliberately to achieve a burlesque or satirical effect; by contrasting contemporary customs or morals with an alien age the writer or artist re-evaluates the past or present, or both.

Thus Mark Twain wrote of a Connecticut Yankee visiting King Arthur's court, and James Ensor painted Christ entering Brussels.

ANACLETUS (CLETUS), **SAINT**, the third pope, who occupied the papal chair 76–88 or 79–91. According to Epiphanius and Rufinus, he directed the Roman Church with Lindus, successor to St. Peter, during Peter's lifetime. He died probably as a martyr during the reign of Domitian. His feast day is April 26.

ANACONDA, a city in southwestern Montana, U.S., about 26 mi. N.W. of Butte; the seat of Deer Lodge county. Copperopolis was suggested as the name for the town, which was laid out under the direction of Marcus Daly (*q.v.*) in 1883. Anaconda was chosen since another Daly mining camp had the name of Copperopolis. The city marks its effective beginnings from 1884 when Daly located a copper smelter on Warm Springs creek, the closest source of a good water supply to his Butte mines. Large plant expansions in 1892 and 1902 and subsequent modernization made it one of the world's largest nonferrous and reduction works, which rank it still held after mid-20th century. The plant employed about 4,000 smelter workers after mid-20th century. The plant's smokestack, the largest of its kind, stands 585 ft. high and dominates the landscape. The manufacture of phosphate products is also an important industry.

Daly had hoped to make Anaconda the capital of Montana. His Montana hotel was one of the most ornate in the nation at the end of the 19th century, and his newspaper, the Anaconda Standard, had a plant as modern as any in New York city at the time, although the population was less than 5,000. (For comparative population figures see table in MONTANA: Population.)

Nearby recreational areas include Georgetown lake and adjacent fishing streams, as well as the rugged mountains, adjoining the federal Pintlar Primitive area (145,000 ac. in the Deer Lodge, Beaverhead and Bitterroot forests), which provide excellent hunting in season.

(M. G. Bu.)

ANACONDA (*Eunectes murinus*), an aquatic boa (*q.v.*; family Boidae), inhabiting the swamps and rivers of Brazil, north-eastern Peru and the Guianas in South America. The nonvenomous anaconda is the largest of American snakes and rivals the reticulated python (*q.v.*) as the largest snake in the world. Early travelers told exaggerated tales of its size and swallowing capacity, but the largest known do not exceed 30 ft. in length. There is great dread of this snake among the Indians, though authenticated cases of its having attacked man are few.

The general colour of the anaconda is olive-brown, with large oval black spots arranged in two alternating rows along the back, and with smaller white-eyed spots along the sides. The belly is whitish, spotted with black. The head is elongate, flat and very distinct from the neck. The nostrils are situated between three large shields.

ARTHUR W. AMBLER FROM NATIONAL AUDUBON SOCIETY
ANACONDA (*EUNECTES MURINUS*)

The anaconda feeds chiefly at night upon birds and other animals, which it kills by constriction. Good-sized caymans are regularly killed and eaten by anacondas. In contrast to the boa constrictor, the anaconda spends most of its time in the water, lying submerged with only a small part of its head above the surface, waiting for any suitable prey. Only seldom does it establish itself in the branches of trees as the boa does.

The young, born alive, are about 36 in. long at birth. A brood of 72 has been recorded.

A smaller species of anaconda, *Eunectes notaeus*, inhabits Paraguay and the northern part of Argentina. Other species have been described from northern South America.

See also SNAKES.

ANACREON (b. c. 570 B.C.), after Archilochus the most important writer of personal lyric poetry in the Ionic dialect of Greek, was born at Teos in Ionia (now Sigaliki in Turkey). There is no direct evidence in his poetry that he accompanied the Teians to Abdera on their evacuation of Teos before the Persian advance

(c. 545). His working life is associated mainly with the courts of "tyrants," the great patrons of art and literature in the 6th century. He appears first at the court of Polycrates of Samos (c. 539–522), and according to Herodotus he was actually in the room when Polycrates was assassinated by a Persian envoy. From Samos he is said to have been brought to Athens in a warship on the orders of Hipparchus, son of Pisistratus, the "tyrant" of Athens. It is not certain how long he survived the assassination of Hipparchus (514 B.C.), but his poems suggest that he lived to a considerable age, and his later popularity at Athens (attested by quotations and references in 5th- and 4th-century writers and Pausanias' statement that his statue stood on the acropolis beside that of Xanthippus, father of Pericles) allows the inference that he lived long enough to ingratiate himself with at least some elements in the Cleisthenean "democracy" (perhaps even into the 5th century).

Pausanias describes the attitude of the statue mentioned above as "such as might be that of a man singing when in liquor"; and Anacreon's reputation throughout antiquity was that of a man for whom almost anything might be "an excuse for a glass," and any glass would inspire him to love and song. Few, if any, of his poems have been preserved complete; and it may be that those who have quoted short snatches of his poetry have done him an injustice by omitting the serious poems which there is reason to believe that he wrote, but it is true that most of the fragments which have survived deal with wine and love (and his beloved objects were of both sexes). His language and his metres are alike smooth and simple; and his technique is all but perfect. It is no wonder that many people in later times tried their hand at imitating him (whence the large collection of poems which go under the name of Anacreontics).

BIBLIOGRAPHY.—Complete edition of fragments by B. Gentili (1958); most fragments ed. by J. M. Edmonds with Eng. trans. in *Lyra Graeca*, 2:120–221, Loeb series (1924). See also M. F. Galiano, "La lirica greca a la luz de los descubrimientos papirológicos," in *Actas del I congreso español de estudios clásicos*, pp. 111–119 (1958); C. M. Bowra, *Greek Lyric Poetry*, ch. 7 (1936); Freya Stark, *Ionia*, ch. 4 (1954).

(J. N. A. D.)

ANACREONTICS are poems written in the metre and from the supposed outlook of Anacreon (*q.v.*). In Greek the metre is $\cup\cup-\cup-\cup---$, and in modern European literature the line has seven or eight syllables with three or four main stresses. The

ANACREON AFTER THE ANTIQUE.
VILLA BORGHESE, ROME, ITALY

Anacreontic outlook is one of ironic enjoyment of life.

Greek Christian writers such as Clement of Alexandria, Gregory of Nazianzus and Sophronius wrote religious verse in the Anacreontic metre, but the best-known Anacreontics are the *Anacreontea*, a collection of about 60 short poems composed at various dates in the post-Classical period of Greek literature, first published by Henri Estienne as the work of Anacreon in 1554. These had a great influence on the Renaissance school of French poetry and were translated by Ronsard (1555) and Rémy Belleau (1556).

The word Anacreontiques was first used in England in 1656 by Abraham Cowley, who gives free translations of 11 *Anacreontea*. The following is an example:

Of't am I by the Women told
 Poor Anacreon thou grow'st old,
 Look how thy hairs are falling all;
 Poor Anacreon how they fall.
 Whether I grow old or no,
 By th' effects I do not know.
 This I know without being told
 'Tis Time to Live if I grow old.

There have been many translations of the *Anacreontea* into English, and Robert Herrick, William Oldys and William Shenstone, among others, tried original Anacreontics in English. Thomas Moore translated 60 *Anacreontea* and 19 "fragments," calling them "Odes of Anacreon," into English verse in 1800. The *Anacreontea* also had an influence on Italian and German literature.

See J. M. Edmonds, *Elegy and Iambus*, vol. 2, Loeb series (1931) for the *Anacreontea* with verse translation. (J. W. T.)

ANADYOMENE (Gr. *anaduomenē*, "emerging"). By a legend as old as Hesiod, Xphrodite was born from the sea. Hence in a famous picture by Apelles she was represented as having just emerged from the sea and in the act of wringing her tresses. This painting was executed for the temple of Asclepius (Xesculapius) at Cos, from which it was taken to Rome by Augustus, in part payment of tribute, and set up in the temple of Caesar. In the time of Nero, because of its dilapidated condition, it was replaced by a copy made by the painter Dorotheus.

ANADYR, a gulf of the Bering sea, a river and a town of the U.S.S.R. The gulf is in the extreme northeast of the Soviet Union on the coast of the Chukot National Okrug of the Russian Soviet Federated Socialist Republic, U.S.S.R. It lies between Cape Chukotski to the north and Cape Navarin to the south.

The river rises in the Anadyr plateau and follows a tortuous course of 694 mi. to the gulf of the same name; it drains about 57,915 sq.mi. and its average discharge is 5,000 cu.ft. per second. It is navigable to the village of Markovo. Its basin is bleak, thinly populated tundra but coal was discovered and is mined in small quantities.

The town lies on the south shore of the estuary of the Anadyr, centre of the Chukot National Okrug and a port on the Northern Sea route. It is a centre of fishing and reindeer-herding and since 1929 has produced small amounts of coal. A meteorological station of the Northern Sea Route administration is located there.

(R. A. F.)

ANAGNI, a town of central Italy in the province of Frosinone in Lazio (Latium), is on a hill above the Sacco valley, 38 mi. by road E.S.E. of Rome. Pop. (1957 est.) 15,520 (commune). The cathedral (1074) with its separate campanile is on the top of the hill and has a fine triple apse. The 13th-century Casa Barnekow stands at the entrance to the town. The Palazzo Comunale and the palace of Boniface VII are 12th- and 13th-century buildings. The ancient city walls still stand. Buses connect with the station (6 mi. S.W.) on the Rome-Cassino-Naples railway. The Via Casiliana from Rome to Naples, and the Autostrada del Sole from Milan to Naples pass below the town. Anagni is an agricultural centre, and there are distilling, gas and rubber industries. In classical days as Anagnia it was capital of the Hernici (*q.v.*), losing its independence to Rome in 306 B.C. It was besieged by the Saracens in A.D. 877. Its leading medieval families were the Conti and Caetani. Four popes came from Xnagni: Innocent III, Gregory IX, Alexander IV and Boniface VIII, who was captured there

in 1303 (*see* BONIFACE). Damaged during World War II, Anagni was taken by the Allies in June 1944. (G. VI.)

ANAGRAM, the transposing of the letters of a word or group of words so as to produce other words that possess meaning. The construction of anagrams is of great antiquity, its invention being ascribed without authority to the Jews, probably because the later Hebrew writers, particularly the Cabalists, were fond of it, asserting that "secret mysteries are woven in the numbers of letters." Anagrams were known to the Greeks and also to the Romans, although the known Latin examples of words of more than one syllable are nearly all imperfect. They were popular throughout Europe during the middle ages and later, particularly in France, where a certain Thomas Billon was appointed "anagrammatist to the king."

The transposed word or words should, ideally, bear a logical relation to the original. The making of anagrams was an exercise of many religious orders in the 16th and 17th centuries, and the Angelical Salutation *Ave Maria, gratia plena, Dominus tecum* ("Hail Mary, full of grace, the Lord is with thee") was a favourite base; it was transposed to hundreds of variations, as, for example, *Virgo serena, pia, munda et immaculata* ("Virgin serene, holy, neat and immaculate"). Among other anagrams is that from Florence Nightingale into "Flit on, cheering angel." The pseudonyms adopted by authors are often anagrams. Some of the scientists of the 17th century—for example, Galileo, Christian Huygens and Robert Hooke—embodied their discoveries in anagrams with the apparent design of avoiding the risk that, while they were engaged in further verification, the credit of what they had found out might be claimed by others. For a kind of word play similar to the anagram, *see* PALINDROME. In the 20th century, anagrams were frequently used in crossword puzzles, both in the clues and the solutions.

See H. B. Wheatley, *Of Anagrams* (1862); Archer Taylor, *A Bibliography of Riddles* (1939).

ANAH, a town of Iraq, lies on the Euphrates river 192 mi. below Dayr az Zawr and 119 mi. above Hit. Pop. (1957) 11,070, mostly Sunni Arabs. It retained its name at least from the beginning of the 2nd millennium B.C., but the actual site seems to have changed slightly. As late as the early 14th century A.D. it was on an island in the Euphrates, where the remains of a fortress and a minaret could still be seen in the middle of the 20th century. During the 17th century it lay on both banks of the river and was the residence of amirs of the al-Mwali tribe, which controlled the right bank from the territory of Tadmor to Hit. The town was sacked by the Persians shortly before 1629; became increasingly subject to raids from the desert and declined in size and prosperity. Alois Musil in 1912 reported the population as 700 Muslim and 500 Jewish families. Anah was confined 50 years later to a single, long street on the right bank of the river. Until the coming of motor transport it remained a staging post of some importance on the Euphrates valley route: which was joined at Anah by the desert route from Tadmor; but the modern road from Baghdad to Amman and the desert track to Damascus leave the Euphrates at Fellujah, and Anah became a local market town. It was formerly known for its wine and later for its palm groves; its products include butter and wool, and the strip of fertile land along the river yields cereals, fruit and dates. (E. E. D. M. O.)

ANAHEIM, a city of Orange county, Calif., U.S., 25 mi. S.E. of Los Angeles, in the fertile plain of the Santa Ana river. The area produces oranges, lemons, avocados, walnuts and vegetables. More than 130 industries have made Anaheim the largest industrial area in the county.

Anaheim was the first co-operative settlement in southern California. In 1857, 50 Germans organized an association in San Francisco; bought 1,165 ac. of land and prepared it for occupancy. The tract was then divided into 20-ac. shares, which were distributed among the members by lot, with bonuses and rebates to equalize the differences in value. The town took its name from "Ana," the name of the river and "heim," the German word for home. The town was incorporated in 1870 and received a city charter in 1888; in 1950 a council-manager form of government became effective. The town grew steadily through the end of the

19th and the first half of the 20th centuries. to 14,556 by 1950. In the following decade the population increased more than 500% chiefly because of the arrival of new industries and the rapid annexation of contiguous territory, and in 1960 the population was 104,184. (For comparative population figures see table in CALIFORNIA: Population.)

In addition to local recreational facilities (the city has established a park site adjacent to each elementary school playground), the southern California beach, mountain and desert resorts are within short driving distances of the city. Disneyland, the amusement park, was opened in Anaheim in 1955. (Wm. H. K.)

ANAHUAC, a historical-geographic district of Mexico with indefinite boundaries. This was the heartland of Aztec Mexico, and in Nahuatl (Aztec) the name means "land by the water." In colonial times Anáhuac designated that part of New Spain which in 1821 became independent Mexico. The original Anáhuac of the Aztecs was the central plateau valley of Mexico, an area about 50 mi. long by 30 mi. wide, in which present-day Mexico City is located. When the Spaniards arrived in 1519 the valley contained five large interlocking lakes: Zumpango, Xaltocan, Texcoco, Xochimilco and Chalco. The Aztec capital Tenochtitlán (modern Mexico City, *q.v.*) was situated on islands in the middle of this series of lakes. Its streets were Venicelike canals and three long causeways connected the city to the mainland.

In 1607–08 the engineer Enrique Martínez dug a ditch and tunnel northward to the headwaters of the Pánuco river system and drained off much of the water of the five lakes. In the 20th century shrunken Lake Texcoco was further drained. Its salt marshes still remain, as do Xochimilco's "floating gardens," but the vast water area is now gone. Saline deposits made the reclaimed land almost unfit for agriculture. The lake beds also gave Mexico City a very unstable subsoil which necessitates the use of deep foundation piles in the construction of heavy buildings.

The Pánuco system drains the valley into the Gulf of Mexico, and the Lerma river drains the contiguous basin of Toluca (just west of Anáhuac) into the Pacific. The average elevation of Anáhuac is 7,500 ft., and its mean temperature is 60° F. May is the warmest month (65°) and January is the coldest (54.3°). Rainfall is heaviest in July (4.5 in.) and lightest in January (0.2 in.). See also MEXICO: *Physical Geography*. (J. A. Cw.)

ANALCITE, sometimes referred to as analcime, is a common mineral of the zeolite group that usually occurs, associated with other zeolitic minerals, as beautiful glassy crystals lining amygdaloidal or vapour cavities in basic volcanic rocks such as basalt and melaphyre. Crystallizing in the cubic system, the common form is the icositetrahedron, either alone or in combination with the cube; it is often perfectly colourless and transparent with a brilliant glassy lustre, but sometimes it is opaque and white or pinkish-white. The Tertiary basalts of the north of Ireland frequently contain cavities lined with small brilliant crystals, and larger crystals of the same kind are found in the basalt of the Cyclopean Islands, Sicily. Large opaque crystals of the pinkish-white colour are found in cavities in melaphyre at the Seisser Alpe in southern Tirol. Analcite occurs in other zeolite areas, as in New Jersey and Nova Scotia, and good crystals have been found in copper mines in the upper peninsula of Michigan and at Table mountain, Colorado. Chemically, analcrite is a hydrated sodium and aluminum silicate, $\text{NaAlSi}_2\text{O}_6 + \text{H}_2\text{O}$. The hardness is 5 to 5.5, and the specific gravity, 2.25. Before the blowpipe the mineral readily bubbles and gives up water, as other zeolites, and fuses to a colourless glass. It is decomposed by acids with separation of gelatinous silica. See ZEOLITE.

ANALGESIA is the name given to the loss of the sensation of pain, and is the result of an interruption of the nervous pathway between skin and brain. Different forms of sensation from one area of skin, such as touch, temperature and pain, travel to the spinal cord by different nerve fibres in the same nerve bundle. Hence any injury or disease affecting such a nerve would abolish all forms of sensation in the area supplied by it. However, when the sensory nerves reach the spinal cord their fibres separate and pursue different courses on their way upward to the brain. Thus it is possible for certain forms of sensation to be lost, while

others are preserved. in diseases which affect only certain areas in the spinal cord. Since the sensations of pain and temperature travel the same path, they are usually lost together. Diseases of the cord which may cause analgesia without loss of the sensation of touch are *tabes dorsalis*, syringomyelia and tumours of the cord. Analgesia may also be a manifestation of hysteria. The term is used for types of pain relief induced by the giving of various drugs. The term is used extensively in obstetric practice. See ANESTHESIA AND ANESTHETICS; OBSTETRICS.

ANALOGY. The term analogy (*ana logon*, "according to a ratio") was originally used by the Greeks to mean similarity in proportional relationships. Thus in Euclid's *Elements*, books v–vi, the word is used for a proportionate resemblance between two or more quantities. This may be a similarity between two figures (*e.g.*, triangles) which differ in scale, or a formula by which it is possible to calculate an unknown quantity if it is known that it stands in a relation to another quantity similar to that in which two other known quantities stand.

Thus, if $2:4::4:x$, it can be seen that $x = 8$. Another form of analogy noted by the Greeks was that of similarity of function performed by two elements in their respective contexts. (This kind of inference is now commonly known by psychologists as "educing the correlate," and the ability to perform it is held to be one of the tests of intelligence.) Aristotle (*Topics*, i, 17) states the formulas of these two kinds of analogy: "As A is to B, so C is to D"; and "As A is in B, so C is in D."

Plato makes particular use of analogies in the sense of arguments from similarity of function, of which the similes in his *Republic*, book vi, are among the most famous: for instance, the Idea of the Good is said to fulfil a function in making knowledge possible in the intelligible world similar to that performed by the sun in making vision possible in the perceptible world. A relationship not yet understood is indicated as analogous to one which is already familiar.

In the middle ages widespread use was made of arguments from analogy, on the belief that the universe formed an ordered structure of such a kind that the macrocosmic pattern of the whole was reproduced in the microcosmic pattern of the parts, so that it was possible to draw inferences from the one to the other. This belief underlay the mediaeval conception of the law of nature, in which the juridical sense of law, prescribing the fitting order of human relationships, could be assimilated to the physical sense of law, describing what was held to be the order obtaining in the natural world. The natural world was held to exhibit hierarchical degrees of subordination, from which it was argued that the proper ordering of human relationships should exhibit degrees of subordination, such as those of the patriarchal family as described in Aristotle's *Politics*.

Arguments which may seem purely allegorical can be seen to be built on this belief in an identity of pattern in different contexts, both as between the macrocosm and microcosm and as between the structure obtaining in one part of the world and that obtaining in another. Such parallels were held to constitute arguments and not merely allegorical illustrations; for instance, it was contended that, as there are two luminaries to light the world, the sun and the moon, and two authorities set over man, the spiritual authority of the papacy and the temporal authority of the empire, as the moon's light is reflected from the sun, so the imperial authority must be derived from the papal. Dante in his *Monarchia*, while arguing against this particular analogy and claiming that the most that it could show is that the empire derives light, which is grace, and not *authority* from the papacy, nevertheless accepts the principles on which such arguments were built.

Analogy in Theology. — A uniquely important case of analogy was the comparison between God and His creatures, since no statement could be made about the Divine Nature which did not involve it. The classical treatment of the theological use of analogy is to be found in St. Thomas Aquinas (*Summa contra Gentiles*, I, xxx–xxxiv). He asks how we can use the same terms of God and creatures. They cannot be used univocally (in an identical sense), or we ignore the difference between infinite and finite being; they cannot be used equivocally (in quite unconnected senses), or we

say nothing meaningful about God by using them. Nor should they be used only metaphorically, as when it is said that God may be imagined for purposes of illustration as doing something like what a creature does (*e.g.*, "the name of *lion* applied to God means only that God manifests strength in His works as a lion in his": St. Thomas, *Summa Theologica*, I, i, qu. 13, art. 6).

They must be used analogically, that is, in such a way as to say something positive about the Divine Nature while at the same time recognizing the distinction between the way in which God exists and the way in which creatures exist. Aristotle had already remarked (*Metaphysics*, vii, 1) that "being" is a term which is used in different senses in different categories: when we say that a quality exists, "exists" is not used in just the same sense as when we say that a substance exists.

According to St. Thomas God is not in any category therefore to say that He exists will not mean that He exists as a being in the same sense as a man or a material substance exists. He exists as infinite being itself.

The theological analogy which seeks to explain, *e.g.*, "God is wise," has the form called "analogy of proportionality." God's wisdom is said to be related to His infinite being in a way similar to that in which our wisdom is related to our finite being. It will be seen that there is here a double analogy: (1) the relation between God's infinite being and our finite being; and (2) the relation between the way in which God's wisdom is related to His infinite being and the way in which our wisdom is related to our finite being.

The analogy between the meaning of "wise" as applied to God and as applied to us rests therefore on there being a prior analogy between the meaning of "being" as applied to God and qualified by "infinite" and the meaning of "being" as applied to us and qualified by "finite" (*analogia entis*). So unless we know how God's existence stands to ours, we cannot determine the meaning of His wisdom.

To say what any term used of God may mean, it is therefore necessary first to be able to say something about the distinction between finite and infinite being and the relation between them. The distinction is drawn by appealing to the notion of perfection. Finite being is perfectible, while infinite being is perfect. So terms used of God must be used in a sense which expresses perfection, and not all creaturely attributes can be used analogically of God. Thus, it is held, we can say that the infinite existent is good and that it is not corporeal.

While the distinction in the analogy between the meaning of terms applied to infinite being and the meaning of terms applied to finite was drawn by qualifying them through the notion of perfection, the ground for the belief that terms so qualified can be used of God on analogy with what they mean when used of creatures was sought by looking for a positive relation between finite and infinite being to provide a basis for the analogy. This relation was that of the dependence of finite on infinite being. That infinite being exists and that finite being has this relation of dependence on it was claimed to be shown by the "argument from the contingency of the world."

This argument begins by stating that it is always possible in the case of finite beings to say that they might not have existed and goes on to maintain that their actual existence can only be explained by their causal dependence on an infinite being, which, if it existed at all, would exist necessarily; *i.e.*, a being such that it would not make sense to say that as a matter of fact it exists, but it might not have done so.

The argument, then, claims to establish not only the existence of infinite being, but also that finite beings are dependent on it as effects are dependent on cause and will resemble it insofar as they tend to perfection. (The connection between the notions of "infinite," "necessary" and "perfect" as applied to being is here assumed.)

Kant and certain 20th-century logicians have questioned this use of the conceptions of "necessary" and "cause." They hold that to speak of infinite being as "cause" of the world as a whole is not to use the word "cause" in the same sense as when we speak

of causes of contingent facts within the world which are themselves also within the sequence of contingent facts. The legitimacy of this extended use of the term is questioned; and if it is itself an analogy, how can it be appealed to as the basis on which analogies are based? Similarly, the notion of "necessary" is held to apply properly to propositions, and its meaning when applied to "being" is questioned. The problem of the justification of theological analogy is thus not solved but is referred one stage further back. (*See* Kant, "Transcendental Dialectic," *Critique of Pure Reason*; and C. D. Broad, in *Journal of Theological Studies*, vol. xl [1939]. For attempts to restate the argument, see A. M. Farrer, *Finite and Infinite* [1943]; and E. L. Mascall, *Existence and Analogy* [1949]).

It is likely that most forms of theological and metaphysical thinking, where language has to be used beyond its normal contexts, will make use of analogies, and the problem of their justification will be debated. Joseph Butler's *Analogy of Religion* (London, 1736) was, however, so entitled not for this reason but because it sought to show the likeness between religion, natural and revealed, and the course and constitution of nature, both being held to exemplify the same principles and to give rise to similar problems.

Analogy in Science.—In scientific thinking, analogy may be used in inductive arguments to suggest hypotheses. Resemblances between different sets of phenomena may be taken as suggesting, not mere accidental likeness, but the existence of some law or principle common to both sets. This is held to be especially probable where a comparison can be made between the functions of elements in two systems. Sometimes a relationship observed in one context may suggest a clue as to how another sought-for relationship is to be conceived, as when observation of the moons or satellites of Jupiter suggested by analogy the modern conception of the solar system. T. R. Malthus' argument that populations, if left uncontrolled, would tend to increase in numbers beyond the means of their subsistence suggested to Charles Darwin the hypothesis of natural selection as an evolutionary mechanism, whereby only the fittest to their environment survived out of large numbers. The fruitfulness of such analogies for scientific inquiries depends on whether consequences can be deduced from them which can be tested or observed, and this is likely to depend on whether the resemblance selected as analogous is of a fundamental or merely of a superficial kind. Resemblances of a functional kind are more likely to be fundamental than are qualitative resemblances such as those of colour. If structural relations can be reproduced in a simplified form in a different medium, a model may be constructed. For instance, an atom may be portrayed as if the elementary particles revolving round a nucleus were like a miniature solar system. But it would not be legitimate to conclude from this that, for example, the process of nuclear fission is similar to the process by which new planetary systems may be formed or disrupted (*See also* INDUCTION.)

In social and political discussion, analogies often are used because of their persuasive power in bringing home some unfamiliar point in terms of what is more familiar. Thus biological analogies have frequently been used to suggest that the relation of members of a community to one another is an "organic" relationship in a "common life." Such analogies may be useful in so far as they suggest the mutual dependence of parts fulfilling different functions. They are misleading in so far as they omit the fact that individual members of the community also have purposes, rights and responsibilities of their own. An analogy is never an absolute likeness; it points to a similarity in certain respects, shown in contexts which will differ in other respects. In cases where appeal is made to analogy it should therefore be possible to show that the resemblances noted bear relevantly on the point to be established, while the differences are irrelevant for this purpose and can safely be ignored. In many cases it is difficult to be sure of this, and arguments from analogy are therefore precarious unless supported by considerations which can be established independently.

(D. M. E.)

ANALYSIS (IN PHILOSOPHY), sometimes called "logical" analysis, has long been regarded as at least part of the philosopher's task. It was described by Kant as the process of stating, clearly and explicitly, what is already contained, though "covertly," in our concepts. In the 20th century, however, many philosophers have come to hold that analysis is the whole business of philosophy — that philosophy does not consist, as do other sciences, in the attempt to extend our knowledge but consists rather in the activity of making clear what we know already, removing problems and perplexities which are the result not of ignorance of fact but of conceptual confusion and misunderstanding. This view was at one time combined with the metaphysical doctrine that both facts and language could be resolved into their ultimate, absolutely simple elements and that all else could be exhibited systematically as a "construction" founded upon this ultimate basis. But philosophical analysis would now more commonly be regarded as a procedure of conceptual clarification to be pursued until the air is clear enough for one's present purpose or until some particular perplexity has been resolved, and not to be thought of as tending toward any metaphysically ultimate terminus. There is, however, no generally accepted doctrine about actual techniques of clarification; it would probably be denied that any general doctrine could be usefully formulated; and partly for this reason, many philosophers would regard the assertion that analysis is the proper business of philosophy as too vague to merit either acceptance or dissent. But the widespread verbal agreement on this point may serve to emphasize the markedly unmetaphysical character of most contemporary philosophy in English. It should be added that the predicate "analytic," as applied to propositions, is commonly used to distinguish a particular class of necessary truths.

ANALYSIS is one of three main divisions of mathematics, the other two comprising (1) geometry and topology and (2) algebra and arithmetic. In extent, analysis is the largest; it comprises subdivisions which are nearly autonomous and which are easier to describe than the division as a whole.

MEANING OF ANALYSIS

Relation to Science. — Greek mathematics had a geometrical tenor, as the works of Euclid, Archimedes, Apollonius of Perga and Pappus testify. It did initiate some durable topics of analysis, but the organized creation of analysis began only around A.D. 1600. Analysis then came into being in stages, growing up in intimacy with mechanics and theoretical physics. This is not to say that other mathematics does not enter into science, too; in fact, all mathematics does. The two great innovations in physics in the 20th century, relativity and quantum theory, had to rely heavily on existing mathematical tools of geometric and algebraic provenance. But whenever work in basic physics instigated a topic in mathematics spontaneously it was largely in analysis. Thus, differential and integral calculus, ordinary differential equations and the calculus of variations have arisen from mechanics; Fourier series from acoustics and thermodynamics; complex analysis (*q.v.*) from optics, hydrodynamics and electricity; and partial differential equations from elasticity, hydrodynamics and electrodynamics. And even mathematical probability, which falls under analysis, although born from problems of gambling and human chance, drew much of its syllogistic strength in the 19th century from statistical theories of mechanics and thermodynamics.

Derivatives. — Geometry deals with spaces and configurations, topology with spatial deformations, algebra with the general nature of the basic operations of addition, subtraction, multiplication and division, and arithmetic with additive and multiplicative properties of general integers. Analysis also deals with specific operations, namely with differentiation and integration. But it is more appropriate to say that it deals with the mathematical "infinite" in many of its aspects, such as those of an infinite multitude, the infinitely large, infinitely small, infinitely near, infinitely subdivisible. Its first objects and concepts, introductory and yet actively basic, are infinite sequence, infinite series, a function $y = f(x)$, continuity of a function, derivative of a

function $y' = df/dx'$, and integral of a function. The mathematical concept of the derivative is a master concept, one of the most creative concepts in analysis as well as in all of human cognition. Without it there would be in scientific investigation no velocity or acceleration or momentum; no density of mass or electric charge or any other density; no gradient of a potential and hence no concept of potential in any part of physics; no wave equation; no mechanics, no physics, no technology, nothing. The formal textbook definition of the concept took more than 150 years to evolve, but even to the untutored it will be rewarding to savour Isaac Newton's own description of it under the name of "ultimate ratio":

For those ultimate ratios with which quantities vanish are not truly the ratios of ultimate quantities, but limits towards which the ratios of quantities, decreasing without a limit, do always converge: and to which they approach nearer than by any given difference, but never go beyond, nor in effect attain to, until the quantities have diminished *in infinitum*.

Newton's generation was literate enough to listen to a recondite mathematical definition, all in words, without symbols; and the marquise du Châtelet, woman of the world, could undertake to translate Newton's formidable *Principia* from Latin into French, ultimate ratios and all.

The semantic structure of the quoted sentence was well within reach of Greek natural philosophy. Similar sentences can be found in Euclid and Archimedes, and, outside of mathematics, in Thucydides. Now, if the inspiration of Greek thinking had been such as to be able to bring about the cognitive content of this sentence as well, then undoubtedly Aristotle would have devoted much of his "metaphysics" to it or even written a special treatise "On the Art of Derivation," and Archimedes might truly have discovered the 17th-century mathematics and physics which he had been dimly perceiving all his life.

Real Numbers. — Mathematical information of scientific statements introduces a peculiar kind of lucidity and precision into them and it suggests and establishes logical and cognitive relations between them. It also introduces challenging analogies and unifications. For instance, most phenomena of propagations of waves, whether in acoustics, hydrodynamics, electricity or optics, are assumed to be governed at the outset by virtually the same set of differential equations. Thus for a while the theories run parallel, until the actual differences of aim must be begun to be accounted for.

The most basic trait of unification is the fact that ultimately all specific and tangible information in science is quantitative; that is, it may be expressed in ordinary real numbers. Every physical magnitude, whatever its own unit of dimension (simple or composite) may be, is measured by one or perhaps several real numbers, and all these numbers come from the same joint supply. Without this fact, there would be no conservation laws in physics; the law of the conservation of energy, for example, could not be enunciated or even conceived. Space extensions, time intervals, noises, colours, tactile impressions and emotions—all these things are in the end valued quantitatively. The "meaning in depth" of formulas, equalities and inequalities in science comes to life by accompanying interpretations. But the transmittable specific information is all in numbers, whether on graphs or on punched cards or on tape.

This all-pervading arithmetization in physics and mathematics was begun systematically in the 17th century, and in mathematics its manifest outcome was first of all the "analytic" or "co-ordinate" geometry. Mathematics is less insistent than physics on its exclusiveness. To the contrary, 20th-century mathematics abounds and delights in ever introducing and rarely discarding concepts and objects which need not be numerical. But it somehow frequently comes back to numbers, and the effect of the 17th-century arithmetization of space on the course of mathematics cannot be overstated.

Magnitudes. — The Greeks never introduced the system of real numbers as the ultimate quantitative measure for geometry, and in science (excepting astronomy) only a few of their results became unmistakably quantitative at all. Instead, in mathematics, they tried to operate directly with the concept of a general "magnitude" which somehow was always geometrical. In the fifth book of

Euclid's *Elements* the technical term for "magnitude" is the noun *megethos*. In Homer, this noun still means personal greatness or stature (of a hero, say); and it is remarkable that in the French noun *grandeur* and the German noun *Grosse*, for instance, the two meanings of personal greatness and of mathematical magnitude likewise reside simultaneously. Twentieth-century mathematics has "magnitudes" on various levels of generality, but it has them in addition to and not instead of real numbers. The Greek attempt of bypassing real numbers altogether was amazingly mature, but in retrospection it appears to have been too mature. The Greeks took a giant stride, stopped and advanced no further.

STAGES OF DEVELOPMENT

Irrational Numbers.— In the 5th and 4th centuries B.C. the Greeks gave the first known satisfactory solution to a problem in analysis. In a square whose side has length 1, the diagonal has length $\sqrt{2}$. The decimal expansion of $\sqrt{2}$ is the nonterminating quantity 1.4142 . . . , so that $\sqrt{2}$ is the sum of the infinite series

$$1 + \frac{4}{10} + \frac{1}{100} + \frac{4}{1,000} + \frac{2}{10,000} + \dots$$

Now, the Greeks proved that $\sqrt{2}$ is not a rational number, that is, not a quotient p/q for integers p, q . But they apparently found for $\sqrt{2}$ an approximate representation by certain rational numbers, or rather they found for the diagonal of the square approximations by segments which are commensurate with the side of the square. The approximate numbers were what were later called the partial sums of the continued fraction for $\sqrt{2}$, and apparently it was from the study of this problem that there has evolved the so-called Euclidean algorithm. The deepest achievement in this entire context was the development of a general theory of irrational numbers, or rather of incommensurate ratios of certain types of "magnitudes" and of proportions between ratios. The fifth book of Euclid which contains this theory was much admired by the scholar and statesman Isaac Barrow, predecessor to Newton in the Lucasian professorship at Cambridge university, from which post Barrow resigned in favour of Newton in order to devote himself to statesmanship entirely.

Areas and Volumes.— The Greeks also investigated the number $\pi = 3.14159 \dots$, which is the area of a circle of radius 1, and the problem of squaring the circle was so widely known to the Athenian public that Aristophanes could allude to it in his comedy *The Birds*. Computations of other areas and volumes and of centres of masses are known from the works of Archimedes, and these results taken cumulatively can be viewed as a precursor to the 17th-century theory of integration. But these "direct" Greek calculations of many particular areas and volumes by circumscribed and inscribed approximating figures, when compared with the procedures of the integral calculus proper, are heavy, tiring and tiresome.

Set Theory.— The Greeks were also puzzled by the fact that the ordinary number 1 is the sum of the geometric series

$$\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \dots + \frac{1}{2^n} + \dots \quad (x)$$

and this has for them part of a range of problems relating to "infinitely small" and "infinitely large." The preoccupation with such problems is reflected in the paradox of "Achilles and the Turtle" put forward by Zeno of Elea. and in the distinction between "potential" and "actual" infinite as proposed by Aristotle. Partly in order to refute this distinction, the 19th-century mathematician Georg Cantor developed his set theory or theory of aggregates, the first beginnings of which go back even to Galileo. This theory not only strengthened the logical framework of analysis, but soon became a basic innovation in all of mathematics and in all the speculations about its essence and its general background.

Analytic Geometry.— The Greek achievements in analysis were but a prelude. A notable step was taken in the 14th century by Bishop Nicolas Oresme. He discovered the logical equivalence between tabulation and graphing, more or less. and in a way he proposed the use of a graph for plotting a variable magnitude whose value depends on that of another.

However, the systematic theoretical basis for this possibility evolved only later from the work of René Descartes, who in 1637 laid the foundation for analytic geometry; that is, a geometry in which everything is reduced to numbers. In this geometry a point is a set of numbers which are called its co-ordinates. A figure is viewed as an aggregate of points, but it is usually described by formulas, equations and inequalities. This approach to geometry is the basis for the maps, graphs and charts which have penetrated into all walks of life, and for the mathematical concept of a function $y = f(x)$ which, first intended only for analysis, has eventually penetrated into all corners of mathematics and into all areas of rational thinking as well.

Later in the 17th century the culminating event took place when Newton and Leibniz introduced derivatives and laid the foundation for calculus and mechanics. Archimedes had been uneasily groping for the concept of a derivative, especially in his book on spirals, but he could never hit upon it, although otherwise he would have been as well equipped for dealing with it as anyone in the 16th and 17th centuries. The 17th and 18th centuries produced much mathematics in all directions, but analysis was the underlying theme.

Developments in the 19th and 20th Centuries.— In the 19th century, topology, algebra and arithmetic were emerging as independent divisions of mathematics, rivaling analysis in attention; but analysis continued to proliferate and, by sheer bulk, to predominate. Many French treatises on general mathematics simply bore the title *Cours d'analyse*. But by a peculiarity of usage, in memory of the fact that Euclid's *Elements* were always being viewed as a book in geometry, in these same treatises a mathematician in general was frequently referred to as *un gkomktre*, especially when he was *illustre*.

Only in the 20th century were topology and algebra beginning to achieve a status approximating that of analysis. At the same time the lines of demarcation between the main divisions of mathematics were becoming more flexible and uncertain. After the 1930s, on the one hand analysis penetrated into geometry and arithmetic further than ever, and on the other hand topology and algebra began to fit tighter and more streamlined structural schemes on the large body of analysis. Duplications and redundancies could be reduced by syllogistic identifications and assimilations, and in some areas an increase of the substance offered itself naturally (see ANALYSIS, **ABSTRACT**). Furthermore, digital computing machines injected into analysis a certain algebraization, if only marginally. The structure of the machines and the problem of coding both involve algebra of logic, and in computational assignments from analysis, limiting processes must be replaced by approximations within certain maximal numbers of steps.

FUNCTIONS

Higher Derivatives.— A function $y = f(x)$, for real numbers x, y , is equivalent with a graph in an (x, y) co-ordinate system. A graph looks like a curve, but a curve is a figure on ordinary paper whereas a graph is a figure on graph paper; and graph paper represents a Euclidean plane into which some fixed co-ordinate system has been introduced beforehand.

The derivative df/dx , at a value x , is the limit of the difference quotient $\Delta f/\Delta x$ as Δx tends toward 0. It is defined for the numerical function but has an interpretation for the graph as a figure, namely, as the slope of the straight line which is tangent to the figure at the given point with abscissa x . However, the numerical value of the slope does depend on the co-ordinate system given. This dependence becomes more emphatic when one introduces the second derivative of $f(x)$, that is, the derivative of the derivative:

$$\frac{d^2f}{dx^2} = \frac{d}{dx} \left(\frac{df}{dx} \right)$$

In order to form the second derivative one must view—no matter how inarticulately or deficiently at first—the first derivative itself as a new function, and then form the derivative of this new function in turn. Second derivatives were in the forefront of Newton's mechanics. They defined the kinematic concept of acceleration as the instantaneous rate of change of the velocity function, and then,

by an interpretative correlation with it, the dynamic concept of force. The Greeks knew no functions or accelerations, and only varying notions of force.

General Functions.—A comprehensive concept of function was beginning to emerge only in the first half of the 19th century, at first only for numbers x, y and gradually for more general objects x, y . In the case of general objects x, y one also uses instead of the word function the words functional or operator, especially when functions for various types of objects are used in the same context simultaneously. For "working" mathematics, that is, when problems relating to foundations of mathematics are not at issue, the following unsophisticated description of a function $y = f(x)$ in general seems sufficient.

There are given two aggregates of mathematical objects, an aggregate X and an aggregate Y . Let x denote an element of X and y an element of Y . With each element x of X there is associated a certain element y of Y and a single one only. But the same element y may be associated to several different elements x , and on the other hand it is not necessary that each element y shall appear as an associate to some element x . For instance, it is admissible that all elements x have as associates the same element y , in which case the function is called a constant. In general the element y associated to x is denoted by a symbol like $y = f(x)$. It is also called the image of x , or the value of f at the "point" x . The entire object $y = f(x)$ is called a function from X into Y or, more explicitly, from the aggregate X into the aggregate Y .

Syllogistically, a mathematical statement is a certain conclusion drawn from particular assumptions and previous statements. A function in general, as just described, is not sufficiently tangible to start making statements about, even if X and Y are real numbers (except if one of them is a finite set). Rather, in order to start, it is necessary to impose on the functions some restrictions or qualifications, that is, to single out classes of functions with some particular features that may be analyzed. Together with the general notion of function there also began emerging certain over-all descriptive properties with which classes of functions could be singled out: continuity, differentiability, integrability, bounded variation, etc. But before that, especially in the 17th century, it was taken for granted, expressly or not, that a function is a "formula" or "expression" that is a tangible prescription for finding y if x is given. Certain functions, then familiar, were taken as known, being basic, as it were; for instance, $x, x^2, \dots, \sin x, \tan x, \arctan x, e^x, \log x$; and a formula arose by taking one or several such functions and performing a finite number of "natural" operations, such being primarily the four arithmetical basic operations, but including also extraction of roots and, what is important, the substitution of one function into another.

However, there soon appeared in the manipulations certain expressions in which an infinite or unending succession of operations was involved: certain infinite series, infinite products and infinite continued fractions. Of these the infinite series proved the most important by far, and two types of such series have advanced into positions of leadership and command which no phase of development has seriously impaired since, although there have been cases of evasion from authority, half in mathematical sport and a little in earnest. These two are power series and Fourier series.

Power Series.—The simplest power series is the geometric series

$$\frac{1}{1-x} = 1 + x + x^2 + x^3 + \dots$$

and in a broad sense it is very ancient, since, for instance, Zeno's series (1) is a case of it for $x = \frac{1}{2}$ if one subtracts the number 1 from both sides. The general power series has the form

$$a_0 + a_1x + a_2x^2 + \dots + a_nx^n + \dots \quad (2)$$

in which a_0, a_1, a_2, \dots are fixed numbers and x is a variable which for the present we assume to be real-valued. Now, if such a series is convergent for all x in an interval $-R < x < R$, where R is some positive number, and if one denotes the sum by $f(x)$, then this function has "very good" properties. It is continuous, even differentiable, and in fact it has a second derivative, third

derivative, etc. Furthermore, if one knows the values of all those derivatives at one point, namely at the origin $x = 0$, then the coefficients a_n of the series (2) can be computed. They are

$$a_0 = f(0), a_1 = \frac{1}{1}f'(0), a_2 = \frac{1}{1 \times 2}f''(0), \dots,$$

$$a_n = \frac{1}{1 \times 2 \times \dots \times n}f^{(n)}(0)$$

(Brook Taylor, 1715). Also, it is possible to shift the origin $x = 0$ into any other fixed point $x = h$ by starting out with a series

$$a_0 + a_1(x-h) + a_2(x-h)^2 + \dots + a_n(x-h)^n + \dots$$

If this series converges in some interval $x_0 < x < x_1$, which contains the "special" point h , say in an interval $(-R+h) < x < (R+h)$, and if one denotes the sum function again by $f(x)$, then it has derivatives of all orders in the interval; and, moreover,

$$a_0 = f(h), a_1 = \frac{1}{1}f'(h), \dots, \quad (3)$$

$$a_n = \frac{1}{1 \times 2 \times \dots \times n}f^{(n)}(h), \dots$$

In order to compute all these derivatives only for the point h , it suffices to know the function $f(x)$ in some partial interval containing the point h , no matter how small this partial interval may be, and the coefficients a_0, a_1, a_2, \dots , are already determined thereby. If, therefore, we consider the class of functions $f(x)$ which can be represented as sums of power series, we obtain the following uniqueness property: if two such functions are equal in some small interval, then they are equal in any larger interval containing it. Investigators in the 18th century were very impressed with this property because it agreed with a scientific presumption that if a closed mechanical system has been known for a certain time interval, then this knowledge ought to determine it for later time as well. J. L. Lagrange especially claimed, with more insistence perhaps than self-conviction, that mechanics, physics and even "significant" analysis in general ought to be able to do with such functions exclusively. He firmly attached to these functions the name "analytic" (probably already current before) which they have borne since, and in his works he tried to use them in an exclusive sense.

Piecewise Analytic Functions.—However, this exclusiveness still allowed for a certain generalization which Lagrange (like others) was taking for granted due to the following situation: If one throws a ball against a wall and it hits it at the time t_0 , then in the time interval $0 < t < t_0$ the components of position and velocity and other quantities for the ball are analytic functions of the time variable and of each other. After colliding with the wall at the time point t_0 , the ball flies on its rebound during a certain time interval $t_0 < t < t_1$. During the rebound the functions are again analytic, as they were before, but at the instant of collision itself this is not so. For instance at $t = t_0$ the velocity components are not even continuous, let alone analytic. Such "instantaneous" interruptions of analyticity, when the "instants" were only finitely many, were acceptable to Lagrange and others. Their occurrence was taken for granted, and viewed as a necessary generalization of the demand on analyticity if not of its basic definition.

In the 20th century such functions were called "piecewise" analytic, and this manner of generalization became important to many contexts. There are functions which are piecewise continuous, piecewise differentiable, etc. An indispensable method in algebraic topology, which was initiated in 1911 by L. E. J. Brouwer, is built on approximating to continuous functions in several variables by piecewise linear ones.

Fourier Series.—In physics and technology many phenomena are viewed as "waves" (under which "vibrations" and "oscillations" also fall), and there are waves in acoustics, hydrodynamics, electricity, optics, etc. In each context there is a certain first type of wave, not yet too complicated and yet already important, and the interpretations and names that are associated with it are closely analogous from context to context. There is always a certain decomposition of the general wave within that type into

a series of component waves which themselves are no longer decomposable. The first in the series is the "basic," "lowest," "primary," etc.; the later ones are "refinements," "higher," "secondary," etc., and they are supposed to decrease in effect and in influence the later they come in the series. Also, each of these components has certain fixed attributes, such as (wave) length, frequency, phase, amplitude.

This analogy in the phenomena is simply due to the identity of the mathematical instrument used for their "decomposition." Invariably, a certain function of one variable x in $-\infty < x < \infty$ is being represented as a so-called Fourier series, and the attributes of the phenomena are simply attributes of its series.

This function is then a periodic function, that is, there is a fixed number p such that $f(x + p) = f(x)$. We are normalizing it by putting $p = 2\pi$ so that $f(x + 2\pi) = f(x)$, and its Fourier series is then an expansion

$$f(x) = \frac{1}{2}a_0 + (a_1 \cos x + b_1 \sin x) + (a_2 \cos 2x + b_2 \sin 2x) + \dots \quad (4)$$

$$+ (a_n \cos nx + b_n \sin nx) + \dots$$

in which $a_1, a_2, a_3, \dots; b_1, b_2, \dots$ are certain constants. The first coefficient is written with the coefficients $\frac{1}{2}$ in order to make the following formulas uniform

$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos nx \, dx \quad b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx \, dx \quad (5)$$

All terms in the series (4) have period 2π ; however, for the computation of the coefficients a_n, b_n by the formulas (5) it suffices to know the function $f(x)$ only in the interval $-a < x < a$. This agrees with the fact that if a function $f(x)$ is given in the latter interval to start with, then it can be extended to a periodic function by repeating it successively in the intervals $(\pi, 3\pi), (3\pi, 5\pi), \dots$ to the right and similarly in the intervals $(-3a, -a), (-5\pi, -3\pi), \dots$ to the left.

For purposes of theoretical reasoning and of applications in physics it is appropriate to rewrite the series (4) into two more forms. The first is the "complex" version

$$f(x) = c_0 + (c_1 e^{ix} + c_{-1} e^{-ix}) + \dots + (c_n e^{nix} + c_{-n} e^{-nix}) + \dots$$

which arises by the substitution

$$\cos nx = \frac{e^{inx} + e^{-inx}}{2} \quad \sin nx = \frac{e^{inx} - e^{-inx}}{2i}$$

and in this version

$$c_m = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-imx} \, dx$$

for all integers m , positive and negative. The second form arises if, for $n \geq 1$, we introduce the number $\rho_n = (a_n^2 + b_n^2)^{\frac{1}{2}}$ and an angle θ_n , for which $a_n = \rho_n \cos \theta_n, b_n = \rho_n \sin \theta_n$. The series

$$\text{then becomes } f(x) = \frac{1}{2}a_0 + \rho_1 \cos(x - \theta_1) + \rho_2 \cos(2x - \theta_2) + \dots$$

$$+ \rho_n \cos(nx - \theta_n) + \dots$$

In physical applications it is frequently pertinent to replace x by $x - at$, where t is time and a is the velocity of the wave; and

$$\text{the result is } f(x - at) = \frac{1}{2}a_0 + \rho_1 \cos(x - at - \theta_1) + \dots$$

$$+ \rho_n \cos(nx - nat - \theta_n) + \dots$$

The constant term $\frac{1}{2} a_0$ does not represent anything "wavy" and it is frequently zero. However, the next term

$$f_1(x - at) = \rho_1 \cos(x - at - \theta_1)$$

represents the lowest indecomposable component of the wave, and the successive terms

$$f_n(x - at) = \rho_n \cos(nx - nat - \theta_n) \quad (6)$$

the higher ones. Also $2\pi/n$ is the length of (6), $na/2\pi$ its frequency, θ_n its phase and ρ_n its amplitude. The interpretation of the amplitude attaches itself to an important relation, called the Parseval equality. It states that for any Fourier series (4) one has

$$\frac{1}{\pi} \int_{-\pi}^{\pi} (f(x))^2 \, dx = a_0^2 + (a_1^2 + b_1^2) + \dots + (a_n^2 + b_n^2) + \dots$$

$$= a_0^2 + \rho_1^2 + \rho_2^2 + \dots + \rho_n^2 + \dots$$

For some wave phenomena the quantity

$$\frac{1}{\pi} \int_{-\pi}^{\pi} f(x)^2 \, dx$$

represents a certain volume of energy associated with the propagation of the wave. Now, ρ_n^2 is the volume of energy for the component wave $f_n(x)$. Therefore, if one ignores the neutral term a_0 then the Parseval equality states that this energy for the whole wave is the sum of the energies for all component waves.

Analytic Theory of Numbers. — The trigonometric expansion (4) is named after J. B. J. Fourier largely because he found a counterpart to it in which the sum is replaced by an integral. It is the pair of formulas

$$g(y) = \int_{-\infty}^{\infty} f(x) e^{2\pi i y x} \, dx \quad (7)$$

$$f(x) = \int_{-\infty}^{\infty} g(y) e^{-2\pi i x y} \, dy$$

and they belong together in the following sense. For certain classes of functions $f(x)$ in $-\infty < x < \infty$ the first integral exists for all y in $-\infty < y < \infty$, so that a function $g(y)$ arises. With this function one can form the second integral (7) and the resulting function $f(x)$ is the one from which the process started. This pair of formulas has given rise to a theory of "duality" in abstract analysis.

S. D. Poisson and others before him found a formula which combines the Fourier series with the Fourier integrals, and the simplest case of it is

$$\sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} f(x) e^{2\pi i m x} \, dx = \sum_{n=-\infty}^{\infty} f(n)$$

It became one of the most important tools in the analytic theory of numbers when P. G. L. Dirichlet used it in 1837 for giving a new proof for the so-called Gauss reciprocity law. In number theory, the greatest master of this so-called Poisson summation formula was Erich Hecke (1887-1947).

Least-Square Approximation. — There is an amplification to the Parseval theorem which has shaped many conceptions in physics.

Let $f(x)$ be a function in $-\pi < x \leq a$. For a fixed integer $n \geq 1$ take any real numbers $A_n, A_1, \dots, A_n; B_1, \dots, B_n$ and set up the trigonometric sum

$$\sigma_n(x) = \frac{1}{2}A_0 + (A_1 \cos x + B_1 \sin x) + \dots$$

$$+ (A_n \cos nx + B_n \sin nx)$$

A particular case of this sum is the n th partial sum

$$s_n(x) = \frac{1}{2}a_0 + (a_1 \cos x + b_1 \sin x) + \dots$$

$$+ (a_n \cos nx + b_n \sin nx) \quad (8)$$

of the Fourier series (4); that is, it is among the sums $\sigma_n(x)$, the one which arises if one chooses for the coefficients A_m, B_m the numbers a_m, b_m which are given by the formulas (j). But now form the difference $f(x) - \sigma_n(x)$ and ask for which choice of the coefficients A_m, B_m this difference will be a "least possible" one. A good answer to this question arises if one measures the size of the difference by a certain "average" of it, namely by the value of the integral

$$\frac{1}{\pi} \int_{-\pi}^{\pi} |f(x) - \sigma_n(x)|^2 \, dx \quad (9)$$

This quantity is always greater than or at best equal to

$$\frac{1}{\pi} \int_{-\pi}^{\pi} |f(x) - s_n(x)|^2 \, dx \quad (10)$$

so that it is smallest if the trigonometric sum (8) is the corresponding partial sum of the Fourier series for $f(x)$. Furthermore, the function $f(x) - s_n(x)$ has itself a Fourier series which arises by cutting off from the entire series (4) the partial sum $s_n(x)$, thus yielding

$$a_{n+1} \cos(n+1)x + b_{n+1} \sin(n+1)x + \dots$$

Therefore, by Parseval equality, the integral (10) has the value

$$a_{n+1}^2 + b_{n+1}^2 + a_{n+2}^2 + b_{n+2}^2 + \dots \quad (11)$$

and altogether the following result arises. If the degree of approximation is measured by the integral (9), and if $\sigma_n(x)$ is a trigonometric polynomial of prescribed degree n , then the best approximation is brought about by the partial sum of the Fourier series and its size is that given by (11).

This result is not restricted to expansions in which the "simple" functions are $\cos nx$, $\sin nx$, but it holds if they are a so-called complete orthonormal system, and in this way it broadens into a comprehensive proposition in many settings.

Functions of Real Variables.—The uniqueness property for analytic functions is indicative of great regularity of structure. Given a small piece of the function—that is, given the function in a small interval—it thence acquires a natural growth into a larger interval, and uniquely so. Also, if one places the x line on which it is defined as an x axis into the plane of the complex variable $z = x + iy$, then it spreads in a unique manner from the one-dimensional interval on the x axis into a two-dimensional domain of the plane. Syllogistically the decisive phenomenon of this spread is the fact that if a power series (2) is convergent on a real interval $-R < x < R$, and if one replaces the real variable x by the complex variable $z = x + iy$, then the power series with the same coefficients $a_0 + a_1z + a_2z^2 + \dots$ will also converge in the entire disk $|x + iy| < R$.

The complex analytic functions thus arising lead to a theory of great structural variety and beauty. The mathematicians of the 19th century loved and admired it all. They gave it their best, and molded into it all the glamour of the "Victorian era" then regnant everywhere and in everything. Around 1900 and later a number of books on such functions bore the generic title "Theory of Functions" in the expectation that the "other" functions would identify themselves expressly; and so they did, by calling themselves functions of a "real" variable or, of real variables.

The theory of the latter functions somehow was also growing into a compound of many parts, and in the 20th century it was even beginning to gain an ascendancy of interest over the complex analytic area. But then the complex analytic functions started to revitalize themselves by branching out from one into several variables, and a balance of evenly divided interest was establishing itself.

Fourier series are intimately related to the theory of functions of real variables, although not to all of it, and yet they were a great ferment for the development of the theory in all its parts. We will cite the high points and refer for details to the articles on SERIES; and FOURIER SERIES. Functions of bounded variation arose from a paper of Dirichlet giving systematically the first nonobvious convergence criterion for Fourier series. B. Riemann developed the theory of his integral in a paper on trigonometric series and Cantor, by pursuing a problem raised in that paper, was led to constructing the first part of his theory of sets, namely the theory of point sets in Euclidean space. The theory of summability of divergent series, originally designed as an aid for analytic continuation of power series, became lastingly indispensable when L. Fejér applied it to Fourier series. The importance of the Lebesgue integral was recognized when it led to the Riesz-Fischer theorem for Fourier series and to the Plancherel theorem for Fourier integrals; and the Stieltjes integral, originally designed for the so-called moment problem, acquired its stature when it entered Fourier analysis in the theory of probability.

ANALYSIS AND SPACE

Conformal Mapping.—In the plane of Cartesian co-ordinates (x, y) one can introduce the polar co-ordinates

$$\rho = (x^2 + y^2)^{1/2} \quad \theta = \arctan \frac{y}{x} \quad (12)$$

in the following way. On the half line which issues at the point of origin $(0, 0)$ and passes through the point (x, y) , the quantity ρ is the distance between the two points and θ is the angle between the positive half of the x axis and this half line. From (ρ, θ) the numbers (x, y) can be reobtained by

$$x = \rho \cos \theta \quad y = \rho \sin \theta \quad (13)$$

There are some complications in the use of (ρ, θ) . First, the origin

itself, called the pole, is a singularity in the sense that no specific θ can be assigned to it; and second, even omitting the pole, the angle θ cannot be assigned continuously to the entire plane, but only for any sector of the plane, say, the positive quadrant $x > 0$, $y > 0$. These difficulties are familiar from the use of latitude and longitude in measurements on the earth. The earth is spherical, not planar, and due to that feature there are two poles at which no longitude is definable; and if one starts measuring longitude continuously eastward, say from Greenwich, then, on returning to Greenwich, the accumulated longitude is 360° , not 0° as at the start.

Coming back to the relations (12) and (13), we replace the letters ρ, θ by "neutral" letters u, v , and rewrite these relations thus:

$$\begin{aligned} u &= \phi(x, y) & v &= \psi(x, y) \\ x &= A(x, y) & y &= B(x, y) \end{aligned} \quad (14)$$

There are other possibilities for choosing functions ϕ, ψ together with A, B , and each choice creates a so-called curvilinear co-ordinate system, of which polar co-ordinates are a particular instance. In three-dimensional space many kinds of curvilinear co-ordinate systems are useful to computations in mechanics and physics.

The pair of functions (14) can also be interpreted entirely differently. In addition to the given (x, y) plane we introduce another Euclidean plane with co-ordinates u, v , this one also Cartesian, and we view (14) as a mapping which associates with each point $P : (x, y)$ of the first plane a point $Q : (u, v)$ of the second plane. Such a mapping falls under the general concept of function as formulated under General Functions, above, and the word mapping is meant to recall the map in geography that results when the points of a region of the earth are transferred into a certain co-ordinate system on a sheet of paper or on a globe.

Two particular types of mapping are dominant in the geometry of Euclid, congruences and similarities. In traditional geometry two triangles are congruent if, in modern parlance, there is a certain one-to-one mapping of the entire Cartesian plane into itself which carries one triangle into the other. Euclid's geometry characterizes these mappings by certain axiomatic requirements, but in terms of co-ordinate transformations they are

$$u = a + \alpha x + \beta y \quad v = b + \gamma x + \delta y$$

where a, b are any real numbers and $\alpha, \beta, \gamma, \delta$ are real numbers for which

$$\begin{aligned} \alpha^2 + \beta^2 &= 1 & \gamma^2 + \delta^2 &= 1 \\ \alpha\gamma + \beta\delta &= 0 \end{aligned} \quad (15)$$

It follows automatically that $\alpha\delta - \beta\gamma$ is either $+1$ or -1 . If it is $+1$ then the transformation is sense preserving and can be brought about by a rigid motion of the plane; if it is -1 then a change of sense (replacing "clockwise" by "counterclockwise") has to be superimposed.

A Euclidean similarity arises if, more generally, instead of (15) one has

$$\alpha^2 + \beta^2 = c^2 \quad \gamma^2 + \delta^2 = c^2$$

where $c > 0$ is any real number. This c measures the size of the dilation in the similarity.

Such analytic formulations of congruence and similarity suggest the introduction of more general transformations, and prominent among such is conformal mapping which is defined as follows: if one takes any point (x_0, y_0) and all "small" triangles having this point as one of the vertices, then, in the limit, their images are similar to them, but the size of the local dilation may vary with the point (x_0, y_0) ; that is, conformal mapping preserves angles but not distances. Two statements are indicative of the importance of such mappings. First, if one also demands that the sense of the angles be preserved, then conformal transformations are the same as complex analytic functions in the following manner: if a pair of functions (14) constitutes a conformal mapping, and if one introduces the complex variables $z = x + iy$, $w = u + iv$, then there is a complex analytic function $w = f(z)$ such that $f(z) = \phi(x, y) + i\psi(x, y)$; conversely, for any complex analytic function, its real and imaginary parts constitute a sense-preserv-

ing conformal transformation. Second, if one takes in the plane a region bounded by one curve only, then it can be mapped conformally into the interior of a circle, and this also holds if the region is on a sphere or on any two-dimensional surface in space. Thus, for any plot of land on the earth which can be enclosed by one continuous fence one can make a conformal (that is angle-preserving) mapping into the interior of a circle on a flat sheet of paper. The oldest conformal mapping is the stereographic projection of Hipparchus (c. 150 B.C.) and Ptolemy (c. A.D. 150), and its name is due to F. Aguilonius (1613).

Degrees of Freedom.—A point P in space has three co-ordinates (x, y, z) . If there are given N points $P_n, n = 1, \dots, N$, if the co-ordinates of the n th point are denoted by (x_n, y_n, z_n) , and if the points constitute a mechanical system in motion, then at any given time the system is described by the $3N$ numbers $(x_n, y_n, z_n), n = 1, 2, \dots, N$. It suggests itself to introduce a Cartesian space of $3N$ dimension, a point of which is an arbitrary set of $3N$ real numbers, and if one places the mechanical system into this space then the motion of the system reflects itself in an "orbit" of the space. Now, there may be constraints operative in the system. For instance, two of the points, say $P_1 : (x_1, y_1, z_1)$ and $P_2 : (x_2, y_2, z_2)$ may be linked by a rigid rod of length l so that

$$(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2 = l^2$$

In this case it is economical to eliminate one of the co-ordinates, say by putting

$$z_1 = z_2 + [l^2 - (y_1 - y_2)^2 - (x_1 - x_2)^2]^{1/2}$$

so that only $3N - 1$ "free" parameters are left. The physicists then say that the "true" number of degrees of freedom for the system is (at most) $3N - 1$, and it is sometimes preferable to interpret the motion of the system in a space of (at most) $3N - 1$ dimensions. If there are two restraints present, and if they are independent, then there are (at most) $3N - 2$ degrees of freedom, etc.

In mechanics, the theory of degrees of freedom was initiated by Lagrange, and the mathematical aspects of the phenomenon of dependence between functions and the subsequent reduction of the total dimension were put on a sure footing by K. G. J. Jacobi (1804-51) and A. Cayley (1821-95). These studies gradually led to the emergence of a precise concept of dimension and of (topological) manifold. The general public became aware of such possibilities at a rather advanced stage of the development, namely with the introduction in the 1920s of the theory of relativity of A. Einstein, which featured two interlocking hypotheses. It merged the three-dimensional "ordinary" space with the time variable into a physically inseparable four-dimensional space, and it allowed this total space to be a topological manifold which was no longer a Euclidean space in its entirety.

The advance of algebraic topology was especially stimulated by a formula due to L. Kronecker (1823-91), the so-called Kronecker integral, which represents the number of joint solutions of three independent functions

$$u = f(x, y, z) \quad v = g(x, y, z) \quad w = h(x, y, z)$$

in a region of three-dimensional Euclidean space, and similarly for higher dimensional space. The formula subsumes the so-called Cauchy formula in complex analysis and related formulas which are more familiar than Kronecker's formula itself.

Tensorial Functions.—Let a differentiable function $g(u, v)$ denote the height of a building erected over a domain D in the (u, v) plane as base. If one introduces a transformation of co-ordinates (14) then the height becomes

$$f(x, y) = g[\phi(x, y), \psi(x, y)]$$

Such a function is called an absolute scalar. Now, the "sky line" of the building—that is, the shape of its roof—is appropriately described by the two functions

$$\frac{\partial g}{\partial u} \quad \frac{\partial g}{\partial v} \quad (16)$$

In the co-ordinates x, y the corresponding functions

$$\frac{\partial f}{\partial x} \quad \frac{\partial f}{\partial y} \quad (17)$$

are linked to the functions (16) by the relations

$$\frac{\partial f}{\partial x} = \frac{\partial g}{\partial u} \frac{\partial \phi}{\partial x} + \frac{\partial g}{\partial v} \frac{\partial \psi}{\partial x}$$

$$\frac{\partial f}{\partial y} = \frac{\partial g}{\partial u} \frac{\partial \phi}{\partial y} + \frac{\partial g}{\partial v} \frac{\partial \psi}{\partial y}$$

so that in order to obtain either one of the two functions (17) both functions (16) must be known. In this sense the pairs (16) and (17) cannot be separated. In general, over manifolds with local co-ordinate systems, there are many types of groups of functions which must be kept together organically for purposes of finding their values under changes of co-ordinates. Such groupings of functions are called tensors, and the name first arose in elasticity to describe tensors whose components are strains and stresses in different directions. In the topology of manifolds, tensorial functions are vector bundles, more or less.

A very important tensor is the curvature tensor introduced by Riemann and anticipated by C. F. Gauss. It has inaugurated a new era in geometry, and although its adequate description is rather technical, it is a very unifying concept nonetheless. It brings together geometry proper, analysis, topology and even a branch of analytic theory of numbers (automorphic functions in several variables). Also, there would hardly be a general theory of relativity without it. (S. N. B.)

ANALYSIS, ABSTRACT, a term almost synonymous with functional analysis and used to designate that part of mathematics which has resulted from axiomatizing and generalizing classical analysis. Abstracting what appear to be the essential elements in various branches of the latter subject, one sets up axiom systems and proves theorems which include the classical ones as special cases. Often several analogous classical results, as well as concrete results previously unformulated, appear as special cases of a single abstract theorem. Moreover, the process of abstraction has a clarifying effect in removing extraneous elements and revealing unsuspected relationships. The clarification thus achieved not only leads to a deeper understanding of previously known results but often paves the way for further progress.

In addition to its organizing and clarifying role with respect to classical analysis, abstract analysis is concerned with numerous problems of its own. It happens again and again in mathematics that a notion or concept introduced to help solve or clarify some problem suggests an array of questions about itself having little to do with the original problem. The notions of abstract analysis are no exception. Many of these are obtained from notions of abstract algebra by introducing an abstract notion of limit and replacing finiteness assumptions by assumptions about the behaviour of limits. Thus many problems in abstract analysis are generalizations of problems in abstract algebra and have an at least formally similar character. This part of abstract analysis is sometimes called topological algebra and is regarded by many algebraists as a part of algebra as well. In a somewhat similar fashion, abstract analysis overlaps with point set topology and, in general, has no sharp boundary lines.

It is sometimes asserted by enthusiastic abstract analysts that analysis, properly looked at, is just a synthesis of algebra and topology, and one might define abstract analysis as that part of mathematics in which this viewpoint is systematically adopted. On the other hand, it should be pointed out that many classical analysts are unimpressed with the usefulness of the abstract outlook and would regard the above account as a rather optimistic one. It cannot be denied that the more detailed and refined results of classical analysis still have a tendency to pass through the sieve of the abstraction process.

The Central Notions of Abstract Analysis.—Let R denote the set of all real numbers and let $C(R)$ denote the set of all continuous, complex valued functions f defined on R which are identically zero outside of some finite interval depending on f . For each j in $C(R)$ let $\|f\|_0$ be the least number such that $|f(x)| \leq \|f\|_0$ for all x , let $\|f\|_1 = \int_{-\infty}^{\infty} |f(x)| dx$ and let $\|f\|_2 = (\int_{-\infty}^{\infty} |f(x)|^2 dx)^{1/2}$. It is easy to see that $\lambda f + \mu g$ is in $C(R)$ whenever f and g are in $C(R)$ and λ and μ are complex numbers, and that the two operations of addition and multiplication by complex

numbers obey the formal laws laid down in the definition of a *vector space* over the complex numbers (see ALGEBRAS, [LINEAR]). It is also easy to see that whether $a = 0$ or 1 or 2 , $\|f\|_a$ behaves, like the absolute value of a number in the sense that for all f and g in $C(R)$ and all complex numbers λ we have

$$\begin{aligned} \|f + g\|_a &\leq \|f\|_a + \|g\|_a \\ \|\lambda f\|_a &= |\lambda| \|f\|_a \text{ and } \|f\|_a = 0 \end{aligned}$$

if and only iff $= 0$.

Abstracting from these properties of $C(R)$ a *complex normed vector space* is defined as a vector space X over the complex numbers together with a nonnegative real valued function $f \rightarrow \|f\|$ having the properties defined above. A *real normed vector space* is defined similarly. In any normed vector space (real or complex) the "distance" $\rho(f, g)$ between two elements f and g is defined to be $\|f - g\|$. With this distance the normed vector space becomes a "metric space," as defined in TOPOLOGY, GENERAL. As such one can speak of its convergent sequences, of whether or not it is complete, of continuous functions from it to another metric space, etc. A complete normed vector space is called a *Banach space*. $C(R)$ is not complete with respect to any of the three norms described above. However, in each case it may be "completed" by adding certain functions or classes of functions. For example, it becomes complete with respect to $\|\cdot\|_2$ when all measurable functions f such that $\int_{-\infty}^{\infty} |f(x)|^2 dx < \infty$ are added, provided that we identify two functions whenever they differ only on a set of Lebesgue measure zero.

As is shown in TOPOLOGY, GENERAL, many of the properties of metric spaces depend only upon the family of open sets defined by the metric and not on the metric itself. Taking the notion of open subset as basic undefined entity and introducing appropriate axioms, one defines the notion of *topological space* and *Hausdorff space*. A Hausdorff space is a special kind of topological space and every metric space is also a Hausdorff space. Generalizing the notion of normed vector space in a similar fashion, one defines a *topological vector space* to be a vector space (over the real or complex numbers), which is at the same time a Hausdorff space in such a manner that the operations of addition and multiplication by numbers are continuous in both variables simultaneously. The most important topological vector spaces are locally convex in the sense that in every open set containing 0 there is a smaller open set which contains 0 and every point on the line segment joining any two of its points.

Abstracting from the notions of scalar product in classical vector analysis and integral of the product of two functions, one defines an *inner* or *scalar product* in a real or complex vector space X as a real or complex valued function $f, g \rightarrow (f \cdot g)$ defined on pairs of elements f and g of X and having the following properties:

$$\begin{aligned} (f_1 \cdot g) &= \overline{(g \cdot f_1)} \\ (\lambda f_1 + \mu f_2 \cdot g) &= \lambda (f_1 \cdot g) + \mu (f_2 \cdot g) \\ (f \cdot f) &> 0 \end{aligned}$$

for all f, f_1, f_2 and g in X with $f \neq 0$, and all real or complex numbers λ and μ (the bar over a number denotes its complex conjugate). It is easy to show that $\sqrt{(f \cdot f)}$ is a norm for X . A Banach space whose norm is so derivable from an inner product is called a *Hilbert space*. The completion of $C(R)$ with respect to $\|\cdot\|_2$ is an example of a Hilbert space. Hilbert spaces have many properties not shared by Banach spaces in general.

A function T from one vector space to another is said to be linear if $T(\lambda f + \mu g) = \lambda T(f) + \mu T(g)$ for all f and g in the first space and all λ and μ in the appropriate number field. The most important examples are the linear integral and differential operators of classical analysis. If X and Y are normed vector spaces and T is a linear operator from X to Y , then T is continuous if and only if it is bounded in the sense that $\|T(f)\| \leq \|f\|$ is bounded as f varies among the nonzero elements of X . The least upper bound of these numbers is called the norm of T and is denoted by $\|T\|$. The set of all bounded linear operators from X to Y is a vector space itself under the obvious operations and is a normed vector space $B(X, Y)$ with respect to the norm just

defined. This space is complete and hence is a Banach space whenever Y is. When Y is the one-dimensional Banach space of all members of the underlying number field, $B(X, Y)$ is called the *dual* or *conjugate* of X and is denoted by X^* or \bar{X} . Its members are then called *linear functionals*. When X is a Hilbert space there corresponds to each member T of X^* a unique member g of X such that $T(f) = (f \cdot g)$ for all f in X . In this sense a Hilbert space is self-dual. If $X = Y$ and both spaces are complete then $B(X, Y) = B(X, X)$ is not only a Banach space but has further structure as well. Given T and S in $B(X, X)$, we define their product TS as the linear operator $f \rightarrow T(S(f))$ and verify at once that $\|TS\| \leq \|T\| \|S\|$. $B(X, X)$ is an example of a *Banach algebra*; that is, a Banach space in which there is also a "multiplication" $f, g \rightarrow fg$ defined for all pairs f and g in X and having the following properties: (1) the multiplication satisfies the associative and distributive laws and so converts X into a *ring* in the sense of abstract algebra; (2) $(\mu f)g = f(\mu g) = \mu(fg)$ for all f and g in X and all real or complex numbers μ ; (3) $\|fg\| \leq \|f\| \|g\|$ for all f and g in X . Banach algebras are sometimes called *normed rings*. Completing $C(R)$ with respect to the norm $\|\cdot\|_1$ and defining multiplication of functions in the usual manner, we obtain an important example of a Banach algebra which is commutative in the sense that $fg = gf$ for all f and g . $C(R)$ becomes a commutative Banach algebra in rather a different way if multiplication is defined as "convolution": $f * g(x) = \int_{-\infty}^{\infty} f(x-y)g(y)dy$, and the space is completed with respect to the norm $\|\cdot\|_1$.

Abstracting from the notions of "measurable set" and "measure" in the theory of the Lebesgue integral on the line and in n space, a *measure space* is defined as a set S together with a family M of subsets of S and a function μ from M to the nonnegative numbers and the symbol ∞ such that: (1) if E_1, E_2, \dots are in M then the set $E_1 \cup E_2 \cup \dots$ of all elements in at least one of E_1, E_2, \dots is also in M ; (2) if E is in M then the set $S - E$ of all elements not in E is in M ; (3) if E_1, E_2, \dots are members of M , no two of which have any elements in common, then $\mu(E_1 \cup E_2 \cup \dots) = \mu(E_1) + \mu(E_2) + \dots$; (4) the empty set O is in M and $\mu(O) = 0$. If $S = E_1 \cup E_2 \cup \dots$ where $\mu(E_j) < \infty$, the measure space is said to be *a-finite*. For real or complex valued functions defined on a-finite measure spaces, one can define measurable functions and develop the theory of integration of such functions in fairly complete generalization of the classical theory of Lebesgue.

One feature of the classical theory which does not generalize to measure spaces is the important fact that the underlying space S is a commutative group, and that the Lebesgue measure of a set is invariant under group translation. This feature is recaptured in the theory of integration on locally compact topological groups. Generalizing from the continuous groups of S . Lie (considered globally rather than locally), one defines a topological group as a group which is at the same time a Hausdorff space, the topology and the group operations being so related that $x, y \rightarrow xy^{-1}$ is a continuous function of both variables together. Let G be a topological group which as a topological space is separable and locally compact. Let M denote the smallest family of subsets of G which contains all the open sets and satisfies (1) and (2) in the definition of measure space, above.

According to a celebrated theorem of A. Haar, there exists a measure in G defined on M which is finite on all compact sets, invariant under translation from the left by members of G and not identically zero. This measure is essentially unique in the sense that any measure with these properties is a constant multiple of any other. It is called the (left invariant) *Haar measure* for the group. There is, of course, also a right invariant Haar measure. Moreover, one can drop the hypothesis that G is separable, but only at the cost of complicating somewhat the statement of Haar's theorem.

Some Central Topics and Results.—Consider the following two important results of classical analysis.

1. If $K(x, y)$ is a symmetric continuous function defined on the square $0 \leq x \leq 1, 0 \leq y \leq 1$, there exists a complete set of eigenfunctions for the integral operator $T_K: T_K(f)(x) = \int_0^1$

$K(x,y)f(y)dy$; that is, a set of functions ψ_1, ψ_2, \dots , such that $T_K(\psi_j) = \lambda_j \psi_j$ where each λ_j is a real number and every square-summable function on $0 \leq x \leq 1$ has a unique expansion in the form $c_1 \psi_1 + c_2 \psi_2 + \dots$, where the c_j are constants and the series converges in the mean.

2. Every function on the real line which is periodic of period 2π and square-summable on the interval $-\pi \leq x \leq \pi$ may be expanded in a Fourier series $\sum_{m=-\infty}^{\infty} c_m e^{imx}$ where again the c_j are constants and convergence is in the mean.

The first result may be interpreted as stating that the operator T_K may be decomposed as a "direct sum" of operators which are constant multiples of the identity. The second may be interpreted in almost exactly the same way except that now a family of operators is involved. For each n the function e^{inx} is carried into a multiple of itself by all translation operators $f(x) \rightarrow f(x+a)$. A rather large part of abstract analysis is devoted to showing that operators and families of operators may be decomposed into simpler ones in a manner analogous to (but often more complicated than) that of these examples, and to studying the properties of these decompositions.

An abstract generalization of result 1 states that a linear operator T from a Hilbert space H into itself has a "basis" of "eigenvectors" when it is *self-adjoint* in the sense that $(T(f) \cdot g) = (f \cdot T(g))$ for all f and g in H , and completely continuous in the sense that the unit sphere is mapped into a set whose closure is compact. The complete continuity implies the discreteness of the decomposition. When this hypothesis is dropped one has a generalization of 1, in which the summation is replaced by an integration. This generalization can be formulated and proved for operators which are not even bounded or everywhere defined, provided that they are still (in a suitable sense) self-adjoint. It is known as the *spectral theorem*. It leads at once to an "operational calculus" for self-adjoint operators; that is, to the possibility of making sense of such expressions as $f(T)$ where T is a self-adjoint operator and f is a Borel measurable function of a real variable. It plays a central role in the theory of linear differential equations—both ordinary and partial—and in the rigorous formulation of quantum mechanics.

On the other hand, one can drop the requirement that T be self-adjoint and that it acts in a Hilbert space and draw important conclusions from the fact that T is completely continuous. In particular, one can show that such a T behaves in important respects like an operator in a finite dimensional vector space and apply the results of linear algebra.

The translation operators appearing in example 2 are neither completely continuous nor self-adjoint. However, they are normal in the sense that they commute with their adjoints. The adjoint of a bounded operator T in a Hilbert space is the unique operator T^* such that $(Tf \cdot g) = (f \cdot T^*g)$ for all f and g . The spectral theorem can be extended without much difficulty to hold for all normal operators.

The Fourier expansion theorem and the theory of Fourier series in general have a considerable generalization in which functions of period 2π on the line are replaced by functions on a locally compact abelian group G and integration is carried out with respect to the Haar measure of the groups. The set of functions $\{e^{inx}\}$ is replaced by the set of all continuous complex valued functions χ on G which satisfy the identity $\chi(xy) = \chi(x)\chi(y)$ for all x and y in G —the so-called "characters" of G . When G is compact there is an expansion theorem just as in example 2, but when G is only locally compact the summation is replaced by an integration. The resulting formula reduces to the classical Fourier integral when G is the additive group of the real line. The general theory unifies Fourier series and Fourier integrals in one or more dimensions. Important features of this theory arise from the fact that the set of all characters of a locally compact abelian group G can itself be made into such a group in a natural way. It is called the *dual* or *character group* of G . The word dual is justified since G is in a natural way the character group of its character group—locally compact abelian groups occur in dual

pairs. The integration that occurs in the expansion theorem is with respect to the Haar measure in the dual group. This reduces to a summation when G is compact because then the dual is discrete.

The possibility of defining the convolution $f * g(x) = \int_{-\infty}^{\infty} f(x-y)g(y)dy$ of two functions of a real variable depends only upon the fact that the real numbers form a locally compact group under addition. The notion may be extended to functions defined on any locally compact group G and permits one to convert the Banach space $L^1(G)$ of all complex valued functions which are summable with respect to Haar measure into a Banach algebra. This Banach algebra is called the group algebra of G and is commutative if and only if G is commutative. When G is commutative the Fourier expansion theorem sets up a correspondence $f \rightarrow \hat{f}$ between functions on G and functions on the dual \hat{G} of G . In particular, members of $L^1(G)$ correspond to continuous functions on \hat{G} in such a manner that $(\hat{f} * \hat{g})$ is the ordinary product of \hat{f} and \hat{g} . More generally, let A be any commutative Banach algebra. The set M of all "regular maximal ideals" in A may be given a locally compact topology and A may be mapped into the algebra of all continuous complex valued functions in M in such a manner that $(f + g)^{\circ} = f^{\circ} + g^{\circ}$ and $(fg)^{\circ} = f^{\circ}g^{\circ}$ whenever f and g are in A and h° denotes the continuous function on M corresponding to h . When $A = L^1(G)$ and G is commutative, M may be identified with the dual \hat{G} of G and f° with \hat{f} . Many classical theorems in Fourier analysis turn out to be specializations of theorems about the mapping $f \rightarrow \hat{f}$ in commutative Banach algebras. That part of abstract analysis which studies Fourier analysis on groups and commutative Banach algebras is usually called abstract harmonic analysis.

The Fourier analysis of functions defined on locally compact commutative groups may be further generalized by allowing the group to be noncommutative and changing the domain of the functions from the group G itself to some space S on which the G acts as a group of transformations. For example, the group of rotations about 0 in Euclidean three-space transforms the surface S_2 of the unit sphere onto itself. This transformation group is *transitive* in the sense that for each p and q in S there exists x in G such that $x(p) = q$. When one attempts to analyze complex valued functions in S_2 as sums of functions having simple properties under rotation, one is led to the classical spherical harmonics.

More general transitive transformation groups lead to theories of generalized spherical functions. In general, one assumes that S is a measure space and that the measure μ is invariant under the action of G . When S is finite it is always possible to write it as a union of disjoint subsets on each of which G acts transitively. In the infinite case this is not always true—even if one permits continuous summation processes. One is forced to consider a weaker kind of transitivity. The action of G on S is said to be *metrically transitive* or *ergodic* if, whenever E is a measurable subset of S such that each member x of G maps it into a set $x(E)$ differing from E by a set of measure zero, then E is either of measure zero or differs from S by a set of measure zero.

Whether or not G is in some sense transitive on S one can introduce the Hilbert space $L^2(S, \mu)$ of all measurable complex valued functions f on S such that $\int |f|^2$ has a finite integral. For each $x \in G$ the "translation" operator T_x , $(T_x(f))(y) = f([y]x)$ is *unitary* in the sense that $T_x^* = T_x^{-1}$. Moreover, $T_{x_1 x_2} = T_{x_1} T_{x_2}$ for all x_1 and x_2 in G and $(T_x(f) \cdot g)$ is continuous in x for all f and g in $L^2(S, \mu)$. We have, in short, what is known as a *continuous unitary representation* of G . The classical theory of the representation of finite groups by matrices has a generalization to a theory of continuous unitary representations of locally compact groups. The "irreducible" representations of G play the role of the characters in the commutative theory. They may be infinite dimensional. Of course the direct sum decompositions of the classical theory give way to continuous direct sums or direct integrals. In addition there are certain new phenomena which have no classical counterpart. Their existence is closely related to that of metrically transitive transformation groups.

Via the group algebra there is a close connection between the classical theory of group representations and the classical theory

of linear associative algebras. This connection persists in the infinite locally compact case. However, there are several different generalizations of the group algebra. Structure theorems for non-commutative Banach algebras generalizing the classical finite theorems of J. H. M. Wedderburn have been most thoroughly studied when the Banach algebra is a so-called *von Neumann algebra*; that is, a subalgebra of the Banach algebra of all bounded linear operators on some Hilbert space which contains the adjoint of each of its elements and is such that $(A')' = A$. Here A' denotes the set of all T such that $ST = TS$ for all S in A . Again one must deal with continuous direct sum decompositions and with certain new phenomena related to the existence of metrically transitive but intransitive transformation groups. These new phenomena manifest themselves in the existence of certain infinite analogues of full matrix algebras whose idempotent elements can have "fractional dimension"ⁿ—the so-called factors of type II.

When G is the additive group of the real line: the theory of the unitary representations of G can be reduced at once to the theory of self-adjoint operators via a fundamental theorem of M. H. Stone according to which $T_x = e^{ixH}$ sets up a one-to-one correspondence between continuous unitary representations T of G and self-adjoint operators H . The operator iH is called the infinitesimal generator of the group. In particular this theorem allows one to apply the spectral theorem to the analysis of the one-parameter transformation groups which one gets by integrating the differential equations of classical mechanics. This connection with mechanics and its application to certain questions in statistical mechanics has led to the branch of abstract analysis known as *ergodic theory*.

The connection between one-parameter unitary groups and their infinitesimal generators can be considerably generalized. The operator T_x need not be unitary and may act in Banach spaces more general than Hilbert spaces. Moreover, the operator T_x need only be defined for $x > 0$. The resulting theory of *one-parameter semigroups* has important applications to the theory of partial differential equations.

The consideration of Banach spaces more general than Hilbert spaces and of topological vector spaces which are not Banach spaces raises many technical questions. Hilbert spaces have very many special properties not possessed by topological vector spaces in general but possessed by some which are not Hilbert spaces. An important branch of abstract analysis is devoted to exploring the logical interconnections between these properties and to deciding which spaces arising in practice possess them. Of course there are also spaces with useful properties not possessed by Hilbert spaces. Similar classification problems are studied for Banach algebras and the other objects of abstract analysis.

An important aspect of certain applications of abstract analysis to classical analysis is the introduction of "generalized functions" of various sorts. A space whose elements are concrete functions with regular properties may often be imbedded in a natural way in a larger space whose elements are of a more abstract character—this larger space being one in which the operations of analysis may be carried out more freely and in which the theorems take on a simpler and more elegant form. A particularly highly developed theory of this character is the theory of distributions of Laurent Schwartz. The space \mathcal{D} of all distributions on Euclidean n space includes the space of all locally summable complex valued functions and every distribution has partial derivatives of all orders. \mathcal{D} is one of the most important examples of a topological vector space which is not a Banach space.

ANALYSIS, CHEMICAL: see CHEMISTRY: Analytical Chemistry.

ANALYSIS, COMPLEX, is that branch of mathematics which arose historically from the study of analytic functions of one or several complex variables. Beginning with B. Riemann's fundamental discoveries in the middle of the 19th century, there was a gradual but continual shift of emphasis toward the investigation of global properties of analytic functions by topological and algebro-geometrical methods, with the result that complex analysis became rather intricately interwoven with the other principal mathematical disciplines and could be viewed only against the background of mathematical development as a whole, which is characterized in the 20th century by a remarkable synthesis of ideas.

Analysis of the properties of functions of one complex variable (complex analysis in one dimension) had a remarkable growth during the second half of the 19th century as a result of the brilliant research of Riemann and, afterward, of H. Poincaré, F. Schottky, H. A. Schwarz, K. Weierstrass, C. Neumann and others. Shortly after 1900 the general principle of uniformization, conceived by F. Klein and Poincaré, was established by P. Koebe. These developments were presented as a unified theory in 1913 by H. Weyl.¹

During the latter part of the 19th and the beginning of the 20th century, the theory of functions of several complex variables made its appearance, as did algebraic geometry, especially the theory of algebraic surfaces founded by M. Noether, E. Picard, Poincaré and, last but not least, the Italian geometers G. Castelnuovo, F. Enriques and, somewhat later, F. Severi. In 1895 P. Cousin² investigated certain global properties of analytic functions on domains in complex n -space and brought to the attention of mathematicians two problems which were later to bear his name; the study of these and related problems led to some of the most important developments of complex analysis during the first half of the 20th century.

In the years following the publication of Weyl's book, the geometrical concepts, first introduced into complex analysis by Riemann, were studied for their own sake and vastly generalized as a result of the growth of topology as a branch of mathematics. S. Lefschetz made a profound study of the topological properties of algebraic surfaces in his tract,³ which exerted considerable influence on the later development of complex analysis, topology and algebraic geometry. E. Cartan developed and applied systematically the theory of exterior differential forms which merged with topology in the fundamental theorem proved by G. de Rham in 1932 and helped give birth to the concept of cohomology in algebraic topology. S. Bergman⁴ discovered an important type of hermitian metric on subdomains of complex n -space which was subsequently generalized by E. Kahler and became known as a Kahler metric. Beginning about 1932, W. V. D. Hodge⁵ generalized the theory of harmonic functions on Riemann surfaces to harmonic differential forms on higher dimensional compact Riemannian manifolds, and on complex manifolds which possess Kähler metrics. Hodge's theory was developed and perfected during the 1940s by K. Kodaira,⁶ who also generalized the theory to open manifolds and introduced systematically the method of orthogonal projection in Hilbert space.

Simultaneous with the development of the theory of harmonic differential forms, an intensive investigation of questions related to the Cousin problems was made by K. Oka, H. Behnke, H. Cartan, K. Stein and others. Although the methods used by these investigators differed somewhat from those of Hodge, Kodaira and De Rham, the time was becoming ripe for a remarkable confluence of ideas and this took place shortly after 1950 with the introduction into complex analysis of new notions from algebraic topology, namely, fibre bundles and cohomology with coefficients in sheaves. The idea of a fibre bundle was first recognized during the period

1935-40 while the notion of a sheaf was introduced into topology a few years later by J. Leray (similar concepts, never precisely defined, had occurred earlier in various special contexts). The introduction of these concepts had an explosive effect on the development of complex analysis during the following years.⁷

A third advance of great importance in complex analysis, which took place during the period 1935-50, was the development, principally by C. L. Siegel,⁸ of the theory of automorphic functions of several complex variables.

An important generalization of the uniformization principle was provided early in the 1930s by independent solutions of the plateau problem by J. Douglas and T. Rado and by the subsequent investigations of the plateau problem by R. Courant and M. Shiffman. A further important outgrowth of the uniformization principle was the intensive investigation of the family of normalized univalent functions in the unit disk.

In this article the scope of complex analysis will be illustrated by describing briefly a few of the concepts and techniques mentioned above.

Complex n-Space, Functions, Maps.—Denote the set of complex numbers by \mathbf{C} ; *i.e.*, the numbers $z = x + iy$ where x, y are real numbers and $i^2 = -1$. The addition of the complex numbers and multiplication by an arbitrary complex number impart to \mathbf{C} the structure of a complex vector space of complex dimension 1. Generalizing, we obtain complex n -space, denoted by \mathbf{C}^n , where n is a positive integer; it is the n -dimensional complex vector space of n -tuples (z^1, z^2, \dots, z^n) of complex numbers z^1, z^2, \dots, z^n . Addition of (z^1, z^2, \dots, z^n) and (w^1, w^2, \dots, w^n) is defined by $(z^1, z^2, \dots, z^n) + (w^1, w^2, \dots, w^n) = (z^1 + w^1, z^2 + w^2, \dots, z^n + w^n)$, and multiplication of (z^1, z^2, \dots, z^n) , by a complex number w , is defined by $w \cdot (z^1, z^2, \dots, z^n) = (wz^1, wz^2, \dots, wz^n)$.

For simplicity we write $z = (z^1, z^2, \dots, z^n)$ where z^1, z^2, \dots, z^n are the co-ordinates of the "point" z . The conjugate \bar{z} of $z = (z^1, z^2, \dots, z^n)$ is defined to be $\bar{z} = (\bar{z}^1, \bar{z}^2, \dots, \bar{z}^n)$ where z^α denotes the complex conjugate of z^α ; *i.e.*, $\bar{z}^\alpha = x^{2\alpha-1} - ix^{2\alpha}$ if $z^\alpha = x^{2\alpha-1} + ix^{2\alpha}$. The scalar product of z and w is $z \cdot \bar{w} = z^1 \cdot \bar{w}^1 + z^2 \cdot \bar{w}^2 + \dots + z^n \cdot \bar{w}^n$, and the length $|z|$ of z is the square root of $z \cdot \bar{z}$. The distance between z and w is $|z - w|$.

An open set D of \mathbf{C}^n is a set of points of \mathbf{C}^n such that, for any z of D , all points w of \mathbf{C}^n whose distance from z is sufficiently small also belong to D . For example, the ball consisting of all z with $|z| < 1$, and the polycylinder consisting of all points $z = (z^1, z^2, \dots, z^n)$ with $|z^1| < 1, |z^2| < 1, \dots, |z^n| < 1$, are open sets of D of particularly simple type. An open set D of \mathbf{C}^n is called a domain if it is connected; *i.e.*, if any pair of its points can be joined by a polygonal arc lying entirely in D . The ball and the polycylinder are connected and are therefore domains.

Let D and \bar{D} be open sets of \mathbf{C}^m and \mathbf{C}^n respectively, and denote the co-ordinates of \mathbf{C}^m by (z^1, z^2, \dots, z^m) , those of \mathbf{C}^n by (w^1, w^2, \dots, w^n) . A map $F : D \rightarrow \bar{D}$ assigns to each point z of D a point w of \bar{D} . Referring this map to the co-ordinates of \mathbf{C}^n , F can be expressed in the form $F = (f^1, f^2, \dots, f^n)$ where $w^\alpha = f^\alpha(z)$ is a complex-valued function defined over D . The map F is continuous if each "component" f^α of F is a continuous function; it is differentiable if each component f^α is differentiable, etc.

Let f be a complex-valued function on the open set D of \mathbf{C}^n which has continuous partial derivatives of the first order. Let z^1, z^2, \dots, z^n be the co-ordinates of \mathbf{C}^n , write $z^\alpha = x^{2\alpha-1} + ix^{2\alpha}$, and define

$$\frac{\partial f}{\partial \bar{z}^\alpha} = \frac{1}{2} \left(\frac{\partial f}{\partial x^{2\alpha-1}} + i \frac{\partial f}{\partial x^{2\alpha}} \right)$$

where $\partial f / \partial x^{2\alpha-1}, \partial f / \partial x^{2\alpha}$ denote the partial derivatives of f in the usual sense of calculus. The function f is said to be holomorphic (analytic) on D if $\partial f / \partial \bar{z}^\alpha = 0$ for $\alpha = 1, 2, \dots, n$ (Cauchy-Riemann equations). A map $F : D \rightarrow \bar{D}$ is said to be holomorphic if each component f^α of F is a holomorphic function on D .

A topological space is a set on which the notion of open set is given. Hence, on a topological space, the notion of a continuous function is defined. A map of one topological space onto another is said to be bicontinuous, or to be a homeomorphism, if it is one-one, continuous, and the inverse map is also continuous. Two topological spaces are said to be homeomorphic if they are connected by a homeomorphism. Homeomorphic spaces are topologically equivalent: *i.e.*, their intrinsic topological properties are the same. For example, the ball and the polycylinder of \mathbf{C}^n are homeomorphic. On the other hand, the domain $1/2 < |z| < 1$ of \mathbf{C}^n is not homeomorphic to the polycylinder of \mathbf{C}^n .

A map of one open set of \mathbf{C}^n onto another is said to be biholomorphic if it is one-one and holomorphic (which implies that the inverse is also holomorphic). The ball of \mathbf{C}^n cannot be mapped biholomorphically onto the polycylinder of \mathbf{C}^n if $n > 1$. Thus topologically equivalent domains are not generally holomorphically equivalent, except under certain circumstances in the case $n = 1$.

Conformal Maps.—The study of conformal maps arose historically from the necessity of constructing geographic maps. Since the surface of the earth is approximately a sphere, it is readily seen that it cannot be represented on a flat surface with preservation of the proportion of all distances; indeed the same is true for any substantial portion of the earth's surface. The next best property to be preserved is the relative shape of configurations in the neighbourhood of each point; this, in a more precise mathematical formulation, amounts to preservation of the magnitude and sense of angles at each point. Such a map is called conformal. Examples are the familiar Mercator and stereographic projections. In a conformal map of one open set of the plane onto another, it is a simple matter to verify that the map is given locally by a biholomorphic transformation of one complex variable.

On the other hand, a biholomorphic map of one open set of \mathbf{C}^n onto another is not generally conformal if $n > 1$. We therefore suppose throughout this section that $n = 1$.

The preceding local characterization of a conformal map disposes only of the most trivial aspect of it since it gives no information concerning the existence of a conformal map of one given plane domain onto another. Since it is impossible, except in the most trivial cases, to construct conformal maps explicitly, attention has centred mainly on the problems of proving their existence and of determining their properties.

A necessary condition in order that there should exist a biholomorphic (one-one conformal) map of one plane domain onto another is that there should exist a bicontinuous map (homeomorphism) of the one domain onto the other, and it is a remarkable fact that this necessary condition is in some cases sufficient.

Riemann Mapping Theorem.—Let D be a domain of \mathbf{C} which is not the whole of \mathbf{C} , and suppose that D is homeomorphic to the unit disk $|z| < 1$. Then, given an arbitrary point z_0 of D and a direction at z_0 (vector issuing from z_0), there exists a unique biholomorphic (one-one conformal) map of D onto the unit disk $|z| < 1$ such that z_0 goes into the centre of the disk and the given direction at z_0 transforms into the direction of the positive real axis.

Although the whole plane \mathbf{C} is homeomorphic to the unit disk, it is impossible to map it conformally onto the unit disk; this is a consequence of a classical theorem of J. Liouville.

Denote by S the class of functions f of the complex variable z which are holomorphic in the unit disk, which map it one-one conformally onto domains of \mathbf{C} , and which are normalized by the condition that their power series in z , convergent for $|z| < 1$, are of the form

$$f(z) = z + a_2 z^2 + a_3 z^3 + a_4 z^4 + \dots + a_n z^n + \dots$$

In his proof of the general uniformization principle (of which the Riemann mapping theorem is a special case), Koebe introduced the class S and studied some of its properties. This class quickly attracted the attention of a number of mathematicians, including L. Bieberbach, C. Carathéodory, G. Faber, T. H. Gronwall and P. Montel. If the class S is suitably "topologized," then,

for each integer $n > 1$, the map $F^n : S \rightarrow C^n$ which sends the function f of S into the point $(a_1, a_2, \dots, a_{n+1})$ of C^n , determined by the n coefficients a_1, a_2, \dots, a_n , in the power series development of f , is continuous. Denote by B^n the image of S under the map F^n . The set B^n , homeomorphic to the closed unit ball $|w^1|^2 + |w^2|^2 + \dots + |w^n|^2 \leq 1$ of C^n , is called the n th coefficient region of S . The structure of the class S is completely determined by a knowledge of these coefficient regions and the maps F^n . In 1916 Bieberbach proved that B^1 is the region $|a_2| \leq 2$ and, soon thereafter, posed the problem of investigating the regions B^n for all n . He further conjectured that $|a_n| \leq n$ for all n (Bieberbach conjecture). This problem and conjecture were followed by an intensive study of the class S .

In 1923 K. Löwner⁹ approximated an arbitrary function of S by a subclass of functions of S satisfying a differential equation in one real parameter and, in this way, proved that $|a_3| \leq 3$. Next, H. Grotzsch developed a method based on the characteristic conformal invariant (modulus) of a doubly connected domain and proved numerous "distortion theorems" for the class S . L. Ahlfors and A. Beurling developed a "method of extremal length" which systematized and generalized certain aspects of the work of Grotzsch. A variational calculus, which began with a paper¹⁰ by M. Schiffer in 1938, was perfected and applied to the class S by Schiffer and other authors during the following years.¹¹ Variational methods were used, by A. C. Schaeffer and D. C. Spencer¹² in determining explicitly the region B^2 and in investigating the properties of B^n , $n > 2$. In particular, they proved that a function of S maximizing the absolute value of its n th coefficient maps $|z| < 1$ onto the whole plane minus a single analytic slit extending from some finite point to "infinity." P. Garabedian and Schiffer, using variational methods, showed in 1954 that $|a_4| \leq 4$. O. Teichmüller, in a series of papers from 1938 to 1944, developed the theory of "quadratic differentials";

which incorporates those aspects of quadratic differentials bearing on extremal problems and provides a systematic method of investigating the class S .¹³

Finally, the class S is a subclass of a wider class of functions, the so-called multivalent functions, which have been studied intensively by W. K. Hayman.¹⁴ As a corollary of Hayman's investigations, the Bieberbach conjecture for a fixed function f of S and all sufficiently large n has been established, namely: for each f of S there exists a positive integer $n_0(f)$ such that $|a_n| \leq n$ for all n exceeding $n_0(f)$.

Complex Analytic Manifolds.—Riemann surfaces, as conceived by Riemann, are multisheeted coverings of the plane C , or of the sphere obtained by compactifying C with the adjunction of a "point at infinity," and arose from the analytic continuation of multivalued functions over C . It was a natural step, first taken by Klein, to introduce the notion of an abstract Riemann surface as a surface (in the topological sense) every point of which has a neighbourhood which is homeomorphic to an open set of C , this homeomorphism defining on the neighbourhood a local complex co-ordinate z (or local uniformizing parameter). The transformation from one complex co-ordinate to another is biholomorphic (one-one conformal). A Riemann surface is a complex manifold of complex dimension 1.

The concept of a Riemann surface has a natural generalization to that of a complex (analytic) manifold of arbitrary (finite) complex dimension. Namely, a complex co-ordinate manifold of complex dimension n is a topological space together with a covering $\{C_i\}$ of it by overlapping open sets U_i and a system $\{h_i\}$ of homeomorphisms h_i of U_i onto open sets D_i of C^n . For a point p of U_i , the homeomorphism h_i defines $z_i = (z_i^1, z_i^2, \dots, z_i^n) = h_i(p)$ as a system of local complex co-ordinates on U_i , and the transformations from one system of local complex co-ordinates to another must be biholomorphic. Two systems $\{U_i, h_i\}$ and $\{U'_j, h'_j\}$ of "co-ordinatizations" of the given topological space are said to be equivalent if the inverse map of h_i followed by h'_j is biholomorphic (where defined). A complex manifold, or complex structure on a topological space, is an equivalence class of complex co-ordinatizations.

It is usual to impose the further topological condition that the underlying topological space is "paracompact," that is: (1) any two distinct points of it have disjoint neighbourhoods; (2) from any covering of the topological space by open sets, a "locally finite" covering can be extracted, where a locally finite covering is one such that each point has a neighbourhood belonging to only finitely many open sets of the covering. These topological restrictions are important only in that they eliminate from consideration manifolds of a pathological nature.

A complex manifold is compact if, from any covering of it by open sets, a finite covering can be selected.

Complex 12 -space C^n is the simplest example of an open (*i.e.*, noncompact) complex manifold; it is covered by a single system of complex co-ordinates. It can be compactified in a natural way to give a compact complex manifold called complex projective n -space, denoted by $P_n(C)$. Namely, denote by (z^0, z^1, \dots, z^n) the complex co-ordinates on C^{n+1} . Remove from C^{n+1} the origin $(0, 0, \dots, 0)$ and call the resulting (complex) manifold W . Given a point p of W with the co-ordinates (z^0, z^1, \dots, z^n) , the set of points defined by $c \cdot (z^0, z^1, \dots, z^n) = (cz^0, cz^1, \dots, cz^n)$, as c ranges over all nonzero complex numbers, is called a complex line through p . The points of complex projective n -space $P_n(C)$ are the complex lines of W . As homogeneous co-ordinates on $P_n(C)$ we may take (z^0, z^1, \dots, z^n) where z^0, z^1, \dots, z^n are not all zero, and where $(z^0, z^1, \dots, z^n) = c \cdot (z^0, z^1, \dots, z^n)$ correspond to the same point of $P_n(C)$. Let U_i be the open set of $P_n(C)$ composed of points whose i th homogeneous co-ordinate z^i does not vanish. Then U_0, U_1, \dots, U_n cover $P_n(C)$ and $(z^0/z^i, \dots, z^{i-1}/z^i, z^{i+1}/z^i, \dots, z^n/z^i)$ is a system of complex co-ordinates covering U_i . It is easily verified that the transformation from the co-ordinates covering U_i to those covering U_j is biholomorphic.

ONE-HALF OF THE 3-DIMENSIONAL SECTION OF THE 4 REAL-DIMENSIONAL REGION B^2 FOR WHICH a_3 IS REAL

The three lines represent the co-ordinate axes of real Euclidean 3-space. The vertical line is the co-ordinate for the real part of a_3 ; the two horizontal axes represent a_2 ; and the imaginary part of a_3 (the latter pointing toward viewer). The total section is obtained by reflection of the portion shown on the horizontal plane. The boundary of B^2 consists of two 3-dimensional surfaces whose parametric equations are given by different formulas. One of these surfaces appears as the disconnected portions of the boundary (dark areas in the illustration). To each point of the boundary there corresponds a unique extremal function of the class S

these differentials occur in the variational method, namely, the nonlinear differential equations satisfied by extremal functions of the class S are equations connecting a pair of quadratic differentials. J. A. Jenkins, in 1954, proved a "general coefficient theorem"

$P_n(\mathbf{C})$ is a compact complex manifold. The set of points of $P_n(\mathbf{C})$ for which $z^0 = 0$ is a hyperplane E_0 , which is itself a complex projective space of dimension $n - 1$, and $P_n(\mathbf{C})$ is obtained from U_0 , which is equivalent to \mathbf{C}^n , by adding to U_0 the hyperplane E_0 at "infinity," which compactifies it.

The complex projective line $P_1(\mathbf{C})$ is often called the complex-number sphere. In fact, $P_1(\mathbf{C})$ is topologically homeomorphic to a sphere since it is obtained from the plane by adding one point at infinity.

A "nonsingular" compact, complex analytic submanifold of $P_n(\mathbf{C})$ is called a projective manifold. For example, the complex plane E_0 is a projective manifold of complex dimension $n - 1$. A (possibly singular) subvariety of $P_n(\mathbf{C})$ defined by finitely many polynomial equations, homogeneous in the co-ordinates z^0, z^1, \dots, z^n , is called a projective algebraic variety. It follows from a general theorem of W.-L. Chow that a projective manifold is a nonsingular projective algebraic variety. The projective manifolds are the commonest compact complex manifolds. For example, the equation $(z^0)^2 + (z^1)^2 + (z^2)^2 + (z^3)^2 = 0$ defines a nonsingular surface in $P_3(\mathbf{C})$. The study of projective algebraic varieties, from the algebraic point of view, constitutes "algebraic geometry" in the classical sense of the term.

Not all compact complex manifolds are projective. Indeed, in 1958 M. Nagata¹⁵ showed that, to each projective manifold (variety) of dimension $n \geq 3$, there is associated a "birationally equivalent" nonprojective manifold (variety). The condition $n \geq 3$ is essential, as follows from fundamental results of Chow and Kodaira.¹⁶

Uniformization.—The theorem on uniformization established by Koebe may be stated as follows:

General Uniformization Principle.—Any Riemann surface which is homeomorphic to some subdomain of the complex sphere $P_1(\mathbf{C})$ can be mapped biholomorphically (one-one conformally) onto a canonical domain of $\mathbf{P}(\mathbf{C})$, each boundary component ("connected piece of boundary") of which is either a point or a straight-line segment parallel to the real axis (canonical domain of D. Hilbert).

Given any compact Riemann surface V , there is associated to it another (generally open) Riemann surface \tilde{V} , called its "universal covering surface," which, if open, has the property that it is homeomorphic to the unit-disk $|z| < 1$ of \mathbf{C} . Hence, by the uniformization principle, V (if open) can be mapped conformally onto \mathbf{C} (parabolic case), or onto $|z| < 1$ (hyperbolic case). We shall discuss briefly the hyperbolic case. In this case the points of \tilde{V} "lying over" one and the same point of V are mapped into a set of points in $|z| < 1$ which is generated from any one point in the set by a "discontinuous group" G of analytic automorphisms of $|z| < 1$ (biholomorphic maps of $|z| < 1$ onto itself). The Riemann surface \tilde{V} corresponds to a fundamental domain of G in $|z| < 1$ which is the interior of a polygon whose sides are arcs (interior to $|z| < 1$) of circles orthogonal to the circumference $|z| = 1$, these sides being identified in pairs to form a compact surface. The Riemann surface V is entirely determined, up to isomorphisms, by the group G of automorphisms of $|z| < 1$, and the meromorphic functions on V are represented by meromorphic functions in $|z| < 1$ invariant under G —the so-called automorphic functions. The theory of automorphic functions, founded by Poincaré, is one of the most beautiful chapters in the theory of functions of one complex variable.

A compact complex manifold of complex dimension greater than 1 cannot in general be "uniformized"; i.e., represented as a fundamental domain of a discontinuous group operating analytically on a subdomain of \mathbf{C}^n . However, examples of complex manifolds represented as fundamental domains of a discontinuous group operating analytically on a subdomain of \mathbf{C}^n , n larger than 1, have been constructed by Siegel using deep methods.¹⁷

Distribution of Values of **Meromorphic Functions**; **Meromorphic Curves.**—One of the most important contributions to the theory of functions of one complex variable in the first half of the 20th century was the theory of the value distribution of a meromorphic function on an open Riemann surface, which was originated by R. Nevanlinna and developed by Ahlfors and other members of the Finnish school. This theory was later generalized to "meromorphic curves" (analytic curves in projective n -space), whose parameter domain is an open Riemann surface, by Weyl,¹⁸ who investigated the asymptotic behaviour of these curves as the parameter point approaches the boundary of the Riemann surface. Weyl's theory was further perfected by Ahlfors in an important paper.¹⁹ A generalization of this theory to functions of several complex variables has been given by W. Stoll.²⁰

Cohomology With Coefficients in Sheaves.—An n -dimensional complex analytic manifold V may be covered by a finite or (countably) infinite set $U = \{U_i\}$ of open sets U_i . Denote their nonempty intersections by $U_{ij} = U_i \cap U_j$ (where $U_i \cap U_j$ signifies the intersection of U_i and U_j), $U_{ijk} = U_i \cap U_j \cap U_k, \dots$. Cochains with coefficients, or values, in the complex numbers, of dimensions $0, 1, 2, \dots$ are defined by associating to each $U_i, U_{ij}, U_{ijk}, \dots$ complex numbers $c_i, c_{ij}, c_{ijk}, \dots$ depending skew-symmetrically on the indices. Consider, for purposes of illustration, a 1-cochain $c = \{c_{ij}\}$ (cochain of dimension 1). Its coboundary δc is a 2-cochain defined by associating to each U_{ijk} the number $(\delta c)_{ijk} = c_{ij} + c_{jk} + c_{ki}$. A cochain c is a cocycle if its coboundary vanishes. The coboundary of a $(q - 1)$ -cochain is a q -cocycle (cocycle of dimension q) and it is said to be *cohomologous* to zero. The vector space of q -cocycles modulo the q -coboundaries defines the cohomology of the "nerve" of the covering U with coefficients in the complex numbers and it is denoted by $H^q(\mathbf{U}, \mathbf{C})$. The cohomology $H^q(\mathbf{U}, \mathbf{C})$ depends on the covering $U = \{U_i\}$ of V by the overlapping open sets U_i but, by passage to finer coverings or by a suitable "normalization" of the covering, it can be made independent of the choice of the covering and the result is the q -dimensional cohomology of V with coefficients in the complex numbers \mathbf{C} , which is denoted by $H^q(V, \mathbf{C})$.

Now suppose that we replace $c_i, c_{ij}, c_{ijk}, \dots$ by holomorphic functions $f_i, f_{ij}, f_{ijk}, \dots$ on $U_i, U_{ij}, U_{ijk}, \dots$. We then obtain cochains with coefficients in the holomorphic functions and the resulting cohomology is called the cohomology of V with coefficients in the "sheaf" Ω of holomorphic functions; this cohomology, of dimension q , is denoted by $H^q(V, \Omega)$. Over any point of V the sheaf Ω consists of all functions f which are holomorphic in some neighbourhood, depending on f , of the point. In defining this cohomology we have used the fact that holomorphic functions can be added, their sum being again a holomorphic function. More generally, the cohomology can be defined with coefficients in any sheaf of "abelian groups."

Without attempting to define sheaves in general, we remark that various types of cohomology can be defined with coefficients in sheaves related, in various ways, to the complex analytic structure. Further examples will be indicated in the following section.

Complex Line Bundles; Complex Vector Bundles.—A divisor on a complex manifold V is defined by assigning, to each open set U_i of a covering $\{U_i\}$ of V , a meromorphic function f_i on U_i such that $f_i/f_j = f_{ij}$ is a nonvanishing holomorphic function on $U_{ij} = U_i \cap U_j$. Clearly $\{f_{ij}\}$ defines a 1-cocycle in the multiplicative sense, namely $f_{ij} \cdot f_{jk} \cdot f_{ki} = 1$. Hence a divisor defines an element (class) of the cohomology $H^1(V, \Omega^*)$ where Ω^* denotes the multiplicative sheaf of nonvanishing holomorphic functions. This class is trivial if there exists a 0-cochain $\{g_i\}$, with coefficients in Ω^* , satisfying $f_{ij} = g_j/g_i$; then $f = f_i \cdot g_i = f_j \cdot g_j$ in U_{ij} defines a meromorphic function f on V whose divisor is equal to the given one. The cohomology class of the 1-cocycle $\{f_{ij}\}$ cor-

responds to a class of complex analytically equivalent complex line bundles (complex analytic fibre bundles whose fibre is \mathbf{C}). A bundle F of this class may be constructed by taking the "products" $U_i \times \mathbf{C}$ whose points are pairs (z_i, ζ_i) , where z_i is a point of U_i , ζ_i a point of \mathbf{C} , and identifying the points (z_i, ζ_i) , (z_j, ζ_j) of $U_i \times \mathbf{C}$, $U_j \times \mathbf{C}$, respectively, if z_i and z_j are the same point Z of U_{ij} and $\zeta_i = f_{ij}(Z) \cdot \zeta_j$. The functions f_{ij} are called the *transition functions* of the bundle F over V . There is a holomorphic map $\pi: F \rightarrow V$ which is induced by the projection $U_i \times \mathbf{C} \rightarrow U_i$ sending (z_i, ζ_i) into z_i .

A holomorphic section s of the line bundle F over an open set U of V is a holomorphic map $s: U \rightarrow F$ such that s followed by π is the identity map of U . Since the holomorphic sections of F over U form a complex vector space, the cohomology of V with coefficients in the sheaf of sections of a complex line bundle F over V is defined; this cohomology, of dimension g , will be denoted by $H^q(V, F)$.

A complex line bundle is a special case of a complex (analytic) vector bundle. The fibre of a complex vector bundle is \mathbf{C}^m and its transition functions f_{ij} are $(m \times m)$ -matrices of holomorphic functions with nonvanishing determinant at each point of U_{ij} . Cohomology with coefficients in the sheaf of holomorphic sections of an arbitrary complex vector bundle F is defined since the sections form a complex vector space. For each g , the cohomology $H^q(V, F)$ is a complex vector space, which is finite dimensional if V is compact.

The Riemann-Roch Theorem.—Let F be a complex line bundle, over a compact Riemann surface V , defined by a divisor which is given by meromorphic functions f_i in each open set U_i of a covering $\{U_i\}$ of V . Since f_i/f_j is a *nonvanishing holomorphic function* in the intersection U_{ij} of U_i and U_j , a point in U_{ij} which is a zero (pole) of f_i of a certain order is also a zero (pole) of f_j of the same order. The finitely many points of V where the functions f_i, f_j, \dots have zeros or poles are therefore defined, and to each zero or pole there is assigned an integer, positive if the point is a zero and negative if it is a pole, whose absolute value defines the order of the zero or pole. The sum of all these integers is a topological invariant of the line bundle F which is called its characteristic class; it will be denoted by $c(F)$.

A compact Riemann surface is homeomorphic to the (topological) surface obtained from a sphere by cutting g pairs of holes in it and attaching to each pair of holes a "handle," forming a total of g handles, where g is an integer $0, 1, 2, \dots$. The nonnegative integer g , a topological invariant of the Riemann surface, is called its *genus*. For example, the sphere with one handle, topologically the same as a torus, has genus equal to 1.

The classical Riemann-Roch theorem, expressed in the language of sheaf cohomology, asserts that

$$\dim H^0(V, F) - \dim H^1(V, F) = c(F) - g + 1$$

where $\dim H^q(V, F)$ signifies the dimension of the cohomology $H^q(V, F)$. The term $H^0(V, F)$ is the (vector) space of holomorphic sections of F . Since $\dim H^1(V, F)$ is a *nonnegative integer*, we obtain the Riemann-Roch inequality

$$\dim H^0(V, F) \geq c(F) - g + 1$$

In particular, if $c(F) \geq g + 1$, then $\dim H^0(V, F) \geq 2$ and there exist at least two linearly independent holomorphic sections s_1, s_2 of F over V whose ratio s_1/s_2 is a nonconstant meromorphic function f on V . Thus the Riemann-Roch theorem, for a Riemann surface, yields information concerning the existence of meromorphic functions with given divisor on V .

In 1954 Hirzebruch²¹ generalized the Riemann-Roch theorem to complex analytic vector bundles F over projective manifolds V of arbitrary complex dimension. Introduce the Euler-Poincaré characteristic $\chi(V, F)$ of the cohomology of V with coefficients in the sheaf of holomorphic sections of the complex vector bundle F , namely,

$$\chi(V, F) = \dim H^0(V, F) - \dim H^1(V, F) + \dots + (-1)^n \dim H^n(V, F)$$

²¹F. Hirzebruch, "Neue topologische Methoden in der algebraischen Geometrie," *Ergebn. Math.*, new series, 9 (1956).

We note that the Riemann-Roch theorem, for a complex line bundle F over a compact Riemann surface V , expresses $\chi(V, F)$ in terms of topological invariants of V and F . The Riemann-Roch theorem of Hirzebruch expresses $\chi(V, F)$ in terms of topological invariants of V and F called characteristic classes, or Chern classes of V and F (after S. S. Chern, who first gave a precise definition of these classes).

Hirzebruch's proof of his theorem, which is based on a deep and remarkable theory of R. Thom,²² is nonalgebraic in character. A formulation of the Riemann-Roch theorem which contains Hirzebruch's theorem as a special case has been proved by A. Grothendieck²³ using only algebraic methods.

We remark that a knowledge of the value of $\chi(V, F)$ yields less information, concerning the existence of holomorphic sections of F , as the complex dimension n of V becomes larger.

Intrinsic Characterization of Projective Manifolds.—An intrinsic characterization of projective manifolds has been given by Kodaira,²⁴ which is a profound generalization of the classical theorem that every compact Riemann surface is projective. The theorem of Kodaira states that a compact complex manifold is projective if and only if there exists over it a "positive" complex line bundle, that is a complex line bundle F whose characteristic class $c(F)$, an element of the 2-dimensional cohomology of V with integer coefficients, can be represented by a positive-definite hermitian form of degree 2 (Hodge metric).

The proof is based on a "vanishing theorem," due to Kodaira also,²⁵ which states that the cohomology with coefficients in the sheaf of sections of a complex line bundle vanishes in the positive dimensions if the line bundle is sufficiently positive. The vanishing theorem, a generalization of earlier results of Bochner,²⁶ provides a criterion for the existence of holomorphic sections of vector bundles.

Stein Manifolds and Holomorphically Complete Spaces.—Beginning in the 1930s, K. Oka²⁷ made a deep investigation of questions connected with Cousin's problems and related topics in the theory of functions of several complex variables, and proved fundamental theorems which strongly influenced the work of others in this field. In particular, the notion of a "coherent analytic sheaf," an extremely important concept formulated by H. Cartan, has roots in some of Oka's work.

Shortly after 1950 a remarkable unification, by Cartan and J. P. Serre,²⁸ of certain aspects of the work of Oka and of that of Behnke, Stein and others was achieved with the use of sheaf cohomology. Numerous results of the theory of functions of several complex variables were subsumed in two main theorems of Cartan formulated in the language of cohomology with coefficients in coherent analytic sheaves. During the next decade, H. Grauert²⁹ and R. Remmert, using cohomological methods combined with various refined techniques, discovered profound generalizations of some of Oka's work. Other aspects of Oka's work were generalized by H. Bremermann and others of the Münster (Ger.) school of complex function theory, founded several years earlier by Behnke.

Since much of this work is highly technical in nature, explanations will be confined mainly to Cartan's second main theorem.³⁰ Although the theorem is easily stated in the language of sheaf cohomology, it should be emphasized that its proof is difficult.

The nature of the theorem will first be illustrated by an example. Let D be a subdomain of complex n -space C^n . Suppose that there are given a covering $\{U_i\}$ of D by open sets U_i and, in each U_i, U_j, \dots , meromorphic functions f_i, f_j, \dots where $f_j - f_i = f_{ij}$ is a holomorphic function in each intersection U_{ij} of U_i and U_j . The first problem of Cousin is that of determining a meromorphic function f on D such that $f - f_i$ is holomorphic in each U_i . The functions f_{ij} define a 1-cocycle with values in the sheaf Ω of holomorphic functions and hence determine a cohomology class of $H^1(D, \Omega)$. There exists a solution f of the first Cousin problem if and only if this class is trivial; i.e., if the 1-cocycle $\{f_{ij}\}$ is cohomologous to zero. In fact, if the desired meromorphic function f exists, then $g_i = f_i - f$ is holomorphic in U_i and $g_j - g_i = f_{ij}$; i.e., $\{f_{ij}\}$ is cohomologous to zero, and conversely. In particular, Cousin's first problem is solvable on D for arbitrary "Cousin data" $\{U_i, f_{ij}\}$ if and only if $H^1(V, \Omega) = 0$. It was known that Cousin's first problem is always solvable on certain special subdomains of C^n called holomorphy domains, where a holomorphy domain is a domain of C^n on which there exists at least one holomorphic function which cannot be continued analytically (as a holomorphic function) into some larger domain. In the language of sheaf cohomology, the holomorphy domains are characterized by the property that the 1-dimensional cohomology, with coefficients in the sheaf of holomorphic functions, vanishes!

By introducing more general sheaves, namely coherent analytic sheaves, Cartan and Serre were able to characterize the Stein manifolds, previously defined by Stein in a purely function-theoretic way, as those complex manifolds V such that $H^1(V, \mathcal{F}) = 0$, or equivalently $H^q(V, \mathcal{F}) = 0$ for $q > 0$, for every coherent analytic sheaf \mathcal{F} . Topological spaces with the property that the cohomology, with real or integer coefficients, vanishes in the positive dimensions, are called *acyclic*. The simplest acyclic spaces are those homeomorphic to a ball. In Cartan's general theorem, complex analysis found an analogue of the acyclic spaces of topology.

Theory of Deformation of Complex Analytic Structures.

— Deformation of the complex structure of a compact Riemann surface (1-dimensional complex manifold) is an idea dating back to Riemann who, in 1857, calculated the number of independent parameters on which the deformation of the structure of a compact Riemann surface depends and called it the "number of moduli." The questions centring around the deformation of the complex structure of a Riemann surface have never lost their interest. The theory of quadratic differentials and extremal quasi-conformal maps was developed by Teichmüller in the years 1938–44 in order to give a systematic theory of the deformation of Riemann surfaces. Teichmüller's methods were perfected during the following years by Ahlfors, E. Rauch, L. Bers, Weil and others.

The deformation of the complex structure of higher dimensional complex manifolds seems to have been considered first in 1888 by Noether, who calculated the number of moduli for a class of algebraic surfaces in projective 3-space. However, in contrast to the case of complex dimension 1, the deformation of the structure of higher dimensional complex manifolds was neglected during the 70 years following Noether's work until the subject was taken up by A. Frolicher and A. Nijenhuis³¹ and by Kodaira and Spencer.³²

A more or less systematic theory of deformation of the complex structure of higher-dimensional, compact, complex analytic manifolds was given by Kodaira and Spencer,³³ and we now describe it briefly. They defined a differentiable family of compact complex manifolds as a fibre space V over a connected differentiable manifold M whose fibre V_t over the point t of M has a complex structure depending differentiably on the point t . Assume, for simplicity, that M is one dimensional and let U be a sufficiently small interval containing the point $t = 0$ in its interior. Then there exists a covering $\{U_i\}$ of the portion of V over U by open sets U_i where U_i is covered by the co-ordinates $(z_i, t) = (z_1^i, \dots,$

$z_n^i, t)$. Denote by $z_i = h_{ik}(z_k, t)$ the biholomorphic co-ordinate transformations which determine the complex structure of V_t ; i.e., $z_i^\alpha = h_{ik}^\alpha(z_k, t)$ where α ranges from 1 to n . Letting $\theta_{ik}(t) = (\theta_{ik}^1(t), \dots, \theta_{ik}^\alpha(t), \dots, \theta_{ik}^n(t))$, where $\theta_{ik}^\alpha(t) = \theta_{ik}^\alpha(z_i, t) = \partial h_{ik}^\alpha(z_k, t) / \partial t$, we obtain a 1-cocycle $\{\theta_{ik}(t)\}$ which defines a cohomology class $\theta(t)$ of the 1-dimensional cohomology $H^1(V_t, \Theta_t)$ of V_t with coefficients in the sheaf Θ_t over V_t of holomorphic vector fields. The class $\theta(t)$, called the "infinitesimal deformation" of V_t , measures the dependence of the complex structure of V , on the parameter t . In the case where the fibres V , are compact Riemann surfaces: $H^1(V_t, \Theta_t)$ is isomorphic to the vector space of quadratic differentials of the surface, in the sense of Teichmüller.

Proceeding in this fashion, a generalization of Riemann's concept of "number of moduli" was obtained. However, in contrast to the case of Riemann surfaces, this number is not defined for all compact complex manifolds. Particular examples of complex manifolds V_0 , of complex dimension exceeding 2, show that not all cohomology classes of $H^1(V_0, \Theta_0)$ are the infinitesimal deformations of actual deformations of the structure of V_0 . In fact, some classes of $H^1(V_0, \Theta_0)$ may be "obstructed," the obstructions occurring as classes in $H^2(V_0, \Theta_0)$. If $H^2(V_0, \Theta_0) = 0$, then any class of $H^1(V_0, \Theta_0)$ is the infinitesimal deformation corresponding to a deformation of finite magnitude.³⁴

A classical problem³⁵ in algebraic geometry concerning the "completeness of characteristic systems" is to show that all "infinitesimal displacements" correspond to finite deformations of a complex analytic submanifold of a fixed algebraic manifold. A condition introduced by Severi³⁶ for the case of curves in algebraic surfaces was reformulated by Kodaira and Spencer in the language of sheaves and shown to be sufficient for completeness; i.e., for the existence of a finite deformation of the submanifold corresponding to any given infinitesimal displacement of it.

Finally, E. Calabi and E. Vesentini,³⁷ in a paper published in 1960, proved that a compact complex manifold, which is uniformized by an irreducible Cartan domain of at least two complex dimensions, is (locally) rigid; i.e., the number of its moduli is equal to zero. This result again underscores the difference between Riemann surfaces and complex manifolds of higher dimension.

(D. C. SR.)

ANALYSIS SITUS (POSITION ANALYSIS): see TOPOLOGY, ALGEBRAIC; TOPOLOGY, GENERAL: *Combinatorial Topology*.

ANALYTIC GEOMETRY, the representation of the points in space by ordered sets of numbers called co-ordinates. For instance, any position on the earth can be specified by its latitude, longitude and height above sea level.

The one-dimensional case is well illustrated by a thermometer. There is a certain point on the line associated with the number 0; the positive integers 1, 2, 3, . . . are evenly spaced in one direction away from 0, the negative integers $-1, -2, -3, \dots$ in the opposite direction, and the fractional numbers are interpolated in the ordinary manner. The displacement from one point x to another point x' is the positive or negative number $x' - x$.

In the two-dimensional case, the position of a point in a plane may be specified by its distances from two fixed perpendicular lines, the axes. The notion can be traced back to Archimedes of Syracuse (287–212 B.C.) and Apollonius of Perga (about 20 years later) or even to the ancient Egyptians; but it was first developed systematically by two Frenchmen, Pierre de Fermat (1601–65) and René Descartes (1596–1650). In their formulation the two distances were taken to be positive or zero. The important idea of allowing one or both to be negative was supplied by Sir Isaac Newton (1642–1727), and it was Leibniz (1646–1716) who first called them co-ordinates.

For some purposes it is just as easy to use *oblique axes*, as in

FIG. 1.—CARTESIAN CO-ORDINATES. RECTANGULAR AND OBLIQUE

the second part of fig. 1. Starting from the origin O , where the axes intersect, we reach the general point (x, y) by going a distance x along the x -axis OX and then a distance y along a line parallel to the y -axis OY . The x -axis is said to have the equation $y = 0$ because every point $(x, 0)$ satisfies this equation; similarly, $x = 0$ is the equation of the y -axis. On any other line through the origin, consideration of similar triangles shows that the ratio y/x is constant; thus any line through the origin $(0, 0)$ may be expressed as $ax + by = 0$, where a and b are arbitrary constants.

To obtain the equation for any other line, we take a point (x_1, y_1) on it. In terms of new co-ordinates x', y' , derived by "translating" the origin from $(0, 0)$ to (x_1, y_1) , the line may be expressed as $ax' + by' = 0$. Since $x' = x - x_1$ and $y' = y - y_1$, the same line, in terms of the original co-ordinates, is $a(x - x_1) + b(y - y_1) = 0$, or, say, $ax + by + c = 0$. Thus every line has a linear equation, and every linear equation determines a line. In particular, the line that makes intercepts x_0 and y_0 on the axes is $(x/x_0) + (y/y_0) = 1$, for this equation is linear and is satisfied by both $(x_0, 0)$ and $(0, y_0)$. Lines $ax + by + c = 0$ which have the same a/b and various values of c are parallel. The point of intersection of two nonparallel lines is obtained by solving the two simultaneous equations for x and y .

The equation $ax + by + c = 0$ with $b \neq 0$ may be solved for y in the form $y = -(ax + c)/b$. More generally, points whose co-ordinates satisfy an equation $F(x, y) = 0$ or $y = f(x)$ can be plotted by giving values to x and calculating the corresponding values of y . This procedure is particularly convenient when $f(x)$ is a one-valued function of x . In other cases it may be preferable to express the graph by parametric equations, giving x and y as functions of a single variable (or parameter) t . For instance, if P_1 denotes the point (x_1, y_1) , any line through P_1 has parametric equations $x = x_1 + lt$, and $y = y_1 + mt$, where l and m depend on the direction of the line.

Sometimes, for the sake of symmetry, the single parameter t is replaced by two parameters, t_1 and t_2 , related by an auxiliary equation. For instance, the general point (x, y) on the line through two given points P_1 and P_2 is given by

$$x = t_1x_1 + t_2x_2 \quad y = t_1y_1 + t_2y_2 \quad t_1 + t_2 = 1$$

This point P , dividing the distance P_1P_2 in the ratio $t_2:t_1$, is the centroid (or centre of gravity) of masses t_1 at P_1 and t_2 at P_2 . Positions outside the interval from P_1 (where $t_2 = 0$) to P_2 (where $t_1 = 0$) are covered by allowing t_2 or t_1 to be negative (while still satisfying $t_1 + t_2 = 1$); we may justify this by calling them "electric charges" instead of "masses."

Distance. — For problems involving the distance between two points or the angle between two lines, it is often advisable to use rectangular axes, so that the distance from the origin to (x, y) is the square root of $x^2 + y^2$, and the distance between (x_1, y_1) and (x_2, y_2) is the square root of $(x_1 - x_2)^2 + (y_1 - y_2)^2$. Multiplication of the expression $p = ax + by + c$ by a suitable number enables us to normalize the equation $p = 0$ of the general line so that $a^2 + b^2 = 1$. Writing $p = 0$ in the form

$$(x - x_1 + 2p_1a)^2 + (y - y_1 + 2p_1b)^2 = (x - x_1)^2 + (y - y_1)^2$$

where $p_1 = ax_1 + by_1 + c$, we recognize it as the locus of points

equidistant from $(x_1 - 2p_1a, y_1 - 2p_1b)$ and (x_1, y_1) ; in other words, the line $p = 0$ serves as a mirror which interchanges these two points by reflection. It follows that the foot of the perpendicular from P_1 to $p = 0$ is $(x - p_1a, y - p_1b)$, and that the distance from P_1 to the line is $\pm p_1$ (provided $a^2 + b^2 = 1$). In particular, the distance from the origin to $p = 0$ is $\pm c$.

The locus of points at unit distance from the origin is the circle $x^2 + y^2 = 1$, which has the parametric equations $x = \cos \theta$, $y = \sin \theta$; or, with $t = \tan \frac{1}{2}\theta$,

$$x = (1 - t^2)/(1 + t^2) \quad y = 2t/(1 + t^2)$$

Polar Co-ordinates — For problems involving directions from a fixed origin (or pole) O , we often find it convenient to specify a point P by its polar co-ordinates (r, θ) , where r is the distance OP and θ is the angle that the direction of r makes with a given initial line, which may be identified with the x -axis of rectangular Cartesian co-ordinates. When the complex number $x + yi = r \cos \theta + ir \sin \theta$ is represented by the point (x, y) , as in fig. 2 (the Argand diagram), the polar co-ordinates of the same point appear as the modulus and argument of the complex number ($q.v.$). Of course, the point (r, θ) is the same as $(r, \theta + 2n\pi)$ for any integer n . It is sometimes desirable to allow r to be negative, so that (r, θ) is the same as $(-r, \theta + \pi)$.

Given the Cartesian equation for a curve, we can deduce the polar equation for the same curve by substituting

$$x = r \cos \theta \quad y = r \sin \theta$$

For instance, the circle $x^2 + y^2 = a^2$ has the polar equation $(r \cos \theta)^2 + (r \sin \theta)^2 = a^2$, which reduces to $r = a$ (The positive value of r is sufficient, if we allow θ to take all values from $-\pi$ to π or from 0 to 2π). Similarly, the line $y = x \tan a$ has the polar equation $\sin \theta = \cos \theta \tan a$, which reduces to $\theta = a$. (The other solution, $\theta = a + \pi$, can be discarded if we allow r to take negative values.)

Transformation. — Two triangles are said to be similar if their sides are proportional, or if they have the same three angles. Their relationship can be extended to a transformation of the whole plane into itself. Such a similarity transforms every line segment dB into a line segment AB' which is μ times as long, where μ is a constant positive number (called the ratio of magnification).

If $\mu \neq 1$ (and sometimes also if $\mu = 1$), there is a unique invariant point; i.e., a point that is transformed into itself. For instance, if two maps of the same country on different scales are drawn on tracing paper and superposed at random, there is always just one place that is represented by the same spot on both maps (even if one of the maps is turned over before it is superposed on the other). Taking the invariant point as the pole for polar co-ordinates, we find that the similarity transforms each point (r, θ) into $(\mu r, a \pm \theta)$, where a is a constant angle (the same for all points). Taking the upper sign in " $a \pm \theta$," we have a spiral similarity, including as special cases a rotation through a (given by $\mu = 1$) and a dilatation or "enlargement" (given by $a = 0$). Taking the lower sign (as when one of the two maps is turned over), we have a diatropic-reflection, including as a special case (when $\mu = 1$) a simple reflection in the line $\theta = \frac{1}{2}a$.

The rotation $r' = r$, $\theta' = \theta + a$ may be expressed in terms of Cartesian co-ordinates by writing $r \cos \theta = x$, $r \sin \theta = y$, so that by the familiar formulas for the cosine and sine of $\theta + a$,

$$x' = r \cos(\theta + a) = x \cos a - y \sin a$$

$$y' = r \sin(\theta + a) = x \sin a + y \cos a$$

In particular, rotation through a right angle is given by $x' = -y$, $y' = x$; and the condition for two lines

$$ax + by + c = 0 \quad a'x + b'y + c' = 0$$

to be perpendicular is $aa' + bb' = 0$. The Area of a Triangle. — If P_i has polar co-ordinates (r_i, θ_i) ,

FIG. 2.—CARTESIAN AND POLAR CO-ORDINATES (THE ARGAND DIAGRAM)

the area of a triangle OP_1P_2 is taken to be positive if $\theta_1 < \theta_2$, negative if $\theta_1 > \theta_2$. With this convention, the area is

$$\frac{1}{2}r_1r_2 \sin(\theta_2 - \theta_1) = \frac{1}{2}r_1r_2(\sin\theta_2 \cos\theta_1 - \cos\theta_2 \sin\theta_1)$$

or, in Cartesian co-ordinates,

$$\frac{1}{2}(x_1y_2 - x_2y_1) = \frac{1}{2} \begin{vmatrix} x_1 & y_1 \\ x_2 & y_2 \end{vmatrix}$$

To find the area of any triangle $P_1P_2P_3$, choose new axes parallel to OX, OY and passing through P_3 . Since the new co-ordinates of P_i ($i = 1$ or 2) are $(a, -x_3, y_i - y_3)$, the area of any triangle $P_1P_2P_3$ is

$$\frac{1}{2} \begin{vmatrix} x_1 - x_3 & y_1 - y_3 \\ x_2 - x_3 & y_2 - y_3 \end{vmatrix} = \frac{1}{2} \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}$$

It follows that a necessary and sufficient condition for P_1, P_2, P_3 to be collinear is that this three-rowed determinant should be zero. The equation for the line P_1P_2 may be derived from this condition by writing (x, y) for (x_3, y_3) .

Circles.—The circle with centre (p, q) and radius a , being the locus of points (x, y) distant a from (p, q) , is $(x - p)^2 + (y - q)^2 = a^2$. Thus $x^2 + y^2 + 2gx + 2fy + c = 0$ is a circle with centre $(-g, -f)$ whenever $g^2 + f^2 \geq c$, degenerating to a "point circle" (radius zero) when $g^2 + f^2 = c$. If P_1 lies on the circle, the tangent at this point is $x_1x + y_1y + g(x + x_1) + f(y + y_1) + c = 0$, or $(x_1 + g)x + (y_1 + f)y + (gx_1 + fy_1 + c) = 0$. For this line passes through P_1 and is perpendicular to the diameter

$$(x + g)/(x_1 + g) = (y + f)/(y_1 + f)$$

The circle $x^2 + y^2 + 2gx + 2fy + c = 0$ is orthogonal to another circle

$$x^2 + y^2 + 2g'x + 2f'y + c' = 0$$

if, for a suitable P_1 , the centre of each lies on the tangent at P_1 to the other. Adding

$$(x_1 + g)g' + (y_1 + f)f' = gx_1 + fy_1 + c$$

to the analogous relation with primed and unprimed letters interchanged, we see that the orthogonality of the two circles implies

$$2gg' + 2ff' = c + c'$$

Conversely, any two circles that satisfy this relation are orthogonal. In particular, the circles

$$x^2 + y^2 + 2gx + c = 0 \quad x^2 + y^2 + 2fy - c = 0$$

whose centres lie on the x - and y -axes respectively, are orthogonal. Keeping c constant and allowing g or f to take various values, we obtain two orthogonal pencils of coaxial circles. If c is positive, the first pencil consists of nonintersecting circles, including two point circles $(\pm\sqrt{c}, 0)$, called the limiting points of the pencil; the second pencil consists of all the circles that pass through both these points. If $c = 0$, each pencil consists of all the circles that touch one of the axes at the origin.

Barycentric and Areal Co-ordinates.—The centroid of m masses t_i at P_i is the point $(\sum t_i x_i / \sum t_i, \sum t_i y_i / \sum t_i)$. When $m = 2$ this is, as we have seen, a point on the line P_1P_2 . But when $m = 3$, suitable values of t_i will place it anywhere in the plane. A. F. Möbius (1790–1868) called these three masses (t_1, t_2, t_3) the barycentric co-ordinates of the centroid with respect to the triangle of reference $P_1P_2P_3$. They are homogeneous co-ordinates since, for any $k \neq 0$, masses kt_1, kt_2, kt_3 have the same centroid as t_1, t_2, t_3 . The barycentric co-ordinates of P are proportional to the areas of the three triangles $PP_2P_3, PP_3P_1, PP_1P_2$. Accordingly, when normalized so that $t_1 + t_2 + t_3 = 1$, they are called areal co-ordinates.

Projective Geometry.—The German astronomer Johannes Kepler (1571–1630) conceived the idea of extending the Euclidean (or affine) plane by postulating a line at infinity whose points lie on pencils of parallel lines. The plane so extended is called the

projective plane. In terms of barycentric co-ordinates, the line at infinity has the equation $t_1 + t_2 + t_3 = 0$. General projective co-ordinates (x_1, x_2, x_3) are derived by the substitution $t_i = k_i x_i$, where the coefficients k_i are three constants. The line at infinity is now $k_1 x_1 + k_2 x_2 + k_3 x_3 = 0$, and any other homogeneous linear equation represents an ordinary line. The transition to projective geometry is completed by waiving the distinction, so that a point at infinity is treated just like any other point. This vital step was taken by another distinguished German, K. G. C. von Staudt (1798–1867). It enables us to define the points of the projective plane as the ordered triads of numbers (x_1, x_2, x_3) , not all zero, with the convention that (kx_1, kx_2, kx_3) is the same point for all nonzero values of k .

Given two points (x_1, x_2, x_3) and (y_1, y_2, y_3) , or, more concisely, (x) and (y) , we may express an arbitrary point collinear with them in the form $(x + ty)$, meaning $(x_1 + ty_1, x_2 + ty_2, x_3 + ty_3)$. In this notation, two triangles in perspective from (u) may be expressed as $(x)(y)(z)$ and $(x + u)(y + u)(z + u)$. Corresponding sides of the triangles meet in the three collinear points

$$(y - z)(z - x)(x - y)$$

in agreement with the two-triangle theorem of Gérard Desargues (1593–1662).

The general homogeneous linear transformation $x'_i = \sum c_{ij}x_j$ (summed over j), where $\det(c_{ij}) \neq 0$, transforms collinear points into collinear points; i.e., it is a collineation. For instance, the collineation

$$x'_1 = x_1 \quad x'_2 = x_2 \quad x'_3 = kx_3$$

is a homology which leaves invariant every line through the point $(0, 0, 1)$ and every point on the line $x_3 = 0$.

Line Co-ordinates and Envelope Equations.—Julius Plücker (1801–68) provided an analytic expression for the principle of duality by defining co-ordinates not only for points but also for lines: the line $X_1x_1 + X_2x_2 + X_3x_3 = 0$ has co-ordinates $[X_1, X_2, X_3]$. The equation $\sum X_i x_i = 0$ now appears as the incidence condition for the line $[X]$ and the point (x) . If (x) is a fixed point while $[X]$ is a variable line through it, the same equation $\sum x_i X_i = 0$ appears as the envelope equation of the point. Most problems involving envelopes of lines are conveniently treated by line co-ordinates and envelope equations.

A one-to-one correspondence between all the points A and lines a (in the real projective plane) is called a polarity if B lies on a whenever b passes through A . Following J. D. Gergonne (1771–1859), we call A the pole of a , and a the polar of A . If (x) and $[X]$ are related in this manner, we have $X_i = \sum c_{ij}x_j$ and $x_i = \sum C_{ij}X_j$, where $\|c_{ij}\|$ and $\|C_{ij}\|$ are inverse symmetric matrices. In terms of the pair of adjoint quadratic forms

$$(xx) = \sum \sum c_{ij}x_i x_j \quad [XX] = \sum \sum C_{ij}X_i X_j$$

we see that the incidence condition for (x) and $[X]$ may be expressed either as $(xx) = 0$ or as $[XX] = 0$. If the quadratic forms are definite, this condition is never satisfied. If the forms are indefinite, the locus of points that lie on their polars, and the envelope of lines that pass through their poles, is a conic, which thus appears as a curve whose equation (in either point or line co-ordinates) is of the second degree. Such curves were obtained by Menaechmus (about 340 B.C.) as sections of cones. When the special role of the line at infinity is restored, we can distinguish between ellipses such as $x = a \cos t, y = b \sin t$, parabolas such as $x = at^2, y = 2at$, and hyperbolas such as

$$x = a \sec t, y = b \tan t$$

Three Dimensions.—Almost all the above remarks extend easily from two dimensions to three or more. In ordinary space a point has three Cartesian co-ordinates (x, y, z) , a plane has a linear equation $ax + by + cz + d = 0$, and a line may be specified in various ways; e.g., as the intersection of two planes, or as the join of two points, or as proceeding from a given point in a given direction.

The last aspect yields the parametric equations

$$x = x_1 + lt \quad y = y_1 + mt \quad z = z_1 + nt$$

Polar co-ordinates have two spatial counterparts: cylindrical co-ordinates (r, θ, z), where r and θ are related to x and y in the usual way, and spherical polar co-ordinates, which consist of distance from the origin, latitude (or colatitude) and longitude. Barycentric (and other projective) co-ordinates are referred to a tetrahedron $P_1P_2P_3P_4$. The projective theory of collineations extends in a natural manner. The plane $\sum X_i x_i = 0$ has "co-ordinates" [X_1, X_2, X_3, X_4]. The first result that could not have been anticipated by simple analogy is that the matrix for a polarity (relating points and planes) is not necessarily symmetric ($c_{ji} = c_{ij}$): it may instead be skew-symmetric ($c_{ji} = -c_{ij}$), in which case every point lies on its own polar plane, and the lines that coincide with their polar lines form a very remarkable system called a linear complex.

The co-ordinates of three points may be arranged as a matrix having three rows and four columns. If the points are noncollinear, the matrix is of rank 3. By deleting the four columns in turn, we obtain four determinants, respectively equal to $X_1, -X_2, X_3, -X_4$, where [X_1, X_2, X_3, X_4] are Pliicker's co-ordinates for the plane determined by the three points. If, instead of three points, we take just two, say (x) and (y), we have a matrix of rank 2 with two rows and four columns. The six determinants $\{p_{14}, p_{24}, p_{34}, p_{23}, p_{31}, p_{12}\}$, where $p_{ij} = x_i y_j - y_i x_j$, are called the co-ordinates of the line.

The same co-ordinates, in a different order, can be derived by the dual procedure from two planes [X] and [Y] which pass through the line. The six p 's are not arbitrary but always satisfy the quadratic equation

$$p_{14}p_{23} + p_{24}p_{31} + p_{34}p_{12} = 0$$

The above-mentioned linear complex consists of those lines which satisfy (also) the linear equation $\sum \sum c_{ij} p_{ij} = 0$, where

$$c_{14}c_{23} + c_{24}c_{31} + c_{34}c_{12} \neq 0$$

ANALYTIC MECHANICS: see **MECHANICS: Analytical Composition of Forces.**

'ANAN BEN DAVID (8th century). Persian Jew, founder within Judaism of the Karaite sect. See **KARAISM.**

ANANDA, one of the principal disciples of the Buddha, known as his "beloved disciple" and devoted companion, was a cousin of the Buddha. He entered the order of monks in the second year of the Buddha's ministry, and in the 25th year was appointed his personal attendant. According to the Vinaya texts, he persuaded the Buddha, much against the latter's own inclination, to allow women to become nuns. Of the Buddha's intimate disciples, Ananda alone had not attained enlightenment (arhatship) when the Buddha passed away. He attained it, however, just before the first council (c. 544 or c. 480 B.C.), at which he repeated the Discourses (Suttapitaka). He is represented as being interlocutor in many discourses and the actual author of several. A collection of verses is ascribed to him in the Theragatha. According to tradition, he lived to the age of 120 years. (T. R. V. M.)

ANANIAS, the Greek form of Hananiah or Xnaniah, the name of several persons mentioned in the Bible. The most prominent are: (1) A member of the first Christian community who, with his wife Sapphira, was punished by Peter with sudden death for falsehood (Acts v. 1–10). (2) A disciple at Damascus in the story of the conversion and baptism of Paul (Acts ix, 10–17; xxii, 12–16). (3) Son of Nedeaios, a high priest who presided during the trial of Paul at Jerusalem (Acts xxiii, 2; xxiv, 1–5). He was high priest A.D. 47–59 and, having been accused of acts of violence, was sent to Rome for trial (A.D. 52), but was acquitted by the emperor Claudius. As a friend of the Romans he was murdered by the people at the beginning of the Jewish war of revolt.

ANANKE (ANANGĒ), in Greek literature, necessity or fate personified. In Homer the personification has not yet been

achieved, although even the gods admit that they are limited in their freedom of action. She is fairly prominent in post-Homeric literature and theological speculation, particularly Orphic, but is definitely known to emerge into cult only at Corinth, where she was worshiped with Bia (might, force). There are one or two faint and dubious traces of her cult elsewhere, but because of her unalterable nature it was pointless to render her offerings or sacrifice—"nothing is stronger than dread Necessity" was a Greek byword.

In literature she is associated with Atrasteia, the Moirai (or Fates, of whom she was the mother, according to Plato in the *Republic*) and similar deities. In Italy she does not appear to have been worshiped at all; the famous description of Necessitas (Ananke) in Horace's *Carmina*, which makes her attendant on Tyche, is purely literary.

See W. Roscher, *Ausführliches Lexikon der griechischen und römischen Mythologie*. (T. V. B.)

ANANTAPUR, a town and district in Andhra Pradesh, India. The town lies 117 mi. S. of Bangalore (Mysore state) on the Hyderabad-Bangalore main road and on the Guntakal-Bangalore metre-gauge branch of the Southern railway. Population (1951) 31,952. It has a large college of science and arts and an engineering college, both affiliated to Sri Venkateswara university at Tirupathi.

Anantapur was built by a dewan of Vijayanagar (*q.v.*) who is said to have named it after his wife Xnanda.

ANANTAPUR DISTRICT (7,385 sq.mi.; pop., 1961, 1,764,223) is part of the northern rim of the Mysore plateau, sloping from 2,200 ft. in the south to 1,000 ft. across the Pennar river in the north. On the east are the Errakondas ("red hills"). Anantapur is one of the driest districts of south India, and has often been the victim of serious famine. Much of it is a barren undulating plain of red soils, broken by long ridges of equally barren hills, but there are two important agricultural tracts of black cotton soil: one in the northeast ringed by ridges of the Errakondas; the other around Gooty, 30 mi. N. of Anantapur. The main crops are jowar and other millets, gram and other pulses and peanuts, followed by smaller areas of rice and cotton. Granitic formations in dome-shaped masses of great boldness and beauty occur throughout the district.

Potentially economic mineral deposits include widely dispersed corundum and steatite pockets, and diamonds at Wajrakarur, 30 mi. N.W. of Anantapur.

The area of the modern district was within the nucleus of the empire of Vijayanagar, Gooty (Gutti) being taken by the future kings, Harihara and Bukka, in 1336. Penukonda (Punugonda), 41 mi. S. of Anantapur, was the Vijayanagar capital in c. 1570–85, following the decline of the empire. Both had important hill fortresses (now ruined).

Subsequently the district passed to local and imperial Muslim regimes; to Tipu Sahib (*q.v.*); and to the Nizam of Hyderabad, who ceded it to the British in 1800. The district's first British collector (magistrate) was Major (later Sir Thomas) Munro, who introduced the ryotwari land-tenure system, thereby eliminating the intermediate rent collectors or zamindars. Munro's memory as a humanitarian official, and later as governor of Madras, is still cherished by the local people. (G. K.N.)

ANANTNAG (formerly ISLAMABAD), a town in Jammu and Kashmir, India, on the north bank of the Jhelum river, 3 j mi. S.E. of Srinagar. Population (1941) 11,983.

The second town in the Kashmir valley and originally its capital, it is non-decaying. There is an old summer palace, overshadowed by plane trees, and a fine mosque and shrine. There are many springs; below the town is a reservoir fed by one of these called the Anant Nag, slightly sulfurous, from which volumes of gas continually rise: the water swarms with sacred fish.

ANAPAEST, a metrical foot, basically $\cup\cup$ or $\cup\cup\cup$. The Greek anapaestic metron consists of four hicpities (see **PROSODY, CLASSICAL**). It is not, however, usual for two consecutive hicpities to take the double-short form ($\cup\cup\cup$). Thus the metron may take the forms $\cup\cup\cup\cup$, $\cup\cup\cup\cup$, $\cup\cup\cup\cup$, $\cup\cup\cup\cup$, $\cup\cup\cup\cup$, $\cup\cup\cup\cup$, $\cup\cup\cup\cup$, $\cup\cup\cup\cup$, the most common forms being those which do not in-

volve reversal of anapaestic rhythm (*i.e.*, — 00 instead of 00 —). A metron ending with double short can only be followed by a metron beginning with a long; *e.g.*, — 00—00 | — 00— . The anapaestic was a marching rhythm. Early Spartan marching songs were composed in sequences of catalectic anapaestic dimeters, also called "paroemiacs": 000000 | 00— . In Attic drama anapaests appear in "systems," sequences of full dimeters occasionally diversified by monometers and rounded off by paroemiacs. To keep the marching rhythm clear, there is usually diaeresis (word-end) between the two metra of the dimeter. The anapaestic tetrameter catalectic, a verse compounded of a full dimeter and a paroemiac, is used in comedy, especially in debates and in the parabasis. Passages in anapaests also occur in the lyric of tragedy, especially the monodies of Euripides. Lyric anapaests are characterized by spondaic rhythm (spondee: — —), presence of occasional proceleusmatic (0000), absence of diaeresis between metra, consecutive paroemiacs.

In English verse pure anapaestic rhythm produces a galloping effect; *e.g.* (from Byron): "And his cohorts were gleaming in purple and gold."

(L. P. E. P.)

ANAPHYLAXIS: see ALLERGY AND ANAPHYLAXIS.

ANARCHISM is the belief that it is practicable and desirable to abolish all organized government, laws and machinery for law enforcement. Anarchists aim at a stateless society in which harmony is maintained by voluntary agreements among individuals and groups. They envisage a social order without prisons, armies, police or other organized force to maintain property rights, collect taxes or enforce such personal obligations as contracts, debts or alimony.

Government, anarchists believe, is only needed to defend injustice. Without state support, they expect that unjust social arrangements will quickly disappear and be replaced by fair and equitable agreements freely accepted and maintained by all.

Some Basic Attitudes of **Anarchism**.—Man, as anarchists see him, is good. He can be trusted without government, or, at least, he will do less evil without government than with it.

Industrial society, they believe, can and should be run by means of a network of agreements among individuals and groups, associating freely on the basis of locality, region and industrial specialization. The seeming need of society for government, they say, is caused only by the injustice and unreasonableness of the social order, which should be abolished. Anarchists thus believe in radical social change. They wish to see property and class distinctions abolished, so as to leave more room for individual differences based on personality and accepted by consent.

Most anarchists consider themselves, therefore, socialists but they differ radically from most socialists and liberal reformers by their refusal to work through legislation or government. Most consider themselves revolutionaries, but they differ in the methods they are willing to employ. Some are pacifists who will work only through example, persuasion, nonviolent resistance and civil disobedience, in the tradition of Henry David Thoreau, Leo Tolstoy and Mohandas K. Gandhi. Others are willing to support militant group action, including violence in revolution or civil war. Anarchists of this persuasion are often willing to accept the "spontaneous justice" meted out by revolutionary crowds or committees, but would refuse to let these develop into permanent courts or laws. Anarchosyndicalists rely on labour unions ("syndicates") as the main instrument for the revolutionary struggle and for the hoped-for stateless industrial society. (See SYNDICALISM.)

Anarchosyndicalist views were long favoured by some labour unions in some economically underdeveloped regions, particularly of Latin culture, where the workers in the few seaports and industrial centres saw little hope of persuading the large peasant majority to support reform legislation or nationalization measures favourable to wage earners. Anarchosyndicalists wanted a "syndicate" of workers and professional personnel in each industry or service to take over installations from the owners, private or public, and to administer production of its goods or services. In each town or region, councils of representatives of all local syn-

dicates were to agree on local economic policies, and a council of representatives of the national syndicates was expected to agree on similar policies at a national level.

Anarchosyndicalists are confident that members of a syndicate controlling a vital service, such as a hospital or power station, would not use their greater bargaining power to the disadvantage of other workers. Similarly, they feel that the syndicates of geographically or industrially favoured regions will not use their superior bargaining power to the detriment of others. As evidence for their contentions, they point to the relatively brief experience of anarchosyndicalist rule in Catalonia during the early stages of the Spanish civil war in 1936–37.

A minority of anarchists have favoured direct action by individuals, including acts of terrorism and assassination against representatives of governments that they considered oppressive. Between 1894 and 1901 such acts claimed the lives of M. F. Sadi Carnot, president of France; Elizabeth, empress of Austria; Humbert I, king of Italy; and William McKinley, president of the United States. Such acts of terrorism did much to establish an image of the bearded, bomb-throwing anarchist in the minds of generations of newspaper readers.

In fact, however, most adherents of anarchism were never terrorists. Where anarchist terrorism developed, it grew from conditions that also favoured terrorist response from extreme nationalists or members of aggrieved minorities: extreme social or economic deprivation, despair of legal remedies, a mutually reinforcing interplay of provocation and reprisal and fear and resentment of police brutality. After the 1920s and early 1930s, individual anarchist terrorism almost disappeared.

Anarchists of all persuasions refuse to organize political parties or to present candidates for elections. In promoting their beliefs and interests, however, they often play a role in politics through propaganda, manifestoes, demonstrations, strikes and other forms of action; and they are active in founding and leading labour unions, co-operative societies and other voluntary organizations.

History of Anarchism.—Forerunners of anarchism include the Greek philosopher Zeno and some Hussite and Anabaptist religious reformers. Anarchist ideas were expressed by the French writers Rabelais and Fénelon, and were familiar to 18th-century French intellectuals.

The first major modern exposition of anarchism was given by the English writer William Godwin in his *Enquiry Concerning the Principles of Political Justice* (2 vol., 1793). Godwin did not use the word "anarchism" but advocated a stateless society of small autonomous communities and a communist distribution of property, with the substance going "to him who most wants it." In 1796, in a second edition of his work, Godwin modified his communist views.

The name "anarchists" had been used as a term of reproach during the French Revolution by the moderates—the Girondists—for those radicals who continued to press for economic and social changes after the overthrow of Louis XVI. Only in 1840 was the term "anarchism" adopted by an anarchist writer, Pierre Joseph Proudhon, in his *Qu'est-ce que la propriété?* ("What Is Property?"). Proudhon answered, "property is theft," referring to property in its Roman-law sense of the irresponsible right to use and abuse; in its stead he advocated limited rights of possession in a no-government state of society which he called anarchy. Roman-law-type property was to be abolished not by expropriation but by wiping out interest and profits through a new system called mutualism. Under this system, a national bank was to be based on the mutual confidence of wage earners and other producers, who would exchange only strictly equivalent goods and services, reckoned in units of labour. Similar ideas of mutualism had been expressed earlier, in England by William Thompson, John Gray and J. F. Bray and in the U.S. by Josiah Warren.

In Germany, anarchist ideas gained adherents in the 1840s, when such left-wing Hegelians as Moses Hess and Karl Grün advocated anarchism. An extreme individualistic version of anarchism was developed by Max Stirner (Kaspar Schmidt) in his work *Der Einzige und sein Eigentum* ("The Unique Man and His Own"). Later echoes of individualistic anarchist attitudes may be dis-

cerned in the writings of the philosopher Nietzsche, who called for a superbly individualistic "superman" and despised the state as a "cold monster."

The politically most effective versions of anarchism were labour oriented and collectivist in emphasis. In the 1870s an alliance of labour groups with anarchist and mutualist views, principally in the Latin countries—Spain and Italy—and in Belgium and France, split off from the Marxist-influenced International Workingmen's association (*see* INTERNATIONAL, THE). After calling themselves federalists and antiauthoritarians, they eventually developed the doctrines of modern anarchism and accepted the name anarchists. An anarchist international was reorganized in 1881, and international meetings were held thereafter.

An outstanding leader in this development was the Russian Mikhail Bakunin (*q.v.*), a contemporary and opponent of Karl Marx. Major contributions to anarchist thought were made later by Prince Peter Kropotkin (*q.v.*) in *Mutual Aid: a Factor in Evolution, The Conquest of Bread* and other works. A third Russian writer, Count Leo Tolstoy (*q.v.*), without naming himself an anarchist, adopted on religious grounds an anarchist position toward property and government in such works as *The Kingdom of God in Yourselves*.

Anarchism and Communism.—In revolutions and civil wars, communists and anarchists sometimes started as allies but usually ended as adversaries. The anarchist headquarters in Moscow, for example, were attacked by artillery in April 1918, on Trotsky's orders, and all anarchist activity was suppressed.

An international anarchist conference representing almost all major revolutionary syndicalist organizations, held at Berlin in Dec. 1922, repudiated explicitly the Leninist theory of the dictatorship of the proletariat. "Revolutionary syndicalism," it declared, ". . . has not for its object the conquest of political power, but the abolition of every state function in social life." The strongest anarchist movements at that time were those of Spain—the Federación Anarquista Ibérica (F.A.I.) and the syndicalist labour union, Confederación Nacional del Trabajo (C.N.T.), the latter claiming 2,500,000 members—and of Italy—the Unione Anarchica Italiana and the Unione Sindacale Italiana. These movements were driven underground by the dictatorships of Primo de Rivera and Mussolini, but with the fall of the De Rivera regime, the Spanish movement re-emerged.

During the Spanish civil war of 1936–39, anarchists and communists both sided with the government of the Spanish republic against the rebellion led by Gen. Francisco Franco, but eventually hostilities broke out between communists and anarchists, ending in the suppression of the latter and contributing significantly to Franco's victory.

Anarchism in the United States.—In 1882 the anarchist John Joseph Most founded in New York city the German weekly paper *Die Freiheit*. In the following year, an anarchist-led section of the International Workingmen's association was founded at Pittsburgh, Pa. By 1885 this federation claimed 80 sections, totaling 8,000 members. In addition to Most's weekly in New York, its adherents published a German daily newspaper, the *Arbeiter Zeitung*, and an English weekly, *Alarm*, in Chicago, Ill.; the *Voice of the People* in St. Louis, Mo.; and the *Anarchist* in Boston, Mass. The anarchists, with the exception of Most, supported the labour campaign for an eight-hour working day, hoping to give it a more revolutionary character. Anarchists were involved in the famous Haymarket square incident of 1886 in Chicago (*see* CHICAGO: History).

In 1903 congress passed a law to bar foreign anarchists from the United States and to deport alien anarchists found within it. The movement survived, however, and in 1905 an anarchosyndicalist type of labour union was founded, the Industrial Workers of the World (*q.v.*), commonly known as the I.W.W. Despite strong opposition from employers and from the American Federation of Labor, the I.W.W. conducted many strikes, but after World War I it lost most of its importance. The conviction and execution of the I.W.W. organizer Joe Hill (Joseph Hillstrom) on a disputed murder charge at Salt Lake City, Utah, in 1915 is commemorated in a well-known labour song that bears his name.

More stringent legislation was enacted in 1918. During the antired excitement of 1919–20, some foreign-born anarchists were deported to the U.S.S.R., among them Alexander Berkman and Emma Goldman. They returned disappointed and published denunciations of the communist dictatorship. Since anarchists and syndicalists in the 1920s were popularly—and incorrectly—believed to be likely to commit any common crime, some of them were convicted on evidence that would not have been sufficient, in the opinion of many, to convict persons of less unpopular views. On Aug. 23, 1927, two anarchists, Nicola Sacco and Bartolomeo Vanzetti, were executed at Charlestown, Mass., after long delay and world-wide protests, for a murder with robbery that had occurred in April 1920 at South Braintree, Mass. World opinion, including considerable U.S. opinion, held that they had been convicted not so much on any evidence advanced as because of their extreme ideas (*see* SACCO-VANZETTI CASE). From 1952, when the earlier legislation was superseded, U.S. laws listed as deportable those "aliens who are anarchists" and "aliens who advocate or teach, or who are members of or are affiliated with any organization that advocates or teaches, opposition to all organized government." This language might be construed to enjoin aliens from advocating philosophical and nonviolent tenets of anarchism, which native-born U.S. citizens might lawfully do.

Continuing Interest in Anarchist Ideas.—Although anarchism by the mid-20th century had subsided as a political movement, its indirect intellectual influence continued. Anarchists in the late 1950s stressed particularly their belief in the necessity and desirability of decentralization in all areas of human activity. In this, they found some common ground with adherents of political pluralism (*see* POLITICAL PHILOSOPHY).

The development of modern science and technology convinced them more than ever of the necessity for decentralization into a stateless system of small communities. This view was strongly urged by Aldous Huxley in *Science, Liberty and Peace* (1946), which reaffirmed the view of Leo Tolstoy that the application of science would make an unjust social system worse. A similar reaction was expressed by Sir Herbert Read (*The Philosophy of Anarchism*, 1940; *Anarchy and Order*, 1954) and George Orwell (*Homage to Catalonia*, 1938; *Nineteen Eighty-Four*, 1949). Anarchist ideas continued to appear in the English anarchist newspaper *Freedom*, and found new outlets in the *Delphic Review* (founded 1949) and the *University Libertarian* (founded 1955) in Britain and the *Libertarian* of Sydney, Austr. (founded 1958).

ANASAZI, a term derived from the Navaho word meaning "ancient ones," is the archaeological name for the culture of the prehistoric inhabitants of the region around the Four Corners, the only point in the United States common to four states (Arizona, New Mexico, Colorado and Utah). The earliest Anasazi remains come from a Basket Maker village near Durango, Colo., with a tree-ring date of A.D. 46. Modern Pueblo Indians in Arizona and New Mexico, descendants of the Anasazi, preserve a way of life that began about 2,300 years ago. An unusually rich picture of Anasazi life has been reconstructed by analogy with the historic and modern Pueblo inheritors of the prehistoric tradition.

Anasazi characteristics include compact, cellular, masonry or adobe dwellings called pueblos; semisubterranean ceremonial structures called kivas (*see* PUEBLO); black-on-white painted pottery; corrugated, gray utility pottery; and a type of artificial head shaping which flattens the upper part of the back of the head. While these features are found from the upper Rio Grande river in New Mexico to the lower Virgin river in Nevada, and from the Dolores river in Colorado and the middle Colorado river in Utah to the Little Colorado river in Arizona, the Anasazi homeland was in the San Juan river basin. Anasazi farmers established their

tenure of this semiarid plateau by developing special techniques for conserving and using the scarce water resources. The dry climate has preserved such perishable remains as cloth, basketry, wood, feather, fur and the so-called "mummies," which are only desiccated bodies.

The combination of remarkable preservation and standing masonry ruins in a colourful natural setting stimulated pioneer professional archaeologists and led to the early establishment of field schools where many U.S.-trained archaeologists received their field training digging in Anasazi ruins. The basic principles of stratigraphic analysis used by U.S. archaeologists were first demonstrated in the Anasazi area. Tree-ring dating, or dendrochronology (*q.v.*), made control of the time factor possible earlier than in other New World regions and fostered pioneer development of chronological concepts.

Early explorers and settlers of the Four Corners dug in the dry caves for specimens and noticed that deposits with pottery were superimposed over deposits without pottery but with many well-preserved baskets. They called the people who lived during the earlier period Basket Makers, and those who built masonry structures in caves and rock shelters in the canyon walls Cliff Dwellers. The early explorers and settlers thought the Cliff Dwellers were a race distinct from both the earlier Basket Makers and the historic Pueblos. This widespread popular belief persists despite archaeological demonstration that cliff dwellings are simply examples of pueblo architecture crammed into shallow caves.

Archaeologists referred to either Basket Maker or Pueblo remains until A. V. Kidder suggested "Anasazi" for the combined Basket Maker-Pueblo sequence. In 1927 Kidder sponsored an archaeological conference at Pecos, N.M., at which the long Anasazi sequence was subdivided into three Basket Maker and five Pueblo periods. Because of the complexity of the earliest Basket Maker culture then known, the first Basket Maker period was a hypothetical one reserved for the discovery of ancestral Basket Maker material, but nothing was found, and when Frank H. H. Roberts, Jr., revised the Pecos classification he eliminated this hypothetical stage.

About this same time physical anthropologists, especially C. C. Seltzer, showed by studying skeletons of Basket Makers and Pueblos that the physical differences recognized by earlier workers were not caused by the coming of a new race but by the introduction of the cultural practice of artificially shaping the heads of infants. Racial, as well as cultural, continuity was demonstrated for the Anasazi tradition.

Although Paleo-Indians were hunting now-extinct mammoth, horse, camel and bison 12,000 years ago in southern Arizona and on the High (Great) Plains, no evidence of such activity has been found in the Anasazi region. Basket Maker origins may ultimately be found in the Desert culture, a prehistoric way of life in arid North America similar to that of historic Indian groups in the Great Basin. Radiocarbon dates place the Desert culture as early as the Paleo-Indian hunters. The Cochise culture, the best-known Desert culture variant, was ancestral to the Hohokam (*q.v.*) and Mogollon (*q.v.*) cultures, southwestern groups contemporaneous with the Anasazi. The Hohokam (from a Pima Indian word meaning "those who have vanished") made red-on-buff pottery and lived in pole-and-mud houses in the southern Arizona desert, especially the Gila-Salt valley where they built an extensive network of irrigation canals. The Mogollon (named for the Mogollon mountains in southwestern New Mexico, which carry the surname of an early Spanish official) made polished red and brown pottery and lived in side-entered, semisubterranean pit houses in the mountainous regions of east-central Arizona and west-central New Mexico.

Whatever the exact local derivation of Anasazi culture may have been, Anasazi, Hohokam and Mogollon cultures emerged only after maize agriculture, pottery making and other sedentary arts were introduced from Mexico. The earliest Basket Makers raised maize and squash, although they depended as much on hunting and gathering of wild foods as on farming. They made baskets and tanned bags, but no pottery; used the spearthrower instead of the bow; wore little except sandals, fur blankets, and ornaments;

and lived in "wood-and-mud masonry" houses. By A.D. 500 beans, new types of maize, pottery, the bow and arrow and possibly the domesticated turkey were added. Dwellings changed to roof-entered pit houses. The transition to Pueblo culture took place from A.D. 700 to 1100, pueblo-type dwellings replaced pit houses, and kivas were developed out of the pit-house idea. Head shaping, corrugated pottery, cotton, and loom weaving were introduced. The following period, A.D. 1100-1300, often called the Great or Classic Pueblo period, represents the peak of Anasazi achievements in their homeland area. During this time the cliff dwellings were built, but many villages were huge surface pueblos several stories high. The great kiva, a large and elaborate ceremonial structure, was added. The weaving of cotton was highly developed. Black-on-red and polychrome styles of painted pottery were introduced. Outstanding ruins of this period are preserved at Mesa Verde National park in Colorado and several national monuments in Arizona and New Mexico.

By A.D. 1300 the increasingly dry conditions of the 13th century became so severe that most of the Four Corners region was abandoned by Pueblo people who carried the Anasazi tradition into the Rio Grande valley, the Mogollon country in the White mountains of Arizona and even into Hohokam territory. The resulting contacts with other cultures added to the complexity and variety of Anasazi culture and changed the course of its development.

About A.D. 1450-1500 the Pueblo people withdrew from these southern regions into the area where the Spanish explorers first saw them. Navaho and Apache Indians arrived from the north about A.D. 1500. These Athapascan newcomers accelerated the withdrawal of the Pueblos from areas now largely occupied by Apache and Navaho. Although reduction in the area and the number of villages occupied by the Pueblos continued throughout the historic period, the Anasazi way of life was still preserved in the second half of the 20th century at the modern Hopi, Zuni, Acoma and Rio Grande villages. ANASTASIUS, the name of four popes.

ANASTASIUS I, SAINT (d. 401), pope from 399 to 401, was elected on Nov. 27, 399, to succeed Siricius. He earned the praise of St. Jerome (*Epist.* 127) because of his censuring the works of the theologian Origen (d. c. 254), then but recently translated into Latin. In papal letters Anastasius condemned several Origenist writings, and disapproved the spread through translation of Origen's teaching. St. Anastasius died on Dec. 19, 401, and his feast is celebrated on the anniversary of his death.

ANASTASIUS II (d. 498), pope from 496 to 498, was consecrated on Nov. 24, 496. His first epistle to Emperor Anastasius displayed a conciliatory attitude toward Acacius, late patriarch of Constantinople, deposed in 484 by Pope Felix III. Anastasius' reception of the deacon Fotinus, probably occasioned by an anti-Acagian reaction at Salonika, was followed by schism at Rome and the charge of the *Liber pontificalis* that the pope desired to rehabilitate Acacius (see PAPACY: *Twelve First Six Centuries: Twelve Acagian Schism and Theodoric*). Because of Fotinus, Dante (*Inferno*, xi, 8) placed this pontiff in hell. Anastasius II died on Nov. 19, 498.

See P. Jaffé and W. Wattenbach, *Regesta pontificum Romanorum*, new ed., vol. 1 (1956). (H. G. J. B.)

ANASTASIUS III (d. 913), pope from 511 to 913, was a Roman, son of Lucian. He was consecrated about the middle of June 911. His pontificate falling during the period when Rome was under the control of the house of Theophylact, he had little freedom of action. Howel the Good, prince of Wales, consulted him in regard

to a reformed law code.

(A. G. Br.)

ANASTASIUS, IV (Conrad of Suburra) (d. 1154). pope from 1153 to 1154. This aged and amiable successor of Eugenius III, crowned on July 12, 1153, settled two long-standing problems: one with Frederick I over the see of Magdeburg, the other by restoring St. William of York to his see. As cardinal bishop of Sabina (1126) he had staunchly supported Innocent II, whom he served as vicar in Rome, during the schism of Anacletus II. Anastasius II died on Dec. 3, 1154.

See H. K. Mann, *The Lives of the Popes in the Middle Ages*, 2nd ed., vol. ix, p. 221 ff. (1925).

(J. J. Rn.)

ANASTASIUS I (c. 430–518), Byzantine emperor from 491 to 518, was born at Dyrrachium (Durazzo). An administrator of high character in the department of finance, he was chosen as emperor by Ariadne, the widow of his predecessor Zeno, who married him shortly after his accession. His reign began auspiciously. He gained popular favour in the towns by a judicious remission of taxation and displayed great vigour in administering the affairs of the empire. He succeeded in curbing Zeno's countrymen, the overpowerful Isaurians, driving them out of the capital and breaking their authority by a series of campaigns in Isauria itself which lasted until 498. Some of the Isaurians were transplanted and settled in Thrace. On the eastern frontier war was waged against Persia (502–505). Theodosiopolis (Erzurum) and Amida (Diyarbakir) were captured by the enemy, but the Persian provinces also suffered severely and the Byzantines recovered Amida. Peace was concluded in 506 by a treaty restoring the *status quo*. As Slavs and Bulgars were devastating the Balkan provinces of the empire, Anastasius in 512, in order to protect Constantinople and its vicinity, built the long wall stretching from the Black sea to the Sea of Marmara, about 30 mi. west of the capital.

In religious matters Anastasius began by maintaining the *Henoticon* (edict of union), Zeno's compromise, which satisfied neither Orthodox nor Monophysite. At his accession he had promised not to introduce any ecclesiastical innovations, but he gradually veered toward the Monophysite position. This won him the support of the Monophysites in Syria and Egypt, but antagonized the European provinces and the capital, particularly the city faction of the Blues, an important political party supporting Orthodoxy against the Greens who favoured Monophysitism. These differences caused many riots and revolts. The unpopularity of Anastasius' Monophysite policy gave an opportunity for a rebellion in 513 led by Vitalian, the commander in chief in Thrace, supported by Huns and Slavs. Vitalian attacked the capital by land and sea, and in 514 Anastasius came to terms and appointed him master of the soldiers in Thrace. Rebellions again, Vitalian was decisively defeated in 515. Seeing how any religious compromise with Syria and Egypt only caused trouble in Constantinople and the more central provinces, in his last years Anastasius attempted to treat with the papacy and with the Chalcedonian party, but was unsuccessful.

Anastasius' reign was marked by important financial reforms. He tried to stabilize the currency and reorganized the system of tax collection, both in urban and in rural districts. He tended to favour trade and industry at the expense of agriculture. His policy was not always popular and contributed to the unrest in the empire toward the end of his reign, but his careful and prudent administration filled the treasury and laid the foundation for the splendours of Justinian's reign. He died during the night of July 9, 518.

(J. M. Hy.)

ANASTASIUS II (d. A.D. 721), Byzantine emperor from 713 to 715, was called Artemius before he was raised to the throne on the deposition of Philippicus, whose chief secretary he had been. Anastasius sent an army under Leo the Isaurian (afterward emperor) to defend Syria against the Arabs. He adopted wise and resolute measures for the defense of Constantinople, attempted to reorganize the army and dispatched to Rhodes a formidable naval force. But the troops of the Opsician province mutinied, slew the commander of the forces and proclaimed a tax collector, Theodo-

sius, emperor in 715. After a six-months siege, Constantinople was taken by Theodosius. Anastasius, who had fled to Nicaea, submitted to the new emperor and became a monk in Thessalonica (716). In 720 he tried to regain his lost throne, heading a revolt against Theodosius' successor, Leo III; this failed, and Leo had him executed.

See G. Ostrogorsky, *History of the Byzantine State* (1956); J. B. Bury, *History of the Later Roman Empire*, vol. 2 (1889). (J. M. Hy.)

ANASTIGMAT, or anastigmatic lens, a photographic lens free from astigmatism (*q.v.*). See PHOTOGRAPHY: *Photographic Lenses*.

ANASTOMOSIS, in anatomy, the intercommunication between two vessels or nerves. The term is also used in operative surgery to signify the formation of a passage joining two spaces or organs that normally are separated. See SURGERY.

ANATOLI, JACOB (fl. 13th century), physician, preacher and translator from the Arabic, was a member of the Jewish community of Narbonne in Languedoc. During a stay in Naples he enjoyed the friendship of the emperor Frederick II and of Michael Scot. Among his more important services were translations of works by Averroes. His philosophical homilies are collected in his book *Malmaḥ ha-Talmidim* ("The Students' Instruction").

ANATOLIA (Gr. *anatolē*, "sunrise," *i.e.*, eastern land), in ancient geography, the country east of the Aegean, *i.e.*, Asia Minor (*q.v.*). It is now used by the Turks in the form *Anadolu* as the equivalent of Turkey in Asia.

See also Index references under "Anatolia" in the Index volume.

ANATOLIAN LANGUAGES are the indigenous languages (also called Asianic) spoken in ancient Asia Minor, or Anatolia, until the first centuries of the Christian era, when they were gradually supplanted by Greek. Archaeological exploration of this area lagged behind the 19th-century rediscoveries of more pivotal cultures of the ancient near east, notably Egypt and Mesopotamia. "Anatolian languages" has been a vague but comprehensive term, covering a general ignorance of the linguistic history of this exceptionally complex period and deriving from meagre, secondhand, Greek sources. Great progress, however, has been made, especially since 1900; there have been copious finds of inscriptional material. These epigraphs, together with archaeological and historical evidence, have led to important new conclusions.

History.—The history of Anatolia, like that of the Aegean world, begins about a millennium later than that of Mesopotamia. In Mesopotamia, the more fertile region, during the 3rd millennium B.C., the aboriginal Sumerian language (*q.v.*) was progressively absorbed by the expanding Semitic idiom of the Akkadian invaders; the presence of the likewise isolated Elamite language farther east is also recorded. Anatolia, however, exhibits only archaeological traces of a relatively primitive culture. Yet there is every indication of a basic stratum of autochthonous population from neolithic times, and of an irreducible substratum of indigenous languages, elements of which show an extraordinary persistence into historical times.

The early 2nd millennium B.C. was characterized by two important developments: the arrival of Indo-European-speaking conquerors (the Hittites and related tribes) from the north via the Bosphorus or, more probably, the Caucasus; and the advent of literacy in the form of Mesopotamian cuneiform writing. The earliest recorded traces of Anatolian language are found in the records of Old Assyrian trading colonists at the ancient site of Kaneš (Kiltepe) in central Asia Minor, where many proper names have a clearly indigenous character. The standard Anatolian cuneiform reached the Hittites via the Hurrians, who had invaded the eastern confines of Asia Minor and northern Mesopotamia from the northeast. Like the somewhat later Kassite conquerors of Babylon, the Hurrians spoke a language of obscure affinities: it is related to the much later Haldian (9th–7th century B.C.), the immediate predecessor of the Indo-European Armenian in the general region of Lake Van. Ultimately it is perhaps connected with the Caucasian language group.

Subsequently, during most of the 2nd millennium B.C., the Hittites dominated in Asia Minor, and the official language was that of the capital city of Hattusas (now Boğazköy) in north-central

Anatolia, an Indo-European speech which had been superimposed on Khattish (or Hattic), the native tongue of the aboriginal population. The central archives of the Hittite empire reflect a cosmopolitan culture and international intercourse in Hittite, Akkadian and Hurrian, which must have contrasted sharply with the dialectal multiplicity and localism of the hinterland. The ritual texts reveal the continued use of Khattish as a religious language in the worship of indigenous deities. Similar records show that in the province of Palā, northwest of Hattusas, a different, though closely related, Indo-European language was in use. In the southern territories (Arzawa, Kizzuwatna) Lûish (also known as Luvian or Luvian) was spoken. Besides inherited distinctions, the influence of variant substrata differentiated Hittite, Pall. and Lûish. In the centuries following the collapse of the Hittite empire (c. 1200 B.C.) political subdivision precipitated a decline in literacy. Cuneiform disappeared, but some literacy persisted in the form of hieroglyphic Hittite inscriptions in the so-called Late Hittite city-states. This peculiarly Anatolian word-syllabic writing system had also been in use during the empire for monumental purposes. The language seems to be a form of Lûish, and the same may be true of the still obscure stele of Ördek-burnu in the same region; written in an archaic West-Semitic consonantal alphabet.

Until the collapse of the empire, the central cultural orientation of Anatolia had been directed toward the southwest, and a corresponding preponderance of epigraphic material is found there. The connections of the Hittite empire with western Asia Minor are notoriously obscure, and there is little evidence of the language there in the 2nd millennium B.C. The centres of cultural diffusion in the near-ere Minoan Crete and Mycenaean Greece, which, however, exerted most of their influence on the maritime regions, especially Cyprus and the Syrian coast. The vast inland of Anatolia remained impervious to their penetration. Nevertheless, the ethnic and linguistic connections between the early inhabitants of the Aegean and those of western Asia Minor were considerable, as is shown clearly by the toponymy (place-names) of both regions. The Greek mainland was settled by Indo-European-speaking Greeks in the early 2nd millennium B.C., and so at least was Cnosus in Crete in the late 15th century. Their variety of Minoan script represents the Greek language, but those attributed to the Minoan Eteo-Cretans and Cypro-Minoans remain undeciphered (see MINOAN LINEAR SCRIPTS I).

Beginning about 750 B.C., after several centuries of illiteracy in the Aegean area and Anatolia, the advent of the Greek alphabet resulted in a profusion of written documents; most of Asia Minor was directed westward, especially after the ascendancy of the Ionian Greek colonies on the west coast. The exception was Cyprus, where the Cypriote syllabary, a late offshoot of the Cypro-Minoan script, was used not only for Greek inscriptions but also for the obscure Eteo-Cypriote texts from Xmathus. The disunion of Asia Minor remained as pronounced as ever. Rarely did a strong political power emerge before the Persian conquest. Phrygia, which was founded by Indo-European invaders on the ruins of Hittite power in north-central Anatolia, held sway from the 9th to 7th century, and left a small number of Old Phrygian inscriptions, unquestionably Indo-European, written in a variety of early Greek alphabet. Many centuries later New Phrygian is attested in numerous inscriptions in the region.

Most sections of Asia Minor were reputed in Greek tradition to have distinct forms of indigenous speech. Many of these are known only by name or in scant and questionable traces, viz., Paphlagonian, Cappadocian, Cilician, Lycaonian, Isaurian and Pisidian. The Celtic Galatian, brought in by Indo-European invaders in the 3rd century B.C., was in a class by itself. Other languages are found in isolated inscriptions, as Sidetic in Pamphylia, Mysian and Tyrrhenian (stele of Leninos, in the Aegean); the last is akin to Etruscan (*q.v.*) in Italy, being presumably a vestige of the ancient pre-Indo-European idioms of the Aegean region known in ancient tradition as Pelasgian, Tyrrhenian and Lelegian.

More important are the better attested languages of Caria, Lydia and Lycia. Carian is found in about 71 short inscriptions of Carian mercenaries in Egypt c. 600 B.C., and in a score of texts

from Caria proper, notably the important Kaunos inscription. The writing system is a peculiar mixture of signs recalling either the Greek alphabet or the Cypriote syllabary. The language remains uninterpreted; it may be akin to the Eteo-Cretan of the 2nd millennium, traces of which are found in the later alphabetic Traesus inscriptions and in an Egyptian medical papyrus. Lydian appears in about 50 inscriptions, mostly from the old capital city of Sardis; these are generally monotonous epitaphs, some in verse, including a couple of short Lydian and Greek texts, and one longer Lydian-Aramaic bilingual, which is the chief clue to an understanding of Lydian so far available. Lycian is known from about 200 inscriptions and coin legends, including several short Lycian-Greek bilinguals and the long inscription of the stele of Xanthus, part of which is written in a divergent archaic type of Lycian known as Milyan.

Description. — Both Lydian and Lycian contain unmistakable Indo-European elements; the latter probably is merely a late vestige (5th–4th century B.C.) of the Ldish language in southern Anatolia. Their grammatical structure, though imperfectly known, has enough similarity with that of Hittite to enable us to speak of an Anatolian subdivision of Indo-European languages, comprising Hittite, Palā, Ldish-Hieroglyphic-Lycian and Lydian. It belongs to the western (*centum*) branch of Indo-European, but has pronounced tendencies of its own. It includes the most anciently attested Indo-European speech material, but shows an advanced stage of formal evolution compared with both Greek and Sanskrit.

The influence of the native substrata appears in various ways. There is a tendency to lose the feminine gender (except perhaps in Lydian), or the gender altogether (Lycian). Most of the vocabulary is of uncertain or unknown, but presumably indigenous, origin, and differs from one language to another. It is to some extent possible to discern a northern substratum, actually attested in Khattish, and characterized by a suffix *-il* denoting appurtenance, which figures prominently in Hittite and Lydian as a grammatical element, largely as a substitute for the genitive case. The southern equivalent is also a native suffix (*-ass-*) of the pre-Lûish substratum, which expresses the genitive concept in Lûish and Lycian. This southern Anatolian stratum contains the toponymic suffixes *-nd-* and *-ss-* which loom large in the place names of southwestern Asia Minor and the whole Aegean world, and are seen in Greek *Korinthos* and *Halikarnassos, Labraunda* (Caria), Lûish *Purandas* and *Dattassas*, among many others. The pivotal point of the linguistic history of ancient Anatolia is the partial fusion of largely obscure and indirectly inferable native substrata with the languages of early Indo-European invaders. The influence of the indigenous element was strong in many fields, notably religion: it came to dominate the vocabulary of the intruding idioms, while the basic grammar remained Indo-European.

ANATOMY (ARTICLES ON). The article ANATOMY, GROSS surveys the principles that govern this branch of biology, which deals with form and structure; describes the plan of construction that characterizes the higher vertebrates, including man; and summarizes the history and subdivisions of anatomical science. The closely related field of botanical anatomy is outlined in PLANTS AND PLANT SCIENCE, and its major subdivisions are discussed in the articles listed under BOTANY (ARTICLES ON).

ANATOMY, COMPARATIVE discusses the branch of anatomical science which provided the source material for the concept of evolution, and which has since contributed an immense body of evidence to its validation. HOMOLOGUE explains the distinction between homologues—similarities of animal structure that can be traced to an evolutionary relationship—and the superficial similarities known as analogues. Discussions of form and structure as the product of evolution will be found also in ANTHROPOLOGY, particularly the section *Old and New Concepts in Physical Anthropology*; BIOLOGY; EVOLUTION, ORGANIC; MAN, EVOLUTION OF; PALAEOLOGY, particularly the section *Evolutionary Evidence*; TAXONOMY, which describes the methods used in classifying plant

and animal forms; and ZOOLOGY. ANATOMY, MICROSCOPIC discusses the composition and architecture of biological tissues and of the minute cells that constitute their building blocks; also, the development of this science, from the days of the first crude instruments to the era of the electron microscope, so powerful that it can bring into focus a single protein molecule or a virus.

The substance that constitutes the physical basis of all forms of life is described in PROTOPLASM. The organization of protoplasm into the minuscule complications of cell structure is treated in CYTOLOGY, and the types of tissue formed by groups of these cells are described in HISTOLOGY. The subject of anatomical changes incident to old age, summarized in a section of ANATOMY, GROSS, is treated in detail in GERONTOLOGY AND GERIATRICS.

The distinction between anatomy and physiology as areas of study is largely a matter of emphasis; obviously, the form and structure of an arm, an eye, a hand or an internal organ cannot be fully explained without reference to the functions for which these organs were evolved. Therefore PHYSIOLOGY and PHYSIOLOGY (ARTICLES ON) should be consulted. Human anatomy is discussed from the point of view of the artist in DRAWING (TECHNIQUES OF).

Many articles deal with the anatomy of components of the human body—for example: GASTROINTESTINAL TRACT; ARTERIES; BONE; BRAIN; CIRCULATORY SYSTEM; CONNECTIVE AND SUPPORTING TISSUES; EYE, HUMAN; HEART, ANATOMY OF; JOINTS AND LIGAMENTS; LIVER; LYMPH AND LYMPHATIC SYSTEM; NERVE; NERVOUS SYSTEM; OLFACTORY SYSTEM; REPRODUCTIVE SYSTEM; RESPIRATORY SYSTEM, ANATOMY OF; SKELETON, VERTEBRATE; SKULL; SPINAL CORD; URINARY SYSTEM; VEINS. For comprehensive information on any part of the body the Index should be consulted, since it serves as a guide not only to the survey article on the subject but to specific sections of related articles. For example, in addition to the article HAND, the Index refers to discussions of the subject under BONE; DRAWING (TECHNIQUES OF); and JOINTS AND LIGAMENTS. Another example is the subject of the pancreas. In addition to the article under that title, the Index gives references to relevant discussions under GASTROINTESTINAL TRACT, DISEASES OF; CALCULUS (IN MEDICINE); CANCER; ENDOCRINOLOGY; HORMONES; and VERTEBRATE EMBRYOLOGY. Also, the material listed under PANCREAS in the Index includes a microscopic photograph of the pancreatic cells, under HISTOLOGY; and the biographical article LOEWI, OTTO, which summarizes the work of the originator of "Loewi's test" for pancreatic function.

Biographical articles deal with the work of many leaders in the field of anatomical science, ancient and modern. Additional articles of interest to students of anatomy will be found under MEDICINE AND SURGERY (ARTICLES ON).

ANATOMY, COMPARATIVE, is the branch of zoology that deals with the structure of related animals. It is largely confined to the study of vertebrates, since members of the major invertebrate groups do not show the evolutionary connections with which the science is now concerned.

Modern comparative anatomy may be dated from the work of Pierre Belon, who showed in 1555 that the skeletons of man and bird are constructed of similar elements arranged in the same way. Subsequent studies led to the realization that all animals are constructed according to a limited number of fundamental ground plans, each plan being subject to a great number of variations. This is particularly true among the vertebrates, in which a series of changes may be discerned from fishes through amphibians and reptiles to birds and mammals.

The likenesses discovered in the skeletal, digestive, circulatory and other systems of animals as diverse as the lizard, bird and dog did not at once lead to any inference about relationships. The resemblances were rather thought to reveal the basic ideas underlying the original creation. Not until the 19th century was it realized that different structures having some similarity may be developed through the alteration or loss of elements in a line of descent from a common ancestral structure. Darwin made extensive use of comparative anatomy in advancing the theory of evolution.

Since Darwin's time, the study of comparative anatomy has

largely centred on the theory of homology. Structures in two different animals are held to be homologous if they can be traced to a common structure in an animal ancestral to both. Thus the skeletons of the wing of a bat and the arm of a man are homologous because both are evolutionarily traceable to the fins of crossopterygian fishes, in which the arrangement of the skeletal elements was first established. In this case the homology is revealed by the obvious resemblance of the two skeletons, but in other cases study of fossil forms must be resorted to; e.g., fossil ancestors of the horse reveal how loss and reduction of elements have made a one-toed hoof out of a five-toed paw (see EQUIDAE). Sometimes examination of developmental stages is essential, as in the establishment of homology between two tiny bones in the ears of mammals and the hinge bones in the jaws of reptiles. Embryology is also important in elucidating the relationships of the soft parts of the body, for which there is no fossil record.

See also Index references under "Anatomy, Comparative" in the Index volume.

ANATOMY, GROSS. The science of anatomy is part of biology (*q.v.*), the comprehensive science which studies both plants and animals—those which are now living and those which have lived in the past. It seeks understanding of life—elucidation of the processes which constitute life and of the phenomena which those processes present. Anatomy is one of the morphological branches of biology. It is concerned with a critical analysis of structural detail of organisms, and is of general interest because all our activities are limited by our structure and because it tells us who our remote ancestors were and something of what they did. This article is restricted to gross anatomy as distinguished from microscopic anatomy (see ANATOMY, MICROSCOPIC).

The anatomy of plants, covered in the botanical articles, is excluded here, but it is in order to note that it has thrown much light on the anatomy of animals and that the word "anatomy" was introduced into scientific nomenclature by the botanist Theophrastus (d. 287 B.C.), who was Aristotle's pupil and successor.

Surface form may be studied from the outside, but the internal structure cannot. Some method of revealing internal structure must be used, and obviously the first method was dissection. The earliest record of its use was made by the Greeks, and Theophrastus called dissection "anatomy," from *ana temnein*, "to cut up." It is an unfortunate name, however, in two ways. First, dissection can be practised only on dead bodies, whereas the objective of anatomy is the understanding of living bodies—it is only a means to an end; second, it is only one of many techniques which anatomy uses to reveal structural detail. A better name for the science would be morphology. The term morphology (*q.v.*), however, has been used to indicate all the biologic disciplines concerned with the study of form and structure of organisms, without regard for the functions associated with structure. This definition establishes the morphological studies as antithetical to the physiological (see PHYSIOLOGY). Moreover, morphology has come to have another and a narrower meaning: it connotes a specific study of the general form and arrangement of parts of an organism and the relationships of parts to the whole.

Subdivisions.—Subdivisions of the science are made according to special interest: (1) in the part of the animal kingdom included—species anatomy (including human anatomy), comparative anatomy, paleontology (anatomy of extinct animals); (2) in the age of the animals studied—embryology, comparative embryology, gerontologic anatomy (old age) (see GERONTOLOGY AND GERIATRICS); (3) in the method of study—gross and microscopic anatomy, roentgenologic anatomy, anthropometry; (4) in parts of bodies to which the study is especially devoted—histology, histogenesis and tissue culture, organology (devoted to organs), systematic anatomy (devoted to systems of organs with associated functions), topographic anatomy (devoted to special regions); (5) in the special objective of study—descriptive anatomy, morphology (laws of structure), artistic anatomy, surgical anatomy (see SURGERY), racial anatomy (physical anthropology) (see

ANTHROPOLOGY). These subdivisions, which do not exist in nature, are all academic conveniences. All the laws of all nature cooperate harmoniously in everything we are and in everything we do. In addition to gross human anatomy, which is considered here, other subdivisions are treated in special articles. (See GASTRO-INTESTINAL TRACT; CIRCULATORY SYSTEM; MUSCLE AND MUSCULAR SYSTEM; NERVOUS SYSTEM; SKELETON, VERTEBRATE; see also BRAIN; EAR, ANATOMY OF; HEART: ANATOMY OF.)

GENERAL PLAN OF STRUCTURE

Comparative anatomists and comparative embryologists have shown that one common plan appears in the bodies of man and the higher vertebrates. In the adult it appears in the trunk region—the thorax and abdomen; in the embryos: with their less complex bodies, it is more evident.

The body wall is like a cylinder (see fig. 1), open at one end,

MODIFIED FROM J. S. KINGSLEY, "OUTLINE OF COMPARATIVE ANATOMY OF VERTEBRATES": BY LEFFLY OF MCGRAW HILL BOOK COMPANY, INC

FIG 1.—GENERAL PLAN OF BODY STRUCTURE. DIAGRAM BASED ON EARLY EMBRYONIC STAGES. IN THE CROSS SECTION THE LEFT SIDE SHOWS A STAGE OF DEVELOPMENT EARLIER THAN THAT SHOWN ON THE RIGHT SIDE

tapering to a stem at the other. One rod and two tubes extend through the length of the cylinder. The tubes are on opposite sides of the rod, one, the neural tube, being dorsal and the other, the alimentary tube, being ventral. From the sides, somewhat ventral to the axial rod, four limbs grow out, two anterior and two posterior. The tubes extend above the open end of the cylinder, the neural tube to get information, the alimentary tube to get food. The whole is enclosed in a thin membrane, the epidermis, which covers it everywhere. The diagram represents simple embryonic stages of development, an earlier one on the left and a later one on the right. Both sides, of course, would actually be at the same stage of development at any one time.

The essential parts are: (1) the outer enclosing epidermal membrane (in the embryo called ectoderm); (2) the dorsal neural tube; (3) the supporting central rod around which the vertebral bodies grow (in the embryo called notochord); (4) the ventral alimentary tube which becomes the lining of the stomach and intestine (in the embryo called entoderm); (5) the intermediate mass (in the embryo called mesoderm): (6) a rather fluid tissue which fills the interspaces, derived from the mesoderm and in the embryo called mesenchyme.

The mesoderm constitutes a considerable pad of tissue on each side extending all the way from the most dorsal to the most ventral part of the body wall. It is hollow, for a cleftlike space appears in it on each side. These are the right and left body cavities. In the dorsal part of the body they are temporary: in the ventral part they are permanent, forming the two pleural cavities, the peritoneal cavity (originally double—most of the ventral mesentery is temporary) and the pericardial cavity. The dorsal mesoderm becomes separated from the ventral mesoderm and divides itself into serial parts like a row of blocks, 31 on each side (human); these are the mesodermal segments (mesoblastic somites). They grow dorsalward, ventralward, centralward (around the notochord) and outward toward the ectodermal membrane. They form bones, muscles and the deeper, leathery part of the skin. Dorsally they form bony arches protecting the

spinal cord, and ventrally the ribs protecting the alimentary canal and heart. Thus they form the body wall and the limbs—much the weightier part of the body. They give the segmental character to the body wall in neck and trunk and, following their lead, the spinal cord becomes correspondingly segmented. The ventral mesoderm is not so extensive: it remains near the alimentary tube, is never divided into segments and forms the continuous muscle layer of the stomach, intestine, etc., and the lining of the two body cavities: it becomes the smooth, shining, slippery pleura and peritoneum (fig. 3). The mesenchyme forms blood and lymph vessels, the heart and the loose cells of connective tissues. Everything in the body is formed from one or more of these six parts.

The neural tube itself is formed from the ectoderm at a very early stage. At first it dips in along the dorsal mid-line as a trough; fig. 2 shows it in cross section. Then the trough closes dorsally and it becomes a tube separate from the epidermis (fig. 3). Headward it extends above the open end of the cylinder and is enlarged to form the brain. It is not in immediate contact with the epidermis, for the dorsal mesoderm grows up around it and around the roots of the cranial nerves as a covering, separating the brain from the epidermis.

If the cylindrical body wall is followed headward it is found to terminate ventrally as the tongue, dorsally in the skull around the brain, ears and eyes. There is a considerable interval between eyes and tongue.' This is occupied partly by a deep depression of the epidermis between them, which dips in to join the alimentary tube (lining of the mouth) (fig. 1).

Headward, the alimentary tube extends up in front of the notochord and projects above the upper part of the body wall (tongue) and in front of and below the brain to join the epidermal depression. From the epidermal depression are formed the teeth and most of the mouth lining; from the upper end of the alimentary canal is formed the pharynx with its gill slits and gill arches and the larynx, trachea and lungs.

The notochord terminates headward in a blunt mass under the middle of the brain.

Tailward, the neural tube terminates in the adult opposite the first lumbar vertebra (farther tailward in embryos). The notochord and mesoblastic somites extend to the tip of the tail (coccyx in man), the ventral body wall joins the dorsal at the coccyx, thus terminating the body cavities. The alimentary canal at its tail end splits longitudinally into two tubes—an anterior and a posterior—in all mammals except the lowest: the anterior tube becomes the bladder, urethra and lining of the vestibulum vaginae where it joins a depression of the ectoderm; the posterior (dorsal) tube becomes the rectum and ends just in front of the coccyx by joining another ectodermal depression (the anus).

The units of structure are the cells (see CYTOLOGY). Each living cell comes from the division of a pre-existing cell and gets its life and its character from it. Living cells may be killed or die in the future; they have never died in the past. All cell; now living in any living being have come in a continuous unbroken line from the first cells that lived on the earth.

Changes in Structure Appearing in Mammalia.—Among others, two new features introduced by the mammals were sucking and a long uterine gestation. The first required a small closable throat, which in turn required that food be masticated by

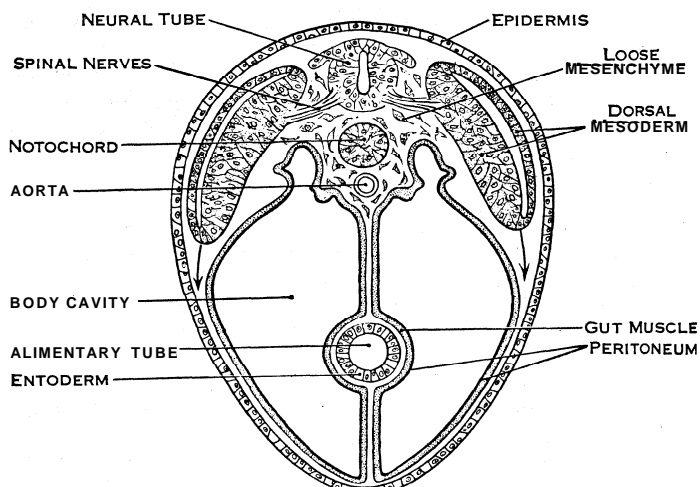

ADAPTED FROM W. WALOEYER, "EIERSTOCK UND EI," W. ENGELMAN AND COMPANY

FIG. 2.—FETAL MEMBRANE, SHOWING GERM LAYERS AND FORMATION OF THE NEURAL TUBE

molar teeth; it required also a firm imperforate hard palate. The second resulted in a fetus much larger at birth. But the parturient passages were smaller because the cloaca had been subdivided. This involved very high maternal intra-abdominal pressure at birth; it would have embarrassed the pumping apparatus—heart and mechanism of respiration. The diaphragm was interposed, increasing abdominal pressure by its action but not thoracic pressure. This interposition required the elongation of the esophagus to extend from the pharynx to the stomach which is caudad from the diaphragm.

Changes From Assumption of the Erect Position.—This posture, especially characteristic of the human animal, is not attained by simple rotation of the hind limbs through an angle of 90°, nor maintained without great modification of many parts of the body. The centre of gravity is shifted, involving changes in all the joints and especially in the vertebral column. The vertebrae are piled into a column of support, to which the thickened intervertebral discs give curvatures and elasticity. These discs reduce the impact of shocks, and the nucleus pulposus, like

MODIFIED FROM J. S. KINGSLEY, "OUTLINE OF COMPARATIVE ANATOMY OF VERTEBRATES"; BY COURTESY OF MCGRAW HILL BOOK COMPANY, INC

FIG. 3.—FORMATION OF THE BODY CAVITIES AND THEIR RELATION TO THE ALIMENTARY CANAL AND ITS MESENTERIES

a large marble in the centre of each, gives the whole column facility of movement. The cervical and lumbar curvatures appear and the lumbar segment is proportionally increased from 27% of total length in chimpanzees to 32% in adult men. It permits changing of the position of the relatively immobile thorax and its attached forelimbs.

The basis of bodily movement is reduced from the friction of four feet with the ground to that of two. This has important consequences for the feet, which develop heels and arches, a stronger bone structure and a very strong, half ligamentous bow-string muscle—the so-called abductor hallucis. The ankle joint becomes mortised and the work of knee and hip joints becomes greatly increased and complicated. The erect position requires the tonic contraction of muscles, especially of the extensors which prevent bending at the joints and the exquisitely delicate and automatic, unconscious action of the short (and other) muscles around the hip joint which promptly correct any tendency to falling or to undesired motion at that joint.

The support of the viscera is profoundly altered. The mesentery of the intestines becomes attached to the posterior abdominal wall. Notwithstanding this, almost the whole weight tends to be concentrated in the lower part of the abdomen on the anterior wall and on the pelvic diaphragm. The wall is strengthened in the inguinal region, but hernias occur through it. The weak pelvic diaphragm becomes effectively supported by the enlarged medial border of the gluteus maximus (hip) muscle holding the ischioanal fat pad securely against its lower surface.

The mechanism of respiration is changed. The shoulder girdle is no longer supported from the ground and so cannot continue to

be a base for muscular action producing inspiration. Instead it is a dead weight on inspiration. Some head muscles hold it up—trapezius and sternocleidomastoid. The thorax becomes flattened anteroposteriorly instead of laterally as in quadrupeds. Profound changes appear in the circulatory system. In fishes the heart is in the lowest part of the body. It pumps the blood up and gravity brings it back down. Land animals require limbs; they lift the heart to a height some distance above the lowest parts. Gravity can no longer effect all the return circulation. Assumption of erect posture in man lifts the heart higher above the ground than in any other animal now living except the giraffe and elephant. The return circulation is embarrassed. Valves are numerous in the veins of lower extremities but varicose veins are still common in later life. Changes throughout the body are required for the automatic adaptation through the sympathetic nerves of local blood supply during various activities.

Changes Incident to Old Age.—Because of the lengthening life expectancy, an increasing proportion of the population falls into the group past middle life. However, the imprints of time on human bodies do not come at the same age in each individual; some persons are as capable at 75 as others at 33.

The skin is one of the most accurate registers of the years. The soft, smooth, pink velvet of infancy becomes gradually the hard, wrinkled, seared parchment of old age. The head hair grays and falls out, though other hairs flourish and increase. Wounds take longer to heal; some replacements take five times as long at 60 as at 10 years of age. The brain is somewhat smaller after 40 and shrinks markedly after 75, especially in the frontal and occipital lobes. Sensory fibres in spinal nerves become fewer in number; the ganglion cells become pigmented and some of them die. In the auditory apparatus some nerve cells and fibres are lost and the ability to hear high notes diminishes. In the eye the lens loses its elasticity.

The bones become lighter and more brittle; they are friable and indentable; destruction overtakes new formation. They give up some of their calcium, which increases in arteries and cartilage, in ligaments and in the tendinous attachment of muscles. In joints the cartilage covering the ends of bone becomes thinner and sometimes disappears in spots, so bone meets bone directly and the old joints creak and burn. Muscular strength decreases but with marked individual variability.

Elastic tissue like old rubber, loses its elasticity. This is the one tissue in the body which never rests. In the skin it makes cuts gape open, in the arteries it resists the ever-present blood pressure, in the connective tissues it restores the resting position after every movement. So it is apt to wear out early—in some families at 45; in others it may last until 60. In the lungs the air sacs (alveoli) get bigger because the elastic tissue in their walls degenerates and the lungs increase in size (emphysema of old age). Elastic tissue is at its best at 25 years. When lost in old age, it is not repaired.

The arteries become fibrous and sclerosed. Because of decreasing elasticity in their coats they tend to become rigid tubes. Yellow fatty spots, which appear in their lining even in youth, are always present in old age. Lymphoid tissue undergoes a general shrinkage after middle age. In glands the parenchyma shrinks and the protoplasm seems to become more sluggish.

Repairs of parts are made more slowly if at all and sometimes are made by tissue different from the original (metaplasia). Pigment appears in increasing amounts in the skin, the heart muscle, liver, kidney and nerve ganglia and in the cells of the central nervous system. Cells have less energy for division. Young tissues change and adapt themselves to changing conditions much more readily than do old fully differentiated tissues and thus the old lose a factor of safety.

These processes of aging are just as physiological as the processes of growing. Some of them appear in human embryos before birth. In evolution many structures which are functional in early forms undergo involution and are changed or replaced in later forms. The pronephros went; the mesonephros was changed. These involutions occur in human embryos. The ductus arteriosus goes at birth, the thymus during adolescence. Major involu-

ANATOMY, GROSS

PRINCIPAL PARTS OF THE HUMAN BODY

This Plate on gross anatomy comprises 14 Views, 12 of which are transparent, showing all principal parts of the human anatomy. Below is a list in English (insofar as this is possible) of the names of the parts illustrated. The number immediately following the name is the code number for that part; the other number or numbers indicate the View or Views on which it is shown. A key to the Plate, with Latin names, is given on the last page.

ANATOMY, GROSS

KEY TO PLATE II, VIEWS 1-14

On the list below, the number at left is a code number for the part of the body named.
The number or numbers at right indicate the View or Views on which that part of the body is shown.

Abbreviations: A. (Arteria); L. (Ligamentum); M. (Musculus); N. (Nervus); and V. (Vena).

1. Anulus inguinalis profundus, 1,2
2. Anulus inguinalis superficialis, 1
3. Aorta, 5,6,10,11,14
4. Aponeurosis m. obliquus externus abdominis, 1
5. Appendix vermiformis, 4,12,13
6. A. axillaris, 5,6,14
7. A. brachialis, 5,6,14
8. A. carotis communis, 5,14
9. A. femoralis, 5,6,14
10. A. iliaca communis, 5,6,14
11. A. iliaca externa, 5,6,14
12. A. iliaca interna, 5,6,14
13. A. lienalis, 5
14. A. mesenterica inferior, 5,6,14
15. A. mesenterica superior, 14
16. A. pulmonalis, 5,10,11,14
17. A. renalis, 6,14
18. A. subclavia, 5,6,14
19. Atrium sinistrum, 11
20. Bronchus principalis, 5,14
21. Cartilago thyreoidea, 3
22. Cerebellum, 11,14
23. Cerebrum, 11,14
24. Clavicula, 1,2,7,8,9,14

202. Vesicula seminalis, 6

tions appear in increasing numbers as the higher decades pass.

Length of life differs greatly in different cells and body structures: nerve and muscle cells can live a lifetime and so never need replacement; head hairs live a few years. The longevity of the whole body differs for each species. The potential longevity of the human body has been estimated at 100 years; it appears to have been determined by man's gorillalike, anthropoid ancestors in the Pliocene period, perhaps 10,000,000 years ago.

Some scientific suggestions for the cause of old age, involution and death are failure of tissue nutrition through arterial degeneration, accumulation of waste products or of deleterious substances absorbed from the intestine or the atmosphere, failure of coordinated influence of hormones, the progressive diminution of oxygen consumption after 12 years of age or a combination of all of these. Doubtless all of these contribute.

FORM AND SIZE

Anatomists commonly recognize nine stages in a human life running its full course, and the body form changes from stage to stage. In none of these stages is the form static; it is reacting actively with the environment. Life before birth consists partly and after birth largely of such reaction, but though interaction with environment leads to local changes the body's deep fasciae preserve its general contours.

Form and size of the whole body and of its parts are inherited. The effects of present conditions modify the old adaptations. The resultant form is seldom perfect for life under present conditions but it is adapted to present needs well enough to maintain life with the least waste of energy.

Both form and size were determined in Pliocene times by a combination of internal and environmental forces. Among the internal forces were inheritance and growth. Among the external, gravity was one of the most important. In animals that moved on the surface of the earth, gravity confined life to one plane—the horizontal. Gravity dictated that one side should be up and one down and ventral and dorsal surfaces resulted. Limbs had to be on the underside. Since animals moved with one end first, head and tail evolved, and the head end, coming into contact with the environment first, developed sense organs. Animals that moved rapidly had to be bilaterally symmetrical.

Gravity was not only the chief agent in producing these qualities of form universal among the vertebrates, but also had a great influence on size. If a little animal with form perfectly adapted to its environment were to double its length while its form remained the same, it would have four times as much surface and eight times as much weight. Such a change of proportion might be serious in relation to gravity and water and air resistance.

Gravity has also an influence on the relative size of parts. The lancelet (*amphioxus*) has a straight and so a short intestine. As animals get longer the intestine becomes coiled. If the length of the animal were multiplied by ten and the form remained the same, the absorptive intestinal surface would be multiplied by only 100 but the weight by 1,000. To feed the greater bulk the intestine would have to be much longer than the body and so coiled. The human alimentary canal is 12 times as long as the straight line between its ends.

Gravity is thus an important determinant of form, but it works chiefly on large and heavy things. In early embryonic stages, when growth is most active, the body is too small for gravity to exert effective influence. In those tiny masses other intermolecular factors are more effective—capillarity, cohesion, surface tension, adsorption, electric charge, chemical action. These are the important internal and external forces operating at that stage of organization. They are co-operative with inheritance. Many antecedents and determinants of form in the early embryological stages have been revealed. The organizers of H. Spemann and the morphogenetic hormones of J. Needham are among them.

PHYSIOLOGICAL ANATOMY

For a long time physiology and anatomy were combined in universities; Johannes Müller was professor of both at the same time in Berlin. Later for academic convenience they were separated.

In nature, however; all anatomy is physiological.

A new morphologic concept developed rapidly after 1940. Researches into the form and structure of small animal bodies and their parts (embryos and cells) showed them to be very sensitive to biochemical influences. Morphogenetic hormones are largely biochemical in nature and are the causes or determinants of many of the form changes in embryonic development.

The study of form in minute anatomy promised to be heuristically extended beyond the reach of visible light to include the structure of organic molecules, especially the giant protein molecules of which man's structure is composed.

HISTORY OF ANATOMY

The story of the development of the science of anatomy may properly be divided into four periods, during each of which the science had different orientations: (1) until thorough scientific dissection, by Andreas Vesalius (A.D. 1543); (2) until the advent of scientific physiology with William Harvey (1628); (3) until the demonstration of the unity of all life by Charles Darwin (1859); and (4) after Darwin.

Until Thorough Scientific Dissection by Vesalius (A.D. 1543).—*The Period of Ignorance of Anatomy.*—None of the very early scientists dissected a human body. Men regarded the dead body with superstitious awe. Spirits were everywhere and surely the spirit of this body was hovering near its forsaken mansion. There was a belief in life after death and a disquieting uncertainty concerning the resurrection of the body. The disintegration of buried or drowned bodies was troubling. In the Talmudic writings is a theory of the "bone called Luz"—the resurrection bone (perhaps the sacrum). It was a nucleus around which the separated molecules were to be reassembled. The Mohammedan religion forbade dissection and the Christian church was not always mindful of St. Paul's statement, "It is sown a natural body, it is raised a spiritual body."

For surgeons, however, knowledge of the "natural body" was a vital necessity and for all men who could and dared to think it was of the greatest interest. Embalmers learned a little anatomy in preparing mummies, as did surgeons in treating wounds. The Edwin Smith surgical papyrus (3000–2500 B.C.) contains some anatomy of the head and brain. The Ebers papyrus (1600 B.C.) contains more. Early knowledge was pitifully vague.

Hippocrates and *Aristotle.*—More than a millennium later lived Hippocrates, the great physician (c. 460–c. 374 B.C.). Some writings on anatomy are dubiously ascribed to him, but there is no evidence that he dissected a human body. Nor did Aristotle (384–322 B.C.). Both thought the heart was the seat of the intellect.

Aristotle studied animals and was the founder of comparative anatomy. His comparisons of structure led him to construct a "ladder of nature" ascending from the lowest to the highest. He saw a unity in nature—the foundation of the concept of organic evolution. Aristotle did not see it, but Charles Darwin, standing on his shoulders, did. "Linnaeus and Cuvier were my Gods," said Darwin, "but they were mere schoolboys compared to old Aristotle."

Herophilus and Erasistratus.—About 40 years after the deaths of Aristotle and his patron, Alexander the Great, the Ptolemies ruled in Egypt and encouraged dissection. At Alexandria appeared Herophilus (fl. 300 B.C.), the greatest of the Greek anatomists. Before him, human anatomy was speculative rather than descriptive. But he dissected the human body, and for the first time anatomy was given a considerable factual basis. He dissected the brain and recognized it as the centre of the nervous system and the seat of intelligence. He distinguished motor and sensory nerves, showed that the aorta and arteries contained blood, not air, and described the lymphatic vessels of the intestine—the lacteals, which were "discovered" by Gasparo Aselli (1622), the contemporary of Harvey. He described and named the duodenum. If his book *On Anatomy* had not been lost, the world might not have had to wait 1,800 years for some account of structure of the human body resulting from thorough scientific dissection.

Erasistratus (fl. 300 B.C.) was a younger contemporary. He believed that arteries contained air or *spiritus vitalis*. Arteries,

veins and nerves were in his view all tubes. He had a theory that the whole body was made of tubes, for the most part too fine to see. He might have arrived at an idea of the circulation of the blood, for he suspected that the ultimate branches of arteries and veins were connected by smaller branches beyond the limits of visibility. He first saw that the veins, like the arteries, centre in the heart, not the liver. He described the valves of the heart and named the tricuspid. Like Hippocrates, he called the trachea *arteria tracheia*, the rough air holder.

Marinus and Galen.—Three hundred years after Erasistratus, there lived in Alexandria the important teacher Marinus (c. A.D. 110), who wrote a book unfortunately lost. The influence of his personality and his teaching was so great that it reached down through four teachers who followed him and inspired Galen (c. A.D. 130–c. 200).

Galen was an Asiatic Greek who practised medicine in Rome from A.D. 164 to 199 (except when he fled from epidemics). He had ability, education, wealth, industry, self-assurance and a quarrelsome disposition. His patients (emperors and consuls) encouraged him to write and lecture. Some writings were lost in a fire; a vast number remain—59 books on anatomy. They abound in polemics and self-glorification. His nomenclature is inconsistent and indefinite. His science is vitiated by two a priori theories to which he adhered dogmatically. The first was the old one of the pneuma and spirits: the pneuma was cosmic life taken in with the breath; the spirits were three—natural in the liver, vital in the heart and animal (mental) in the brain; thence they traveled through veins, arteries and nerves respectively with an ebb and flow motion like the tides or the breath. The second was his self-made religion in which a creator had made every structure of the body perfect for its use. The first dogma precluded any thought of the blood circulation (he knew nothing of injections); its detail required the existence of canals through the interventricular septum of the heart. He could not find them in any animal but described them nevertheless. The religious dogma assumed that he knew everything of structure and function, and so could explain every phenomenon.

Much of what he knew of human anatomy, principally about bones and joints, he learned through Marinus. For other structures he offered the anatomy of the Barbary ape, the pig and the ox as human. But since his dogma suited the Stoics and also the new Christian religion, he was supported by the authority of state and church. His books were preserved while others were lost. Since Galen was perfect, no further study was needed or permitted.

Galen's service consisted in assembling and arranging all the discoveries of Greek anatomy. His disservice consisted in the establishment of an authoritative fictitious anatomy.

Middle Ages.—Galen's period, which has been aptly called the Indian summer of Greek science, was followed by a long period during which anatomy as a science languished. For a dozen centuries the Arabs kept it barely alive. When they took Alexandria in A.D. 640, Paul of Aegina was there and he taught them Galen's anatomy. They also studied Greek science in commentaries translated into Arabic by Syrians, Nestorians, Christians and Jews. These were essentially Aristotle and Galen with all Arab colour. Rhazes, Ali Abbas and Avicenna made the most important ones and of these the last was the most famous. The Canon of *Medicine* of Avicenna, the "medical Bible," published in A.D. 1000, contained a considerable section of second- or third-hand anatomy, much of it from animals and scarcely ever tested by fresh observation. It spread throughout the Arab world, through Egypt and Africa to Spain.

Eventually the originals from which the Arab works had been abstracted were found, and through them men began to look at the wonders of nature. Hut at first, only through them. Men studied the books—not nature. Scholasticism made authorities of Galen and Aristotle. It did not attack problems by the study of nature but by metaphysical dialectic based on those books. Research was forbidden in some universities and physicians were punished if they dared to differ from Galen. But there was some interest in anatomy. The dissection of executed felons was authorized and public demonstrations, "anatomies," were held. An

"anatomie" was a reading from Galen (animal anatomy). Half of the names used were Arabic. The professor (of medicine) presided solemnly. Seated in his elevated chair, he read a translation of Galen. To a menial was given the task of verifying from the cadaver the text as read. He tried to do it though the text was wrong. The sessions were long and collations were served.

The law courts obtained permission to have autopsies made, being sometimes suspicious of the ostensible causes of death. Mondino de'Luzzi (Mondinus), professor of medicine at Bologna, performed some and published (1316) an autopsy manual of 40 small pages called *Anathomia*.

Leonardo.—Artists encouraged the study of anatomy, for they wanted accurate representations of the body. Dissections were performed by Leonardo da Vinci (1452–1519), Albrecht Dürer (1471–1528), Michelangelo (1475–1564) and Raphael (1483–1520). Leonardo began with surface measurements, proportions and anatomy of muscles, but it was not as an artist that he went on to study heart, brain, digestive system, fetus, etc. He became an anatomist and dissected 30 bodies (largely as autopsies) until stopped by Pope Leo X. He made more than 750 anatomical drawings and wrote 120 anatomical notebooks.

Altogether, his works on anatomy surpass in extent, accuracy and beauty the work of many centuries after his death. A long list of his discoveries has been made; all were rediscovered by later anatomists. Leonardo studied and trusted nature rather than books.

Leonardo's magnificent achievements in many fields brought him the admiration and reverence of his contemporaries. His spirit and influence prepared the way for the "restorer of anatomy." Vesalius, whose great book was published 24 years after Leonardo died.

Until the Advent of Scientific Physiology With Harvey (1628).—*Vesalius.*—Andreas Witing came of a distinguished medical family in Wesel on the Rhine; hence he was called Vesalius. In 1533 at the age of 19 he went to the University of Paris, where he studied medicine under the famous Sylvius (Jacques Dubois of Amiens), who was the most popular medical teacher of his time. In his lectures he presented Galen with so much eloquence and clearness that students flocked to Paris. Though he was professor of medicine, Sylvius lectured on anatomy. Sylvius knew Galen much better than he knew the body, however, and often the demonstrator could not find the structures Galen described. Neither could Sylvius. So Vesalius and his fellow student, Michael Servetus, would dissect bodies and confront the great professor with the evidence—an unforgivable offense.

At Paris Vesalius saw that he was an anatomist and that his teachers were not. He resolved that he would devote himself to the science of anatomy.

At the age of 22 he went to Venice. Within a year he took his doctor's degree in Padua where he became famous for his knowledge and skill in anatomy and surgery and accepted the chair of surgery and anatomy in the university (1537). He was the first to receive a salary as professor of anatomy in any university. Vesalius himself served as the dissector and his mechanical skill was marvelous, as was also his ability as a teacher. He covered the margins of Galen's book with notes of the author's mistakes.

Everyone came to his lectures—students, professors from all departments, artists, the Clite of Padua and Venice, public officials and the clergy. In 1540 he demonstrated at Bologna the skeletons of a man and an ape, side by side. It became clear to Vesalius that where Galen was wrong for man he was right for the ape. Vesalius thus resolved to prepare a new account of human anatomy from his own dissections and illustrated with the best pictures that could be made. For three years he worked constantly; he dissected, wrote and made drawings. He engaged one of the best artists of Italy, said to be his friend and countryman, John de Calcar, Titian's pupil, to make drawings and woodcuts. The drawings of the skeleton reportedly were made by Calcar, those of the muscles probably by Vesalius himself. Many pictures are posed so as to show the entire body in the postures and environment of life. Vesalius was interested in the living man and the artists of Italy had much to do with securing the permission by

which the few bodies were obtained on which Vesalius' work was done.

The book, *De humani corporis fabrica* (Basel, 1543), was a great success. For the first time men could see, in beautiful and accurate illustrations, the structure of their own bodies. There was fierce and bitter contemporary criticism, however. Many physicians and anatomists were opposed. Their reputations were at stake. They had taught Galen too long. Sylvius belittled the illustrations and wrote Vesalius asking why he had not published his little work as an appendix to Sylvius' edition of the complete works of Galen. Realdo Colombo, Vesalius' pupil at Padua, ridiculed him and said that he had overlooked important things like the duct between the stomach and the spleen. Vesalius challenged him to show it. He announced public dissections and invited all who knew him wrong to be present and show on the human body wherein he was mistaken. Crowds attended. Colombo could not find his gastrosplenic duct because it was not there. Vesalius says of others that, though urged to state his errors, they were silent as though their tongues had been cut out.

In a fit of despondency, Vesalius gave up anatomy. He burned everything he had on hand, the old Galen with the marginal notations and a great volume of anatomical notations. He became court physician to Charles V and afterward to Philip II of Spain.

But his work was well done, and his book triumphed by its own truth. It is the first real textbook of anatomy, but it is much more than that. With the publication of the *Fabrica*, medical science entered the modern period.

The Period of Discovery at Padua.—After Vesalius left Padua (about 1546) his chair was occupied by a series of five eminent anatomists following in succession until 1625. The first of these was his assistant Realdo Colombo (1516?–59), who, as mentioned previously, was critical of his former teacher. But he followed the methods of Vesalius and added to the knowledge of the serous membranes, the eye and the lung.

Gabriello Fallopius (1523–62), canon of Modena, succeeded. He also had been an assistant to Vesalius. He gave loyalty, admiration and affection to Vesalius and his students and colleagues gave them to him. Though he died at 39 he added much of permanent value to our knowledge of anatomy. Accuracy was his distinguishing characteristic. The uterine tubes and the canal carrying the facial nerve through the temporal bone are still known by his name. Two of his pupils became great anatomists—Volcher Coiter and Fabricius. The latter succeeded him.

Hieronymus Fabricius (Geronimo Fabrizio) (c. 1533–1619) came of a noble and wealthy family in Aquapendente near Orvieto. For nearly 50 years, from 1562 to 1613, he was professor of anatomy at Padua. His many publications cover anatomy, embryology and physiology. They contain excellent illustrations made from copper plates and justify his position among the greatest of anatomists. Bernard Albinus of Leyden republished his *Opera omnia* in 1738.

In his long life, he attained the greatest fame and it has not lessened. Galileo chose him as his physician. He was knighted in 1608. William Harvey lived in his house and began with him the study of blood circulation and of embryology.

Julius Casserius (Casserius) (1552–1616) was nominated by Fabricius as his successor. He had been a house servant, pupil and later assistant to Fabricius and was expert in all the techniques of anatomy of his time. Most of his plates were published after his death by his successor, Spigelius. There were 98, including 22 on the vocal organs and 17 on the ear.

The last of the six great Paduans was Adrian van der Spiegel (Spigelius) (1578–1625), who succeeded Casserius in 1618. Like Vesalius and Calcar, he was born in Belgium. His book, published in 1627, is illustrated by the magnificent plates of Casserius. His discoveries relate mainly to the muscles of the spinal column and to the viscera. The lobus caudatus of the liver is still commonly called the Spigelian lobe. He reformed the nomenclature, but died relatively young of blood poisoning from infections incurred in handling the poorly preserved material with which he worked; such infections were common among anatomists until after Pasteur's time. After Spigelius, Padua ceased to hold the

place so long maintained as leader in the work of gross anatomy. And as yet there was no other anatomy.

Other Italian and European Laboratories.—At Bologna, Jacopo Berengario da Carpi (d. 1530) had added knowledge of the vermiform appendix and the thymus gland. Giulio Aranzio (Arantius) (1530–89) studied the heart (corpora Arantii) and Costanzo Varoli (1543–75) described the brain (pons Varolii).

In Rome Bartolomeo Eustachio (Eustachius) (1524–74) made many discoveries. His great fame was posthumous, achieved through the drawings of his *Tabulae anatomicae*. He published only eight of these himself; 38 others did not appear until 1714, 140 years after his death, though completed much earlier (1552?). He made the drawings himself and was among the first to have them reproduced on copper plates instead of on wood. In accuracy of detail, they surpass the splendid illustrations of Vesalius. A list of the structures, of which he has given us the first accurate knowledge, is impressive. The tuba auditiva (Eustachian tube) is named for him. His drawings include a magnificent representation of the sympathetic nervous system far beyond any antecedent knowledge. He also introduced the study of variations.

Had his plates been published when they were made, the progress of anatomy would have been accelerated by a century and Eustachius would perhaps have taken his rightful place beside Vesalius as one of the two "fathers of anatomy."

In France Jacobus Sylvius (Jacques Dubois) (1478–1555), professor of medicine in Paris and sometime teacher of Vesalius, made some additions to knowledge of bones of the head and a real reform in anatomical nomenclature.

He unintentionally immortalized himself by his comments on the *Fabrica* of Vesalius when it was published in 1543. He said that anatomy had changed since Galen's time, that the femur was more curved then but had been straightened by the style of tight breeches; that the sternum did consist of eight bones when Galen described it—it needed more in the robust chests of ancient heroes than in men of the degenerate days of 1543. He made a pun on Vesalius' name and referred to him as Vesanus (madman).

In Switzerland Felix Platter (1536–1614) of Basel wrote an excellent account of the eye, the foundation of modern knowledge.

The learned, capable and religious Spaniard, Michael Servetus (1511–53) of Aragon, mentioned previously as the friend of Vesalius at Paris, described the pulmonary circulation accurately for the first time in his book *Christianismi restitutio* (1553). If he had lived longer it is probable that he would have discovered the general circulation 70 years before it was demonstrated by Harvey. An ardent Christian who made for himself a "Christocentric world," he did not agree with authorities in some doctrines concerning the Trinity, and Calvin and his associates condemned him to be burned alive.

In England Thomas Vicary published in 1548 a small book called the *Anatomic* of the Bodie of Man, probably the first book on anatomy in the English language. In 1651 the College of Physicians created a lectureship in anatomy and two years later built in Knight Rider street an anatomical theatre. In 1615 a lecturer in that foundation named William Harvey was appointed.

William Harvey.—Returning to England after four years with Fabricius, William Harvey (1578–1657) was already concerned with the problems of his life: circulation and generation.

Although he respected Galen and Aristotle, he had learned not to worship them. He learned all the facts anyone else had ever learned about the heart and added more which he perceived for the first time. Above all, he put all the facts together better than any other person and so saw the general principle underlying what formerly had been merely witnessed—the circulation of the blood. In anatomy and physiology this was a fundamental truth for all subsequent work and subsequent thought.

The physiologists hold that he was a physiologist; the anatomists that he was an anatomist. He was both; the separation is an artificial one. That he was an anatomist is attested by the fact that his work is based on structure and that he calls his book *Exercitatio anatomica de motu cordis*.

He had seen with everyone else the arterial tree and the venous

tree (the metaphor comes from Hippocrates) with their great trunks and branches. He said the fluid blood passed somehow from the arterial twigs to the venous tree twigs. Many said that was like saying that the sap goes up this tree and then crosses over and goes down the tree over there. Harvey spent the rest of his life hunting the connecting capillaries. He never saw them, but he foresaw them. Actually, they are an enormous network connecting the terminal twigs of the arterial and venous trees. There are more than 60,000 mi. of them in the muscles alone. In 1628, when Harvey published his paper on circulation, a boy was born in Italy who did see them. Four years after Harvey died in 1657, Marcello Malpighi, then 32 years of age, stood on a hillside near Bologna looking toward the glow of the Italian sunset. He held up to the light a preparation—a spread-out piece of a frog's lung. He saw the terminal twigs of arteries and veins, and with a magnifying glass saw for the first time the tiny capillaries, with the blood in them, connecting the twigs.

Until the Demonstration of the Unity of Life by Darwin (1859).—*The Period of Consolidation, Illustration and Teaching.*—The century following Harvey became the heroic age of microscopic anatomy and embryology. Gross human anatomy was characterized in this period by the foundation of scientific and philosophic societies, the development of texts, atlases and museums, advances in knowledge made chiefly by surgeons and the establishment of special schools of anatomy, the beginning of anatomical work in the United States and the passing of anatomical acts.

Treatises.—The epoch-making *Fabrica* of Vesalius was followed by the text of another Paduan, Spigelius, in 1627. The intense interest aroused and nourished by the work of the Italians resulted in much anatomical investigation throughout western Europe, reported in many monographs on special topics. The scientific societies, founded about this time, were also receiving reports of similar work. It was desirable that all this should be brought together, and in several countries textbooks appeared in which all the knowledge available was assembled and arranged.

Investigations in Gross Human Anatomy.—This was left largely to surgeons. They were ardent anatomists. In preanesthetic days, speed in operation was of prime importance. This required exact detailed knowledge of structure and relations. They introduced the new overabundant detail of description and nomenclature in regions where operations were frequent—mouth, neck, inguinal region, perineum, etc.

Sometimes emultrition had unhappy consequences. J. G. Wirsung and an associate "discovered" the pancreatic duct. Wirsung reported it (1642). He was later murdered. The associate was suspected, the motive being jealousy. O. Rudbeck of Sweden and T. Bartholinus of Denmark both "discovered" independently, 1651 and 1652 respectively, the lymphatic system and its termination in the neck veins. Their work was admirable, but their dispute over priority was bitter. All these jealousies were futile, for Eustachius' plates, so long unpublished, had shown the facts about a century before.

Schools of Anatomy.—On the continent, anatomy was taught throughout this period in the universities, usually in association with surgery or medicine. But in England, biology was an orphan child whom the dormant universities were slow to adopt. Anatomy was born and grew up outside them. The surgeons established extramural schools. It became clear to them that if the public were to have good medical service, medical students and physicians must know anatomy better than they did. William Hunter, at his own expense, established the famous school on Great Windmill street in 1770. It contained his collection of preparations, dissecting rooms, an amphitheatre and his dwelling house. He lived in the school and for it. When he died 13 years later, he had expended £100,000 on his museum. There he, his more famous brother, John Hunter, and William Hewson taught, superintended dissection and initiated many into investigation of special problems. The school, which continued 63 years, made a great contribution to the teaching and development of anatomy throughout the English-speaking world.

In the school's early days, Benjamin Franklin was a frequent

visitor and a great friend of Hewson. When the latter died from blood poisoning contracted in his work (one of nine who died of that cause in the school), Franklin induced his widow and children to move to Philadelphia, where some of their descendants became well-known physicians. Other similar schools were established. In 1828 there were in London seven private schools of anatomy plus four in the hospitals.

In Edinburgh anatomy was taught in the university. The Alexander Monros, father, son and grandson, held the chair for 126 continuous years—from 1720 to 1846. The two elders taught 12,800 students and made Edinburgh a great centre of medical teaching. There was also an extramural school in which the famous brothers John and Charles Bell taught. These schools gave to dissection the qualities of thoroughness and technical precision which have characterized it ever since.

William Hunter's museum was bequeathed to Glasgow, where it remained a centre of interest in modern times. John Hunter later parted from his brother and assembled his own famous anatomical collection, which became one of the most treasured and useful possessions of the Royal College of Surgeons in London.

Anatomy Acts.—The schools required human bodies to teach anatomy. Since there were no legal provisions for supplying them, they were obtained clandestinely. Resurrectionists dug them up and the schools bought them. Trouble came abundantly, culminating in the Burke and Hare atrocities in 1827 (see BURKE, WILLIAM). This led to the passing in 1832 of the British Anatomy act, long urged by leading medical men. It permitted use of unclaimed bodies by specially licensed teachers. A similar act had been passed in 1831 by the legislature of the state of Massachusetts, an example that was soon followed in other states.

Gross Anatomy in the United States.—In America anatomy followed the traditions of the old British schools, at first of the Monros of Edinburgh and later that of the Hunters of London. About 1730 Thomas Cadwalader opened a private school for anatomy in Philadelphia. He had been a pupil of Cheselden. New York had one in the 1750s. From 1752 to 1755, another William Hunter, of the same Scottish family as the famous brothers in London, gave a series of demonstrations in Newport, R.I.

In 1765 two young men, William Shippen and John Morgan, organized a school of medicine in connection with Pennsylvania college, afterward the University of Pennsylvania. They had been pupils of both the first Monro and of the Hunters. Shippen was professor of anatomy, surgery and obstetrics; Morgan wrote a monograph on the art of preserving material. Thus was founded the school of medicine of the University of Pennsylvania, which contributed much to making Philadelphia the medical capital of America throughout this period. Caspar Wistar, who was professor of anatomy there, 1808–18, wrote a textbook and founded a museum extended by William Horner (professor, 1831–53), who first described the tensor tarsi muscle and wrote a standard text.

This first American medical school was followed in 1768 by another at King's college (later Columbia university) in New York city. The departments of anatomy in both experienced difficulties in obtaining bodies for dissection similar to those experienced in Britain. Shippen's house in Philadelphia was mobbed and King's college was raided.

Afterward a department of anatomy was organized in Harvard college in Cambridge, Mass., in 1782, where John Warren, professor of anatomy and surgery, had 20 students in anatomy and had one cadaver dissected in each course. In that school, Oliver Wendell Holmes, Sr., the poet, the "autocrat of the breakfast table" and the apostle in America of I. P. Semmelweiss' demonstration of the cause of puerperal fever, became professor of anatomy in 1847, one of the ablest and most popular teachers of anatomy in U.S. schools. Departments of anatomy were founded at other U.S. colleges in rapid succession: Dartmouth, University of Maryland, Yale, Brown, Transylvania, Bowdoin and the University of Virginia. In 1825 Jefferson Medical college was organized in Philadelphia. G. S. Pattison of London was a professor there. In 1839 a third medical college was organized in Philadelphia with S. G. Morton as professor of anatomy. He published in 1839 an

excellent monograph, *Crania Americana*, based on a thorough study of 600 skulls of various American stocks, and in 1849 an illustrated system of human anatomy.

Anatomy in the U.S. made some contributions to knowledge, but was active during this period mainly in teaching and encouraging dissection. It was a recognized laboratory discipline of medical students a century before such discipline was established in other subjects.

After Darwin.—The Period of Biological Anatomy.—The demonstration by Charles Darwin in 1859 of the origin of species from pre-existing species implies the unity of all life that has ever been on the earth—all came from the life that first existed. Each organism is just one manifestation of that life and all organisms are related. The form, structure, development and reactions of bodies other than ours could be experimentally studied with results of significance for our own.

This was the greatest generalization in the history of biology. It led to a radical revolution in biological sciences. It had been foreshadowed by Aristotle's ladder of life and by Harvey's *omne vivum ex ovo*. The comparative anatomists and paleontologists had gathered facts which indicated it, but it required the great synthetic mind of Darwin to see that living beings are hereditarily related. The conception and the demonstration were based on anatomical facts. The implication of the unity of all life was slowly appreciated and more slowly accepted. Even Darwin is said not to have used the word "evolution." But it was inescapable and before the end of the 19th century evolution had been generally accepted. This united human anatomy with animal anatomy and plant anatomy. All biological sciences entered an immeasurably wider field of research grounded in anatomy; human anatomy had a new orientation. Investigative work was no longer limited to dead human bodies. Most of it was not conducted on human material but on other animals with whom we share a common life. Even relatively simple organisms have told us much about ourselves. For example the study of chromosomes in fruit flies and J. G. Mendel's experiments on the hybrids of peas yielded results of great significance in heredity. Lower mammals became a field of study of most of man's life processes both in health and in disease.

Though research in anatomy of form, structure, growth and evolution was turning into the wider and more fertile fields of animal anatomy, where material is abundant and experiment on the living practicable, work in gross human anatomy continued in the medical schools and in laboratories of zoology, anthropology, biometry and other associated sciences.

In the medical schools, dissection is required. For centuries such dissection was dangerous; now it can be conducted in cleanliness and safety. Louis Pasteur's demonstration of the causes of infection and Joseph Lister's antiseptic campaign (begun in 1869) were followed by the injection of antiseptics, usually carbolic acid or formalin solutions: into the blood vessels of cadavers so that they became and long remained innocuous. Study by dissection was correlated with that of microscopic anatomy necessarily (but unfortunately) prosecuted in other laboratories, and correlated in study rooms with that of special preparations. Formalin hardening combined with freezing and cross sections preserved the form and relations of parts undisturbed by dissection. The relations of the brain and all other internal organs to one another and to the surface were seen as they appear in cadavers. But all this left the real objective unattained. The study of gross anatomy never was directed simply to mapping the topography of cadavers; that was only a step toward knowledge of the living. In the 20th century the main line of advance was emphasis on the study of the living rather than of cadavers. The latter continues, necessarily, with fossil discoveries, microscopic preparations, etc., but in the study of the living, action is added to structure. The time element is introduced; fluoroscopy permits observation of internal organs and motion pictures record what is seen; radiograms show changes in normal life and in disease.

The allotment of time to gross anatomy in the four-year medical curriculum was steadily (and rightly) reduced during the 20th century. Other essential sciences have been greatly and rapidly

developed. This precipitated a problem in the medical teaching of anatomy. Attempts to solve it have been mainly along two lines: first, emphasis in the required courses on what appears now to be clinically essential; and second, correlation with other parts of the curriculum. The textbooks have become ponderous reference tomes. A. B. Howell, J. C. B. Grant, D. Mainland and others published shorter ones for medical students.

While the curriculum of the medical schools must continue to put dissection of human bodies in a basic and important place, it constitutes, nevertheless, only a minor fraction of the work of anatomy. Structure, form and their response in living beings to the influences of environment are its real work. Those influences are demonstrated mainly by the physical sciences, which were developed so much by the middle of the 20th century that we seem only beginning to understand the nature of life and the relation of living beings to our universe.

All biology has a new outlook. Research in gross human anatomy seems almost completed. All the facts discovered from Hippocrates to D. J. Cunningham are in the reference textbooks. The idea that we know it all now or are on the road to complete understanding has been common but perilous in all ages of science, but work in anatomy has turned into new channels. Old methods and the old simple equipment are no longer adequate. To the dissecting rooms and lecture hall of the old period have been added many university laboratories where anatomy is studied on all kinds of animals and by many techniques. The larger university departments or institutes of anatomy provide space and equipment for investigation in many fields: microscopic anatomy (the new electron microscope); cytology (centrifuges, apparatus for sudden fixation in liquid air and for irradiation of tissues and even of individual constituents of cells); tissue culture; embryology (safes for storing precious human material and provision for experiments with hormones and other chemicals); fluoroscopy; neurology. Animal rooms provide for the maintenance of many kinds of animals, both terrestrial and aquatic, and operating rooms contain equipment for asepsis. Work in all these fields throws light on form and structure or on the processes of heredity and growth.

NOMENCLATURE

The study of anatomy has been carried on chiefly among Indo-European-speaking peoples, who are believed to have had a common ancestral language. Before writing was introduced, however, the race had separated into many branches. From the written records of these peoples, philologists have reconstructed what they believe were the words of that old, unwritten vanished speech.

The *Dictionary of Selected Synonyms in the Principal Indo-European Languages* by Carl D. Buck (1949) lists many such words. A few, selected because of their association with anatomy, are: blood-*esen* (Eng. sanguinous); bone-*ost* (osteo); eye-*ok* (ocular); brow-*bhru*; ear-*aus* (auditory); nose-*nas*; mouth-*os* (oral); tongue-*dnghwa*; tooth-*dont* (dental); throat-*gel* (gullet); chin (and knee)-*genu* (genuflexion); shoulder-*omesos* (humerus, bone of the shoulder); arm-*armos*; elbow-*el*; finger-*deig* (digit); heart-*kerd* (cardiac); foot-*ped*; nail (finger or toe)-*onogh* (onychia). Such words constitute the beginning of anatomical nomenclature.

When physicians and surgeons appeared they were especially interested in anatomical names. The Greek physicians of the Coan (Hippocratic) school, 500–400 B.C., have given us a few names still in use: raphe, symphysis, arthron, diarthrosis, synarthrosis, brachium, olecranon, cubiton. Aristotle introduced the names colon and aorta (for the artery); Hippocrates used it for the trachea). The Alexandrian school, 300–250 B.C., gave us duodenum, choroid (plexus), calamus scriptorius. The Greeks adopted from their Cretan (Minoan) predecessors the shield idea in the name of the thyroid gland.

After 250 B.C. wars and politics greatly hampered the further development of anatomy in Greece and Egypt. After Rome had emerged as the dominant power, about A.D. 30, Aulus Cornelius Celsus compiled an encyclopaedic work. The anatomical section gathers up the results of the sporadic work of the three preceding

centuries and presents it in beautiful literary Latin. From it have come our names abdomen, anus, cartilage, humerus, occiput, patella, radius, scrotum, tibia, uterus, vertebra and others.

The best Roman anatomist was the emperor's physician, Galen (see above). However, his nomenclature was unsystematic, indefinite and confused. Various phrases refer to single anatomic structures, and he used numbers instead of names to identify many of them. Despite his frequent carelessness, he passed on to us many of the names we use, among them anastomosis, carotid, epididymis, glottis, hyaloid, meconium, pancreas, peritoneum, psoas, ureter and zygoma. They are mostly of Greek origin.

Galen's contemporary, Julius Pollux (AD 139-192), wrote an *Onomasticon* (vocabulary) with definitions, explanations and quotations. To him we owe amnion, anthelix, antitragus, atlas (for the first vertebra), axis, canthus, clitoris, cricoid, epistropheus, gastrocnemius, tragus and trochanter.

After Galen there followed more than a millennium during which the old knowledge was maintained only in translations into Arabic and Hebrew. The Greek originals that were not lost were not re-discovered and reprinted until Renaissance times. During these dark ages, anatomic (and medical) names were Arab words except as Jewish translators used Hebrew names. Vesalius in his first publication (*Tabulae anatomicae* sex, 1538) used some Arabic and Hebrew names and many Hebrew characters. A few Arab words still appear in the nomenclature: nucha, basilic, cephalic, saphena (Arabic, "concealed"), dura and pia mater (translations from Arabic). Vesalius gave us the names atlas, alveolus, choana, mitral valve; Sylvius of Paris, corpus callosum and many names of muscles and blood vessels. From the strange and pathetic mind of Theophrastus Paracelsus comes the term synovia.

The introduction of printing did much to spread the use of anatomical names, but there was no uniformity in nomenclature. The enthusiastic activity in anatomical laboratories resulted in great increase in knowledge and still greater multiplication of names. Thousands were added, for each writer followed his own nomenclatorial fancy, usually expressing it in a Latin form. Some words were borrowed from botany—amygdala arbor vitae. Some came from animals—tragus, hircus, hippocampus. Many words were used with a significance very different from the original one: *musculus* (originally "a little mouse"); *arteria* ("air holder"); *nervus* ("a bonstring"); *sacrum* ("sacred" or "big"); *glandula* ("a little acorn").

Association of muscles and mice suggests a probable origin of the name muscle. Some Stone Age hunter skinning an animal was startled when, in response to an accidental stimulus, he saw a contraction have run along one of the long muscles. "Ah, a little mouse." Later another called it a little lizard. The little lizard which flashes along the sunny walls in Italy was called *lacertus*, which is an alternate name for muscle and is still used for part of the biceps. Sacrum is stated to be the neuter of sacer, the bone having been considered sacred. It probably meant big. The Greeks sometimes called big things "sacred"—"sacred Troy," "sacred bridge." It has been suggested that it may have been the resurrection bone, Luz, of rabbinical literature.

In the long list of names that have been used, mythology, religion, ribaldry and humour all played parts. Among the mythological are cornu ammonis (in the brain), tendo Achillis, iris, hymen, mons veneris. Among the religious are morsus diaboli (in the uterine tube), pomum Adami, musculus religiosus (inferior rectus of the eye), lyra Davidis and psalterium (in the brain). Among the ribald were musculus ani sculptor (latissimus dorsi) and many names for parts of the brain, mammae, nates etc., introduced, says one Italian anatomist, to make neurology more interesting to the young. Among the humorous were musculus amatorius—the lateral rectus of the eye which makes the side-long "come hither" glance; m. osculatorius—the orbicularis oris; m. humilis—the inferior rectus of the eye which makes the cast-down eye of the humble; m. attentionis—the superior auricular, much used by horses; m. dormilator—the orbicularis oculi which helps to shut the eyes.

Origin of Curious Names.—Bones—Astragalus and talus (originally taxillus) were bones used by Roman soldiers for dice—

"rolling the bones." Originally astragalus was a vertebra, talus was a horse's anklebone. Astragalus, because of its bad company, was degraded from the vertebral column to the ankle. Coccyx—cuckoo—was said to be so called because it is shaped like a cuckoo's bill. The coronoid processes were said to be so called because they are shaped like a crow's beak (korone, "a crow"). But *korone* was also a hook at the end of a bow to engage the bowstring which these processes resemble.

Muscles.—*M. nauticus* was one name for the tibialis posterior—it helped the sailor's foot in climbing the mast. *M. cucullaris* was the trapezius because the two trapezius muscles together are shaped like a monk's hood. *M. sartorius* is so called because it helps the tailor take the cross-legged position he assumes when sitting on the tailor's bench.

Viscera—The origin of the word "stomach" is obvious if we leave off the final "ch." *Stoma* means "mouth." The stomach is part of the head gut and is innervated by the vagus. The old Greek name for intestine or gut was chorde. From the guts of animals the early Greeks made bowstrings, and just as we call some sutures "gut" they called these strings "gut" (*chorde*). Hence come the names spinal cord, notochord, spermatic cord, etc. The name ileum for intestine means twisted or folded.

The Bible talks of "bowels of mercies" (Col. iii, 12). Our emotions are expressed largely by our facial muscles; every one of them is a gut muscle derived from the first or second visceral arch and innervated by a gut nerve. The anatomical association is direct; the psychological association between our emotions and our viscera is closer perhaps than we realize or would like to admit.

The pancreas (*pan kreas*, "all flesh") is so called because it has so little connective tissue in it.

Vessels.—The word artery is Greek and means "air holder." After death the blood went to the veins, and the arteries when opened held air, hence the name. The big air holder (windpipe) was *arteria tracheia*—"the rough air holder." It is now called simply trachea. We have omitted "arteria" from the name of the only one that carries air and kept it for all those that do not. The "stupid" artery (carotid, from *karos*, "stupor") was so called by Galen because compressing it against the carotid tubercle of the sixth cervical vertebra caused stupor. Vesalius called that artery *somnifera*. The translation of *venae cavae* ("empty veins") is a mistake. The names are themselves a translation from Galen. Galen's name, *kozlos*, meant "empty," but it also meant "cavity." The upper *koilos* was the thorax, the lower the abdomen. The superior vena cava is the upper cavity vein, the inferior the lower cavity vein.

Basilic and cephalic veins got their names from the Arabs. The Arab words *al-basilik* and *al-kifal* indicated medial and lateral veins. But when put in Latin form by the monk Gerard of Cremona, basilic was supposed to mean kingly or governing. The doctors of the middle ages said the left basilic vein governed the functions of the spleen and the right those of the liver, and the cephalic those of the head; they bled their patients accordingly from the proper side. The therapy was founded on a philological error, but was in any case futile. The word "anastomosis"—*ana stoma*, "mouth by mouth"—was sometimes thought to mean "kissing," but it did not. Erasistratus used it for bleeding—mouth forming—a hole in a blood vessel.

Nerves.—*Nervus* is the Latin form of the Greek neuron. Originally *neuron* meant "bonstring," and the name was given by Hippocrates and others indiscriminately to all strings—to nerves, tendons, ligaments and even to ducts (parotid). It is still used in the original sense in a hymn, "Awake my soul! stretch every nerve and press with vigour on." The phrenic nerve was so named because it passed the heart, long regarded as the seat of the mind.

Use of the Vernacular.—Anatomical names are usually Latin. The names of diseases are usually Greek, for example, pulmo- and pneumonia, musculus and myositis. There is hardly an exception. It is amazing for how long a time Latin continued to be in all European countries the language of medical science. Harvey, Thomas Willis and Thomas Sydenham wrote in Latin. But in 1770 William Hunter published his atlas with a text in two parallel columns, one in Latin and one in English. About 1800 Latin began

to yield to the vernacular on the continent, though it persisted in some medical lectures in Vienna until 1859.

Standardization of Anatomical Nomenclature.—By the end of the 19th century the confusion caused by the enormous number of names had become intolerable. Medical dictionaries sometimes listed as many as 20 synonyms for one name. More than 50,000 names were in use somewhere in the world and they differed in the various countries and schools. This placed a discouraging burden on students and hampered publication and diffusion of the results of investigation, not only in anatomy but in all medical sciences.

In 1887 the Deutsche Anatomische Gesellschaft undertook the task of standardization. A commission was appointed in 1889 and worked untiringly for six years. The co-operation of anatomists in other countries was sought. The Anatomical Society of Great Britain in 1893 appointed a special commission to adapt the proposed nomenclature to English needs. In 1890 a society of United States anatomists studied the question and submitted a list.

There was much divergence of opinion as to the inclusion of personal names. Against their use, it was urged that they often imply historical injustice. Thus the aqueduct of Sylvius was described long before either of the two Sylviuses lived; the circle of Willis was described by Casserius and dissected for Thomas Willis by Edmund King. It was decided to retain only those so firmly established in the language (and affection) of anatomists that they could not be left out—146 names of 103 men.

The attempt to include histological and comparative anatomical names was abandoned but some embryological names were given. There was much discussion of the "anatomical position." It was necessary to postulate a basic position for terms such as anterior and posterior, superior and inferior, etc. It was decided that this position should imagine the body standing erect, arms at the sides, palms forward. In the forearm and hand the terms volar and dorsal were used instead of anterior and posterior; in the foot, plantar and dorsal instead of superior and inferior.

The completed list was approved at the Basel meeting of the Gesellschaft in 1893 and published as the *Basle Nomina Anatomica* (B.N.A.). It reduced the 50,000 terms to 5,528, being the best of the terms already in use. It was immediately adopted in German-speaking countries, in Great Britain, Ireland, the U.S. and Japan. After World War I there was some tendency to regard it as a German nomenclature and to substitute nationalistic names. But the Deutsche Anatomische Gesellschaft was *anatomische* rather than *Deutsche*. Its membership in 1895 comprised 145 German and 129 non-German members from ten other nations.

But after 40 years, revision was needed on strictly scientific grounds. Parts of the science had grown and even metamorphosed. Neurology had developed so greatly that the B.N.A. nomenclature was inadequate and had many implied inaccuracies. In 1933 the Anatomical Society of Great Britain and Ireland made a British Revision (B.R.). In 1936 the International Anatomical congress meeting in Milan created an International Anatomical Nomenclature committee, which was to have reported at a meeting in London in 1939. The American Association of Anatomists appointed a committee to co-operate with the International commission. It sent to the International commission a 57-page report which was never published, apparently lost during the war. In 1936–37 the parent Gesellschaft adopted another nomenclature at its meeting in Jena, the *Jena Nomina Anatomica* (I.N.A.).

Because of wars, anatomists were unable to convene after 1936 for consideration of a report by the International Anatomical Nomenclature committee, looking toward a world-wide unity of names and co-operation in study and investigation.

In 1950 during the Fifth International Anatomical congress held at Oxford, the International Anatomical Nomenclature committee was appointed. This committee was composed of representatives from a large number of countries and adopted the following seven rules as principles upon which an international anatomical nomenclature should be based:

1. That, with a very limited number of exceptions, each structure shall be designated by one term only.
2. That every term in the official list shall be in Latin, each country

to be at liberty to translate the official Latin terms into its own vernacular for teaching purposes.

3. That each term shall be, so far as possible, short and simple.
4. That the terms shall be primarily memory signs, but shall preferably have some informative or descriptive value.
5. That structures closely related topographically shall, as far as possible, have similar names—*e.g.*, Arteria femoralis, Vena femoralis, Nervus femoralis, etc., etc.
6. That differentiating adjectives shall be, in general, arranged as opposites—*e.g.*, major and minor, superficialis and profundus, etc., etc.
7. That eponyms shall not be used in the official nomenclature of gross or macroscopic anatomy.

In 1955 this committee submitted to the Sixth International Anatomical congress at Paris a revision of the B.N.A. which included many terms of the B.R. as well as of the I.N.A. This revision received approval by the congress and is now known as the *Nomina Anatomica Parisiensis*, or N.A.P.

USE OF X-RAYS IN ANATOMY

Although X-rays are widely used in clinical medicine, in anatomy dissection of the cadaver is, and presumably will continue to be, the basic approach. Fluoroscopy and radiography serve as secondary but valuable tools.

X-ray pictures or radiographs may be made of material from cadavers. Such radiographs supply information not easily obtained by other means. It is in the study of the anatomy of living subjects, however, that the X-rays are most useful.

When large, thick sections of the frozen cadaver are subjected to prolonged dehydration at low temperatures, individual muscle bundles become slightly separated from one another by layers of air so that they stand out in sharp contrast in radiographs. Radiographs of longitudinal sections of the long bones illustrate structural details not easily demonstrated by other means, and radiography is the method of choice for studying the development of bone in specimens too large to be made transparent.

One of the best means of demonstrating the size and distribution of the bursae about a joint such as the knee is to radiograph the joint after inflating the bursae with air. The study of stereoscopic radiographs of the vascular system (following the injection of a mixture of gelatin, glycerin and lead salts) is a helpful preliminary to the dissection of the part. By special techniques even the lymphatic vessels of the cadaver may be filled with a material such as mercury that casts a shadow when X-rayed, and then be demonstrated by radiographs.

One of the most important roles of X-rays in anatomy is the demonstration in the living subject of the variable size, shape and location of the organs. Even in the freshly dead body these features of the organs are altered, and by the time the cadaver has been made ready for dissection the deviation from the conditions existing during life may be very great.

Equally important is the use of X-rays in the study of function. In the past, functional anatomy was based largely on the study of structural relationships in the cadaver and examination of the surface of the living body; but as more and more of the functions of the body are submitted to direct study on the fluoroscopic screen or in X-ray motion pictures, more and more of the old deductions are found to be incomplete. The relative roles of the thoracic wall and of the diaphragm in breathing, the mechanism of swallowing and the change in the size and shape of the heart during the cardiac cycle are typical problems in which radiology provides the most direct avenue of approach. X-rays may also be used to advantage in analyzing the relationship of muscle function to changes in the joints in such structures as the shoulder and the spine.

X-rays serve also to increase the volume and selection of material available for study by the anatomist. Under the best of conditions, the available cadavers are scarce and constitute a distorted sample of the population with elderly, chronically ill males predominating. By the use of radiological procedures, however, certain anatomical studies may be made of healthy bodies throughout the entire prenatal and postnatal life span in both sexes.

Typical of the anatomical problems that have already yielded to the X-ray approach are: the cataloguing of abnormalities, individual variations, functional and age changes of the skeleton, organs and blood vessels; an understanding of the relationship of body build and changing posture to the position of the organs; and a clarification of the sexual differences in the pelvic bones and obstetrical significance of variation and size of the female pelvis.

ANATOMY, MICROSCOPIC. This division of the science of anatomy embraces all of the knowledge that can be gained only through the use of lens systems of some sort. Microscopic anatomy is usually considered as lying within the domain of biology; it involves the analysis and resynthesis of information concerning the finer structure of the organs and parts of living organisms. It might be possible to broaden the concept of microscopic anatomy by including also the intimate structure of organized inanimate matter. Indeed, the sciences of petrology and metallurgy have long used the microscope as a tool for obtaining data on the composition and arrangement of rocks and metals. But such types of endeavour are better assigned to the more general category of microscopy (*q.v.*). Certainly the examination of dust, single-celled animals, spores, pollen grains and the like clearly belongs in the province of microscopy, and this activity just as plainly lies outside the field of microscopic anatomy, which predicates a grosser sort of organization that permits the recognition of component systems. Actually the term microscopic anatomy has been used in two senses: probably the commoner usage is inclusive, embracing the subsiences of cytology (cell structure), histology (tissue structure) and organology (organ composition); but microscopic anatomy also has been used as a synonym for organology. In the latter usage the microscope is thought of as being employed to dissect the organs visually into component parts, somewhat as the scalpel and forceps reveal the grosser components of total organisms. The cytology of the animal and plant kingdoms is fundamentally the same; their histology and organology are parallel but unlike, and plant microstructure is much the simpler in both of these categories. When the term microscopic anatomy is employed, the connotation is always in contradistinction to gross anatomy and, usually, with regard to higher animals in general and mammals and man in particular. The development of form and structure is embryology; like anatomy of the adult, it is a category under the more inclusive science of morphology. A particular phase of microscopic anatomy is obviously contained in the development of tissues, organs and organ systems, but embryology is usually considered a coordinate discipline rather than an integral part of microscopic anatomy.

The Rise of Microscopy.—The discovery of the image-enhancing power of the simple lens is lost in antiquity. It seems reasonable that this property of water droplets and clear crystals of lenticular form must have been noted by primitive man. Seneca (4 B.C.—A.D. 65) was perhaps the first to record clearly the effect of a simple lens: "Letters though small and dim seem larger and more distinct through a glass-globe filled with water." But the use of such an optical aid in studying animalculae or other marvels of nature was never mentioned in any ancient writing. Not until the middle of the 17th century was the value of the simple microscope in discovering minute, previously unknown features coming to be understood and its application to the systematic pursuit of knowledge envisioned. Three pioneer microscopists, working in the last half of the 17th century with simple lenses, produced results that still stand as models of accurate, objective observation.

Foremost, in the sum of his contributions to anatomy and physiology, was Marcello Malpighi (*q.v.*). Among his achievements were the demonstration of the structure of the lungs (with the presence of air cells separated from the blood by a thin membrane) and the flow of blood through their capillaries, the germinative (Malpighian) layer of the epidermis, the renal (Malpighian) corpuscles, the splenic (Malpighian) nodules and the nature of the lingual papillae. Jan Swammerdam (*q.v.*) burned himself out in an intemperance of intense work and was the most critical and detailed observer of the three. His work dealt largely with minute anatomy in relation to the life history of insects; yet he was the first to observe and describe the blood corpuscles. Anton van Leeuwenhoek (*q.v.*) was a general microscopist who ground simple lenses capable of magnifying at least 270 diameters. Among his diverse microscopical observations was the important first demonstration of the capillary connection between arterioles and venules; he thus completed by ocular proof what William Harvey had left undone in his theory of the circulation of the blood, and he also extended the observations of Swammerdam on the red blood corpuscles to all vertebrate groups except reptiles. Among his other discoveries pertaining to anatomy were the cross striping of skeletal muscle, the branched character of cardiac muscle, the structure of the crystalline lens, the occurrence and action of cilia and the appearance of mammalian spermatozoa.

The compound microscope was invented about the end of the 16th century, but for a long time it was inferior to some of the simple instruments such as those used by Leeuwenhoek. A better compound microscope depended on improving the objective lens system, and two centuries passed before any notable advance was achieved. But from 1830 onward, one improvement followed another until, in 1886, the production of the apochromatic objective and compensating eyepiece brought the compound microscope to its highest peak of perfection (see **MICROSCOPE**). In general, the most exacting observation has been directed to the interpretation of cell structure.

The Discovery of Protoplasm.—The concept of protoplasm as the jellylike living substance that represents the physical basis of life was fundamental to any rational advances in the understanding of cells and tissues. Although protoplasm had been observed previously in the amoeba animalcule and in a few favourable plant cells, Félix Dujardin (*q.v.*) in 1835 was the earliest to study and describe this primitive slime of animal cells, which he named "sarcode," and to distinguish it from other viscid substances such as albumen. Several years later Hugo von Mohl (*q.v.*) distinguished the firmer, jellylike content of plant cells from the more internally located, watery cell sap and brought the word protoplasm, already suggested by Johannes Purkinje (1787–1869), into general use. Several workers began to realize that the sarcode of the zoologists and the protoplasm of the botanists were one and the same substance, but it was left to Max Johann Schultze (1825–74) to establish the identity of protoplasm in lower forms and higher forms, and in animals and plants alike, on an unassailable basis. Thus the two decades between 1840 and 1860 were extremely important for the future of biology, because an appreciation of the nature of protoplasm, both as to structure and function, is the foundation stone of biological understanding.

During this period the true import of such concepts was brought to a proper focus. Protoplasm can be defined as the essential substance of living organisms in which all the vital phenomena are manifested; as such, it represents the seat of chemical changes both constructive and destructive in nature. Physically this colloidal complex is colourless, translucent, viscous, ductile, hydrous, semifluid and jellylike.

Discovery of the Cell as a Biological Unit.—Yet another concept had to be established before the structural analysis of living organisms could be pursued intelligently and interpreted correctly. This was the concept of unit masses of protoplasm and the recognition of their role as the fundamental building stones out of which all tissues and organs are constructed. This idea of the cell, based on actual observations, had been vaguely foreshadowed for nearly two centuries before it became solidly established as a basic truth for both animals and plants. Various early

observers saw and sketched cells without understanding their real significance. Even 2,000 years earlier, Aristotle had reached the theoretical conclusion, as the result of pure reasoning, "that animals and plants, complex as they may appear, are yet composed of comparatively few elementary parts, frequently repeated." In the 17th century Robert Hooke examined thin shavings of dead cork tissue, which he described as being composed of "little boxes or cells . . . in the manner of a honeycomb, but not so regular." His drawings are the earliest to depict cells, though it is more accurate to say that what he saw and emphasized were the prominent cellulose cell walls; indeed, it was the concept of a walled, empty compartment that suggested the term cell as an appropriate designation. Within a few years, several contemporaries published drawings showing the cellular construction of plants so plainly that it might seem that the foundation of the cell theory was then established, but actually these illustrations were little more than accurate records of plant fabric as seen. Malpighi came closest to the truth by understanding that the boxes he drew were separable "utricles," united to produce plant tissue, but he failed to generalize that these were uniform elements in the organized structure of living things. One century later C. F. Wolff (1733-94), as the result of his important studies in development and in support of his epoch-making opposition to the theory of preformation, concluded that every organ is composed at first of unorganized, viscous fluid in which cavities are developed that become the subsequent cells; and this process, he said, is identical in the early developing organs of an animal or a plant. Although he fell into the error of believing in a primitive semifluid mass which lacked organization of any kind, he nevertheless must be considered the chief forerunner of the more generally recognized co-founders of the cell theory.

For nearly a century after Wolff, the popular theory was that animals and plants are composed of "globules" and formless material; some of the globules that were described can now be identified with the nucleated cells depicted by later writers. The discovery of the nucleus in plant cells by Robert Brown (1773-1858) was an important preliminary to the enunciation of an ultimately satisfactory cell theory. In 1838 a collaborative conclusion by two friends, though separately presented and supported, produced what has been termed the "master stroke in generalization." M. J. Schleiden (1804-81) was a botanist and Theodor Schwann (*q.v.*) an anatomist; almost accidentally they came to realize the similarity of their independent observations, but the major role was played by Schwann, who formulated a comprehensive cell theory. Previously the prevailing view had been that cells existed as incidental components of plant and animal tissues, but at that time the character of the cell had not been determined clearly, and little importance was attached to it as a unit of organization. By contrast, Schwann maintained that "the elementary parts of all tissues are formed of cells in an analogous, though very diversified, manner; so that it may be asserted that there is one universal principle of development, and that this principle is the formation of cells." The original presentation of the cell theory, nevertheless, was imperfect and contained basic errors of fact. Other investigators showed later that the cell wall about a hollow cavity is not the important feature; that the essential part of the cell is an internal mass of protoplasm containing a nucleus; that the cell is not only the unit of structure but also the unit of function, since all vital activities take place within it; that parental sex cells, after merging, proliferate and lead to the production of a new organism; that the manner of propagation of cells by cell division is quite different from the method originally proposed; and that the nucleus plays a dominant role in hereditary transmissions. The corrected theory is now firmly established as a basic truth of biology, and its concept can better be designated as the cell doctrine. The cell can now be defined properly as a discrete, tiny mass of protoplasm, containing a nucleus and bounded by a limiting membrane; its cytoplasm contains living, self-perpetuating specializations called organoids, which serve as "cell organs," and also nonliving substances either synthesized by the cell or captured by ingestion; its nucleus contains threadlike chromosomes which, in turn, bear the definitely spaced genes that

are concerned with the mechanism of hereditary transmissions.

The Rise of Histology.—When comparative anatomy, under the leadership of Georges Léopold Cuvier, was placing the organs of animals in comprehensive series, a contemporary scientist undertook a still deeper analysis into the kinds of structural materials out of which organs are fabricated. Marie F. X. Bichat (1771-1802) can be called the founder of the science dealing with the minute anatomy of the tissues, which he studied extensively even though, remarkably, he did not employ the microscope. He distinguished 21 kinds of tissues which enter into different combinations in producing the organs of the body; but of far greater importance was the method of inquiry he developed and the systematic treatment he gave to the study of histology in its relations to both physiology and pathology. This influence initiated a scientific epoch by providing the stimulus that set scientists to making new investigations of the minute structure of tissues and organs, investigations that presently placed the sciences of histology and organology on a sound basis.

Most notable as a successor to Bichat in the general field of histology was A. von Kölliker (1817-1905), equally famous in embryology. As a specialist in the field of the nervous system and sense organs, Santiago Ramón y Cajal (1852-1934) stands without peer. The extension of inquiry into all groups of multicellular animals (comparative histology) showed that common structural trends characterize the cells and tissues of all animal groups, and that comparable organs also have much in common architecturally.

Details of the minute anatomy of the cells and tissues can be found under the topics CYTOLOGY and HISTOLOGY, whereas the architecture of organs and organ systems is described under the individual entries for those parts. Similarly, the relations of microscopic structure to development, sex determination and heredity are included in the accounts of VERTEBRATE EMBRYOLOGY, CYTOLOGY and HEREDITY. There remains, for a general account such as this, a review of the approaches, old and new, by which profitable information can be gained.

Microscopes and Techniques Used.—The ordinary bright-field microscope produces useful magnification to about 1,200 diameters and resolves point detail to 0.0002 mm. Phase contrast is a system by which objects, ordinarily transparent, become visible through the enhancement of contrast differences. Polarization refers to the use of Nicol prisms which detect double refraction in objects and demonstrate the orientation of particles too small to be seen. Fluorescence may occur under ultraviolet radiation, and objects then emit visible light of different colours and qualities. The dark-field microscope employs strong, oblique illumination; the only light that enters the objective comes by reflection, and the presence of particles far too small to be seen directly by bright light can be demonstrated. Invisible radiation is used successfully, images being recorded on suitably sensitized film. Thus ultraviolet rays and quartz lenses yield double the resolution (0.0001 mm.) possible with visible light. The electron microscope has beams of electron rays replacing light, and electromagnetic or electrostatic fields replacing lenses, the final image being visualized on a fluorescent screen and photographed; by these means a usable image of 50,000 diameters or more can be produced and the resolution pushed to 0.000001 mm. Electron microscopy is the favoured technique for revealing details hitherto deemed unapproachable.

The Observation of Living Tissue.—Direct observation can be done on some intact animals, such as the tail of a tadpole. Quartz-rod illumination can be used to transmit cold light into the interior of functioning organs. Glass windows can be inserted into a rabbit's ear and left indefinitely. Micromanipulation (*q.v.*) uses delicate needles to isolate, cut, tear or stretch cells, or capillary tubes to inject or suck the cell contents. Tissue cultures can be grown indefinitely in plasma. Motion pictures made with the microscope, in either slow motion or time lapse, can demonstrate motion otherwise not analyzable. Vital staining occurs when living cells store nontoxic dyes.

The Observation of Dead Tissue.—Fixation is the process of preserving protoplasm with the least amount of alteration, rendering it insoluble and increasing its affinity for future staining.

Chemical solutions are most commonly employed as fixing agents; the least alterations, however, are introduced by the freezing-drying technique, which freezes tissue in isopentane, chilled to -170° C. and dehydrated in a vacuum.

Embedding involves dehydrating and hardening the fixed tissue in alcohol, clearing it in a chemical that is soluble in both alcohol and the embedding medium and encasing the tissue in a solid block of paraffin or nitrocellulose. Sectioning produces thin slices (commonly 0.003–0.010 mm.) of the blocked tissue, which are affixed to a glass slide, whereupon the embedding medium is dissolved. Multiple staining reveals the various cell constituents.

Miscellaneous Techniques.—Teasing and spreading bits of tissue permit them to be examined fresh or after supravital staining. Maceration serves to soften binding material and hence to isolate cells, glandular units and the like. Microincineration of tissue slices leaves ash that retains the finest structural details, and so permits the localization of mineral content. Centrifuging gives information on the relative weights and sturdiness of displaced cell constituents.

Radioautography demonstrates the presence of tracer isotopes segregated in a tissue and also gives information as to their length of stay there; the radioactive elements will affect a photographic emulsion when brought into contact with it, thus recording their exact locations with respect to cells. Microchemical testing by qualitative analytical methods on local areas is possible. A large number of organic compounds, many more inorganic ones and numerous enzymes thereby becoming identified and localized by suitable tests; this field of vigorous current endeavour is consolidating into the new subsience of histochemistry.

ANAXAGORAS (c. 500–c. 428 B.C.), Greek philosopher, was born, probably about 500 B.C., at Clazomenae in Asia Minor. He went to Athens, which was rapidly becoming the headquarters of Greek culture (probably c. 480 B.C.), and it was he who brought philosophy and the spirit of scientific inquiry to Athens from Ionia. He had a great influence upon Pericles, and the poet Euripides derived from him an enthusiasm for science and humanity. He was celebrated for his discovery of the true cause of eclipses and was known generally for the ascetic dignity of his nature and for his superiority to ordinary weaknesses. After 30 years' residence at Athens he was prosecuted on a charge of impiety (for holding the opinion that the sun was an incandescent stone somewhat larger than the Peloponnesus; see below). This prosecution was intended as an indirect political attack on Pericles; and although Pericles managed to save him, Anaxagoras was forced to leave Athens. He retired to Lampsacus, the Milesian colony, where he died about 428 B.C.

Only a few fragments of Anaxagoras' writings have been preserved, and very divergent interpretations of his system have been given. It is unnecessary to describe them all here (see below, *Bibliography*). A careful examination of the existing fragments and of Aristotle's evidence makes it possible to arrive at an interpretation which yields a self-consistent and chronologically appropriate system and one by which Anaxagoras might reasonably have

conceived himself to be solving the problems which in fact confronted him; no interpretation that fails in these respects can be satisfactory.

The Ionian predecessors of Anaxagoras had attempted to explain the physical universe on the assumption of a single ultimate stuff. Parmenides (*q.v.*) had shown that on this assumption it was impossible to explain the phenomena of movement and change. As a way out of the impasse, an obvious possible alternative assumption (which was in fact made by Empedocles and by Anaxagoras) is that of a plurality of ultimate stuffs. Empedocles posited four, Anaxagoras an infinite number. Anaxagoras says that at the beginning "all things were together" (fragment 1), that "all things are together now" (fr. 6) and that "there is a portion or 'share' of every thing in every thing" (fr. 6, fr. 12). What are these "things"? Earlier thinkers had selected their basic stuff or stuffs more or less directly from the traditional repertory—the cold stuff, the hot stuff, the solid, the fluid, the dark, etc. Anaxagoras, perhaps because he felt that these substances were not sufficiently relevant biologically, introduced for the first time in addition to them an entirely new set of ultimate stuffs; viz., those which are found in living bodies, substances such as flesh, bone, bark, leaf. (Aristotle when listing these substances applies to them his own generic term for them, "the uniform substances"; from this purely Aristotelian term some serious misunderstandings of Anaxagoras have arisen.) These substances, Anaxagoras held, as well as the hot stuff, the fluid stuff, etc., were ultimate, elementary; for, he asked, how can flesh come from what is not flesh? (fr. 10).

With these sets of elements Anaxagoras had a complete equipment for describing existing objects and for explaining change, especially biological change; and the latter problem accounts for the most striking feature in his system. The changes that we observe are manifold, varied and remarkable: we take food and drink, and our flesh, bone and hair grow. To meet the extraordinary range and multiplicity of change, Anaxagoras said that "there is a portion of every thing, *i.e.*, of every elementary stuff, in every thing"; but "each is and was most manifestly those things of which there is most in it" (fr. 12). For instance, in a pint of milk there is a portion of every thing: but it appears to us to be fluid and white and milk, because there is in it a larger portion of the fluid, of the white and of milk than of any other things, although there is a portion of each of them in it too, including flesh, hair and bone; and a pint of milk will differ from a lump of wood, because in the latter, although "all things" are present, wood, the hard and the dark will predominate. These elementary stuffs, then, are inseparable from each other; and their inseparability carries with it the further principle of infinite divisibility, as Anaxagoras himself points out (fr. 6), "because there cannot be a smallest, therefore all things are together." It is their ability to undergo unlimited division that enables them always to remain associated together. Thus there is an identical set of ingredients ("portions") in every lump of matter, though in one lump portions *a*, *b* and *c* will be the largest, in another lump portions *f*, *g* and *h*.

Hence there is in Anaxagoras no notion whatever of "atoms," indivisible particles of a fixed size and shape but possessing no other sensible characteristics. Anaxagoras carried to its utmost possible limit the old Ionian view, which assumed that the ultimate nature of physical reality consists in characteristics such as our senses perceive. The Ionian viewpoint was accepted by Aristotle; the other view, that sensible characteristics are not ultimate but are derived from shape, size, number and arrangement, originated with the Pythagoreans and was adopted in differing ways by the atomists and by Plato (in the *Timaeus*). But although there were no atoms in Anaxagoras' scheme, at the beginning the portions of all things were so minute that none of their characteristics would have been discernible, or only a few. The general appearance of the mixture was that of "air" and "aether" (fire), because the chief components of these were preponderant then, as they are now. (Note that for Anaxagoras earth, air, fire and water—and also minerals and metals—were not elements but conglomerations of portions of all the true elements.)

The stages in the formation of the cosmos were, broadly, two, and both mere brought about by *nous* ("mind" or "reason"). At

the first stage, *nous* caused the mixture to begin revolving (a process which is still extending), one result of which was that "like came to like" (the dark came together, the light came together, etc.), producing the large expanses of air, water, etc., which we see. Yet even so there was no complete separation; all things were still "together." The heavenly bodies were some of the stones which the eddy had carried to the circumference, where they became ignited as the aether swept them round. In the second stage, also controlled by *nous*, which is "in" living things especially: the process of "like to like" began to affect also the biological elements (flesh, etc.), and portions of these large enough to be significant were formed. This stage was effected not by a process of revolution but by means of the seeds of animals and plants, which had already existed in the original mixture. It is the power of *nous* in living organisms which enables them to extract from their foods those substances which their growth requires (though never so as to remove the whole of any one substance).

Anaxagoras uses physical language to describe his *nous*: it is the "thinnest" of all things, but it is not an ingredient of the mixture: it controls the mixture and determines what changes shall occur. It is incorrect to say that Anaxagoras uses *nous* as a *deus ex machina*; he states explicitly that it "knows" all things and has power over all things, and he clearly conceives it as controlling everything now.

The essence of the objection voiced by Socrates in the *Phaedo* (98 b) and repeated by Aristotle (*Metaphysics*, A 985 a) is that Anaxagoras did not show that *nous* acted and acts for the best; but Anaxagoras may have assumed that this was obvious. Aristotle commends Anaxagoras for his introduction of *nous* as the source of order in the universe: he was like a sober speaker coming after idle babblers (*Met.*, A 984 b, where Aristotle's words hint that this cosmic function of *nous* was suggested to Anaxagoras by its role in living organisms). It was for his introduction of *nous* that Anaxagoras was best known in succeeding ages.

ANAXARETE, in Greek legend, was a beautiful young girl of Cyprus, loved by Iphis, who came incessantly to her home. But she, "like a rock," spurned him, so that he hanged himself at her door. Under her window passed his funeral procession, which she could not avoid seeing, and in seeing it she turned to stone. The story was told of a statue that stood in Salamis of Cyprus, inscribed "The Venus who looks from the window." in Ovid's *Metamorphoses*. (T. V. B.)

ANAXIMANDER (fl. 6th century B.C.), Milesian natural philosopher, the first known to have developed anything like a cosmological system, was born, according to Apollodorus, in 610 B.C. and was alive in 546. He was an associate of Thales, and his interests were wide. Attributions of particular discoveries to early philosophers are usually dubious, but it seems certain that Anaximander left written treatises, which survived until late antiquity, covering geography, astronomy and cosmogony, and that he made a map of the known world.

Anaximander derived the world from a nonperceptible substance called the unlimited, a unity behind the multiplicity of phenomena,

trying, it would seem, to describe a primitive condition before things were differentiated by the contrary characteristics (hot and cold, wet and dry, etc.) on which perceptibility depends. The only surviving sentence of his writings characterizes the emergence of individual substances such as water or fire in terms of human society as an "injustice" for which time makes them "give reparation," alluding to the fact that, for instance, neither hot nor cold ever prevails permanently, but a balance is kept in the whole (a clear reference to the cycle of the seasons).

The cosmos is generated by a process of "separating-out" of the opposites from the unlimited. As Aristotle saw, this implies that in some sense it contained them all the time and hence was not a genuine unity. Nevertheless it may be said that Anaximander's intention was monistic, to seek a unity behind multiplicity: the objection that; at least potentially, the opposites must always have been present belongs to a more advanced stage of thought. The "eternal motion" which brings about the separation is not itself explained, because, like all thinkers at that date, Anaximander regarded the primal being as animate. It was "the divine," which meant for a Greek everlasting, living (hence self-moving) and conscious. How far he had advanced from popular anthropomorphic ideas and what he retained from his religious heritage thus may be seen.

Cosmogony began when, somewhere in the unlimited, hot and cold began to separate, forming a nucleus in the shape of a sphere of fire enclosing a cold, moist mass with mist between. Thenceforth the process continued through the natural properties of the opposites. The centre dried and hardened into earth. The fiery envelope was parted and the dark mist closed around it forming separate rings of fire for the most part hidden from sight. Sun, moon and stars are really these rings of fire wheeling around the earth, but encased in tubes of mist with only a hole or holes through which the fire streams. The earth (which, by a remarkable advance in thought, remains unsupported at the centre "because of its equal distance from everything") is drum-shaped, its height one-third of its circumference. Relics of sacred numbers appear both here and when the sun's ring is said to be 27 times the earth's diameter away from it and the moon's ring 18. Further details are uncertain, but the process of "separation" still continues: e.g., the sea, a relic of the primal moisture, is contracting and will one day dry up. As the cosmos had a beginning, Anaximander probably intended that it should end by reabsorption into the unlimited, but here the sources are obscure and the question is disputed.

Continuing "separation" accounts for the origin of life, which began in water through the action of heat. The first animals were a sort of sea urchin. Even human infants were produced first in a fishlike creature and protected by it until they could fend for themselves. (This, rather than an evolution of men from fish, seems to be the purport of some rather obscure passages.)

Kranz, *Die Fragmente der Vorsokratiker*, vol. i, 7th ed. (1954). (W. K. C. G.)

ANAXIMENES (fl. 6th century B.C.), of Miletus, Greek natural philosopher, was a younger contemporary of Anaximander (*q.v.*). His writings, which survived into the Hellenistic period, are now lost. For Anaximander's "unlimited" he substituted *aer* (meaning "mist" or "vapour" as well as "air") as the primary substance or matrix of everything. When "most evenly distributed" it is invisible atmospheric air, but by condensation it becomes visible first as mist or cloud, then as water and finally as solid matter such as earth or stones. When further rarefied it turns to fire; hotness and dryness go with rarity, cold and wetness with density.

Anaximenes' cosmology seems to have been more naïve than Anaximander's, but in the fragmentary sources not all details are clear. The earth (we are not told why) was formed first, by "felting" of the air. It is flat and buoyed up by the air beneath it. By thus returning to a material support, Anaximenes retreats from Anaximander's bold conception of an earth floating freely in

space. The heavenly bodies arose from the earth, which gave off moisture that was finally rarefied into fire. However implausible, this account suggests remarkable emancipation from religious pre-conceptions, but it must be remembered that in the mythical cosmogony of Hesiod (*Theogony*, lines 126–127) "Earth first bore starry Heaven." Nearer to mythology also was Anaximenes' picture of the universe as effectively hemispherical, not a complete sphere like Anaximander's. The stars pass round, not under, the earth and disappear because hidden "by its higher parts." There are also earthy bodies in the sky, unseen because lacking fire to give light, which may have been intended to explain eclipses. The sun, being flat "like a leaf," "rides upon" the air like the earth; and so also do the stars. An isolated passage in Aetius seems to say that the stars arc "fixed like nails in the crystalline," but its accuracy is suspect. Some have supposed that Anaximenes distinguished fixed stars from planets. (It is just possible that the words translated "nails" and "crystalline" have another meaning. See A. K. C. Guthrie in *Classical Quarterly*, 1956.) He is reported to have said that the stars give no heat because of their great distance, thus contradicting Anaximander's strange view that they are nearer the earth than is the sun.

To account for the changes of density which produced the world, Anaximenes assumed (as Anaximander did) everlasting motion in the aer. For him too this implied that it possessed life; and that may be a clue to his choice of air as the origin of all things, since the primitive and universal identification of life with air or breath was certainly current among his contemporaries. Being everlastingly alive, aer was divine, and other gods, like everything else, were produced from it, though nothing further is said about these. There is evidence that, like his follower Diogenes of Apollonia, he emphasized the analogy between the divine air that sustains the universe and the air in us, that is, the human soul. This equation naturally played a great part in mystical religion as well as in philosophy, but Anaximenes can hardly be credited with mystical tendencies.

The evidence suggests that he was a practical man, with a taste for vivid imagery and a certain talent for observation. He notes an occasional moon rainbow and describes the phosphorescence from an oar blade breaking the water. His thought is typical of the transition from mythology to science, entirely rational in intent (the rainbow is no longer a goddess but the effect of the sun's rays on compacted air), yet only partly liberated from earlier mythological patterns. His permanent achievement is to have suggested a known natural process (condensation and rarefaction) as operative in the making of a world and to have reduced apparent qualitative differences to differences of quantity. This not only made Milesian monism consistent but had incalculable consequences for the future of scientific thought.

ANAZARBUS, an ancient city in the eastern plain of Cilicia (*q.v.*), on the right bank of the Sumbas Chay, a tributary of the Ceyhan (Pyramus) in southern Turkey. The acropolis crag, which rises to more than 600 ft., dominates the lower walled city to the west of it. Under the Roman empire it was known as Caesarea by Anazarbus and reckoned as having been refounded in 19 B.C. In the 3rd century A.D. it rivaled Tarsus, the provincial capital, and later became the recognized metropolis of Cilicia Secunda. Under the Byzantine empire it was an archbishopric. Devastated by earthquakes in the 6th century, it was rebuilt, first as Justinopolis, later as Justinianopolis. Under Muslim occupation, Anazarbus (as Ayn Zarba) retained its strategic importance and so was refortified by the caliph Harun al-Rashid in 796 and probably also by al-Mutawakkil (847–861). Regained for Byzantium by Nicephorus Phocas about 962 and subsequently devastated during the crusades, it became, as Anavarza, the capital of Cilician Armenia early in the 12th century. Captured by the Egyptians in 1375, it was never again reoccupied.

The castle (Byzantine and Armenian) is the finest medieval

monument in Cilicia. Inside the city are baths, a triumphal arch and two early Byzantine churches. Outside are two aqueducts, another church, the theatre, stadium and amphitheatre.

(M. R. E. G.)

ANBAR, a ruined town in Iraq, lies on the left bank of the Euphrates, downstream from the modern Ramadi and just south of the Sakhlawiye canal. Previously called Massice (Parthian *mshyk*), it was renamed Peroz-Shapur (Pirisabora) by King Shapur I after his victory there over the Roman emperor Gordian III (A.D. 244). Rebuilt after its destruction by the emperor Julian in 363, it became known from at least the 6th century as Anbar ("the Store"). Jews from the academy of Pumbeditha took refuge there from persecution in 588, and it became a Jewish centre. It was the capital of the Abbasid caliphs till the founding of Baghdad (A.D. 762), but thereafter slowly decayed. (M. A. B.)

ANCAEUS, in Greek legend, son of Zeus or Poseidon, king of the Leleges of Samos. In the Argonautic expedition, after the death of Tiphys, helmsman of the "Argo," he took his place. It is said that, while planting a vineyard, he was told by a soothsayer that he would never drink of its wine. As soon as the grapes were ripe, he squeezed the juice into a cup, and raising it to his lips, mocked the seer, who retorted with the words, "there is many a slip between the cup and the lip." At that moment it was announced that a wild boar was ravaging the land. Ancaeus set down the cup, leaving the wine untasted, hurried out and was killed by the boar.

ANCASH, a department in Peru, lying between the Pacific ocean on the southwest and the Rio Marañon on the northeast, with the department of La Libertad on the north east, and that of Lima on the southeast. Area 14,019 sq.mi.; pop. (1958 est.) 644,413. The capital is Huarás. The terrain of Ancash is extremely rugged, for the arid coast is separated from the deep Marañon valley by some of the highest mountains in Peru, the Cordillera Blanca. In the high country northwest of Cerro de Pasco, the Rio Santa has its headwaters. This river, the largest on the Pacific coast of Peru, flows northwest between the Cordillera Blanca and the Cordillera Negra for about 100 mi., descending from nearly 14,000 ft. to about 7,000 ft. The zone in the mid-course of the Rio Santa, where Huarás is located, is the most densely populated part of the department. At this point the Rio Santa plunges into the Cañon del Pato, dropping 1,400 ft. in six miles. There it turns abruptly toward the ocean and empties into the sea a little north of Chimbote. The Rio Santa has been harnessed with a series of hydroelectric plants.

Most of the people of Ancash support themselves by subsistence farming, growing potatoes and barley at the higher altitudes and maize, rice, alfalfa and sugar cane at the lower altitudes. The major economic production of Ancash comes from its mines and industries. The Ancos-Galgada coal field contains the largest reserve of good quality coal in all Latin America. Minerals include silver, lead, gold, copper and tungsten. At Chimbote there is a modern steel plant, supplied with coal from nearby mines and operated with electric power from the Rio Santa development. The Pan-American highway runs along the coast, and a railroad climbs inland to the coal mines. But Huarás is reached only by a difficult mountain trail. Ancash was formed as a department in 1836 and was formerly called Ancachs. (P. E. J.)

ANCESTOR WORSHIP. The worship, tendance and veneration of ancestors are manifestations of various attitudes toward the dead existent in diverse cultures and religions—primitive, middle and higher. The living and the dead are as much related as any other two classes of a given community, for death does not make a person cease to belong to his social unit (family, clan, tribe, village, nation). The dead may be regarded as friendly, as kindred beings with whom kindly relations are possible; they may be for a time displeased and angry with their people, but such displeasure may be dispelled when proper respect, reverence and worship are manifest. The dead, particularly the spirits of deceased strangers, also may be regarded as unfriendly to the living persons of a given community, as malevolent spirits capable of rendering harm to individuals or to the entire community. Attitudes toward the dead may be dominated by a continuation of the

natural affections that preceded death in association with prospective beneficent efforts by the dead and living in behalf of each other; by fear, in light of the extensive powers the dead are thought to possess; or by respect. the ancestors being regarded as the repositories of the traditional wisdom of their people and, in certain societies. as influential elders and rulers of the people.

These attitudes toward the dead are further complicated by the following considerations: (1) All dead, as such, are terrible, because death is contagious, and where one person has died (especially if by violence): more deaths are likely to follow. (2) The dead are not able to provide for themselves and hence should be provided with necessities by the living, either because they are beloved and venerated members of the community or because in the absence of such provisions malevolent consequences might follow. (3) The dead, or those of the dead (such as chiefs, shamans, elders) who have been powerful in life! become even more powerful after death. for they are spirits relieved of bodily limitations and able to help or harm; propitiation of them hence is imperative. This often is reinforced by (1). (4) In some societies, the dead are thought of as capable of returning or of being reborn into the community. (5) Some older dead, if not quite forgotten, tend to become vague, idealized figures, often approaching the status of gods.

Indifference to or neglect of the dead is rare; awe or fear, with or without affection, as for kinsmen or fathers and mothers, is the prevailing attitude. Notions suggested in (2) lead to tendance of the dead (offerings of food, etc.. at their graves, soul feasts: destruction of all or some of the dead man's property to be of use to him in the other world, proper funeral ceremonies) more than to actual worship. Attitudes toward the dead suggested in (1), (3) and (5) may and often do lead to worship of one sort or another, and this should be distinguished from mere tendance. With regard to (4), if it is possible for the dead to be reborn or to re-enter the community. it is imperative for such procedures to be followed as will assure the re-entry of only the "good" dead, the powerful, the wise, the efficient, the observers of community customs. Included in these procedures are proper funeral ceremonies, which vary for chiefs. for shamans, for ordinary custom-observing persons, for criminals, for men killed by wild beasts, for women who die in childbirth, etc. Worship is not necessarily implied by such procedures. but prayers are addressed to those of the dead who are expected to return.

A practice that appears, at first sight: to be like ancestor worship is the worship of what may be called the lifestream. The object of this cult is not any man. living or dead, but the power that enables the community to continue to exist by natural increase—a power that may be embodied for the time being in the head of the family or clan and worshiped by him and his dependents. An example of this is the Roman *genius*, in its earliest form.

Types of Ancestor Worship.—Worship directed toward ancestors, believed to possess such powers as those suggested above, is of several types.

Communal Worship.—The dead may be worshiped by an entire group—family. clan, tribe or nation—of which they mere members while living. Such communal worship was manifest in the Roman cult of the *manes* or the cult of the *parentum*, which involved the tendance of all the dead of a particular line. The dead individual as such was not the object of worship, but the life-force or *genius*. The cultic practice involved the provision of food at the Lemuria or in the form of a communal banquet shared by the spirits of the dead.

Individual Worship.—More prevalent is the worship of individual ancestors. which may be combined in various ways with communal worship. as in the Roman emperor cult, Egyptian worship of ancestral rulers and Japanese worship of members of the imperial household.

Gvades of Ancestors.—Not all ancestors are equally worthy of worship. for some are regarded as being more powerful than others. Ordinary members of a group, when dead, are tended only by their immediate relatives or perhaps not at all or not for very long, while the spirits of great personages become the focus for more elaborate cultic expression by an entire community. In the Greek

hero-cult. for example, prominent personages were singled out as those toward whom cultic expression was directed. Seniority as well as prominence may have brought about the emergence of a dead person to the rank of a worshipful ancestor. The founder of a family, for example, may be worshiped by that family for an indeterminate number of generations. The Aruntas of Australia direct reverence toward their mythical alcheringa, and the Greeks described themselves as "sons or descendants of such a One" (e.g., Iamidae, descended from the legendary seer Iamus, son of Apollo) and worshiped their founder, honouring him above all intervening ancestors. Such a worshiped ancestor in time may fade vaguely away into the mass of the departed, for the number of generations that he can be remembered is not without limits.

Ancestors as Gods.—Some one ancestor may so combine in his image all the worshipful qualities desired in a worthy ancestor, or show such pre-eminence in some one quality, that he is no longer treated as a departed spirit but is given the status of a god. An apparent example is Asclepius, worshiped in many parts of Greece as a god but also spoken of as a hero, with a cultic clan (known as the Asclepiadae, a guild of physicians) committed to revere him (see ASCLEPIUS). The Fijian Ndengei, once representative of an ancestor and tutelary deity, became a symbol of creation and eternity, represented in serpent form.

Assistance Rendered.—Ancestral spirits may be called upon to assist the community of the living in many ways: to assure the continuation of the line, even if by intervening to beget a much desired child (the ancestors naturally would be interested in the continuance of the line that worships or tends them); to avert illness or plague; to assist in the obtaining of good crops (in many cultures ancestors are viewed as living in the ground); to intercede with gods, since they are associated with gods and often are viewed as living in the sky or in the abode of the deities. There is almost nothing that an ancestral spirit may not be called upon to grant or to avert. Generally, the relation of ancestral spirits to gods is that of inferior to superior, but they are commonly viewed as having a larger share of divine favour than the living.

Diffusion of Ancestor Worship.—Ancestor worship, though not so nearly universal as tendance and fear of spirits of the dead, occurs in widely distributed cultures. It is prevalent in primitive societies of Africa, Asia and the Pacific area; existed among the ancient Mediterranean peoples and the people of ancient Europe; and is manifest in Asian cultures, particularly in India, China and Japan.

Modern Primitive Society.—Among modern primitive societies ancestor worship has been observed in Melanesian cultures. where it provides a basis for the system of government. The Fijians direct worship to the ancestors of the chief, and this attitude forms a foundation for authority in a patriarchal society. Ancestors came to be regarded as *Kalou-vu* ("Root Gods"), with a temple and hereditary priesthood devoted to their worship. Among the Bantu peoples of South Africa, each family has its group of *chikwembo* (ancestral spirits) who are worshiped on occasions of family interest (marriage, death, etc.), while cultic prayers and sacrifices are directed to the ancestors of the reigning chief of a given tribe when the welfare of the community is concerned. The reverence the chief received during life is intensified after his death, when his powers are felt to be enhanced; a deceased chief hence becomes a focus of tribal worship until such time as his successor supplants him. In Polynesia, though ancestor worship is less pronounced than it is in Melanesia, attention is paid to *oramatuas* (ancestors) who dwell between the living and the atua or gods; most often they are regarded as malevolent, though beneficence is not beyond their capacity.

Ancient Mediterranean World.—Among the ancient Mediterranean peoples, the Babylonians had a cult of the dead: which involved offerings necessary for their well-being in the life beyond, and ancestor worship, which applied only to families of rulers and chiefs and which included sacrifices, festivals in honour of the dead and the deification of certain ancestors. In Egypt. where the Pharaohs were regarded as representatives on earth of the sky-god Horus and as containing something of deity within them, ancestor worship was not highly developed except in the cases of Pharaohs

(as Seti I and Ramses II) who made offerings to ancestors. Deceased royalty were venerated by Egyptians as symbolic of their loyalty to the ruling dynasty. Other dead were not worshiped as individuals but were thought to join Osiris, the god of the dead, who was worshiped.

Reference has been made above to the hero-cults of ancient Greece, in which it was thought that persons of exceptional merit or ability might be elevated after death to a status of immortality and hence be worthy of worship by members of the state, tribe or clan (*i.e.*, Asclepius). It is likely that heads of households, recent dead who had served their state and heads of colonies received honours and reverence tending toward worship (especially in the 5th and 6th centuries B.C.). A cult of the dead in the early Roman period (before the end of the republic) was associated with the notion that the dead, though not possessing individuality beyond death, joined collectively the manes (the "good gods"). On certain occasions the manes could return to earth, visit the living members of the families to which they had belonged and thus exercise an influence on the living. Offerings and sacrifices were included in the cultic worship of ancestors, especially during the Parentalia (a nine-day February festival including eight days of private worship of ancestors and a ninth day of public celebration) and the Lemuria, a May festival involving three days of family ceremony. Later, during the early centuries of the Christian era, as the *genius* came to be thought of in terms of individuality, the *manes* tended to become a group of individual deities, and the worship of the genius of the emperor (following his death, and even before his death in certain cases) became part of a state cult. (See GENIUS; MAKES.)

Though the cult of the dead was not a part of the religion of Zoroaster and the early Avesta, it survived in popular belief in Iran and was reflected in later Zoroastrianism. The fravashi was regarded as a personification of the soul or *genius* of a person that looked after him during life and would receive him after death. The fravashis came to be regarded as the souls of the dead, and a cult of the fravashis developed. The fravashis were invoked, among other times, during the period of Hamaspathmaedaha, March 10–20, when they descended to the villages, capable of beneficent influence if the duties of the living in their behalf were fulfilled.

Europe.—Various European peoples looked to their ancestors in reverence and worship. Teutonic peoples regarded the spirits of the dead as proper recipients of worship. In Scandinavia deceased rulers and other prominent persons were the focus of cultic worship by families, friends and dependents. In Iceland the dead were thought to proceed to certain hills where sacrificial shrines were located. Banquets in commemoration of the dead were common among ancient Russians; and souls of dead relatives were worshiped in White Russia. Lithuanians worshiped deities of the dead and sacrificed to the dead on the anniversaries of their deaths. It is likely that the Celts and related peoples practised ancestor worship, though certain evidence to substantiate this is lacking.

Asia.—The *sraddha* (funeral) rites in India suggest the importance of ceremonies for the dead in Indian religious practice. These rites are intended to provide the departed spirit or subtle self with an "intermediate" body during that period between death and reincarnation. The *sraddha* rites performed by living relatives nourish, protect and support the spirit of the dead, aiding it in its pilgrimage from lower to higher realms before its reincarnation and reappearance on earth. In some villages in India there are annual rites during which those who have died during the preceding year are honoured, offerings of food are presented for them, and rites are conducted by the village priests.

In the traditional and complex culture and religion of China reverence for and worship of ancestors played a prominent part, apparently from the reign of Shun (perhaps 2255 B.C.) and certainly from the time of Wu Wang (early Chou dynasty, 1122 [or 1027] B.C. *et seq.*). Ancestral authority, so cardinal to the culture, was the dominant characteristic of the continuing relationship between the dead and the living. The family group—the dead, the living and coming generations—was regarded as a unit in which the strength and prestige of any member became the strength and prestige of the

group. The dead, who passed on to a "world of spirits," were not to be forgotten by the living. The dead generally were considered to have three residences: the graveyard; the family ancestral shrine of each household, in association with which the names of the most prominent and recent ancestors were kept on tablets; and clan temples in which resided all the spirits of the wider clan which were not in any family shrine. Ceremonies at death were intended to ease the spirit's entry into the "spirit world," to provide it with comfort and to make known the respect directed toward it by the living. Cultic and ritual commemoration of the ancestors through offerings of food and incense, pilgrimages to burial places and communal worship were intended to maintain the relationship between the living and the dead, to invoke the dead to pursue their duties to the living, to preserve remembrance of and knowledge about the dead, and to provide for the continuing life of the deceased.

In ancient Japan the cult of the dead was largely ambiguous, regard being directed to ancestors in proportion to their prominence during life. Under the influence of Chinese culture (6th century A.D. *et seq.*), Japanese tradition became more systematized, and the gods of nature were combined with the imperial ancestors in Japanese religion. The imperial household, its members descended from Amaterasu, came to be of central importance to the welfare of Japan and its people. In the Nihongi both prayer to and worship of the ancestors of the emperors were reflected. On a more popular level the dead spirits of the departed were thought to be present, especially on the anniversaries of their deaths, sharing in the efforts of the living.

ANCHIETA, JOSÉ DE (1534–1597). Jesuit missionary and educator, known as the "Apostle of Brazil," was born in the Canary Islands. He was educated in Portugal, and in 1551 joined the Society of Jesus at Coimbra. In 1553 Anchieta was sent by his superiors to Brazil, where he remained until his death. He was one of the founders of the Jesuit college of Piratinga (São Paulo) in 1554 and was also its most devoted teacher. He served as provincial of the Brazilian Jesuits from 1577 to 1587. In 1582 he founded, as some authorities believe, the Misericórdia hospital of Rio.

Anchieta was a man of many talents. He was a poet, a dramatist, epistler, nurse, teacher, philologist, shoemaker and historian. He wrote the first grammar of the Tupi Indian language and also the first dramatic pieces to be written in Brazil. His poem, *De Beata Virgine Dei Matre*, written in 1563 while he was a hostage of the Tamoio Indians, was the first composition of its kind in the new world. Anchieta's virtues were declared heroic on Aug. 10, 1736, by Pope Clement XII. (M. CA.)

ANCHISES, in Greek legend, son of Capys and Themis, grandson (according to Hyginus, son) of Assaracus, of the junior branch of the royal family of Troy, king of Dardanus on Mt. Ida. There Aphrodite met him and, enamoured of his beauty, bore him Aeneas. For revealing the name of the child's mother, he was killed or struck blind by lightning. In later legend, adopted by Virgil in the *Aeneid*, he was conveyed out of Troy on the shoulders of his son Aeneas (*q.v.*) and died in Sicily.

ANCHOR. The most ancient anchors consisted of large stones, baskets full of stones, sacks filled with sand or logs of wood loaded with lead. Of this kind were the anchors of the ancient Greeks; they held the vessel merely by their weight and by the friction along the bottom. When iron was introduced for the construction of anchors, an improvement was made by forming them

FROM THE "MANUAL OF SEAMANSHIP," BY PERMISSION OF THE CONTROLLER OF H. M. STATIONERY OFFICE
 FIG. 1.— FRONT AND SIDE VIEWS OF AN ADMIRALTY PATTERN ANCHOR

with teeth or flukes to fasten themselves to the bottom.

Until the beginning of the 19th century anchors were of imperfect manufacture, the means of effecting good and efficient welding being absent and the iron poor, while the arms, being straight, generally parted at the crown when weighing from good holding ground. However, curved arms were introduced in 1813, and after 1852 the admiralty anchor was supplied to ships of the British navy. The present form of admiralty pattern anchor, which is still used for light work and in boats, is shown in fig. 1. It will be noted that, by removing the keep pin, the anchor can be unstocked for stowing. The anchor must be stocked before letting go, to ensure that one of the flukes takes the ground.

The patent or stockless anchor, patented in England in 1821, became widely used principally because of the ease in handling and stowing in the hawsepipe. Its arms are in one plane and are pivoted so that they can turn through an angle from 35° to 45° on either side of the shank. One of the latest types is shown in fig. 2. Stockless anchors have replaced the old-fashioned stock anchor, fig. 1, almost entirely in ships of the U.S. navy and the merchant marine. However, the stock anchor is still widely used in fishing boats and small cargo vessels.

The principal advantage of the stockless anchor is that it can be hoisted into the hawsepipe, secured there and kept ready for letting go quickly. A disadvantage is that the anchor has a tendency to turn over with an upward pull on the ring or if the ship swings from side to side. Many attempts have been made to overcome this disadvantage while preserving the anchor's handiness; one of the best results is found in a lightweight anchor with extra-long, sharp flukes and an anti-rolling rod, called the stock, through the crown. Under a steady pull this anchor shows a tendency to bury itself deeper in the bottom and a disinclination to roll.

The mushroom anchor, fig. 3, so named because of its shape, has had wide use as a permanent mooring for lightships, dredges and lighters. Its excellent holding qualities result from its tendency to bury deeply and from the suction created by its shape.

Types of Anchors.— Ships and boats may carry many kinds of anchors, among which are the following:

Bower anchors— starboard bower and port bower— are so named because they are carried in the bow; they are used for all anchoring except where a smaller anchor or a special type may be required.

The sea anchor is a floating device, usually made of spars and canvas, to keep the bow of a ship headed into the wind and sea; it also is used to reduce leeway and for riding heavy seas in greater safety.

The drogue is a sea anchor used by small boats when landing through a surf to prevent being thrown broadside (broaching).

The stream anchor is a medium-weight anchor, usually about one-fourth the weight of a bower, used to keep a ship from swinging.

The grapnel is a lightweight, stockless anchor with four or five curved, clawlike arms; it is used for dragging to recover objects on the bottom and for anchoring small boats such as skiffs and dories.

The kedge is a small anchor, of the stock or stockless type, used to move a ship short distances by carrying the anchor out in a boat, letting it go and then hauling the ship up to it; it also may be used to change the heading of a ship by moving the bow or stern around, a process called warping.

Windlasses.— A ship's windlass is used primarily for handling the anchor and chain, but it often is fitted with a concave metal drum, called a capstan, for handling mooring lines, lifting heavy loads, etc. Windlasses are generally classified according to the type of drive: hand, steam, electric or electric-hydraulic. The windlass consists of a vertical or horizontal shaft upon which is mounted a wildcat, a sprocket wheel, which engages the links of the anchor chain; the wildcat may be locked to the shaft for drawing in the anchor chain, or released to rotate independently for dropping the anchor. The use of hand windlasses is limited to small vessels on which only light anchor gear is employed.

ANCHORAGE. the largest city of Alaska, U.S., is a major air and railway transportation centre. Located at the head of Cook inlet, it was founded in 1915 as a construction port for the Alaska railroad, whose headquarters are there.

Construction of Elmendorf air force base and Ft. Richardson during World War II made Anchorage a key aviation and defense centre, and construction produced a boom as concrete and steel buildings crowded frontier shacks. Its achievement of third place among U.S. cities in volume of air traffic by the late 1950s was due to strategic location and favourable year-round flying weather. It became a regular stop on Seattle-Tokyo and transpolar Scandinavia-Japan air routes and air, rail and truck transportation provided a basic civilian industry.

Anchorage has about 40 churches, a community college, symphony orchestra and community chorus, daily newspapers, television and radio stations, sports clubs and an annual winter carnival. For comparative population figures see table in ALASKA: Population. (J. E. CL.)

ANCHOVY, common name for a family (Engraulidae) of small fishes related to the herring family and distinguished by the large mouth extending posterior to the eye. The pointed snout extends far in front of the mouth. Most of the species resemble the drawing. Members of the Indo-Pacific genus *Coilia* differ in having a longer posterior region, rounded caudal fin, and many more rays in the anal fin.

Most of the more than 100 species live in shallow tropical or

warm temperate seas, where they often enter the brackish water around the river mouths. A few tropical anchovies are restricted to fresh water. Some occur in cold-temperate seas where their occurrence is associated with warm years or warm waters. Shallow waters such as the Zuider Zee have a higher summer temperature than the adjacent European seas and anchovies are able to spawn there. In the winter such fish migrate to other waters that have less seasonal change and therefore are relatively warmer.

Anchovies lay large numbers of elongate, transparent floating eggs. The eggs hatch in about two days and the larvae sink to the bottom. Young and adults feed on plankton, and growth is rapid. Adults congregate in small or large schools.

Anchovies grow to lengths of about four to ten inches. Temperate water types are important food fishes and tropical ones are important bait fishes, especially in the tuna fishery. Many species, however, are very susceptible to injury and are killed by contact with a net or other solid object. (C. Hu.)

ANCIEN RÉGIME, a French expression meaning "old order," commonly used to denote the social and political system of the old kingdom of France (with particular reference to the form given to it under the Bourbon kings in the 17th and 18th centuries), overthrown by the Revolution of 1789. See FRANCE: HISTORY.

ANCIENS ET DES MODERNES, QUERELLE DES, a dispute in France in the 17th century between those who maintained that the classics were the only models for literary excellence and the "moderns" who challenged the supremacy of classical writers and recommended subjects from Romance legends and the Bible as proper for poetry. See also FRENCH LITERATURE: The 17th Century.

This is to state the case at its simplest. It is as difficult to define the points at issue in the dispute, as to trace its origins. It was an age of controversy: intellectual France was divided into a number of circles, grouped around outstanding thinkers and members of the church and the nobility, but with a constant ebb and flow of ideas between them, so that those apparently closely identified with one side of the argument may be found supporting the opposite view. Personal friendships and enmities became involved; extravagant judgments by reputable critics might depend on the vagaries of patronage. The violent feelings raised by the quarrel itself can only be understood against the background of Cartesianism (see CARTESIANS) with its emphasis on reason and distrust of historical tradition per se and Jansenism and Gallicanism (*qq.v.*) which, in their political aspects, affirmed the national principle against the claims of supranational authority. More purely aesthetic and literary problems with which the dispute became involved were the discussions of the idea of true beauty as the expression either of a perfected reality or a sublime ideal; and of the nature of poetry: whether it was best as it was most reasonable, pure and exact, or whether it should aim at representing what is most otherworldly in man and nature. A further confusion was introduced in that both sides made use of the same terms, and both might lay claim to Cartesian "good sense" (*le bon sens*), differing only in defining its meaning, and the best means to attain it.

The beginnings of the attack on the ancients (*c.* 1659) may be traced to circles influenced by Cartesian thought, especially those associated with Habert de Montmort and the abbé de Marolles. At first it was leveled at those who knew all languages but their own and all history but that of their own time: but it became concentrated on poetry with the publication of heroic poems based, not on classical mythology, but on Carolingian or biblical stories. Notable were *Clovis* (1657) by Desmarests de Saint-Sorlin (*q.v.*), one of the chief disputants, and *Charlemagne* (1664) by Louis le Laboureur, a friend of the abbé de Marolles. The dispute gained force in a number of treatises, and broke into storm on the publication of Boileau's *L'Art poétique* (1674) (see BOILEAU-DESPREACX, NICOLAS). Boileau defined the case for the ancients. Essentially he upheld the great classical tradition in French poetry, established by the Pléiade (*q.v.*), and modified by Malherbe, Chapelain, Maynard and J. L. de Balzac (*qq.v.*). From then on the quarrel became personal, and more explicit. Desmarests' new edition of *Clovis* (1673) contained a "Traité pour juger poktes grecques, latines et françoises"; the abbé de Marolles, inspired

partly by dislike of its author and partly by critical objections to the poem, changed sides (a lesson to those who like to see the disputants ranged into neatly opposed camps) and attacked Clovis; the entry of Pierre Daniel Huet (*q.v.*), a classical scholar and humanist, into the Académie Française was made the occasion of a demonstration that the Académie was unquestionably with the moderns, led by Philippe Quinault and Charles Perrault (*qq.v.*). The salon of the duc de Richelieu took its stand with the ancients and the Cartesians were even more closely identified with the moderns. The appeal to patriotism was openly made in the *Défense de la poésie et de la langue française* (1675): to follow the classics was to disregard the glory of France. It was carried further by Perrault's poem *Le siècle de Louis le Grand* (1687) and his *Les Parallèles des anciens et des modernes* (1688 and 1697). Perrault was supported by Fontenelle, Boileau by La Fontaine and La Bruyère (*qq.v.*).

Like all such disputes, the affair died down and the bitter personalities exchanged in a series of polemical fables, lampoons and letters ended with Boileau's apology to Perrault (1700), recognizing the virtues of the 17th century as equal in some ways to those of antiquity. Meanwhile the dispute had been spread to England by Sir William Temple (*q.v.*), who published an essay on ancient and classical learning (1690) and became involved in the quarrels surrounding Richard Bentley. Its chief importance there, however, was to inspire Swift, then employed as Temple's secretary, to write his *Battle of the Books* (1704).

See studies by H. Rigault (1859) and H. Gillot (1914); R. F. Jones, *Ancients and Moderns: a Study of the Background of the Battle of the Books* (1936).

ANCIENT LIGHTS, a phrase in English law referring to a windows and other openings in a building that have been used without interruption for at least 20 years, thus creating the right to prevent the owner of adjoining land from obstructing the light received through these openings. An owner of land can acquire an easement (*q.v.*) of light by express or implied grant. The doctrine of ancient lights permits acquisition of such an easement by prescription (*q.v.*). The fact that a window faces a boundary line does not bar the neighbour from building on his own land even though the effect of his action is to obstruct the flow of light to the first building. When, however, a window has been unobstructed for a long time (20 years under the Prescription act of 1832 in England), the light becomes an "ancient light," which English law protects from disturbance. An obstruction constitutes a disturbance if it shuts out enough light to render the occupation of the building uncomfortable according to "ordinary notions of mankind."

In the United States most courts rejected this doctrine at an early date. It was felt that there was sufficient land available so that the first to build did not have to locate his building on the boundary line; he could protect himself by setting his building back. It was also felt in the United States that it was improper to give an easement by prescription where the owner of the adjoining land had no judicial protection against acquisition of the easement. The only protection under the English rule was for the adjoining owner to build to his boundary line within 20 years of construction of the first building. (A. D.M.)

ANCILLON, CHARLES (1659–1715), French lawyer who was the leader of Protestant refugees in Germany, was born on July 28, 1659, at Metz. His father, David Ancillon (1617–92), a prominent figure in the Society for Promoting Christian Knowledge, was obliged to leave France on the revocation of the Edict of Nantes, and became pastor of the French Protestant community in Berlin. Charles Ancillon studied law at Marburg, Geneva and Paris. In 1699 he replaced his uncle Joseph Ancillon (1629–1719) as judge of the French refugees in Brandenburg. He died in Berlin on July 5, 1715. His history of the French refugees in Brandenburg (1690) is a valuable document of the period. Other of his works deal with the Edict of Nantes (published anonymously) and the habits of eunuchs (published under the anagram C. Ollincan). The biographical source on the family is C. Ancillon, *Mélange critique de littérature, recueilli des conversations de feu M. Ancillon*, 3 vol. (1698).

ANCILLON, JOHANN PETER FRIEDRICH (JEAN PIERRE FRÉDÉRIC (1767–1837), Prussian statesman and historian representative of the reaction against liberalism after 1814, was born in Berlin on April 30, 1767, of Huguenot descent. After studying theology at Geneva, he visited Paris in 1789 and was appointed pastor to the French Protestant community in Berlin in 1790. Through the favour of Prince Henry of Prussia, Ancillon became professor of history at the Berlin military academy in 1792 and official historiographer in 1803. His *Tableau des révolutions du système politique de l'Europe depuis le XVe siècle*, 4 vol. (1803–05), gained him admission to the Berlin Academy in 1803. He was appointed tutor to the royal princes in 1808, councilor of state in 1809 and private tutor to the future Frederick William IV in 1810. He powerfully influenced his pupil, instilling in him hatred and fear of revolution. Ancillon also strongly opposed K. A. von Hardenberg's constitutional projects, which he had at first favoured.

Ancillon entered the ministry of foreign affairs in 1814, becoming director of its political department in 1818 and head of the ministry in 1832. He aimed to preserve the Vienna settlement of 1815 in close association with Austria and believed the rigid Prussian class system to be the ideal basis for a state and representation by "estates" to be the essential constitutional principle. His ideas were rooted in Prussian nationalism, and he was close to the Romantic movement, which fertilized contemporary nationalism by its feeling for the past. Typical of his method of avoiding clear conclusions are his collected essays, *Zur Vermittlung der Extreme in den Meinungen* (1828). Ancillon died in Berlin on April 19, 1837.

His works include: *Mélanges de littérature et de philosophie*, 2 vol. (1809); *Über Souveränität und Staats-Verfassung* (1816); *Über die Staatswissenschaft* (1820); *Über Glaziben und Wissen in der Philosophie* (1824); *Über den Geist der Staatsverfassungen* (1825); *Pensées sur l'homme*, 2 vol. (1829); and *Essais de philosophie, de politique et de littérature*, 4 vol. (1832).

See P. Haake, J. P. F. Ancillon und Kronprinz Friedrich Wilhelm IV von Preussen (1920) and *Die preussische Verfassungskämpf vor 100 Jahre* (1921).

ANCONA, a city and Adriatic seaport on the east coast of central Italy. capital of Ancona province, lies 185 mi. N.E. of Rome by rail (132 mi. direct). Pop. (1957 est.) 94,810 (commune). The town stands on the farthest branch of the promontory which descends among valleys and hills from the Conero massif. There the promontory divides into the two spurs of Monte Astagno and Monte Guasco, on which is the cathedral of S. Ciriaco. This is supposed to occupy the site of a temple of Venus, mentioned by Catullus and Juvenal as the tutelary deity, of which remains have been discovered. The present building, which has Romanesque-Gothic elements, is an enlargement (12th–13th century) and conversion into Greek cross shape of a basilica (5th–6th century). Two crypts have bishops' tombs and saints' relics. Pope Pius II died in the episcopal palace in 1464. Sta. Maria della Piazza has an elaborate arcaded façade (1210). The Palazzo del Comune (13th century, restored) has façade sculptures attributed to Marigaritone d'Arezzo. Fine late Gothic buildings include the churches of S. Francesco and S. Agostino, the Palazzo Benincasa and the Loggia dei Mercanti, all by Giorgio Orsini (da Sebenico), and the prefecture which has Renaissance additions. There is an archaeological museum in the Palazzo Ferretti, including material from the Picene Iron Age. To the west of the town is the harbour, originally protected only by the elbow-shaped promontory from which the town takes its name (Gr. *angkon*, "elbow"), now an oval basin.

Ancona is on the main east coast line of Italy from Milan and Bologna to Foggia and Brindisi; another main line runs to Rome. Ships ply to the Italian ports Rimini, Ravenna, Venice and Trieste, and Yugoslav ports. Industries include shipbuilding, and the production of machinery, metalwork, chemicals, medicines, foodstuffs, textiles, clothing, furniture, bricks and wood. Ancona is also an important market centre, trading in cloth, silk, stockings, skins, dried fish, coffee, drugs and colonial wares, cereals, chemical and pharmaceutical products, coal, timber, ironwork, building mate-

rials, liquid and compressed gas, rubber products, hygienic and sanitary materials, paper and pasteboard. Since World War II an oil refinery has much increased the port's activity.

Ancona was founded by Syracusan colonists in 390 B.C., Greek merchants establishing a purple dye factory there. The first Roman colony was in the time of the Gracchi (2nd century B.C.) and its own coinage was used for some time afterward. It was occupied as a naval station in the Illyrian War of 178 B.C. and taken by Caesar just after he had crossed the Rubicon. Trajan enlarged the harbour before starting on his second expedition to Moesia and Dacia in A.D. 105, the marble triumphal arch on the quay being set up in his honour in 115. Pope Clement II further enlarged the harbour. Attacked by Goths, Lombards and Saracens, Ancona recovered its importance in the middle ages, being one of the cities of the Pentapolis under the exarchate of Ravenna, the others being Fano, Pesaro, Senigallia and Rimini (see RAVENNA, EX-ARCHATE OF), and eventually became a semi-independent republic under papal control until Gonzaga took it for Clement VII in 1532. Captured by the French in 1797, it became a democratic state until absorbed into the Italian kingdom of 1808. It returned to papal control in 1816. Lamoricière capitulated there on Sept. 29, 1860, 11 days after his defeat at Castelfidardo, and Ancona became part of Italy. In World War I it was bombarded by the Austrian fleet on May 24, 1915, and thereafter. It was frequently bombed by Allied aircraft in 1943–44 during World War II. It fell to Polish forces under Gen. Wladyslaw Anders on July 18, 1944.

ANCRE, CONCINO CONCINI, MARQUIS D' (d. 1617), Italian adventurer whom the favour of Marie de Médicis made all-powerful in France during her regency. The errant son of a good family, Concini followed Marie de Médicis when she left Florence to marry Henry IV of France (1600). He married the queen's foster-sister, Leonora Galigai. The queen, already dominated by his wife, fell so completely under Concini's influence that Henry IV wanted more than once to banish him from the court. A Spanish agent, Concini was involved in the shady intrigues that led to the assassination of the king (1610). With Marie de Médicis as regent for the young Louis XIII, Concini, now marquis d'Ancre, and his wife enjoyed boundless influence, which they first used to enrich themselves. His ostentation and arrogance made him generally odious and particularly so to the young king, whom he constantly humiliated. He was made marshal of France in 1613. After two civil wars the prince de Condé (Henry II de Bourbon) seemed likely to seize power, whereupon the marshal intervened directly in politics by having Condé arrested and causing a strong government, including the future cardinal de Richelieu, to be formed (1616). His unpopularity, however, made failure inevitable. When another civil war was threatening, Louis on the advice of his own favourite Charles d'Albert de Luynes, decided to kill the marshal, who was shot by the royal guards on the drawbridge of the Louvre on April 24, 1617. The populace dismembered his corpse and sacked his house. His widow, condemned to death for sorcery, was beheaded and burned on July 8, 1617.

ANCUS MARCIUS (7th century B.C.), traditionally 4th king of ancient Rome 640–616 B.C. Although his name may be historically acceptable the details of his reign must be regarded as largely legendary. Among these are the settlement of the Aventine hill, the first extension of Rome beyond the Tiber to the Janiculum hill and the founding of the port of Ostia. (R. B. LD.)

ANCYLOPOD, a name applied to the chalicotheres, an extinct group of clawed ungulates, by those who believe these animals to be a separate order of mammals. However, despite their extraordinarily specialized feet, chalicotheres appear to form

BY COURTESY OF AMERICAN MUSEUM OF NATURAL HISTORY
SKELETON OF LOWER MIOCENE MOROPUS

no more than a superfamily of the order Perissodactyla related to horses and titanotheres. See also PERISSODACTYLA: *Chalicotheres*. (B. PA.)

ANCYLOSTOMIASIS, or intestinal hookworm disease of man, is produced chiefly by *Ancylostoma duodenale* or *Necator americanus*. It is also called uncinariasis and miner's anemia. See HOOKWORM.

ANCYRA (mod. ANKARA in Turkey), an ancient city of Galatia in Asia Minor, on a tributary of the Sangarius (Sakarya). The date of its foundation is uncertain but it was a prosperous city under Phrygian rule. It was occupied by Alexander the Great in 333 B.C. and after his death fell to Antigonos I's share of his empire. In 281, however, it came under the rule of Seleucus Nicator. Later in the 3rd century B.C. it became the centre of the Tectosages, one of three Gaulish tribes that had settled in Galatia. In 189 B.C. it was occupied by the Roman general Gnaeus Manlius Vulso. In 63 B.C. Gnaeus Pompeius organized it and the surrounding territory under local Tectosagan rule, which continued until Ancyra was made the capital of the Roman province of Galatia in 25 B.C. Christianity was introduced perhaps as early as the 1st century A.D. The Ancyran Church is first mentioned in A.D. 192.

Later, as a city of the Byzantine empire, Ancyra occupied a position of considerable importance and was a target for attacks by several invading armies. A Persian army under the Sassanid king Khosrau II and an Arab army under the caliph Mu'awiya occupied it for short periods in the 7th century, and it was again occupied by Arab armies late in the 8th century during the reign of Harun al-Rashid. In 1073 it fell to the Seljuk Turks. (For the later history of the city see ANKARA.)

Of the many extant remains of the Roman and Byzantine periods the most important is the Augusteum, a temple of white marble erected to "Rome and Augustus" during Augustus' lifetime by the common council of the three Galatian tribes. On its walls is engraved the Monumentum Ancyranum (see ANCYRANUM, MONUMENTUM), a long inscription in Latin and Greek describing Augustus' achievements. See also GALATIA.

ANCYRANUM, MONUMENTUM, an inscription engraved soon after A.D. 14 on the walls of the temple of Rome and Augustus at Ancyra (*q.v.*; mod. Ankara) in the Roman province of Galatia, giving the Latin text and official Greek translation of the obituary of Augustus known as the *res gestae divi Augusti*. Fragments of the Latin version have also been discovered at Antioch in Pisidia and of the Greek version at Apollonia in Pisidia. The *res gestae* ("achievements") were composed by Augustus himself, who directed in his will that they should be engraved in bronze on two pillars in front of his mausoleum in Rome. The inscription recounts (1) his early career and the magistracies and other honours conferred upon him or offered to him by the senate and people; (2) the public benefactions which he had made from his private means, including games and buildings and distributions of money and land to citizens and veterans; (3) his warlike and diplomatic achievements. It ends with his claim to have restored the republic and with the honours that he received therefor. There follows a summary of his benefactions, added after his death. This inscription gives an invaluable picture of how Augustus wished to be remembered. It is factually accurate, but sometimes not entirely ingenuous in its selection and presentation of the facts.

See V. Ehrenberg and A. H. M. Jones, *Documents Illustrating the Reigns of Augustus and Tiberius*, 2nd ed. (1955); Jean Gagé, *Res Gestae Divi Augusti* (1935). (A. H. M. J.)

ANDALUSIA (Spanish ANDALUCÍA), a region including most of Spain south of the Sierra Morena, corresponding roughly to the Roman province of Baetica and divided after 1833 into the eight provinces of Almeria, Cadiz, Córdoba, Granada, Huelva, Jaén, Malaga and Seville (*qq.v.*). The origins of the name are uncertain; scholars have attempted to connect it with the occupation of the country by the Vandals in the 5th century A.D. The Arab form al-Andalus designated at various periods the whole peninsula, the area under Muslim rule, and the four kingdoms of Seville, Cordoba, Jaén and Granada.

Andalusia consists mostly of high, heavily eroded mountain chains and their foothills, broken in the west by the Guadalquivir

depression and in the east by the Almeria and Almanzora rivers. Settlement has been heaviest in the valleys and coastal plains and in the folds of the south-facing mountain spurs. The climate and fauna and flora, often varying considerably within a few miles from subtropical coastal type to alpine, correspond to those of certain parts of the North African littoral. Other shared features are flat-roofed houses, cave-dwelling communities and the intensive cropping of irrigated hill terraces with the consequent proliferation of *minifundia* (small holdings), though stock-rearing *latifundia* are the rule in the plains. (For further description of physical features see SPAIN.)

History.—Andalusia's history was closely linked with that of the north African coast until the last decade of the 15th century, when the process of integration was partially suspended by the fall of Granada in 1492 to the monarchs of Castile and Aragon, who forbade their former Muslim subjects to communicate with Africa under pain of death, even after their conversion to Christianity. Both areas had been occupied successively by Punic, Roman and Visigothic settlers; after the invasion of southern Spain from Tangier by Tarik ibn Ziyad in 711, the strait of Gibraltar virtually ceased to exist as a human frontier for the next eight centuries, even though political strife between Spanish and African Muslim dynasties was often intense. In the 10th century the caliphate of Córdoba (*q.v.*) drew its military strength largely from Berber mercenaries, just as Algiers in the 17th was garrisoned largely by deported Spanish Moriscos (*q.v.*). Most of the distinguished figures of the Muslim period divided their lives between the two continents; for example, Averroës (*q.v.*), the greatest of Spanish Muslim philosophers, who was born at Cordoba in 1126, was qadi of Seville and later of his native city, and, except for a few years of banishment, served after 1182 until his death as court physician in Marrakesh, where he did most of his writing.

Whereas the Andalusian contribution to north Africa in the medieval period was mainly cultural and artistic, the African Muslims repaid their coreligionists in Spain by reinvigorating their fighting power and religious zeal at times when discord and tolerance were weakening their resistance to the Christians. The invasions of Spain by the Almoravids (*q.v.*) in the 11th century and by the Almohads (*q.v.*) in the 12th prolonged the life of the petty but highly cultured Muslim principalities which arose from the ruins of the caliphate. These invasions also played a part as important as, though less direct than, that of the rivalry between the Christian monarchs in the birth of the Nasrid sultanate of Granada in 1232. The defeat of the Marinids, one of the three great Berber groups, at the Salado (1340) and Palmones (1343) rivers, by Alfonso XI of Castile and León put an end to effective north African intervention in the peninsula; but the tide of the Christian reconquest of Spain was stemmed for a time by civil war in Castile, strife between crown and feudal nobility and mutual distrust among the Christian princes.

For more than a century the Muslims who had thronged to Granada for asylum were saved by the slowing of the Christian advance. While their frontiers were the scene of a fluctuating guerrilla warfare which inspired the most colourful and moving of the Spanish ballads, their cities saw the revival of a score of fine crafts; Almeria and Málaga traded with Italy and north Africa; the vegas and terraced slopes were cultivated to yield a wealth of fruits; the mulberry-planted mountainsides produced the finest silks in Europe; and even the poorest hillsides bore fast-growing crops of panic grass and millets. Above the thickly populated city of Granada itself, on an outlying spur of the Sierra Nevada, rose the fortress and palace of the Alhambra (*q.v.*), flanked by the Generalife and other pleasure palaces which fell into ruins soon after the reconquest. (See SPAIN: History.)

Muslim Institutions.—The government of Muslim Spain, whether under the caliphs of Cordoba, the taifa kings or the sultans of Granada, was not radically different from that of the eastern caliphate. The office of ruler was nominally hereditary, though in practice he was frequently elected and deposed by military, aristocratic or merely local factions. A favourite of the ruler, or a military dictator who seized power, often took the title of

hajib (chamberlain) and stood above the viziers (the ruler's delegates or ministers) who with the royal secretaries (kuttab) formed the diwan or council of state. Local authority was delegated to civil and military governors called walis, each of whom administered a province or chief city, while on every frontier there was a military chief who enjoyed a large measure of independence. Armies consisted of paid mercenaries or were recruited on a tribal or clan basis and rewarded with the spoils of a raid; frontiers, however, were garrisoned by ascetic warrior sects, the Sufis, who corresponded to the military orders of the Christians.

Muslim law, which is canonical insofar as it derives ultimately from the Koran, was administered by the qadis, who were chosen from scholars versed in the traditions of Islam (the fakihs). As the office of qadi became increasingly onerous in Spain, criminal offenses were relegated to a special judge, the *sahib-al-shurtah*, while under the caliphate a magistrate residing in Cordoba, the *sahib-al-mazalim*, reviewed complaints against all public officials. In addition, most cities had a municipal justice, the *muhtasib* (Sp. *almotacén*), who directed the police, judged offenses against public morality and retained after the reconquest his function of supervising markets, weights and measures.

The income of the state was derived from the *zakah*, a tithe imposed originally on the incomes of individual Muslims, but later on the products of agriculture, industry and commerce; from the capitation tax levied on non-Muslims, which declined after the expulsion of the Mozarabs (*q.v.*); from rents on the state lands recorded in the chancery registers, which became increasingly important; and from import and export duties, supervised by the officials of the revenue minister. In Granada under the Nasrids the silk trade was an important source of revenue; silks could be bought and sold only in three marts, to which they were taken by elected deputies and stored until sold by the brokers. There was a variety of local taxes on consumer goods, public utilities and irrigation, mostly devoted to defraying the personal expenses of the ruler's household. In addition, the pious bequeathed property to a public welfare fund which supported mosques, schools, leper houses and lunatic asylums, provided maintenance for fakihs and students and ransoms for captives and even served to repair roads, bridges and defense works.

At the time of the reconquest, when Islamic law was completely replaced by Roman and canon law, many administrative and fiscal institutions of the Muslims were guaranteed to them in their capitulations; in this way they were retained or copied by the Christians and survived until the advent of the Bourbon dynasty in Spain. This was especially true of municipal and guild regulations, which were often translated from the Arabic and incorporated in local *ordenanzas*.

Survival of Islamic Influence.—While the most valuable contribution of Muslim Andalusia to the European heritage was in the realms of philosophy and literature (see ARABIC PHILOSOPHY; ARABIC LITERATURE) the most striking survivals of the Islamic occupation to be seen in modern Spain are agricultural and domestic. Many of the crops grown in Andalusia were introduced by the Arabs (for example, sugar cane, apricots and almonds—though two of the most characteristic features of the landscape, the maguey, or American aloe, and the prickly pear, come from the new world); and many of the elaborate irrigational constructions date from the Muslim period and have Arabic-derived names (*aljibe*, a well; *acequia*, a water channel; *noria*, a water wheel). The traditional Andalusian house, though Roman in origin, owes many of its refinements to the Muslims. A spacious porch gives access to the central patio, decorated with blue tiles and horseshoe arches with stuccowork arabesques, in the centre of which a fountain plays among citron trees, flowering shrubs and fragrant edgings of myrtle clipped in geometrical patterns. In summer life revolves around the patio and the cool rooms leading off it; in winter the family moves upstairs to heavily carpeted rooms heated by a large round copper brazier standing in a polygonal surround of marquetry and burning, by a process of downward combustion, powdered charcoal made from olive stones. The house is covered by a flat roof and from the outside presents an unrevealing white façade broken only by a few small openings with elaborate

wrought-iron grilles. Behind these the family lives in greater seclusion than is usual elsewhere in Europe, and guests other than kinsfolk are rarely invited. Modern Andalusian cooking obtains many of its ingredients from the new world; but the use of olive oil is associated primarily with the Muslims, for the Christians proved their faith by using lard until a comparatively recent date.

Much of what is accepted as typically Andalusian derives from periods before the Muslim conquest (as castanets and some flamenco dancing) or from later periods, being attributable to the influence of the new world, the gypsies, the bandit and smuggler tradition of the 18th century, and the absentee landlords and political bosses of the 19th and 20th centuries. Perhaps the most lasting, though not the most immediately obvious, impress left by the Muslims on the Andalusian character is the gift for crystallizing the most fleeting emotion, aesthetic perception or witty thought in improvised music and verse. From the unknown poet who engraved on the tracery of the Alhambra

This fountain is like a believer in ecstasy, rapt in prayer; and when the fountain shifts, it is the worshipper who stoops to genuflect and resumes his prayer

to the poetic vision of Luis de Gongora there is but a step; and the same tragic appreciation of the impermanence of material beauty unites both the Arab and the Gongoran tradition to Federico Garcia Lorca.

King, *The Structure of Spanish History* (1954). (K. GA.)

ANDALUSITE, an aluminum silicate mineral. The crystals usually are roughly developed and rude columnar masses, frequently partially altered to kaolinite or mica, are common. Such crystals, opaque and of a grayish or brownish colour, occur in a mica schist near Innsbruck, Tirol, Aus., and in Andalusia, Spain, from which the mineral derives its name. In addition to characteristic occurrences in small amounts in many contact metamorphic rocks (see METAMORPHISM), andalusite occurs in commercial quantities at White Mountain, Calif., Oreana, Nev., Kazakhstan, U.S.S.R., and the Transvaal, Africa. Such deposits are mined as a raw material for refractories and porcelain used in spark plugs and other products.

The unaltered mineral is found as transparent pebbles in the gem gravels of Minas Gerais, Braz., and in Ceylon. The pebbles are often dichroic, appearing greenish or reddish brown according to the direction of viewing, and are sufficiently hard ($H. = 7.5$) to make effective gem stones. A variety known as chialiolite, characteristic of clay slates near a granite contact, consists of elongated prismatic crystals enclosing symmetrically arranged wedges of carbonaceous material, and in cross section show a black cross on a grayish ground. Cross sections may be polished and worn as charms.

In addition to its natural occurrences, andalusite has been produced synthetically at moderate temperatures under moderate water-vapour pressures. It has the same chemical compositions as kyanite and sillimanite (*q.v.*), Al_2SiO_5 . As in sillimanite its crystalline form is orthorhombic, the latter having the form of almost square prisms. For discussion of its thermal behaviour, see MULLITE.

See *American Mineralogist*, vol. 39, 140 (1954). (DA. R.; RU. R.)

ANDAMAN AND NICOBAR ISLANDS, a centrally administered territory of the Republic of India. Formed in 1872 by uniting the Andaman Islands and the Nicobar Islands (*q.v.*) under one administration, the territory was included under part D of the first schedule of the Indian constitution, 1950. It is administered by the president of the republic through a chief commissioner, who is advised by a local council of five members. The

administrative headquarters are at Port Blair (pop. [1951] 8,014) on South Andaman; and an assistant commissioner is stationed on Car Nicobar in the Nicobar Islands. Port Blair is connected with India by a radio link, and a mail steamer running between Calcutta and Madras calls every three or four weeks. During the Japanese occupation of 1942-45 some roads were built, notably on Car Nicobar, and jetties were constructed at Malacca (Car Nicobar) and Nankauri (Nancowry) (central Nicobars). The total area of the territory is 3,215 sq.mi.; pop. (1961 census) 63,438 excluding the aborigines of the Andamans, who try to avoid contacts with civilization.

See Andaman and Nicobar Islands *Administration* Report (annual).

ANDAMAN ISLANDS, a group of islands in the Bay of Bengal, administratively part of the Indian chief commissioner's territory of the Andaman and Nicobar Islands (*q.v.*). The total population of the Andaman Islands, excluding the Andamanese (see *The People*, below), was 18,962 in 1951. The seat of administration is Port Blair. The Andamans, area 2,589 sq.mi., include 204 islands and islets, which lie 650 mi. from the mouth of the Hooghly and 120 mi. from Cape Negrais in Burma, the nearest point on the mainland. The extreme length of the Andamans is about 310 mi.; the greatest width is under 30 mi. There are three chief islands in the main group—North, Middle and South Andaman—so closely adjoining each other that they have long been known collectively as Great Andaman. Grouped with the chief islands are, on the extreme north, Landfall Island; Interview Island, off the northwest coast of Middle Andaman; the Labyrinth Islands, off the southwest coast of South Andaman; Ritchie's archipelago (or the Archipelago Islands), off the east coast of South Andaman; Baratang, wedged in-between and on the east of Middle and South Andaman; and Rutland Island, at the southern end of South Andaman. Little Andaman, roughly 26 by 16 mi., forms the southern extremity of the whole Andaman group and lies 31 mi. S. of Rutland Island across Duncan passage, in which lie the Cinque and other islands. Besides these are a great number of islets lying off the shores of the main islands. The Andaman Islands are separated from the Nicobar Islands (*q.v.*) to the south by the 90 mi.-wide Ten Degree channel.

Topography.—The islands forming Great Andaman consist of a mass of hills enclosing very narrow valleys, the whole covered by dense tropical forest. The hills rise, especially on the east coast, to a considerable height; the highest is Saddle peak (2,400 ft.) on North Andaman. Little Andaman, with the exception of the extreme north, is practically flat. There are no rivers and few perennial streams in the islands. The scenery is everywhere strikingly beautiful and varied, and the coral beds of the more secluded bays in its harbours are conspicuous for their exquisite colouring. The coasts of the Andamans are deeply indented, forming a number of safe harbours and tidal creeks, often surrounded by mangrove swamps. The principal harbours are Port Blair in South Andaman, Port Cornwallis in North Andaman and Elphinstone and Mayabandar in Middle Andaman.

Geology.—The Andaman Islands form the higher parts of a lofty range of submarine mountains, 700 mi. long, stretching from Cape Negrais, the southernmost point of the Arakan Yoma range of Burma, through Sumatra and Java to the Lesser Sunda Islands and the Moluccas. This range separates the Bay of Bengal from the Andaman sea and it contains much that is geologically characteristic of the Arakan Yoma (see BURMA: Geomorphology), and formations common also to the Nicobars and to Sumatra and the adjacent islands. The older rocks are probably early Tertiary or late Cretaceous, but there are no fossils to indicate age. The newer rocks, common also to the Nicobars and Sumatra, are chiefly in Ritchie's archipelago and contain radiolaria and foraminifera.

Climate.—Rarely affected by a cyclone, though within the influence of practically every one that blows in the Bay of Bengal, the Andamans are of the greatest importance because of the accurate information relating to the direction and intensity of storms which can be communicated from them, better than from any other point in the bay, to the vast amount of shipping in this part of the Indian ocean. A well-appointed meteorological station was established at Port Blair as early as 1868. Generally, the climate

of the Andamans may be described as normal for tropical islands of similar latitude. It is always warm, but tempered by pleasant sea breezes, and it is very hot when the sun is northing. The rainfall is irregular, but usually there is very little during the northeast and a great deal during the southwest monsoon.

Flora and Fauna.—A section of the forest department of India was established in the Andamans in 1883. In the neighbourhood of Port Blair 156 sq.mi. were set apart for regular forest operations, these being long conducted by convict labour. The chief timber of indigenous growth is Andaman redwood, or padauk (*Pterocarpus dalbergioides*), used for buildings, boats, furniture, fine joinery and all purposes to which teak, mahogany, hickory, oak and ash are applied. This tree is widely spread and forms a valuable export to European markets. Other first-class timbers are koko (*Albizia lebbek*), white chuglam (*Terminalia bialata*), black chuglam (*Myristica irya*), marblewood or zebrawood (*Diospyros kurzii*) and satinwood (*Murraya paniculata*), which differs from the satinwood tree of Ceylon (*Chloroxylon swietenia*). Among the imported plants are tea, Siberian coffee, cocoa, Ceara rubber, aback fibre (manila hemp), teak, coconut and a number of ornamental trees, fruit trees, vegetables and garden flowers. The general character of the forests is Burmese with an admixture of Malay types. Great mangrove swamps supply unlimited firewood.

Animal life is generally deficient throughout the Andamans, especially as regards mammalia, of which there are only 20 separate species in all, including the dugong of the surrounding seas. Some of these are peculiar to the islands and others, including a monkey (*Macaca leonina*), the house mouse and various rats, have been introduced. There is a small pig (*Sus scrofa andamanensis*), important to the food of the people, and a carnivore, a palm civet (*Paguma larvata tytleri*); but the bats and rats constitute four-fifths of the known mammals. Many of the Andaman species differ from those of the adjacent Nicobar Islands. Each island group has its distinct harrier eagle, red-cheeked parakeet, oriole, sunbird and bulbul. Fish are very numerous and many species are peculiar to the Andaman seas. Turtles are abundant and supply the Calcutta market. (X.)

The People.—The Andamanese belong to the negrito stock which is represented also by the Semang of Malaya and the pygmies of the Philippines. Their remoteness and their practice of killing all foreigners preserved them from any considerable physical or cultural modification. They live by hunting and collecting, cultivation being unknown. The dog, introduced in the 19th century, is the only domestic animal. The only indigenous weapon is the bow. Fish arrows have up to four points and pig arrows have detachable heads fastened by cord to the shafts, which catch in the undergrowth. They had no traps or fishhooks. Turtle, dugong and fish are caught with nets and harpoons; the latter are used from single-outrigger canoes. Pottery is made throughout the group, and fragments occur in ancient middens. Iron, obtained from wrecks, has been used for arrowheads, knives and adzes at least since the 18th century. It is shaped by breaking and grinding, a technique derived from the working of shell. The Andamanese were unique in knowing no method of making fire.

There were several tribes, each consisting of a number of small independent groups with a common language. Most Andamanese are now detribalized, but the old life survives among the Jarawa and Onge of the interior of South Andaman, Rutland Island and Little Andaman. (B. A. L. C.)

History.—Because of their position athwart the trade routes from India to Burma and the far east the existence of the islands has been known from earliest times. They are mentioned by the Chinese Buddhist monk I'Tsing (A.D. 672); the Arab travelers of the 9th century; Marco Polo (1286); Friar Odoric (1322); and Nicolo Conti (1430). The derivation of the name "Andaman" is uncertain. It seems possible that the Agathou Daimonos Nesos (Good Spirit Island) of Ptolemy was a misunderstanding of some form like Agdaman. It has been suggested that Angamanain (the name used by Marco Polo) is an Arabic dual indicating "the two Andamans." According to Conti the name means Island of Gold. The name is probably derived from the Malay Handuman, coming from the ancient Hanuman ("monkey"). Later travelers repeat

the stories, too well founded, of the ferocious hostility of the people. In Sept. 1789 Capt. Archibald Blair, acting under instructions from the government of Bengal, established a penal colony on Chatham Island, in the southeast bay of the Great Andaman, now called Port Blair but then Port Cornwallis. Two years later, urged by Adm. Sir William Cornwallis, the government transferred the colony—together with its name of Port Cornwallis—to the north-eastern part of Great Andaman, where a naval arsenal was to be established. But the scheme did poorly; and in 1796 the government put an end to it. In 1844 the troopships "Briton" and "Runnymede" were driven ashore there. The natives showed their usual hostility, killing all stragglers. Outrages on shipwrecked crews continued to be so frequent that the question of occupation was revived, and in 1855 a project was formed for a settlement and a convict establishment. This scheme was interrupted by the Indian Mutiny of 1857, but as soon as the revolt was broken it became more than ever urgent to provide such a resource on account of the great number of prisoners falling into British hands. A new settlement was established at the beginning of 1858 near the site of Blair's original Port Cornwallis and, to avoid confusion, was named Port Blair. For some time sickness and mortality were excessively high, but the reclamation of swamp and clearance of jungle on an extensive scale by Col. Henry Man was ultimately successful. The Andaman colony obtained a tragic notoriety from the murder, by a Mohammedan convict, of the viceroy, the earl of Mayo, when on a visit to the settlement on Feb. 8, 1782.

The islands were occupied by the Japanese on March 23, 1942, and reoccupied by the government of India on Oct. 8, 1945, when the abolition of the penal settlement, which had been going on gradually since 1926, was finally effected. As a result of the foundation of the penal settlement there is a considerable Indian population.

Development.—In the 1950s the islands were colonized with displaced persons from East Pakistan, evacuees from Burma and Indian emigrants from British Guiana. There were 20,000 ac. of forest land being cleared. Ten acres of land were given free to each family who also enjoyed exemption from land revenue for two years and received loans and facilities for cutting timber. Timber, especially Andaman redwood, gurjun for plywood and softwoods for match factories, coconuts and copra are exported to India. There is a high school and a well-equipped hospital.

ANDEAN CIVILIZATION. The term Andean civilization refers to the aboriginal American Indian cultures that developed and flourished in the highlands of northwestern South America from several thousand years B.C. until their subjection by the Spanish in 1532. In its basic economic elements it persists today in the large Indian populations of Peru, Bolivia, Ecuador and Colombia. Though termed "Andean" it also includes, especially in its early phases, the peoples of the Peruvian coast.

The climatic range is even greater than the geographical one, extending from sea level to heights of over 13,000 ft. (4,000 m.) in the altiplano of Bolivia. The Peruvian coast is absolutely arid, with rain unknown in some parts, and vegetation only in the lush valleys of the many small rivers that descend from the Andes, while the highlands are verdant in the summer rainy season, October to May. On the coast, fish and seafoods are important staples, but in the highlands hunting is of slight importance. On the other hand, the highlands are characterized by the domestication of the American cameloids, the llama and alpaca.

Like all civilizations, the Andean was founded on agriculture, permitting a large and sedentary population with leisure time to devote to cultural improvement between harvest and sowing. This

civilization naturally developed from an earlier and sparser hunting people.

PRE-INCA PEOPLES

The Inca were preceded during possibly 4,000 years by agricultural peoples who gradually developed high cultures; these are known only by archaeological excavations. The earliest known Andean people were a small group at Huaca Prieta at the mouth of the Chicama river. They lived in semisubterranean houses. Ignorant of maize and of pottery, they cultivated squash, gourds, chili pepper and cotton! fished and made coarse cloths and baskets. They are given a radiocarbon date of about 2500 B.C.

Chavin.—For 2,000 years, of which little is known, culture developed, maize was introduced, and the arts of pottery making, architecture and others were brought to a high state of development. One excavation at Guañape (Peru), dated at about 1250 B.C., affords data on the close of this period. The earliest-known culture of any sophistication was the Chavin with its apparent centre at Chavin de Huántar in the northern highlands of Peru, and a coastal phase at Cupisnique. Chavin, dated at about 700 B.C., was apparently the centre of a religious cult whose influence was felt over much of the Peruvian coast, especially in the art style in which the jaguar predominated. The main building at Chavin is immense, of excellent masonry, consisting of three stories, with stairs, ramps and even ventilating shafts. Maize was now the staple food, and all the arts including pottery, weaving and metallurgy had reached a high plane.

Experimental Period.—The cultures of the next period, sometimes called the Experimental, probably about 500-300 B.C., are not so well known, but include the Salinar, Gallinazo and several others. Several sites of this period have also been discovered in the highlands, Chanapata near Cuzco, and Chiripa on Lake Titicaca (Peru-Bolivia). The masonry architecture and the agricultural terraces show considerable skill, but apparently the highland cultures at this time lagged behind those on the coast. This cannot be stated with certainty, however, for in the highlands all objects made of perishable materials are gone while the cemeteries of the arid coast preserve all handicrafts in excellent condition. This was a dynamic period in which many new techniques appeared. The extent of agricultural lands was increased by irrigation canals! and agricultural terraces were built.

Florescent Period.—In the first few centuries of the Christian era—authorities differ by several centuries in their estimates, though allowing 600 to 800 years for the length of the period—high civilizations developed on the coast of Peru. In pottery making, weaving, metallurgy and other arts, as well as in engineering, this was the apogee of Peruvian culture; the period is known as the Florescent. The river valleys were densely populated, with intensive agriculture. The best-known civilization of that time is the Moche or Mochica of the region of Trujillo (Peru), where are found the enormous adobe mud pyramids of the Sun and the Moon. The former measures 750 by 450 ft. and, although much eroded, stands 60 ft. high; it has been estimated to contain 130,000,000 mud bricks. One of the great irrigation canals is said to have been 75 mi. long. Especially famous are the pottery vessels, modeled in naturalistic forms that reveal much of the native life. Apparently there were mere social classes, and, judging by figures of warriors, militarism had arisen.

On the southern coast, in the Pisco, Ica and Nazca valleys, other civilizations, the Paracas and Nazca, arose. The former are famous for their great exquisite embroidered mantles, the latter for their beautiful pottery vessels painted in polychrome colours. Other less-known peoples occupied the central coast. Less is known of the highland peoples of the period, but there must have been dozens of groups of slightly variant cultures and of a grade of civilization approaching that of the coastal peoples.

Tiahuanaco.—Probably early in the second half of the 1st millennium A.D. there arose the first of the great highland cultures. Its most important site, though probably not its actual centre, was at Tiahuanaco near Lake Titicaca in present Bolivia, an enormous, obviously ceremonial site with hundreds of great megalithic carved stones and monuments. The Tiahuanaco art style is very

characteristic, and its influence spread all over Peru. It was probably the result of the spread of a religious cult, not a conquering megalithic empire as was once believed. This period throughout much of Peru seems to have been one of unrest, with increasing urbanization, social stratification and militarism.

Chimú.—In the last few centuries before the rise of Inca power one civilization is outstanding, that of the Chimú of the northern coast of Peru. It resembled the Inca on a smaller scale, with one great capital city, Chan Chan (*q.v.*), a large domain (probably achieved by conquest), a highly developed governmental system and social stratification from the humble farmer to the divine "king." The population was probably dense and largely urbanized, agriculture was carried to its ultimate limit, and craftsmanship was perfected. Handicrafts, however, were somewhat standardized, with quantity production. On a lesser scale, this was probably the pattern for most of Peru at this period, though the local cultures elsewhere are less well known. On the southern coast the successors of the Nazca people are known as the Ica.

The capital, Chan Chan, not far from Trujillo, now utterly deserted and uninhabitable for lack of water, is one of the world's most notable archaeological sites, with six to ten square miles of rectangular blocks and streets, great walls, reservoirs and pyramid temples, all built of adobe mud. The aboriginal population must have numbered many thousands.

INCA HISTORY

To most persons the term Andean civilization means the civilization of the Inca, and seldom is a popular concept more true. For practically our entire knowledge of Andean civilization is that of the Inca. In this it is not necessary to depend on archaeology, for the writings of many Spanish chroniclers of the time of the Conquest are extant. Unfortunately, however, there is considerable disagreement among them, especially regarding Inca history. As the Inca has no system of writing, the history was of course oral tradition. The following sketch seems to meet the known facts most logically, but in its earlier stages it differs greatly from other accounts preferred by some earlier historians.

Like the Aztec, the Inca came late upon the historical scene; even their legends do not predate A.D. 1200, with the first emperor. For, like old world peoples, and unlike other aboriginal Americans, the Inca recounted their history by kingly reigns. Most of the accounts agree on 13 emperors:

- | | |
|-------------------------------|---------------------------------------|
| 1. Manco Capac (c. A.D. 1200) | 9. Pachacutec Inca Yupanqui (1438-71) |
| 2. Sinchi Roca | 10. Tupac Inca Yupanqui (1471-93) |
| 3. Lloque Yupanqui | 11. Huayna Capac (1493-1525) |
| 4. Mayta Capac | 12. Huascar (1525-32) |
| 5. Capac Tupanqui | 13. Atahualpa (1532-33) |
| 6. Inca Roca | |
| 7. Yahuar Huacac | |
| 8. Viracocha Inca | |

The first seven emperors were legendary, local and of slight importance; their traditions are full of impossible or improbable events, especially those of the quasi-mythological founder Manco Capac. In this period the Inca were a small tribe, one of many, whose domain did not extend many miles around their capital, Cuzco (*q.v.*). They were almost constantly at war with neighbouring tribes of equal importance.

The incredibly rapid expansion of the Inca empire began with Viracocha's son Pachacutec (1438-71), one of the great conquerors, and one of the great men, of history. Also with his accession in 1438 reliable history began, almost all the chroniclers being in practical agreement. Pachacutec was called by Sir Clements Markham "the greatest man that the aboriginal race of America has produced." He and his son Tupac Inca may be aptly compared to Philip and Alexander of Macedon. Pachacutec was evidently a great civic planner as well; tradition ascribes to him the city plan of Cuzco as well as the erection of many of the massive masonry buildings that still awe the visitor to this ancient capital.

The sudden great expansion of the Inca empire was one of the most extraordinary events of history. It covered a little less than a century from the accession of Pachacutec in 1438 to the conquest by Francisco Pizarro (*q.v.*) in 1532, and most of it was apparently accomplished by Pachacutec and Tupac Inca in the

30 years between 1463 and 1493. At its maximum the empire extended from the present Colombia-Ecuador border to central Chile, a coastal distance of over 2,500 mi., encompassing approximately 380,000 sq. mi., about equal in area to France, Belgium, the Netherlands, Luxembourg, Switzerland and Italy combined. Inca expansion, like the other great conquests of history, was motivated by the thirst for power and aggrandizement.

First the Aymara-speaking rivals in the region of Lake Titicaca, the Colla and Lupaca, were defeated, and then the Chanca to the west; the latter attacked and nearly captured Cuzco. After that there was little effective resistance. First the peoples to the north were subjugated as far as Quito, Ecuador, including the powerful and cultured "(kingdom" of Chimú on the northern coast of Peru. Tupac Inca then took over his father's role and turned southward, conquering all northern Chile as far as the Maule river, the southernmost limit of the empire. His son, Huayna Capac (1493-1525), continued conquests in Ecuador to the Ancasmayo river, the present border between Ecuador and Colombia. The difficulties of transport for such great distances being so great, it is doubtful that the empire could have been expanded farther.

The conquest of the great empire by Pizarro and 180 Spaniards is one of the most amazing events of history. Huayna Capac's two sons, Huascar and Atahualpa, had quarreled and fought over the throne, and Huascar was taken prisoner. Pizarro captured and executed Xthualpa, but not before the latter had ordered Huascar to be killed. So ended Inca rule. So well ordered was Inca authority that Pizarro stepped into Atahualpa's shoes! gave orders in his place, and the routine of government went on as before. The story has been well told by William H. Prescott and others.

INCA CULTURE

The basis of Inca culture was agriculture, including maize, white and sneet potatoes, squash, tomato, peanuts, chili peppers, coca, manioc and cotton; almost all of these were then unknown in Europe. Guinea pigs and ducks were raised and eaten; llamas and alpacas were used as beasts of burden and for their wool but rarely for food. Clothing was made of woven woolen and cotton cloth. Dwelling houses were of stone or adobe mud. Practically every man was a farmer, producing his own food and clothing.

The empire was a "welfare state" with complete regimentation. No one starved but there was little initiative; no one changed his location or work to improve his lot. The land was public and apportioned annually to families in relation to their size. It was divided into three classes, aith the product for the state, for the church or for the people, though the latter nere required to cultivate for all. The harvests of state lands went into storehouses

for the use of the nobility. for the army and men engaged in other public service, and for the people in time of crop failure or other calamity. Llamas were also mainly the property of the state. In lieu of taxes every man was periodically called to service in the army or on public works such as building roads or temples, or mining; this service was known as *mita*.

Craftsmen were also government employees, their products going to the nobility and the priests. Others exempted from *mita* service were the *yanacuna*, superior boys selected to be permanent servants and aids to the emperor and the nobility. Beautiful girls were also chosen at a youthful age and taken to Cuzco for training as concubines of the emperor and nobles or as "Virgins of the Sun," living in a convent and weaving the clothing of the emperor, nobles and priests.

The emperor or "Inca" was divine, a descendant of the Sun, and enjoyed maximum privileges. He had a large seraglio and many descendants; most emperors married their sisters. The emperor's word was law, but, bound by custom, he was never a tyrant. His relatives formed a large body of nobility who were placed in positions of authority, especially over conquered lands. Beneath them were minor officers known as *curaca*, and so on down to foremen supervising ten households.

Religion was highly organized, with a numerous priesthood and many temples to the Sun. The priests conducted elaborate ceremonies, often lasting for many days, performed sacrifices, made divinations, consulted oracles and heard confessions. Sacrifices were usually of llamas; human sacrifice was rare. in contrast to the practice of the Aztec. The ceremonies were held at regular times, with one major one each month. There were hundreds of sacred places of various grades of sanctity, known as huacas. The great creator god, Viracocha, was little worshiped; the Inca adored primarily the Sun, with many subsidiary deities of various attributes.

Medicine and surgery were rather highly developed, and skulls were frequently trephined, whether to relieve fractures or to release demons is not clear. The Inca, like all American civilizations except the Maya, had no system of writing, and all knowledge and lore were orally transmitted. However, numerical records were kept on knotted cords called quipu, which were used primarily for such purposes as censuses but could be adapted by a trained *quipucamayoc* as mnemonic aids for almost anything.

Especially in later years, war was a state policy. All men were liable for service, and the Inca armies were large, well equipped and well trained. Like all ancient armies, they fought mainly hand to hand with clubs, axes and spears, plus the sling for short range. Their ability to conduct campaigns at great distances was due primarily to the system of roads with storehouses of food and equip-

ment located at short intervals. As soon as the conflict ceased, conquered peoples were well treated, given Inca overlords, and most of them probably found their economic condition bettered. Intransigent groups were moved en masse to regions closer to Cuzco and replaced by more docile people; the latter were known as *mitimae*. Often some men from prominent families among conquered tribes were taken to Cuzco as hostages.

Works of engineering and architecture were outstanding. Roads were made from Cuzco to all parts of the empire, and on them relay runners (*chasqui*) were stationed at short distances to carry messages and packages quickly. Suspension bridges were built over small canyons, hillside terraces were constructed to increase agricultural production, long irrigation canals were built and immense fortresses were erected. Great edifices were built of massive and perfectly tooled masonry, many of which still remain in Cuzco. The stones brought to and erected in the fortress of Sacsahuaman at Cuzco are incredibly large.

Though the Inca did not excel some of their more ancient predecessors in handicraft, the Peruvians did admirable work in copper, silver, gold, pottery and especially textiles. Some of their weaving has never been surpassed for fineness and beauty, and they knew practically every technique known to the modern textile manufacturer. All textiles were woven by women on small backstrap looms.

ANDEIRO, JOÃO FERNANDES, COUNT OF OURÉM (d. 1383), a statesman in the service of Portugal, prominent in that country's negotiations with England. A Galician by birth, he supported the claim of Ferdinand I of Portugal to the throne of Castile after the murder of Pedro I of Castile by his bastard brother Henry (who then became king as Henry II) in 1369. Portuguese military reverses obliged Andeiro to seek refuge in England in 1371, whereupon he supported John of Gaunt, duke of Lancaster, as candidate to the throne of Castile. He acted as intermediary between the English and Portuguese courts during the treaty negotiations in 1372 and 1373, and when Anglo-Portuguese relations were resumed in 1380. He returned to Portugal in 1381 with the English naval squadron under Edmund of Langley (afterward duke of York) and was made count of Ourém. Hated for his part in arranging the marriage of Ferdinand's daughter Beatriz with John I of Castile, and for his own scandalous liaison with Ferdinand's wife, Leonor, Andeiro was murdered by the mestre de Aviz (later John I of Portugal) on Dec. 6, 1383. (V. R. R.)

ANDERMATT, a summer and winter resort in Uri canton, Switz., is situated 4,760 ft. high in the Alps below the Gurschenstock (9,523 ft.) and above the St. Gotthard tunnel, 111 km. (69 mi.) by road south of Zurich. Pop. (1950) 1,231. Wooden snow-deflectors protect the town from avalanches. The Schollenen railway connects it with the St. Gotthard railway far below. The road from Lucerne and Zurich to Italy crosses the road from Lake Geneva to the Engadine there. Andermatt is also an important military station. St. Columban's church is mentioned in 712 and Ursern, or Andermatt, in 1309, but it remained unimportant until the opening of the St. Gotthard tunnel in 1882. (L. E. M.)

ANDERS, WLADYSŁAW (1892–), Polish army general, after 1945 a leader of the Poles in exile, was born on Aug. 11, 1892, at Blonie, near Warsaw, the son of a land agent. From 1911 he studied at the Technical college of Riga in Latvia (then part of Russia). In World War I he served in a Russian cavalry regiment, but after the Communist Revolution of Nov. 1917 he joined the Polish army corps in Belorussia. Appointed chief of staff of the Polish army in Poznan, he fought the Red army on the Polish eastern front (1919–20). In 1922–24 he studied at the Paris École Supérieure de Guerre. In World War II he fought the Germans and the Russians in Poland in Sept. 1939 and, severely wounded (for the eighth time), was captured by the Russians. He was confined at the Lubianka prison in Moscow. Released in Aug.

1941, under the Polish-Soviet agreement, he was appointed commander in chief of the Polish army to be formed of prisoners of war and deportees in the U.S.S.R. Finding that he could not organize an independent Polish army in the U.S.S.R., he suggested the transfer of his Polish soldiers to the middle east. As Winston Churchill was asking Stalin for the same, 115,000 Poles left the U.S.S.R. in the summer of 1942 for Iran and Iraq. In Italy in 1944-45 the 2nd Polish army corps, under Anders, fought alongside the British 8th army, captured Monte Cassino, took a major part in liberating the Adriatic coast and completed its campaign at Bologna. During the last months of World War II Anders was acting commander in chief of the Polish forces in the west. Being opposed to Communism, after the war he remained in Great Britain, where Polish forces were organized into the Polish Re-settlement corps. On Sept. 26, 1946, the Warsaw Communist government deprived Anders and 75 senior officers of Polish citizenship. In 1954 the Polish national council in exile elected Anders a member of the Council of Three, a leading organ of Poles abroad. Anders received many Polish and foreign honours. His writings include *An Army in Exile* (1949) and *Hitler's Defeat in Russia* (1953).

ANDERSEN, HANS CHRISTIAN (1805-1875), Danish writer of world-famous stories. He was born in the slums of Odense, on the island of Fyn (Fünen), on April 2, 1805, the son of a poor shoemaker and his superstitious and almost illiterate wife. His grandfather was insane, and his grandmother, a pathological liar, spoiled him. He was a sensitive child, and preferred daydreaming, playing with the puppet theatre made for him by his father and making up stories to playing with other children and learning a trade. His father volunteered for service in the Napoleonic Wars, and, returning broken in health and spirit, died in 1816. His mother married again, and Andersen, after apprenticeship to various trades, where he suffered from the crude jokes of his companions, determined to go to Copenhagen "in order to become famous." He set off in 1819, with very little money, centring all his ambitions on the Royal theatre, where he hoped to win fame as a singer, dancer, actor or even playwright. He succeeded in getting a job as a supernumerary there, but suffered great hardship and only survived because some of the best-known writers and composers of the period became his benefactors. When his voice broke, and he was dismissed from the Royal theatre, he tried writing tragedies, which were rejected as "completely unsuitable for performance." Jonas Collin, one of the directors of the theatre, then took an interest in him and raised money to send him, in 1822 at the age of 17, to the grammar school at Slagelse. The choice was unfortunate, for Simon Meisling, the headmaster, made Andersen the butt of his humour and reduced him to the brink of despair. In 1826 Meisling moved to Elsinore, taking Andersen with him, but he and his wife made his life so miserable that Collin arranged private tuition for him so that by 1828 he was able to enter Copenhagen university.

Andersen's first book, *Ungdoms-Forsøg* ("Youthful Attempts"), was published in 1822 under the pen name Villiam Christian Walter (his own name plus those of Shakespeare and Scott), and his first poem, "Det døende Barn" ("The Dying Child"), was printed in 1827. In 1829 came his first important work, *Fodreise fra Holmens Canal til Østpynten af Amager*, an imaginative arabesque in the style of E. T. A. Hoffman (*q.v.*), describing a journey on foot through the streets of Copenhagen. It brought him his first real fame, and in the same year his first play was performed at the Royal theatre. In 1831 he traveled in Germany and on return wrote the first of many travel sketches. For the next two years he tried writing poems, librettos, dramatic translations and original plays, but they were not well received and in 1833 he sought inspiration in Italy. The literary results were an unsuccessful dramatic poem, *Agnete og Havmanden* ("Agnete and the Mermaid"), and his first and most successful novel, *Improvisatoren* (1835), autobiographical in theme but in an Italian setting. The German and English translations (The *Improvvisatore*, 1845) mark the beginning of his world fame. Other autobiographical novels followed: *O.T.* (1836; Eng. trans. 1845); *Kun en Spillemand* (1837; Eng. trans. *Only a Fiddler*, 1845); and, later, *De to Baronesser* (1848;

Eng. trans. *The Two Baronesses*, 1848); *At være eller ikke være* (1857; Eng. trans. *To Be, or Not to Be*, 1857); and *Lykke-Peer* (1870; Eng. trans. *Lucky Peer*, 1871).

While seeing *Improvisatoren* through the press, Andersen began to write his first four tales for children, *Eventyr, fortalte for Børn* ("The Tinderbox," "Little Claus and Big Claus," "The Princess and the Pea," "Little Ida's Flowers"), published in the spring of 1835. But neither he nor his Danish critics realized that he had entered the field in which he was to become the supreme master. Two further instalments of stories made up the first volume of *Eventyr* (1837); a second volume was completed in 1842: to these was added *Billedbog uden Billeder* (1840; Eng. trans. *A Picture-Book Without Pictures*, 1847). He continued to write fairy tales (*Eventyr*) and stories (*Historier*) (his own distinction between tales with and without supernatural elements) until 1872, writing 168 altogether. Many have become classics all over the world, being translated into more than 80 languages. Their perfection as works of art, their appeal to both children and grownups (for Andersen is never afraid of introducing feelings and ideas beyond a child's immediate comprehension, yet never loses touch with the child mind), their imaginative power and their roots in the folk legends he had heard in his own childhood and in the happenings he had himself known and observed have made them immortal.

In many of Andersen's tales inanimate things come alive, a darned needle or a shirt collar talk and behave like human beings, thus exposing and ridiculing some form of human weakness. In others, trees, plants and animals are endowed with human feelings; the fir tree, the daisy and the inhabitants of the farmyard are strange reflections of the human world. The fairy-tale world, too, acquires an oddly topical resemblance to our own world; thus both "The Swineherd and the Princess" and "The Nightingale" are aimed at those who prefer cheap imitation to genuine art, and "The Emperor's New Clothes" possesses a humour and satire that retains its topicality in every country. Many of Andersen's tales reveal an optimistic belief in the victory of goodness and beauty and harmony (*e.g.*, "The Snow Queen"), while others are deeply pessimistic, depicting the ultimate victory of the imitator and the parasite (*e.g.*, "The Shadow"). In the majority of his stories the autobiographical element is clearly distinguishable: Andersen himself is identified with the ugly duckling, the little mermaid, the fir tree, the soldier in "The Tinderbox" and the storyteller in "The Flying Trunk," etc., and yet his stories are all about universal human problems—that of being an outsider or outcast, that of lacking the capability to enjoy the moment of happiness, or of being predestined either to happiness or to a nostalgic longing for a lost happiness. As a stylist Andersen was an innovator who courageously used the idioms and constructions of the spoken language, thus deliberately breaking with the literary traditions of his time.

From 1840 to 1857 Andersen was constantly traveling, visiting the other Scandinavian countries, Italy, always the land of his dreams, and also Spain, Portugal, Greece, Asia Minor and Africa. His impressions are recorded in a number of travel books (*e.g.*, *En Digters Bazar*, 1842, Eng. trans. *A Poet's Bazaar*, 1846; *I Sverrig*, 1851, Eng. trans. *Pictures of Sweden*, 1852; and *I Spanien*, 1863, Eng. trans. *In Spain*, 1864), and in his diaries and pen drawings. In Germany and France he mixed with many leading writers and artists, and on his first visit to England (1847) he was lionized by society, and met many distinguished writers, among them Charles Dickens, with whom he stayed for five weeks at his home at Gad's Hill in 1857. In Denmark he was often the guest of members of the nobility, but he regarded the house of Jonas Collin as his real home, though he suffered from never feeling entirely accepted by the family and his friendship with Edvard, the eldest son, was rent by violent storms. He remained a bachelor, though he fell deeply in love several times, notably with Jenny Lind, the Swedish singer, whom he met in 1843, and who became a close friend, inspiring some of his best stories. Much of his imaginative writing centres round himself, and he wrote three autobiographies: one private in 1832 (published in 1926), one for his German publisher (1847; Eng. trans. 1847) and one in Danish, *Mit Livs Eventyr* (1855; Eng. trans. 1871; a continuation was

published posthumously in 1877). During his last years his closest friends were the families of M. R. Henriques and M. G. Melchior. He died at Melchior's house in Copenhagen on Aug. 4, 1875.

Few people are so intimately known to posterity as Andersen. He rarely destroyed anything connected with himself and his diaries (mainly unpublished) and thousands of letters reveal a man both vain and humble, sensitive to criticism, quick-witted, a keen observer and a true artist. The ingenious simplicity of his stories is appreciated all over the world, but his humour, vivid, racy style and mastery of form are often lost in translation.

BIBLIOGRAPHY.—The most important Danish editions are *Samlede Værker*, 15 vol. (1876–80); *Eventyr*, a critical ed., 5 vol. (1919); *Andersens Romaner og Rejsekildringer*, 7 vol. (1943–44); *Hundrede Digte* (1948); and *Mit Livs Eventyr. Revideret Tekstudgave*, 2 vol. (1951). Among the many editions of letters from and to Andersen the most important are those published by C. S. A. Bille and N. Bøgh (*Breve til Andersen*, 1877; *Breve fra Andersen*, 1878) and by H. Topsøe-Jensen (including Andersen's correspondence with Jonas Collin and others, 3 vol., 1945–48; with Edvard and Henriette Collin, 5 vol., 1933–37; and with Henriette Wulff, 3 vol., 1959–60). *Anderseniana* (1933 *et seq.*) contains many valuable essays and documents. For English editions, see E. Bredsdorff, *Danish Literature in English Translation*, with a supplement on Andersen (1950). The best translations are by R. P. Keigwin, *Fairy Tales*, world edition, 4 vol. (1950–60), Paul Leyssac, *Its Perfectly True, and Other Stories* (1938), R. Spink, *Fairy Tales and Stories* (1960), and Jean Hersholt, *The Complete Andersen*, 6 vol. (1952). For biography and criticism, see G. Brandes, *Kritiker og Portrætter* (1870); E. Collin, *Andersen og det Collinske Hus* (1882; new ed. 1929); H. Brix, *Andersen og hans Eventyr* (1907); H. Helweg, H. C. Andersen: *En psykiatrisk studie* (1927); P. V. Rubow, H. C. Reumert, *Aizdersen som han var* (1925; Eng. trans. 1927); S. Toksvig, *The Life of Andersen* (1940); C. Burnett, *The Shoemaker's Son* (1943); Rumer Godden, H. C. Andersen (1955). (E. L. Bf.)

ANDERSEN, HANS NIELS (1852–1937), Danish shipowner and merchant who founded one of that country's most far-reaching and influential business enterprises, was born at Nakskov, in poor circumstances, on Sept. 10, 1852. He went to sea and in 1884, having gained experience by trading with the east, he founded the business of Andersen and company at Bangkok, opening in 1894 a branch house in Copenhagen. In 1897 he established at Copenhagen Det Ostasiatiske Kompagni (the East Asiatic company), which soon became the largest commercial enterprise in Denmark and one of the few Danish undertakings of world-wide renown. In 1912 at Copenhagen the company launched the first large motorship. Andersen rendered important services to his country during World War I. He died on Dec. 30, 1937. (B. Ko.)

ANDERSON, ALEXANDER (1775–1870), U.S. engraver, the first to make wood engravings in the United States, was born in New York city on April 21, 1775. At an early age he made his first attempts at metal engraving, fashioning his own tools and plates, but in 1789, in compliance with his father's wish, he began the study of medicine, graduating from Columbia in 1796. In 1793, having seen wood engravings by Thomas Bewick, he obtained boxwood blocks, made tools himself and began the practice of that technique. In 1798 his entire family died from yellow fever, and this caused him to abandon his career as a physician to devote himself entirely to engraving, finally working exclusively in wood engraving.

Anderson illustrated many books and produced an enormous volume of work, being active even during the last years of his long life. He was also skilled as a painter of miniatures and portraits. Best known of his book illustrations are those for Webster's *Elementary Spelling Book*, engravings for the plays of Shakespeare and about 300 cuts after the works of Thomas Bewick. He died in Jersey City, N.J., on Jan. 17, 1870.

See F. M. Burr, *Life and Works of Alexander Anderson* (1896); J. Lossing, "Memorial of Alexander Anderson" (1872) in *Bibliographical Society of America Papers* 45, no. 4 (1951). (H. Es.)

ANDERSON, CARL DAVID (1905–), U.S. physicist, received the 1936 Nobel prize in physics jointly for discovering the positron (1932). He participated in discovery of the meson (1937) and became a leading investigator of the properties of

other new cosmic ray particles. He pioneered in magnetic cloud chamber studies of cosmic rays in 1930 with Robert A. Millikan (qv). Born in New York on Sept. 3, 1905, he received his Ph.D. (1930) at the California Institute of Technology where he remained, becoming professor of physics in 1939. (L. A. D.)

ANDERSON, ELIZABETH GARRETT (1836–1917), English physician and pioneer in the professional education of Englishwomen, daughter of Newson Garrett, of Aldeburgh, Suffolk, was born in 1836. She was educated at home and at a private school. In 1860 she resolved to study medicine, an unheard-of procedure for a woman in those days. Miss Garrett managed to obtain some irregular instruction at the Middlesex hospital, London, but was refused admission as a full student there and at many other schools. She studied anatomy privately at the London hospital, as well as with some of the professors. She had difficulty in gaining a qualifying diploma to practise medicine; but in the end the Society of Apothecaries, London, allowed her to enter for the licence of Apothecaries' hall, which she obtained in 1865. In 1866 she was appointed general medical attendant to St. Mary's dispensary, a London institution started to enable poor women to obtain medical help from qualified practitioners of their own sex.

The dispensary soon developed into the New Hospital for Women. In 1870 she obtained the Paris degree of M.D. In 1871 she married, but did not give up practice. She worked steadily at the development of the New hospital, and also from 1874 at the creation of a school of medicine for women in London. Both the New hospital and London university have since been suitably housed and equipped; the New hospital is now the Elizabeth Garrett Anderson hospital. Dr. Anderson was elected president of the East Anglian branch of the British Medical association in 1897 and in 1908 mayor (the first woman) of Aldeburgh. She died at Aldeburgh on Dec. 17, 1917. Her daughter, Louisa Garrett Anderson (1873–1943), took an active part in the suffrage movement. During World War I she was joint organizer of the women's hospital corps and (1915–18) chief surgeon of the military hospital at Endell street.

ANDERSON, MARIAN (1902–), U.S. singer, one of the foremost contraltos of her time, was born at Philadelphia, Pa., Feb. 17, 1902, of poor Negro parents. Her early musical training, in the choir of the Union Baptist church, which she joined when she was six, was followed by lessons with Giuseppe Boghetti, who in 1925 entered her for a contest for an appearance with the New York Philharmonic orchestra. She was placed first among 300 competitors. She had already undertaken several concert tours, and, despite struggles against poverty and racial discrimination, was beginning to make a name for herself. Real success came in 1933 when she went to Europe. She returned to New York in 1935, and succeeded in achieving at home the position due her voice. She was asked to sing at the White House, and also at the Metropolitan Opera. Her work for the people of her own race and her warmth of personality added to appreciation of her vocal and interpretative powers, and she was made a delegate to the United Nations. As a singer, her outstanding characteristics are wide range, richness and purity of tone and mastery of a variety of styles.

See her autobiography *My Lord, What a Morning* (1957); K. Vehanen (her accompanist), *M. Anderson: A Portrait* (1941).

ANDERSON, MARY (1859–1940), U.S. actress, was born in Sacramento, Calif., on July 28, 1859. At the age of 15, with the advice of the actress Charlotte Cushman, she began to study for the stage, making her first appearance at the age of 16 in Louisville, Ky., as Juliet in 1875. Her remarkable beauty created an immediate success, and she played in all the large cities of the United States with increasing popularity. Between 1883 and 1889 she had several seasons in London, and was the Rosalind in the performance of *As You Like It* which opened the Shakespeare Memorial theatre at Stratford-on-Avon. Among her chief parts

were Galatea (in W. S. Gilbert's *Pygmalion and Galatea*), Clarice (in his *Comedy and Tragedy*, written for her), Hermione and Perdita (in Shakespeare's *The Winter's Tale*), Lady Macbeth, and Ion (in Noon Talfourd's *Ion*). In 1889 she retired from the stage and in 1890 married a British subject, Antonio de Navarro, and settled in England. She died there on May 29, 1940.

See William Winter, *Stage Life of Mary Anderson* (1886), and her own *A Few Memories* (1896).

ANDERSON, MAXWELL (1888–1959), U.S. playwright who achieved success in many dramatic forms. Born in Atlantic, Pa., on Dec. 13, 1888, Anderson was educated at the University of North Dakota (Grand Forks) and Stanford university (California), taught English for a time and became a journalist. He first made his mark in the theatre with the pungent World War I comedy *What Price Glory?* (1924), a collaboration with Laurence Stallings. But Anderson was not content with realism and prose drama and became equally successful in the field of poetic drama, especially with his historical plays *Elizabeth the Queen* (1930), *Mary of Scotland* (1933) and *Anne of the Thousand Days* (1947). Even the success of his Pulitzer prize-winning satire *Both Your Houses* (1933) did not deflect him from his purpose, and he reached the peak of his career with two poetic plays set in his own times, *Winterset* (1935), a tragedy inspired by the Sacco and Vanzetti case of the 1920s, and *High Tor* (1936), a romantic comedy that expressed the author's displeasure with the materialism of the modern world. Collaborating with the composer Kurt Weill, Anderson also invaded the musical theatre with the political satire *Knickerbocker Holiday* (1938) and with *Lost in the Stars* (1949), a dramatization of Alan Paton's South African novel *Cry, the Beloved Country*. He died Feb. 28, 1959. (J. W. G.)

ANDERSON, RICHARD HERON (1821–1879), Confederate general in the American Civil War, was born on Oct. 7, 1821, at Statesburg, S.C. After graduating from West Point in 1842 he saw routine cavalry duty for several years and served with distinction in the Mexican War. At the start of the Civil War he resigned from the U.S. army and entered the Confederate service. Anderson served in the army of northern Virginia from the Peninsula campaign through the battle of Gettysburg as an able and modest brigade and division commander, attaining the rank of major general on July 14, 1862. In the Wilderness campaign, in May 1864, he succeeded to the command of the 1st corps when Longstreet was wounded. After saving Spotsylvania by a brilliant night march, Anderson was given the rank of temporary lieutenant general. He later participated in the defense of Petersburg and Richmond. After the war Anderson became a railroad official in South Carolina and then state phosphate inspector. He died on June 26, 1879, at Beaufort, S.C. (W. W. Ha.)

ANDERSON, ROBERT (1750–1830), Scottish author and critic, whose principal work was his edition of *The Works of the British Poets, With Prefaces Biographical and Critical* (1792–1807). He was born at Carnwath, Lanarkshire, Jan. 7, 1750, and died at Edinburgh, Feb. 20, 1830.

ANDERSON, SHERWOOD (1876–1941), U.S. author, whose *Winesburg, Ohio* strongly influenced the technique of the American short story, was born in Camden, O., Sept. 13, 1876. As a youth in Clyde, O., he attended school intermittently and worked as a newsboy, house painter, farm hand and race-track helper. At 22 he served in Cuba during the Spanish-American War. On his return, he studied for a year at Wittenberg academy, Springfield, O.; then he became a writer of advertising in Chicago and later a paint manufacturer in Ohio. In 1913, dissatisfied with the life of a businessman, he returned to Chicago to write fiction.

Encouraged by Floyd Dell, Theodore Dreiser, Carl Sandburg and Ben Hecht, leaders of a Chicago literary movement, Anderson began to contribute experimental verse and short fiction to the *Little Review*, the *Masses*, the *Seven Arts* and *Poetry*. Dell and Dreiser arranged the publication of his first two novels, *Windy McPherson's Son* (1916; rev., 1921) and *Marching Men* (1917), both written while he was still a manufacturer. His reputation as an author was made by *Winesburg, Ohio* (1919), his first mature book; this volume of interrelated short sketches and the short stories in *The Triumph of the Egg* (1921), *Horses*

and *Men* (1923) and *Death in the Woods* (1933) comprised his best work. Anderson's stories, simply told, presented sympathetically the lives of middle western townspeople who were warped into inarticulate grotesques by isolation and frustration of love and creativity. His novel *Poor White* (1920) studied one cause of these psychological ills—the industrialization of the small town.

In 1921 Anderson was awarded the first Dial prize of \$2,000. His later books included *Many Marriages* (1923) and *Dark Laughter* (1925), highly subjective psychological novels; *A Story Teller's Story* (1924) and *Tar: a Midwest Childhood* (1926), autobiographical sketches; *Hello Towns* (1929); *Perhaps Women* (1931) and *Puzzled America* (1935), essays on American industrial conditions; and the posthumous *Memoirs* (1942) and *Letters* (1953).

In 1925 he moved to Marion, Va., where he published both of the town's newspapers, one Democratic, the other Republican. He died March 8, 1941, in Colón, Pan., while on a tour of South America.

See James Schevill, *Sherwood Anderson: His Life and Work* (1951); Irving Howe, *Sherwood Anderson* (1951). (W. L. Ps.)

ANDERSON, a city of Indiana, U.S., 35 mi. N.E. of Indianapolis, in a rich corn- and wheat-producing region; seat of Madison county. Its importance as a manufacturing centre dates from the discovery of natural gas in 1887; the automobile industry was most responsible for the city's later growth; a wide range of parts and accessories are produced there. (For comparative population figures see table in INDIANA: *Population*.)

Platted in 1823 by John Berry on the site of a Delaware Indian village, Anderson was named for a Delaware subchief, Kikthawenund, whose English name was Captain Anderson. First known as Anderson's Town, it was incorporated in 1838. Later it surrendered the incorporation and remained a village until 1853, when it was reincorporated as the town of Anderson; in 1865 it was incorporated as a city.

The Anderson Bible Training school was founded there in 1917 by the Church of God. In 1929 it became a coeducational liberal arts college and was renamed Anderson College and Theological seminary. Mounds State park is 3 mi. E. of Anderson and contains the largest single known earthwork in Indiana as well as several other mounds erected by prehistoric inhabitants. See MOUND BUILDERS. (E. R. Bo.)

ANDERSON, a city in northwestern South Carolina, U.S., in the foothills of the Blue Ridge mountains; the seat of Anderson county. The city and county were named for a local Revolutionary War hero, Gen. Robert Anderson. (For comparative population figures see table in SOUTH CAROLINA: *Population*.)

Anderson is one of the largest manufacturing areas in the state, with a large and long-established textile industry, as well as newer industries including Fiberglas, metals, chemicals, plastics and sewing machines. After mid-20th century, cotton growing, once the county's chief agricultural occupation, was yielding to the cultivation of Turkish tobacco, grain, trees, legumes, vegetables and fruits and to livestock raising.

Although the area was settled by the end of the 18th century, on what had been Cherokee Indian land, the county was not created until 1826; the city was chartered the same year and was incorporated in 1882. The original settlers were, in large part, descendants of Scotch-Irish migrants from Virginia and Pennsylvania. Anderson has been called the "electric city" because of early (1898) long-distance transmission of power from the Seneca river.

The history of Anderson junior college began in 1848 when it was first opened as the Johnson Female seminary. Clemson Agricultural college is located at Clemson, 17 mi. N.W. of Anderson. Near Anderson, on the Savannah river, is the \$100,000,000 hydroelectric Hartwell dam. (E. M. L.)

ANDERSONVILLE, a village of Sumter county, Ga., U.S., on the Central of Georgia railway, about 60 mi. S.W. of Macon, was the site of a Confederate military prison from Feb. 1864 to May 1865. In the summer of 1863 the federal authorities ended an agreement under which captives were exchanged; the increased number of prisoners of war confined in Richmond constituted a danger to the Confederacy and seriously pressed upon the food

supply. In Nov. 1863, under orders of Gen. J. H. Winder, Capt. W. S. Winder selected the Andersonville site and began to construct a stockade of 16½ ac. (later enlarged to 26 ac.). Pressure in Richmond led to prisoners being sent to Andersonville before barracks and other facilities were constructed. Drainage was poor and the water supply was inadequate. Prisoners received poor and uncooked food. Many were diseased and fatigued before arrival and disease was rampant in the prison. In six months, 42,686 cases of diseased and wounded prisoners received treatment from the inadequate medical staff and hospital. Nearly 13,000 prisoners died. After Sept. 1864 the prison was largely a hospital. Conditions in Andersonville were utilized as propaganda material in the South, where Secretary of War Edwin M. Stanton ordered retaliation on Confederates held in Union prisons.

After the war, Capt. Henry Wirz, commander of the prison, was tried by a military commission and on Nov. 10, 1865, he was hanged. The site of the prison has been preserved as a federal park.

Partisan accounts of Andersonville abound. Hundreds of prisoners wrote their reminiscences. Conflicting views are to be found in J. McElroy, *Andersonville* (1879) and R. R. Stephenson, *The Southern Side* (1876). A later analysis is in W. B. Hesseltine, *Civil War Prisons* (1930). (W. B. HE.)

ANDES or **LOS ANDES**, the great mountain system which extends the full length of the western part of South America. It stretches from Tierra del Fuego at the southern tip of the continent to the Caribbean coast approximately 4,000 mi. to the north. Many of its peaks are more than 22,000 ft. high, and Aconcagua, north of Santiago (Chile), is the highest peak in the western hemisphere. The origin of the name is obscure. It has been suggested that it is derived from *anti*, the Quechua word for "east;" a name applied by the Quechua Indians to the range east of Cuzco. Other suggested origins of the name are the Quechua words *antasya*, "region of metal," or *anta*, "copper." The term "Cordillera of the Andes" is sometimes erroneously used as a name for the whole Andean system, and in South American nomenclature is often applied to the most important range of a given section of the system. From its original form, "Las Cordilleras de los Andes," a term applied by the Spanish conquerors to the series of parallel ranges of which the Andes appeared to be composed, is derived the present widespread use of the word "cordillera," meaning an extensive mountain range or system of ranges.

The Andes are narrowest at the southern end and broadest in the central or Bolivian section and at their northern end, where they divide into four distinct ranges. In Tierra del Fuego their trend is nearly east and west; on the mainland the trend is north and south as far north as latitude 18° S., where, in one of its two broadest sections, the system turns westward to form an almost semicircular curve convex to the west and follows the configuration of the west coast as far north as southern Colombia. There it spreads out into three distinct ranges, the easternmost of which again divides into two ranges, one of which forms the northern section of the Venezuela-Colombia boundary while the other crosses the boundary south of Lake Maracaibo and extends north-eastward toward the Caribbean sea.

The following sections of this article describe the main ranges of the Andes—from the Patagonian Andes in the south to the Andes of Venezuela in the north—the geology of the region, climate, minerals, population, transportation and famous mountaineering expeditions.

The Patagonian Andes.—Until recently the Andean system was pictured as a great mountain barrier, with a well-defined crest line of lofty peaks which coincided with the water divide between the Pacific and Atlantic drainage systems and effectively separated them from each other. As late as 1881, when the governments of Chile and the Argentine republic signed a treaty in which their common boundary was defined, they described it as following the highest crest of the Andes, which formed the water divide between the Atlantic and Pacific oceans. When the demarcation of this boundary was undertaken it was found that throughout the greater part of the cordillera the topography did not correspond to the conception of it on which the treaty was based. South of

latitude 38° S. the Andes were found to be not a simple ridge but a broad zone, from 25 to 40 mi. wide, of mountain chains and narrow valleys. The higher summits shift back and forth from one chain to another and do not, except in a general way, mark the water divide. These summits rise above a broad base, represented by high valleys and broad passes, to an average elevation of about 6,500 ft. Few are lower than this average altitude, and some individual peaks exceed 7,500 ft. Those that have a fairly uniform altitude have been carved by erosion from the older Andean rocks of the plateaulike base. The higher peaks are volcanic cones built up on the plateau. The eastern side of this part of the Andes is divided into two sections—a northern from Lake Aluminé to Lake Nahuel Huapi, and a southern from Lake Nahuel Huapi southward, which includes the island of Tierra del Fuego. Both sections are characterized by a succession of glacier-fed lakes which stretch back like fiords into the heart of the cordillera, and by valleys cut from west to east across the Patagonian tableland through which, at one time, the lakes drained toward the Atlantic.

Settlement of the boundary came by arbitration in 1902 and was commemorated by erection of the famous statue known as "Christ of the Andes" near Uspallata Pass. (See ARGENTINA; CHILE.)

In the northern section high transverse ridges separate the lake basins and more or less effectively obstruct passage from one to another. These ridges connect the mountain zone with the Patagonian tableland, and all but one of the streams of this section rise in the westernmost range and flow eastward to the Collón Curá and Limay rivers. Lake Lácár now discharges across the western range to the Chilean lake region, but there is evidence that it, too, once drained to the Atlantic.

In the southern section the tableland is separated from the cordillera by a longitudinal depression which marks the line of contact between the folded cordillera and the flat tableland. It extends southward from the low pass between Lake Nahuel Huapi and Lake Bariloche and is continued beyond the mainland by the Canal Ancho of the Strait of Magellan, Useless bay, and White-side and Admiralty sounds. The continuity of this depression has, however, been frequently exaggerated. It is really divided into several compartments by masses of different kinds of rocks and by granite ridges. Between Lake Argentina and Lake Buenos Aires it is interrupted by the tableland which rises to a height of 5,000 ft. and butts against the cordillera. Similarly, between Lake Buenos Aires and Lake General Paz there is no great difference in level between the tableland and the depression.

lost of the lake basins there, as well as in the northern section, are continued eastward across the Patagonian tableland as distinct valleys. This is the case even in the submerged southern end of the depression, where the east end of the strait is a submerged valley on the axis of Otway bay and Useless bay and is continued eastward across northern Tierra del Fuego by the depression which ends in San Sebastián bay. The valleys are now, however, with few exceptions, dead valleys, for the drainage is mostly west to the Pacific by way of narrow canyons in the cordillera and the interoceanic water divide follows the terminal moraines of the old glaciers which confine the lakes on the east.

On the Pacific side of the cordillera a great longitudinal plain extends from the Chacabuco range, by which the basin of the Aconcagua river is enclosed on the south, southward to the Gulf of Ancud. The northern part of this region is narrow and irregular and is cut by ridges into small, almost completely separated valleys, and interrupted by isolated hills. At about latitude 36° S. it widens out to a width of 20 to 40 mi. A line of recent volcanoes begins a little south of Santiago and is aligned on the cordillera to about 35° S., where it gradually departs from the cordillera until in the south it stands well out in the central plain and forms a less continuous but higher chain west of the cordillera proper. The northern part of the plain is filled with recent geological deposits and forms the fertile Vale of Chile. South of latitude 39° S. it is sown with glacial lakes or depressions formerly occupied by lakes. Not only because of the greater precipitation on the west side of the cordillera in the belt of the westerly winds south of 39° S. but also because of the great condensation of moisture caused by the line of volcanoes in front of the cor-

ANDES MOUNTAIN SYSTEM SHOWN IN RELATION TO THE CONTINENT OF SOUTH AMERICA

dillera, the glaciers of the Glacial period advanced much farther from the water divide on the western slope than on the eastern, with the result that the glacial lakes on the Chilean side of the cordillera are at a much lower level than those on the Argentine side, and part of them, as, for instance, Ranco and Llanquihue, lie completely separated from the cordillera.

The cordillera of Patagonia is divided into a series of massifs separated by longitudinal and transverse depressions. Some of these depressions cut completely through the cordillera and are occupied by rivers which drain lakes on the Argentine side, or by fiords which extend through to the Argentine side. Between latitude 41° and 46° S. the altitude of these massifs is from 6,500 to 8,000 ft., only Tronador (11,660 ft.) attaining a higher altitude. Between 46° and 50° the cordillera reaches altitudes of from 10,000 to 13,000 ft. It is lower and broken up between Smith

channel and the Strait of Magellan, but again rises to more than 6,500 ft. on Tierra del Fuego.

South Chilean Andes.—Northward from latitude 39° S. to 30° S. the character of the Andes is greatly simplified. It consists of a double line of crests, the westernmost of which carries the Argentina-Chile boundary. The high valleys between the crests are at an altitude of from 10,000 to 13,000 ft. The passes to the east and west in the northern part are between 13,000 and 15,000 ft. in altitude. South of 31° S. they are somewhat lower. Isolated summits rise from 5,000 to 7,000 ft. above the high valleys, and between 32° and 34° S. include three of the highest peaks of the Andes: Mercedario (22,211 ft.), Aconcagua (22,831 ft.) and Tupungato (22,309 ft.). The interior valleys have a direction slightly oblique to the general trend of the cordillera and corresponding to the direction of the folds. The whole section has effective drainage of normal type. The water divide which the boundary follows shifts back and forth from one ridge to another, and the boundary pillars, which are located, in general, on high passes between head waters, follow a tortuous line. Eruptions from the chain of recent volcanoes which appears a little south of the latitude of Santiago and extends southward on the Pacific side of the main axis of the cordillera to the Gulf of Ancud have greatly complicated the topography of the cordillera by filling up high valleys or damming up lakes.

East of the cordillera in this section a continuous depression extends northward from the Mendoza river for more than 160 mi. between the cordillera and the precordillera (a series of short ranges reaching out into the Argentine plain). The precordillera continues south of the Mendoza river to about latitude 36° S. It attains heights of 13,000 ft. in the latitude of San Juan and 11,000 ft. on the Paramillo plateau above Mendoza. In spite of their narrow width the Andes in this section offer serious obstacles to movement from one side to the other because of their elevation and covering of snow. They have no mineral wealth and the few routes across them, which include the Transandine railway between Santiago and Mendoza, are solely for the purpose of crossing the cordillera and not for exploiting its subsoil. The high valleys furnish some summer pasture and the rivers and lakes afford water for irrigation. Settlements lie not in the mountains but on their border, and the location of the more important of those on the Argentine side has been influenced by the position of the most practicable passes, since it is to cattle and goods trade with Chile that they owe their origin and growth.

The Puna de Atacama.—North of latitude 30° S. the Andes

again lose their simple character. The mountain belt widens and long extensions of it reach out southeastward to the Argentine plain, enclosing in the depressions between them long embayments of the plain. At about the 28th parallel the main range divides into a western and an eastern range, with a belt of very high and extremely cold and desolate country between them (called the Puna de Atacama), made up of mountain chains, isolated peaks, and basins of salt deposits known as salars, arranged along dominating north-south lines. The average height of the basin floors of the Puna is between 11,000 and 13,000 ft., with the interior peaks and ridges rising only from 1,000 to 5,000 ft. higher. The range which forms the western border of the Puna is known as the Cordillera de los Andes or Maritime cordillera and consists chiefly of a line of high volcanoes with lava flows between them. The passes in the Maritime cordillera average about 15,000 ft. while the peaks reach 20,000 to 23,000 ft. In the range that forms the eastern border of the Puna the passes are from 16,500 to 17,000 ft. high, but the peaks average only from 18,000 to 20,000 ft. In contrast with the western cordillera in which the volcanic cones are high and have been built up on a lower basement of lava, the cones of the eastern cordillera are low and have been built up on broad beds of lava. West of the western cordillera is a line of depressions between 3,000 and 4,000 ft. lower than the average level of the Puna and enclosed on the west by the Cordillera Domeyko, which contains a number of salars, among them the Salar de Atacama and the Salar de Punta Negra.

East of the eastern border of the Puna, the Andes of the Argentine provinces of Jujuy, Salta and Tucuman form a broad belt of ridges oriented from north to south and separated by deep depressions. Their altitudes diminish as they extend eastward into the Argentine plains, and their summits, as well as those of the secondary ranges along the main mountains, exhibit an older aspect than their ravined borders. The tops and high upper slopes are covered with grass. The steep headwater slopes and narrow declivities of the ravines, cut into them as the result of recent uplift, are youthful features in contrast to the lawnlike high-level slopes which they are gradually invading.

The Central Andes.—The northern limit of the Puna de Atacama is a transverse range of high snow-capped peaks and ridges at about the 23rd parallel, which separates it from the drainage basin of the Salar de Uyuni. The high plateau continues northward as the altiplano or *altiplanicie* of Bolivia. This altiplano has no outlet to the sea, and is therefore one of the world's great basins of interior drainage. It is about 500 mi. long by 100 mi. wide, and slopes gently from a little under 12,500 ft. at Lake Titicaca to slightly more than 12,100 ft. at Lake Poopo, and a little lower at the Salar de Uyuni. It differs from most interior drainage basins in that it contains a large body of fresh water (Lake Titicaca) and an important river drainage (the Desaguadero river). Lake Titicaca is the highest large body of navigable water in the world and has a length of about 110 mi. It owes its existence to a deep tectonic depression in close proximity to a high snow-capped mountain range (the Cordillera Real) that keeps it supplied with water. Farther south the altiplano becomes more and more like other interior semideserts, for the windward mountains become lower, so that they condense less moisture, and broader, so that the precipitation is more widely distributed. As it flows southward, the Desaguadero river, the outlet of Lake Titicaca, grows smaller and smaller until Lake Poopo, into which it empties, is a shallow pond with only a small overflow to the nearby salt lake or marsh called Coipasa. The altiplano lies between two great tablelands with superimposed peaks and ranges. Its eastern edge is particularly well defined by the sharp rise and straight form of the eastern cordillera. The western edge is less clearly defined because of the volcanic debris that has encroached upon it from the western or Maritime cordillera, forming hilly districts of irregular outline. Between the Salar de Coipasa and the Salar de Uyuni, the altiplano is divided into two interior drainage basins by a line of volcanoes and hills which extend from the western cordillera nearly across to the eastern. North of Lake Titicaca the bordering scarps converge in the Nudo de Vilcanota at about latitude 14° S., and enclose the altiplano on the

north.

The western cordillera descends by relatively smooth slopes to the coastal deserts of Tarapacá and Atacama, famous for their nitrate deposits, and the desert region of southern Peru. In the rare cases in which its streams permanently reach the piedmont, they furnish water to small but important fields of vegetables and alfalfa. Viewed from the west, the cordillera presents, for long distances, a strikingly even skyline, generally the line along which the uplifted peneplain has been warped up to form the highlands, broken only by the summits of the highest volcanoes which stand back toward the altiplano, or, in places, by volcanoes like the Misti and Tacora, which rise on the western edge of the cordillera. The most recent of these volcanoes, such as Misti, Tacora and Sajama, are symmetrical cones surmounted by craters; but the greater number are much older than these and have more or less lost their original form by erosion.

The eastern cordillera, where it borders the altiplano, falls into two sections of quite different physiographic aspect. In the northern section the character of the uplifted peneplain has been almost completely destroyed because the concentration of the rainfall in a narrow belt in this region and the relatively steep gradient of the rivers have combined to enable the streams to cut the old surface to pieces, leaving only the lofty snow-clad Cordillera Real standing on a narrow base. The Cordillera Real is a central core of resistant rocks whose superior hardness and greater initial elevation have preserved it from the effects of great denudation recognizable all around it. The Cordillera Real is cut between the Nevado de Illimani and the Nevado de Quimsa-Cruz by the chasm of the La Paz river, a tributary of the Madeira river of the Amazon system, which, by virtue of the enormous condensation of moisture on the eastward slope of the eastern cordillera, has been able to break through this great barrier to the altiplano; but the axis of the Cordillera Real extends southward across the La Paz valley through the Nevados de Araca, Quimsa-Cruz and Vera Cruz, forming a line of heights as definite in trend and structure as the Cordillera Real and continuing its features southward nearly 50 mi.

Northward from Lake Titicaca the western range turns northwestward, while the eastern range, which has already in the Cordillera Real taken a northwesterly trend, turns still farther to the west and cuts off the altiplano by merging with the western range in a rough mountain mass known as the Nudo de Vilcanota. The eastern cordillera, there called the Cordillera de Carabaya, is a lofty snow-capped range separated from the Cordillera Real by a narrow and relatively low divide between the headwaters of the Mapiri river (a tributary of the Beni) and the Lake Titicaca drainage. On the west flank of the Cordillera de Carabaya is a group of glacial lakes in narrow depressions between the spurs of the range. There is no record of any soundings having been made in them, but from descriptions of their deep colouring and the character of the depressions in which they lie, they appear to be among the deepest of the high glacial-fed lakes of the Andes. The Cordillera de Carabaya lowers very rapidly to the northeast to the Amazon plain, and larger tributaries of the Beni cut directly across the lines of low ranges which front it on the east. Farther north, however, the valleys of the tributaries of the Madre de Dios have a longitudinal trend and have cut deep troughs oriented from southeast to northwest like the ridges which separate them.

The Peruvian Plateau.—The Andes of Peru, north from the Nudo de Vilcanota, are usually described as three distinct ranges which merge in the Nudo de Pasco and then continue north again as separate ranges. Recent studies show that they are a single broad plateau from 13,000 to 15,000 ft. high, on which narrow cordilleras rise to 18,000 and 21,000 ft.; and that the *nudos* or knots are only gigantic erosion remnants. The Amazon tributaries have cut deep gorges almost to the western edge of the plateau, while the numerous streams of the arid Pacific slope are short and, with the exception of the Rimac and Santa rivers, carry little water as far as the ocean.

The Andes are divided into three natural regions—the montaña, the eastern slopes of the Amazon forest; the sierra, the temperate regions of the slopes and secondary valleys of the

BERNARD G. SILBERSTEIN FROM EUROPEAN
URUBAMBA RIVER AND VALLEY IN THE ANDES. CUZCO DEPARTMENT. PERU

plateau; and the *puna*, cold, monotonous regions in the cordilleras, of vast extent at altitudes of from 10,000 to 15,000 ft. In isolated sections above the *puna* are areas known as *jalcas*, which resemble the paramos of Colombia and Ecuador. They are covered with a dense, steppelike vegetation that varies but little from season to season. Northwest of the Nudo de Vilcanota is a narrow trough sunk below the level of the plateau to an elevation of 11,000 ft., known as the Cuzco valley, from the city of Cuzco which lies at its upper end, on the site of the ancient Inca capital. The trough is 19 mi. long and is divided into three basins of flat-lying land arranged like the links of a chain. Its bordering rims have an average altitude of 13,500 ft., with peaks exceeding 14,500 ft., and are cut through in many places by streams leading to the Urubamba and Xpurimac rivers. The valley itself is drained by the Huantaney river which flows through the chain of basins and joins the Urubamba through a broad pass in the mountain mall. The most broken section of the Peruvian Andes is between Abancay and Huancayo where the Apurimac, Pachachaca, Pampas and Mantaro rivers have cut deep gorges 6,000 ft. and more below the surface of the *puna*. The zone of the interoceanic water divide is there a gently undulating plateau, with lakes of glacial origin which the recently eroded valleys have not yet reached. The many secondary valleys, such as those of Ayacucho and Lircay, have long been centres of grain cultivation.

From the Huancayo to Cerro de Pasco the plateau is chiefly the basin of the upper Mantaro river. In the Cordillera de Huarochiri through which the Central railway from Lima to La Oroya cuts, at an altitude of nearly 16,000 ft., on red porphyritic sandstones between crests of dark andesites, the divide rises to elevations of over 17,000 ft. On the western slopes of the Cordillera de Huarochiri are many glacial cirques, and immediately north of the route of the Central railway as it enters the cordillera is a great cluster of lakes at different levels, still fed by glaciers, which drain into the Kimac river close to the edge of the plateau. East of the crest a network of glaciated valleys with many lakes descends in steps to the Mantaro river. East of the Mantaro a little-known range, whose snow-capped summits approach 16,500 ft., cuts off the horizon northeast of the plain of Jauja. Its altitude diminishes to the northwest, and north of Tarma no longer carries permanent snow.

The Mantaro river rises at an altitude of about 15,000 ft., near the mining town of Cerro de Pasco, in a marshy plain with many shallow lakes. Most of these are only small ponds, but Lake Junin, the largest of them, is about 20 mi. long. A group of partially glacier-fed lakes close to the main divide, of which Lake Punrún (7 mi. long) is the largest, also drains to the Rlantaro river near the outlet of Lake Junin. The blantaro flows south-eastward in a long limestone gorge to the plains of Jauja and

Huancayo. These plains stand at 12,500 ft. and 11,600 ft., respectively, and together form a depression, 25 mi. long by 6 to 8 mi. wide, bordered on both sides by rows of bare hills behind which rise snow-capped ranges. The Mantaro leaves the depression in a deep gorge and swings round in a great bend to the Amazon plain about 80 mi. below Huancayo. The Cerro de Pasco region, north of the plain of Junin, has been given great importance in descriptions of the Peruvian Andes as a mountain knot in which are merged three distinct cordilleras. In reality it does not exceed the altitude of the *puna* and is only a fragment of the continuous plateau of sandstones and limestones, with occasional crests of andesite, which extends north of the plain of Junin and south between the plains of Junin and Jauja.

From Cerro de Pasco to the Pongo de Manseriche the plateau forms the drainage basin of the Huallaga and the upper Marañón rivers. Northwest of Cerro de Pasco the Cordillera de Huayhuash forms the interoceanic divide. The Marañón river flows from a chain of glacier-fed lakes on its northeast flank, while on the same slope, a short distance to the south, are the sources of the Huallaga river. The Huallaga valley is fairly wide as far as the gorge east of Huánuco in which it turns northward toward the Amazon and the valley floors of both the main streams and its tributaries in the plateau are well irrigated and have a considerable population. Below the Huánuco the Huallaga is a swift-flowing stream, with many rapids and gorges, and flows in a northerly direction through the foothills and low ranges for 180 mi. before it finally breaks through to the Amazon plain in the gorge or *pongo* of Aguirre, at latitude 6° 30' S. The Marañón flows in a deep trench and has only a sparse population of Indian communities, which occupy the upper basins of its affluents, and occasional sugar plantations at the mouth of the larger tributaries or at rare points where the valley widens.

The Cordillera Blanca, north of the Cordillera de Huayhuash, has the same southeast to northwest trend as the latter but stands slightly to the west of its axis. These are both lofty snow-capped ranges with elevations that may be classed among the highest of the whole Andean highland; Cerro Carnicero in the Cordillera de Huayhuash being 21,688 ft. high and Cerro Huascaran in the Cordillera Blanca 22,198 ft. The valley of the Santa river (known as the Callejon de Huaylas), which separates the Cordillera Blanca from the Cordillera Negra (so called because its crests do not exceed 16,800 ft. and, therefore, bear no permanent snow), is the most densely populated district of this section of the Andes. The river has its source in Lake Conococha in the high *puna*; flows, with a descent of 6,500 ft. in 60 mi., through a string of lacustrine basins of rich alluvial soil; and carries a large permanent stream through a gorge across the Cordillera Negra to the Pacific ocean.

Ecuador.—North of the Peru-Ecuador boundary the plateau is higher, rising to altitudes of over 10,000 ft., but the interoceanic divide continues narrow as far north as latitude 3° S. From there northward to the Nudo de Pasto, in southern Colombia, the Andes appear to be a single broad plateau, the top of which is in places 40 mi. wide, surmounted by irregularly distributed volcanic masses which rise to elevations from 11,000 to 12,000 ft. above the plateau, and divide it into a number of separate basins (*hoyas*) at an average elevation of from 7,500 to 9,000 ft. It has been the custom to describe this section of the Andes as consisting of two parallel cordilleras (a western cordillera and an eastern cordillera, or Cordillera Real) with a high plateau between them which is divided into separate basins by cross ranges from the main cordilleras. Present knowledge does not support this description, and it seems to be only the rather general north and south alignment of some of the outstanding volcanoes on the east and west borders of the basins and, particularly, of the Quito and Latacunga-Riobamba basins themselves, that has given rise to such a characterization. In the interior basins is concentrated the population of the plateau. Their rich volcanic soil and temperate climate had permitted their Indian inhabitants to attain, long before the conquest, a state of civilization far above the savage. They are in the rain-shadow of the mountain masses which enclose them on the east and west, and have, at the most, only moderate

rainfall and, in some cases, require irrigation. By contrast, both outer slopes have very heavy rainfall at about the level of the basins and are covered with luxuriant vegetation, while above 10,000 to 11,000 ft. they have very heavy rainfall on both sides. These high regions of heavy rainfall are the regions of the paramos, cold, desolate areas on both the slopes of the cordilleras and on the cross ranges, with a covering of moss and other bog growths and enshrouded in almost perpetual mist.

The Cuenca basin, in the south, and the Latacunga-Ambato and Riobamba basins, in the central plateau, drain to the Amazon; while the Alausi basin, north of the Cuenca basin, and the Quito and Ibarra basins in the north, drain to the Pacific. The Andes in this section slope steeply to both the Pacific and the Amazon plains. The streams from the basins have, therefore, steep gradients. Because of this and the steady supply of water from the adjoining mountaintop paramos, the streams have eroded deep beds and few lakes remain, of which San Pablo, in the Ibarra basin, is the only one of considerable area. Erosion is slight at the parts of the basins farthest from the outlet through the mountains, but deepens rapidly as the outlet is approached. In the case of the Guallabamba river, which drains the Quito basin, the total depth is over 3,000 ft., of which 1,200 is a steep-sided canyon.

An essential characteristic of the northern half of the Andes of Ecuador is the volcanoes which not only border the western side of the interior basins, from Chimborazo to the Nudo de Pasto in southern Colombia and the eastern side from nearly latitude 2° S. to the equator, but are grouped in many places between the basins and, in places, stand completely in them. They really owe more than half their height to the base of ancient rocks on which they stand, but so impressive are they that even conscientious observers have frequently exaggerated the steepness of their slopes. The principal volcanoes of the more westerly line of volcanoes are Chimborazo (20,702 ft.), Canhuairazo (16,784 ft.), Quilotoa (13,156 ft.), Illiniza (17,398 ft.), Pichincha (15,705 ft.), Cotacachi (16,292), Cimal (15,715 ft.) and Chiles (15,682 ft.); of the eastern. Altar (17,729), Tungurahua (16,689 ft.), Cotopaxi (19,498 ft.), Antisana (18,228 ft.) and Cayambe (19,160 ft.). Sangay (17,464 ft.) lies still farther to the east, and Sumaco (12,559 ft.), which is believed to be a volcanic cone, lies far out on the eastern slope east of the Cordillera Guacamayo.

The eastern slopes of the Andes of Ecuador are little known. Recent explorers have described the Amazon lowland as joining the base of the plateau at elevations averaging between 3,600 and 4,000 ft., and sloping gently eastward with a descent of 1,000 ft. in the first 70 mi. There has been no exploration of the southern part of the lowland. North of the Napo river recent explorations have revealed a number of short ranges and mountain masses of moderate elevation rising above the general level. Among these are the Cordillera Guacamayo and the Cordillera Galeras, with elevations reaching 8,000 ft. and 6,000 ft., respectively, and the cone-shaped Sumaco. Still farther north a short range on the equator called the Cordillera Lumbaki and two high mountain masses northwest of Sumaco have been discovered.

The Cordilleras of Colombia.—In southern Colombia the Andes divide into three separate ranges: the western cordillera, or Cordillera de Chocó; the central cordillera, or Cordillera del Quindío; and the eastern cordillera, or Cordillera de Bogotá. The valley of the Magdalena river, which separates the eastern cordillera from the central, and part, at least, of the Patia and Cauca valley between the central and western cordilleras are not narrow, eroded trenches but broad tectonic depressions with a deep alluvial cover. The western cordillera forms the coast range of Colombia in the south and, to the north, extends on the east side of the valleys of the San Juan and Atrato rivers to the Caribbean coast. It is the lowest of the cordilleras, with elevations varying, in the southern section, from a little over 5,000 ft. on the Pacific railway between Buenaventura and Cali to 7,200 ft. west of Cartago and 10,000 ft. west of Popayán, and rising to elevations of 11,000 and 13,000 ft. in the west and northwest of the province of Antioquia. The southern 250 mi. of the depression between the western and central cordilleras is occupied by a series of three

broad longitudinal plains. The southernmost is drained by the Patia river to the Pacific ocean, while the northernmost, with a length equal to the combined length of the other two, is the famous Cauca valley and drains to the Magdalena by the Cauca river. The central plain, in which is the city of Popayán, contains the low divide between these two drainage basins. Its elevation (6,000 ft.) is 3,000 ft. higher than those of the Cauca and Patia plains, and its northern and southern borders are, therefore, deeply trenched. The Cauca plain has many aspects of an old lake basin filled with detritus. The city of Cali stands slightly above the level of the plain on a gently sloping alluvial fan. North of the Cauca plain the Cauca river flows by a series of gorges through a region of hills and valleys between the western and central cordilleras. Its lower plain is bordered by gradually disappearing spurs until it finally merges in the plains of the lower Magdalena river.

The central cordillera is the highest of the cordilleras of Colombia and the shortest, its last spurs disappearing south of the junction of the Cauca river with the Magdalena, 170 mi. from the Caribbean. It contains the only recent volcanoes in the Colombian Andes. Of these, Tolima (18,425 ft.) and Ruiz (18,340 ft.) are the most important. At latitude 5° 30' N. the cordillera widens to form the plateau of Antioquia, whose last spurs extend as far as 8° N., where they are lost in the plains of the Magdalena. This plateau appears to be a block of ancient crystalline rocks with intrusions of diorites and diabases divided into two parts by the deep trench of the Porce and Nechi rivers. The groups of highlands on both sides of the Porce river preserve, in their gently broken surfaces, traces of a very ancient cycle of erosion. The larger of these covers an area of about 1,200 sq. mi. N. of Medellín and has an average elevation of 8,500 ft., with diminishing heights toward the northeast. The other extends southeast of Medellín, and contains the upper valley of the Nare or Negro river. Medellín, the second city of Colombia, occupies an advantageous position in the Porce valley, where it widens out for a distance of about eight miles into a fertile alluvial plain.

The eastern cordillera is somewhat analogous to the Andes of Ecuador in that its most marked characteristic is a series of high intermontane plains or savannas, at a nearly uniform elevation of 8,000 to 9,000 ft., of which the most important are at the headwaters of the Bogota, Suárez and Sogamoso rivers on the eastern border of the Magdalena basin. Their subsoil is formed of beds of fine gravels and clays, with some beds of peat, and the majority contain shallow lagoons and bogs which are partly submerged during the rainy season. Most of them have areas in their centres too wet for cultivation, so that the population is grouped about their edges. These high savannas were the centre of the pre-colonial Chibcha civilization and now contain a third of the entire population of Colombia. The Savanna de Bogota is the largest and most densely populated of them, and has only a narrow strip of useless bog land in its centre. Bogotá is built on its eastern edge.

East of Girardot and Honda the cordillera is a series of parallel ranges, running from south-southwest to north-northeast, of which only the easternmost, the Sierra de Cocuy (18,044 ft.), reaches the level of permanent snow. North of the Sogamoso river the ranges have a north-south direction and in the latitude of Bucaramanga are united in a broad block. Farther north the central ranges stop and the western and eastern continue on, diverging toward the north and northeast as the Cordillera de Ocaña, of which the Sierra de Perijá forms the boundary between Colombia and Venezuela, west of Lake Maracaibo. Northeast of the delta of the Magdalena river, the Sierra Nevada de Santa Marta, a triangular massif with steep slopes to the north and west, rises abruptly from the Caribbean coast to snowy summits 17,000 ft. high. It is separated from the Sierra de Perijá by the valleys of the César and Ranchería rivers.

A great many lakes exist in the cordillera east of Bogota and on both sides of the upper Sogamoso, but the paramos have usually gentle forms and show traces of a long erosion period. It is, however, only on the high plains and the paramos that the streams of the interior now meander. They are rapidly cutting the greater part of their courses and upon leaving the savannas they flow through deep canyons. The falls of Tequendama southwest of

Bogotá are the most striking example of the manner in which these streams have dissected the borders of the high plains, but the Suárez and Sogamoso rivers exhibit the same characteristics. Tributaries of the Orinoco river have cut through the eastern range to the neighbourhood of the savannas at points south of the Sogamoso and Tunja rivers. South of Bogotá the eastern cordillera is narrow. The Paramo de Sumapaz reaches elevations of 14,000 ft., and snow remains there throughout most of the year, but farther south the range is much lower. In the Sierra de Motilones, which forms its northern extremity, the cordillera narrows to about 16 mi., and its highest crests do exceed 12,000 ft.

Venezuela.—The Andes of Venezuela are separated from the eastern cordillera of Colombia by a depression of about 4,600 ft. altitude, between the Táchira and Torbes rivers! and extend north-east and east for about 500 mi., across the northern part of the country. Transverse valleys cut them into three sections, the area and altitude of which decrease from west to east. The westernmost section, from the sources of the Torbes river to the sources of the Tocuyo river, is known as the Sierra de Mérida. It is about 160 mi. long and 30 to 50 mi. wide. Its snow-capped summits are all above 10,000 ft., and in the Sierra de Santo Domingo and the Sierra de Mérida exceed 16,000 ft. In the Andes of Venezuela the coastal sierras have a west to east direction, and are separated from a second line of much lower mountains by a depression in which are the basins of Lake Valencia and the Tuy river. Eastward from Puerto Cabello the range rises steeply from the coast. Its western end is only a little over 5,000 ft. high near Nirgua, but it reaches 9,000 ft. on the Silla de Caracas northeast of Caracas, and falls to 7,500 ft. west of Cape Codera. The Caracas valley, in which is the city of Caracas at an altitude of 2,600 ft., is only six miles from the sea, and is not a part of the central depression. It appears to be, rather, a subsided local block covered with alluvial soil.

East of Cape Codera the Gulf of Barcelona interrupts the mountain zone for a distance of 80 mi. Only a narrow line of sandstones and limestones continues eastward from the interior range along the flat coast. Its altitude lowers rapidly from 4,000 to 1,600 ft., and it is completely interrupted by the Unari and Aragua rivers, which drain a part of the llanos to the Gulf of Barcelona. The Sierra de Cumaná extends for 80 mi. between the Aragua river and the Gulf of Paria. Its interior is a mass of sandstones and folded limestones which rises to 7,500 ft. in the Cerro Turumiquire. The double peninsula of Araya and Paria is a narrow belt of crystalline schists, with an altitude of 1,300 ft. west of the town of Carúpano and a little over 3,000 ft. at its eastern end near the Boca del Dragón, beyond which it is continued as the northern range of Trinidad Island.

Geology.—The beds of the Primary series are found in the Andes in a longitudinal zone on the eastern side of the cordillera. They form the eastern part of the plateaus of Bolivia and northern Argentina, where the high anticlinal ranges are of Cambrian quartzites, while Silurian schists: surrounding the recent granite crests of the Cordillera Real, cut by deep valleys and overlapped in the synclines by Devonian and Secondary red sandstones, form the base of the series. They are found, also as Silurian sandstones, schists and Devonian sandstones, on the eastern side of the Chile-Argentine cordillera as far south as latitude 35° S. and in the precordillera.

The zone of the Secondary beds is of much greater length. Breccias and porphyritic conglomerates are the most common formation, forming almost the whole of the western part of the In-Indian system. In Peru they are succeeded to the east by gray limestones, which cover the greater part of the plateau. Still farther east, on the Marañón and upper Huallaga rivers, the ridges are of Secondary sandstones above Silurian schists. In Ecuador the Secondary conglomerates of the western side of the plateau rest directly upon the Andean gneisses and mica schists, of which the eastern part is composed. In Colombia the central cordillera is formed of mica schists, with almost no trace of sedimentary covering; while, in the eastern cordillera, even on the border of the plains of the Orinoco, the conditions that prevail farther south are completely reversed and the Secondary beds have their

greatest development. The importance of the Secondary marine deposits in the Andes, especially in the Jurassic and Cretaceous series, seems to indicate that, during the Secondary period the region of the Andes was a geosyncline inundated by the sea between two continental masses, one of which occupied the place of the present Pacific ocean. The relations between the Andes and the vorland to the east is obscured by an enormous development of alluvial forms which partly cover the zone of contact between the lowlands and the cordilleras. It has been suggested that it is a rigid zone against which were exerted the forces to which the folding of the geosynclinal Andes was due.

The beginning of the folding of the Andes dates from the upper Cretaceous and continued during a part, at least, of the Tertiary. Tertiary marine forms are, therefore, lacking in the interior of the cordillera and are known only in eastern Patagonia, on the extreme edge of the cordillera. The Tertiary is represented in the greater part of the Andes by continental deposits without fossils, which furnish no precise information on the age of the folding. North of the Patagonian Andes as far as latitude 4° S. the western ranges contain Jurassic rocks and porphyritic rocks of similar age folded together. Both are of interest, the Jurassic because they are the only marine sediments of that age south of the equator, the porphyritic—because they are the most important evidence there is of volcanic activity in Mesozoic times. North of latitude 4° S. the Jurassic and porphyritic rocks are comparatively rare and the Primary rocks are absent. The majority of geological cross sections that have been made in the Andes indicates foldings of the simple Jura type rather than the complex type of the Alps. The cross sections are, however, still comparatively few, and greater complexity may be revealed by further studies.

Evidence of the uplift of the Andes is found not only in the existence of Tertiary and Quaternary marine deposits on the Pacific coast and many examples of uplifted shore-lines but also in the frequent occurrence throughout the cordillera of surfaces which could only have been formed at an altitude near sea level. These areas are found even in the more humid parts, where the contrast between them and the deep ravines of the headwater streams which are now invading them is most striking. The peneplain has been most completely conserved, however, in the desertic Maritime cordillera of northern Chile and southern Bolivia. In the terracing of the valleys, particularly on the eastern side of the cordillera, there is evidence of a succession of vertical movements, interrupted by periods of rest; while in the coastal terraces all the way from Paita to Antofagasta there is evidence not only of periods of rest but also of at least one subsidence followed by an uplift, which is still in progress at the present time. In fact, along the entire western seaboard the region has suffered enormous disturbances in the past, while the frequent earthquakes that have occurred in recent years in many parts of the coastal region and the cordillera are evidence that these disturbances are still going on. The abrupt transition from high tableland to abyssal ocean depths that is characteristic of the entire coast indicates the remarkably unstable condition of the region. In addition to the general or regional movements of uplift and subsidence, the existence of drop faulting has been noted throughout the whole length of the cordillera. The upper Magdalena valley, the Cuzco basin, the Iglesia and Calingasta valleys between the cordillera and the precordilleras of Argentina, and the central valleys of Chile have all been thus explained.

The volcanoes of the Andes occur in three notable groups, southern Colombia and northern Ecuador, southern Peru and northern Chile, and the group of central Chile, Neuquén and Patagonia. All types are present, from ancient volcanoes almost completely destroyed by erosion and extinct volcanoes, with or without craters but still fresh in form: to active volcanoes. They have played an important part in the leveling of the interior basins. Fluid lavas exposed appear only on the Patagonian plateau. Elsewhere the lavas are chiefly of the viscous acidic type and, although accumulated to great depths in many places (as much as 1½ mi. deep in the Cordillera de Vilca pampa in southern Peru), have not been removed far from the craters. The volcanic ash, however, has been carried away by erosion in such quantities

that they have overcharged the streams and filled depressions and valleys to a great depth.

Climate.— It is not on the equator but between latitude 15° and 20° S. that the highest temperatures of the Andes are found, and it is necessary to go south of the tropics to find mean annual temperatures comparable to those on the equator. The abnormal depression of temperatures in the equatorial Andes is due to the heavy rainfall, and it is the lack of rainfall that raises the temperatures to the south. The effect of the higher temperatures of the drier Andes is to elevate the upper limit of agriculture and human occupation. In Colombia the highest agricultural zone is between 6,500 and 10,000 ft., while on the moister portions of the Bolivia *altiplano* agriculture is carried on over 3,000 ft. higher. The rich agricultural basins of Cuzco and Jauja, if they lay at the same elevation in the humid equatorial Andes, would not belong to the agricultural regions at all. The lower limit of the colder agricultural zone is not, however, parallel to the upper limit, and as one leaves the equator frosts occur at lower and lower levels. As a result, sugar cane, which grows at a level of 6,500 ft. and more in Ecuador and Colombia, does not reach above 3,000 ft. in northern Argentina.

The lower limit of perpetual snow in the tropical Andes is between 15,000 and 16,000 ft. Because of the increasing aridity, it rises rapidly south of the equatorial region to 17,000 ft. on the western ranges of the Peruvian Andes, above Lima, and to 18,000 and 20,000 ft. in the summits that border the Puna de Atacama, to the northeast. South of the Puna de Atacama it lowers again to 18,000 ft. in the Famatina ranges, and to between 14,500 and 16,500 ft. in the ranges of Juan and Mendoza. From these it falls rapidly to 6,500 ft. at latitude 37° S., 5,000 ft. at 40° S., and 2,300 ft. on Tierra del Fuego. In the tropical and subtropical sections of the Andes the present glaciers rarely extend beyond the snow line. South of 40° S., however, they have more extensive fields of supply, and come well down into the valleys. South of 46° S. the ice fields, though only a shrunken remnant of the ice fields of the Glacial period, still form a continuous cap over the entire central zone of the cordillera. Throughout the Andes there have been recognized, in front of the present glaciers and in regions today free of ice, glacial moraines, cirques, outwash plains and lakes confined behind glacial dams, which are proof of several periods of extensive Quaternary glaciation.

Minerals.— Mining is an important industry in all of the Andean countries. In Chile and Bolivia it far exceeds all other industries in the value of its products. The most important mineral deposits are those of the younger igneous rocks which include the gold quartz lodes of Colombia, the silver-bearing copper deposits of Peru and Chile, and the tin-silver-bismuth deposits of Bolivia. The copper deposits, which are found in many sections of the Andes but are particularly abundant in Chile and Peru and, to a lesser degree, in Bolivia, differ greatly in their geological occurrence and characteristics. They occur most frequently as replacements of rock near intrusions of igneous material. At Portrerillos, Chile, they have replaced the easily soluble limestone. At the Braden mines, near Rancagua, Chile, and the Cuquicamata mines, the copper minerals have filled cracks and openings in less soluble rocks with little or no replacement. In many places, as at Cerro de Pasco, Peru, rich silver ores at the surface give place to copper ores at lower levels. The tin deposits of Bolivia are true fissure veins or disseminations filled by products of igneous intrusives. The only gems occurring in the younger igneous rocks are the emeralds of Colombia. Of the ores that occur mainly in association with the ancient crystalline rocks, gold-bearing and silver-bearing veins in the Pre-Cambrian schists, gneisses and granites, in many places in the cordilleras, and iron ore, chiefly magnetite, in Chile, are the most important. Mineral deposits of economic value in the sedimentary rocks are not extensive. Chile, Peru and Colombia have extensive coal deposits, but they are of inferior quality as compared with foreign coals and, except in Chile, are so inaccessible that they have been worked but little, except for local use. Petroleum resources have been studied intensively, and indications of oil-bearing strata have been reported on the eastern border of the Andes all the way from Venezuela to Tierra

del Fuego. The areas that are at present yielding the most valuable flows are the Maracaibo basin in Venezuela, the basin of the Sogamoso river on the western border of the eastern cordillera of Colombia, and the coastal region of northern Peru at Talara. Of the placer minerals, gold is the most important, and the extensive placer operations have of recent years been mainly confined to Colombia, particularly in the Choco district, where they yield considerable platinum.

Population.— From the standpoint of human occupation, the Andes are divided into three sections—an unpopulated section extending north to the Puna de Atacama; an arid central section from the Puna de Atacama to northern Peru, where mining is the chief industry; and a humid northern section, of which the chief industry is agriculture. The southernmost section has little mineral or agricultural resources, and the population is, therefore, not in the mountain zone but on its borders, concentrated in irrigated districts on the eastern side and more uniformly distributed in the central valleys of Chile on the western side. In the Puna de Atacama there is a sparse population of shepherds, and a still smaller element engaged in collecting salt from the salars for sale in the settlements on the mountain border. From there north to the Caribbean sea, however, the greater part of the population of the west coast and Caribbean republics, and, with few exceptions, the chief cities, are on the plateau. This populated section of the Andes contains a third of the whole population of South America. It consists of two sections of distinctly different character. The southern and more arid section is a region in which mining is the dominant industry, and practically the only source of export. All other industries are maintained for the purpose of supplying it with food, clothing and means of transportation. Railways which penetrate into the cordillera from the Pacific coast were constructed solely to transport the products of the mines to the nearest ports. The influence of the mining industry, since the mining districts are mainly on the high paramos, combined with climatic conditions to raise human habitation to levels which are among the highest in the world. Since before the conquest the characteristic of this section of the Andes has been the establishment of small agricultural communities on the alluvial floors of high, sheltered valleys close to the mining centres which form the sole market for their produce. In the more humid Andes of Ecuador, Colombia and Venezuela mining is of secondary importance; the chief industries are agricultural and the chief exports the products of the tropical levels—cacao in Ecuador, coffee in Colombia and Venezuela. There the internal trade is not the supplying of agricultural products to a dominant industry but an exchange of products between zones at different levels and, therefore, of different climates.

Transportation.— Throughout the populated sections of the Andes, transportation between different parts of the plateau, between the plateau and the eastern lowlands and, to a considerable extent, between the plateau and the Pacific coast continued to be chiefly by pack trail. The mule came to be the principal pack animal, largely supplanting the llama of pre-conquest times, although the latter was still used locally in large numbers. In parts of Colombia the ox was still used for long trips with bulky commodities such as coffee and tobacco, while in the montañas of the eastern slopes and in the Chocó region of Colombia, transportation remained dependent upon Indian bearers. Everywhere the *arrieros*, or muleteers, became an important element of the population. Whereas the railway supplanted the pack train on most of the long routes from the plateau to the Pacific coast, the number of *arrieros* in the Andes as a whole probably was not decreased, since the penetration of the railways into the plateau increased the demand for foreign goods and, consequently, for means of distributing them from the railheads.

Except in the broad central plateau of Bolivia, the Andes offer such obstacles to road and railway construction that the west coast republics between Chile and Colombia are effectively divided into two lowland regions separated by the cordilleras. From the point of view of government administration and national solidarity, railways across the Andes to connect the two lowland regions are of much importance; but the great cost of construction and

maintenance limited them. (Most rail connections in the mountain zone were built to connect important mining or agricultural districts with the nearest seaports.) The most famous of the routes crossing the Andes is the railway opened in 1911 between Los Andes, Chile, and Mendoza, Arg., which crosses the Chile-Argentine boundary by a tunnel 10,000 ft. long and 10,500 ft. above sea level, affording direct rail connection between Buenos Aires and Valparaíso. The transandine railway from the Bolivia-Argentine boundary to Uyuni was connected on the Bolivian altiplano with three railways to the Pacific coast, giving through routes from Buenos Aires to Antofagasta and Arica by rail, and by rail and steamer on Lake Titicaca, to Mollendo. In 1948 a railway between Antofagasta and Salta, Arg.; was opened. Roads for motor transport have helped to improve communication in the Andes though the difficulties of construction have been great. Air travel, since the first flights over the Andes in 1918, has been of outstanding importance. (For railway lines eastward from the altiplano of Bolivia, see BOLIVIA. For railways, highways and air lines that penetrate the Andes in Peru, Ecuador, Colombia and Venezuela, see articles on these countries.) (R. R. P.)

Mountaineering Expeditions.—Regions of the Andes offering the greatest challenge to mountaineers are found in Ecuador, Peru, Bolivia and the highest summits of the frontier between Argentina and Chile. Scientific exploration of the Andes began in the 18th century, but it was not until late in the 19th century that organized mountain climbing became established. The pioneer climbers concentrated upon the great volcanoes near the Pacific coast. Later they sought peaks farther inland, finally reaching the so-called "hidden ranges," mainly in Peru, the existence of which in many instances was unknown until the 20th century. The outstanding early climbers were Englishmen, Germans and Italians. More recently, climbers from the United States, France, the Netherlands, Belgium and Japan have appeared. After World War II, Europeans, North Americans and South Americans shared about equally in the activity.

The peaks of Ecuador were the first to be ascended and explored. Those best known among 30 important volcanoes located in the western cordillera are Cotacachi (16,292 ft.), Pichincha (15,705 ft.), Ihliniza (17,398 ft.), Canhuairazo (16,784 ft.), and Chimborazo (20,702 ft.); in the eastern cordillera, Cayambe (19,160 ft.), Antisana (18,228 ft.), Cotopaxi (19,498 ft.), Tungurahua (16,689 ft.), Altar (17,729 ft.) and Sangay (17,464 ft.). Chimborazo and Cotopaxi, whose summits are dominant in the group, were the objectives of the first climbing expeditions. Cotopaxi is usually regarded as the most active fire mountain in the world and one of the most beautiful.

The volcanic region of Ecuador was investigated between 1736 and 1744 by one of the first scientific expeditions to study a mountain range. This was led by Pierre Bouguer and C. M. de la Condamine of France and Antonio de Ulloa and Jorge Juan of Spain. From data gathered by this expedition it was concluded that Chimborazo was the highest mountain in the world, a misconception that persisted until the Himalayas and the southern Andes became known. In 1802 the German scientist Alexander von Humboldt and his companions, Aimé Bonpland and Carlos Montúfar, made attempts on the summits of Chimborazo and Cotopaxi, failing in each instance but reaching a height of 19,286 ft. on the former. Joseph Boussingault, in an attempt on Chimborazo in 1831, attained 19,698 ft. Chimborazo was finally ascended in 1880 by the great English alpinist Edward Whymper (*q.v.*), who had been first to climb the Matterhorn 15 years previously. In addition to Chimborazo, which he climbed twice, Whymper reached the summits of Cotopaxi, Sincholagua, Cayambe, Antisana, Saurauru, Canhuairazo and Cotacachi. Hans Meyer and Rudolph Reschritter made two attempts upon Chimborazo in 1903, both unavailing, but ascended Cotopaxi and several other peaks.

Following the successes on the Ecuadorian volcanoes, mountaineers looked to the southern Andes for new peaks to conquer. One of the major triumphs there was the ascent of Aconcagua (22,831 ft.), the highest summit in the Americas. Lying on the boundary between Chile and Argentina, the peak itself is in Mendoza province of Argentina. The first attempt on Aconcagua was

made in 1883 by Paul Giissfeldt, a noted German climber, who reached a point 1,300 ft. below the summit. Aconcagua fell to Stuart Vines and Matthias Zurbriggen of the Edward A. Fitzgerald expedition in 1896–97. Sir Martin Conway, another well known British climber, made the ascent soon thereafter.

The third great Andean region for mountaineering is in Peru and Bolivia. In Peru it was Huascarán (22,198 ft.), in the Cordillera Blanca, that first lured the mountaineers. In 1904 C. R. Enock, an Englishman, reached 17,000 ft. before being forced to retreat. In the same year, and again in 1906 and 1908, Miss Annie S. Peck of the United States made several attempts on Huascarán, finally reaching the north summit of the mountain's twin peaks. In the period 1932–39 members of the Austro-German Alpine club ascended the south summit of Huascarán and 14 other peaks exceeding 20,000 feet. In 1952 the summit of Huantsán (20,981 ft.) was reached by members of the Dutch party which included C. G. Egeler, T. de Booy and the French alpinist Lionel Terray. The Franco-Belgian expedition, with Georges Kogan, Raymond Leininger and their wives, climbed Alpamayo (20,080 ft.) in 1951. In the nearby Cordillera Huayhuash the summit of the formidable Yerupaja (21,765 ft.), also known as El Carnicero ("The Butcher"), was attained in 1950 by two members of the Harvard Andean expedition. David Harrah of Stanford university and James C. Maxwell of Harvard. Farther south in Peru rises Coropuna (21,079 ft.), an amassivemountain of gently rounded form. first climbed in 1911 by members of the Yale Peruvian expedition led by Hiram Bingham.

Among the Andean ranges in Bolivia, the peaks bordering the plateau on the north, called the Cordillera Real, are better known to mountaineers than those to the south. Illimani (21,184 ft.), near La Paz, is the best known of this group. Conway ascended the most southerly of Illimani's twin peaks in 1898 in the belief that it was the higher of the two; it was not until 1950 that the north peak was discovered to be about 100 ft. higher. Sajama (21,555 ft.), the highest Bolivian mountain, was climbed in 1939 by Joseph Prem, a German, and Piero Ghigliani, an Italian.

Peaks of lesser height, but in many instances of difficult character, are found in the far northern and southern limits of the Andes. Among them is the range called Sierra Nevada de Santa Marta, rising in Colombia near the Caribbean coast. Many of the peaks there were found to exceed 18,000 ft., which ranks them among the world's highest coastal mountains. Mountaineering has also been carried on in the ranges south of Santiago, Chile, and a large number of imposing peaks there remain unclimbed. The Fuegan archipelago, in the extreme south, was explored by the English expedition, which included Charles Darwin, during the period 1826–36. Mt. Sarmiento (7,333 ft.), the highest peak of the Darwin range, was explored by Conway in 1898.

ANDESINE: see FELDSPAR.

ANDESITE, a great family of rocks playing an important part in the geology of most of the volcanic areas of the globe. The name first was applied to a series of lavas from the Andes. Not only the Andes but most of the cordillera of Central and North America consist largely of andesites. The same rock type is found in abundance in volcanoes along practically the entire margin of the Pacific basin outside the andesite line (see PACIFIC ISLANDS).

The volcanoes Montagne Pelée, the Soufrière of St. Vincent, Krakatoa, Bandaisan, Popocatepetl, Fuji, Ngauruhoe, Shasta, Hood and Adams have emitted great quantities of andesitic rock.

The term andesite has been used in many different definitions. Thus it has been used for rocks containing silica from an excess represented by 35% quartz to a deficiency represented by 15% olivine or 11% nepheline; rocks containing as much as 50% ferromagnesian minerals (pyroxene, biotite, etc.) have also been included. Most commonly the term andesite is used for fine-grained, usually porphyritic rocks, corresponding roughly to diorite in composition, and consisting essentially of a soda lime or plagioclase feldspar approximately andesine in composition ($60 \text{ Na}_2\text{O} \cdot \text{Al}_2\text{O}_3 \cdot 6\text{SiO}_2 - 40 \text{ CaO} \cdot \text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$) and one or more ferromagnesian minerals. Smaller amounts of sanidine or potassium-rich feldspar may be present. The plagioclase feldspar of the phenocrysts is more calcic than that of the matrix, and is usually zoned, with still more calcic cores. The larger feldspars and ferromagnesian minerals are often visible to the naked eye, lying in a finer groundmass, usually crystalline, but sometimes to a large extent glassy or vitreous. When fresh they are dark-coloured if they contain much glass, but paler in colour and red, gray or pinkish when more thoroughly crystallized. Andesites occur mainly as surface deposits, and to a lesser extent as dikes and small plugs. Many of the deposits are not normal lava flows but rather flow breccias, mud flows, tuffs and other fragmental rocks; the peperino near Rome and the tuff of the Eifel district in Germany are examples. There are three great subdivisions of this family of rocks, the quartz-bearing andesites or dacites (sometimes considered to be a separate family), the hornblende- and biotite-andesites and the pyroxene-andesites. The dacites, a term first applied to quartz-bearing andesites of Transylvania or Dacia, contain primary quartz and are the most siliceous members of the family; their quartz may appear in small blebs or phenocrysts, or may occur only as minute interstitial grains in the groundmass (see DACITE); other dacites are vitreous (dacite-pitchstones). The hornblende- and biotite-andesites, being comparatively rich in feldspar like the dacites, are usually pale pink, yellow or gray. They resemble the trachytes both in appearance and in structure, but their feldspar is mostly plagioclase, not sanidine. The biotite and hornblende are alike in both of these groups of rocks and are often surrounded by black borders, produced by corrosion and partial resorption by the magma. Augite is common in most andesites, and bronzoite or hypersthene is common in many. Pyroxene-andesites are darker, more basic rocks, with a higher specific gravity, and approach basalts and dolerites, especially when they contain a small amount of olivine. They are the commonest type of andesite, both at the present and in former geological periods, and occur in amounts comparable to those of basalt.

In addition to the accessory minerals zircon, apatite and iron oxides, which are practically never absent, certain others occur which, because of their rarity and importance, are of special interest. Sharply formed little crystals of cordierite are occasionally found in andesites, presumably from the more or less complete digestion of fragments of aluminous rocks in the molten lava, although some of these crystals were later shown to be a new mineral; osumilite. A rose-red variety of epidote is a secondary product in certain altered andesitic rocks; the famous red porphyry (*porfido rosso*) is of this type (see PORPHYRY).

Many theories have been proposed for the origin of andesitic rocks. Andesitic magma is commonly thought to originate from basaltic magma, either by direct crystal fractionation or by reaction with siliceous rocks of the continents. Many ore deposits of gold, silver and other metals are associated with andesitic rocks. In most such cases, however, the minerals of the andesite have been altered to form an aggregate of chlorite, epidote, zeolites, carbonates and hematite termed propylite. The genetic relationships of this alteration to the ore are not certain.

(E. RR.)

ANDHRA PRADESH is one of the constituent states of the Republic of India, and was redefined by the States Reorganization Act which came into force on Nov. 1, 1956. The realignment of the states of peninsular India was on a language basis and

Andhra Pradesh is designed to include the bulk of the Telugu-speaking peoples. Prior to independence in 1937 the majority of Telugu speakers were in Madras presidency north of Madras city and in the eastern half of Hyderabad appropriately known as Telingana. In 1953 Andhra was first constituted a separate state by the partition of Madras; the big addition in 1956 was of half of Hyderabad when Hyderabad city became the capital. Hyderabad city had a population (1961) of 1,252,337. Other large towns are Vijayavada, Warangal, Guntur, Vishakhapatnam and Rajahmundry, all over 100,000. Andhra is bounded by Madras to the south; Mysore to the west; Maharashtra, Madhya Pradesh and Orissa to the north and by the Bay of Bengal to the east.

Physical Geography.—The state comprises two distinct parts: the western half which lies on the plateau of peninsular India and the eastern half which consists of coastal plains. The Andhra section of the plateau, in contrast with the lava-covered areas of the former Bombay state, consists of ancient metamorphic rocks. In places these are mineralized but the chief mineral product of the state is the mica of Nellore. The old rocks yield an indifferent soil and, as the state as a whole suffers from a low and somewhat precarious rainfall, cultivation is mainly in the shallow basins in the plateau surface where streams are dammed to form temporary lakes or tanks. These conserve the water beyond the rainy season but dry up later in the year. The plateau in the southern part of Andhra lies in the basin of the Penner river. Large-scale irrigation works were attempted many years ago but were only partly successful. The heart of the plateau lies in the basin of the great Krishna (*q.v.*) river. On its tributary, the Tungabhadra, a huge dam, inaugurated in 1953, irrigates nearly 1,000,000 ac. in Andhra and Mysore. The Nagarjunasagar irrigation and hydroelectric scheme on the main river was started in 1955. In the north of the state is the Godavari river; and on the Machkund river a joint scheme with the government of Orissa provides both hydroelectric power and irrigation water.

Although the eastern edge of the Deccan plateau is known as the Eastern Ghats it does not form a continuous range, being broken by the great river valleys. Spurs and isolated hills extend into parts of the coastal plain, but where the latter is broad it has been built up by the alluvial deltas of the great rivers, affording much fertile agricultural land.

Along this coastal belt is found an interesting range in climate. In the south, near Madras, October–November rains are added to the rains of the normal Indian wet season, June–September, but northward rainfall becomes inadequate. Irrigation is needed in the delta lands of Guntur, Krishna and Godavari districts, but northward again, along the Northern Circars (Sarkars) coast toward Orissa, the rainfall increases once more. (L. D. S.)

History.—The country of the Andhras is mentioned in Asokan inscriptions and appears in Sanskrit literature: it lay between Kalinga and Dravida; *i.e.*, Orissa and Nellore. Jainism and Buddhism, once flourishing in Andhra, became extinct there by about the 9th century, except as philosophies. Well-known to the Puranas, the Satavahana, Satakarni or Xndhra dynasty ruled the Deccan from the 1st century B.C. to the 3rd century A.D. except when expelled from its western side by Kshaharata satraps in the 1st century A.D. Simuka is said to have killed the last Brahman king of the Kanva dynasty in the Ganges valley about 28 B.C. Gautamiputra Yajna Sri was the most powerful Satavahana ruler. Successors of the dynasty were the Vakatakas (north central Deccan), Ikshvakus (east central), Pallavas (southeast) and Vishnukundins (east coast). Acquiring the greater part of the east coast the Pallavas from their capital at Kanchi or Kancheepuram (*q.v.*) fostered the arts and trade with the west and with Burma, and furthered the Hindu cultural colonization of southeast Asia. The Western Chalukyas (*see* CHALUKYA) gained a hold on Vengi (between the Godavari and the Krishna), and the Eastern Chalukyas ruled there as the Pallavas' rivals. In the 9th century the Cholas (*q.v.*) extinguished Pallava power, and the Eastern Chalukyas merged with the Cholas under Kulottunga in 1070. Thereafter the Western Chalukyas occupied Vengi fitfully until the Kakatiyas of Warangal subordinated it to an inland Andhra power. Ganapati Kakatiya, Rudrama (praised by Marco Polo)

and Pratapa Rudra administered efficiently and founded Andhra nationality. Pressure from Delhi destroyed the dynasty in 1323. Muslims controlled as far south as the Krishna by 1354. After the disappearance of the Eastern Ganges of Orissa in the early 15th century, the Andhra coast was ruled by Reddis and Chodas, whose rivalries invited Muslim intervention and subsequently Vijayanagar conquest. The Gajapati dynasty of Orissa fought Vijayanagar (1428), annexing the Reddis' lands in 1446. Kapilesvvara Gajapati reached the Tamil country by 1470, but a disputed succession gave Vijayanagar access to the southern and the Muslims to the northern districts of Andhra. Before 1510, however, Purushottama Gajapati took Warangal from the sultan of Golconda, and by 1515 he submitted to Krishnadevaraya of Vijayanagar and received back Andhra north of the Krishna. Yet by the middle of the century Muslims were in power over southern Andhra.

In the 17th century, the Mogul empire absorbed the Deccan sultanates. The viceroy of the Deccan gained the Northern Circars (see CIRCARS), and appointed the Nawab of the Carnatic to the remainder of Andhra. The British gained the Northern Circars from Hyderabad and administered them, somewhat inconveniently, from Madras. Masulipatam, which had been a British "factory" since 1611, did not grow into a centre of government. Bellary and other Telugu-speaking districts were added after the Mysore wars. The ryotwari system, in which the land revenue was periodically settled with the cultivators, was found more practical than the "permanent settlement" system imitated elsewhere from Bengal. For a fuller statement on the modern history of the states out of which Andhra Pradesh was created see HYDERABAD, former state; MADRAS, state; INDIA (Bharat).

(J. D. M. D.)

Population. — The area of the state is 106,052 sq.mi. and the population, adjusted on the basis of the 1961 census, 35,977,999. This figure includes a number of backward and tribal groups (such as the Chenchu) not fully integrated into the rural population. The state includes the following districts from the old Madras presidency, with district headquarters in parentheses and population figures from the 1961 census (many of the district boundaries were changed after 1951): Anantapur (Anantapur) 1,764,223; Chittoor (Chittoor) 1,913,169; Cuddapah (Cuddapah) 1,342,140; East Godavari (Kakinada) 2,609,311; Guntur (Guntur) 3,009,997; Krishna (Masulipatam) 2,076,103; Kurnool (Nandyal) 1,909,644; Nellore (Nellore) 2,033,963; Srikakulam (Srikakulam) 2,342,291; Vishakhapatnam (Vishakhapatnam) 2,288,976; West Godavari (Eluru) 1,978,434. The town of Kurnool, in Kurnool district, was for a time the capital of Andhra Pradesh, and consequently grew much larger than Nandyal. The districts of Telingana that were transferred from the former Hyderabad state to Andhra Pradesh are as follows: Mahbubnagar; Medak; Nizamabad; Karimnagar; Adilabad; Warangal; Nalgonda, Khamman and Hyderabad. A special feature of the governmental system is the regional committee for Telingana, whose duty is to see that the views of the people of Telingana are given proper consideration.

(S. CH.)

Social Conditions. — By the 1960s primary and secondary education was being imparted in over 33,500 recognized institutions to more than 3,000,000 pupils, two-thirds of whom belonged to rural areas. Compulsory education for children of the age group 6–12 had been introduced in over 300 towns and 1,600 villages and covered more than 400,000 children. The census for 1961 recorded 29.7% literacy for males and 11.8% for females. Filariasis is endemic in some parts of the state but government efforts in the field of preventive medicine produced remarkable results in reducing its incidence and that of malaria, cholera and other diseases. In 1958–59 there were 6 medical colleges, 376 hospitals and 921 dispensaries. Thirty-three welfare extension projects were functioning by 1959. These provided free educational facilities to children, crèches, maternity centres, social education, craft training and cultural activities for women. A separate social welfare department looks after the welfare of the scheduled castes and other backward classes by providing scholarships, free books and clothes to students, wells, free housing sites, cottage industries and agricul-

tural implements.

(S. B. L. N.)

Economy. — As elsewhere in India agriculture is the leading occupation and about 16,000,000 ac. are cultivated out of an estimated total of cultivable land of 24,000,000 ac. Where irrigation is not possible the chief "dry zone" crops are millets (jowar and bajra), peanuts and cotton; wherever irrigation is possible these give place to rice with some sugar cane and also, on the Orissa border, some jute. In the early 1960s it appeared certain that the extension of irrigation, then in hand, would add greatly to the area under rice and so to the ability of the state to support its population. A specialist crop is tobacco and Andhra produces about two-fifths of India's total. A fifth of the state is forested; especially on the hills of the Eastern Ghats there are valuable stands of sal (Skorea) and other timber trees.

Mineral deposits include manganese, mica and a little coal. The mica belt of Nellore also has uranium deposits.

As hydroelectric power becomes available industrial development is likely to increase. Especially in and near Hyderabad city there are textile mills; elsewhere sugar mills, paper mills, cement and glass factories have been developed and there remains a wide range of cottage industries.

The coast is a gently shelving one and breakers prevent the approach to the shore. For long the only harbour serving the whole coast was the artificial one of Madras; in the 1930s Vizagapatam (now Vishakhapatnam), partly sheltered by a rocky headland known as the Dolphin's nose, was provided with an artificial harbour and was at the same time linked by railway with the heart of the northern peninsula. This remains the state's chief port; it now has an oil refinery and the chief shipbuilding yards of India. The dangerous coastwise journey for shipping was early obviated by the salt water Buckingham canal running parallel to the coast, and leading from the Krishna river to Madras.

The railway system (Southern) affords broad-gauge lines along the coastal plain from Madras to Vishakhapatnam, where the Eastern line to Howrah (Calcutta) is joined. There is a broad gauge line inland from Vijayavada (formerly Bezvada), where the Krishna is bridged, to Nagpur in the heart of the plateau, but access to the capital Hyderabad is circuitous and a mixture of gauges is involved. Roads play an important role and the state of Andhra forms a relatively compact unit.

See also separate articles on the main towns and districts.

ANDIZHAN, an *oblast* and town in the Gzbek Soviet Socialist Republic, U.S.S.R. The area is drained by the Syr-Darya and most of it is under cotton cultivation. Cattle are raised where water is available. The oil fields south of Andizhan town and east of Leninsk produce oil and natural gas, the latter being piped to these two cities. There is an oil refinery at Palvantash. The population—768,000 (173,000 urban) in 1959—is mostly Uzbek. There were 450 schools and 75 libraries in the oblast in 1956. Uzbek and Russian newspapers are published.

Andizhan town is the capital of the oblast (pop. [1959] 129,000) and is a railway centre. It has cotton-ginning and cottonseed oil extracting industries, food-processing plants and metal works. It lies in an earthquake area; the earthquake in 1902 destroyed the town.

(G. E. WR.)

ANDOCIDES (c. 440–after 391 B.C.), Athenian orator and politician, was born of one of the most prominent families in Athens. His career was interrupted when he was imprisoned on

suspicion during the scandal of the mutilation of the Hermae in 415 (for the occasion, and the connected case of the profanation of the Eleusinian mysteries, see *ALCIBIADES*). He was then induced to turn informer to stop the general panic, and though the historian Thucydides is not sure that his information was genuine it was accepted, and those who were implicated were condemned. Andocides went into exile. After two unsuccessful attempts to return, he came back under the general amnesty of 403, when Thrasybulus restored the democracy. In 400 he was tried for impiety, but he had powerful support and was acquitted. In 392, during the Corinthian War (see *GREECE: History*), he went with three colleagues to negotiate peace with Sparta, but Athens rejected the terms and exiled the ambassadors.

Andocides is one of a canon of ten Attic orators who are the subject of *Lives of the Ten Orators*, a work wrongly attributed to Plutarch. An unconvincing politician, he was the least admired of these canonical orators, though he had a gift for vivid narrative. Three of his speeches survive. *On His Return; On the Mysteries*, his defense in 400; and *On the Peace* (392). A fourth, *Against Alcibiades*, has been attributed to him but is spurious.

See R. C. Jebb, *Selections from the Attic Orators*, 2nd ed. (1888). (A. AS.)

ANDORRA, a small, autonomous principality (officially PRINCIPALITY OF ANDORRA) in the Pyrenees between France and Spain, is bounded to the north and east by the French *départements* of Ariège and Pyrénées-Orientales and to the south and west by the Spanish province of Lérida. The population was 5,664 in 1954, about the same as it was in 1900, and in 1960 was given as 8,392. It has an area of 175 sq.mi. and the capital is Andorra la Vella (Andorra la Vieja).

Physical Geography.—Andorra is a cluster of mountain valleys whose waters unite to form the two-branched Valira, a tributary of the Segre, chief affluent of the Ebro. The frontier with France is determined largely by the watershed; that with Spain was finally delimited in 1863. The territory is ringed, save to the southwest, by towering peaks, the highest, the Pic d'Estats, being 10,295 ft. The main Pyrenean crestline exceeds 8,000 ft. Valleys, rarely below 3,000 ft., end in steep, impassable cirques. The *ports* (passes) of Siguer, Soldeu and Envalira may be blocked for months at a time, while the Valira defile below Sant Julià de Loria offers little easier, if more permanent, communication with Spain. The stratigraphy shows three main bands of Paleozoic crystalline formations running east-west: a southern granitic, a central of Silurian and Devonian slate and limestone, and a northern of metamorphic gneiss, the whole overlaid with Quaternary deposits and much influenced by glacier erosion.

The climate is severe, proportionately to altitude, for much of the year; extreme winter temperatures reach 5° F. at 3,500 ft. and -22° F. at 7,800 ft. Snow lies, on an average, from a month in Andorra la Vella to 7½ months in Portella Blanca. May, June and October are the rainiest months. Above 4,500 ft. drought becomes serious, making irrigation indispensable for the high meadows, which reach to the alpine zone; it is common in the lower valleys also, where torrents limit cultivable soil: the widest stretches being found about the capital. The best soil is provided by artificially terraced slopes. Forests have been largely destroyed. Trees include the evergreen oak, pine, spruce and poplar. Game abounds: there are hare, rabbit and partridge, with quail and chamois on the heights.

People and Population.—No prehistoric remains attest settlement earlier than that to be inferred from the Greek historian Polybius for the 3rd century B.C. Iberian and Roman coins have been found near Sant Julià. The territory was among the last occupied and first evacuated by the Muslims, who left no traces. The official language is Catalan (French and Spanish are widely understood), and the official religion Roman Catholic. The population of 5,664, according to the 1954 census, excluded about 1,400 foreigners, chiefly French and Spaniards; that of the parish comprising the capital was 1,382. Cluster-type settlements are both permanent and temporary. The former, found up to 6,000 ft., are generally on slopes facing south, the largest in the plains about Andorra la Vella and Encamp. Temporary (summer) habitations

range from 5,200 to 6,500 ft., peasants spending up to nine months of the year in some districts at the high villages (*cortals*), where pastures are held in common.

History.—Andorran independence is traditionally associated with Charlemagne and his son Louis I, who recovered Barcelona from the Muslims in 801 and is reputed to have made over to the Spanish bishop of Urgel some part of his suzerainty. The bishop's mitre and crosier figure in the country's crest. Later bishops for long saw their overlordship contested by the French counts of Foix until, in 1278, arbitration confirmed the valleys in their independence under a popularly elected council with bishop and count as co-princes *pro indiviso*. The rights of the house of Foix passed by marriage to that of Béarn, thence, with the accession of Henri IV in 1589, to the French crown, and finally to the president of the French republic. In 1793 revolutionary France renounced, on grounds of principle, its feudal rights, which Napoleon re-assumed in 1806, acceding to a petition from the Andorrans. The co-princes have mutually checked innovations, and on occasion each other, in a land where medieval usages persist. Differences of policy or interests between them, or between one and the council, have led periodically to the closing of one or another frontier. A feudal anachronism: it remains a suzerainty (*q.v.*), paying nominal annual tribute of 960 fr. to the president of France and 460 pesetas to the bishop of Urgel.

Administration.—The *Manual Digest* of usages of Fiter Rosell (1748) enjoys semiofficial acceptance in lieu of a constitution; a "Reform" of 1566 introduced electoral modifications. Legislative power is vested in the co-princes. A council general of 24 elected by heads of families of the six parishes (Andorra la Vella, Encamp, La Massana, Ordino, Canillo, Sant Julia de Loria) chooses a syndic as chief executive (term unlimited). Representatives (*veguers* or *viguers*) of the co-princes nominate two civil judges (*bailles*) of first instance. A judge of appeal is appointed alternately by the co-princes, with a supreme court at Perpignan and an ecclesiastical court at Urgel. *Veguers* and the appeal judge try criminal cases. Schools (primary only) are maintained by France and Spain, parish priests by the bishop of Urgel.

Economy.—With no ordinary taxes (until 1954 no budget), revenue comes chiefly from import duties. French and Spanish currencies are alike legal tender. Smuggling is rife, notably of tobacco and of consumer goods (especially automobiles) from France into Spain. Tobacco-growing and stock-raising are the major economic activities. In summer, with large-scale transhumance from the distant plains of the lower Segre and the Ariège, about 30,000 sheep graze on the high pastures. Lower slopes support horses, moles, cattle and goats. Difficulties of winter fodder mean large autumn fairs: held both in Andorra and across the Spanish border. Wheat, rye and potatoes are the chief crops. Mineral deposits include silver, lead and iron ores. A hydroelectric station at Les Escaldes (capacity 26,500 kw.) supplies Barcelona province. Industry is merely domestic; however, after World War II the tourist trade became important. A good road runs from L'Hospitalet, France, over the Port d'Envalira (8,022 ft.) to Xndorra la Vella and on to Seo de Urgel, Spain. Another joins the capital to Ordino. Roads are maintained by Fuerzas Hidroeléctricas de Andorra, S.A., posts and telegraphs by France, telephones by Radio Xndorra.

ANDOVER, a municipal borough and market town of Hampshire, Eng., lies among chalk hills on the Anton, a tributary of the Test, 14 mi. N.W. of Winchester by road and 17 mi. N.E. of Salisbury by rail. Pop. (1961) 16,974. The district is rich in prehistoric earthworks and tumuli. The witenagemot met there and it is the place where Aethelred II, "the Unready," met Olaf

Tryggvesson, afterward king of Norway. in 994. Andover is a borough by prescription, its earliest known charter having been granted in 1175. In the 14th century the town had a sheep fair, a woolen industry and an iron market and also manufactured parchments and silk fabrics. It is the centre of a large agricultural district; water cress is grown; there are flour mills, timber yards and printing works; and agricultural equipment and plastics are manufactured. Andover grammar school was founded in 1571. At Enham, in the northern part of the borough, is a village founded after World War I for disabled ex-servicemen. As the result of an Egyptian gift in Oct. 1945 of a substantial sum to commemorate the battle of El Alamein, the village was enlarged and officially renamed Enham-Alamein in Oct. 1947. There are many military and air force establishments in the locality, including the Royal Air Force staff college.

See O. G. S. Crawlford, *The Andover District* (1922 and 1923).

ANDOVER, a township of Essex county, Mass., U.S., on the south rim of the Merrimack valley, 23 mi. N. of Boston. (For comparative population figures see table in MASSACHUSETTS: *Population*.) The original settlement was incorporated in 1646, and named after the English home of early colonists. North Andover was separated in 1855. A council-manager form of government became effective in 1959.

It is both an industrial and an educational centre. Textile mills began as early as 1813; woolen and worsted goods are still important products. Shawsheen village, once a "model" community, was created at Andover by the American Woolen company. Rubber goods have been produced for more than a century.

The first educational institution of note was Phillips academy, founded in 1778 "for the purpose of instructing youth, not only in English and Latin grammar, writing, arithmetic, and those sciences wherein they are commonly taught, but more especially to learn them the great end and real business of living," according to the constitution written by Samuel Phillips, Jr. (1752-1802). The extensive grounds include those occupied 1808-1908 by Andover Theological seminary, now Andover-Newton Theological school at Newton, Mass. The Addison Gallery of American Art and the archaeological museum house important collections.

The town is also the home of Abbot academy, founded in 1829 by Sarah Abbot. This was the earliest incorporated school exclusively for girls in New England. Merrimack college in North Andover opened in 1947.

(CA. M. C.)

ANDRADA E SILVA, JOSÉ BONIFÁCIO DE (c. 1763-1838). Brazilian scholar, statesman and father of Brazilian independence. Born at Santos, of a prominent colonial family, he went as a student to Portugal, where he remained until the age of 56. He was the outstanding Brazilian scholar of the time, a professor at the University of Coimbra (in Portugal), permanent secretary of the Lisbon Academy and internationally renowned as a naturalist and geologist. Returning to Brazil in 1819, he devoted himself to politics. As an adviser and later minister of Dom Pedro, he worked actively for independence under a monarchy, was instrumental in the establishment of the empire of Brazil on Sept. 7, 1822, and became prime minister.

In the constituent assembly of 1823, Andrada led the opposition to Pedro's Portuguese counselors and was exiled until 1829. However, Andrada returned to the emperor's cause and continued to support it even after Pedro's abdication in 1831, when he became the tutor of young Pedro II. He was arrested for political intrigue in 1833.

He retired to Niterói, where he died on April 6, 1838. See also BRAZIL: *History*.

(R. E. P.)

ANDRÁSSY, GYULA, COUNT (1823-1890), Hungarian statesman, the first premier of Hungary in the Austro-Hungarian dual monarchy and as Austro-Hungarian foreign minister, a strong supporter of an alliance between Austria-Hungary and Germany, was born at Kassa (Kosice in Slovakia) on March 3, 1823, son of Count Károly Andrassy and Etelka Szapáry. He early joined the radical reformers in Hungary and entered the diet of 1847 pledged to their cause. In the subsequent hostilities (see HUNGARY: *History*) he saw some fighting in command of a battalion of volunteers against the Austrians, then was sent by Lajos Kossuth, in

May 1849, as diplomatic envoy to Turkey. After Hungary's surrender at Világos he spent some years in exile, chiefly in Paris; he was condemned to death in absentia by the Austrian government (Sept. 1851) and later hanged in effigy. In 1856 he married Countess Katinka Kendeffy. In 1857 he obtained an amnesty and returned to Hungary. When, in 1859, negotiations opened between the crown and the Hungarian leaders, Andrassy supported Ferencz Deák (q.v.), demanding the restoration of the 1848 legislation, and mediated between him and the court. When the Austrian emperor Francis Joseph agreed to appoint a responsible Hungarian ministry, Deák suggested that Andrassy should lead it. Appointed Hungarian premier and minister of defense on Feb. 17, 1867, Andrassy presided over the coronation of Francis Joseph as king of Hungary, the final codification of the Compromise (*Ausgleich*) and the settlement of certain questions left outstanding (over which he encountered stubborn resistance from Vienna).

Andrassy was always acutely aware of the Slav danger to Hungary, as represented by Russian ambitions and by the nationalist stirrings among the Slavs of the monarchy. For him safety against these two interlinked threats lay in the maintenance of the supremacy of the German element in Austria and of good relations between Austria and Germany. Consequently, already as Hungarian premier he intervened to quash both K. S. von Hohenwart's project for reorganizing Austria on a federal basis (as desired by the Czechs) and F. F. Beust's plan for taking revenge on Prussia for the Seven Weeks' War by means of alliance with France; it was because of his insistence that Austria declared itself neutral in the Franco-German War. When, thereafter, Francis Joseph abandoned the policy of revenge, he appointed Andrassy Austro-Hungarian foreign minister in place of Beust (Nov. 14, 1871). In this capacity Andrassy worked with much success to strengthen Austria's international position, always with an eye on the Russian danger. The outbreak of serious unrest in the Balkans in 1875 created a difficult situation for him (see EASTERN QUESTION). The *status quo* had vanished beyond recall; to let Russia alone profit by its disappearance was dangerous; but so was any increase of the number of Slav subjects of the monarchy, either in Hungary or in Austria. The occupation by the monarchy of Bosnia-Hercegovina, decided by the congress of Berlin in 1878, was Andrassy's solution as the least harmful course, but it was unpopular in both Hungary and Austria, and Andrassy resigned on Oct. 8, 1879. The previous day he had, however, secured the signature of the Austro-German alliance which until 1918 was to be the sheet anchor of the monarchy's foreign policy. Thereafter he still took part in the work of the upper house and the delegations. He died at Volosca in Istria on Feb. 18, 1890. He left a daughter and two sons, the younger of whom, Gyula, was also a distinguished statesman.

Andrassy was a man of great charm and natural ability. He was neither versed nor indeed interested in domestic politics, but in the field of foreign policy was undoubtedly a man of European outlook and format. There is an edition of his speeches, in Hungarian, by B. Lederer (1891).

See E. von Wertheimer, *Graf Julius Andrassy: sein Leben und seine Zeit*, 3 vol. (1910-13); G. Andrassy (the younger), *Bismarck, Andrassy and Their Successors*, Eng. trans. (1927).

(C. A. M.)

ANDRÁSSY, GYULA, COUNT (1860-1929), Hungarian statesman, the last foreign minister of Austria-Hungary, was born at Töketerebes (Trebisov in Slovakia) on June 30, 1860, the younger son of Count Gyula Andrassy (1823-90). After some diplomatic experience as attaché in the embassies in Berlin and Istanbul, he entered the Hungarian parliament in 1885. Dedicated to carrying on his father's work, especially in the foreign political field, he joined the Liberal party, the chief supporter of the Austro-Hungarian Compromise (*Ausgleich*) of 1867. His talents and his rectitude won for him great influence in the party, but he never got on well with its official leader, Count István Tisza, and was also not unsympathetic to some of the wishes of the opposition. In 1904 he left the Liberals in protest against Tisza's dictatorial methods and founded a Constitutional party. He was minister of the interior in the coalition government from April 6, 1906, to Jan. 17, 1910, when he resigned and dissolved his party. On

Oct. 25, 1918, in the last days of World War I, he became foreign minister of Austria-Hungary in an attempt to save its integrity by a separate peace. Pres. Woodrow Wilson's unbending reply and revolution in the monarchy itself swept him from office. He reentered the Hungarian parliament of 1920 as leader of the Christian National party. When, in Oct. 1921, King Charles (the ex-emperor of Austria) made his second attempt to recover his Hungarian throne, Andrassy joined him, was taken prisoner with him and was held in prison for several months. Released, he returned to parliament as a legitimist. He died in Budapest on June 11, 1929.

Andrassy wrote several works on Hungarian constitutional history, books of memoirs (including *Diplomacy and the War*, Eng. trans. 1927) and a study of his father's work, *Bismarck, Andrassy and Their Successors* (Eng. trans., 1927). (C. A. M.)

ANDRÉ, JOHN (1750-1780), British soldier executed as a spy during the American Revolution, was born in London, May 2, 1750, of a Genevese father and Parisian mother. He was a younger friend of the poet Anna Seward and became engaged to her friend, the beautiful Honora Sneyd. When the engagement was terminated, without heartbreak on either side, André bought a commission in the army in Jan. 1771. He studied military engineering at the University of Gottingen, Ger., and traveled on the continent until 1774 when he joined his regiment in Quebec.

Taken prisoner in the surrender of Ft. St. John's on Nov. 3, 1775, André was interned in central Pennsylvania until exchanged at the end of 1776. He then went to New York, was promoted captain and became aide to the notorious Gen. Charles Grey. He was active in the successful Philadelphia campaign, 1777, and during the winter occupation of the city promoted various entertainments and wrote light verse. After the British forces evacuated Philadelphia and returned to New York, André became aide to Gen. Sir Henry Clinton, the new commander in chief.

In May 1779 the American general Benedict Arnold (*q.v.*) offered his services to the British in return for pay and equal rank. As André was in charge of intelligence and knew Mrs. Arnold, he carried on the secret correspondence. It was broken off in October because the British would not commit themselves on payments. André became deputy adjutant general with the rank of major. He sailed to Charleston, S.C., with General Clinton in December and took part in the siege of that city. Upon his return to New York in June 1780 he found a new note from Arnold stating that he expected to obtain the command of West Point.

André arranged to meet Arnold under a misuse of a flag of truce. They met up the Hudson river on the night of Sept. 21 and agreed on the sum of £20,000 for the surrender of West Point, including the garrison and supplies. Half that amount was to be paid if Arnold should fail and join the British empty-handed. As the British sloop "Vulture" which brought André to the rendezvous was fired upon and forced to drop downstream, André was compelled to pass the night within American lines. The next day he was persuaded to exchange his uniform for a civilian disguise and to set out overland for New York, carrying a pass provided by Arnold. Suspicious American militiamen stopped and searched him on the morning of Sept. 23 and found papers about West Point in his boot. They held him while word was innocently sent to Arnold, enabling him to escape down river to the British lines.

The stunning disclosure left Andre as scapegoat. Out of uniform and in disguise, he was clearly acting the role of spy and could be executed immediately, but General Washington moved cautiously. He convened a board of officers to examine the prisoner. The board concluded that Andre "ought to be considered a spy, and that, agreeable to the law and usage of nations, it is their opinion he ought to suffer death." During the few days' delay, word was carried to Clinton that André could be saved if Arnold were given up. Clinton refused the tempting proposition. Andre was hanged at Tappan, N.Y., on Oct. 2, 1780.

Andre had literary talent and personal charm, and his fate excited sympathy among several American officers who attended him. The British army went into mourning for him. A memorial to Andre was placed in Westminster abbey, and his brother was made a baronet. Andre's military journal of June 1777 to the close of

1778 was taken to England by General Grey and finally published in 1904.

ANDREA DEL SARTO: see SARTO, ANDREA DEL.

ANDREANI, ANDREA, Italian woodcut artist, is famous for his work in chiaroscuro printing. The dates of his birth and death are not known. He was active in Florence from 1584 until 1585, in Siena from 1586 to 1593 and in Mantua in 1599. Between 1607 and 1610 he appears as a publisher of prints, not his own. He is said to have died in Mantua in 1623 at an advanced age.

All of Andreani's woodcuts are from the works of others. His style possessed a fine vigour and simplicity, and he is best known for his use of the chiaroscuro, the method of technique of printing a subject from more than one block and with colour. His works are from the compositions of Giovanni da Bologna, Domenico Beccafumi, Jacopo Ligozzi, Alessandro Casolani and others. The most famous of all is the group of 12 large woodblocks representing the "Triumph of Julius Caesar," painted by Andrea Mantegna. Here each block has an individual character, yet fits into its place in the unified whole; the several sections were intended to be pasted together or mounted as a single frieze. The importance of this work is such that it is to be found in all large collections that attempt to give a survey of masterpieces of print making.

(H. Es.)

ANDREE, KARL THEODOR (1808-1875), German geographer and writer, best known for his geography of world trade, which, though out of date, had not been replaced by the mid-20th century. Andree was born at Brunswick on Oct. 20, 1808. After studying history and political science at Jena, Berlin and Göttingen, he worked as a journalist until, influenced by Karl Ritter and Alexander von Humboldt, he turned entirely to geography and ethnography. In 1862 he founded the important periodical *Globus*, and with S. Ruge was the co-founder of the Dresden Geographical society. Andree's principal works include *Nordamerika in geographischen und geschichtlichen Umrissen* (1854), *Geographische Wanderungen* (1859) and *Geographie des Welthandels* (1862-77). He died suddenly at Bad Wildungen on Aug. 10, 1875.

RICHARD ANDREE (1835-1912), his son, edited *Globus* from 1891 to 1903 and in 1881 published *Allgemeiner Handatlas*.

(K. A. S.)

ANDREEV, LEONID NIKOLAEVICH (1871-1919), Russian novelist whose contemporary reputation has not lasted but whose best work has a place in Russian literature for its evocation of a mood of despair. Born at Orel, June 18, 1871, he went to St. Petersburg university in 1891, but attempted suicide and lived a restless life for some time. He subsequently studied law at Moscow and became a barrister and then a law and crime reporter, publishing his first stories in newspapers and periodicals. Encouraged by Gorki, who became a close friend, he was at first regarded as his successor as a realist. His "Zhili-byli" ("Once There Lived . . .") attracted attention, and was included in his first collection of short stories (1901). Two stories of 1902 caused a storm by their treatment of sex. Andreev's work became widely discussed and he acquired fame and wealth with a series of novels and short stories which at their best resemble Tolstoi, subdued in style but powerful in theme and showing an ironic sympathy for suffering humanity. They culminated in 1908 with *Rasskaz o semi poveshennykh* (*The Seven That Were Hanged*, 1909); among the best are *Gubernator* (1905; *His Excellency the Governor*, 1921) and *Krasny smekh* (1905; *The Red Laugh*). *T'ma* (1907; *The Dark*, 1922) shows his second style: its cloudy imagery reflects an increasingly nihilistic philosophy.

Andreev's fame as a novelist declined rapidly, however, and the ambitious *Sashka Zhegulev* (1912) attracted little attention. He began a career as a popular dramatist: his first play appeared in 1905. His most successful, *Zhizn' cheloveka* (1907; *The Life of Man*, 1915) and *Tot kts poluchayet poshchechiniy* (1914; *He Who Gets Slapped*, 1921), were allegorical dramas, but he also attempted realistic comedy.

During World War I Andreev became editor of a government-

inspired newspaper, and his writings were predominantly patriotic. A fervent antirevolutionary, he moved to Kuokkala, Fin., and his last work, *S.O.S.* (1919), was an appeal to the Allies to save imperial Russia. He died at Kuokkala, Sept. 12, 1919.

BIBLIOGRAPHY.—Andreev's collected works were published in 16 vol. (1910–15). Most have been translated into English. For full bibliography, see A. Kaun, *L. Andreyev: a critical study* (1924).

ANDREINI, FRANCESCO (1548–1624). Italian actor, was a distinguished exponent of the *commedia dell'arte* (*q.v.*) and a leader of its most famous company, the Gelosi, with which he visited Paris in 1600 at the invitation of Henry IV. His wife, ISABELLA ANDREINI (née Canali; 1562–1604), the company's brilliant and beautiful leading lady, whom he married in 1578, was also a minor poet, publishing a pastoral, *Mirtilla*, and a book of songs, sonnets and other poems. Of her seven children, the most famous was GIAMBATTISTA ANDREINI (*c.* 1578–1654), a distinguished actor who became well known in France under the name of Lelio. He was a leader, and probably founder, of the Fedeli company, which was popular with Louis XIII. He was also a prolific author, and it has been claimed that his play *L'Adamo* ("Adam"; 1613) suggested to Milton the idea of *Paradise Lost*.

ANDREIS, (ANDREW JAMES) FELIX (BARTHOLOMEW) DE (1778–1820), Vincentian priest and pioneer missionary to the American west, was born at Demonte, Piedmont, Italy, on Dec. 13, 1778. He pronounced his vows in the Congregation of the Mission of St. Vincent de Paul on Sept. 21, 1800, and was ordained at Piacenza, June 19, 1802. He performed numerous pastoral duties in that region until he was transferred in 1806 to Rome where he acquired a reputation as a preacher, professor of theology, retreat master and apostle to the poor. William DuBourg, bishop of Louisiana, visiting Rome in 1815, secured the services of Father Andreis for his diocese. Father Andreis was appointed temporary vicar-general and superior of a little band of missionaries that embarked for the American missions; among them was Joseph Rosati, first bishop of St. Louis. After a long delay at the Seminary of St. Thomas in Kentucky, where he spent several months teaching theology, Father Andreis arrived in St. Louis on Oct. 17, 1817. His first assignment was to the little village of St. Genevieve, but he was soon recalled to St. Louis and appointed vicar-general. He was professor and administrator of two colleges, one for clerical students and one for laymen, established by the bishop. He also supervised the erection of a novitiate for his congregation at the Barrens, 80 mi. S. of St. Louis. Although he appointed the Rev. Joseph Rosati first superior of the novitiate, Father Andreis continued to train the novices in St. Louis while the new buildings were under construction. He died in St. Louis on Oct. 15, 1820. During his lifetime he gained a reputation for sanctity and several miracles were attributed to his intercession after his death.

See Joseph Rosati, *Life of the Very Reverend Felix De Andreis, C.M.* (1900); Alceste Bozuffi, *Il Servo di Dio Felice de Andreis*, Direzione "Annali della Missione," Collegio Alberoni (1927). (F. G. McM.)

ANDRÉ LE CHAPELAIN (ANDREAS CAPELLANUS), medieval French writer on the art of "courtly love," and chaplain at the French court (whence his surname), was born in the second half of the 12th century, and probably held his office under Philip Augustus (1180–1223). His famous treatise, *Liber de Arte honeste amandi et de Reprobatione inhonesti Amoris*, written at the beginning of the 13th century and translated twice into French during the century, is an interesting source of information concerning medieval manners and morals, and the "court of love" in particular. There are 12 manuscripts extant, of which the most important are the 13th-century manuscript in the Vatican, the 14th-century manuscript in the Bibliothèque Nationale and the 15th-century manuscript in the Ambrosian library, Milan.

BIBLIOGRAPHY.—There is an English translation, *The Art of Courtly Love*, by J. J. Parry (1941); see also R. Bossuat, *Manuel bibliographique de la litt. fr. au moyen âge*, nos. 2759–80 and (*Supplément*) 6540–47, particularly E. Trojel, *Andree Capellani regii Francorum De Amore libri tres* (1892—rare), reproduced by Xmadeo Pagès (1929).

(F. J. WE.)

ANDREW, SAINT, brother of Simon Peter, one of the 12

apostles, always mentioned in the first of the three groups of four names in the apostle lists (Matt. x, 2; Mark iii, 18; Luke vi, 14; Acts i, 13). The name is Greek, meaning "manly." In the Synoptic Gospels Andrew is a fisherman from Capernaum (Mark i, 16, 29); together with Peter, James and John he asks Christ on the Mount of Olives about the signs of the end time, which is the occasion for the eschatological discourse (Mark xiii, 3). In John's Gospel he is the first disciple named; his home town is Bethsaida (i, 44) and he was a disciple of John the Baptist before Christ's call. He plays a part in the multiplication of the barley loaves and fishes (vi, 8) and acts as a go-between for the Greeks who want to see Jesus (xii, 22).

Early Byzantine tradition (dependent on John i, 40) calls Andrew *protokletos*, "first called." Legends of the early church recount his missionary activity in the area about the Black sea, in Scythia (according to Origen as quoted by Eusebius), in Epirus (Gregory of Kazianzen) and in Achaea, Greece (Jerome). Apocryphal writings were ascribed to him such as the Acts of Andrew, Acts of Andrew and Matthias, Acts of Peter and Andrew, etc. A 4th-century account reports his death by crucifixion at Patras in Greece in the year 60 under the governor Aegaeates. Late medieval art depicts the crucifixion on a cross shaped like the Greek chi (Χ). From the 4th century on his feast was celebrated on Nov. 30 (ancient Gothic calendar; Roman martyrology). Jerome records that his relics were brought to Constantinople by command of the emperor Constantius II in 357; from there they were taken to Amalfi, Italy, in 1208. St. Andrew is the patron saint of Scotland.

See Peter M. Peterson, *Andrew, Brother of Simon Peter: His History and His Legends* (1958); Francis Dvornik, *The Idea of Apostolicity in Byzantium and the Legend of the Apostle Andrew* (1958). (J. A. FL.)

ANDREW, SAINT, OF CRETE (*c.* 660–740), who was born at Damascus *c.* 660 and died on the island of Hierissus in 740, is regarded by the Greek Church as one of its greatest hymn writers. From his monastery in Jerusalem he was sent to Constantinople where he stayed and became deacon of Hagia Sophia. During the reign of Philippicus Bardanes he was made archbishop of Gortyra in Crete, took part in the Monothelite synod in 712, but recanted his heretical views in 713. Andrew helped to introduce in Constantinople the liturgy of Jerusalem which was based upon the Rule of St. Sabas and favoured hymn singing. Byzantine hagiography ascribes to him the invention of the Kanon, the new genre of hymnography which consisted of nine odes in strophic form, each of them sung to a different melody, and replaced the Kontakion, a homiletic hymn of which all stanzas were sung to the same melody. Andrew was the author of many hymns and Kanons which still figure in Greek liturgical books. His most famous work is the "Great Kanon" for Thursday in the fifth week of Lent, consisting of 250 stanzas which are divided into four sections. The Greek Church keeps July 4 as the feast day of St. Andrew of Crete (who should not be confused with St. Andrew of Crete, the Colybite).

See L. Petit, "André de Crète" in *Dict. d'archéol. chrétienne et de liturgie*, vol. i, 2034–41 (1903); R. Cantarella, *Poeti bizantini*, pp. 100–111 (1948). (E. J. Wz.)

ANDREW II (1175–1235); king of Hungary, of the house of Árpád, was a son of Béla III and succeeded his nephew, the infant László III, in 1205. His reckless generosity, forced on him by the powerful magnates, impoverished the crown and made the monarchy dependent on the great feudatories, who reduced Hungary to a state bordering on anarchy. His first wife, Gertrude of Meran, was murdered in 1213 by rebellious nobles who objected to the prodigality of her German retinue. In 1217 Andrew set out on a crusade to the Holy Land with an army of 15,000 men, about 10,000 of whom sailed from Venice to Acre. The expedition failed, and on Andrew's return the barons extorted from him the Golden Bull (1222), which has been called the Hungarian Magna Carta. The Golden Bull, one of the most important sources of the Hungarian constitution, limited royal privileges and prerogatives, confirmed the basic rights of the nobles and smallholders, promised to improve the coinage of the realm and guaranteed justice for all. It also granted the nobles the right to resist by force any illegal

royal decree (*jus resistendi*). Andrew came into conflict with the Teutonic Order (*q.v.*), which, after occupying parts of Transylvania for 14 years, challenged both royal and ecclesiastical authority. This controversy resulted in the Teutonic Order's expulsion from Hungary (1225). Andrew was married three times. St. Elizabeth of Hungary was his daughter by his first wife, Gertrude.

(GE. GR.)

ANDREW (BOGOLYUBSKI) (ANDREI YURIEVICH) (1111?-1174), grand prince of Vladimir, the most powerful Russian prince of the 12th century. The son of the grand prince Yuri Dolgoruki, he ruled the "land of Rostov-Suzdal" in the upper Volga region from 1157. He moved his capital to the city of Vladimir on the Klyazma river and enlarged, fortified and beautified his new residence, as well as his summer residence, called Bogolyubovo (from which his surname is derived). He built many churches, among them a magnificent cathedral of Our Lady in L'ladimir. He actively colonized the Rostov-Suzdal-Vladimir land, inviting servicemen, peasants and craftsmen from other regions into his realm. He strove to extend his authority over other Russian principalities. In 1169 his troops, with the troops of princes allied to him, stormed Kiev, the ancient Russian capital. Instead of coming himself to Kiev, however, Andrew put one of the allied princes on the throne there. In the following year his troops threatened the republic of Novgorod but were defeated by the Novgorodians. Soon after their victory, however, the Novgorodians saw themselves compelled to sue for peace and to accept a prince sent by Andrew. Andrew's policy aimed at establishing his sovereign power over other Russian princes, who regarded themselves as "younger brothers" of the grand prince but not as his vassals. Within his hereditary principality Andrew wished to be absolute master of all his subjects, including the boyars (*q.v.*), whom he treated as his common servitors and who were not accustomed to such full submission. When Andrew had inflicted the death penalty on one of his boyars, his embittered courtiers formed a conspiracy and in July 1174, at Bogolyubovo, killed their haughty prince.

See George Vernadsky, *Kievan Russia* (1948). (S. G. PU.)

ANDREW OF LONJUMEL (LONGJUMEAU, LONGUMEAU, etc.) (fl. 1238-1253), French Dominican, diplomat and traveler, noted for three diplomatic missions which he performed between 1238 and 1252. Nothing is known of Andrew's early life. In 1238 Louis IX (St. Louis) of France dispatched him to Constantinople to fetch the sacred Crown of Thorns which he had redeemed from the Latin emperor Baldwin II. Andrew carried the holy relic to Sens, where St. Louis met him, and thence to Paris where it was placed in the Sainte Chapelle. In 1247 he accompanied the mission under Friar Ascelin sent by Pope Innocent IV to the Mongols. At the Tatar camp near Kars, he met a certain David who appeared the following year at the court of Louis IX in Cyprus. Andrew, who was at that time with St. Louis, interpreted David's message, an offer of alliance from Elchigaday (Ilchikadi, Ilchikdai), the general in command of the Mongol hosts in Armenia and Persia, and a proposal for a joint attack upon Islam for the conquest of Syria. In reply St. Louis sent Andrew as ambassador to the great Khan Kuyuk.

Early in 1249 Andrew, accompanied by several ecclesiastics including John of Carcassonne, John Godericke and Gilbert of Sens, left Cyprus with letters from St. Louis and the papal legate, and rich presents including a chapel tent lined with scarlet cloth and embroidered with sacred pictures. From Cyprus the embassy went to Antioch and thence to the khan's court in central Asia; their route lay along the southern and eastern shores of the Caspian (its inland nature was demonstrated by their journey), and then through Talass, northeast of Tashkent; the journey took a year. On reaching the supreme Mongol court—located either on the Imyl river near Lake Ala-Kul or at or near Karakoram—Andrew found the great khan dead, poisoned as he concluded by agents of Batu Khan, who reigned supreme on the Volga.

The gifts which the embassy carried were regarded by the Mongols as evidence of submission to a dead khan. Andrew and his companions were received by the regent-mother, Ogul Gaimish (the "Camus" of Rubruquis), who dismissed them with presents

and a letter for King Louis; the insolent language of the letter marked the mission a failure. It is generally held that Mangu Khan, Kuyuk's successor, was elected before the embassy left Tatarly. The missionaries returned to the west to find St. Louis at Caesarea, sometime between March 1251 and May 1252.

Notwithstanding displeasure at the letter, St. Louis, on hearing shortly after that a son of Batu Khan was a "baptised Christian," sent William of Rubruquis (or Rubrouck) on an informal mission to the Mongols; it was William who recorded Andrew's account of his embassy. Andrew's narrative was a mixture of fact and fiction. His description of Tatar customs was fairly accurate, and his statements about the prosperity of Mongol Christianity, although exaggerated, were basically true. His route was marked by mounds of bones, witnesses to devastations recorded in detail by other historians. On the other hand his location of the Tatar homeland close to the prison of Gog and Magog and his account of the Mongols' rise to greatness and the struggles of their leader with Prester John rest upon fable. Nothing is heard of Andrew after 1253.

See especially William of Rubruquis in *Recueil de voyages*, Paris Geogr. Soc., iv, pp. 261, 265, 279, 296, 310, 353, 363, 370 (1539); Abel Rémusat, *Mémoires sur les relations politiques des princes chrétiens, et particulièrement des rois de France, avec les empereurs Mongols*, p. 52 ff. (1822 et seq.). (E. M. J. C.)

ANDREW, JOHN ALBION (1818-1867), U.S. political leader and Civil War governor of Massachusetts, was born at Windham, Me., on May 31, 1818. He graduated from Bowdoin college, Brunswick, Me., in 1837, studied law in Boston, was admitted to the bar in 1840 and practised his profession in Boston. He was a prominent member of the Unitarian Church and was assistant editor for some time of *The Christian World*. He entered political life as a "conscience Whig" in opposition to the Mexican War, joined the Free-Soil movement in 1848, and after the passage of the Kansas-Nebraska act in 1854 took part in the organization of the Republican party in Massachusetts. He served one term, 1858, in the state house of representatives. The following year he defended the abolitionist John Brown (*q.v.*) so vigorously that he was summoned to Washington to appear before a senatorial investigating committee. In 1860 he led the Massachusetts delegation at the Republican convention at Chicago, which nominated Lincoln for the presidency; and from 1861 to Jan. 1866 he was governor of Massachusetts, becoming known as one of the ablest and most energetic of the "war governors" of the North.

Governor Andrew anticipated military conflict with the South and had young men drilled and supplied so that Massachusetts troops began to muster in Boston on April 16, the day after Lincoln called for volunteers. At his own request, he was authorized by the secretary of war in 1863 to raise several Negro regiments with white commissioned officers. Although Governor Andrew criticized Lincoln for timidity during the war, he rejected in 1865 the more radical views of his party and supported most of Pres. Andrew Johnson's program. On retiring from the governor's office he resumed the practice of law with great success. In 1865 he presided at the first national convention of the Unitarian Church. He died suddenly of apoplexy, at Boston, on Oct. 30, 1867.

See Henry G. Pearson, *Life of John A. Andrew* (1904).

(N. A. G.)

ANDREWES, LANCELOT (1555-1626), English bishop, was a key figure in the theological and liturgical development of the English Church from the uncertainties of the 16th century to the Restoration settlement. Descended from an ancient Suffolk family, he was born in London in 1555 and was educated at Cooper's Free school, Radcliffe, at Merchant Taylors' school and at Pembroke hall, Cambridge. Elected fellow of Pembroke in 1575, he was ordained deacon in 1580. He was master of Pembroke and vicar of St. Giles', Cripplegate, London (1589-1605), prebendary of St. Paul's and of Southwell minster (1589-1609), prebendary (1597-1601) and dean (1601-05) of Westminster. He refused the sees of Salisbury and Ely because Elizabeth I required his concivance in their spoliation by the crown. Consecrated bishop of Chichester in 1605, he was translated to Ely in 1609 and to Winchester in 1619. Andrewes was lord almoner to James I (1605-

19) and dean of the chapels royal (1619–26). He died at Southwark, Sept. 25, 1626.

The English Church's distinctive position in a divided Christendom was defined to the accompaniment of violent controversy, and Andrewes' own contribution to Anglican theology inevitably took a polemical form. His university career coincided with the great Puritan attempt to make Cambridge a stronghold of Calvinistic orthodoxy, while the years of his episcopate were marked by prolonged debates with Roman Catholics, precipitated by the Gunpowder plot and the resultant anti-Roman Catholic legislation. Despite his early exposure to Puritan influences, Andrewes was a cautious but consistent critic both of Calvinist dogmas and of Puritan reform platforms. His major writings, however, were devoted to anti-Roman Catholic apologetics, in which he combined a critique of distinctively Roman Catholic dogmas with a positive statement of Anglican teaching on such themes as patristic tradition, episcopacy and the sacraments.

The same Catholic-minded churchmanship was expressed both in Andrewes' learned, eloquent and influential preaching and in his dignified liturgical practice, and was further commended by his austere life and reputation for sanctity. His ardent devotion and private integrity were indisputable. However, his public failings, such as pluralism in his own career, nepotism in his exercise of patronage, an exaggerated deference to royal authority and a tendency to evade responsibility, both marred the image of sanctity and limited Andrewes' role in the rebuilding of the English Church.

BIBLIOGRAPHY.—P. A. Welsby, *Lancelot Andrewes, 1555–1626* (1958), is the only adequate biography; it contains full bibliographies. See also R. L. Ottley, *Lancelot Andrewes* (1894), a good sketch. The "Library of Anglo-Catholic Theology" includes Andrewes' *Collected Works*, 10 vol. (1841–54). Separate editions and translations of his *Preces privatae* are numerous. (E. R. F.)

ANDREWS, CHARLES McLEAN (1863–1943), U.S. educator and historian, was born in Wethersfield, Conn., on Feb. 22, 1863. He was educated at Trinity college, Hartford, Conn., graduating in 1884, and at Johns Hopkins university, where he received the degree of doctor of philosophy in 1889. He taught history at Bryn Mawr college from 1889 to 1907; was professor of history at Johns Hopkins university from 1907 to 1910; and served as professor of American history at Yale university from 1910 to 1931. For two years after his retirement as a professor he served as director of historical publications at Yale and continued to serve, as he had since 1912, as editor of the *Yale Historical Publications*.

Though his graduate training and first teaching led him to work in European history, Andrews soon shifted to exclusive specialization in American colonial history. By the time he went to Yale in 1910 he was well started on his important guides to colonial materials in English archives. Emerging at once as a leader in the school of colonial historiography, since called "the imperial school," which insists that as the American colonies were dependent parts of the English system the centre of the colonial story belongs in the mother country. Andrews oriented all his work that way. Such an interpretation runs through his books, all of which received wide acceptance, and through the writings of historians trained in his seminar. He served as president of the American Historical association in 1924–25 and in 1935 the first volume of his four-volume work, *The Colonial Period of American History*, won a Pulitzer prize. He died in New Haven, Conn., Sept. 9, 1943.

Among his extensive historical writings are: *Colonial Self-Government, 1652–1689*, vol. v of *The American Nation, a History* (1904); (with F. G. Davenport) *Guide to the Manuscript Materials for the History of the United States to 1783 in the British Museum, in Minor London Archives and in the Libraries of Oxford and Cambridge* (1908); *The Colonial Period* (1912); *Guide to the Materials for American History, to 1783, in the Public Record Office of Great Britain*, 2 vol. (1912–14); *The British Merchants and the Non-Importation Movement* (1917); *Fathers of New England and Colonial Folkways in "Chronicles of America Series"* (1919); *The Colonial Background of the American Revolution* (1924); *The Colonial Period of American History*, 4 vol. (1934–37).

See A. S. Eisenstadt, *Charles McLean Andrews: a Study in American Historical Writing* (1956). (C. A. Ba.)

ANDREWS, FRANK MAXWELL (1884–1943), U.S. soldier and air force officer, was born in Nashville, Tenn., on Feb. 3, 1884. Graduating from the U.S. Military academy at West Point in 1906, Andrews was commissioned in the cavalry, serving in the Philippines and Hawaii, but in 1917 he transferred into the new air service, rising to lieutenant colonel by the end of World War I.

After holding routine service assignments during the postwar period, in 1935 he was named commander of the new general headquarters air force, the first independent U.S. air striking force. A determined though moderate advocate of strategic air power, Andrews in his four years' command of G.H.Q. air force contributed signally to the evolution of American bombardment aviation; the development of the Boeing B-17 bomber during these years was in large measure attributable to his vision, and G.H.Q. air force became the model for the powerful army air forces of World War II. During the war, Andrews, as air commander in the Caribbean and later as head of the Caribbean defense command, was the first U.S. airman to hold theatre command. He was promoted to lieutenant general in 1941.

In Feb. 1943 he assumed command of all United States forces in Europe, succeeding Gen. Dwight D. Eisenhower. He was killed in an airplane accident in Iceland on May 3, 1943.

(W. R. E.)

ANDREWS, ROY CHAPMAN (1884–1960), U.S. naturalist and explorer, popularly known best for books on his central Asiatic field trips. Born at Beloit, Wis., on Jan. 26, 1884, he entered the American Museum of Natural History, New York, immediately after his graduation from Beloit college in 1906 and went to Alaska on his first exploring trip in 1908. In 1909–10 he accompanied, as a naturalist, the U.S.S. "Albatross" on its voyage to the Netherlands Indies, Borneo and Celebes; in 1911–12 he explored northern Korea; and in 1913 was with the Borden Alaska expedition.

Until 1914 he specialized in the study of whales and other water mammals. From that date he devoted himself, as chief of the division of Asiatic exploration of the American Museum of Natural History, to the exploration of the lesser known portions of central Asia, China and Borneo, also serving in the U.S. intelligence service in China in 1918.

The expeditions under his leadership explored successively Tibet, southwest China, Burma, north China, Mongolia and central Asia. In Mongolia they found some of the richest fossil fields known to the world. The fruits of the expeditions which he led in 1921–22 and 1925 into central Asia included the discovery of new geological formations, large fossil fields, dinosaur eggs and the skull and other parts of the *Baluchitherium*—the largest known land mammal.

The expeditions discovered some of the oldest known mammals and continued work in central Asia until 1932. He was director of the American Museum of Natural History from 1935 to 1942, when he retired. He died March 11, 1960, in Carmel, Calif.

He wrote *Whale Hunting With Gun and Camera* (1916), *Camps and Trails in China*, with Yvette Borup Andrews (1918), *Across Mongolian Plains* (1921), *On the Trail of Ancient Man* (1926–27), *Ends of the Earth* (1929), *The New Conquest of Central Asia* (1933), *This Business of Exploring* (1935), *This Amazing Planet* (1940), the autobiographical *Under a Lucky Star* (1943) and *An Explorer Comes Home* (1947), and *Beyond Adventure* (1954), as well as numerous monographs and scientific bulletins.

ANDREWS, THOMAS (1813–1883), Irish chemist and physicist, is best known for his experiments in the liquefaction of gases which displayed great skill and resourcefulness. He was born on Dec. 19, 1813, at Belfast. Following periods of study in Glasgow, Paris, Dublin and Belfast, he attended the University of Edinburgh, where he received a degree in medicine in 1835. In 1841 he was appointed vice-president of the newly established Queen's college, Belfast, and, in 1849, professor of chemistry, offices which he held until 1879, when failing health compelled his retirement. He died on Nov. 26, 1885.

Andrews carried out a very complete inquiry into the laws expressing the relations of pressure, temperature and volume in carbon dioxide, in particular establishing the conceptions of critical temperature and critical pressure, and showing that the gas passes from the gaseous to the liquid state without any breach of continuity.

ANDRIA, a city of southeastern Italy in the region of Puglia and province of Bari, is situated on the slopes of the Murge, 55 km. (34 mi.) W.N.W. of Bari by road. Pop. (1957 est.) 70,050 (commune). The city has several notable Roman remains and a restored 10th-century cathedral. The cloister of S. Domenico church is Gothic. There are several Renaissance palaces with decorated doorways and balconies: Casa Margiotti and Casa Toma are particularly good examples. The convent of Sta. Maria Vetere has pictures by Antonio Vivarini. Andria is on the railway from Bari to Foggia. Agriculture, especially the cultivation of vines, olives and almonds: is the chief industry; wine, oil and spun goods are also made. Andria may be the *Netion* of Strabo. Its recorded history began when the Normans came and Pietro I, count of Trani, enlarged and fortified the modest *Locum Andrae*. Subsequently it became the favourite home of Emperor Frederick II, who built in 1240 the Castel del Monte, 17 km. S., a massive octagonal Gothic structure, with plumbing installations exceptional for those days. Eventually the city passed to the Angevins, Otto of Brunswick, and the Orsini, Acquaviva and Carafa families. In World War II Andria was captured by the Allies in Sept. 1943. (M. T. A. N.)

ANDRIC, IVO (1892–), Yugoslav novelist and author of short stories who was awarded the Nobel prize in literature in 1961. He was born at Travnik, Bosnia, and studied at Zagreb, Cracow, Vienna and Graz. His potentialities as a writer of both prose and verse were recognized early, and his reputation was established with *Ex Ponto* (1918), a contemplative lyrical prose work written during internment for political activities during World War I. Collections of his short stories were published at intervals from 1920 onward. Of his three novels; written during World War II, two—*Travnicka hronika* (1945; Eng. trans. *Bosnian Story*, 1959) and *Na Drini cuprija* (1945; Eng. trans. *The Bridge on the Drina*, 1959)—are concerned with the history of Bosnia. Although his career in the Yugoslav diplomatic service took him to Rome, Bucharest, Madrid, Geneva and Berlin, it is his native province that has provided the wealth of themes and psychological studies to be found in his works. These reveal his deterministic philosophy and his sense of compassion, and are written objectively and soberly, with economy and clarity, and in language of great beauty and purity. The Nobel prize committee commented particularly on the "epic force" with which he handled his material, especially in *The Bridge on the Drina*. (V. J.)

ANDRIEUX, FRANÇOIS GUILLAUME JÉAN STANISLAS (1759–1833), French lawyer hostile to Napoleon Bonaparte's civil code and dramatist who achieved contemporary fame as an ultraclassicist, was born at Strasbourg on May 6, 1759. Under the Convention (1792–95) he was a judge in the civil division of the court of cassation, which had power to annul the verdicts of lower tribunals. He became president of the Tribunat, the deliberative assembly opposed to the civil code, and was therefore displaced from the law in 1802. Andrieux then returned to dramatic writing, having achieved success with *Les Étourdis* (1787). His later plays include *Molière avec ses amis* (1804), *La Comédienne* (1816) and *Lucius Junius Brutus* (1830). As professor of literature at the Collège de France (1814) he maintained the classical tradition against the growing romantic school. His advice to the young Balzac (*q.v.*), to choose any profession rather than the writing of plays, is often remembered as a sign of his biased judgment. He became permanent secretary to the Académie Française in 1829, and the 1835 edition of the *Dictionnaire de l'Académie* was prepared partly under his direction.

Andrieux died in Paris on May 9, 1833.

ANDROCLES (**ANDROCLUS**) (fl. 1st century A.D.), a Roman slave, is the hero of a story by Aulus Gellius, taken originally from Apion's *Aiguptiaka* and also found in Aelian's *De natura*

animalium (vii, 48), which tells that Androcles had taken refuge from the cruelties of his master in a cave in Africa, when a lion entered the cave and showed him his swollen paw, from which Androcles extracted a large thorn. The grateful animal subsequently recognized him when he had been captured and thrown to the wild beasts in the circus and, instead of attacking him, began to caress him; he was then set free. The story is the subject of the play *Androcles and the Lion* by G. Bernard Shaw.

ANDBRMACHE, in Greek legend, the daughter of Eetion, prince of Thebe in Mysia, and wife of Hector (*q.v.*). All her relations perished in or shortly after the taking of the town by Achilles. After the capture of Troy her son Astyanax (or Scamandrius) was hurled from the battlements. When the captives were allotted, Andromache fell to Neoptolemus (Pyrrhus), the son of Achilles, whom she accompanied to Epirus and to whom she bore three sons. When Neoptolemus was slain at Delphi, he left Andromache and the kingdom to Helenus, the brother of Hector. After his death Andromache returned to Asia Minor with her youngest son, Pergamus, who there founded a town named after himself.

ANDROMEDA, one of the constellations of the northern sky, near Perseus and Cassiopeia, named for the Andromeda of Greek legend, the daughter of Cepheus and Cassiopeia (*see* PERSEUS). The most famous feature of the constellation is the Great Andromeda Nebula, the brightest of the spiral nebulae. The distance of the nebula from the solar system was estimated by Walter Baade to be about 2,000,000 light-years, and it can be seen without much difficulty with the naked eye, being recognizable by its diffuse appearance. It is an "island universe" probably containing millions of stars and of the same general nature as our own stellar system, though apparently of somewhat smaller dimensions. (See NEBULA.) A number of outbursts of novae (temporary stars) have been observed in the nebula. Nearly all the spiral nebulae are receding from us with large velocities, but the Andromeda nebula is one of the exceptional approaching systems, its velocity in the line of sight being 300 km. per second. Photographs show in great detail its beautiful spiral structure; the plane of the spiral is tilted with respect to the Earth, giving the nebula an apparently elongated form.

The double star γ Andromedae is a favourite object for observation with a small telescope because of the striking contrast of colour of the two components.

The Andromedids are a swarm of meteors which made a notable display on Nov. 27, 1872, and provide some of the November meteors year by year; the swarm is believed to be the debris of Biela's comet which was last seen in 1852.

ANDRONICUS I (**ANDRONICUS COMNENUS**) (*c.* 1100–1185), Byzantine emperor from 1183 to 1185, was a son of Isaac and a grandson of Alexius I Comnenus. Captured by the Seljuk Turks in 1141 but ransomed a year later he went to Constantinople to the court of his cousin, the emperor Manuel I. Andronicus repeatedly fell into disgrace with the emperor because of his doubtful loyalty. Fascinating and well-educated, he was a born adventurer and most unscrupulous. He spent much of Manuel's reign in exile, wandering from court to court, living at Kiev or at Antioch or in Syria, Mesopotamia and the Caucasian districts. Finally he returned and submitted to Manuel and was then appointed governor of Pontus. The accession of a minor, Alexius II (*q.v.*), and the unpopular regency gave him his opportunity. He advanced through Asia Minor and reached Chalcedon. A revolt broke out in Constantinople, accompanied by a massacre of the Latins (May 1182), and Andronicus then entered the capital as the protector of Alexius II. He was crowned co-emperor in Sept. 1183, but soon killed Alexius and married Agnes, his child-widow.

The short reign of Andronicus was characterized by strong and wise measures. He attempted to suppress many administrative abuses, but, above all, to check the power of the great landed magnates and to reverse the pro-Latin policy of his predecessor. The people, who felt the severity of his laws, at the same time acknowledged their justice and found themselves protected from the rapacity of their superiors. The aristocrats, meanwhile, were infuriated against him and frequent conspiracies occurred, which

he ruthlessly suppressed. He also faced external danger in the form of a Norman invasion. In 1185, William II of Sicily invaded Epirus and advanced as far as Thessalonica, which he took and sacked. At the news of the approaching Normans, a riot broke out in Constantinople. Isaac II Angelus was proclaimed emperor, and Andronicus was handed over to the mob, at whose hands he died on Sept. 12, 1185.

BIBLIOGRAPHY.—G. Ostrogorsky, *History of the Byzantine State* (1956); A. A. Vasiliev, *History of the Byzantine Empire* (1952); C. Diehl, *Figures byzantines*, vol. 2 (1906). (J. M. Hy.)

ANDRONICUS II (ANDRONICUS PALAEOLOGUS) (1258–1332). Byzantine emperor from 1282 to 1328, was the eldest son of Michael VIII, who proclaimed him heir-presumptive in 1261 and co-emperor in 1272 and whom he succeeded in Dec. 1282. An intellectual and a theologian rather than a statesman or soldier, he found it hard to deal with the new and urgent military problems of his reign. The danger from the west, which had determined his father's foreign policy, had collapsed with the Sicilian Vespers in 1282 (see *VESPERS, SICILIAN*), but Andronicus was faced with the revived aspirations of the Serbs under Milutin (1282–1321) and with the fresh inroads of the Ottoman Turks. He held the Serbs off by giving his infant daughter in marriage to Milutin; but his attempt to stem the Turkish tide by accepting the help of Roger di Flor and his Catalan mercenaries, the *Almogávares* (*q.v.*), proved disastrous. The Catalans fell out of favour, their leader *n-as* murdered and they turned on their employers, while the Turks overran almost the whole of Asia Minor, leaving only a few isolated places (such as Nicaea and Nicomedia) in Byzantine control.

Internally Andronicus' reign was marked by a steady disintegration of centralized authority and by the concentration of power in the hands of the landed aristocracy. He tried to offset the depreciation of the currency by new measures of taxation and unwise economies. His reduction of the strength of the Byzantine army and navy led to an increasing reliance on foreign mercenaries; and by playing off the Genoese against the Venetians he involved the empire in their private disputes and made it almost entirely dependent on the Italian republics for its maritime trade and defense. In some respects, however, his reign was enlightened and progressive. Culture and the arts revived, and such men as the philosopher Theodore Metochites and the historian Nicephorus Gregoras were among his friends and counselors. He completely revised the diocesan lists of the empire and transferred Mount Athos from the jurisdiction of the emperor to that of the patriarch. He repudiated his father's attempt to save the empire by enforcing union with the Roman Church and deposed the unionist patriarch John Beccus. In 1320, however, Andronicus quarreled with his grandson Andronicus III and excluded him from the succession.

Civil war ensued and in May 1328 he was forced by his grandson to abdicate. He died on Feb. 13, 1332, as the monk Anthony.

See G. Ostrogorsky, *History of the Byzantine State* (1956).

(D. M. N.)

ANDRONICUS III (ANDRONICUS PALAEOLOGUS) (1296–1341). Byzantine emperor from 1328 to 1341, was the son of Michael IX and the grandson of Andronicus II. His youthful extravagance lost him the favour of his grandfather, who deprived him of his right to the crown after one of his escapades had brought about the murder of his brother and the death of his father Michael (1320). The family quarrel then developed into civil war. Andronicus had many supporters among the younger Byzantine nobility, particularly the wealthy John Cantacuzenus. He obliged his grandfather to recognize him as ruler of Thrace and part of Macedonia in 1321, and to accept him as co-emperor in 1325. War broke out again in 1327, the Bulgars and the Serbs taking opposing sides, and the elder Andronicus was forced to abdicate in May 1328. Andronicus III, although a brave soldier, left the direction of imperial policy to his friend Cantacuzenus. His reign was one of constant warfare, principally with the Ottoman Turks and the Serbs. He encouraged the Seljuks against the Ottomans, and the Bulgars against the Serbs. But the Ottomans captured Nicaea and Nicomedia, and the Serbs defeated the

Bulgars at Velbuzhd (Kyustendil) in July 1330. Andronicus' efforts to break the Genoese control of Byzantine waters and to reorganize an imperial fleet led to the recovery from Genoa of Lesbos, Chios and Phocaea. His greatest achievement, however, was to win back the districts of Epirus and Thessaly, which had been under separatist Greek rule since the fourth crusade (1204). He died on June 15, 1341.

See G. Ostrogorsky, *History of the Byzantine State* (1956).

(D. M. N.)

ANDRONICUS OF CYRRHUS (fl. c. 100 B.C.), Greek astronomer, is best known as the builder of the horologium at Athens, the so-called "tower of the winds." A considerable portion of the tower still exists. It is octagonal, with sundials and figures carved on each side, these figures representing the eight principal winds. A brazen Triton on the summit, with a rod in his hand, turned round by the wind, pointed to the quarter from which it blew. From this model is derived the custom of placing weathercocks on steeples (see *ATHENS: Topography and Antiquities: Roman Period*). Andronicus also built a multiple-faced sundial in the sanctuary of Poseidon on the Island of Tenos.

ANDRONICUS OF RHODES (1st century B.C.), 11th head of the Peripatetic school and editor of the treatises of Aristotle and Theophrastus. The works Aristotle had published were mainly dialogues in a popular style; his mature thought had been expressed in lectures to his students, which had been transmitted through several generations in a state of confusion, the *disjecta membra* of important treatises being thrown together with trivial by-products of Peripatetic research. Andronicus disengaged the master's authentic works from this miscellaneous material and arranged them in a logical order, justifying his procedure in a long treatise (later lost) in which he gave a biography of Aristotle, treated of questions of authenticity and explained the structure of the Aristotelian system. He also collected Aristotle's letters and wrote commentaries on some of the treatises. He proceeded in the same way in his edition of Theophrastus. A treatise *On the Emotions* and a paraphrase of Aristotle's *Ethics* which were printed under the name of Andronicus were not written by him.

See P. Moraux, *Les Listes anciennes des ouvrages d'Aristote* (1951).

(D. J. A.)

ANDROS, SIR EDMUND (1637–1714), one of the ablest English colonial governors in 17th-century America. He was born in London on Dec. 6, 1637, the son of Amice Andros, royal bailiff of the Island of Guernsey. He was brought up as a page in the royal household and remained loyal during the Commonwealth exile. In 1674 his loyalty was rewarded by his appointment as governor of New York and the Jerseys. He was a military man of aristocratic background, able but tactless. His ability as an administrator and his conscientious devotion to the prerogatives of the crown made him unpopular and he was recalled in 1681. The restoration policy of colonial consolidation returned Andros to America in 1686 as governor of the Dominion of New England, ultimately to include Massachusetts, Maine, Plymouth, Rhode Island, Connecticut and New Hampshire. Two years later his jurisdiction was extended to include New York and the Jerseys. His imposition of Episcopal worship in the Old South meetinghouse in Boston, his vigorous enforcement of the Navigation acts, his conservative financial policies, his demands that taxes and quit rents be paid, his requirement that landholders take out non-land patents, and his limitations upon town meetings and right of local taxation antagonized the colonists. When the news of the overthrow of Charles II reached Boston, Andros was summarily deposed and arrested. In England he was tried and immediately released. In later years he served as governor of Virginia (1692–98), Maryland (1693–94) and Guernsey (1704–06). In Virginia he encouraged cotton culture and promoted the establishment of William and Mary college. He died in London, Feb. 24, 1714.

(RA. Mu.)

ANDROS, the most northerly island of the Cyclades (*q.v.*), Greece, lies 6 mi. S.E. of Euboea and about 2 mi. N. of Tenos. It is nearly 25 mi. long and its greatest breadth is 10 mi. The population is 14,705 (1951), among whom are many Albanians, especially in the north. It is mountainous, with many fruitful

and well-watered valleys. Andros, the capital, on the east coast, has 1,859 inhabitants. The ruins of Palaeopolis, the ancient capital, are on the west coast; the town possessed a famous temple, dedicated to Dionysus. The ancient population was mainly Ionian, perhaps with a Thracian admixture. Originally dependent on Eretria, in the 7th century B.C. it sent colonies to Chalcidice (Acanthus, Stageirus, Argilus, Sane). In 480 it supplied ships to Xerxes and was subsequently harried by the Greek fleet. Though enrolled in the Delian league it remained disaffected toward Athens, and was obliged to admit Athenian settlers. It revolted in 411 and was attacked by Athens. In the 4th century it was again an uneasy member of the revived, anti-Spartan Delian league. In the Hellenistic period Andros was coveted as a frontier post by the naval powers of Macedonia and Egypt. In 200 it was captured by a combined Roman, Pergamene and Rhodian fleet, and remained a possession of Pergamum until the bequest of that kingdom to Rome in 133 B.C. Before falling under Turkish rule, Andros was from A.D. 1207 to 1566 governed by the Zeno and Sommariva families under Venetian protection. It became part of Greece in 1829 and is now an eparchy.

See T. Sauciuc, *Andros* (1914).

(J. Bo.)

ANDROSCOGGIN, a river that serves as the outlet of Umbagog lake in Errol, N.H. It flows southerly 39 mi. to Gorham, N.H., thence easterly 65 mi. to Jay, Me., and southerly 67 mi. to the sea. The river drops a total of 1,245 ft. between Umbagog lake and tidewater with two steep drops at Berlin, N.H., and at Rumford, Me. Water power, process water and spruce fir forests of the drainage basin have combined to make it one of the leading pulp and paper manufacturing areas in New England. Similar resources account for textile manufacturing in Auburn and Lewiston, Me. Shoe manufacturing is most important in the diversified industry group. The excellent hunting, fishing and boating on the river and lakes attract thousands of sportsmen. (A. S. CN.)

ANECDOTE, a brief humorous story told as true about a person well known to the circle of listeners. Nationally prominent figures and locally celebrated characters attract anecdotes, and often the same story is tied to different personalities. The anecdote is therefore a form of folklore. An urban anecdote tells how Winston Churchill, accused of ending his sentences with prepositions, declared, "This is a criticism up with which I shall not put." Earlier Disraeli, faced with the same charge from Gladstone, supposedly replied, "That is something I cannot be bothered with." The same anecdote also is told as a joke. In World War II a hillbilly captain, nettled by the criticism of his grammar from a Harvard-educated private, seriously posted on the bulletin board the same statement attributed to Churchill.

An anecdote popular in small towns is told on the local Munchausen. He passes a friend at work, who says to him banteringly, "Tell me a lie." "I haven't time," replies the wag, "your father has just cut himself awful and I'm after a doctor." His friend rushes home only to find that the noted liar has indeed told him a lie. This anecdote is told on American storytellers like Gib Morgan of the oil fields, and has circulated widely in Europe and Asia. (R. M. DN.)

ANEMIA is a condition of variable severity in which the concentration of hemoglobin in the circulating blood is reduced below normal. Hemoglobin, an iron-containing protein, gives the blood its red colour and is a direct measure of the capacity of blood to transport oxygen from the lungs to the tissues (see BLOOD). Consequently, the severity of anemia is best determined in practice by laboratory measurement with a photoelectric colorimeter of the intensity of the blood's hemoglobin colour. The reduced amount of oxygen in the blood of anemic patients is a major cause of their symptoms and of the concurrent dysfunction of organs such as the heart, skeletal muscle and brain. Anemia is always a sign, either predominant or incidental, of some underlying congenital condition or acquired disease.

Normally the blood consists of about five litres of a liquid containing a prodigious number of small hemoglobin-containing red corpuscles which are kept in suspension by the turbulence of the passage of the liquid through the blood vessels. When venous blood is centrifuged the slightly heavier red corpuscles pack to-

gether below the pale yellow plasma and occupy about 45% of the sample. Under the microscope the red cells appear as biconcave discs with an average diameter of about 0.0075 mm. (a common pin is about 1 mm. thick). Blood of normal human adult males contains on the average 5,400,000 red cells, that of normal adult females 4,800,000, per cubic millimetre, as enumerated after manifold dilution in a ruled counting chamber under the microscope. Each red cell holds about a third of its volume of hemoglobin. Collectively the red cells in 100 c.c. of adult male blood contain 16 g. of hemoglobin on the average, while the same quantity of adult female blood contains 14 g. Knowing the number of red cells, the amount of hemoglobin and the volume of the centrifuged red cells in a sample of blood permits easy calculation of the hemoglobin concentration and volume of the average red cell. These are often useful indexes of the nature of an anemia. Microscopic inspection of films of blood dried on glass slides and stained with aniline dyes allows observations of variations in the size and colour of individual red cells. It also permits identification of the two other cellular constituents of the blood, the so-called white corpuscles, which are nucleated and are larger than red cells, and the dustlike blood platelets.

SYMPTOMS AND SIGNS

In all types of anemia the decreased amount of oxygen carried by the blood requires compensatory adjustments by the body. These usually consist of (1) an increase in the amount of blood pumped through the tissues by the heart; and (2) an increase in the proportion of oxygen removed from the blood by the tissues. The effect of the first compensatory mechanism is perceived by the patient or his physician as more forceful or rapid heart action and pulse; the second is detectable only by laboratory analysis of the venous blood. The symptoms of tissue oxygen deficiency include pulsating noises in the ears, dizziness, fainting, poor appetite, shortness of breath and increased amounts of urine. In certain kinds of anemia the underlying condition itself may produce other symptoms in, for example, the nervous, digestive or genitourinary system. Abnormal physical signs include pallor, jaundice, skin hemorrhages, inflamed tongue or gums or enlargement of the heart, liver, spleen or lymph nodes. Aside from microscopic examination of the blood and bone marrow and chemical study of the blood plasma, X-ray examinations of the stomach, bowels, lungs or bones may be necessary for determination of the underlying cause of the anemia.

CAUSES AND TREATMENT

Red cells are formed within the marrow cavities of the central bones of the adult human skeleton (skull, spine, ribs, breastbone and pelvic bones), the marrow comprising altogether an organ larger than the liver. Samples of the active red bone marrow are easily obtained by needle or trephine puncture of the sternum or other accessible bones. Under the microscope the marrow shows hosts of nucleated red cells at all stages of development toward the mature, adult, nonnucleated, hemoglobin-containing cell that will be released into the circulation. When, as after a hemorrhage, more adult red cells are needed, the primitive cells develop rapidly, making possible a six- to eightfold increase in red cell production in certain types of anemia.

In the normal person sufficient red cells to contain about 7.5 g. of hemoglobin are released daily from the bone marrow into the blood stream. Those newly arrived in the circulation are recognizable for two or three days as reticulocytes when stained in a way to display their characteristic threadlike network. When the bone marrow is actively producing red cells, reticulocytes are numerous. Each day's crop of new red cells survives for about 100 days before succumbing to old age. The hemoglobin is then released and digested by specialized reticuloendothelial cells lining the capillary blood vessels, especially those of the spleen and liver, into its components: iron, a red pigment with a ring-shaped structural formula (porphyrin) and a protein (globin). The iron remains in the body to be used over and over again in the formation of new hemoglobin, but the porphyrin ring opens and changes chemically to become the yellow pigment of the blood plasma,

bilirubin. This is then excreted by the liver, giving the bile its characteristic colour. In patients whose anemia is due to increased destruction of red cells, excess amounts of bilirubin in the yellow plasma cause the patient to appear to be slightly jaundiced, and the excess bile pigments darken the excreta.

In a healthy person, constant levels of red cells and hemoglobin exist in the circulating blood because the same enormous numbers of red cells are produced as are destroyed daily. Anemia results when either (1) the production of red cells and hemoglobin temporarily lags behind the normal rate of their destruction; or (2) an excessive rate of destruction temporarily exceeds the capacity of the bone marrow to produce red cells. Unless, at some reduced hemoglobin level consistent with life, these two opposed processes again become equivalent, the patient will die. This may happen quickly if too rapid destruction of red cells occurs. On the other hand, in chronic anemia in which only diminished red cell production is involved, this balance may result in a relatively constant but reduced level of circulating hemoglobin. The rate of production of red cells by the bone marrow is normally controlled by a physiological feedback mechanism analogous to the thermostatic control of temperature in a room. Thus, when the hemoglobin level in the circulating blood falls below normal, production of red cells in the bone marrow is accelerated, apparently as the result of a chemical signal carried to the marrow by the plasma.

REDUCED PRODUCTION OF RED CELLS

There are three principal causes of anemia of this type: (1) anatomical derangements of the bone marrow; (2) deficiency of essential chemical substances involved in the formation processes or required in the composition of the red cell; (3) "poisoning" or inhibition of the red cell forming processes. In general, in such anemias the reticulocytes in the peripheral blood are few and the bilirubin in the plasma is not increased.

Anatomical Derangements of Bone Marrow.—These may result from several causes, one of which is invasion by cancer cells carried by the blood stream from a tumour situated frequently in the breast, prostate gland or lung. The proliferating cells of leukemia (*q.v.*), a "cancer" of the white cell precursors in the bone marrow or lymph nodes, may also overgrow the bone marrow. Some forms of chronic marrow white cell leukemia (myeloid metaplasia) or chronic exposure to organic chemicals may stimulate replacement of the active red cellular bone marrow by fibrous tissue or bone. Only when very extensive, however, will any of these processes significantly reduce the production of red cells by the marrow. A characteristic sign in the peripheral blood of such mechanical interference is the appearance of many irregularities in the size and shape of the red cells and of nucleated red cells, which normally never leave the bone marrow. Unless the process invading the marrow can be suppressed (by use of X-rays, anti-leukemic or adrenocortical drugs), the patient's life can be prolonged only by frequent blood transfusions.

The so-called aplastic anemia (frequently of unknown cause) represents a challenging but fortunately comparatively rare form of anatomical bone marrow failure. In this condition the normally red bone marrow becomes fatty and yellow and fails to form enough of any of its three cellular products. Consequently, anemia with few reticulocytes, bone marrow white cells (granulocytes) and platelets in the peripheral blood is characteristic. The lack of granulocytes, which normally ingest bacteria when they invade the tissues, invites infections of the mouth or gums. The lack of platelets leads to bleeding, disfiguring and harmless in the skin but quickly fatal in the brain. In many patients it has been found that onset of aplastic anemia was preceded by extensive exposure to such organic chemicals as benzol or to hair dyes or insecticides containing benzollike chemicals. In some instances a peculiar sensitivity of the patient to a drug useful and harmless to hundreds of others has been responsible. Aplastic anemia also results from overexposure to various types of radiation, whether from external X-rays or internally absorbed radioactive substances, provided their destructive energy reaches the cells of the marrow. The only useful treatment is repeated blood transfusions and, when infection develops, administration of antibacterial drugs, in the hope of sus-

taining the patient until spontaneous recovery of bone marrow function occurs.

Deficiency of Essential Nutrients and Regulators of Bone Marrow Function.—Such deficiency causes several types of curable anemia and represents an area of great increase in knowledge that began in 1926. In that year, George R. Minot and William P. Murphy of Boston, Mass., reported that a large series of patients with pernicious anemia, previously an invariably fatal disease, showed prompt clinical improvement after being placed on a diet rich in liver: and that within a few weeks normal red cell and hemoglobin levels were attained. This work was suggested in part by experiments with chronically bled dogs, conducted by George H. Whipple of Rochester! N.Y., in which the efficacy of liver and meat in promoting formation of hemoglobin was demonstrated. It is now known that the activity of these foods in the dogs was due chiefly to their iron content, whereas the substance in liver active in pernicious anemia was principally vitamin B₁₂. The latter discovery was the result of scientific work of the pharmaceutical industry in the United States in 1945 and shortly afterward in England. Long before that time, liver extracts for oral use and later purified extracts for injection had been developed, providing one of the most dramatic of modern medical triumphs over death. The combined work of Whipple, Minot and Murphy, to whom the 1934 Nobel prize in medicine was awarded, converted the clinical study of anemia from a largely descriptive to a dynamic and actively pursued experimental subject.

Deficiency of Vitamin B₁₂.—This red, cobalt-containing vitamin is found in animal but not in vegetable foods. Unlike other vitamins, it is not formed by higher plants but only by certain bacteria and molds (as, for example, in its commercial production) and in the rumina of sheep and cattle, provided traces of cobalt are present in their fodder. In other species, including man, vitamin B₁₂ must be obtained passively, by eating of animal foods. The vitamin, however, is successfully assimilated from the human intestinal tract only if a mucoprotein secretion of the stomach, the so-called intrinsic factor, is available to concentrate the vitamin on the intestinal wall.

In pernicious anemia, a condition first described by Thomas Addison of London in 1855 and usually affecting patients past middle life, all stomach secretion spontaneously fails and vitamin B₁₂ ceases to be assimilated. However, if even as little as a millionth of a gram of vitamin B₁₂ is injected daily, numerous reticulocytes begin to appear in the blood within a few days, and within six weeks the patient is well and no longer anemic. The half pound of liver a day originally prescribed by Minot and Murphy usually contained enough vitamin B₁₂ to force the assimilation of the necessary daily millionth of a gram of vitamin B₁₂ despite the absence of the stomach factor. Today it is possible but inefficient to treat the patient by a combination of hog stomach intrinsic factor and vitamin B₁₂. In practice the most reliable treatment is the injection of small amounts of vitamin B₁₂ at monthly intervals.

Without vitamin B₁₂ all bone marrow activity slows down and reticulocytes, granulocytes and platelets appear in reduced numbers in the circulation. In the marrow the nucleated red cells become abnormally large (megaloblastic) and show signs of delayed maturation of the nucleus. The adult red cells eventually formed are unusually large (macrocytic). Because they are well filled with hemoglobin, the bone marrow defect clearly lies in cell production rather than hemoglobin production. Deficiency of vitamin B₁₂ also results in a red cell destroying process in the bone marrow, with elevated plasma bilirubin and clinical jaundice.

Lack of vitamin B₁₂ also occasions defective formation of the papillae of the tongue, giving an appearance of abnormal smoothness. It often causes defective function of the intestine, resulting in "indigestion" and sometimes constipation and diarrhea. Most serious, because if it has been present for some time treatment with vitamin B₁₂ may not correct it, is the degeneration of certain motor and sensory tracts of the spinal cord that vitamin B₁₂ deficiency may cause. Initial complaints of numbness and tingling of fingers or toes may, without treatment, eventually progress to great instability of gait or virtual paralysis.

Vitamin B₁₂ deficiency also may result from complete vegetarianism or from competition for vitamin B₁₂ by the broad tape-norm or by intestinal bacteria growing in cul de sacs or above partial obstructions. In these, as in such primary intestinal diseases as chronic celiac disease, tropical sprue or regional ileitis that affect the absorptive capacity of the small bowel, additional nutritional deficiencies (as of folic acid or iron) are likely to develop.

Deficiency of Folic Acid.—Folic acid is found in leafy vegetables and is also synthesized by certain intestinal bacteria. In man, deficiency of this vitamin is sometimes the result of a highly defective diet, of chronic intestinal disease including celiac disease and tropical sprue, or of cirrhosis of the liver; and in some way pregnancy increases the requirement for the vitamin. The macrocytic anemia and megaloblastic bone marrow that folic acid deficiency causes are indistinguishable under the microscope from those of vitamin B₁₂ deficiency, but the nervous system is never affected. In 1937 Lucy Wills of London found that some patients did not respond to the injection of purified liver extract, subsequently recognized to be virtually a pure solution of vitamin B₁₂. Eventually it was discovered that such patients have low levels of folic acid in the plasma and that they respond to the daily administration of as little as 250-millionths of a gram of pteroylglutamic acid, a synthetic folic acid. In 1946 it was found that 20 or more times that daily dosage also causes temporary blood response in pernicious anemia. However, anemia and nervous system damage may appear later. In rare instances additional dietary deficiency of vitamin C may produce clinical signs of scurvy and interfere with the conversion of dietary folic acid in the liver to its internally active form. Unless folic acid deficiency is complicated by the presence of intestinal or liver disease, its treatment rarely requires more than that a normal diet be instituted. Otherwise pteroylglutamic acid can be given daily by mouth.

Deficiency of Iron.—This is probably the commonest cause of anemia in all parts of the world. To it many different names have been applied: nutritional anemia in babies, chlorosis in adolescent girls, idiopathic hypochromic anemia in adult women, hookworm anemia, etc. To prevent such anemia, an adequate endowment of iron must be supplied by the mother to the unborn infant, and children of both sexes must obtain from food sufficient iron to maintain an ever-expanding pool of circulating hemoglobin until full growth is attained. At that time about 2.6 g. of iron, which constitutes 0.34% of the hemoglobin molecule, are present in the blood and 4.6 g. in the entire body. Thereafter, in the adult male, unless bleeding and consequent iron loss takes place (as from peptic ulceration, hookworm infestation, bowel cancer or hemorrhoids), there is virtually no more need for iron. In the adult female, however, recurrent menstruation or pregnancies make the demand for iron continuous. Milk is a poor source of iron; meat and green leafy vegetables are good sources, provided the normal stomach secretion of hydrochloric acid is present to render the iron soluble and provided there is no defect of assimilation due to intestinal disease.

Lack of iron quantitatively limits the hemoglobin available for red cell manufacture; hence the developing cells in the marrow have normal nuclei but small amounts of hemoglobin-containing cytoplasm. Red cell production is relatively less reduced than is that of hemoglobin, and the adult red cells released into the blood are small and pale. Granulocytes and platelets are produced in normal quantities. The plasma contains little bilirubin. The plasma iron is low and the granules of storage iron seen in the reticuloendothelial cells of the normal marrow are absent.

Victims of iron deficiency anemia are pale but not jaundiced. The deficiency of iron-containing enzymes in the tissues results in a smooth tongue, brittle, flattened fingernails and lustreless hair. The only treatment required is oral administration of iron salts in some palatable form. In instances of intestinal disease in which iron by mouth may be irritating or not well assimilated, organic iron compounds are available for injection. Within a few days the patient feels stronger, the reticulocytes increase temporarily and the hemoglobin level rapidly rises as new red cells, well filled with hemoglobin, pour into the blood stream.

Endocrine Deficiency.—Of more theoretical than practical interest are the mild anemias associated with deficiencies of the anterior pituitary, thyroid, adrenocortical or testicular hormones. The major symptoms of such patients are not due to the insignificant anemia; rather they are characteristic of the lack of a particular endocrine function as it affects general or specific metabolism. Unless complicated by deficiencies of vitamin B₁₂ or iron, these anemias are never severe and are readily abolished by appropriate treatment with the lacking hormone.

Inhibition of Red Cell Forming Processes.—Such inhibition is due to the effect of various "poisonous" substances absorbed from outside or elaborated within the body by disease. In addition to anemia with few reticulocytes, reduction in the numbers of granulocytes and platelets may or may not occur. The so-called antifolic drugs, useful in the treatment of certain acute leukemias in children because they deprive the abnormal marrow white cells of an essential growth factor, may for the same reason also adversely affect red cell production. Chloramphenicol, a useful antibacterial drug, in rare patients has a toxic action upon the bone marrow. Far commoner are the anemias that result from the inhibitory effects of chronic infection, widespread cancer or uremia resulting from any kind of chronic kidney failure. The bone marrow looks surprisingly normal under the microscope, which suggests that it is powerless to increase its cellularity in response to the developing anemia. The removal of the offending drug may allow spontaneous recovery; but with toxins of internal origin only the elimination of the chronic infection, the temporary suppression of the cancerous growth or the relief of uremia will lessen the anemia.

INCREASED DESTRUCTION OF RED CELLS

There are two principal causes of anemia of this type: (1) inherently defective red cells; or (2) environment hostile to red cells. Both result in short red cell survival—sometimes of only a few days' duration in severe anemia. In general, the reticulocytes in the peripheral blood are numerous and the bilirubin in the plasma is increased as are the deposits of iron in the tissues. The patients look jaundiced, and the increased excretion of bile pigments may lead to the formation of gallstones.

Although profuse blood loss causes anemia, the immediate clinical symptoms and signs are due to the reduced blood volume, for which replacement by transfusion is urgently required. In fact, anemia develops only after the blood has become diluted with fluids derived from the tissues. Unless iron deficiency anemia results from continued bleeding, recovery is spontaneous over a few weeks and is initially associated with a transient rise of reticulocytes.

Defective Red Cells.—Of these, there are three principal hereditary types recognizable by the appearance under the microscope: spherocytic, target (target-oval) and sickle cell. One additional acquired type, an acid-sensitive red cell defect, causes chronic hemolytic anemia with paroxysmal hemoglobinuria.

Spherocytic Anemia.—In spherocytic anemia (hereditary hemolytic jaundice, spherocytosis) many of the red cells appear to be small, stain densely for hemoglobin and look nearly spherical. Such cells are mechanically fragile and readily swell up and burst osmotically in dilute salt solution. The chronic anemia is usually moderate or so slight that it may go unnoticed for years. However, anemia may become suddenly severe when an incidental respiratory infection briefly suppresses the increased production of red cells necessary to meet the constantly increased rate of red cell destruction (aplastic crisis). Congenital spherocytic anemia is transmitted by either parent as a Mendelian dominant. Studies with patients' red cells labeled with radioactive chromium, which emits gamma rays detectable at body surface, show that the radioactivity accumulates in the spleen. This occurs because the spheroidal shape of the red cells prevents them from readily passing through the spleen as normal discoidal cells do. Therefore, as might be expected, operative removal of the enlarged spleen permanently cures the anemia by eliminating this critical filter. Splenectomy is a harmless procedure except sometimes in infants. It does not, of course, prevent the future hereditary transmission of the disease.

Target-Cell Anemia.—In this disease, often called hereditary leptocytosis or, because of its usual geographical origin, Mediterranean anemia, the unusually flat red cells display central pale-staining areas (target cells) and irregular variations from the usual circular outline. The cells resist osmotic desruction in dilute salt solution. The mild form of the disease is associated with only slight anemia and a normal life expectancy. Development of the severely anemic form of the disease, which appears in infancy and is usually fatal before puberty, requires that both parents have the milder form. Although in the severe form the spleen and liver are usually enlarged, splenectomy is not usually beneficial, presumably because the short-lived red cells are destroyed elsewhere. Moreover, there is a diminished rate of hemoglobin production that is not corrected by iron therapy and that results in a blood level of hemoglobin constantly lower than that of red cells. Transfusions yield temporary benefit only.

Sickle-Cell Anemia.—In sickle-cell anemia (or sicklemia) most of the red cells of a sample of fresh blood look normally discoidal until deprived of oxygen, when the characteristic sickle- or crescent-shaped forms with threadlike extremities appear. Re-exposure to oxygen causes immediate reversion to the discoidal form. Only patients with the homozygous, *i.e.*, inherited from both parents, form of the disease are anemic. Their red cells begin to sickle when exposed to oxygen concentrations like those of the normal venous blood. Much lower oxygen concentrations are required to cause sickling of the cells of the nonanemic, heterozygous, *i.e.*, inherited from only one parent, form. In 1949 the sickling phenomenon was shown by Linus Pauling of the California Institute of Technology to be associated with the presence of hemoglobin with an abnormal electric charge on the molecule, accounting for most of the hemoglobin in the severely anemic form but for only about half that in the heterozygous patient's cells. In 1950 John W. Harris of Boston, Mass., demonstrated that cell-free solutions of sickle-cell hemoglobin when deoxygenated became viscous and under the microscope displayed parallel alignment of the hemoglobin molecules in elongated masses looking very like sickled cells. In the next few years, as a result of the wide clinical use of paper electrophoresis, several other hereditary varieties of abnormal hemoglobin were discovered in patients with mild forms of target-cell anemia alone or in genetically determined combinations with sickle-cell hemoglobin. Especially in these last, significant degrees of anemia may be present.

Sickle-cell anemia occurs almost exclusively in Negroes! of whom, in the United States, about 7% carry the sickle-cell trait. Only the homozygous form is clinically important because of the accompanying severe chronic anemia and painful crises. These last are apparently due to blockage of capillary beds in various organs by masses of sickled red cells: giving rise to fever and episodic pains in chest, abdomen or joints that are difficult to distinguish from other diseases. The homozygous anemic patients usually die in childhood after a period of some years of disability. At first the spleen is enlarged and congested with sickled red cells, but later it withers away. No treatment other than transfusion has been found useful. Oxygen inhalation suppresses red cell production more than it reduces sickling.

Environment Hostile to Red Cells.—This is invariably an acquired situation. It may be the result of (1) exposure to red cell destroying (hemolytic) chemicals; (2) development of antibodies (allergy) against red cells; or (3) increase of red cell trapping. The microscopic appearance of the red cells is not distinctive, and careful questioning and subtle tests for abnormalities of plasma or red cells are required for diagnosis.

Chemicals.—Chemicals that destroy red cells are usually themselves oxidants or are transformed into oxidizing substances in the body. Injury may be accidental, as with moth ball (naphthalene) ingestion in children or the undesirable effects of a drug such as sulfanilamide or primaquine. The anemia develops rapidly over a few days and without transfusions may be fatal. The oxidizing activity of the substance in the plasma may be sufficient to destroy any kind of red cell. In 1953 Alf S. Alving, of Chicago, Ill., discovered that the red cells of certain Negroes were abnormally susceptible. These particular red cells were lacking in a protective

enzyme, and when exposed to oxidant chemicals in the patient or in the test tube readily developed oxidized hemoglobin (methemoglobin) and microscopic Heinz bodies. Treatment consists of transfusions for severe anemia and future avoidance of potentially toxic chemicals.

Allergy.—Antibodies against red cells are found in the plasma and clearly cause acute hemolytic anemias in paroxysmal hemoglobinuria due to cold, erythroblastosis fetalis of newborn infants, or after a drug such as stibophen has combined with and antigenically altered the red cells. Plasma antibodies are special proteins formed by the body against foreign protein (antigens), never against its own unaltered proteins. Syphilis occasionally causes a hemolytic plasma antibody to develop which quickly destroys red cells after exposure of the blood to cold in the test tube or in the patient. The hemoglobin released from the red cells pours out in the urine (hemoglobinuria). For such a patient, cold feet are indeed a hazard.

In erythroblastosis fetalis (hemolytic disease of fetus and newborn) no red cell destroying process can be demonstrated in the test tube. However, when the infant's plasma is slightly concentrated the red cells are clumped (agglutinated). When these "sensitized" or "coated" cells are labeled with radioactive chromium and are injected into a suitable normal person they are quickly removed by the spleen and destroyed by some unknown process. This is presumably also the case in the affected infant's own enlarged spleen. In 1940-42, chiefly through the researches of Philip Levine, Karl Landsteiner and Alexander Wiener of New York, the mechanism of sensitization was explained. It was found that 85% of normal persons had in their red cells, irrespective of Landsteiner's classical blood group ABO factors, a new factor, Rh (*Rhesus*). The other 15% did not, and hence were called Rh-negative. If an Rh-negative person was injected with Rh-positive red cells or if an Rh-negative mother received such cells from an Rh-positive fetus (father Rh-positive) through a break in the placental blood vessels during pregnancy, anti-Rh antibodies frequently developed in the mother, sometimes in high concentration in the plasma. When these antibodies passed into the fetus, as do other maternal plasma proteins, a red cell destroying process was set up with severe anemia and hemolytic jaundice. The jaundice may be so severe as to cause yellow staining and damage to the central nervous system (kernicterus). Fortunately the lives of most affected infants who survive to the end of pregnancy can be saved by prompt exchange transfusions, which remove Rh-antibodies and introduce Rh-negative, unagglutinable red cells into the infant's circulation. Although the mother develops no anemia she may again build up anti-Rh antibodies during any subsequent Rh-positive pregnancy. Rh-incompatibility between husband and wife is by no means necessarily followed by maternal sensitization, which in many past instances resulted from ill-considered transfusion or injection of Rh-positive blood into Rh-negative female children or young women. (See also FETAL DISORDERS: *Erythroblastosis Fetalis*; BLOOD: Individuality of *Human Blood*.)

Increase of Red Cell Trapping.—This occurs with true agglutinating antibodies, as noted above, and also in other acquired hemolytic anemias associated with obscure red cell agglutinating (but not hemolyzing) properties of the plasma. The circumstance that the red cells of these patients, like those in erythroblastosis fetalis, are apparently sensitized has understandably led to the assumption that they also are coated by antibodies. However, the antigens of the hypothetical "autoantibodies" are unknown. Moreover, in 1956, James H. Jandl of Boston, Mass., showed that exposure of normal red cells to certain heavy metal salts in plasma at once endowed them with the hallmarks of sensitized red cells. Conservatively it may be supposed therefore that the affinity of an abnormal plasma protein for the surface of the red cell is often merely fortuitous.

Whatever the initial coating mechanism, hemolytic anemias of this type are found in patients with leukemias and other tumours of the white cells, especially those arising from lymph node cells (Hodgkin's disease). Less commonly, patients with ovarian tumours, cancers and chronic infections resembling generalized tuberculosis (sarcoid) develop this kind of hemolytic anemia.

However, in half these patients no such association is found. The spleen is usually enlarged and in many patients can be shown to remove selectively and destroy the patient's red cells. Consequently, splenectomy is frequently useful in such patients. However, treatment by other means, including X-rays, antitumor chemotherapy or steroid drugs (cortisone), is effective only temporarily in those with underlying malignant disease.

Hemolytic anemia is also the result of an increase of the filtering capacity of the spleen for uncoated red cells (hypersplenism). Anemia in part due to this cause occurs acutely when the spleen enlarges in response to infections such as pneumonia, typhoid fever or endocarditis. When the spleen is enlarged as a result of chronic obstruction to its venous outflow, as in cirrhosis of the liver, or as a consequence of infiltration by certain types of leukemic cells, splenic sequestration of the patient's uncoated red cells is the dominant cause of the chronic hemolytic anemia.

ANEMOMETRY is the measurement of air speed. Because of the difficulty of visibly tagging a small volume of air, it is not practical to observe its motion directly for a known time interval and so compute its speed. Instead, it is necessary to observe some physical effect associated with air motion. Among such effects are: the drift of objects suspended in the moving air; the pressure developed by resisting the motion of the air; the cooling of heated objects by the air stream; and changes in the speed of sound waves resulting from their passage through moving air. Anemometers have been built utilizing each of these effects. The anemometers based on the drift of an object in air (rotating cup and fan types) are the most common means of obtaining wind-speed data for weather forecasting purposes.

Pressure, heat-loss and acoustic types are special-purpose instruments used primarily for measurements taken under unusual conditions or for special speed ranges.

The rotating cup anemometer consists essentially of three or four cups, hemispherical or bluntly conical, placed at the ends of light arms arranged like spokes of a wheel around a vertical rotating shaft (see fig. 1). The wind force is greater on a cup that has its concave face to the wind than on a cup on the opposite side of the wheel that has its convex back to the wind. The net force on a pair of opposite cups is then such that the wheel will rotate in that direction which

FIG. 1.—A CUP ANEMOMETER
Standard anemometer used by the U.S. weather services. The rate of revolution of the cups is indicated or recorded at a distance by electrical means. The instrument body contains a transmitting mechanism and a counter dial

allows the concave faces to retreat before the wind. The useful range of a standard cup anemometer is about 5 to 100 m.p.h. In fluctuating winds, the cup anemometer does not slow down as rapidly as it speeds up. The resulting error, called overrunning, gives an indicated average wind velocity greater than the true wind.

In very gusty wind, overrunning may produce an error as great as 30%. A contact mechanism within the box on the shaft housing allows a remote electrical indication to be made of each shaft revolution or mile of wind by means of a buzzer or flashing light. A simultaneous recording may be made by a magnetically operated pen bearing on a chart attached to a clock-driven drum.

Another form of mechanical anemometer is the fan-type anemometer. This consists of from 3 to 15 flat or curved blades mounted on a horizontal shaft which has a wind vane attached (see fig. 2)

to keep the fan facing into the wind, in the manner of a windmill. When its rotating mechanism is very light and is mounted on jeweled bearings, the fan anemometer is especially adapted to measuring low air speeds in the range 1 to 25 m.p.h. (100-2,000 ft./sec., 1.5-35 ft./min.).

It is not feasible to compute the calibration factor of a mechanical anemometer from its dimensions. Its performance must be determined by observation in a wind tunnel whose air speed is known. This latter is best obtained by previous measurement with a pressure-type anemometer.

The common pressure anemometer consists of two thin-walled rigid tubes facing into the air stream. One is a Pitot tube (after Henri Pitot, French physicist [1695-1771], its end cut off square and open to the air stream. The other is a static tube, closed and rounded at its upstream end, but having at some distance back a ring of small holes around the circumference of the tube. These permit an equalization of pressure within the tube and in the air streaming past just outside the holes. (See fig. 3, while the tubes are shown separated, it is common to surround the Pitot tube with the static tube.) A pressure gauge is connected to the tubes and indicates the differential pressure between them.

When a stream of air strikes the open mouth of the Pitot tube, it is brought to rest with a rise in pressure exactly equal to one-half the product of the air density and the square of its speed. When the static holes are located at least five tube diameters back on the cylindrical portion of the static tube, the air stream flowing smoothly over them will cause the pressure within the tube to be exactly equal to the static pressure outside. Since the static pressure also exists within the open Pitot tube, it will appear on both sides of the differential gauge with no effect. Only the dynamic pressure will be effective. The gauge may be calibrated either in pressure or air-speed units according to the rule given above. Pressure anemometers are best used in strong and steady

air streams, as in wind tunnels and on aircraft.

In the air-speed range below five miles per hour, where all but the most sensitive mechanical and pressure tube anemometers fail, the heat-loss anemometer becomes useful. One form, the hot resistance wire anemometer, consists of a heated wire, a source of electric power and an electric meter to show the heating current. The wire is of a metal chosen to give a large change in electrical resistance with temperature. When a rise in air speed increases the rate of heat loss, the wire temperature falls, the consequent resistance drop permits more current to flow, more heat is generated and a balance between heat gain and loss is again obtained, but at a new temperature. The electric-current meter may be calibrated in terms of air speed.

Another form, the heated thermocouple (see THERMOMETRY), employs an alternating current to heat the couple. The equilibrium temperature is measured as a direct current potential without interference by the heating current in the same circuit.

Heat-loss anemometers are especially valuable in observing air motion in very small spaces, where other types are too big to be inserted or would upset the flow they are intended to measure.

Acoustic anemometers measure the speed of sound in moving air. Since this speed is constant and known in still air, any deviation from it is a measure of the drift of the air in which the sound wave is traveling. The use of acoustic anemometers is limited to experimental researches in which small, rapid changes in very high air speed occur which cannot be detected by the more sluggish mechanical and pressure types.

See W. E. K. Middleton and A. F. Spilhaus, *Meteorological Instruments* (1953). (D. P. K.)

ANEMONE, or WINDFLOWER, a genus of the buttercup family (Ranunculaceae), containing about 100 species, mostly in the north temperate zone. *Anemone nemorosa*, wood anemone, occurs in Britain.

The plants are perennial herbs with an underground rootstock, or tuberous-rooted, and radical, deeply cut leaves. The elongated flower stem bears white, red, blue or, rarely, yellow flowers; there is an involucre of three bracts below each flower. The fruits comprise a cluster of short-beaked achenes, or long, plumose fruits in the pasqueflowers.

Many are favourite garden plants; among the best known is *Anemone coronaria*, the poppy anemone, a tuberous-rooted plant with divided leaves, and large, showy poppylike blossoms on stalks from six to nine inches high: the flowers are scarlet, crimson, blue, purple or white. There are also double-flowered varieties.

The genus contains many other spring-blooming plants, of which *A. hortensis* and *A. fulgens* have less-divided leaves and rosy-purple or scarlet flowers. They are of easy culture, especially when started from tubers. The splendid Japanese anemone, *A. japonica* (also called *A. hupehensis*), is a fine autumn-blooming perennial. It is started from tubers or plants set out in early spring, preferably in a partially shaded place in any ordinary garden soil. Of the many varieties of the Japanese anemone outstanding are Alba (white), September Charm (silvery pink), Alice (rose-pink), Prince Heinrich (deep pink), Rubra (red) and Marie Manchard (white). All bloom from September to frost, and in severe climates need a winter mulch.

A group of dwarf species, represented by the European *A. nemorosa* and *A. apennina*, are beautiful spring flowers.

In the United States and Canada there are about 20 species, with representatives in all regions from arctic America and Alaska south to Florida, Texas and California. Among these are some of the most attractive North American wild flowers. Noteworthy

species are the American wood anemone (*A. quinquefolia*), very similar to the wood anemone of Europe; the tall windflower, or thimbleweed (*A. virginiana*), with greenish-white flowers, growing in woods from Nova Scotia to Alberta and south to Georgia and Arkansas; the mountain windflower (*A. lancifolia*), with large white flowers, often growing with the lily of the valley, native to the Appalachian region; and the red windflower (*A. multifida*), silky-hairy with red or greenish flowers, found throughout northern North America. The pasqueflower of Europe (*A. pulsatilla*) and its American representative (*A. patens*), both often called *Pulsatilla*, are showy examples of the genus.

The poppy anemone and its close relatives *A. hortensis* and *A. fulgens* are spring-flowering florist's plants.

The American species of Anemone, as well as the European wood anemone, are woodland plants that thrive in rich humus, in full or partial shade, and preferably out of the wind. The pasqueflowers do better in the gritty soil of the rock garden than in rich loam. Both species yield from their freshly crushed foliage an acrid volatile oil from which is extracted anemone camphor, somewhat used medicinally. See RANUNCULACEAE; PASQUEFLOWER.

(N. Tr.)

ANESTHESIA AND ANESTHETICS. Anesthesia is loss of feeling or sensation, and anesthetics are agents capable of producing anesthesia. Anesthesia is induced to spare the patient the pain of surgical operations, but it also occurs as a symptom of certain diseases of the brain or spinal cord. Surgical anesthesia may be classified as general or local, general anesthesia being that in which total unconsciousness and muscular relaxation are produced and local anesthesia that in which only one area of the body is deprived of sensation.

The word analgesia (*q. v.*), which is sometimes erroneously used synonymously with anesthesia, describes a basically different phenomenon. "Analgesia" is used to indicate that either all or part of the patient's body has been so affected that the patient does not actually feel pain, but is conscious of touch and can sense pressure. Anesthesia, on the other hand, whether it affects part or all of the body, is brought about in such a manner that the patient is not conscious of any sensation in the anesthetized part of the body or in the whole body, whether the anesthesia is general or local.

History.—Oliver Wendell Holmes is credited with suggesting the words anesthesia and anesthetic, after William T. G. Morton (*q. v.*), on Oct. 16, 1846, first demonstrated publicly the use of ether to produce insensibility to pain during surgical operations. Before that time there had been, from the beginning of history, a search for means of relieving pain. With the discovery of nitrous oxide (1772) and oxygen (1774) by Joseph Priestley, there was continued study of these and other agents that led to the eventual discovery of anesthesia for surgical purposes. Humphry Davy described the anesthetic properties of nitrous oxide in 1799 and suggested its use during surgical operations, but his suggestion was not developed. Henry Hill Hickman showed that partial asphyxiation and carbon-dioxide inhalation would produce unconsciousness and relief of pain. He published his findings in 1824 without arousing interest. Michael Faraday inhaled ether and reported its effect. On March 30, 1842, Crawford W. Long (*q. v.*) used ether to produce surgical anesthesia but did not publicize his discovery. Horace Wells, in Dec. 1844, had nitrous oxide administered to himself for extraction of a tooth. A public demonstration by him of its use for a surgical operation ended in a fiasco. Later demonstrations proved successful. Local anesthesia dates from 1881, when Carl Koller, a Viennese physician, first used cocaine in surgery of the eye.

General Anesthesia.—*Inhalation.*—Inhalation anesthesia is produced by gaseous or volatile agents that are inhaled by the patient. The method of administering inhalation anesthetics by tube directly into the trachea, rather than through the mouth or nose, increased the safety and adaptability of these agents. Constant improvement and modifications of equipment contributed to the wider application of special anesthetic techniques. Soda lime is used to absorb the carbon dioxide from anesthetic mixtures, effecting a reduction in the amount of anesthetic agent necessary

J. HORACE MCFARLAND CO.
MEADOW ANEMONE (ANEMONE
CANADENSIS)

to maintain anesthesia. The explosion hazard in anesthesia has been studied, and safety measures have been recommended and used.

Nitrous oxide, which first was used for anesthetic purposes in 1844, has continued to be used extensively though with an increasing awareness by the anesthetist of the need for precaution against insufficient oxygenation and subsequent danger of cerebral damage. Because it is a weak anesthetic agent, its greatest usefulness is in combination with other agents.

Diethyl ether holds a dominant place among the inhalation anesthetics. Many ethers have been prepared and used experimentally, among these being cyclopropyl methyl, cyclopropyl ethyl, *n*-methyl propyl, ethyl-*n*-propyl, propenyl ethyl, Propethylene, cyprome, cypreth, cyprethylene and cyclopropyl vinyl ether. Some of these have been given clinical trial. Divinyl ether (vinethene, divinyl oxide) is more powerful than diethyl ether, but its usefulness is limited by the occasional ill effects that may result from prolonged administration.

Chloroform, which first was introduced by James Y. Simpson in 1847, is more potent and more toxic than ether. Its use as an anesthetic has decreased with increased knowledge of its dangers.

Trichloroethylene appears to be less toxic to the heart than chloroform, but it does not always produce complete muscular relaxation.

When trichloroethylene is administered in a closed circuit, toxic oxidation products caused by the interaction of trichloroethylene and soda lime may produce untoward results. The drug also may break down into toxic products under the influence of heat, such as heat from an electric cautery.

Ethylene, an explosive gas, was introduced in 1923. It is more potent than nitrous oxide and more oxygen may be used with it.

Ethyl chloride has a limited usefulness as an inhalation anesthetic, but it is similar to chloroform in its toxicity. Ethyl chloride is used for freezing of superficial tissues by applying it as a spray.

Cyclopropane, a potent, explosive gas, was first used clinically in 1934. It has the advantage that a large amount of oxygen may be used with it. The question of its action on the heart has been debated. The usefulness of this agent was enhanced by the introduction of curare (see below).

Fluothane (halothane; 1,1,1-trifluoro-2,2-bromochloroethane) came into extensive use in the late 1950s. It is colourless, volatile, has a pleasant odour and is neither inflammable nor explosive when mixed with oxygen in any concentration. Fluothane produces vasodilatation, hypotension and bradycardia, however, and a number of fatalities were reported from its use.

Rectal.—Rectal anesthesia is a method by which unconsciousness is produced by introducing the agent into the rectum. Ether, the barbiturates and tribromoethyl alcohol in amylene hydrate are the drugs that have been used most often in this method. Tribromoethyl alcohol in amylene hydrate has been used for release of a ureteral stricture around a kidney stone by direct injection of the agent into the ureter. It was used by the intravenous route to produce anesthesia in World War II.

Hypnotism.—Hypnotism has found a limited usefulness in obstetrics and in prisoner-of-war camps in the absence of adequate anesthetic agents, and in dentistry.

Intravenous.—Intravenous anesthesia, the method by which the anesthetic agent is introduced directly into the blood stream, has been used extensively and proved most valuable for anesthesia in warfare. The barbiturates have been employed satisfactorily. After a long search for a suitable agent, thiopental sodium (Pentothal Sodium) probably has gained more approval and use than any other barbiturate. Surital gives results comparable with those of thiopental sodium. Alcohol, injected intravenously, has been used for relief of postoperative pain. Procaine hydrochloride, administered intravenously, has been used to relieve many forms of pain and sometimes for operative anesthesia. Vascular spasm as well as itching has been relieved by this method of administering procaine hydrochloride.

Attempts to improve on thiopental sodium as an anesthetic agent for intravenous use have had little success. A widely favoured combination consists in premedication of the patient the night be-

fore and again on the morning of the operation, followed by intravenous administration of thiopental sodium and succinylcholine (a muscle relaxant), with nitrous oxide plus oxygen, just before the operation. This procedure also calls for the use of an intratracheal tube through which the gaseous anesthetic agent is given. Then, after the tube is in place and in use, curare is administered. By means of this combination, anesthesia and relaxation are produced without the hazard of fire and explosion attendant upon the use of open methods for giving gaseous agents.

Intraosseous.—It has been found that anesthetics such as thiopental sodium may be administered by injecting the solution into the bone marrow, called intraosseous anesthesia.

Local Anesthesia.—Local anesthesia is the method by which local insensibility is produced. Many agents have been used, the safest being procaine hydrochloride. Piperocaine hydrochloride, dibucaine hydrochloride and tetracaine hydrochloride also have been used.

Block.—When the local anesthetic agent is injected so that it blocks the nerve supply, the method is known as block or conduction anesthesia. Special types of blocks, such as caudal, sacral, brachial plexus and spinal, the name depending on what part of the spinal cord is injected, have been developed. A modification of caudal anesthesia is the continuous method, in which a needle or catheter is left within the caudal canal and repeated injections of the local anesthetic are made to produce continuous anesthesia. This method has been used chiefly in obstetrics.

Spinal anesthesia is a special form of block anesthesia in which the local anesthetic agent is deposited in the spinal fluid. The single-injection method has been modified by the continuous method, in which the needle or a catheter is left in position and intermittent injections are given to maintain continuing insensibility. By this method, smaller, safer doses of the drug may be given in each injection, and the value of the method is increased because the limited time element of the single-dose method is overcome.

Penicillin has been added to local anesthetic solutions in an attempt to increase the safety of the injection, especially in infected areas. Studies have shown that procaine hydrochloride did not interfere with penicillin activity.

One of the commonest applications of local anesthesia is in dentistry, where dental nerves are anesthetized with a local anesthetic agent to permit extraction of teeth and the use of many types of dental treatment that otherwise would be painful. General anesthesia has been employed in dentistry only for about 50 years. Usually, nitrous oxide and oxygen, with or without a local anesthetic agent, are used. However, there has been a tendency to employ intravenous anesthesia, even in the dental office, and sometimes trichloroethylene or vinethene is added in small doses to the nitrous oxide and oxygen to produce analgesia rather than anesthesia. The current concept is that when teeth are extracted under local anesthesia, postoperative pain is greater than when a general anesthetic agent is employed for this purpose.

Refrigeration.—Refrigeration (cryo-anesthesia) also is a form of local anesthesia. By application of ice to an extremity or to a skin area, reducing the local temperature to near freezing, insensibility to pain of amputation has been produced. Skin grafts have been removed painlessly and amputation of an extremity, especially in cases of diabetes, has been done with greatly decreased operative risk.

Cold has been found to be valuable also in the treatment and prevention of shock and in the retardation of infection. It is also being used in cardiac surgery.

Dangers of Anesthesia.—Inhalation general anesthesia is brought about many times by the use of inflammable and explosive anesthetic agents, and therein lies a real danger, since an explosion may take place in the patient's lungs. This is especially true of ether, ethylene and cyclopropane. When gaseous anesthetic agents are used, a gas machine must be used to regulate the flow of gas from a cylinder to the breathing bag. There is always danger that the oxygen cylinder may become empty without being noticed immediately; if that occurs, the patient will experience asphyxia, which may be fatal. It has happened that the cylinders were not

placed in the proper positions and that not enough oxygen was used for safety. The anesthetic gases and the oxygen are under considerable pressure in the cylinders, and occasionally difficulty has been experienced in the handling of the cylinders. Cylinder valves have been knocked off and when that happens the cylinder will speed about as if it were jet-propelled.

Certain anesthetic agents, such as trichloroethylene, can cause cardiac arrest when administered in full anesthetic dose. In the case of local anesthesia the danger is that the quantity of the local anesthetic introduced into the blood stream may be sufficient to cause convulsions or even cardiac arrest. Convulsions can be controlled by intravenous administration of a barbiturate such as thiopental sodium. Oxygen can be administered, the rationale for this being that death occurring during a convulsion is due essentially to inability to breathe. Blood pressure may fall to a dangerously low level. These catastrophes occur when anesthesia is administered by untrained and unskilful persons: they seldom take place when the anesthesiologist is experienced and skilful.

Even spraying the throat with a surface anesthetic may be dangerous if the patient swallows part of the local anesthetic, since the concentration of the solution used for spraying is fairly high, and therefore a small quantity of the solution contains a relatively large dose of the anesthetic agent.

A few persons are very sensitive to certain local anesthetics. Extreme care must be taken to keep them out of danger. Many times the addition of epinephrine to the anesthetic will detain the anesthetic in one spot longer than would be possible if epinephrine were not added, and it thus assures that the anesthetic effect at the desired site will not be dissipated. Epinephrine constricts blood vessels and reduces the blood flow to the area, so that the local anesthetic is carried away only slowly by the blood. At the same time, bleeding in the area is reduced, which is convenient for the surgeon. However, certain nervous persons in whom a considerable amount of epinephrine is produced by the body when the prospect of an operation is at hand will react unfavorably to the inclusion of epinephrine in the local anesthetic and sometimes will collapse.

Choice of Anesthetic Agent.—Many factors influence the choice of an anesthetic agent. If there is no one in the hospital who knows how to use a certain agent or method, that method or agent obviously is not the most desirable. The operation itself may be one that requires much relaxation of the patient. Such relaxation requires either a powerful anesthetic that can produce such an action or the addition of a muscle relaxant. Muscle relaxants have been great influencing factors in present-day anesthesia. Thiopental sodium does not produce muscular relaxation. Nitrous oxide and oxygen seldom do. The use of drugs such as succinylcholine or curare (*see below*) to produce relaxation is not a problem, and the development of these two agents greatly changed the use of anesthetics.

Intravenous anesthesia is very easy to produce. Once the vein has been punctured, no great skill is required to inject the solution, but it does require some judgment as to how fast the drug should be given or how much of it should be used. Rectal anesthesia is the method of choice for small children who are to undergo surgery. It is especially useful for tonsillectomy and adenoidectomy, since the child can go to sleep in his crib or his bed and then is taken to the operating room, where an inhalation anesthetic is administered. Usually an intratracheal tube is put in place to facilitate breathing. When the child returns to his room he has no knowledge that he left it, and he is not frightened by knowing that an operation has been performed.

There are times, however, when the anesthesiologist hesitates to administer a general anesthetic agent. For example, if a patient's heart is extremely irregular, cardiac arrest might develop if the patient became at all anoxic or did not have enough oxygen in his blood stream, whereas if he were under the influence of spinal anesthesia he probably would not experience much difficulty so long as the blood pressure did not become too low. However, the site of operation might not permit the use of spinal anesthesia at a high enough level.

Procedures.—Probably the most frequently used adjunct to

anesthesia is medication the night before the operation to ensure the patient a good rest. The patient is asked not to smoke from the evening before operation until after operation the next day, so that coughing may be avoided. Then sufficient medication is used before operation so that the patient will be unexcited and may even be somewhat drowsy. Part of the burden of pain thus is relieved by the action of the preliminary medication. In the operating room thiopental sodium is administered by vein and succinylcholine is given. An intratracheal tube often is put in place; nitrous oxide and oxygen are administered through the tube, and thiopental sodium and curare are introduced intermittently into the vein. Patients are protected against too shallow breathing by the use of other drugs.

There are reasons why this combination, sometimes called "balanced anesthesia," is so useful, one of them being freedom from the danger of fire and explosion. Others are that the patient is better satisfied than when some other methods are used; relaxation can be produced to whatever degree is necessary; the patient remains quiet; relatively small doses of anesthetic agent can be used; and plenty of oxygen can be given.

Related Agents.—In 1954 F. H. Shaw called attention to the use of $\beta\beta$ methyl ethyl glutarimide as an antagonist for barbiturate poisoning; this substance later found application in anesthesia because of the fact that it will stimulate respiration when surgical anesthesia is to be terminated. The facility for terminating intravenous anesthesia by means of a barbiturate, added to the previously known fact that barbiturates will induce anesthesia, embodied a new concept. There are other antagonists, and by use of such drugs it was expected that many standard anesthetic drugs could be used in larger doses than previously, and with safety. Antagonists to standard drugs also can be very useful in the post-operative period for the control of pain. Amiphenazole, reported on by Shaw and G. Bentley in 1952, is a milder respiratory stimulant that permits the use of large doses of analgesic agents for the control of acute chronic pain.

Certain visual aids make it possible to teach technical steps quickly. One of these is a gauge for visualizing the position of the tip of the intratracheal tube when it is thrust the proper distance into the trachea. The tube is marked so that when it is inserted between the vocal cords the mark remains visible. This calibration prevents much of the difficulty that was encountered previously when the tube was thrust too far into the trachea.

The development of the esophageal stethoscope augmented the facilities for the immediate detection of difficulties of the heart and lungs, or all these structures.

Other related agents include the sulfonamide drugs, which have been studied in relation to anesthetics. Procaine hydrochloride was found to have an antisulfonamide action. Acetylation of the amino group of *p*-aminobenzoic acid leads to a 10,000-fold decrease in its antisulfonamide activity. Other studies of the sulfonamide drugs in relation to anesthetics showed that inhalation anesthetics were most controllable in patients who had sulfonamide therapy. Sulfonamide drugs in large doses were found to affect the toxicity of thiopental sodium in rats. In actual use, no ill effects were noted in patients heavily medicated with sulfonamides and anesthetized with thiopental sodium, and no synergism between the two drugs was seen. Sulfonamides were found not to increase the operative risk of animals in shock; indeed, in some instances, the sulfonamides seemed to be beneficial.

Curare (d-tubocurarine, intocostrin), which first was used in connection with anesthetics in 1942, is not an anesthetic but is used in conjunction with anesthetics to increase muscular relaxation. It may be administered intravenously or intramuscularly. Respiratory depression or arrest occurs from an overdose or from too rapid administration of curare. Artificial respiration and neostigmine and the quickly effective anticholinergic Tensilon are the antidotes for curare. Other drugs that have a curarelike action have been studied, including salts of erythroidine, quinine ethochloride, nicotine, thiamine, magnesium, quinine and quinine derivatives. (*See CURARE*)

Vitamins in relation to anesthesia as well as the vitamin state in the preanesthetic and postanesthetic periods, have been inves-

tigated. Vitamin C deficiency was found to increase the anesthetic induction time and recovery time. Vitamin B₂ has been found to be necessary for adequate functioning of the cell respiratory mechanism:

Shock existing before the administration of anesthetics as well as that which may develop during operation has been studied extensively, and supportive measures have been used successfully in its prevention and treatment. Flood transfusion; plasma transfusion and the so-called plasma substitutes, or plasma volume expanders, have decreased the incidence of operative shock.

Gas therapy is often given under the supervision of the anesthetist. Postanesthetic administration of oxygen, carbon dioxide and oxygen or helium has proved valuable in preventing complications. Helium, oxygen and carbon dioxide are used in conjunction with anesthetics as well as in gas therapy.

Diagnostic, preoperative, operative and postoperative tracheo-bronchial aspiration has reduced the incidence of serious pulmonary complications.

Postanesthesia observation rooms have been set aside in some institutions to facilitate the immediate postanesthetic care of the patient. Resuscitation is often done by the anesthetist because of his familiarity with the circulatory and respiratory physiology. Research in physiology as related to anesthesiology also added many factual data. See SURGERY and articles on the various anesthetic drugs. See also Index references under "Anesthesia and Anesthetics" in the Index volume.

ANEURYSM (ANEURISM) is essentially an abnormal, localized dilatation of some artery that contains fluid or clotted blood. The causes are those that result in weakening of the arterial wall in a localized area, and they include a variety of injuries and diseases. Aneurysms are pulsating tumours that are progressive in character and may ultimately rupture, causing hemorrhages of varying degrees. They produce sounds called bruits. Aneurysms cause changes in the surrounding tissues mostly because of pressure and erosion from their enlargement and pulsation. They sometimes establish a communication with adjoining veins. Their names are derived from their shapes, characters and locations. Diagnosis is made by the clinical history, physical findings and X-ray examination. Treatment varies with the type and location, and its effectiveness depends upon early recognition, location and type. Surgical procedures may be valuable. See also BLOOD VESSELS, SURGERY OF. (F. L. A.)

ANGARA, a river in the U.S.S.R., the outlet for Lake Baikal (*q.v.*), is one of the major right bank tributaries of the Yenisei (*q.v.*). The river flows for 1,151 mi. across the southern part of the central Siberian plateau to join the Yenisei just above Yeniseisk and drains about 408,000 sq.mi., which includes the drainage basin of Lake Baikal and its tributaries.

The upper Xngara (Verkhnyaya Angara) rises in the Transbaikal mountains and flows west-southwest into the northern end of Lake Baikal, where it has formed a wide delta. It is 281 mi. long and its basin covers 5,436 sq.mi. The chief tributaries of the Angara proper are the Taseyeva (770 mi.), Oka (605 mi.) and Irkut (290 mi.) on the left bank and the Ilim (373 mi.) on the right. The Angara is navigable upstream as far as the village of Boguchany and again from Bratsk to Lake Baikal, but the middle reaches, where the river cuts across basalt flows, are broken by many rapids. Average annual discharge is 116,560 cu.ft. per second with maximum flow coming in autumn.

Flowing through the newly developing Angara industrial region,

the river has great value as a source of hydroelectric power. A barrage was completed at Irkutsk. (R. A. F.)

ANGARSK, a town of Irkutsk *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies southwest of the Angara river, about 30 mi. below Irkutsk on the Trans-Siberian railway. The town grew very rapidly in the 1950s, in connection with the development of a new major industrial region in the Xngara basin. Machine-building (especially mining equipment for the nearby Cheremkhovo coal field) and timber-working are the major industries, power for which is supplied by a thermal power station in the town and from the Irkutsk hydroelectric plant. Pop. (1959) 134,000. (R. A. F.)

ANGARY, RIGHT OF. This term denotes the right of belligerents to requisition for their use neutral merchant vessels, aircraft and other means of transport that are within their territorial jurisdiction against payment of compensation. Although this right was received into international law only in the 17th-century, the term "angary" itself is of great antiquity. It has been traced back to ancient Persia, where it applied to royal messengers or couriers, and to Greek usage. In Roman law it related to the compulsory service of means of transport, including ships for public purpose. The right was invoked frequently in the 18th century but rarely in the 19th. As originally practised, it included the right to requisition the crew along with the vessel. This is no longer regarded as justifiable.

It is generally agreed that the right of angary should be applied only in case of pressing need in time of war, and that compensation is due to the neutral owner. It was applied on several occasions during World Wars I and II. By proclamation of March 20, 1918, the president of the United States took over merchant vessels of Dutch registry lying in U.S. territorial waters. Similar action was taken by Great Britain, France and Italy. During World War I, neutral powers invoked the right of angary against ships of belligerents in their ports. Thus Italy in 1915 requisitioned 34 German vessels, Portugal in 1916 requisitioned 72, and Brazil in 1917 requisitioned 42. Germany declared war upon Portugal on the ground that, in requisitioning the ships, it had violated the treaty of 1908, which provided that agreement on compensation must precede requisition. Spain in 1918 took over about 90 German vessels but paid no compensation in view of the sinking of Spanish vessels by German submarines. In World War II some neutrals also requisitioned ships of belligerents but it is doubtful whether, juridically, their action was based on the right of angary or on other grounds. The United States in 1941, while formally still neutral, took over foreign vessels lying idle in waters within its jurisdiction. This, however, was not done pursuant to the right of angary but in virtue of the authority conferred on the president by the Idle Foreign Vessels act of June 6, 1941 (55 U.S. Stat. 242).

A specific recognition of the right of neutrals to apply the right of angary is seen in the Hague convention of 1907 respecting the rights and duties of neutral powers and persons in war on land. Article 19 of this convention confers upon neutral powers the right, in case of necessity and against compensation, to retain and utilize railway materials coming from the territory of a belligerent power which, under like conditions, requisitioned railway stock coming from the territory of that neutral. The difficulty in connection with the resort to the right of angary by neutrals against belligerents arises from the fact that the former cannot invoke its underlying reason, namely military necessity.

In World War I the question arose whether a belligerent may requisition neutral ships and cargoes seized on the high sea and brought in for, but prior to, adjudication by a prize court. The British judicial committee of the privy council (*The Zamora*, [1916], 2 X.C. 77) affirmed the right in principle, subject to the conditions that there must be urgent necessity, a real question to be tried and approval by a prize court. This is frequently regarded as an extension of the right of angary to things other than means of transport and other than those found within territorial jurisdiction. It is an open question whether the right of angary can be stretched so far or whether there is any need for

this. Requisitions in such circumstances may well be explained on other grounds.

ANGEL, a term used in the Jewish and Christian religions and in others influenced by them (belief in the angels is an essential tenet of Islam) to designate a created spirit essentially inferior to God but superior to man in natural endowments of intellect and will. As St. Augustine notes (*Sermo* 7. 3), the name itself (from the Greek *aggelos*, "messenger") indicates office or function rather than nature.

Belief in the existence of intermediary beings between God and the visible universe was common to most primitive religions, but the Judaeo-Christian doctrine of angels has its origins in the revealed word of God as contained in the Scriptures. Angels are mentioned repeatedly precisely in those parts of the Pentateuch and of other Old Testament books, e.g., Job i, that, according to critics, derive from the most ancient documents or sources.

Old Testament.—In the pre-exilic period, the numerousness of the angels loomed large in the sacred writings, so that God himself was called the "Lord of hosts" (I Sam. i. 3. 11). Angels constitute God's heavenly court, and in his name fight Israel's battles. Most often, however, they are portrayed as God's servants charged with particular missions on earth, from guarding the entrance to the garden of Eden after man's fall (Gen. iii. 24) to protecting the faithful (Ps. xci. 11), punishing the remiss (Ps. xxxv, 5) and, above all, carrying God's important messages to man (Gen. xvi, 7 ff.; xxii. 11 ff.; Ex. iii. 2). Their appearances would seem to have been in human form (Gen. xviii. 2, 16).

In the Persian and Greco-Roman periods, after the exile, angels

play a still larger role (cf. the books of Job, Ezekiel, Daniel, Tobit). This was probably due to the growing emphasis on the transcendence of God as much as to the influence of neighbouring religious beliefs and folklore. A hierarchy among the angels is affirmed, and for the first time personal names occur: Michael, Gabriel, Raphael, whom later Scripture (Jude 9) and tradition have identified as archangels.

Particularly prominent in Old Testament angelology are the cherubim and seraphim. Both are superior orders of angelic being, in close attendance on God's throne of majesty, guarding it from profanation (Ezek. i; Isa. vi, 2. 6). It is not surprising, therefore, that representations of the cherubim (and probably also of the seraphim) became accepted features of the Temple decorations. The figures of the two cherubim who with their wings overshadowed the mercy seat on the top of the ark in the

Holy of Holies constituted nothing less than God's throne among his people (Ex. xxv, 18-21).

At the time of Christ, the inroads of hellenistic rationalism brought about a reaction: the Sadducees refused to acknowledge the very existence of angels (Acts xxiii. 8) though the Pharisees continued to believe in them, and among the Essenes and in contemporary apocalyptic writings angelology flourished as never before.

New Testament.—Very striking in the New Testament is the role which the evangelists assign to angels in the major events of Christ's life and work: his birth, the beginning of his public ministry, his agony, resurrection and ascension. In his teaching Jesus frequently refers to angels, suggests the idea of a guardian angel for children (Matt. xviii. 10) and stresses the presence of the angelic multitudes at his final coming in glory. But it is especially in St. Paul's letters and in Revelation that the doctrine concerning angels is presented with greatest amplitude. Christ is the head of the angels as well as of men. Seven group-names receive mention: angels, archangels, principalities, powers, virtues, dominions and thrones (I Thess. iv. 16; Rom. viii. 38; Eph. i. 21; Col. i. 16; ii. 15). Together with the cherubim and seraphim, named in the Old Testament, this listing gave rise in patristic times to the theory of the nine choirs of angels (cf. Dionysius the Areopagite, *The Celestial Hierarchy*). In the New Testament, too, is found clearer reference to the sin of the fallen angels (Jude 6; II Pet. ii. 4), and to the power of the Devil as "the ruler of this world" (John xiv. 30).

Doctrine.—Perhaps because of fear of syncretistic confusion with Gnostic and pagan doctrines of divine emanations and demigods, the early Fathers spoke of angels only incidentally. There was general agreement on their having been created by God, but not about the time of their creation: whether before or together with the visible world. Their role as messengers and agents of God was now extended to the performance of the Christian liturgy: Tertullian's famous "angel of baptism" has his counterpart in other sacraments, and especially in the Eucharist. In fact, the eucharistic celebration was widely viewed as an earthly participation as well as anticipation of the heavenly liturgy of the angels—a thought that has left its imprint on the Latin canon of the Mass to the present day (cf. the prayer "*Supplices*"). Very early, too, the doctrine of an angel assigned to each man as guardian gained currency.

Only very gradually, however, did Christian tradition arrive at the conviction of the nature of angels as pure spirits. Even August-

tine inclined to the view that angels possessed a body of some ethereal matter. The concept of pure spirit seemed too essentially a divine prerogative. Though Gregory of Nyssa, followed by Dionysius the Areopagite (*q.v.*) and Gregory the Great, taught clearly that angels were pure intelligences, it was not until the period of the scholastics that this teaching was fully accepted. Thomas Aquinas made it the basis of his extensive and pioneering speculation on angels: from it, for example, he concluded that angels were not composed of matter and form, that each of the myriads of individual angels consequently constitutes a distinct species, that their knowledge is intuitive and immediate rather than discursive like man's, that they are free from passions, etc.

Actual definitions of faith by the Catholic Church concerning angels are few. The fourth Council of the Lateran (1215), echoed by the Vatican council (1870), teaches their creation by God "from the beginning of time"; but the exact meaning of the concluding phrase has not been clarified. Though not explicitly defined by any official solemn pronouncement, the nature of angels as pure spirits, their creation before man, the existence of different ranks or hierarchies (but not their number or nature) and the angels' guardianship over mankind (though not necessarily a special angel for each man) also are deemed to be sufficiently based on revelation to demand belief.

Veneration of angels in Christian tradition may appeal to certain Old Testament parallels (Gen. xviii, 2; Josh. v, 14), but a recognized and official cult of angels is a specifically Christian phenomenon. Initial hesitation generally disappeared about the time of Augustine, when there seemed to be no longer any danger

of infiltration of pagan or idolatrous and superstitious misinterpretations. It was especially St. Michael, the powerful warrior, who attracted devotion. Shrines in his honour appear as early as the 4th century in both east and west, continued to be erected throughout the middle ages and play prominent roles in the devotional life of several countries. At present two feasts honouring St. Michael are celebrated annually according to the Roman calendar. Alcuin (d. 804) assigned a votive mass in honour of the angels to every Tuesday free of other feasts, a practice still retained in the Roman missal. In 1670 a feast of the guardian angels was promulgated for the universal church by Pope Clement X.

Iconography.—The iconography of angels likewise has undergone development in the course of the centuries. It is generally

agreed that Egyptian and Assyrian sculptures of winged beasts guarding the royal palaces were a major influence in determining the graphic representations of the cherubim of the Old Testament. Christian art in the catacombs offers no identifying traits for its angels; only toward the end of the 4th century do nimbus and wings begin to make their appearance. The figures themselves are those of men or youths, clad in white tunic and pallium. Under Byzantine influence, exemplified for instance in the magnificent mosaics of Ravenna, the angels are shown as noble winged attendants at Christ's or the Virgin's throne, vested in precious court apparel. At the height of the middle ages, when devotion to the humanity of Christ and his sufferings was predominant, artists pictured the angels carrying the instruments of the sacred passion and grieving over their Lord. Isolated instances of child-angels, or of winged child-heads, are found in the 12th century, and then became increasingly popular; in the time of the Renaissance, under the additional precedent of classic pagan representations of Eros

ALINARI
FIG. 4.—ASSYRIAN WINGED GENIUS FROM PALACE OF ASHURNASIRPAL II AT NIMRUD, 9TH CENTURY B.C. IN THE LOUVRE, PARIS

or Cupid, these find a joyous welcome among the sculptures and paintings of the baroque churches. The mighty cherubim at Yahweh's throne have become playful and all too obviously non-heavenly cherubs—not necessarily to the increase of sound Christian piety; Cupid refused to be baptized. The early Renaissance, finally, introduced the female angel, and before long, especially in Italy, she was decked in the current fashion, with occasionally a stole over it all to suggest sacred function. Angels in various stages of undress and without wings also appear, all for the laudable purpose of humanizing them and thus making them less forbidding to man's love and devotion. A return to a more worthy iconography of angels is making headway in the 20th century.

ANGEL, a gold coin, first used in France (*angelot, ange*) in 1340, introduced into England by Edward IV in 1465 as a new issue of the noble, hence called the angel-noble. It varied in value between 1465 and 1634 (when it was last coined) from 6s. 8d. to 10s. The name was derived from the design on the obverse representing the archangel St. Michael piercing the dragon. The angel was the coin given to those who came to the throne to be touched for the disease known as "king's evil" (*q.v.*), probably because of its religious inscription: PER CRUCEM TUAM SALVA NOS CHRISTE REDEMPTOR. After it ceased to be coined, medals called touchpieces with the same inscription were given instead. See also NUMISMATICS. (Jo. M. L.)

ANGELA MERICI, SAINT (1474-1540), Italian foundress of the Ursulines, the oldest and largest order of women in the Roman Catholic Church founded for teaching, was born on March 21, 1474 (or perhaps 1470), at Desenzano, a small town on Lake Garda in northern Italy. From a very early age she showed signs of a special religious vocation. Orphaned young, she went to Salò to live at the home of an uncle, and while there joined the Third Order of St. Francis in order to ensure the privilege of frequent communion. About the age of 20 she returned to Desenzano, where she gathered about her a group of girls who taught catechism to the children of the village. In 1506, while praying in the fields of Brudazzo, Angela Merici had a vision in which she was told that she would found at Brescia a society of virgins, and from that time her determination to fulfill this mission never wavered, although 40 years of waiting followed. During those years her motherly charity, deep prayer, humility, extraordinary penance and ability to help souls won her the love and esteem of all who knew her.

On Nov. 25, 1535, at Brescia, Angela Merici and 27 companions consecrated themselves to God by a vow of virginity, and the Company of St. Ursula was born. By the end of the year it numbered 60 members. The following year she drew up her Rule, which

ALINARI
FIG. 3.—TWO PUTTI BY ANDREA DEL SARTO, 1528. IN THE UFFIZI, FLORENCE

provided for the Christian education of girls in order to restore the family, and through the family all of Christian society. In 1537 she was unanimously elected superior-general of the company, which she ruled wisely and with great maternal affection. Before her death on Jan. 27, 1540, she dictated her *Testament and Souvenirs*, which contain her counsels to her daughters and are the embodiment of her spirit. They read like modern documents with their insistence on interest in the individual, gentleness and the efficacy of persuasion over force.

A cult to St. Angela grew up in and about Brescia almost immediately. She was not declared "blessed," however, until 1768. On May 24, 1807, Pius VII canonized her. Her feast day is June 1.

St. Angela Merici is hailed not only as a foundress of a worldwide order of religious women famous for the education of girls, but also as a woman of extraordinary vision and courage who founded an entirely new form of religious life in the church and who enjoined her daughters to make changes according to the needs of the times.

ANGELFISH, the popular name for several widely differing species of fishes.

Squatina squatina, also called the monkfish, is an elasmobranch skatelike shark found in tropical and subtropical seas, including the Mediterranean. It takes its name from the large winglike pectoral fins and reaches a length of four feet.

In Bermuda, fishes (family Chaetodontidae) of the genus *Holocanthus*, and especially *Angelichthys* are called angelfish. These fishes are laterally compressed and brilliantly coloured. They haunt coral reefs. *Angelichthys* may reach a weight of four pounds and are delicious eating. In this same family the genus *Pomacanthus*, also of warm seas is known as angelfish.

Chaetodipterus faber, sometimes called spadefish, is also known as the angelfish. It occurs from Cape Cod to Rio de Janeiro. A very similar species occurs on the west coast of Mexico

To the tropical fish hobbyist *Pterophyllum scalare* and two related species of South American origin are the popular angelfish of the aquarium. (See **AQUARIUM: Aquariums in the Home.**) They have silvery, black-barred, laterally compressed bodies, four to six inches long, with gracefully extended fins. Breeding has produced other form and colour variants of extraordinary beauty

ANGELICA, a large genus of aromatic herbs of the family Umbelliferae. The most important species is the Eurasian *A. archangelica*, the roots and fruit of which yield angelica oil used to flavour liqueurs and in perfumery, while the tender shoots are used in making certain kinds of aromatic sweetmeats. In the Faeroe Islands and in Iceland, where the plant grows abundantly, it has been used as a vegetable. The genus is represented in Britain by one species, *A. sylvestris*, a tall perennial herb with large bipinnate leaves and large compound umbels of white or purple flowers. In the United States the common name alexanders (*q.v.*) is applied to *Angelica Atropurpurea*

ANGELICO, FRA (GIOVANNI DA FIESOLE, originally GUIDO DI PIETRO) (c. 1400–1455), Italian painter, one of the greatest 15th-century religious artists, was born at Vicchio in the Mugello (Tuscany). If, as is likely, his reception into the Dominican order at S. Domenico at Fiesole took place about 1418–20, he would have been born about 1400. About 1423–25 he was ordained priest. At the Dominican house of Fiesole Angelico must have been deeply

influenced by the teachings of Giovanni Dominici, the leader of the observant or reformed Dominicans and by the personalities of his disciples, St. Antoninus and the Blessed Lorenzo of Ripafratta. The writings of Dominici, in particular the *Lucula Noctis*, a defense of traditional spirituality against the onset of humanism, establish the intellectual and spiritual climate in which Angelico's style was formed.

His earliest surviving work, an altarpiece painted about 1425 for S. Domenico at Fiesole, where it is still preserved, was adapted about 1500 from a polyptych into a single panel altarpiece and has been stripped of its pilasters (two sections now in the Musée Condé, Chantilly) and its predella (now in the National gallery, London). Other paintings executed at this time are a polyptych from S. Pietro Martire (now in the Museo di San Marco, Florence) and a "Virgin and Child Enthroned" in the same museum. More clearly indicative of the course Angelico was to pursue are three early frescoes painted for S. Domenico, in which an attempt was made to develop a style conducive to contemplation and capable of playing its own part in the community's spiritual life. One of these, a Crucifixion, is still in the convent of S. Domenico, and the others, a much damaged "Virgin and Child With SS. Dominio and Thomas Aquinas" and a second Crucifixion, are respectively in the Hermitage, Leningrad, and in the Louvre, Paris.

The earliest securely dated work by Angelico is a triptych (now in the Museo di San Marco) of the Virgin and Child, with the two SS. John on the interior of the mobile wings and SS. Peter and Mark on the exterior. Though this work owes its great popularity mainly to the small figures of music-making angels around the central figure, the Linaiuoli triptych is remarkable above all for the monumental treatment of the Virgin and the lateral saints, which reflect the influence of Masaccio. At a date not far removed from that of the Linaiuoli triptych, Angelico executed for S. Domenico at Cortona a great altarpiece of the Annunciation, now in the Museo del Gesu. This is one of the most inspired Florentine Renaissance paintings. Also for S. Domenico at Cortona, Angelico executed a fresco in a lunette over the west door of the church, and a polyptych with a predella containing scenes from the life of St. Dominic, which was probably painted about 1436. Closely related in style to the latter work is a polyptych in the Galleria Nazionale dell'Umbria, Perugia, painted for S. Domenico at Perugia in 1437. Thereafter Angelico abandoned the polyptych form and concentrated upon the production of altarpieces on single panels, boldly confronting the unfamiliar compositional demands presented by this new form. The most masterly of these altarpieces are a "Coronation of the Virgin" in the Louvre, painted for S. Domenico at Fiesole, and the high altarpiece of S. Marco in Florence.

The S. Marco altarpiece (now in the Museo di S. Marco) was probably completed in 1440. Its main panel is much abraded, but the eight panels of the predella, with scenes from the legend of SS. Cosmas and Damian, now distributed between the Museo di San Marco, the National Gallery of Art in Washington, the Alte Pinakothek at Munich, the Louvre and the National Gallery of Ireland, are in the main well preserved and exemplify the lucid command of narrative that is one of the glories of Angelico's work. On a larger scale these qualities are manifest again in two altarpieces, both in the Museo di San Marco, the first a "Lamentation Over the Dead Christ" executed for Sta. Maria della Croce al Tempio, and the second a moving "Deposition" painted about 1440 for S. Trinità. In the latter painting the Masacciesque idiom of the Linaiuoli triptych is developed into a soft and deeply individual style, in which a great wealth of emotion is expressed without disruption of the prevailing visual harmony. In the background is an extensive landscape; on the strength of this and of the landscapes in the predella panels at Cortona and in the Louvre, Angelico must be regarded as one of the greatest landscape painters of the 15th century.

The Dominican community had taken possession of the premises of S. Marco in Florence in 1436, and the rebuilding of the church and convent was begun in the following year. All of Fra Angelico's many frescoes in the convent appear to date from after 1443. These fulfilled the same function as the early frescoes in S. Domenico at Fiesole, and were intended for devotional and medita-

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

BLUE ANGELFISH (ANGELICHTHYS ISABELITA)

tive purposes. They comprise, in the cloister, frescoes of "Christ on the Cross Adored by St. Dominic," and five lunettes; in the Sala del Capitolo on the ground floor a colossal fresco of the Crucifixion with attendant saints; and on the upper floor frescoes of "Christ on the Cross," the "Annunciation" and the "Virgin and Child With Saints" in the corridor, and 44 frescoes in the cells. The latter vary in quality, and many of them were executed by conventual pupils. The frescoes in the cloister and the Sala del Capitolo, however, are autograph paintings by Angelico! as are two of the three frescoes in the corridor. Outstanding among the cell frescoes are the "Noli Me Tangere," "Annunciation," "Mocking of Christ," "Presentation in the Temple," "Coronation of the Virgin" and "Transfiguration," in which each event is represented in its simplest terms with the minimum of visual distraction, and the monumental forms achieve the utmost eloquence. The bulk of these frescoes were probably completed by 1447, when Fra Angelico moved to Rome to undertake work in the Vatican.

Angelico's principal commissions in the Vatican at this time were for the decoration of the Chapel of Pope Nicholas V and of the pope's studio (destroyed). The chapel (which was probably completed by 1449) is frescoed on three walls with scenes from the lives of SS. Lawrence and Stephen. In the execution of these scenes some use was made of studio assistants, though Angelico was responsible for all of the designs. The style in which they are conceived is more closely related to that of the vivid panels of the S. Marco predella than to the austere scenes in the convent cells, but all of them are admirably organized, and the receding classical architecture of the "Ordination of St. Lawrence" and "St. Lawrence Distributing Alms" marks the farthest point of Angelico's development as a Renaissance artist.

In 1449 Angelico left Rome on his election as prior of S. Domenico at Fiesole. The most remarkable of the works executed at this time is a cycle of 35 panels of scenes from the life of Christ and other subjects, painted for the doors of a silver chest which stood in the church of SS. Annunziata. Though much damaged and extensively repainted, these scenes have become widely known. When Angelico's term of office as prior expired in 1452, he seems to have returned to Rome, where he decorated the Chapel of the Sacrament in the Vatican (destroyed). A triptych with the "Last Judgment" in the Galleria Nazionale in Rome and a "Christ on the Cross" in the Fogg museum at Cambridge, Mass., perhaps date from this time. Angelico died in Rome on March 18, 1455, and was buried in the north aisle of the church of Sta. Maria sopra Minerva, where his tomb slab is still preserved.

Fra Angelico occupies a unique position in the history of Italian painting. In G. Vasari's biography he is depicted as a naïve artist of great simplicity, whose appeal was due primarily to the sincerity of his convictions, and in the 19th century (when his work became more popular than that of any other religious artist except Raphael) this interpretation of his personality and work was widely propagated. Subsequent study has tended to lay stress on the artistic qualities which entitle him to rank with the greatest European painters.

ANGELL, JAMES BURRILL (1829-1916), U.S. educator and diplomat, was born in Scituate, R.I., on Jan. 7, 1829. He

was graduated in 1849 from Brown university, Providence, and was professor of modern languages and literature there from 1853 to 1860. He was president of the University of Vermont, Burlington, from 1866 to 1871 and of the University of Michigan, Ann Arbor, from 1871 to 1909. He was United States minister to China in 1880-81 and to Turkey in 1897-98. Angell's success in bringing the University of Michigan to a high standard of quality at a time when it was pioneering in many ways, his ability as an eloquent and persuasive orator, his achievements in active diplomacy and his scholarship in international law made him one of the most prominent and highly respected educators of his time. Besides contributions to periodicals, he published *Progress in International Law* (18; 5), *Reminiscences* (1912) and *Selected Addresses* (1912). He died at Ann Arbor, Mich., April 1, 1916.

(H. H. Hr.)

ANGELL, JAMES ROWLAND (1869-1949), psychologist and university president, was born at Burlington, Vt., on May 8, 1869, the son of James Burrill Angell (*q.v.*). Graduating from the University of Michigan, he was drawn into philosophy and psychology under John Dewey and studied also at Harvard and Halle. While he was instructor in philosophy at Minnesota he was called by Dewey to be assistant professor of psychology at The University of Chicago (1894) where he rose to be professor and head of the department (1905), dean of the faculties (1911) and acting president (1918-19). In 1920 he accepted the presidency of the Carnegie corporation, whence he was called to be the 14th president of Yale, the first non-Yale president since the early Harvard-trained rectors. Under his administration (1921-37) Yale prospered materially, socially and intellectually. The spirit of inquiry replaced the spirit of discipline in Yale college, and the whole institution was infused with university standards. His works included *Psychology* (1904; rev. ed., 1908), *Chapters From Modern Psychology* (1911) and *American Education* (1937). Angell died at Hamden, Conn., on March 4, 1949.

See G. W. Pierson, *Yale: the University College, 1921-1937* (1955). (G. W. P.)

ANGELL, SIR NORMAN (1874-), English economist and worker for international peace, awarded the Nobel peace prize in 1933 with Arthur Henderson, was born at Holbeach, Lincolnshire, on Dec. 26, 1874. He became a journalist on U.S., French and English newspapers successively, and was editor of *Foreign Affairs* from 1928 to 1931. In 1928 he invented "The Money Game," a card game teaching the elements of economics. Of his many publications the best known is *The Great Illusion* (1910; revised 1933), which has been translated into many languages. He was knighted in 1931 and published his autobiography, *After All*, in 1951.

ANGELUS, the name of a family that gave three emperors to the Byzantine throne. The Angelus family was famous neither for its breeding nor its wealth until the 12th century, when Theodora, youngest daughter of the emperor Alexius I Comnenus, married Constantine Angelus of Philadelphia (Asia Minor). Other members of the family held high positions under Manuel I Comnenus and were deeply involved in the aristocratic revolution that overthrew Andronicus I Comnenus (1185). Isaac II (*q.v.*), who was raised to the throne by that revolution, and his brother Alexius III (*q.v.*), who deposed and blinded him in 1195, were among the least competent of all the Byzantine emperors and contributed much by their intrigues and squabbles to the enfeeblement of the empire. Alexius IV (*q.v.*), by his appeal to the west to help him restore his father Isaac II to the throne, must bear part of the blame for the diversion of the fourth crusade to Constantinople. He and his father were set up as emperors for a few months by the crusaders in 1203. The despots of Epirus and Thessaly, who saved much of northern Greece from conquest by the Latins after 1204 and whose dynasty survived until 1318, were direct descendants of Constantine Angelus and Theodora. One of the last prominent members of the family was John Angelus, appointed governor of Thessaly by John VI Cantacuzenus in 1342.

See G. Ostrogorsky's article in the jubilee publication of the Russian Archaeological Society in the Kingdom of Yugoslavia, pp. 111-129 (1936). (D. M. N.)

ALINARI
DETAIL OF THE ARCHANGEL GABRIEL
FROM THE S. DOMINICO ALTARPIECE,
"ANNUNCIATION," BY FRA AN-
GELICO, IN THE MUSEO DEL GESÙ,
CORTONA, ITALY

ANGELUS, a devotion in the Western Church in memory of the Incarnation. It consists of three Ave Marias with versicles and a collect. It is recited three times daily, about 6 A.M., noon and 6 P.M., when the Angelus bell is rung. In a simpler form the devotion can be traced back (as a night observance) to the 13th century, but it did not become widely used until the 17th.

See H. Thurston, S.J., "The Angelus," *The Month*, 98:483-499 and 607-616 (1901), and 99:61-73 and 518-532 (1902).

ANGELUS SILESIUS (favourite pen name of JOHANNES SCHEFFLER) (1624-1677), mystical poet and controversialist, who was born at Breslau (now Wrocław, Pol.) in 1624 and died there on July 9, 1677. Son of a Lutheran Polish nobleman, Scheffler was court physician to the duke of Oels in his native Silesia when readings in the mystics, especially Jakob Bohme (q.v.), and in the church fathers led him to the Roman Catholic Church, into which he was received in 1653. Thereafter he devoted himself almost entirely to writing. Following his ordination to the priesthood in 1661 he contributed some 55 polemical pieces to a Lutheran-Catholic controversy, notable even in that day for asperity and bad manners on both sides. His abiding fame derives from his poetry, published in 1657: *Geistreiche Sinn- und Schlussreime* ("Epigrammatic Verses on the Spiritual Life"), a collection of couplets on various religious truths better known under the title of its second edition (1674), *Der Cherubinischer Wandersmann* ("The Pilgrim of Truth"); and *Heilige Seelenlust* ("Holy Pleasure of the Soul"), religious songs celebrating the nuptials of the soul with God, many of which have found an honoured place in both Protestant and Catholic hymnals. The best edition of the poems is H. L. Held's *Angelus Silesius: Gesammelte Werke*, 3 vol. (1952). *Angelus Silesius* (1909) is a selection, translated into English by P. Carus, from *Der Cherubinischer Wandersmann*.

BIBLIOGRAPHY.—The standard biography is that of G. Ellinger, *Angelus Silesius, ein Lebensbild* (1927). See also H. Plard, *La Mystique d'Angelus Silesius* (1942); W. Dhrig, *Zur Frömmigkeit des Angelus Silesius in Amt und Sendung* (1950). (E. O'B.)

ANGERMAN (ANGERMANALVEN), a river of Sweden, rises in Lapland and, joined near Näsåker by the Fjällsjöälven, flows for 279 mi. southeast to the Gulf of Bothnia. In the plateau region crossed by this river and its tributaries are lakes such as the Vojmsjon (1,355 ft. above sea level, 31 sq.mi.) and Flåsjön (873 ft., 43 sq.mi.). These long, narrow lakes have been formed by glacial dams and are valuable in regulating the river flow. There are a number of hydroelectric power stations. The estuary is navigable for large vessels for 20 mi. inland to Nyland. The river is much used for timber floating and alongside the estuary are extensive sawmills, but Solleteå and Kramfors, the largest towns, have less than 15,000 inhabitants. (A. C. O'D.)

ANGERONA, an early and obscure Roman goddess. According to ancient authorities, she relieved men from pain and sorrow, or delivered the Romans and their flocks from angina (quinsy); or she was the protecting goddess of Rome and the keeper of the sacred name of the city, which might not be pronounced lest it be revealed to Rome's enemies. The cult was older than the explanation of it, which tried to account for the goddess's name and her singular posture, with her mouth bound and sealed.

Modern scholars regard her as akin to Ops and Acca Larentia; or as the goddess of the new year and the returning sun. Her festival, called Divalia or Angeronalia, was celebrated Dec. 21, the winter solstice. The priests offered sacrifice in the temple of Volupia, the goddess of pleasure, in which stood a statue of Angerona. She was worshiped as Ancharia at Faesulae where an altar belonging to her was discovered.

See Georges Dumézil, *Déeses latines et mythes vdkiques* (1957). (T. V. B.)

ANGERS, a city and prefecture of the *département* of Maine-et-Loire in western France, and the former capital of Anjou, is situated on the Maine river 5 mi. above its junction with the Loire 55 mi. E.N.E. of Nantes. Pop. (1954) 93,838. Three bridges span the Maine at Angers, the old city being on the left bank and on the right the suburb of Doutre. The town is dominated by the cathedral of St. Maurice (12th- and 13th-century), which with its twin spires and magnificent portal possesses fine stained-glass

windows and rich tapestries. The prominent castle (13th-century) is an irregular pentagon surrounded by a moat and bastioned by 17 large towers from 420 to 525 ft. high. Inside are the 16th-century chapel of Yolande of Aragon and the room containing the Apocalypse series of tapestries designed by Jean de Bandol and woven by Nicolas Bataille, unique in its size and artistic merit. The Logis Pincé, a Renaissance building, is now a museum. The Logis Barrault (15th-century) houses the public library, an art museum and the sculpture of Pierre Jean David d'Angers (q.v.), born in the city. Close by is the prefecture in the former St. Aubin's abbey (11th-century) with Roman arcades. The church of St. Serge was part of a former abbey and has a 13th-century chancel. The 12th-century Holy Trinity church is across the Maine in Doutre. Nearby is the hospital of St. Jean, a beautiful example of French Gothic style; part is an archaeological museum, but the main hall, chapel, cloisters, cellars and upper rooms are still to be seen. There are several fine 15th- and 16th-century houses. Angers is on the main line from Paris to Nantes, other lines run to Tours, Bordeaux and Brest. Cables, woolen goods, radio and television apparatus and umbrellas are manufactured. There is an important slate quarry. Angers is a market for the flowers, fruit and wines grown in the district.

Angers was first known as the capital of the Andegavi, the Celtic tribe of the state of Andes, and was called Juliomagus by the Romans. It had its hereditary counts from an early age, the best-known being Fulk Nerra, the "builder." The reign of the Plantagenets was marked by the construction of magnificent monuments of which the hospital of St. Jean is particularly well known. St. Louis (Louis IX) erected the castle. Philip Augustus in 1203 recaptured Anjou, which was attached to the crown of France by the treaty of Paris in 1259. The religious and revolutionary wars left their mark on the city. The medieval Universitas Andegavensis was refounded as the Faculté Catholiques de l'Ouest in 1875 by Bishop Charles Émile Freppel. In World War II Angers was occupied by the Germans from June 1940 to Aug. 1944; since then it has been almost entirely rebuilt. See also ANJOU.

(M. M.)

ANGILBERT (c. 740-814), Frankish poet and prelate at the court of Charlemagne. Of noble parentage, he was educated at the famous palace school at Aachen, under Alcuin. The known details of his life do little more than confirm his close connection with the court and the imperial family. In 800 he accompanied Charlemagne to Rome, and he was one of the witnesses to his will. He was made abbot of Centula (St. Riquier), Picardy, in 790 and died there in 814. He is said to have been the father of two children by Charlemagne's daughter Bertha, one of whom, Nithard, became a well-known chronicler.

Angilbert's Latin poems show the culture and tastes of a man of the world. A fragment of an epic, probably by him, describes life at the palace and the meeting between Charlemagne and Leo III, and earned him the nickname of "Homer" from Alcuin. Shorter poems show skill in versification and are interesting for their picture of the imperial circle. The passionate lover, the worldly cleric, the penitent abbot, depicted in contemporary references by other members of the court circle, is only glimpsed in Angilbert's own works.

BIBLIOGRAPHY.—Angilbert's poems were ed. by E. Dümmler in *Poetae latini Carolini Aevi*, vol. I (1881). See also D. Tardi, "Fortunat et Angilbert" in *Archivum Medii Aevi Latinitatis* (1925); F. J. E. Raby, *A History of Secular Latin Poetry in the Middle Ages* (1935).

ANGINA PECTORIS, a paroxysm of pain in the chest usually brought on by exertion in patients with diseased coronary arteries (see ARTERIES, DISEASES OF). An attack of angina pectoris begins suddenly as an agonizing pain, usually in the region of the heart but radiating through the chest in various directions and frequently extending down the left arm. A feeling of constriction and of suffocation accompanies the pain, although there is seldom actual difficulty in breathing. The sufferer becomes pale, his pulse feeble and he often feels that death is imminent. He is obliged to rest, and after two or three minutes the paroxysm subsides as quickly as it began. The attacks are apt to recur on less and less exertion as the coronary artery disease progresses. Attacks may

be precipitated also by fits of anger. Angina pectoris is rare under middle life and is much commoner in males than in females.

(C. P. M.)

ANGIOLIERI, CECCO (c. 1260–1312), the best known of the Italian "comic" poets, was born at Siena. It is known that he married and had children, that he did military service, was exiled for a time and that he sometimes fell foul of the law. His sonnets should not be taken too seriously as revealing Cecco's own character and relationships, since their subjects and style belong to a European tradition which owes much to the "Goliard" poets (see GOLIARD). He expresses a love of women: wine, dice and money, and complains bitterly of his father's meanness and longevity. Many of the sonnets addressed to Becchina parody the stil noao writers, especially the Dante of the *Vita Nuova* and Guido Cavalcanti (*q.v.*). Although Cecco is not original in his themes or in his deliberate use of colourful and unrefined language, he is a considerable artist whose lively verse expresses his sense of the comic and incongruous and reacts against the more exalted tone of love poetry in the "tragic" style.

ANGIOSPERMS. All living seed-bearing plants are divided into two groups, the gymnosperms (*q.v.*) and the angiosperms. The gymnosperms have naked ovules and seeds, while the angiosperms have ovules enclosed within the ovary of a pistil, and the seeds are enclosed in the ripened ovary, which is the fruit. Angiosperms are the only plants producing flowers. There are also marked differences between these two groups in vegetative anatomy, modes of reproduction and embryology. After an introductory discussion of the history, prevalence, derivation of the angiosperms, this article considers them in terms of their characteristics, divisions and modern taxonomy, or classification.

The botanical term Angiospermae (from Greek angeion, "receptacle," and sperma, "seed") was coined by Paul Hermann in *Flore Lugduno-Batavae Flores* (1690) for one of his primary divisions of the plant kingdom which included flowering plants possessing seeds enclosed in capsules. (Hermann also coined the term Gymno-

plants used for food, clothing and shelter. Of even greater importance is their significance as the dominant vegetation over the land surface of the earth. They preserve established watersheds and thus prevent the planet from becoming a great desert, and they are essential to the maintenance of a balance in all of nature through their role in the nitrogen cycle.

The angiosperms occupy every land area of the earth. They are abundant in rivers and fresh-water lakes; *e.g.*, members of Najada-ceae and Potamogetonaceae. Some grow in shallow waters of the oceans; *e.g.*, Zostera. Some persist in tropical desert areas with less than an inch of rainfall every few years; *e.g.*, members of Aizoaceae and Cactaceae. They are among the tallest of trees (Eucalyptus), the longest of rain-forest lianas (the rattan palm, Calamus), and the smallest of flowering plants, with tiny green thalloid bodies less than one-sixteenth inch across (the duck weed, *Wolffia*).

Between these extremes is every conceivable gradation, embracing aquatic and terrestrial herbs, developing a creeping erect or climbing habit growing as woody shrubs or trees, and presenting great variety in size, shape and colour of flower, of fruit and of seed.

Derivation.—The origin of the angiosperms is unclear, but as a group they are of more recent evolution than the gymnosperms or ferns. The most reliable evidence is that provided by the fossil record, and it is too fragmentary to be conclusive. Studies of this record, together with those of angiosperm analogies and homologies with other plant groups—living and extinct—have resulted in various theories and hypotheses in explanation of angiosperm origins.

Certainly these flowering plants are not derived from present-day gymnosperms or ferns. There is some suggestion of alliance with or derivation from extinct seed-bearing tree-fern-like plants called pteridosperms. There is also some evidence of derivation from stocks which may have been ancestral also to a fossil group known as the Caytoniales. It is believed that the angiosperms have been a dominant component of the earth's vegetation since the latter part of the Mesozoic era (probably since the mid-Cretaceous period) and that establishment of their dominance seemingly developed suddenly (in the sense of geologic time). There is also evidence from the fossil record that before this there were plants clearly angiospermous in character existing back into the mid or Early Jurassic period.

CHARACTERISTICS

Angiosperms are distinguished from gymnosperms by both vegetative and reproductive features. (see PLANTS AND PLANT SCIENCE: Anatomy).

Vegetative Characters.—Distinctions are found in the roots, stem and leaves. The roots of angiosperms and gymnosperms are similar except for the predominance in the former of fibrous roots and in the latter of taproots. The stem tissue of the typical angiosperm possesses a xylem element which includes vessels for water conduction (absent in a few primitive groups; *e.g.*, Winteraceae) and wood fibres for support, whereas the gymnosperm xylem consists primarily of tracheids that function both for conduction of liquids and for support.

The evolutionary advancement of the angiosperms over the gymnosperms is further evidenced by the presence in the angiosperms of soft herbaceous stem tissue (absent in the gymnosperm) and by the usually diffuse mode of branching (deliquescent) as opposed to the single primary axis Christmas-tree type of branching (excurrent) characteristic of most gymnosperms. The leaves of angiosperms differ from those of gymnosperms (exclusive of some cycads) by the presence of extensive mesophytic tissue and of conspicuous pinnate or parallel venation.

Reproductive Characterem—The reproductive distinctions of the angiosperms are more fundamental and significant than are the vegetative, but often being microscopic are not, for the most part, so readily observable. The reproductive unit of the angiosperm is the flower, whereas in the gymnosperm it is the strobilus or cone. Typically, the angiosperm flower consists of a very short central axis bearing one or more apical megasporophylls (the ovule-containing organ), subtended by microsporophylls (the pollen-

spermae—Greek, *gymnos*, "naked," and *sperma*, "seed"ⁿ—defining that group as one whose fruits had only one seed or which divided into separate one-seeded portions—each piece being regarded as a naked seed.)

In 1827 Robert Brown established the existence of truly naked seeds in cycads and conifers, entitling them to be called correctly gymnosperms. Wilhelm Hofmeister demonstrated in 1851 the differences in embryology between the gymnosperms and angiosperms, a discovery showing the fallacy of acceptance to that time of the gymnospermae as a subordinate group within the angiospermae. August Wilhelm Eichler was the first, in 1875, to revise the classification of seed plants treating the angiosperms and gymnosperms as the two primary and co-ordinate categories of the seed plants.

Prevalence.—The angiosperms are the dominant plants of the earth's vegetation and are the largest group of the plant kingdom, consisting of about 325 to 350 families, 12,500 genera and somewhat more than 250,000 species. Economically they are the most important group of the plant kingdom, providing the majority of

containing organ) and by two sets of sterile bractlike appendages collectively termed the perianth (composed of petals and sepals). In the gymnosperm strobilus the axis is long and bears either megasporophylls (each subtended by a sterile bract) or microsporophylls. It lacks any perianth.

In the angiosperm flower, in its simplest form, the ovules are borne along the inner margin of the megasporophyll—like peas in

pylar end of the gametophyte, three remain at the other end (where they become the antipodal cells) and two remain together in the centre of the gametophyte. One of the three "micropylar nuclei" becomes the egg nucleus (the female gamete), the other two are the synergids. There is no archegonium (flask-shaped organ containing an egg) in the angiosperm female gametophyte, as is present in vestigial form in gymnosperms.

The male gametophyte is more simple. Cells of meristematic tissue (tissues containing cells that retain the power of division) within the developing anther give rise to four-cell groups, termed a microsporangium, or pollen sac. By mitotic division there is produced within the pollen sac a group of diploid pollen mother cells. Each divides twice by meiotic (reduction) division to produce four microspores or pollen grains. Each pollen grain contains the haploid number of chromosomes. The pollen grain divides once while yet in the anther, forming a regenerative nucleus and a tube nucleus. This is an immature stage of the male gametophyte. It is at this stage that the anther usually dehisces (splits open along definite lines) and pollination of the flower (transfer of pollen from anther to stigma) takes place.

Pollination in the angiosperms may be effected by wind, water, gravity, insects or animals. But unlike lower forms of plant life, there are never any free-swimming or motile gametes or sperm produced. Fertilization in the angiosperms takes place entirely within the carpel of the flower.

Pollen grains have proved to be of considerable value in identification and classification studies. From these, the relatively new science of palynology has emerged, and through it renewed studies (*e.g.*, on stratified peat) have produced many data valuable as evidence of plant distributions and associations of earlier interglacial and preglacial periods. Studies of the morphology of the pollen grain have given new characters for classification purposes. These relate particularly to (1) the size, shape and symmetry of the grain; (2) the position and number of its colpi (furrows) and germ pores (apertures); (3) the types of surface or adornment of the exine (outer spore wall, sporoderm); (4) whether the grains are borne singly, cohere in tetrads (fours) or are agglutinated in pollinia; and (5) the number of nuclei present at the time the pollen grain (or microspore) is discharged from the anther. For details see book cited below by G. Erdtman (1953).

Among these characters, that of furrow type is accepted to be of major phyletic significance. Monocolpate pollen grains (bearing a single furrow) are characteristic of the extinct seed ferns (Pteridosperms), cycads and ginkgo (both are gymnosperms), and most monocotyledons and are considered primitive. A few dicot groups (all in the Ranales—see below) have monocolpate pollen. This order, Ranales, is also the only angiosperm group known to have both pollen types. Those families producing monocolpate grains are considered primitive. In one angiosperm family, Casuarinaceae, the pollen grains are acolpate (lacking furrows).

Fertilization follows pollination. After the pollen grain (microgametophyte) reaches the receptive stigmatic surface of the pistil (megasporophyll), a pollen tube is developed within, and into it

FIG. 2.—HYPOTHETICAL EVOLUTION OF SIMPLE AND COMPOUND OVARY

(A) three-lobed carpel with submarginal ovules (dotted lines indicate vascular strands); (B) the same, somewhat involute; (C) simple ovary derived from (B) by infolding of ovules and connation of ventral margins; (D) axis bearing three involute open carpels; (E) compound ovary derived from (D) by connation of edges of adjoining carpels; (F) axis with three open carpels with adjoining sides more or less parallel; (G) compound ovary derived from (F) by connation of adjoining sides and margins; (H) cross section of (G), hypothetical; (I) cross section of (G), actual, showing loss of carpellary demarcation in the three septa

the pod (see fig. 2[C]). In ancestral forms this megasporophyll, more commonly termed a carpel, is believed to have been open and leaflike, but in all modern angiosperms is closed and fused marginally, with the ovules in the loculus (cavity) thus formed (see fig. 2). This folded marginally fused carpel is termed the pistil and consists of the ovary (the ovule-containing organ) and its apical stigma. Usually there is a constricted necklike region between the ovary and stigma, termed the style (see fig. 3). By contrast, in the gymnosperm strobilus the megasporophyll is essentially flat, and its few to many ovules are borne exposed on its surface. Similarly, in the pollen-producing strobilus of the gymnosperm, the microsporophylls are flat and the pollen-producing microsporangia are exposed. In the angiosperm flower the microsporophylls are closed until maturity when they open and their pollen is released. They are termed stamens: the pollen-producing part is the anther and the supporting stalk the filament. The angiosperm gametes are both microscopic and reduced to the simplest possible elements: an egg nucleus and a sperm nucleus.

The female gametophyte is enclosed within the ovule. The ovule consists typically of two outer closely appressed basally fused layers termed integuments. These open at the tip by a pore known as the micropyle. The two integuments envelope a body of soft nutritive tissue, the nucellus. Borne within and near the micropylar end of the nucellus is a single multicellular megasporangium. One cell divides (mitotic division) and produces the megaspore mother cell; its chromosomes are of the diploid, or $2n$, number. By reduction division it divides twice to form a row of four megaspores, each possessing a haploid, or n , number of chromosomes. Three of the megaspores degenerate and die; the fourth becomes the female gametophyte. This gametophyte (small sexual plant), by subsequent cell divisions, is composed of seven or eight nuclei within a thin embryo sac. Three of the nuclei move to the micro-

FIG. 3.—PLACENTAL AND CARPELLARY TYPES

(A) pistil with simple ovary and marginal placentation (unicarpellate); (B) compound ovary with parietal placentation, each placenta intruded and spreading (biocarpellate)

moves the regenerative nucleus. This nucleus divides once and forms two male nuclei. Each of these male nuclei is a male gamete. Stimulated by the environment created in the stigma, the pollen tube grows through the wall of the pollen grain and into the tissue of the stigma and its style. This growth continues down the style until the tube penetrates the ovary. Growth continues and when the tube reaches the ovule it enters the micropyle (or elsewhere through the integuments) and finally the female gametophyte. As pollen-tube growth progresses from stigma to female gametophyte it carries with it both male nuclei.

Growth of the tube at the forward end is accompanied by degeneration at the other. On approach to the egg nucleus, within the female gametophyte, the two haploid male nuclei are released. One unites with the haploid egg nucleus and forms the diploid zygote, the other unites with the polar nuclei to form a triploid endosperm nucleus.

The zygote thus formed is a new generation. In contrast to the haploid gametophytes, it is a diploid sporophyte. It becomes the embryo within the seed. The endosperm nucleus, together with the embryo sac, multiplies to form the endosperm tissue of the seed.

The Embryo.—The angiosperm zygote (enclosed by a membrane) undergoes a series of divisions leading to wall formation (not true at this stage in the gymnosperm embryo) separating the terminal cell from the basal cell. This wall may be transverse or longitudinal. The terminal cell continues to divide to produce the axis or hypocotyl of the embryo from which is later produced the two cotyledons (one if a monocot) or seed leaves. The basal cell divides to form a chain of cells that functions as a suspensor, and the lowest is attached to the embryo sac and ultimately gives rise to the root and root cap of the embryo.

The Endosperm.—This tissue is the result of union of three nuclei ("double fertilization"): the two antipodal nuclei and the polar nucleus. It has a triploid (3-n) number of chromosomes, unlike the embryo which has a diploid (2-n) number. The tissue multiplies as the embryo develops, but the bulk of it is digested by the embryo. In most angiosperms some of the endosperm remains in the seed (none is produced in the orchid, where the initial cells of the tissue degenerate soon after formation), and the amount and its structure varies with different orders or families. Alexander C. Martin (1946) made extensive use of endosperm character in classifying flowering plants on the basis of seed type.

The seed consists typically of (1) two seed coats—the outer is the testa, the inner the tegmen—developed from the ovule integuments; (2) the embryo with its radicle (root initial) hypocotyl and cotyledon (s); and (3) the endosperm. In mature dicot seeds lacking endosperm, e.g., in beans, the embryo and its cotyledons are very large and possess abundant carbohydrate material. In those dicot seeds possessing endosperm tissue, e.g., castor bean, buckwheat or members of the sterculia family, the embryo is comparatively small. In all monocot seeds, except those of the Orchidaceae, the embryo is small and the endosperm tissue abundant; e.g., cereal grains, maize.

The position of the two cotyledons in dicot seeds is usually one of four basic types. In all types they are face to face by their ventral surfaces, the primordial bud of the axis is situated between them and at their base. The pair lie in the seed turned back against the hypocotyl. When arranged so that their edges are against the hypocotyl they are termed accumbent; when flat against it, incumbent; when folded down on both sides of the hypocotyl, conduplicate; and when conduplicate cotyledons are so large as to again be folded back on themselves, doubly conduplicate. These types are of identification value, especially when separating genera of the Cruciferae (mustard family).

The fruit of all angiosperms is the matured seed-bearing ripened ovary. The structure and formation of the fruit varies markedly but is often constant for a particular genus or family. These variations provide many recognized types useful in angiosperm classification and identification.

Many classifications have been made of fruit types but unfortunately most of them are so artificial as to have no direct correlation with the comparative morphology of the groups concerned; e.g., most soft berrylike fruits are no different from that of a banana,

or an orange or a watermelon, yet each of these fruits is given a different name in most systems of fruit classification. There is much need for a thorough comparative study of all angiosperm fruits, correlating each with the floral morphology of the parent flower. (See FRUIT; and papers in *Bibliography* below by H. Winkler [1939] and Guseleac [1938].)

DIVISIONS

Since the last half of the 17th century the angiosperms have been divided into the Dicotyledonae (or dicotyledons) and Monocotyledonae (or monocotyledons). Nehemiah Grew, of England, was the first to propose this division of the flower plants (1672) but it was John Ray who first used it in a formal system of their classification (1686–88). The distinctions between the two groups are expressed by a combination of characters rather than by any single character. Characters identifying each group are:

Dicotyledons:

Embryo with two cotyledons (seed leaves)

Stems producing secondary growth by successive cylinders of xylem tissue

Veins of leaves are typically arranged in a network

Leaves, generally petioled, margins often toothed

Flowers with petals and sepals mostly four or five, or in multiples of four or five

Pollen grains mostly tricolpate (with three furrows)

Monocotyledons:

Embryo with one cotyledon

Stems without secondary thickening, the vascular strands scattered through the stem and no cylinders of secondary xylem tissue produced

Veins of leaves arranged in parallel, the blades generally lack a petiole, margins entire

Flower parts in multiples of three, sepals often petal-like

Pollen grains always monocolpate (with one furrow)

The dicotyledons are the larger group, containing an estimated 260–270 families, 9,500 genera and in excess of 200,000 species. The monocotyledons total an estimated 65–70 families, 3,000 genera and 50,000 species.

The dicotyledons were long considered to have been ancestral to the monocotyledons, but in recent decades evidence—admittedly fragmentary—has been accumulating to indicate that either the reverse is true or that primitive forms of each group arose from a now extinct but common ancestor.

MODERN TAXONOMY

Darwin's and Alfred Russel Wallace's theories of descent and evolution, and information gained as the result of the development of the microscope, produced a more scientific system of plant classification. (See BOTANY: *Taxonomy*.)

Modern scientific systems of flowering plant classification attempt to subdivide the dicotyledons and the monocotyledons into major groups called orders and families. The effort is made to arrange these in the sequence in which they are believed to have evolved. This is the phylogenetic approach. While it is comparatively easy to determine that two species are closely related, or belong in the same genus, it becomes increasingly difficult to postulate lines of evolution or degrees of relationship for larger groups. The problem is further complicated by the presumed extinction of entire groups that may have "connected" modern ones, or that may have been a common ancestor to two or more divergent lines of descent.

Phylogeny is the evolutionary history of a plant, or group of related plants—large or small. It attempts to account for the origin and development of the group. The goal of phylogenetic research within the angiosperms is to produce a system of classification that would place the oldest, most ancestral and most primitive units at the base, and the most recent and advanced units at the top. While progress is being made, the absence of known origins for the angiosperms reduces most phylogenetic views close to the level of philosophical speculation.

There is abundant evidence that through evolutionary development, organs or floral parts common to their ancestors have been lost through reduction. This results in some seemingly "simple" flowers being evolutionarily and phylogenetically more advanced than a seemingly complex flower. Acceptance or rejection of this

tenet of evolutionary theory, *i.e.*, a pattern of simple to complex and back to simple, has resulted in two groups of classification systems: those following the lines of Charles E. Bessey or John Hutchinson and those of Adolf Engler and Karl Prantl.

The German team of Engler and Prantl accepted Darwin's theories of evolution as fundamental to an understanding of plant relationships, but in their system of classification rejected the view that simplicity of floral organization could be by reduction. They considered wind-pollinated flowers to be more primitive than insect-pollinated; the herbaceous habit to be ancestral to the woody; land plants to be derived from aquatic; and the monocotyledon plants to be more primitive than the dicotyledons. This system became widely adopted however, not because of the correctness of Engler and Prantl's interpretation, but because their great publication *Die natürlichen Pflanzenfamilien* (20 vol., 1887-1915) accounted for all the families and genera of the world's flora, complete with keys and descriptions. No other modern work was, or is, so comprehensive and detailed. A second and more ambitious publication, *Das Pflanzenreich* (107 vol., incomplete, 1900-56), attempted to do the same for every species and variety of the higher plants. By these two publications they provided botanists throughout the world with a common working tool. It was this universality of application that has caused their system to exert a dominance that continued into the second half of the 20th century.

The opposing concept, which holds that many apparently simple structures are simple by evolutionary reduction has been advanced by the contemporary classification systems of Bessey of Nebraska (1897, 1915) and of Hutchinson of England (1926, 1935, 1948). These two systems were based on earlier ones dating back to Antoine Laurent de Jussieu of Paris (1789), and modified successively by Augustin P. de Candolle (1813), John Lindley (1830) and George Bentham and Joseph D. Hooker (1862-83).

Botanists from De Candolle to Hutchinson have listed criteria by which characters believed indicative of primitiveness are contrasted with those believed to represent evolutionary advancement. Those now most widely accepted postulate that: the woody habit was ancestral to the herbaceous in any one family or genus; herbaceous perennials were ancestral to annual or biennial plants; aquatic plants were derived from land plants; monocotyledons were derived from dicotyledons; spiral arrangement of parts preceded cyclic or whorled arrangement; numerous pistils or stamens in a flower are a more primitive condition than a solitary pistil or a few stamens in a flower; bisexual flowers preceded unisexual flowers; flowers with sepals and petals were ancestral to those without them; separate sepals and petals preceded conditions where fusion of parts occurs; flowers with superior (hypogynous) ovaries were ancestral to those with inferior (epigynous) ovaries; and actinomorphic flowers were ancestral to zygomorphic ones.

Angiosperms having all of the primitive features, whether those listed above or others, would themselves be considered the most primitive, *i.e.*, the least advanced, the lowest in terms of evolutionary development and the most simple; those with the most advanced features would be the most highly developed in the evolutionary scale, and likewise the most modern in terms of evolutionary development. One can only indicate probabilities; it is not possible to say that a particular genus or family is the most primitive or the most advanced.

Flowers with their parts (sepals, petals) distinct (not fused) and in spirals usually have numerous stamens and/or pistils that are also arranged in spirals and borne on a central axis; *e.g.*, *Magnolia*. Flowers with their parts in whorls or cycles usually have a few or a definite number of stamens and pistils. There were believed to have been primitively two whorls of stamens and two whorls of perianth parts.

Flowers with a corolla of separate and distinct petals (polypetalous) are more primitive than those with petals marginally connate into a tube- or saucer-shaped structure (gamopetalous). Reduction of perianth parts to the point of extinction is considered to be an advanced condition. Similarly, reduction of stamens (in number of whorls or of stamens) is evidence of advancement, and a species bearing unisexual flowers (the extreme of sexual reduction)

is considered to be more advanced in that character than is one producing bisexual flowers.

Flowers with the ovary borne above the point of origin of the perianth are hypogynous (the ovary superior). Those with the ovary borne seemingly below the point of origin of the perianth and stamens are epigynous (the ovary inferior). In those flowers where the perianth and stamens seemingly originate from the rim of a cuplike structure, within which "sits" the ovary, are perigynous. The hypogynous condition is accepted to be primitive. The epigynous condition is considered to be advanced and in most instances is the result of fusion of perianth and filament bases to the sides of the ovary. The perigynous condition may be equally advanced and, with few exceptions, differs from epigyny only in that the fused parts are not adnate (fused to another structure from beginning of development) to the ovary. The theory that the epigynous ovary is enveloped by the receptacle (stem tissue) is now generally rejected.

No one system of classification can be said to be more correct than another. There is increasing support for the view that the monocotyledons originated from primitive dicotyledons and that the Liliales (Lily order) are the most primitive of monocotyledons and the Orchidales (Orchid order) the most advanced.

Subdivision into Orders.—The dicotyledons may be subdivided into about 45 orders. Among the larger and more important are the following (given in the general sequence of primitive to advanced):

Ranales (Magnolia and Buttercup order). This is the most primitive of dicots. Flowers of plants in this order typically have many sepals, petals, stamens and many simple pistils, all spirally arranged and with no fusion of parts. Advanced members within the order show reductions in numbers of parts and some approach toward cyclic arrangements. Members of the order include buttercup, magnolia, tulip tree, marsh marigold, barberry, lotus, custard apple and nutmeg.

Rosales (Rose order). As in the *Ranales*, but to a lesser extent, flowers of the primitive members of this order possess many stamens and pistils (as in rose, strawberry, blackberry, potentilla) but the parts are more often cyclic than spiraled. In advanced members reduction of number of parts has sometimes progressed to extremes; *e.g.*, cherry, *Chrysobalanus*. The order includes the apple, cherry, legumes, saxifrage, witch hazel, sedum and the plane tree.

Papaverales (Poppy order, sometimes called Rhoeadales). Primitive members have very many stamens and multicarpellate pistils, cyclically arranged. Advanced members, such as the mustard family, Cruciferae, have the petals reduced to four, the two whorls of stamens reduced to an outer whorl of two and an inner of four, and a complex carpellary situation. Included in the order are poppy, cabbage and relatives, mignonette and bleeding heart.

Geraniales (Geranium order). Possibly derived from the *Rosales* via the *Malvales* (Mallow order), not described here, the *Geraniales* have the pistils several (distinct or connate) but the number of parts generally few and cyclic. Both whorls of stamens are usually present. The order is large and includes the citrus group, oxalis, euphorbia and allies, flax, castor bean and rubber.

Umbellales (Carrot order). This is somewhat intermediate in degree of advancement: the floral parts are few, cyclic, distinct, but presence of epigyny is evidence of advancement. It contains members of the carrot family, English ivy and the dogwoods.

Rubiales (Madder order). This group, believed to be derived from the *Umbellales*, exhibits fusion of perianth parts as well as epigyny. Here belong the honeysuckle, coffee, cinchona and teasel.

Campanulales (Bellflower order). This is one of the most advanced orders, with the flowers epigynous, of few parts, gamopetalous and synsepalous (petals and sepals connate), stamens often connate either by anthers or filaments to form a cylinder around the style. Included are the bellflowers and members of the aster family (Compositae).

Caryophyllales (Pink order). This is a group of intermediate position having in common characters of seed and endosperm, and to some degree of carpellary situation in the pistil. Primitive

members have polypetalous and advanced members have gamopetalous corollas. In some the petals have become lost by reduction and the many distinct sepals are petallike (Aizoaceae). In others bisexual flowers have become reduced to unisexual flowers. Examples include the pinks, portulaca, pokeweed, pigweed, spinach, buckwheat, primrose, sea lavender and thrift.

Ericales (Heath order). This small but important group is believed to have affinities with the hypogynous-flowered Geraniales, but with the corolla gamopetalous, the embryology more advanced and the anthers opening by pores instead of slits. Here belong rhododendron, mountain laurel, blueberry, cranberry, pyrola, sweet pepperbush, shortia and galax.

Gentianales (Gentian order). This advanced, probably terminal, group, whose ancestors may have had a geranianian alliance, has gamopetalous hypogynous flowers but shows advancement by loss of one whorl of stamens (in the olive family only two stamens are usually present), the leaves opposite and the corolla lobes often contorted or twisted in bud. In some advanced members the ovules are reduced to one in each of two carpels, and in others the pollen grains of each anther are in tetrads or are agglutinated into a bony mass. Included are gentian, buddleia, olive, privet, ash, dogbane, vinca, milkweed and stapelia (carrion flower).

Polemoniales (Polemonium order). The origin of this group is similar to that of the Gentianales, but its members are not so advanced. It too shows the twisted flower bud, the loss of a stamen whorl, and a two-carpelled ovarv. The flowers of advanced members show some zygomorphy. Members include morning-glory, phlox, forget-me-not, potato, tobacco and petunia.

Lamiales (Mint order). This group is a small offshoot of advancement over the Polemoniales, in which zygomorphic flowers predominate, the leaves are opposite, the plants mostly herbaceous, and stamens show reductions and advancement in morphology. It contains the mints, salvia, verbena, teak and lantana.

Scrophulariales (Snapdragon order). This is a large, probably terminal group of polemoniaceous alliance (by some authorities considered ancestral to those plants), but showing advancement in the usually zygomorphic corolla, in the frequent appearance of parasitism or saprophytism and in the prevalence of parietal placentation which has been derived from an ancestral axile placentation. Included are snapdragon, mimulus, trumpet vine, unicorn plant, benne, broomrape, gloxinia, bladderwort and acanthus.

It is difficult to present these ideas diagrammatically, for in the 20th century there exist angiosperm families of such great evolutionary advancement as to show no direct relationship with any other group. The linkages having been lost in the geologic past. These disjunctive dicotyledonous families include the Salicaceae (willows and poplars), Casuarinaceae (the Australian pine *Casuarina*, and not a true pine) the Proteaceae of Australia and South Africa and the Fagaceae (beeches and oaks). Rather than to think of these scores of families as a much-branched tree, it is safer to view them as from above a cloud layer with their branches protruding through, sometimes as large clumps, sometimes as small ones, sometimes as solitary stalks, and each of varying degrees of remoteness, stature and branching. "Islands in the sky" is an apt expression for this representation. Gradually some of the cloud formation clears and more islands are brought together. That is the state of knowledge of angiosperm interrelationship. It is a field rich in opportunities for further research along many lines. The promise of satisfying achievement for the investigator is great. See DICOTYLEDONS; FLOWER; FRUIT; GYMNOSPERMS; see also Index references under "Angiosperms" in the Index volume.

ANGKOR, Cambodian word from Sanskrit *nagara*, city, state (cf. Malay *negeri*, *negara*; Thai *nakhon*; also Cambodian *nokor*). It is used loosely to refer to the region around Siemreap, the site of the ruins of the capital of the Khmer empire. The remains include those of Xngkor Thom and Angkor Wat (c. 1140), and earlier remains. The capital city was founded in the 9th century A.D. and abandoned c. 1440. See also CAMBODIA: Archaeology; INDONESIAN ARCHAEOLOGY. (A. H. CE.)

ANGLE, in plane geometry, a pair of half lines emanating from a point called the vertex of the angle. The half lines are called the arms, sides or legs of the angle. As shown in fig. 1, the angle consisting of the half lines (l_1, l_2) is distinct from the

FIG. 1.—(A) ACUTE ANGLE: (B) REFLEX ANGLE

angle (l_2, l_1). If rotation is taken as a concept more primitive than angle, then the angle (l_1, l_2) can be defined as the (counterclockwise) rotation or amount of turning about the vertex required to make l_1 coincide with l_2 . Two angles (l_1, l_2) and (m_1, m_2) with the same vertex are equal if the rotation sending l_1 into l_2 sends m_1 into m_2 . A straight angle is an angle ($l, -l$) made by the two half lines of any line through the

FIG. 2.— STRAIGHT ANGLE

vertex. (See fig. 2.) A right angle (l_1, l_2) is one for which (l_1, l_2) = ($l_2, -l_1$).

Angles are measured either by radians or degrees. If a circle of radius 1 with centre at the vertex is drawn, an angle cuts out an arc of this circle. The radian measure of this angle is the length of this arc. Since the length of an arc is the same before and after a rotation, equal angles have equal radian measure. Also, if two angles have the same radian measure, they are equal. The radian measure of a straight angle is π while that of a right angle is $\frac{\pi}{2}$. If the radian measure of an angle is less than $\frac{\pi}{2}$ it is

FIG. 3.— RIGHT ANGLE

called acute; if between $\frac{\pi}{2}$ and π , it is obtuse; if between π and 2π , it is a reflex angle. In rotary motion where rotations exceeding a complete revolution occur, it is useful to allow angles of radian measure greater than 2π . Negative angles can be used to symbolize clockwise rotations, i.e., $(l_1, l_2) = (l_2, l_1)$. An angle of radian measure $-x$ also has radian measure $2\pi - x$. A straight angle is assigned a value of 180° so that an angle of x radians will be an angle of $\frac{180}{\pi}x$ degrees. The angle of $90 - a$ degrees is the complement of the angle with a degrees. The angle of $180 - a$ degrees is the supplement of the angle with a degrees.

FIG. 4.—CURVILINEAR ANGLE

The curvilinear angle between a pair of intersecting smooth directed curves c_1 and c_2 in a plane is the angle of the pair of tangent half lines at their points of intersection (see fig. 4). If a pair of intersecting smooth directed curves lie on a surface, the angle between them is the angle of the pair of tangent half lines in the tangent plane of the surface. This angle is the spherical angle if the two curves are great circles on a sphere. Other extensions of the original idea of angle include a dihedral angle (a pair of intersecting planes in space), a trihedral angle (three planes intersecting at a point in space) and a polyhedral angle (any number of planes intersecting at a point).

If two half lines l_1 and l_2 in three or higher dimensional space meet in a vertex, they lie in a plane and their angle is the angle in this plane. Since the plane is not oriented, that is, the counterclockwise direction has not been specified, the convention is to use either (l_1, l_2) or (l_2, l_1) whichever is less than or equal to π .

ANGLER (ANGLER FISH), in a wide sense any fish of the order Lophiiformes (Pediculati), having the front dorsal spine modified to form a "fishing rod" whose "baited hook" projects over the mouth. The order includes the goosefishes (family Lophiidae), frogfishes (Xtenuariidae) and batfishes (Ogcocephalidae). All of the angler fishes are bottom-living predators; some deep-sea anglers, as the sea devils (Ceratiidae), live in the darkness of the middle depths of the ocean, from about 1,500 to 6,000 ft. below the surface.

The term has been restricted often to one of the goosefishes, *Lophius piscatorius*, abundant along the coasts of Europe and eastern North America. It has an enormous mouth, with long, backwardly directed, depressible teeth and a large flattened head. The fish walks along the bottom

by means of its paired fins, which are modified for this purpose. The first three rays of the anterior dorsal fin are long filaments placed on the head; the first, the longest, is freely movable and acts as a lure to attract other fish. So large is the mouth and so extensible the stomach that the angler can engulf fish almost as big as itself. It may reach a length of five feet. The spawn consists of a transparent gelatinous sheet which may be 2 or 3 ft. broad and 25–30 ft. long; in this the eggs are embedded.

The small blackish sea devils, which have luminous lures: have adopted a curious form of parasitism between male and female: the male is minute and early in life attaches permanently to the female, establishing an organic union. This behaviour has been interpreted as being an adaptation to ensuring mating in the fishes' dark habitat.

See FISHES.

ANGLES (Lat. ANGLI), one of the Germanic tribes that invaded Britain in the 5th century A.D. Tacitus (1st century A.D.),

AFTER NORMAN IN W. C. ALLEE ET AL., "PRINCIPLES OF ANIMAL ECOLOGY" (1955); BY PERMISSION OF W. B. SAUNDERS CO.
FEMALE ANGLER FISH PHOTO-CORYNUS SPINICEPS WITH SMALLER MALE PERMANENTLY ATTACHED TO HEAD

in his *Germania*, mentions them among the worshipers of Hertha (Serthus), a divinity later revered mainly in Scandinavia. Bede in his account of the invaders of Britain places Angulus, the home of the Angles, on the European continent between the Jutes and the Saxons (*qq.v.*). It is natural to identify Angulus with Angel, a district in Schleswig between the Schlei and the fjord of Flensburg. This identification, made by King Alfred in his account of Ohthere's voyages and by Aethelweard (c. 990), is also supported by the legends of the early kings of the Angles, which are placed in Schleswig (see OFFA of Angel; WERMUND). Ptolemy's localization of the Angles on the middle Elbe (*Geographia*, ii, 11, 15) can therefore be regarded as wrong. Bede stresses that the continental home of the Angles was left deserted by them and there is no doubt that they practically all emigrated. Place names in Thuringia, such as Engelin and Englide, and a reference in the preface to one copy of the Thuringian laws show that they had had an earlier expansion in another direction. It has been objected that Angel was too small to have provided the invaders of so large a part of Britain, but it need only be regarded as their centre, and indeed Alfred assumes that they were widely dispersed in the area.

Bede's clear distinction of Angles and Saxons is not always observed by himself; e.g., he writes *Anglorum sive Saxonum gens* (*Historia Ecclesiastica* i, 15). Both Angli and Saxonnes used of all the English are found elsewhere, and Gregory the Great addresses Aethelberht of Kent as *rex Anglorum* (Bede, *Historia Ecclesiastica* i, 32). It may be said on the whole that Angli is in English and continental writings the commoner term, and in Old English *Engle* was the general term, *Seaxe* meaning specifically Saxons. But Celtic writers use *Saxonnes* of all the Germanic invaders, following the usage of their vernaculars. See also XSGLO-SAXONS.

See R. G. Collingwood and J. N. L. Myers, *Roman Britain and the English Settlements*, 2nd ed. (1937), and works there cited. (AL. C.)

ANGLESEY, ARTHUR ANNESLEY, 1ST EARL OF (1614–1686), British statesman who exercised a moderating influence in the religious controversies during the reign of Charles II, was born at Dublin, Ire., on July 10, 1614. His father was created Viscount Valentia in 1621. Annesley was educated at Magdalen college, Oxford, and admitted to Lincoln's Inn in 1634. He entered the house of commons as member for Radnorshire in 1637 and in June that year concluded a treaty with the duke of Ormonde, lord lieutenant of Ireland, on behalf of the parliamentary cause. He was hostile to Cromwell and by the end of 1659, as lord president of the council, was actively working for the Restoration. He was made a privy councilor in June 1660 and was created Baron Annesley and earl of Anglesey in 1661.

He was not a strong figure in the turbulent politics of the period; caught between the rivalry of the duke of Buckingham and the earl of Arlington he suffered from their alternating friendship and enmity. He was appointed treasurer of the navy in June 1667 but by Oct. 1668 Buckingham had secured his suspension. Arlington then helped him procure a pension in compensation. Pet in 1671 Buckingham promised to obtain high office for him and he became lord privy seal in April 1673. Although increasingly crippled by gout he was diligent in attending the house of lords and served on numerous committees of the privy council. In 1682 he published reflections on the duke of Ormonde's conduct of Irish affairs in the 1640s which angered Charles II, and Anglesey was dismissed from all his posts. Although critical of Charles II's later policy he maintained good relations with James, duke of York (afterward James II) up to and after his accession. Anglesey died on April 26, 1686, in Bletchington, Oxfordshire.

A devout Anglican, Anglesey showed moderation in the panic over the "popish plot," and between 1674 and 1650 he dissented from several bills penalizing Roman Catholics. He is credited with having interceded for the life of Lord Staiford although he voted him guilty of treason, and in 1683 he appeared as a witness in defense of Lord William Russell. His public career earned him charges of corruption but Samuel Pepys spoke highly of his administrative ability. He was a learned and cultivated man, and after 1671 built up a fine library which, however, was dispersed at his

death.

(H. G. Ro.)

ANGLESEY, HENRY WILLIAM PAGET, 1ST MARQUESS OF (1768–1854), British soldier who commanded the allied cavalry during the Waterloo campaign, was born in London on May 17, 1768, the eldest son of Henry Paget, and took the title of Lord Paget when his father was made earl of Uxbridge in 1784. After being educated at Westminster school and Christ Church, Oxford, he entered the army and rose rapidly. In the Corunna campaign he commanded the cavalry with conspicuous success. In 1795 Paget married Lord Jersey's daughter Lady Caroline Villiers, who bore him eight children, but he deserted her for Charlotte, daughter of Lord Cadogan and wife of Henry Wellesley, later Lord Cowley; in 1810, after two divorces and a duel, he married her, and by her had six children. This connection with the duke of Wellington's sister-in-law kept Paget from further service in Spain and he saw no fighting, except in the disastrous affair of Walcheren, until 1815. He succeeded his father as earl of Uxbridge in 1812.

In the Waterloo campaign (*q.v.*) Uxbridge skilfully covered the retreat from Quatre Bras. At the battle of Waterloo he led in person the charge of the household cavalry that completed the rout of Drouet d'Erlon's corps. One of the last shots of the day wounded him badly; one leg was amputated. In 1815 he was created marquis of Anglesey for his services. He took George IV's side in the quarrel with Queen Caroline; when a hostile mob forced him to give her health he drank to "The Queen, and may all your wives be like her." In 1827 he was a cabinet minister as master general of the ordnance. Next year he became viceroy of Ireland where his advocacy of Roman Catholic claims made him popular, but disagreements with Wellington led to his recall. Changing sides in politics he returned to Ireland as viceroy again (1830–33) and established the Irish board of education. He was again master general of the ordnance, but outside the cabinet, from 1846, when he was made field marshal. He died on April 29, 1854.

One of his sons, LORD GEORGE PAGET (1818–80), was second-in-command of the light brigade at Balaklava.

See 7th Marquis of Anglesey, *One-Leg: the Life and Letters of Henry William Paget, 1st Marquis of Anglesey* (1961).

(M. R. D. F.)

ANGLESEY (ANGLESEA; Welsh *MÔN* [island], *SIR FÔN* [administrative county]), the ancient Mona, is the largest island of England or Wales, but the second smallest county in Wales (276.2 sq.mi.). It is a country of low relief, an old denuded highland, whose highest points are Holyhead mountain in the northwest (720 ft.) and Parys mountain in the northeast (418 ft.). The island's main geological structure is Pre-Cambrian rock, highly folded and metamorphized, known as the Mona Complex. Between Holyhead and Amlwch these rocks, a mixture of shales, grits, jasper and lava flows, are forced up over the later and softer mudstones of the Lower Paleozoic systems, a distribution resulting in a smooth and gently undulating landscape. To the south, in the centre of the island, the Pre-Cambrian strata appears again partly in the form of gneiss, giving rounded, knobbed hills and outcrops. It is overlaid by the Carboniferous beds of the east coast which stretch inland to Malltraeth marsh, with flat-topped hills and bare platforms of rock along the shore, while the softer Paleozoic shales recur along the southern coast and the great bays of the west. A series of low ridges and little valleys runs from northeast to southwest, the typical Caledonian trend. The Menai strait (*q.v.*), which separates Anglesey from the mainland, is merely another such cleft, made up of the sections of three river beds whose old watershed is in the Swellies between the two bridges. Along the west coast occur stretches of blown sand, penetrating two miles or more inland at Newborough and Aberffraw, with great dunes 100 ft. in height.

The name Anglesey is usually accepted as meaning simply "the island of the Angles." It lay on the prehistoric western sea route linking the Mediterranean with the northern countries. Thus the promontories and islands on both shores of the Irish sea were held together in a network of coastal trading activities. The importance of Anglesey in the Late Neolithic and Early Bronze Ages is attested by the number of great megalithic burial chambers and the standing stones of Bronze Age religious significance. By 100 B.C. the

Celts had colonized the island and it became a famous centre of the Druid religion. When the Romans finally occupied Britain it was to this stronghold of resistance that Suetonius Paulinus sent in his drive across the country in A.D. 61 to slay the Druid priests and destroy the sacred groves. The conquest of the island was completed by Agricola in A.D. 78. The most noted hoard of Celtic objects of the Early Iron Age found in Anglesey was recovered in 1943 from the bog of Llyn Cerrig Bach near Valley and is associated with this period and possibly with these events. Two well-preserved Celtic villages, occupied throughout the Roman occupation, are Ty Mawr on the lower slopes of Holyhead mountain and Din Lligwy on the hillside above Lligwy bay. The Romans left their impress in the shape of two camps, a small rectangular enclosure near Brynisiencyn and the stone walls and bastions of a 4th-century fort at Holyhead (*q.v.*) built on the edge of low but steep cliffs once washed by the sea and within whose shelter stands the parish church of St. Gybi.

The foundation of a number of Anglesey churches in the dark ages suggests that the "saints" of the early Celtic church followed the old trade routes on their missionary enterprises traveling to and fro between Anglesey, Ireland, Cornwall and south Wales. The most noted of the Celtic monastic foundations were those of St. Gybi on Holy (Holyhead) Island and St. Seiriol at Penmon. Anglesey was constantly open to invasion from the sea; Irish pirates, Saxon, Viking and Norman venturers all laid temporary hold upon it, but it was not finally subdued till the Edwardian conquest of Wales in 1282–84. Edward I built the castle in Beaumaris (*q.v.*), which was begun in 1295, and to make room for the English colonists whom he settled beneath its walls he transferred the population of the neighbouring township of Llanfaes to the New Borough which he created for them near the west coast, where a village still bears this name.

The chief household and manor of the princes of Gwynedd, the senior royal house of Wales, was at Aberffraw in the west of the island. The farming of the land by clans of free tribesmen (as distinct from the older villages of bond tenants) was developed in the 12th century. Anglesey became the chief corn-growing district of north Wales and so earned the name of *Môn Mam Cymru* ("Mona the mother of Wales"). After subjugation by the English the chief developments were the slow transformation of the structure of Welsh society with its joint ownership and partitioning of land and the replacement of the straggling Welsh holdings and hamlets by consolidated farms in individual ownership. Two hundred sites of medieval nuclei of settlement have been identified in Anglesey and of these 153 are occupied by single modern farms from 40 to 500 ac. or more in size.

Contact with Ireland has been maintained throughout the centuries and in 1801 Holyhead was established by the government as a packet station for the Irish mail. Plans for an improved route from London to Holyhead under the direction of Thomas Telford as surveyor: began early in the 19th century. By 1823 Telford had completed a road across the island (later part of the main London-Holyhead road) and in 1826 his suspension bridge (reconstructed 1938–41) over the straits was opened, the first and longest in Britain. The harbour at Holyhead was completed by 1824 and enlarged in 1880. Work on the railway from Chester to Holyhead was begun in 1844 under Robert Stephenson (*q.v.*) and the foundations of the tubular bridge were laid in 1846. On June 18, 1849, the Irish mails were carried to Holyhead by rail for the first time.

Though from its earliest settlement Anglesey has remained predominantly an agricultural and stock-raising county, with sea-faring and fishing as secondary activities, industry has played a part in its developments since about the middle of the 18th century. Copper, with other minerals, is found in quantity in Parys mountain and in 1775 was first worked on a large scale. By 1800 half the copper industry of Britain was in the hands of the Mona Mine company, and for a time Anglesey with Cornwall dominated the world market. But by 1844 the workings were largely abandoned and the mine finally closed in 1871.

From the 15th century sporadic attempts were made to extract coal from the seams underlying Malltraeth marsh but these always ended in disappointment. Quarrying is carried on in various parts

of the island, principally at Penmon (whence came the stone for Caernarvon castle) and Holyhead. A few light industries have come to the island since World War II and are situated at Beaumaris, Amlwch and Holyhead and in the administrative centre of Llangefni.

The British railways (London Midland region. Chester to Holyhead branch) cross Anglesey from Menai Bridge to Holyhead (Caer Gybi) and a branch runs from Gaerwen to Amlwch. Beaumaris is the county town and the only municipal borough (pop., 1961. 1,960). There the assizes of the northwest circuit are held. Amlwch (pop. 2,910), Holyhead (10,408). Llangefni (3,209) and Menai Bridge (2 337) are urban districts. The population of the whole island was 51,700 in 1961. Anglesey lies in the diocese of Bangor and has 678 parishes. The county returns one member to parliament.

ANGLESITE, a mineral consisting of lead sulfate, is a minor ore of lead (*q.v.*). It was first recognized as a mineral species in 1783, by W. Withering, who discovered it in the Parys copper mine in Anglesey, Wales; the name anglesite, from this locality, was given by F. S. Beudant in 1832. Crystals from Anglesey are small in size and simple in form; they are brownish-yellow in colour, resulting from a stain of limonite or brown iron ore. Crystals from some other localities, notably from Monteponi in Sardinia, are transparent and colourless, possessed of a brilliant adamantine lustre and numerous faces. The mineral is of secondary origin, having been formed by the oxidation of the lead ore galena in the upper parts of mineral lodes, where these have been affected by weathering processes, and has been found in many localities in Europe, Africa and Australia and in the U.S.S.R., Mexico and the United States. Anglesite crystallizes in the orthorhombic system and there are distinct cleavages parallel to the faces of the prism and the basal plane, but these are not so well developed as in the isomorphous minerals barite and celestite. The formula is $PbSO_4$. The hardness is 3 and the specific gravity, 6.3.

ANGLICAN COMMUNION, a fellowship of independent churches in communion with the archbishop of Canterbury and acknowledging him as *primus inter pares*. They are the Church of England (*q.v.*), the Church in Wales, the Church of Ireland (*q.v.*), the Episcopal Church in Scotland (*q.v.*) and the following others, which originated directly or indirectly from the Church of England: Protestant Episcopal Church in the United States; Church of India, Pakistan, Burma and Ceylon; Church of the Province of South Africa; Anglican Church of Canada; Church of England in Australia and Tasmania; Church of the Province of New Zealand; Church of the Province of the West Indies; Chung Hua Sheng Rung Hui (Holy Catholic Church in China); Nippon Sei Kō Kai (Japan Holy Catholic Church); Church of the Province of West Africa; Church of the Province of Central Africa; Church of the Province of Cganda and Ruanda-Urundi. The Jerusalem archbishopric is semi-independent. There are two groups of missionary dioceses, some directly dependent on the archbishop of Canterbury and others, chiefly in Central and South America, under the jurisdiction of the Protestant Episcopal Church in the United States.

At intervals of about ten years the bishops of the Anglican communion meet in London for Lambeth conferences (*q.v.*).

The Old Catholic churches (*q.v.*) are not in the Anglican communion but are in communion with its member churches.

See *Official Year Book of the Church of England*. (H. M. W.)

ANGLICANISM, a general term for the ecclesiastical system: organization and doctrine of the Church of England and the churches throughout the world in communion with it. See ANGLICAN COMMUNION; ENGLAND, CHURCH OF.

ANGLIN, MARGARET MARY (1876–1958), U.S. actress

who starred for 40 years in modern and classic roles, was born April 3, 1876, at Ottawa, Ont., daughter of T. W. Anglin, speaker of the Canadian house of commons, and Ellen (McTavish) Anglin. She was educated in Toronto and Montreal and was studying at the Empire Dramatic school, New York city, when Charles Frohman cast her as Madeline West in Bronson Howard's *Shenandoah* (1894). After touring with James O'Neill, E. H. Sothern and others, she scored as Roxane, to Richard Mansfield's *Cyrano*, in 1898. From 1900 to 1903 she was leading lady at the Empire theatre, where she made a great impression in *Mrs. Dane's Defence*. Frohman starred her first in his revival of *Camille* (1903). She was responsible for the production of William Vaughn Moody's *Tlze Great Divide* (1907), in which she costarred with Henry Miller. She played Shakespearean repertory in Australia, 1908–09. In 1909 she produced and starred in *The Awakening of Helena Richie* from Margaret Deland's novel. Miss Anglin first tried Greek tragedy in 1910, playing *Antigone* in the Berkeley, Calif., open-air theatre, and she played *Electra* there in 1913. In 1916 she led 1,200 players in *As You Like It* for the Shakespeare tercentenary in Forest park, St. Louis, Mo. In New York she appeared in *Medea* in 1918 and in *Electra* in 1918 and 1921. Her last appearance was on tour as Sara Müller in *Watch on the Rhine* (1943). In 1911 she married Howard Hull, brother of the actor Henry Hull. She died at Toronto, Ont., on Jan. 7, 1958. (B. Ht.)

ANGLING: see FISHING.

ANGLO-JAPANESE ALLIANCE. On Jan. 30, 1902, because of the threat of Russian aggression in Manchuria and Korea, Great Britain and Japan concluded a defensive treaty of alliance. Pledging themselves to uphold the principles of the "open door" policy for commerce in the far east, the signatories also agreed upon mutual assistance in safeguarding their respective interests in China and Korea. Twice renewed during the next ten years the alliance was a cornerstone of British and Japanese policy in Asia until after World War I.

The agreement served Japanese purposes well in the Russo-Japanese War of 1904–05. Though Great Britain was not required to participate, the alliance was influential in deterring Russia's European ally, France, from entering the war. Even before the completion of a Russo-Japanese peace treaty the alliance was renewed on Aug. 12, 1905. Its scope was now, however, extended to include the far east and India, while Japan's paramount position in Korea was more explicitly recognized.

On July 23, 1911, after the Japanese annexation of Korea, the alliance was renewed for a period of ten years. An important addition to the new treaty was a specific provision exempting either contracting power from the obligation of assisting the other militarily in case of war against a state with whom either power had concluded a general arbitration treaty (art. iv). This provision was designed to allay British and U.S. fears that the alliance might necessitate British support of Japan in a war against the United States.

In keeping with the alliance Japan entered World War I on Aug. 23, 1914. At the end of the hostilities, however, the purposes of the treaty were strongly questioned. Not only did they seem to be inconsistent with the obligations imposed by the covenant of the new League of Nations but Great Britain especially was aware of the considerable uneasiness which the alliance was causing in the United States and China. Pressure for the ending of the Anglo-Japanese alliance finally came to a head at the Washington conference (*q.v.*) in Dec. 1921. The aims of peace and security in the Pacific and the far east were met in the Four-Power Pacific treaty (United States, Great Britain, France and Japan), which called for the termination of the Anglo-Japanese alliance. With the exchange of ratifications of the Four-Power Pacific treaty on Aug. 17, 1923, the alliance between Great Britain and Japan was brought to an end. See JAPAN: History.

(Hn. Kn.)

ANGLO-NORMAN LITERATURE, the literature in the French dialect of medieval England, also known as Norman-French or Anglo-French. The latter term is reserved by some for the period when central French influence was superseding Norman. The dialect was introduced into court circles in Edward

the Confessor's time, but its history really begins with the Norman Conquest. It was the vernacular of the court, the law, the church, schools, universities, parliament and later of municipalities and of trade. Even for the aristocracy it became an acquired tongue and its use a test of gentility, but the more widely it was known the more it was corrupted. It was introduced into Wales and Ireland and used to a limited extent in Scotland before and during the wars of independence. The earliest extant literary texts belong to the reign of Henry I, the latest to that of Henry IV. Outside events, not so much the loss of Normandy as the unpopularity of foreigners in the reign of Henry III and the diminution of friendly relations with France during the Hundred Years' War, favoured an increasing use of English. The last strongholds of a French dialect were parliament, where it still survives in a few formulas; and the law. Reports and Readings continued to be in French until the beginning of the 18th century. Oliver Cromwell had abolished "Law French" but the judges revived it at the Restoration. As however there had just been time for a generation of lawyers unfamiliar with it to have grown up, it gradually disappeared.

Most types of literary works are represented in Anglo-Norman as in French, with a slight difference of emphasis. The *chanson de geste* is an exception. The type was not unknown in England, since the only surviving manuscript of the assonanced version of the *Chanson de Roland* is Anglo-Norman, as are the unique manuscripts of *Gormond et Isembard*, the *Chançon de Willame* and the *Pèlerinage de Charlemagne*; there is also an Anglo-Norman version of *Fierabras* but there seem to be no original works of the kind. Imitation was not all on one side. Many Anglo-Norman works were known, copied or imitated on the continent. Such were *St. Rrendan*, the *Bestiaire*, the *Vie de Saint Edouard*, the *Vie de Sainte Catherine*, *Priotesilaus*, *Amadas et Idoine*, the *Quatre Livre des Reis*, the *Apocalypse* and the debased Anglo-Norman Bible. Most of these occur either in manuscripts in the Picard dialect, probably because of the trade relations between England and the northeast of France, or in manuscripts made for the royal family. The clerkly and didactic nature of Anglo-Norman literature has been overstressed, but one important difference between continental and Anglo-Norman literature is that the fourth Lateran council of 1215 led to an outpouring of doctrinal and devotional works for the laity in England which is not paralleled in France. A curious and unexpected feature of Anglo-Norman is that in the early periods it is often in advance of the continent in the development of new literary kinds. History was popular both in Normandy and the continent and while it is true that after the Norman Conquest Latin took the place of English in documents and chronicles, examples of both in Anglo-Norman must not be overlooked. For political reasons the kings after Henry I were anxious to stress their connection with the old English line and particular attention was paid to Alfred and Edward the Confessor. Religious houses caused lives of native saints to be written and the nobility had a taste for romances about the deeds of imaginary English ancestors. Thus social and political differences between the two countries prevent Anglo-Norman literature from being a mere provincial imitation of French.

The Bible.—In the 12th century the oldest substantial prose work in French, *Li Quatre Livre des Reis*, ed. by E. R. Curtius (1911), was written in England, as also were many versions of the Psalter, including the Cambridge or rather Canterbury Psalter, published as *Le Livre des Psaumes*, ed. by F. Michel (1876)—the so-called Oxford Psalter is from Montebourg. Sanson de Nantuil translated into verse the proverbs of Solomon, with commentary, for Alice de Condet. In the 13th century Robert of Greatham wrote the *Miroir* or *Evangile des Domes*—the Sunday Gospels—for a noble lady. The same century saw the beginning of the magnificent series of Anglo-Norman Apocalypses (see the *Anglo-Norman Rhymed Apocalypse*, ed. by O. Rhys, Anglo-Norman Text society, no. 6, 1946), best known for their superb illustrations, which served as a model for the Angers tapestry. In the 14th century the Anglo-Norman Bible was begun, though never completed.

Saints' Lives.—The literature is rich in legends of the saints.

Benedict's Voyage of St. Brendan, ed. by E. G. R. Waters (1928), which achieved popularity on the continent, was dedicated to one of the queens of Henry I and is perhaps the oldest purely narrative French poem in the octosyllabic couplet. The feminine lines are of the lyric type, the final *-e* counting as a syllable. Simund de Freine, a canon of Hereford and friend of Giraldus Cambrensis, wrote a Passion of St. George in heptasyllables which was published in *Oeuvres de Simund de Freine*, ed. by J. E. Matzke (Société des anciens textes français, 1909) and there is a *Passion de seint Edmund* in stanzas. Wace (*q.v.*) was probably the first to write a saint's life in the standard form, but he was followed by Anglo-Norman writers in the 12th century—Denis Piramus, monk of Bury and former court poet, who refers to the *lais* of Marie de France (*q.v.*), wrote the life of *Seint Edmund le Rei*, ed. by H. Kjellman (1935), and Guillaume de Berneville that of *Saint Gilles*, ed. by G. Paris and A. Bos (Société des anciens textes français, 1881); the *Vie d'Édouard le Confesseur*, ed. by Ö. Södergård (1948), is by a nun of Barking, perhaps the Clemence of Barking who wrote the *Vie de Seinte Catherine*, ed. by J. U. Jarnik as *Dve verse starofrancouzské legendy o Sv. Katerině* (1894). Adgar translated a collection of "Miracles of the Virgin" owned by St. Paul's! a revision of which is dedicated to the abbess of Barking, and these were issued as *Adgar's Marienlegenden*, ed. by C. Neuhaus (1886). In the 13th century Simon de Walsingham, monk of Bury, wrote *Seinte Foy (Saint Faith)*, ed. by A. T. Baker in *Romania*, vol. lxxvi, pp. 49–84 (1940); and Angier, canon of St. Frideswide's, translated the dialogues and life of St. Gregory as the *Vie de Saint Grégoire le Grand*, ed. by P. Meyer in *Romania*, vol. xii, pp. 145–208 (1883). Matthew Paris (*q.v.*) translated four lives—17^e de *Seint Auban (Saint Alban)*, ed. by R. Atkinson (1876) in alexandrine laisses—probably holograph—and those of St. Edward, St. Edmund of Abingdon and Thomas Becket in octosyllables (see R. Vaughan, *Matthew Paris*, pp. 159–181, 1958). Becket of St. Alban's wrote another life of Becket in tail rhyme, ed. by B. Schlyter (1911).

Lives connecting religious houses with their patron saints are: *St. Modwenna* (for the abbey at Burton Upon Trent), ed. by A. T. Baker and A. Bell (Anglo-Norman Text society, no. 7, 1947) and *St. Osyth* (for St. Osyth, Essex), ed. by A. T. Baker in *Modern Language Review*, vol. vi, no. 4, pp. 476–502 (1911), vol. vii, no. 1, pp. 74–93 and no. 2, pp. 157–92 (1912). Lives of St. Audrey, St. Richard of Chichester, St. Lawrence, St. Francis: St. Margaret, St. Eustace and many more too numerous to mention are also found. In the 14th century the Franciscan Nicole Bozon wrote seven short lives. For Temple Bruer, Lincolnshire, a version of the *Vitue Patrum* was written. Chardri's *Barlaam et Josaphat* and *Set Dormanz* are the only association of these stories in French, ed. by J. Koch (*Altfranzösische Bibliothek*, no. 1, 1879).

Drama.—The earliest play entirely in French, the semiliturgical *Mystère d'Adam*, ed. by P. Studer (1918, reissued 1949), unfortunately incomplete, is a continental copy of what was apparently an Anglo-Norman original. This is famous for its characterization and poetical quality, as well as for the minute stage directions in Latin. (See also DRAMA: *Medieval*; FRENCH LITERATURE.) The resurrection play, *La Seinte Resurreccion*, ed. by T. A. Jenkins, J. M. Manly, M. K. Pope and J. G. Wright (Anglo-Norman Text society, no. 4, 1943) was probably 12th century, but was rewritten more than once in the 13th century. It is unique in having the stage setting and the action described in passages of verse which seem to have been designed to be read during the performance. Two later fragments of plays in alternative French and English versions have come to light.

Allegory.—There are a few religious allegories; the most important, the *Chateau d'Amour*, ed. by J. Murray (1918), written by Robert Grosseteste (*q.v.*) in which he draws upon his work in optics, is the oldest in French. It was translated into Latin and English.

Moral, Mystical and Didactic Works.—The verse sermon was popular in Normandy and England in the 12th century. Among later sermons in prose is one by the Franciscan Thomas of Hales, who wrote the *Love Ron.* An Anglo-Norman version of

the sermons of Maurice de Sully was frequently copied. The Franciscans John Pecham, archbishop of Canterbury, and Adam of Exeter wrote treatises and Nicole Bozon compiled a set of moral sayings illustrated by fables and tales, *Contes moralisés*, ed. by P. Meyer and L. T. Smith (Société des anciens textes français, 1889). The fourth Lateran council of 1215 led to the compilation of instructive works. The oldest and most attractive is the *Merure de seinte eglise*, by St. Edmund (q.v.) of Abingdon, ed. by H. W. Robbins (1925), translated into Latin and English. The *Manuel des Péchés* was translated into English by Robert Mannyng (q.v.) of Brunne as *Handlyng Synne*. Canon Peter of Peckham, Fetcham or Abernon's *Lumere as Lais* is cast in dialectic form. In the 13th–14th centuries countless treatises appeared on technical subjects—manuals for confession, agriculture, law, medicine, grammar, science, etc. There are also works dealing with manners, hunting, hawking, chess, etc. Two pioneer works on estate management are Walter of Henley's *Hosebanderie* and Grosseteste's *Reules Seynt Robert* written for the countess of Lincoln and translated into English. The legal literature includes the prose *Britton* and *Fet Asaver* and a poem *La Court de Baron*. The spelling treatises and "Manières de Langage" of the late 13th, 14th and 15th centuries are valuable for the light they shed on continental French as well as Anglo-Norman—cf *La Manière de Langage*, ed. by J. Gessler (1934). They were compiled by grammar masters, scribes or students returned from France for future lawyers, proctors of religious houses and merchants. A few are for children.

Romances.—Anglo-Norman literature is rich in romances. In the 12th century one Thomas wrote a courtly version of *Tristan*, ed. by J. Bédier (Société des anciens textes français, 1902–05; Eng. trans. 1960), which survives only in scattered fragments and was used by Gottfried von Strassburg (q.v.) in *Tristan und Isolde* as well as being the source of the Old Norse *Tristramsaga*, the Italian *Tavola Ritonda* and the Middle English *Sir Tristrem*. It is the ultimate source of the libretto of Wagner's opera. Bérout's *Tristan*, also 12th century, was probably written in England but by a Norman. (See also TRISTAN.) Hue de Rotelande (?Rhuddlan) of Credenhill wrote a lively romance of adventure, *Ipomedon*, ed. by E. Koelbing and E. Koschwitz (1889), with a setting in Calabria and Sicily probably provoked by the marriage of Henry II's daughter Joan to King William of Sicily. In this he refers to Walter Map as a notable inventor of lies. Less successful is the sequel *Protesilaus*, dedicated to Gilbert Fitz-Baderon, ed. by F. T. Kluckow (1924). In the next century *Gui de Warewic*, 2 vol., ed. by A. Ewert (1932), possibly by an Osenev canon, was popular and underwent revision. It was known on the continent. *Waldef*, a long confused story of an imaginary king of East Anglia and his sons, has passages of remarkable originality. In the 12th century some romances were composed in the form of the *chanson de geste*. Such are *Horn*, by Master Thomas, ed. by M. K. Pope (Anglo-Norman Text society, no. 9–10, 1955), which is connected with the Middle English *Horn Childe and Maiden Rimnild*, and which is claimed as a sequel of a lost *Aaluf*. Yet another Thomas wrote the *Roman de Toute Chevalerie*, an independent version of the Alexander romance, into which interpolations from the continental poems were afterward made. It is the source of the Middle English romance *Kyng Alisaunder*. Two versions of *Boeve de Haumtone* survive in overlapping fragments, ed. by A. Stimming (*Bibliotheca Normannica*, no. 7, 1899). This romance exists in English, French and other languages. In the 13th century the more courtly type of romance reappears in *Amadas et Idoine*, rewritten in Picard, ed. by J. R. Reinhard (1926), and in *Amis et Amiloun*, perhaps derived from the same source as the Middle English poem *Amis and Amiloun*, ed. by E. Koelbing (1884). (See also ALEXANDER ROMANCES.)

Lais and Fabliaux.—Marie de France wrote her *lais* for the English court and other *lais* were popular in England. Robert Biket's *Lai du Cor* is probably wrongly claimed for Anglo-Norman. The *Folie Tristan d'Oxford*, ed. by E. Hoepffner (1934; rev. ed. 1943), is a neat little work by an imitator of Thomas. Fabliaux are rare, but a few are found, probably for exemplary

purposes, copied in manuscripts from religious houses.

Lyrics and Political Songs.—There is no collection of Anglo-Norman lyrics, but a few occur on flyleaves or the blank pages of manuscripts. They are not of outstanding quality and do not differ in form from continental ones. Anglo-Norman is however rich in political satires and songs (see *Anglo-Norman Political Songs*, ed. by I. S. T. Aspin, Anglo-Norman Text society, no. 11, 1952).

Chronicles and History.—The earliest chronicle in French is the Anglo-Norman verse *Estoire des Engleis*, by Geffrei Gaimar, written c. 1140, ed. by A. Bell in 2 vol. (Anglo-Norman Text society, no. 14–15, 1960). About 1172 Jordan Fantosme wrote a chronicle of the war between the English and Scots, printed in *Chronicles of Stephen, Henry II and Richard I*, vol. iii, pp. 202–377, ed. by R. Howlett ("Rolls Series," no. 82, 1886), in the epic style later adopted by Peter Langtoft (q.v.), whose own *Chronicle*, ed. in 2 vol. by T. Wright ("Rolls Series," no. 47, 1866 and 1868), begins as a *Brut*—a complete chronicle of British history—but became a source for the times of Edward I. It contains fragments of political songs. The later part was translated by Robert Mannyng of Brunne. The Dominican Nicholas Trevet (q.v.) wrote a prose chronicle of European history for a nun at Amesbury, Mary, daughter of Edward I, from which Chaucer derived his *Man of Law's Tale*. Sir Thomas Gray (q.v.) of Heton began a huge prose *Brut* while a prisoner in Edinburgh castle from 1355 to 1357, the contemporary part of which is authoritative. A few monasteries which possessed a French *Brut* kept their annals in Anglo-Norman. Irish history produced some verse chronicles, the best of which is the *Song of Dermot and the Earl*, ed. by G. H. Orpen (1892). Two magnificent biographies of the first earl of Pembroke (William Marshal) and of Edward, the Black Prince, were written for English patrons by foreigners. Official documents, municipal records and letters were often in Anglo-Norman and the Yearbooks, unofficial reports of cases in the common pleas, run from the reign of Edward I to that of Henry VIII. English began to be used in parliament alongside French in the late 14th century.

Natural History and Science.—One of the earliest writers in Anglo-Norman. Philippe de Thaon or Thaün wrote *Li Cumproz* (the *Computus*), ed. by E. Mall (1873), the first French bestiary, *Le Bestiaire*, ed. by E. F. G. Walberg (1900), and a lapidary—a work on precious stones—included in *Anglo-Norman Lapidaries*, ed. by P. Studer and J. Evans (1924). Simund de Freine based his *Roman de Philosophie* on Boethius, to whom the 13th-century *Petite Philosophie*, ed. by W. H. Trethewey (Anglo-Norman Text society, no. 1, 1939) also owes much. All these are allegorical or didactic.

ANGLO-SAXON CHRONICLE. This main source for Anglo-Saxon history was first compiled in the reign of Alfred (871–899), from materials which included some epitome of universal history. Bede's *Ecclesiastical History*, genealogies, regnal and episcopal lists, a few northern annals and probably some sets of earlier West Saxon annals. The compiler also had access to a set of Frankish annals for the late 9th century. Soon after 890 manuscripts were being circulated; one was available to Asser in 893, another, which appears to have gone no further than that year, to the late 10th-century chronicler Aethelweard, while one version, which eventually reached the north and which is best represented by the surviving E version, stopped in 892. Some of the manuscripts circulated at this time were continued in various religious houses, sometimes with annals which occur in more than one manuscript, sometimes with local material, confined to one version. The fullness and quality of the entries vary at different periods; thus the Chronicle is a rather barren document for the mid-10th century and for the reign of Canute, but an excellent authority for the reign of Aethelred the Unready and from the reign of Edward the Confessor until the version which was kept up longest ends with annal 1154.

The Chronicle is extant in seven manuscripts and a fragment. The seven manuscripts are generally known by the letters of the alphabet. The oldest, known as C. C. C. Cant. 173 from the fact that it is at Corpus Christi college, Cambridge, and generally referred to as A, is written in one hand up to 891, and then continued in various hands, approximately contemporary with the entries. It was at Winchester in the mid-10th century, and may have been written there. It is the only source for the account of the later campaigns of Edward the Elder. Little was added to this manuscript after 975, and in the 11th century it was removed to Christ church, Canterbury, where various interpolations and alterations were made, some by the scribe of the F version. The manuscript known as Cotton Otho B xi (from the fact that it forms part of the Cotton collection of manuscripts at the British museum), which was almost completely destroyed by fire in 1731, contained an 11th-century copy of A, before this was tampered with at Canterbury. Its text is known from a 16th-century transcript by L. Nowell and from Abraham Wheloc's edition (1644).

The B version (Cott. Tib. A vi) and the C version (Cott. Tib. B i) are copies made at Abingdon from a lost archetype. B ends at 977, whereas C, which is an 11th-century copy, ends, mutilated, in 1066. Their lost original incorporated into the text in a block after annal 915 a set of annals (902-924) known as the Mercian Register.

The D version (Cott. Tib. B iv) and the E version (kept at the Bodleian library, Oxford, Laud Misc. 636) share many features, including the interpolation of much material of northern interest taken from Bede and from annals also used by Simeon of Durham; hence they are known as the "northern recension." They contain also an entry in the style of Archbishop Wulfstan (*q.v.*). But D differs from E in including annals 893-915, the mid-10th century section with poems on Brunanburh and the recapture of the five boroughs, and some other entries, which are all missing from E but occur in A, B and C. D has also dovetailed into its text the Mercian Register, and contains a fair amount of northern material found in no other version. It is very much interested in the English descent of Queen Margaret of Scotland. C. Plummer accounted for the difference between D and E by postulating an early separation of their archetypes; but it is more likely that D in which is written in hands no earlier than the late 11th century) acquired its present form by a conflation of a version of the E type with a C version at some late period. After about 1031 the close connection between D and E ends; D, which is kept up until 1079, probably remained in the north (though Plummer thought it was moved into the Worcester diocese, to Evesham), whereas the archetype of E was taken south and continued at St. Augustine's, Canterbury, and was used by the scribe of manuscript F.

The extant manuscript E is a copy made at Peterborough, written in one stretch until 1121, and kept up there until the early part of 1155. It has several Peterborough interpolations in the earlier sections. It is the version that was continued longest, and it includes a famous account of the anarchy of Stephen's reign. Plummer believed that the additions to the "northern recension" were made at Ripon, but at least an equally good case can be made for York, and there is evidence pointing to York as the place where the D version was compiled.

The F version (Cott. Domit. A viii) is an abridgment, in both Old English and Latin, made in the late 11th or early 12th century, based on the archetype of E, but with some entries from A. It extends to 1058, and its scribe is responsible for some of the entries into A made at Canterbury. Finally, the fragment H (Cott. Domit. A ix) deals with 1113-14, and is independent of E, the only other version to continue so late.

Several Latin writers possessed versions of the Chronicle which have not survived. Those used by the writers of the Annals of St. Neots and by Aethelweard represented forms closer to the original than any surviving text. Various intermediate stages are seen in the versions available to Asser, William of Malmesbury, Henry of Huntingdon, the compiler of the Waverley Annals and the Anglo-Norman poet Gaimar, while Florence of Worcester seems to have possessed several versions.

BIBLIOGRAPHY.—The edition by B. Thorpe (1861) must be used to compare the various versions, since *Two of the Saxon Chronicles Parallel*, ed. by C. Plummer on the basis of an edition by J. Earle (i, 1892; ii, 1899), contains the full text of only A and E. Plummer's introduction remains a standard work on the subject, and the reprint of 1952 includes a new bibliography and note on the commencement of the year by D. Whitelock. The only edition of Cott. Otho B xi is that of A. Wheloc, *Venerabilis Bedae Historia Ecclesiastica* (1644). Facsimiles exist of A, *The Parker Chronicle and Laws*, by R. Flower and H. Smith (1941), and of E, *The Peterborough Chronicle*, by D. Whitelock (*Early English Manuscripts in Facsimile*, iv (1954)). There is a separate edition of D, *An Anglo-Saxon Chronicle From British Museum Cotton MS., Tiberius B. iv*, by E. Classen and F. E. Harmer (1926); of C, *The C-Text of the Old English Chronicles*, by H. Rositzke (*Beitrag zur englische Philologie*, xxxiv [1940]), and of F, by F. P. Magoun, Jr., *Annales Domitiani Lintini: an Edition (Mediaeval Studies of the Pontifical Institute of Mediaeval Studies, ix, 1947)*. For translations see G. N. Garmonsway in Everyman's Library, rev. ed. (1955), and *English Historical Documents*, i, pp. 136-235 (60 B.C.-1042, by D. Whitelock); ii, pp. 107-203 (1042-1154, by S. I. Tucker) (1953-55).

For general description see, besides Plummer's introduction, F. M. Stenton, *Anglo-Saxon England*, 2nd ed., pp. 679-684 (1947); D. Whitelock, *English Historical Documents*, pp. 109-116. Some of Plummer's conclusions are challenged by F. M. Stenton, "The South-Western Element in the Old English Chronicle," *Essays in Medieval History presented to T. F. Tout* (1925); by Sir Ivor Atkins, "The Origin of the Later Part of the Saxon Chronicle known as D," *English Historical Review*, lv (1940); and by D. Whitelock, introduction to *The Peterborough Chronicle*, pp. 26-34. For further bibliography see the reprint of Plummer (1952), i, pp. 316a-316e; D. Whitelock, *English Historical Documents*, pp. 120-131; K. Sisam, "Anglo-Saxon Royal Genealogies," *Proceedings of the British Academy*, xxxix (1953); R. Vaughan, "The Chronology of the Parker Chronicle," *English Historical Review*, lxxix (1954); Cecily Clark, "Notes on MS. Laud Misc. 636," *Medium Aevum*, xxxiii (1954). (D. Wk.)

ANGLO-SAXON LAW. The body of legal rules and customs that prevailed in England before the Norman Conquest constitutes, with the Scandinavian laws, the most genuine expression of Teutonic legal thought. While the so-called "barbaric laws" (*leges barbarorum*) of continental Europe, including those compiled in the territory now called Germany, were largely the product of Roman influence, the continuity of Roman life was almost completely broken in the island, and even the church, the direct heir of Roman tradition, did not have a continuous existence: Canterbury was not a see formed in a Roman province in the same sense as Tours or Reims. One of the striking expressions of this Teutonism is presented by the language in which the Anglo-Saxon laws were written. They are uniformly norderd in English, while continental laws, apart from the Scandinavian, are all in Latin. The English dialect in which the Anglo-Saxon laws have been handed down is in most cases a common speech derived from West Saxon—naturally enough since Wessex became the predominant English state. After the Conquest Latin or French took the place of English in the compilations made to meet the demand for Anglo-Saxon law texts still applicable in practice.

Classification.—The Anglo-Saxon laws may be divided into three groups: (1) laws and collections of laws promulgated by public authority; (2) authoritative statements of custom; (3) private compilations of legal rules and enactments. To the first division belong the laws of the Kentish kings, Aethelberht, Hlothhere, Eadric and Wihtrid; those of Ine of Wessex, of Xlfred, Ednard the Elder, Xethelstan, Edmund, Edgar, Aethelred and Canute; the treaty between Alfred and Guthrum and the so-called treaty between Ednard and Guthrum. The second division would include the law of the Northumbrian priests and fragments of local customs entered in Domesday Book. The third division would consist of the post-Conquest collections of the so-called *Pseudo-leges Canuti*, the laws of Edward the Confessor (also spurious), of Henry I (a private venture which formed part of the great compilation of the *Quadripartitus*) and of a number of short notices on various matters, such as the formalities of betrothal (*Bewifmannes beweddung*), agricultural conditions (*Rectitudines singularum personarum*), the duties of a reeve (*Gevefa*) and of a judge (*Dema*), wergilds, oaths, ordeals, etc. A fourth group might be made of the charters since they are based on Old English private and public law and supply us with most important materials on the subject.

Direct statements of law would fall under the following heads from the point of view of their legal origins: (1) customary rules followed by divers communities capable of formulating law; (2) enactments of authorities, especially of kings; (3) private arrangements made under recognized legal rules. The first would comprise a great many of the rules entered in collections promulgated by kings; most of the paragraphs of Aethelberht's, Hlothhere's, Eadric's and Ine's laws are popular legal customs that have received the stamp of royal authority by their insertion in official codes. On the other hand, from Wihfred's and Alfred's laws downward, the element of enactment by central authority becomes increasingly prominent, though there are no outward signs enabling us to distinguish clearly between the various categories of laws in the codes nor can we draw a line between permanent laws and personal ordinances of single sovereigns, as has been attempted in the case of Frankish legislation.

Analysis of Content.—Even in the course of a general survey of the surviving legal lore, one cannot help being struck by peculiarities in the distribution of legal subjects. Matters which seem of primary importance and occupy a wide place in modern law-books are almost entirely absent in Anglo-Saxon laws or relegated to the background. While it is impossible to give here anything like a complete or exact survey of the field, a brief statistical analysis of the contents of the royal codes and laws may be made.

There are roughly 419 paragraphs devoted to criminal law and procedure as against 91 concerned with questions of private law and civil procedure. Of the criminal law clauses as many as 238 are taken up with lists of fines, while 80 deal with capital and corporal punishment, outlawry and confiscation, and 101 include rules of procedure. On the side of private law 18 clauses apply to rights of property and possession, 13 to succession and family law, 37 to contracts, including marriage when treated as an act of sale; 18 touch on civil procedure. A subject which attracted special attention was the law of status, and no less than 107 paragraphs contain dispositions dictated by the wish to discriminate between the classes of society. Questions of public law and administration are discussed in 217 clauses, while 197 concern the church in one way or another, apart from purely ecclesiastical collections.

In the public law division it is chiefly the power, interests and privileges of the king that are dealt with, in about 93 paragraphs, while local administration comes in for 39 and purely economic and fiscal matters for 13 clauses. Police regulations are very prominent and occupy no less than 72 clauses of the royal legislation. As to church matters the most prolific group is formed by general precepts based on religious and moral considerations, about 115, while secular privileges conferred on the church comprise approximately 62 and questions of organization about 20 clauses.

A consideration of chronological sequence in the elaboration of the laws reveals interesting results. The code of Aethelberht is almost entirely a list of "compositions" for various crimes, and similar lists figure largely in the laws of Hlothhere and Eadric, Ine and Alfred. In the codes of Edward the Elder and his successors, however, lists of fines for criminal offenses are much less prominent and gradually a new penal system is evolved, based on outlawry, confiscation, capital and corporal punishment.

Fines and compensations throughout the laws are graded carefully, in accordance with the social standing of the persons concerned. In early times it would appear that the different classes of society were more sharply distinguished than they were later. From the time of Aethelstan onward the distinction between the *thegn* or *twelfhynde* man (*i.e.*, the man with a wergild of 1,200 shillings) and the *ceorl* or *twihynde* man (*i.e.*, the man with a wergild of 200 shillings) is the chief dividing line between the classes of society. In the arrangements of the commonwealth the clauses dealing with royal privileges are more or less evenly distributed over all reigns, but the systematic development of police functions, especially in regard to responsibility for crimes, the catching of thieves and the suppression of lawlessness, is mainly the object of 10th- and 11th-century legislation.

Derivation.—The next question to be approached concerns the

pedigree and natural affinities of Anglo-Saxon law. How far has it been influenced by non-Germanic elements, especially by Roman and canon law? The oldest Anglo-Saxon codes, especially the Kentish and the West Saxon ones, disclose a close relationship to the barbaric laws of Lower Germany—those of Saxons, Frisians, Thuringians. We find a division of social ranks which reminds us of the threefold gradation of Lower Germany (*edelings*, *frilings*, *lazzen*—Kentish *eorls*, *ceorls*, *laets*) and not of the twofold Frankish one (*ingenii Franci, Romani*), nor of the minute differentiation of the Upper Germans and Lombards. In subsequent history there is a good deal of resemblance between the legislation of the capitularies of Charlemagne and his successors on one hand and the acts of Alfred, Edward the Elder, Aethelstan and Edgar on the other, a resemblance called forth less by direct borrowing of Frankish institutions than by the similarity of political problems and conditions. Frankish law becomes a powerful modifying element in English legal history after the Conquest, when it was introduced wholesale in royal and in feudal courts. The Scandinavian invasions brought in many northern legal customs, especially in the districts thickly populated with Danes. The Domesday survey of Lincolnshire, Nottinghamshire, Yorkshire, Norfolk, etc., shows remarkable deviations in local organization and justice (*lagmen*, *sokes*), and great peculiarities as to status (*socmen*, *freemen*), while from laws and a few charters we can perceive some influence on criminal law (*nidingsvaerk*), special usages regarding fines (*lahslit*), the keeping of peace, attestation and sureties of acts (*festermen*), etc. But on the whole the importance of the introduction of Danish and Norse elements, apart from local cases, is due chiefly to the conflicts and compromises it called forth and to its social results; the Scandinavians coalesced easily with the natives.

The direct influence of Roman law was not great during the Saxon period: we notice neither the transmission of important doctrines nor the continuous stream of tradition in local usage. But indirectly Roman law did exert a by no means insignificant influence through the medium of the church, which, for all its insular character, was still permeated with Roman ideas and forms of culture. Thus Roman law had already turned its attention to the problem of intent and the church was much concerned with the problems of moral theology which the study of the Bible revealed: long before the matter was finally resolved by the scholastics. Archbishop Wulfstan secured the insertion, among the laws of Aethelred, of his moving appeal to distinguish between youth and age, wealth and poverty, accident and design when considering the moral nature of human acts.

The relations between church and state in Anglo-Saxon England were of capital importance and during the 19th century were variously estimated. It is now recognized that the Penitentials took an active part in supporting the efforts of the secular law to maintain law and order. Then, too, it was frequently suggested that Anglo-Saxon kings, for superstitious motives, allowed churches to exercise wide immunities and legal privileges, thus diminishing the powers of the crown. The more recent and probable view is that the crown was in fact casting upon wealthy churches (such as some of the greater abbeys) a large part of the duty of policing the countryside and that this policy was continued and developed under the Normans. Work of that sort was necessarily done by "the man on the spot"; it was expensive and a severe strain upon the resources of the Anglo-Saxon kings. The Old English "books" are derived in a roundabout way from Roman models, and the tribal law of real property was deeply modified by the introduction of individualistic notions concerning ownership, donations, wills, rights of women: etc. Yet here also the Norman Conquest increased the store of Roman conceptions by breaking the isolation of the English church and opening the way for closer intercourse with France and Italy.

Folkright and Privilege.—The Anglo-Saxon legal system cannot be understood unless one realizes the fundamental opposition between folkright and privilege. Folkright is the aggregate of rules, formulated or latent but susceptible of formulation, which can be appealed to as the expression of the juridical consciousness of the people at large or of the communities of which

it is composed. It is tribal in its origin and differentiated not according to boundaries between states but on national and provincial lines. There may be the folkright of West and East Saxons, of East Angles, of Kentish men, Mercians, Northumbrians, Danes and Welshmen, and these main folkright divisions remain even when tribal kingdoms disappear. The centres for the formulation and application of folkright were, in the 10th and 11th centuries, the shire moots, while the councilors (*witan*) of the realm generally placed themselves on the higher ground of state expediency, although occasionally using folkright ideas. The older laws of real property, of succession, of contracts and the customary lists of fines were mainly regulated by folkright; the reeves employed by the king and great men were supposed to take care of local and rural affairs according to folkright. The law had to be declared and applied by the people themselves in their communities, while the spokesmen of the people were the leading men—the 12 eldest thanes or a similar quorum. Folkright could, however, be broken or modified by special law or special grant, and the fountain of such privileges was the royal power. Alterations and exceptions were, as a matter of fact, suggested by the interested parties themselves and chiefly by the church. Thus a privileged land tenure was created—bookland; the rules pertaining to the succession of kinsmen were replaced by concession of testamentary power and confirmations of grants and wills; special exemptions from the jurisdiction of the hundreds and special privileges as to levying fines were conferred. In time the rights originating in royal grants of privilege overbalanced folkright in many respects and became the starting point of a new legal system—the feudal one.

The King's Peace.—Another feature of vital importance in the history of Anglo-Saxon law is its tendency toward the preservation of peace. Already in Xethelberht's legislation we find characteristic fines inflicted for breach of the peace of householders of different ranks—the ceorl, the eorl and the king himself appearing as the most exalted among them. Peace is considered not so much a state of equilibrium or of friendly relations between parties but rather as the rule of a third within a certain region—a house, an estate, a kingdom. This leads on one side to the recognition of private authorities—the father's, the master's, the lord's—while on the other the tendency to maintain peace naturally takes its course toward the strongest ruler, the king, and we witness the gradual evolution of stringent rules in respect of the king's peace. A more metaphysical conception of "peace" was popularized by H. Brunner and adopted by F. W. Maitland. This concept regarded "peace" as proceeding from the folk and as being something like the theologian's "state of grace" which a criminal has forfeited by serious crime. J. Goebel cast serious doubts upon this interpretation, especially upon its alleged continental origins.

The more ancient documents of Anglo-Saxon law show us the individual not merely as the subject and citizen of a certain commonwealth but also as a member of some group, all the fellows of which are closely allied in claims and responsibilities. The most elementary of these groups is the *maegth*, the association of agnatic and cognatic relations. Personal protection and revenge, oaths, marriage, wardship, succession, supervision over settlement and good behaviour are regulated by the law of kinship. A man's actions are considered not as exertions of his individual will but as acts of the kindred, and all the fellows of the *rnaegth* are held responsible for them. What began as a natural alliance was used later as a means of enforcing responsibility and keeping lawless individuals in order. When the association of kinsmen failed (and it seems to have done so at an early period in England) the voluntary associations—guilds—appeared as substitutes. The guild brothers associated in mutual defense and support, and they had to share in the payment of fines. The township and the hundred were also involved in certain forms of collective responsibility.

In the course of time the natural associations get loosened and intermixed, and this calls forth the elaborate police legislation of the later Anglo-Saxon kings. Regulations are issued about the sale of cattle in the presence of witnesses. Enactments about

the pursuit of thieves and the calling in of warrantors to justify sales of chattels are other expressions of the difficulties attending peaceful intercourse. Personal surety appears as a complement of and substitute for collective responsibility. The *hlaford* and his hiredmen are an institution not only of private patronage but also of police supervision for the sake of laying hands on malefactors and suspected persons. The *landrica* assumes the same part in a territorial district. Ultimately the laws of the 10th and 11th centuries show the beginnings of the frankpledge associations, which came to play so important a part in the feudal age.

ANGLO-SAXONS. The title *rex Angulsaxonum*, with obvious variants like *rex Anglorum Saxonum*, was used sporadically by King Alfred (d. 899) and his successors down to King Edwy (d. 957) and was revived in the 11th century. The expression "Anglo-Saxons" probably arose to distinguish the Saxons of England from those of the continent, the *Antiqui Saxones* of Bede, translated *Ealdseaxe* in Old English. Hence the title "king of the Anglo-Saxons" would at first be merely a variant of "king of the Saxons" and "king of the West Saxons" also used by Alfred. Later the title would be interpreted as "king of the Angles and Saxons." and therefore equivalent to "king of the English."

Except in charters the term "Anglo-Saxons" is rare in English documents before 1066. In one 10th-century poem it occurs in the sense "people of England." It probably originated on the continent, where it was used from the time of Paulus Diaconus (c. 775) onward, and while at first it no doubt meant "Saxons of England," it can scarcely be said to mean more than "English" in surviving sources. Similarly writers in England after the Norman Conquest such as Florence of Worcester and Orderic Vitalis used it in the sense "English." It has been adopted since the 16th century to mean "English of the pre-Conquest period." From it were derived the adjective "Anglo-Saxon," used to describe the period of English history, language and literature which preceded the Norman Conquest, and the noun "Anglo-Saxon," meaning the Old English language. The latter term contrasts with the Old English usage in which the vernacular tongue was called *Englisc*, even by Saxon writers.

ANGO, JEAN (c. 1480–1551), the most famous French ship-owner of the Renaissance period, was born at Dieppe in Nor-

mandy. After taking over his father's import-export business early in the 16th century, he rose to control, by himself or in association with others, a fleet of 70 ships. With this he was able, in Francis I's reign, to ensure that France was represented wherever exploration had opened up new seas. It was Ango who in 1524 equipped the "Dauphine" in which Giovanni da Verrazano explored the east coast of North America, discovering the site of the future New York (which he named Angoulême), and in 1529 the brothers Jean and Raoul Parmentier reached the coast of Sumatra in Ango's ships the "Pensée" and the "Sacre." Ango also sponsored privateering. One of his captains, Jean Fleury, seized three ships on their way to Spain with Aztec treasures from Mexico (1523). When Francis I in 1530 authorized Ango to raid Portuguese shipping until he had compensated himself for losses sustained at Portuguese hands to the value of 250,000 ducats, the Portuguese were so much alarmed that their ambassador came to terms to have the authorization canceled. Francis I generally upheld Ango, as he both borrowed his ships for use against Spaniards and Englishmen and enjoyed the hospitality of his magnificent houses in Normandy. On Francis' death, however, Ango was exposed to his rivals' envy, was imprisoned for a time on a charge of malversation (1549) and died at Dieppe in 1551.

BIBLIOGRAPHY.—E. Guérin, *Ango et ses pilotes* (1901); M. Mollat, *Le Commerce maritime normand à la fin du moyen âge* (1952) and "Jean Ango," *Transmondia*, 69 (1960). (Mr. M.)

ANGOLA, a Portuguese overseas province on the west coast of Africa, south of the equator, is one of the eight Portuguese overseas provinces. The whole province, sometimes designated Portuguese West Africa, is situated south of the Republic of the Congo (former Belgian Congo), except the enclave of Cabinda (Kabinda), which is separated from the main territory by a strip of approximately 25 mi. belonging to the Republic of the Congo. The area of Angola is 481,351 sq.mi., and the population by the 1950 census was 4,145,266, including 78,826 Europeans. The capital is Nova Lisboa (formerly Huambo); population (1950) 28,296.

PHYSICAL GEOGRAPHY

Geology.—The province is divided into two major zones: the first includes the continental plateau and the hills which separate it from the littoral, while the second zone is formed by the littoral itself. The most important geologic system is the Pre-Cambrian Oendolongo, which corresponds to the Witwatersrand system in South Africa.

The central plateau consists of ancient crystalline rocks with granites overlain by unfossiliferous sandstones and conglomerates considered to be of the Paleozoic Age. The outcrops are largely hidden under laterite. The median hills parallel with the coast are composed largely of crystalline rocks with granites and some Paleozoic unfossiliferous rocks. The littoral zone contains the only fossiliferous strata; they are of Tertiary and Cretaceous Ages, the latter rocks resting on a reddish sandstone of an older date. The Cretaceous rocks of the Dombe Grande region (near Benguela) are of the Lower Cretaceous Albian Age and belong to the zone identified by the index fossil *Acanthoceras mamillari*, an ammonoid mollusk. The beds containing fossils of the ammonite *Schloenbachia inflata* are referable to the Gault. Tertiaries are at Dombe Grande, Moçâmedes and near Luanda. The sandstones with gypsum, copper and sulfur of Dombe may be Triassic. Recent eruptive rocks, mainly basalts, form a line of hills almost bare of vegetation between Benguela and Moçâmedes. Nepheline basalts and liparites occur at Dombe Grande. Copal, a fossil resin, occurs in quantity in some superficial rocks.

Physiography.—The northern boundary of Angola follows the Congo river, then goes east to the Kwango (Cuango) river. The eastern and southern boundaries, dividing Angola from the Republic of the Congo, Northern Rhodesia and South-West Africa, are highly irregular. They extend to 24° 05' E. and 18° 03' S. The enclave of Cabinda (*q.v.*) is separated from the neighbouring countries (Republic of Congo [former French Congo]) to the north and northeast and the Republic of the Congo to the south and southeast by land. This area near Matadi was ceded by Por-

tugal in 1927 for the laying of the Boma-Leopoldville railway; Belgium gave in exchange about 1,158 sq.mi. of the Bota de Dilolo, the frontier of the Republic of the Congo passing behind and almost parallel to the Luao river. South from the Congo river (6° S., 11° 41' E.) the coast of Angola is about 1,000 mi. long and goes as far as the mouth of the Kunene (Cunene) river. The coast is divided into two different parts. North of the mouth of the Kwanza river it is hilly; south of that point it is for the most part flat, with occasional low cliffs of red sandstone. Great Fish bay (Baia dos Tigres), a little north of the Angola-South-West Africa frontier, is the one deep inlet. Farther north are Porto Alexandre, Little Fish bay (Baia de Moçâmedes) and Lobito bay, while shallower bays are numerous. The sparsely watered, sterile coastal plain extends 30 to 100 mi. inland. The great central plateau of Africa is approached by a series of irregular terraces covered with luxuriant vegetation. Water is fairly abundant although in the dry season obtainable only by digging in the sandy beds of the rivers. The plateau, altitude 4,000 to 6,000 ft., consists of well-watered, wide, rolling plains and low hills with scanty vegetation. In the east the tableland falls away to the basins of the Congo and Zambezi rivers, to the south it merges into barren sandy desert. The numerous westward rivers, except the Kwanza (Coanza) and Kunene (*q.v.*), are unimportant. The mountain chains edging or dominating the plateau run generally parallel with the coast, as Tala Mugongo (4,400 ft.), Chela and Vissecua (5,250 to 6,500 ft.). In the district of Benguela are the highest points of the territory, Loviti (7,780 ft.) in 12° 5' S. and Mt. Elonga (7,550 ft.) South of the Kwanza river is the volcanic mountain Caculo-Cabaza (3,300 ft.). From the tableland the Kwango and many other streams flow north to join the Kasai (*q.v.*), one of the largest affluents of the Congo. In its upper course the Kwango forms for fully 300 mi. the boundary between Angola and the Republic of the Congo. In the southeast the rivers flow to the Zambezi or, like the Cubango, drain to Lake Ngami.

Climate.—With the exception of the district of Moçâmedes, the coastal plains are unsuited to white people. In the interior, above 3,300 ft., temperature and rainfall, together with malaria, decrease. The plateau climate is healthful and invigorating. The mean annual temperature at São Salvador do Congo is 72.5° F.; at Luanda, 74.3°, and at Caconda, 67.2°. The prevailing winds are west, southwest and south-southwest. The cool season lasts from June to Sept.; and the rainy season from Oct. to May; the heaviest rainfall occurs with storms in April.

Vegetation.—As far south as Benguela the coast is rich in oil palms and mangroves. In the north are dense forests, some of which, especially in the enclave of Cabinda, contain valuable timber; in the south, toward the Kunene, are regions of dense thorn scrub. Rubber vines and trees are abundant but have been reduced by ruthless tapping; the commonest are various root rubbers, notably *Carpodinus chylorrhiza*; species of *Landolphia* are also found. Coffee, cotton and Guinea pepper are indigenous, and tobacco flourishes in several districts. Among timber trees are the tacula (*Pterocarpus tinctorius*), which grows to an immense size, its wood being blood red in colour, and the Angola mahogany. The bark of the musuamba (*Albizia coriaria*) is used in tanning leather. The mulundo bears a hard green-shelled fruit, the size of a cricket ball (about 9 in. in circumference), with scarlet pips like a pomegranate.

Animal Life.—The fauna includes lion, leopard, cheetah, elephant, giraffe, rhinoceros, hippopotamus, buffalo, zebra, kudu and many other species of antelope, wild pig, ostrich and crocodile. Angola is one of the few territories where the great sable antelope (*Hippotragus niger varians*) still exists although it is very rare in spite of being protected. Only a few hundred individuals can be found on the banks of the Luando river. There are two major nature reserves, Quinqama (3,840 sq.mi.) and Moçâmedes (7,200 sq.mi.).

The maritime fauna is extremely rich. There are several kinds of whales, tortoises (*Chelonia imbricata*), lobsters, shell fish and a large variety of fish. Angola has the best fishing grounds of south and southwest Africa, where the Benguela cold current and the Agulhas warm current converge giving maritime temperatures

and upsurges favourable to plankton. The sea is generally calm. Most of the fish common on the Atlantic coast of Europe are found off Angola, as well as African species. The most abundant are stickleback, mackerel, anchovy, tench, gilthead, sardine, whiting and tunny. The river fauna is also very rich, contributing an important part to the food supply of the native populations.

PEOPLE AND POPULATION

In 1950 the population of Angola was composed of 4,035,687 Natives, 78,826 Whites, 26,335 of mixed race, and 105 others. The districts of greatest population density were those of Huambo (48 persons per sq.mi.), Benguela (22) and Luanda (21). The total urban population rose from 128,568 in 1940 to 247,073 in 1950, while the number of Negroes in urban centres rose from 94,818 in 1940 to 187,321 in 1950.

The great majority of the Negro population is of Bantu stock, though in the Congo district it is mixed with pure Negro. In the southeast there are various tribes of Bushmen. Bantu-Negroes include the Kongo and Ambundo in the north, and the Xambo in the south, etc., but the most important group is that of the Ovimbundo, whose language is spoken or understood by over 2,000,000 native?. Fetishism is the prevailing religion. (See also AFRICA: Ethnography (*Anthropology*): West Central Africa.)

Churches and Missions.—Angola forms a diocese of the Roman Catholic Church, in the province of Lisbon. This church began work at São Salvador do Congo in 1491 and controlled all educational activities until 1908. The Benidas, Cazombo, Cuando, Lilobo, Moxico and Vila Luso missions belong to the Benedictines, those of Andulo, Silva Porto, Cachingues, Chinguar, Entre Rios, Nova Sintra, Nhareia, Saurimo, Minungo, and Mussuco to the Order of the Holy Ghost; and those of Cuchi and Caiundo to the Redemptorists.

The Baptist Missionary society has headquarters at São Salvador do Congo. The American Methodist Episcopal Foreign Missionary society works in the Luanda district and the Canadian and American Congregational Churches and the Plymouth Brethren have missions in the highlands east of Lobito bay. In the Moçâmedes district are stations of the South African mission and the Swiss mission. In all there are in Angola about 50 non-Catholic missions, almost half of them British and most of the rest American with a few Portuguese and Swiss. They run schools, especially for agriculture, and their welfare work has been outstanding.

Immigration and Settlement.—The Portuguese government has, since 1945, increased facilities for emigration; between 1950 and 1957 an average of 17,000 people a year left Portugal for Angola. The economic development of the territory is partly attributed to this immigration. In addition there have been some experimental settlements organized by the government. Those of Cela (planned to accommodate 2,000 families) and the Kunene valley (for 8,000 families) are of particular note. In Cela, situated at an altitude of 4,600 ft., villages were prepared, fields cleared and bridges, roads, irrigation canals, etc., built before the settlers arrived. Each village has a community well, a public storehouse for crops, a combined church and schoolhouse and a first-aid station. Each family is provided with housing and a few livestock, 12 ac. of irrigated land, 30 ac. of nonirrigated land and about 100 ac. of rough mountainside grazing. There are tractor and machinery pools for the colony, though a few individual farmers buy tractors for their own use and for contract work among their neighbours. Native labour cannot be hired, so that each European community has to be independent of the African. In this respect Cela is a positive experiment. The houses are similar to small farmhouses in Portugal and are well-built and attractive.

Rice, wheat, maize (corn), potatoes, fruits and vegetables are the principal crops grown at Cela.

The Kunene valley settlement was created for natives and Europeans. The most important crops grown there are sugar cane, tobacco and cotton. There are in addition six experimental colonies for natives only at Damba, Chimube, Toto, Loge, Culo and Caconda.

HISTORY

Portuguese navigators exploring the west coast of Africa in search of the road to India reached the coast of Angola in 1482. In that year Diogo Cam (Cão) (*q.v.*) discovered the whole coast line of Angola and erected stone pillars at the mouth of the Congo river and at St. Augustine cape. He brought to Portugal several Negroes whom he took back to Angola on his next trip in the following year. He then came into contact with the Mani Congo, or king of Congo, who sent an ambassador to the Portuguese court. In 1491 another fleet arrived at Angola and followed the Congo river for over 120 mi. E., reaching the capital of the king. This king and many of his relatives were baptized soon after and a Portuguese embassy was permanently established at his capital. Trade relations were then started with the natives and the influence of the Portuguese ambassadors and missionaries increased rapidly, mainly in the territories ruled by the kings of Congo.

With the arrival of Paulo Dias de Navais in 1575 the phase of territorial occupation south of the Congo river began. He founded Luanda (the capital city until Nova Lisboa was named the capital in 1927; it remained the administrative centre), overcame several native chiefs and promoted the settlement of the first white colonists. During the next 50 years the Portuguese slowly expanded their territories. In 1617 the city of Benguela was founded, and after that date the sovereignty of Portugal over the coast line of Angola was undisputed, except between 1640 and 1648. During that time the Dutch, attempting to take Angola from Portugal, captured the most important ports. After a heroic resistance at Massangano, which lasted seven years, Salvador Correia de Sá reconquered Luanda in 1648 for Portugal and expelled the Dutch from the whole territory.

During the following two centuries the economic development of Angola was slowed down by the fact that, in spite of the efforts of the Portuguese government to develop the agricultural resources, its main source of income was the slave trade with Brazil, which was not abolished until 1830, large scale exportation of indentured labour continued into the 20th century (see ST. THOMAS [SÃO TOMÉ]: History) and forced labour was not prohibited until 1953 (see below). In 1877 H. A. de B. Capello and R. Ivens began their famous voyages from Benguela to the lands of Saca through Bié and along the Cuango river. At the same time Serpa Pinto (*q.v.*) explored the route between Bié and Durban. In 1881 religious missions were established in the southern plateaus (Huila) and at São Salvador do Congo. There were also Boer migrations toward the Huila plateau; most of these immigrants later returned to the Transvaal. In 1884 Capello and Ivens started from Moçâmedes heading toward the upper Congo and reached Quelimane in Mozambique seven months later during which time they walked 2,800 mi. Of the 124 men that accompanied them 68 died during the journey. In 1886 Angola was connected with Europe by submarine cable. In 1890, at the end of a military revolt led by Artur de Paiva, a more intensive occupation of Bié began. Six years later the first royal commissioner was appointed. Systematic colonization of the territory continued, especially after 1902 when the authorization for the construction and exploration of the Benguela railway was given. The influence of railways was extended from 1905 to 1909 with the construction of the Moçâmedes and Malanje lines. Primary schools, mainly aimed at educating the natives, were founded from 1906, and the first secondary school in 1918. At the same time military operations against inland tribes continued; they were concluded only in 1915. Pavia Conceiro was governor from 1907 to 1909 and his short mandate was one of the greatest in the history of Angola. He contributed to the development of railways, ports (Luanda, Moçâmedes, Benguela and Lobito), roads, the telegraphic network, education, European immigration, religious missions, medical assistance, etc.

In the transition period that followed the proclamation of the Portuguese republic in 1910, Angola was governed by a man of great equilibrium and tolerance, the Goan Portuguese Caetano Gonçalves. In 1912 Norton de Matos was appointed governor and he showed himself to be a follower of Conceiro's policies. He reformed the administrative system, developed agriculture, created

new urban centres, stimulated commerce and industry, opened roads and regulated native work. His rule was interrupted by World War I during which Angola was attacked in the south by the Germans. The Cuanhamas seized this favourable opportunity to rebel but Pereira d'Éça defeated them. In 1917 the existence of diamonds in Lunda was proved and the Companhia de Diamantes de Angola (Diamang) was founded. Portugal created the high commissioner system, endowing him with ample administrative, financial and legislative powers. In 1920 De Matos was appointed high commissioner. He was succeeded by Vicente Ferreira, ex-minister of finance, who continued the work of economic development, European settlement and occupation begun by De Matos and founded the Banco de Angola. He resigned in 1928. To a territorial financial crisis two further adverse facts were added: the world economic crisis of 1930-31 and the locust invasions which lasted for six years. Meanwhile between 1930 and 1933 government regulations concerning Portuguese overseas territories were issued: the Colonial act, budget bases and the Organic Charter of the Empire and Overseas Administrative Reform. Since then administration has been improved and economic progress has been speeded up. In 1938 the first development plan was approved and in 1945 and 1951 two further plans. In 1953 the first national plan was put into operation; this and the one following covered both Metropolitan and overseas territories. In these plans special attention was paid to transport and energy questions and also to credit organization, industrialization and labour problems. After the revision of the Portuguese constitution in 1951, a law was passed in June 1953, which ruled that native labour for the state must be remunerated and forbade the coercion of natives to work for private enterprises. Natives could only be employed compulsorily on public works, in execution of judicial sentences or in fulfillment of taxation obligations.

ADMINISTRATION AND SOCIAL CONDITIONS

Government and Administration. — Angola is governed under the organic charter for overseas territories of June 1953 and the statute of July 1955. A governor general appointed by the Lisbon government and responsible to the minister for overseas territories has wide powers both for legislation and administration. He is advised by a legislative council of 26 persons, of whom 18 are elected either by direct polling or by economic and social organizations, and the other 8 appointed. The competence of the governor general to legislate normally requires the agreement of the legislative council.

By a decree of Oct. 20, 1954, the territory was divided into 13 districts: Cabinda, Congo, Luanda, Cuanza Norte, Cuanza Sul, Malanje, Lunda, Benguela, Huambo, Bié-Cuando Cubango, Moxico, Moçâmedes and Huila. Each district is divided into *concelhos* (counties) and *circunscrições civis* (circumscriptions or subdistricts) each under an administrator who is the resident magistrate. Several minor local bodies with limited powers also exist, the most important of which are the *câmaras municipais*, which administer the *concelhos*. There are 55 *concelhos* and 20 subdistricts.

The Portuguese overseas provinces situated on the west coast of Africa constitute a judicial district under an appeal court at Luanda.

Welfare Services. — Sleeping sickness appears especially in the northeast but is rapidly decreasing as a result of the campaigns of mass vaccination which have taken place yearly since 1949. Common diseases are tuberculosis, malaria, hookworm, smallpox, leprosy, elephantiasis and goitre (among the women of the uplands). There are about 60 state hospitals and as many private hospitals, 70 village infirmaries and 4 leprosarium. In the Congo district there is a special medical service for sleeping sickness and in the Baixo, Kunene and Gambos areas a special service for bubonic plague. There is a separate fund for medical assistance to natives.

Education. — By 1960 there were 5 state and 22 private secondary schools, 10 state and 5 private technical schools, and one teachers' training college. State primary education was provided by about 150 schools; primary and rudimentary education is also pro-

vided for native children in about 1,000 schools by the Portuguese Catholic and Evangelical missions. Schooling lasts for four years and all education is carried out in Portuguese. The teachers' training college, Teófilo Duarte, at Cuima is subsidized by the state and entrusted to the Portuguese Catholic missions. Here educated natives of both sexes can graduate as primary school teachers. Two of the secondary schools are in Luanda and the other three in Benguela, Nova Lisboa and Sá da Bandeira.

Technical education covers commercial, industrial and agricultural fields. After 1949 it increased considerably to keep pace with the territory's economic development. The courses in highest demand are those in mechanics and bookkeeping. The Dr. Vieira Machado Agricultural and Husbandry college has accommodations for 100 resident pupils and covers an area of 37,500 ac. The courses are of three or four years duration. The accommodations are modern and include stables, aviaries, laboratories and warehouses.

THE ECONOMY

Agriculture. — Angola is primarily an agricultural country. Its range of altitude enables it to produce crops of both tropical and temperate zones. Coffee is the principal export crop and the chief market is the United States. Four types are grown, the best being that of Novo Redondo. Maize is an important crop and is exported in large quantities. It is grown almost entirely by the Africans, mainly in the Benguela and Huambo districts and about Luanda. Sisal, also an export crop, is grown extensively in the Malanje and Benguela districts. Broad beans are a declining export from the same districts. Coconuts are grown in the north. Other oil-producing seeds are castor beans, grown almost exclusively by the Africans, chiefly in the Benguela, Bié, Malanje and Huila districts; palm kernels collected by the Africans in the coastal plain; peanuts, used mainly as a native food crop; and sesame, also used as a native food crop.

Cotton is grown chiefly in the Malanje district, and almost the entire crop is exported. Wheat does well on the Benguela plateau, in Bié and Huila. Potatoes, rice, peas and other vegetables are commonly grown in the highlands. Cacao does well in Cabinda and in parts of the area around Amboim. Manioc is cultivated almost everywhere by the Africans. Bananas thrive in all areas, except in the higher parts of the south; tropical fruits, such as pineapples, guavas and pawpaws, grow almost everywhere, while Mediterranean fruits are successfully grown in the highlands. Tobacco of rather inferior quality is grown at middle altitudes as well as in the highlands, and its production in the 1960s was being developed, especially by the Europeans. Sugar cane is one of the most important products of Angola and contributes significantly to the territory's exports; and the extraction plants have modern machinery. Rubber is found in the interior districts and is the basis of trade with the Africans. Fine timber, principally hardwoods, is cut especially in the northern parts of the territory though it is still exported in only limited quantities. The chief woods are bulletwood, African mahogany and ebony. There are government agricultural stations at Luanda on the coast and in the interior.

Stock Raising. — There is excellent grazing land in many parts of Angola, especially in the Huila, Huambo and Benguela districts. Forage is also available, but the tsetse fly has been prevalent in many districts. Stock being raised includes cattle, goats, pigs, sheep, asses and horses. Portuguese and French merino sheep have been imported to improve the quality of the wool, and Persian blackheads from South Africa have been introduced for mutton. Angola has an exceptional ability for Karacul raising. British firms have extensive cattle raising concessions in the vicinity of the Benguela railway. Honey and beeswax are produced almost entirely by the Africans. The export of beeswax has been on the decline.

Mining. — Thick beds of copper, probably outcrops of the Katanga mines of the Republic of the Congo, are found in the Bembe region in the north. Other deposits are found in the Quibala area and in the Moçâmedes district, also on the Cuvo. Iron is found in many parts: at Oeiras (on the Lucala affluent of

the Kwanza river), near Andulo, around Bailundo and in other places in the south. It is believed that about 8,000,000 tons of ore are available and production is expanding. Petroleum was discovered in 1955 and proved to be of good quality. The Mulemba refinery was opened in 1958 with an initial capacity of 100,000 tons of refined oil per annum. Salt is worked by natives in several places along the coast. Gold occurs near the source of the Kunene and at Cassinga; lead on the Lucala east of Vila Salazar; lignite in the Kwanza valley; coal at Calucala, Quilungo, Dondo and on the Benguela plateau. The coal, of high volatile content, is exported while ordinary coal is imported. Diamonds are worked in the Lunda district under concession from the government which shares in the profits (see DIAMOND: World Occurrence). Other minerals are mica, manganese and sulfur.

Industries.— Much effort has been directed to the development of electric power resources. Angola had 450 thermal power stations by 1959. There were three dams supplying hydroelectric power: Mabubas on the Dande river, Biapio on the Catumbela river and Matala on the Kunene river. Others have been planned.

The most important manufacturing industries are those processing palm, whale and fish oil and resin and its derivatives; milling cereals; salting fish; preserving meat; and producing sugar, beer, cotton fabrics and cement. Fishing is an important occupation and includes a whaling station at Porto Amélia (near Moçâmedes). Several factories produce vegetable fibres while other industries include ceramics, brick and tile making, carpentry and joinery, wagon building and sawmills. Tobacco is processed in modern factories in Luanda, local gronths being mixed with imported ones. There are foundries and railway shops connected with the state railways. New factories include those for rubber tires, nitrogenous fertilizers, cellulose, cement and glass.

Trade.— The chief articles of import are textiles, foodstuffs, beverages, iron and steel goods, automobiles and industrial machinery. The chief exports are coffee, diamonds, fish meal, maize, cotton, sisal and sugar.

About one-third of the trade is with Portugal, which provides about half the imports and purchases one-fifth of the exports.

Finance.— The chief sources of revenue are customs, direct taxes (including native personal tax) and participation in private enterprises (mainly the diamond corporation). The chief expenditures are investments in the economic development of the territory, administration and defense.

Transport and Communications.— Benguela, Lobito, Luanda, Novo Redondo, Moçmedes and Amboim are the principal ports along the coast, although there is some shipping from Ambriz, Great Fish bay and Ambrizete. There are regular steamship communications between Portugal, England, Germany and South Africa from Lobito. The Portuguese line which carries the bulk of the cargo is subsidized by the Portuguese government.

Railway mileage totals about 1,600 mi. Five lines run inland from the coast. The most important is the Benguela railway completed in 1927, 837 mi. from Lobito to its connection with the Katanga lines at the Republic of the Congo frontier. Of standard gauge (3' 6"), it permits through shipment to the Republic of the Congo, Rhodesia, Mozambique and to South Africa by connecting lines. The service has been extended to Beira (Lobito to Beira, 2,920 mi.) and to Lourenço Marques (3,295 mi.). The Luanda-Malanje line (364 mi, of 1 m. gauge), said to have been the most expensive railway to construct in tropical Africa (£8,942 per mi.), was bought by the government in 1918.

There are in Angola more than 22,000 mi. of primary roads and 20,000 of secondary roads.

There are regular international air services from Lisbon, Léopoldville, Lourenço Marques, Pointe Noire, Brazzaville, etc., and internal lines connect Luanda, Ambriz, Ambrizete, Cabinda, Lobito Sa da Bandeira, Moçamedes, Nova Lisboa, Silva Porto. Porto Alexandre, etc. Luanda airport is one of the international airports of west Africa.

Land telegraph lines extend more than 8,000 mi. and telephone lines 3,500 mi. Cables connect Angola with Europe and South Africa. There are about 30 radio stations.

ANGORA GOAT: see GOAT: MOHAIR.

ANGOULÊME, CHARLES DE VALOIS, DUC D' (1573–1650), the natural son of Charles IX of France by Marie Touchet, chiefly remembered for the intrigues of his early life, was born at Fayet, near Montmélian, on April 28, 1573. Henriette d'Entragues, the future marquise de Verneuil and mistress of Henry IV of France, was his half sister. Favourably received at the French court because of his ready wit and good looks, he was granted the title of comte d'Auvergne and made colonel general of the cavalry. He served Henry IV in his campaigns against the Catholic league but became disaffected when Queen Margaret successfully contested his rights over Auvergne (though he retained his title). Involved in the marshal de Biron's conspiracy in 1601, he was arrested with Biron but pardoned. He then engaged in more treasonable plots with Spain, in concert with his half sister (1604). When these were exposed he went into open rebellion. Captured in 1605 he was condemned to life imprisonment but was released from the Bastille in 1616 to serve against the enemies of the marshal d'Ancre. After the marshal's fall he was sent to campaign in Piedmont. Then in 1619 he was made duc d'Angoulême. The cardinal de Richelieu, whose favour he courted, gave him military commands at the sieges of Montauban (1621), of La Rochelle (1627) and in Lorraine (1635), but was well aware of his proneness to speculation (Angoulême was accused even quite widely of coining). Cardinal Mazarin gave him a military command in the north in 1643. Old and wise enough to take no part in the Fronde, the duc died on Sept. 24, 1650. Angoulême had in 1644 married, as his second wife, the 20-year-old Françoise de Nargonne, who lived until 1713 and thus gave rise to the paradox whereby "Charles IX's daughter-in-law" is said to have been living 139 years after Charles's death (1574). The duc's *Mémoires*, first published in 1667, are reprinted in the Michaud-Poujoulat *Nouvelle collection des mémoires*, vol. 11 (1836).

ANGOULÊME, LOUIS ANTOINE DE BOURBON, DUC D' (1775–1844), the last dauphin of France, elder son of the comte d'Artois (afterward Charles X) and of Marie Thérèse of Savoy, was born in Versailles on Aug. 6, 1775. In 1789 he left France with his father. After residing in Poland and in England he returned to France in 1814 and with Wellington's help raised the royal standard again at Bordeaux. He did much for the restoration of the Bourbon rule after the overthrow of Napoleon and on Napoleon's return in 1815 made a valiant but futile attempt to raise a royalist army in the south. Unprepossessing and without personal ambitions he loyally supported the king's policies, being favourable to the Constitutionnels under Louis XVIII and to absolutism under Charles X. In 1823 he commanded the French expedition to Spain in support of Ferdinand VII. In 1830, when his father was compelled to abdicate, he renounced his claims to the throne and went into exile. He died at Gorizia, in Austrian Venetia, on June 3, 1844.

In 1799, at Mitau (Jelgava) in Courland, the duc d'Angoulême had married his cousin MARIE THÉRÈSE CHARLOTTE (1778–1851), daughter of Louis XVI and Marie Antoinette. Born at Versailles on Dec. 19, 1778, she was imprisoned during the French Revolution from Aug. 1792 until 1795, when she was released in exchange for members of the National Convention who had been handed over to the Austrians by Gen. Charles Dumouriez. In 1814 she returned to France with Louis XVIII. In March 1815, after Napoleon had re-entered Paris, she was able to maintain for ten days Bordeaux's loyalty to the royal family. She died at Frohsdorf, in Austria, on Oct. 19, 1851.

See Eugène de Guichen, *Le Duc d'Angoulême* (1909); Roger Langeron, *Madame Royale* (1958). (G. DE B. DE S.)

ANGOULÊME, a city of southwestern France, capital of the *département* of Charente, is situated on a high plateau above the confluence of the Anguienne and the Charente rivers 72 mi. N.N.E. of Bordeaux by road. Pop. (1954) 38,060. Angoulême is surrounded by boulevards on the site of the fortifications. At the western end is the Jardin Vert, a park with extensive views. The centre of the town is the Place de l'Hôtel de Ville. The town hall (1868) is built on the site of the chateau of the counts of

Angoulême of which the tower of Valois (15th century) and the tower of Lusignan (13th century) remain. To the west is the cathedral of St. Pierre (1128, restored in the 19th century): its façade has 75 statues representing the last judgment and is flanked by two towers: the north transept is surmounted by a tower 194 ft. high. Inside, the roof of the nave is made into four cupolas, very typical of the region. Close by the cathedral is the former bishops' palace, now the museum. The shopping streets radiate from the Place Lou-el, near which the church of St. André stands, with a 12th-century porch and 15th-century nave. On the neck of land joining the plateau with other high ground is the archaeological museum. Angoulême has cultural and economic links with Bury, in Lancashire, Eng. It also has U.S. connections, since the district on which New York is built was originally known as the Land of Angoulême. The city is on the main line from Paris to Bordeaux. There is an aerodrome at Ruelle (2 mi. N.E.). Papermaking is one of the chief industries and felt, wire gauze used in papermaking, iron, bricks, tiles, refrigerators and slippers are manufactured.

Angoulême was taken by Clovis from the Visigoths in 507 and attacked by the Normans in the 9th century. Ceded to England by the treaty of Bretigny in 1360, it was regained by the French under Charles V in 1373. Angoulême suffered in the religious wars when it was taken by the Protestants in 1569 under the orders of Admiral Coligny. The countship of Angoulême dates from the 9th century. (F. E. G.)

ANGOUMOIS, an old province of France, nearly corresponding to the modern *département* of Charente, represented the possessions of the counts of Angoulême (*q.v.*) in the feudal period. Having long shared the fortunes of Aquitaine (*q.v.*), it was recovered by France from the English in 1373. Henry IV subordinated it to the *gouvernement* of Orléanais. Under Louis XIV it was made part of a joint *gouvernement* of Saintonge and Angoumois.

ANGREN, a city on the Angren river in the Tashkent *oblast* of the Uzbek Soviet Socialist Republic, U.S.S.R. Pop. (1959) 55,000. Developed during World War II it is the newest and largest coal-mining centre in Soviet central Asia. It is linked by rail and a coal-gas pipeline with Tashkent, and furnishes coking coal to the Begovat steel mills. (G. E. WR.)

ANGSTROM, ANDERS JONAS (1814–1874), Swedish physicist, was a pioneer in providing useful standards for spectroscopy (*q.v.*); the Angstrom unit was named in his honour. Born on Aug. 13, 1814, at Lögdö, Medelpad, Sn-eden, he was educated at Uppsala university, where in 1839 he became *Privatdocent* in physics. In 1843 he became observer at Uppsala Observatory. In 1858 he succeeded Adolph Ferdinand Svanberg (1806–1857) in the chair of physics at Uppsala, and there he died on June 21, 1874.

His most important work was concerned with the conduction of heat and with spectroscopy. In his optical research *Optiska Undersökningar*, presented to the Stockholm academy in 1853, he not only pointed out that the electric spark yields two superposed spectra, one from the metal of the electrode and the other from the gas in which it passes, but deduced from Euler's theory of resonance that an incandescent gas emits luminous rays of the same refrangibility as those which it can absorb. This statement entitles him to rank as one of the founders of spectroscopy.

From 1861 onward he paid special attention to the solar spectrum. He announced in 1862 the existence of hydrogen, among other elements, in the sun's atmosphere, and in 1868 published his great map of the normal solar spectrum, which long remained authoritative in questions of wave length although his measurements were inexact to the extent of one part in 7,000 or 8,000, the metre which he used as his standard having been slightly too short. He was the first, in 1865, to examine the spectrum of the aurora borealis and to detect and measure the characteristic bright line in its yellow green region; but he was mistaken in supposing that this same line, which is often called by his name, is also to be seen in the zodiacal light.

His son KNUT JOHAN ÅNGSTRÖM (1857–1910) became professor of physics at Uppsala in 1896. He investigated the radia-

tion of heat from the sun and its absorption by the earth's atmosphere and devised various delicate methods and instruments, including his electric compensation pyrheliometer, invented in 1893, and apparatus for obtaining a photographic representation of the infrared spectrum (1895).

ANGSTROM UNIT, the unit employed for measuring wave lengths of light, being equal to one ten-millionth of a millimetre, *i.e.*, 1×10^{-10} metre. The usual abbreviation for this unit is Å. See SPECTROSCOPY: *Wave Lengths*; see also Index references under "Ångström Unit" in the Index volume.

ANGTHONG, a province of central Thailand (Siam). It has an area of only 379 sq.mi. and, with a population (1960) of 192,774, has an average of 509 persons per sq.mi. The people live primarily in villages; the only city of any size is the provincial capital, Angthong, in which live about 11,000. Angthong is about 55 mi. S. of Bangkok and occupies a bank site on the Chao Phraya river. It is linked by road to Xyutthaya (*q.v.*). This province receives 50 in. of rainfall annually with 47 in. falling during the months of April through November. Its rich alluvial soils are irrigated by the Chao Phraya river. The province is noted for the production of rice, corn and oilseeds. (T. F. B.)

ANGUIER, FRANÇOIS (?1604–1669) and **MICHEL** (?1613–1686), French sculptors, were brothers, natives of Eu in Normandy. After some independent and local training, they traveled to Rome together in about 1641 and joined Alessandro Algardi's workshop. François stayed with him till 1643. Michel till 1651. The depth of feeling for contemporary Roman sculpture which they attained can be clearly measured in the tomb of the duc de Montmorency (Moulins) on which they worked between 1648 and 1652. This vast wall tomb, alike in design to Giacomo della Porta's Aldobrandini tomb in Sta. Maria sopra Minerva, is Italian in everything except the reticence and calm of the individual figures.

François' later works, almost all tombs, show no major change in style. His funerary statue of Gaspard de la Chbtre (Louvre) is perhaps his most characteristic and distinguished work. He died in Paris, Aug. 9, 1669.

MICHEL, on the other hand, was a more restless and versatile artist. In 1655–58 he collaborated with G. F. Romanelli on the decoration of Anne of Austria's apartments in the Louvre, again with a Roman model in mind, this time Pietro da Cortona's scheme for the Pitti palace. He worked with Charles Le Brun and André Le Nôtre at Vaux. His most important commission was the decoration of the Val-de-Grâce in Paris, completed in 1667. He was responsible for the reliefs in the spandrels and vault of the nave and, in a totally different style, the dramatic marble "Nativity" group on the high altar (1665; moved to St. Roch). He returned to a rather severe classicism in his reliefs for the triumphal arch of the Porte Saint-Denis (1674). Michel died in Paris, July 11, 1686. The Anguiers' reputation was overshadowed by the importance of the following generation of sculptors.

(X. A. B.)

ANGUILLA: see SAINT KITTS.

ANGUISCIOLA (ANGUSSOLA), SOFONISBA (c. 1528–c. 1625), Italian portrait painter of whom Van Dyck is said to have declared that he had derived much knowledge of the true principles of his art from her conversation. She was born at Cremona about 1528. In 1560, at the invitation of Philip II, she visited the court of Madrid, where her portraits elicited high praise. She painted several fine portraits of herself, one of which is at the Cffizi gallery in Florence. She had five sisters who were also celebrated artists. She died at Palermo.

ANGUS, EARLS OF. Angus was formerly one of the seven provinces of Pictish Scotland and was administered by a mormaor and later by an earl. The Celtic line of earls ended with MATILDA *id. c.* 1267, countess of Angus in her own right, but her marriage in 1243 to GILBERT DE UMFRVILLE (d. c. 1245) began the Norman line of four earls which lasted until 1331. They were in effect English barons, and their support of English against Scottish kings led to loss of their Scottish lands and to the creation, before 1329, of JOHN STEWART (d. 1331) of Boncle in Berwickshire, as earl of Angus in a new line. This third creation ended with MARGARET

STEWART (d. c. 1418), countess of Angus in her own right. By an irregular connection with William, 1st earl of Douglas, she became the mother of GEORGE DOUGLAS (c. 1378–1402 or 1403), who was created earl of Angus by Robert II in 1389. He died in England some time after being captured at the battle of Homildon hill (Sept. 1402).

George's great-grandson ARCHIBALD DOUGLAS (c. 1449–c. 1514), 5th earl in the Douglas line and known as the "Great Earl," was nicknamed "Bell the Cat" for his capture and execution (1482) of Robert Cochrane and the other favourites of James III. He engaged in frequent intrigues with English kings and in 1438 took part in the successful rebellion against James III. Ultimately he gained favour at the court of James IV and was chancellor from 1493 to 1498. He died at Whithorn in Galloway (mod. Wigtown) a few months after his two eldest sons were killed at the battle of Flodden (1513); a third son was Gavin Douglas (*q.v.*), bishop of Dunkeld.

ARCHIBALD DOUGLAS (c. 1489–1557), 6th earl, son of George, master of Angus, who was killed at Flodden, succeeded on his grandfather's death. By his second marriage in 1514 to the queen dowager Margaret (*q.v.*) Tudor, he aroused the jealousy of the nobles. Margaret was supplanted in 1515 as regent and guardian of the infant James V by the duke of Albany and fled to England. On her return she found that Angus had formed a liaison with a daughter of the laird of Traquair and she therefore allied with Albany against her husband. He was charged with high treason in 1522 and sent to France. But he returned two years later with the support of Henry VIII of England, entered Edinburgh in 1525 and called a parliament. He and the Douglasses then wielded supreme power until Margaret obtained a divorce and James V escaped from his stepfather's tutelage (1528), issuing a decree of forfeiture against him. Angus took refuge in England, and James took vengeance on his relations, burning at the stake (July 17, 1537) Angus' sister Janet, Lady Glamis. After the death of James V in 1542, Angus returned to Scotland and the act of forfeiture was annulled. He was commissioned to arrange a marriage between Mary Stuart and Prince Edward (afterward Edward VI of England), but his English sympathies were mitigated by the earl of Hertford's marauding expedition of 1544. He was appointed lieutenant of southern Scotland, defeated the English at Ancrum moor on Feb. 27, 1545, and led the van when the Scots were defeated at Pinkie in 1547. He died at Tantallon castle in Jan. 1557, after a career in which national interests were completely subordinated to those of his family. His only surviving legitimate child, by Margaret Tudor, was Margaret who married Matthew, 4th earl of Lennox, and became the mother of Lord Darnley. He was succeeded by his nephew DAVID DOUGLAS (c. 1515–1557), 7th earl, son of Sir George Douglas of Pittendriech.

ARCHIBALD DOUGLAS (1555–1588), 8th earl and earl of Morton from 1586, was the son of the 7th earl. During the regency of his uncle, the earl of Morton, he rose rapidly to power. He became privy councillor and sheriff of Berwick (1573), lieutenant general of south Scotland (1574), warden of the west marches and steward of Fife (1577) and lieutenant general of the whole realm (1578). But when Morton fell in 1581 Angus was declared guilty of high treason for supporting him and fled to London. After a brief reconciliation with James VI he joined the rebellion of the earl of Mar and the master of Glamis, and sentence of attainder was pronounced against all three. The rebels fled to Newcastle, which became a centre of Presbyterianism and of projects against the Scottish government encouraged by Elizabeth I. They returned to Scotland in Oct. 1584 and secured from James the restoration of their estates and a share in the government. Angus was appointed warden of the marches and lieutenant general on the border, but his support of Presbyterianism prevented his gaining real favour with the king. He died at Smeaton near Dalkeith on Aug. 4, 1588.

His cousin, WILLIAM DOUGLAS (1533–1591), became the 9th earl. He was succeeded by his son WILLIAM (1554–1611), the 10th earl, who was converted to Roman Catholicism and became involved in various conspiracies against the government. He joined the rebellion of the earls of Huntly and Erroll in 1593, but the revolt failed and in 1597 all three renounced their religion, de-

clared themselves Presbyterians and were restored to the lands and honours they had forfeited. Angus recanted in 1608 and withdrew to France, dying at Paris on March 3, 1611. He was succeeded by his son WILLIAM (1589–1660), 11th earl, who became 1st marquess of Douglas in 1633. Thereafter the title earl of Angus was given by courtesy to the eldest son of the marquess or duke of Douglas. Since 1761 the title has been held by the dukes of Hamilton.

BIBLIOGRAPHY.—D. Hume of Godscroft, *History of the Houses of Douglas and Angus*, legendary in some respects, 4th ed. (1748); Sir W. Fraser, *The Douglas Book* (1885); Sir H. Maxwell, *History of the House of Douglas* (1902). (G. S. P.)

ANGUS (FORFARSHIRE), an eastern county of Scotland, is bounded on the north by the shires of Kincardine and Aberdeen, on the west by Perthshire, on the south by the Firth of Tay and on the east by the North sea. The Bell rock (*q.v.*) or Inchcape is also in the county. The ancient name of Angus was officially adopted in 1928 instead of Forfarshire. The land area is 874 sq. mi.

Physical Features.—The county is compact in shape, roughly bisected by the Highland boundary fault line running northeast-southwest from Edzell to Lintrathen. The Highland part contains dissected plateaus of 2,000–3,000 ft. rising to Glas Maol (3,502 ft.) to the south of the granite massif of Lochnagar and White Mounth. These high, rolling moorlands are cut by three broad glens trending northwest-southeast—Glen Isla, Glen Clova and Glen Esk—and by minor valleys. During the Quaternary glaciation the plateaus were protected by névé; the main glens carried weak glaciers; few ribbon lakes were excavated (*e.g.*, Loch Lee in Glen Esk now used as a reservoir), but there was considerable deposition of terminal moraine. The impressive Highland edge faces the softer, gentler Old Red Sandstone corridor of Strathmore strewn with ground moraine from great southwest Highland glaciers which came via the Tay (*e.g.*, the drumlins southwest of Kirriemuir). There are some fluvioglacial sands and gravels and a few lowland lakes in hollows in the glacial drift (*e.g.*, the Loch of Lintrathen supplying water to Dundee and parts of Angus). Then the Sidlaw hills, also with the northeast-southwest Caledonian trend, are a northwest-dipping hill range of andesite and basalt lavas of the Old Red Sandstone Age, scoured and molded by southwest Highland ice (*e.g.*, the three small lochs of Fithie, Rescobie and Balgavie near Forfar). The scarp face of the Sidlaws looks southeast across more till-covered Old Red Sandstone lowlands. Postglacial raised beaches, at about 25 ft., 50 ft. and 100 ft. above mean sea level, fringe the shore with its many sand dunes (as on the complex cusped foreland at Buddon Ness at the mouth of the Firth of Tay).

The climate is generally the dry east coast type with many cool dry springs commonly accompanied by coastal sea mists (January mean coastal temperature about 37° F.; July about 59° F.; high inland areas a little colder in winter, especially in frost hollows). The late summer is fairly sunny (August mean approximately four and one-half hours per day) and it remains fairly sunny into the autumn enabling the generally late harvest to be gathered in.

In the uplands soils are thin and poor, an acid peaty layer overlying a whitish leached horizon, and there is much rock protruding, with peat on flat areas. A heather bilberry plant association predominates, with better grasses in the glens—a country of ptarmigan and red grouse, red deer and occasional golden eagles. In the lowlands soils are developed chiefly on the red boulder clays in which Old Red Sandstone is mixed with other glacial debris. Light, well-drained soils develop on the fluvioglacial and raised beach sands and gravels, while some fertile carse clays surround the Montrose basin. The lowlands are largely tilled except for the moorland crest of the Sidlaws and some wooded estates mainly on gravelly soils. Fulmar petrels breed in several coastal sites. Both the North Esk and South Esk rivers have heavy runs of salmon and sea trout. (A. T. A. L.)

History.—There are no authentic records of the struggles between the Picts and their predecessors the Scots, although at Forfar loch there are traces of crannogs, or lake dwellings, in which the early Caledonians must have defended themselves. By Roman times Angus was inhabited by the Picts. There are remains of weems or underground houses and there are vitrified forts at

Finavon. Drumsturdy Muir and the Laws near Monifieth, but the best examples of Pictish or pre-Pictish forts are found on the hills known as the White C'aterthun and the Brown Caterthun near Menmuir. Traces of Roman camps and roads are common.

From A. D. 500 Teutons and Danes invaded Angus from the sea, and Angles from Northumbria invaded it by land. In 685 the Angles were defeated at the battle of Nectan's Mere, near Dunnichen, and in the 11th century the Vikings were defeated at Barry and Aberlemno. In the next century the Flemings established linen and woolen industries and the county enjoyed a prosperity which was little affected by the War of Independence, although it was at Stracathro, near Brechin, that John de Baliol surrendered his kingdom to Bishop Bek, representing Edward I, in 1296. However during the English Civil War in the 17th century the marquis of Montrose and General Monk ravaged the countryside, both Dundee and Brechin being sacked.

Among interesting buildings are: Brechin cathedral with its 12th-century round tower; the ruins of Arbroath abbey and Edzell castle with a 17th-century walled garden; the remains of Forter castle, destroyed by the earl of Argyll in 1640; and 14th-century Glamis (qv) castle, the childhood home of Queen Elizabeth, consort of George VI, and the birthplace of Princess Margaret.

Population and Administration. — The population of Angus in 1961 was 278,370, including the county of the city of Dundee (182,959). Arbroath (19,533) is a large burgh, while Montrose (10,702), Forfar (10,252), Brechin (7,114), Carnoustie (5,511), Kirriemuir (3,485) and Monifieth (3,475) are small burghs. The county town is Forfar. Dundee returns two members to parliament, while Angus returns one member for South Angus and joins with Kincardineshire in returning another member who represents North Angus and Mearns. Sheriff courts are held at Arbroath, Dundee and Forfar and there are burgh courts in each of the other burghs.

Industries and Communications. — The higher parts of Angus are mainly in large sheep farms with only one sheep to several acres. There is also rearing of beef cattle in the glens. About two-fifths of the county is cultivated, mainly in the lowlands, where the large red sandstone farmsteads lie amid big, square, tidy fields showing red when ploughed. The rotation emphasizes the fodder crops — oats, particularly, and turnips — for this is an arable-and-stock economy, but potatoes are an important cash crop, high-grade seed potatoes being exported all over the world, while wheat, barley and sugar beet are also grown. Small holdings, in contrast, produce large quantities of raspberries and other soft fruit, partly for jam: especially on light, gravelly soils. Angus is the native county of the Aberdeen Angus black cattle, dating from 1808, and there are many well-known pedigree herds, as also of Shorthorns, while there are pedigree flocks of Border Leicesters and Black-face Highland sheep. (See CATTLE; SHEEP.) Fattening bullocks and sheep are brought in from the glens and elsewhere.

Although farming takes first place, Angus also has a well-developed industrial economy. The staple industries in the towns are the manufacture of jute and linen products, carried on extensively at Dundee, Arbroath, Montrose, Brechin, Forfar and Kirriemuir. Other long-established industries are shipbuilding, particularly at Dundee, and engineering at Arbroath. There is however in Dundee a large, modern industrial estate providing employment in a considerable number of light industries, while in all the Angus towns alternative industries are being developed. In Carnoustie, for example, which is a holiday resort: there is a firm which specializes in stonecutting machinery, and in Brechin a precision-tool firm employs a considerable number of workers. In Arbroath there is a thriving whitefishing industry with ancillary fish-curing establishments, and the netting of salmon between Arbroath and Montrose is a profitable occupation. Throughout the county there has been a considerable increase in the facilities provided for the canning of fruit and vegetables.

Two main railway lines pass through Angus. The one from Glasgow to Aberdeen runs up Strathmore to Forfar, Guthrie, Dutton and Marykirk. That from Edinburgh to Aberdeen, which enters the county across the Firth of Tay by the Tay bridge (2 mi. long), follows the coast through Montrose and joins the other line

to the north of that town.

ANHALT, a former German state which was a duchy from 1863 to 1918 and a *Land* until 1945, when it was merged in Saxony-Anhalt. Saxony-Anhalt was a *Land* of the German Democratic Republic from 1949 to 1952, when it was broken up into *Bezirke* or districts, the former territories of Anhalt being divided between the *Bezirke* of Magdeburg and of Halle.

Territorially the duchy of Anhalt was divided into two major parts (the eastern one comprising Zerbst, Dessau, Cöthen and Bernburg, the western one being centred on Ballenstedt) and five smaller ones, all of them enclaves within the geographical boundaries of the Prussian province of Saxony.

The level country around the upper Elbe river from which Anhalt was constituted was in the 11th century still part of the duchy of Saxony. It was united in the 12th century in the possession of Albert (*q.v.*) the Bear, margrave of Brandenburg. With the death in 1212 of Albert's son Bernard, duke of Saxony, the countship of Anhalt was detached from the duchy and given to his son Henry, who in 1218 took the title of prince and was the real founder of the house of Anhalt. (See ASCANIAN DYNASTIES.)

On Henry's death (1252) his three sons partitioned Anhalt between the lines of Aschersleben (extinct in 1315 after which its lands passed to the bishops of Halberstadt, thus dividing the two major parts of the Anhalt possessions), of Bernburg (extinct in 1468) and of Zerbst. The Zerbst line inherited the Bernburg lands but was itself divided by the end of the 15th century into the lines of Anhalt-Dessau and Anhalt-Cöthen. All Anhalt, however, was reunited in 1570 under Joachim Ernest, but four of the latter's five sons partitioned the principality again in 1603, founding new lines of Dessau, Bernburg, Zerbst and Cöthen. The third son (who in 1611 was to receive Plotzkau, in appanage only, from Bernburg) reserved for himself and his descendants the right of succession to any princely line that should become extinct, with the result that in 1665 his line succeeded to Cöthen. In 1665 moreover the princes of the four lines agreed on an inheritance treaty intended to prevent further division of the territory. In 1793, on the extinction of the Zerbst line, its territory was divided among Dessau, Bernburg and Cöthen. The three princes each took the title of duke in 1806, on the dissolution of the Holy Roman empire. Cöthen passed to Anhalt-Dessau in 1847 and finally, with the extinction of the Bernburg line, all Anhalt was united under Leopold IV of Anhalt-Dessau in 1863.

In the 16th century Anhalt accepted the Reformation. Princes of Anhalt-Dessau served in the Prussian army in the 17th century and Anhalt came to be increasingly overshadowed by Prussia. The dukes joined the Confederation of the Rhine in 1807 and supported Napoleon till 1813. They joined the Germanic confederation in 1815 and the Prussian *Zollverein* in 1828. In 1859 a new constitution was established for Bernburg and Dessau jointly. Having been a state of the German empire from 1871, Anhalt in 1919 became a free state (*Land*) of the republican German Reich.

(HE. K.)

ANHALT-DESSAU, LEOPOLD I, PRINCE OF (1676–1747). Prussian field marshal, the reorganizer of the Prussian army in the years immediately preceding the notable victories of Frederick the Great. The only surviving son of George II of Anhalt-Dessau, he was born at Dessau on July 3, 1676. His long career of active service began in the Netherlands in 1695–97, when he was present at the siege of Namur.

In 1698 he married Anna Luise Fose, the daughter of a chemist in Dessau. At the time this marriage was much resented by Leopold's family, especially by his mother, but in the event it proved a great success. Later his wife was accorded the title of princess. Anna Luise was a woman of ability and character. During her husband's absence on service she frequently acted as regent; at other times she accompanied him in the field. She died in 1745—the year of her husband's last battle. Leopold himself was a man of fiery temper, whose keen sense of duty and upbringing as a devout

member of the Lutheran faith often led him to excessively hard measures against erring subordinates and delinquent subjects. It was said that his wife was very successful in mitigating the effect of some of his harsher judgments.

Leopold's career as a military commander of distinction began with the War of the Spanish Succession (*q.v.*), when he took the field as commander of a Prussian corps on the Rhine and participated in the sieges of Kaiserwerth and Venlo. He was also present at a number of other engagements, including Blenheim, Cassano, Turin, Tournai and Malplaquet, in most of which he played a distinguished part. In 1710 he became commander of all the Prussian forces at the front. In 1712 he was responsible for a particularly smart piece of work when the Dutch garrison at Mōrs (near Dusseldorf) was surprised and the castle captured without a shot being fired or a single casualty occurring. In the same year he was made a field marshal. In 1715 he commanded a corps of about 40,000 men against Sweden. It was largely due to his skill that the campaign ended so favourably for Prussia, his most notable successes being on the island of Riigen (Nov. 16, 1715) and at the siege of Stralsund.

Up to this time Leopold had spent the greater part of his military career (1695–1715) on active service. There followed a long period of peace and it was probably during these years that he performed his greatest, although least spectacular, service to his country in the reorganization and training of the Prussian army. He was first and foremost an infantry soldier. It was said that he tolerated cavalry and artillery, but considered them entirely secondary to his own arm. Although Frederick the Great's victories were mostly won by cavalry action, infantry played a leading part in providing the firm base from which his mounted troops operated. Frederick's infantry was said to be superior to that of any other army in the proportion of five to three. This deservedly high reputation was due to the thorough training given to them by "Old Dessauer"—which was Leopold's popular name—in the years preceding Frederick's campaigns. This training was founded on the most rigid discipline; he also introduced the system of fire control for which Frederick's infantry became famous and which put them in a class by themselves in defense.

During the War of the Polish Succession (1733–35) Leopold served under Prince Eugène of Savoy. Although Frederick benefited from his prior preparation of the army and often sought his advice on matters of organization and training, the king did not often take Leopold on service. He found him a difficult and stubborn subordinate who, in his later years, regarded himself as the leading soldier in Europe—a not incorrect self-appraisal at a time when Frederick had yet to make his mark. In 1745 he was in command of an army on the Saxon frontier, in anticipation of trouble from that quarter, while Frederick was engaged elsewhere. His last battle was on Dec. 14, 1745, at Kesselsdorf, when he was in his 70th year. On this occasion Frederick was hastening toward Dresden to meet the Austrian-Saxon threat, but before he arrived the old marshal had engaged and defeated the enemy. A story is told of him on this day, the origin of which has since been attributed to others, who may perhaps have copied his example. As a devout churchman it was his custom to pray before battle, and at Kesselsdorf his prayer is said to have been as follows: "Oh God let me not be disgraced in my old days. Or if thou wilt not help me, do not help these scoundrels: but leave us to try it ourselves." After this campaign he retired to Dessau where he died on April 7, 1747.

Leopold of Anhalt-Dessau has hardly received the credit due to him as a soldier. In the field he was conspicuously successful and even more so as a trainer and organizer in peace. He introduced the iron ramrod—a big technical advance in musketry—and other improvements into the Prussian army. He was unfortunate in being an immediate predecessor of Frederick the Great, who captured most of the attention of military historians of that period; but much of Frederick's success was due to the spaden-ork of Leopold. He was survived by three sons: Leopold II Maximilian who succeeded him as prince of Anhalt-Dessau; Dietrich; and Moritz. All had successful careers as generals in the Prussian army under Frederick the Great. Moritz was in Prussian service

from 1725 until two years before his death in 1760.

ANHWEI (AN-HUI SHENG), a province of China lying astride the Yangtze river on the western edge of its delta (area 54,015 sq.mi.; pop. [1953] 30,633,407). Anhwei falls into two parts, divided almost equally north and south by the Ta-pieh range north of the Yangtze. Northern Anhwei is part of the north China or Yellow plain, a level depositional surface traditionally flooded by the Huai river and often the Yellow river. Wheat, millet, beans and cotton are grown there. Southern Anhwei is part of the green Yangtze hills country, with a more genial climate. Terraced hillsides produce the world-famous Ch'i-men tea, lumber and bamboo, while rice and tung oil grow on the valley floors. Huang shan rises there, 5,500 ft. high, a rugged granitic mass beloved by Chinese poets and artists for centuries for its strong shape and lush vegetation. Some 60 mi W. at Ma-an-shan is a large high-grade iron ore deposit averaging 50% iron content, with 11 blast furnaces, the main supply centre for pig iron down the Yangtze to Shanghai. Near Huai-yuan in northern Anhwei is central China's largest coal-mining area, the Huai-nan mines, having a yearly output of over 1,000,000 tons. The government developed a great flood-control project for the Huai river after 1950. Nine concrete multiarch dams in the mountains of Anhwei. Hupeh and Honan have been erected to impound the tributaries of the Huai to irrigate farm land, to supply electric power and to improve navigation. Along with middle Huai in Anhwei, four sluice-gate dams with flood-detention basins have been built, with better drainage facilities downstream in Kiangsu also. Presumably the reconstruction of the Grand canal not only will open another flood outlet to the sea but will also permit Huai-nan coal to move south economically into the Yangtze delta cities. Formerly the largest cities, Wu-hu and Huai-ning, the one-time capital, were important as Yangtze trade and rice-shipping centres, but with the increase in mining and large water conservation projects along the Huai river, Peng-pu (pop. [1953] 253,000), where the Ch'ing-p'u railway spans the Huai, and Ho-fei (pop. [1953] 183,600), the provincial capital, are growing. (T. E. H.)

ANHYDRIDE, a compound which may be prepared by the removal of water or the elements of water from another compound. An oxide which combines with water to form an acid or which may be formed by the removal of water from an acid is called an acid anhydride; one which unites with water to form a base or which a base yields upon the loss of water is called a basic anhydride. See also ACIDS AND BASES.

ANHYDRITE, an important calcium mineral, differing chemically from the more commonly occurring gypsum in containing no water of crystallization, being anhydrous calcium sulfate. Anhydrite is most frequently found with salt deposits in association with gypsum as in the cap rock of the Texas-Louisiana salt domes. For discussion of its origins occurrence and alterations, see SALT DOME; GYPSUM. See also CALCIUM.

Anhydrite crystallizes in the orthorhombic system and has three directions of perfect cleavage parallel to the three planes of symmetry. Distinctly developed crystals are somewhat rare, the mineral usually presenting the form of cuboidal cleavage masses. The hardness is 3.5 and the specific gravity 2.9. The formula is CaSO₄. The colour is white sometimes grayish bluish or reddish. On the best developed of the three cleavages the lustre is pearly; on other surfaces it is of the ordinary glassy or vitreous type.

A peculiar variety of anhydrite occurring as contorted concretionary masses is known as tripestone, and a scaly granular variety, from Vulpino, near Bergamo, in Lombardy, as vulpinites; the latter is cut and polished for ornamental purposes.

ANICETUS, SAINT, pope from c. 155 to c. 166, called a martyr, worked to combat the errors of Valentine and Marcion and to prevent heresies. During his pontificate Polycarp (*q.v.*) visited Rome to confer with him about the controversy over the date of Easter. St. Anicetus' feast day is April 17.

ANIENE, a river of central Italy, is 67 mi. long, with a drain-

age basin of 569 sq.mi. The Aniene (anc. Anio), one of the main tributaries of the Tiber (*q.v.*), rises from two springs in the Simbruini mountains southeast of Rome, near the town of Subiaco. flows through a narrow valley to Tivoli (*q.v.*) where through a series of falls it descends to the level of the Roman Campagna and after numerous meanders joins the Tiber. Nero created a group of artificial lakes in the upper course of the river above Subiaco and built a villa there whose remains still can be seen. The falls at Tivoli were one of the main scenic attractions of the Roman countryside, but the heavy use made of the Aniene's waters by hydroelectric plants and by aqueducts reduced the once famous falls to a small trickle. The middle valley of the Aniene is followed by the Rome-Pescara railway and motor road. (G. K.H.)

ANILINE, an organic base first obtained from the destructive distillation of indigo in 1826 by O. Unverdorben, who named it Crystallin. In 1834, F. Runge isolated from coal tar a substance which produced a beautiful blue colour on treatment with calcium chloride: this he named kyanol or cyanol. In 1841 C. J. Fritzsche showed that by treating indigo with potassium hydroxide it yielded an oil, which he named aniline, from the specific name of one of the indigo-yielding plants, *Indigofera anil*, *anil* being derived from the Sanskrit *nīla*, dark-blue, and *nīlā*, the indigo plant. About the same time N. N. Zinin found that on reducing nitrobenzene a base was formed, which he named benzidam. A. W. von Hofmann investigated these variously prepared substances and proved them to be identical, and thenceforth they took their place as one substance, under the name aniline or phenylamine having the composition $C_6H_5.NH_2$.

By the action of nitrous acid in acid solution, aniline is transformed into a diazonium salt. (See DIAZO COMPOUNDS.) This reaction represents the first step in many important syntheses of dyes and other substances. The great commercial value of aniline is due to the readiness with which it yields, directly or indirectly, valuable dyestuffs. The discovery of mauve in 1858 by Sir W. H. Perkin was the first of a series of dyestuffs which are now to be numbered by hundreds. Reference should be made to the article DYES for more details on this subject. It is a starting product for the manufacture not only of dyestuffs but of many drugs.

Aniline is manufactured by reducing nitrobenzene with iron borings and water slightly acidified with hydrochloric acid, the product being purified by steam distillation followed by distillation under reduced pressure. The action of ammonia on chlorobenzene at high pressure and temperature in the presence of a catalyst is also employed in the manufacture of aniline. Mono-methyl- and dimethyl-aniline are colourless liquids prepared by heating in an autoclave at 220° aniline, aniline hydrochloride and methyl alcohol, or aniline, methyl alcohol and about 0.5% of iodine. They are of great importance in the dye industry. Mono-methylaniline boils at $193-195^\circ$; dimethylaniline at 192° .

Properties.—Pure aniline is a basic substance of an oily consistence, colourless, melting at -8° and boiling at 184° C.; it dissolves in 31 parts of water. On exposure to air it absorbs oxygen and slowly resinifies, becoming deep brown in colour. It possesses a somewhat pleasant vinous odour and a burning aromatic taste; it is highly poisonous, having a destructive action on the red corpuscles of the blood.

Aniline is a weak base and forms salts with the mineral acids. Aniline hydrochloride is the "aniline salt" of commerce. Although aniline is but feebly basic, it precipitates zinc, aluminum and ferric hydroxides from their salts and expels ammonia from ammonium compounds when warmed with them. When aniline hydrogen sulfate is baked at 200° C. sulfanilic acid,

is produced. Xnildes, compounds in which the amino group is substituted by an acid radical, are prepared by heating aniline with certain acids; antifebrin or acetanilide (*q.v.*) is thus obtained from acetic acid and aniline. When aniline vapour and hydrogen are passed over finely divided nickel heated at 190° C., the reduction products, *cyclohexylamine*, *dicyclohexylamine* and *cyclohexylaniline* are produced. The oxidation of aniline has been carefully

investigated. Chromic acid converts it into quinone, while chlorates, in the presence of certain metallic salts (especially of vanadium), give aniline black. Hydrochloric acid and potassium chlorate give chloranil. Potassium permanganate oxidizes it in alkaline solution to azobenzene: Caro's acid, H_2SO_5 , converts it into nitrosobenzene. Hypochlorous acid gives para-aminophenol and para-aminodiphenylamine (E. Bamberger). Bleaching powder gives a purple coloration.

ANIMAL, in biology, any member of the kingdom Animalia, a group of living organisms distinguishable from plants (kingdom Plantae) on the basis of certain somewhat arbitrary differences: in morphology and physiology.

Until the discovery of the complexity of the cell and the series of investigations by which it was established that the cell was a fundamental structure essentially alike in both animals and plants (see CYTOLOGY), there was a vague belief that plants, if they could really be regarded as animated creatures, exhibited at the most a lower grade of life. It is now known that insofar as life and living matter can be investigated by science, animals and plants cannot be described as being alive in different degrees. Animals and plants are extremely closely related, alike in their fundamental characters and each grading into organisms that possess some of the characters of both classes or kingdoms (see PROTOZOA).

The actual boundaries between animals and plants are artificial and are based solely on the ingenious analysis of the systematist. The most obvious distinction is that the animal cell wall is either absent or composed of a nitrogenous material, whereas the plant cell wall is composed of a carbohydrate material—cellulose.

The animal and the plant both require food to repair waste, to build up new tissue and to provide material which, by chemical change, may liberate the energy which appears in the processes of life. Both have the same general chemical composition, being made up of water, inorganic salts, carbohydrates, fats and proteins. Both animals and plants take their water and inorganic salts directly as such. The animal cell can absorb its carbohydrate and protein food only in the form of complex organic substances; it is dependent, in fact, on the pre-existence of these organic substances, themselves the products of living matter, and in this respect the animal is essentially a parasite on existing animal and plant life. The plant, on the other hand, if it is green (that is, containing chlorophyll) is capable, in the presence of light, of building up both carbohydrate material and protein material from inorganic salts; if it is a fungus (devoid of chlorophyll) it is dependent on pre-existing carbohydrate material and is also capable of absorbing, as an animal, protein material. (See PLANTS AND PLANT SCIENCE.)

On these basic differences are founded most of the characters which make the higher forms of animal and plant life so different. The animal body, if composed of many cells, follows a different architectural plan; the compact nature of its food and the relative elasticity of its cell walls, result in a structure, of more or less limited growth, consisting essentially of tubular or spherical masses of cells arranged concentrically round the food cavity. The relatively rigid nature of the plant cell wall and the attenuated inorganic food supply of plants make possible and necessary an unlimited form of growth in which the greatest surface is exposed to the exterior, and thus the plant body is composed of flattened blades and elongated branching growths.

The distinctions between animals and plants are in fact obviously secondary and adaptive and point clearly toward the conception of a common origin for the two forms of life, a conception which is made still more probable by the existence of many low forms, the protists—bacteria, protozoans, slime molds, etc.—in which the primary differences between animals and plants fade out.

An exact definition, delimiting all animals from all plants, is therefore impossible. In general, however, an animal is a living organism that is incapable of synthesizing carbohydrates and proteins from inorganic or simple organic substances, but must ingest them in complex form as food.

In general, also, animals are distinguished from plants by freedom of spatial movement.

For the classification of the animal kingdom, see ZOOLOGY.

See also Index references under "Animal" in the Index volume.

ANIMAL BEHAVIOUR, refers, generally speaking, to the action of an animal with reference to its entire repertory of behaviour and to its interaction with living and nonliving things. A given behaviour pattern may start in response to some external change or it may be initiated by internal stimuli, the nature of which escapes analysis. Behaviour is an aspect of response physiology, as contrasted with developmental, maintenance or toleration physiology. It is extremely hard to draw definite lines between these phases of physiology. The spinning of a cocoon by a moth involves complex behaviour patterns but is not greatly different in original stimulus or in end result from the hardening of the hypodermis to form the bare outer covering of the pupating butterfly.

It is difficult to observe animal behaviour without trying to understand its meaning and without trying to correlate the observed action with similar activities shown by other animals lower or higher in the evolutionary scale, particularly with the behaviour of man. Many students also attempt to puzzle out the complicated stimulus-response processes that are involved. Close study usually reveals a complex situation with many variables and leads directly to some of the most fundamental biological and philosophical problems. These include traditionally the problems associated with mechanism *versus* vitalism in biology; the extent to which nonhuman animals have what in man is called consciousness and mind; and much of the controversy about whether purpose exists in nature. (See also MECHANISM; TELEOLOGY.)

Plants as well as animals show behaviour responses of many kinds. Some turn toward the sun; others give so-called sleep movements at night; and certain forms actively catch insect prey. Plant actions are usually so slow that they escape observation, yet viewed with the help of a motion-picture film made from time-lapse exposures, the self-propelled activity of plants rooted in the wind-free forest floor are quite evident. The leaflet-folding of sensitive mimosas is easily seen, and algal swarm spores swim across a microscope field as actively as do protozoans. The behaviour of plants is closely related to that of animals in many fundamentals, even though movements in higher plants are usually produced by changes in turgor or by growth responses. (See TROPISM; PLANTS AND PLANT SCIENCE.)

Nonliving things also show varied behaviour patterns. The activity of electrons, ions, atoms, molecules, colloidal particles, the earth's crust, the planets and their satellites, the sun and other stars and galaxies of stars is as truly behaviour in the broad sense as is the flight of a bee or the tantrum of a child. One of the great problems is the extent to which the behaviour of living things is basically like that of nonliving nature. Those who believe that this unity will ultimately be demonstrated are called mechanists. This is the working hypothesis of students of experimental behaviour of lower organisms and other phases of experimental biology. In contrast: vitalists hold that a distinctively new vital principle or force is involved in the behaviour of living things. This fundamental problem is by no means solved.

Animal behaviour is not limited to that shown by the individual. Organisms are frequently integrated into more or less social communities that themselves behave as units of a higher order. Under such conditions animals give both individual and group responses. A further discussion of such matters will be found in the article SOCIOLOGY, ANIMAL.

Animal behaviour, as a part of biology, cuts across many boundaries. It is, of course, an integral part of psychology, of ecology and of the general and comparative phases of physiology, as well as of sociology. It draws from the lore and methods of all these fields and is used as a tool in the solution of problems in the four disciplines just mentioned.

Although it is difficult to give a definite outline of the subject matter usually treated under the heading of animal behaviour, there are at least four broad categories which will be discussed here.

1. The first of these deals with the sensory capacities of animals—the way in which organisms perceive the world around them. This has long been a fascinating subject for experimentalists in the various disciplines involved in animal behaviour. The sensory physiologist particularly has made many investigations of the colour vision of various animals, the limits of auditory behaviour, etc. (See also HEARING; VISION.)

2. A second area which has been explored is that of orientation, which deals not only with the primary orientation of animals—*i.e.*, the posture or attitude an organism takes in relation to its environment—but also with the way in which they find their way about. An example of the latter would of course be such behaviour as homing and migration (see MIGRATION OF ANIMALS), which still remain one of the greatest riddles of animal behaviour.

3. A third category is that of innate behaviour patterns, which may be considered the heart of the study of animal behaviour. It was long a subject of controversy and reached a rather sterile plateau by the turn of the 20th century, when most of the work dealing with instinctive behaviour consisted largely of categorizing and pigeonholing various behaviour patterns. The trend, fortunately, has since changed and real attempts at analysis of instinctive behaviour have been made, particularly by the European ethologists.

4. The last of the general areas of investigation is that of learned behaviour. This has long been the province of the comparative or animal psychologist and in most instances has dealt with a determination of the learning ability of various species in the phylogenetic scale. The psychologist has sought, in particular, to rank animals in relation to their intelligence by attempting to use universal tests. The outstanding one of these tests has certainly been that utilizing the maze, an apparatus that has been responsible for thousands of papers. The animals that have been used for such experiments complete the entire phylogenetic range. Yet there is little that can be said about the intelligence of an animal on the basis of such maze-learning experiments, because the normal behaviour of the organism may lend itself very well to maze-learning behaviour and still give little index of the intelligence which the test was intended to measure. For example, a rat learns a maze very quickly, while an ape or a monkey may have considerably more difficulty with this problem because its normal behaviour does not involve traversing dark alleyways.

Below are discussed in more detail some representative examples of these broad categories of animal behaviour.

This article is divided into the following sections:

- I. History
- II. Problems of Animal Behaviour Study
 - A. Methods
 - B. Sensory Capacities of Animals
 - C. Physicochemical Principles Applicable to Behaviour
- III. Animal Behaviour Patterns
 - A. Inherited Behaviour
 - B. Instinctive and Learned Behaviour
 - C. Conditioned or Learned Behaviour

I. HISTORY

Aristotle recorded a somewhat systematic account of the behaviour of many kinds of animals and exerted an influence on this phase of biology that was hardly equaled until the time of Charles Darwin. Well into the period after 1859, the men who contributed to knowledge concerning animal behaviour were, like Aristotle and Darwin, also prominent in other fields. The list includes Pliny the Elder and Plutarch, who, like other Romans, had a rather high opinion of animal intelligence. Thomas Aquinas and René Descartes separated man sharply from even the higher nonhuman animals. Konrad von Gesner (1516–65) helped in the revival of the spirit of inquiry of the classical Greeks. R. A. F. de Réaumur (1683–1757) worked actively with insects. Erasmus Darwin, Lamarck and Herbert Spencer were concerned, each in his own way, with the development of instinct and intelligence in animals.

In the Greek period students asked: (1) Do animals have souls? (2) If so, do their souls continue to live after their bodies die? (3) Do animals reason? By way of comparison, the queries of the early post-Darwinian students of behaviour were: (1) Have ani-

mals sensation? (2) Have animals memory? (3) How are these and other animal activities related to those of man? (4) Do animals reason? Darwin himself entered this field of study, and his followers have been concerned with the problem of the ancestry of the human mind. G. J. Romanes, W. Preyer, J. Fabre, K. Groos, C. O. Whitman and E. G. and G. W. Peckham were among the outstanding students of behaviour during the early Darwinian period.

Modern experimentation in behaviour dates from the 1880s. Of the four pioneers in the movement, Sir John Lubbock and later C. Lloyd Morgan stemmed from the post-Darwinian tradition. Max Verworn and Jacques Loeb developed their ideas in part from the studies of the plant physiologists, who, unaffected by the controversy over the ancestry of man, had been actively studying growth and movement in plants since T. A. Knight in 1805 demonstrated the effect of gravity on the direction of growth of seedlings.

These four early experimentalists were alike in discounting the use of anecdotes as a tool in analyzing animal activities. They all attempted to describe behaviour in objective terms and without anthropomorphisms. They studied animal behaviour for its own sake, without regard to the mental evolution of man. Loeb and later Lloyd Morgan applied what may be called the general scientific principle of parsimony. In the words of C. L. Morgan: "In no case may we interpret an action as the outcome of the exercise of a higher psychical faculty if it can be interpreted as the outcome of one which stands lower in the psychological scale" (*An Introduction to Comparative Psychology*). All four men adopted, to some extent, physicochemical explanations of behaviour, Loeb much more than others.

The next advance came with the work of H. S. Jennings (1897 and after), who, like Verworn and Loeb, concentrated upon the behaviour of the lower organisms. Although in the early years of the 20th century there was a sharp conflict between the supporters of the tropism theory of Loeb and those who accepted the more complex trial-and-error explanations of Jennings, the observations of the two groups were largely complementary.

By 1896 C. B. Davenport in his *Experimental Morphology*, which covered a much wider field, could give extensive historical treatment to such topics as the following reactions and the stimuli to which they are responses: chemotaxis (chemicals), hydrotaxis (water), tonotaxis (sound), thigmotaxis (touch), stereotaxis (space), rheotaxis (water currents), geotaxis (gravity), electro-taxis or galvanotaxis (electric current), phototaxis (light) and thermotaxis (heat).

The experimentalists did not always remember that they should master the normal responses of animals before introducing experimental complications. The implied naturalistic emphasis introduces the questions that ecologists began asking in the decades just before and after 1900: (1) Do animals have definite reactions that enable them to find habitat niches that match their ecological tolerances? (2) Are animal responses adaptive? (3) Is a given behaviour pattern innate or conditioned (learned)?

Outstanding advances during the 20th century include I. P. Pavlov's demonstration of conditioned reflexes. In a simple, direct experiment Pavlov showed that a dog on which the sound of a bell produces no observable effect can be trained to secrete saliva when the bell rings. This is done by ringing a bell when food is presented. A hungry dog salivates in the presence of food. After sufficient training, the sound of the bell stimulates the salivary glands to activity even in the absence of food.

A second major advance came from G. E. Coghill's proof that behaviour patterns in the developing vertebrate embryo depend on the growth of detailed nervous connections. Coghill also showed that the embryo first gives broadly generalized responses like the flexure of the trunk or generalized limb movements; finer, more individualized patterns develop later. Another set of recent advances came from the demonstration of the existence and effectiveness of neurohumoral substances and of the control of much of behaviour by hormones in general. Pituitary and sex hormones are especially potent in initiating and regulating behaviour.

The third major advance in the field of animal behaviour stems from the work of ethologists, a term that means, roughly, students of the objective behaviour of organisms. Konrad Lorenz, in 1935,

published a paper on social behaviour and early-experience effects in birds. This led to a development of behaviour study by workers such as N. Tinbergen, G. Baerends and others in which total life histories were observed and then behaviour was analyzed into component parts. The concepts of releaser (a simple stimulus which can result in a complex instinctive response) and "imprinting"—both discussed below—were developments of this group. Much of the modern work on animal behaviour comes from this group.

II. PROBLEMS OF ANIMAL BEHAVIOUR STUDY

There is a fundamental difficulty in the study of animal behaviour due to the inability of animals to convey to the student their perceptions or experiences. This is particularly true in the area of sensory processes, where it often is necessary to use devious means to determine what a particular animal can hear or see. Examples of methods in this area therefore may be discussed as representative for other types of behaviour.

A. METHODS

There are four basic methods which can be used as testing procedures to determine given sensory capacities in organisms: (1) measurement of the electrical activity of the neurons involved in the sensory systems, called action potentials; (2) neural extirpation or interruption—the elimination of certain pathways leading from sense organ to central nervous system; (3) measurement of learned responses to certain stimuli; and (4) measurement of innate, or unlearned, responses.

Measurement of Action Potentials.—A major advantage of action-potential investigation is the fact that sensory processes can be measured directly. However, caution must certainly be used when evaluating experimental results obtained with this method. It is possible to record action potentials in neurons leading from sensory receptors that indicate a stimulus discrimination with the animal giving no behavioural evidence of such discrimination. Investigation by the microelectrode technique of colour receptors in the retinas of cats shows well-defined peaks of colour sensitivity, yet there is no evidence that colour vision plays a role in the behaviour of the cat. In other words, it appears that an animal may sometimes possess the requisite for discrimination of certain stimuli peripherally—that is, at the retinal level—without being able to make use of the information centrally, in the brain.

Neural Extirpation or Interruption.—In order to test a hypothesis of sensory physiology it is sometimes necessary to remove a part of the central nervous system or to sever a neural pathway. This method, obviously, seldom gives sufficient information by itself; it is usually supplemented by one of the two methods described below.

Measurement of Learned Responses.—This is the commonest method for determining sensory processes and capacities in organisms. The method may be adapted in a variety of ways. The classical conditioning procedure uses a natural (unconditioned) stimulus, such as food, to produce a natural (unconditioned) response, such as salivation. A neutral (conditionable) stimulus, such as a tone signal, is presented immediately prior to the natural stimulus. In this example, if the animal learns to salivate to the tone signal as it precedes the food, then it is possible to say that the particular tone used lies within the boundaries of the animal's discrimination. Many kinds of sensory discrimination have been tested in this manner.

Another variation on the same method is the one customarily called instrumental conditioning, where an animal has to act on the basis of a signal or cue to be rewarded or to escape punishment. The trend is away from the use of the discrimination apparatus in which the animal must move a certain distance to reach a goal; more popular is the Skinner-box type of discrimination apparatus, in which the animal may do nothing more than press an appropriate lever when the correct stimulus is presented. Failure to perform correctly in the learned-response method is sometimes taken as evidence that discrimination is lacking, but predictions based on such negative results are often unwarranted and sometimes incorrect. The animal may actually possess the discrimina-

tion ability but cannot show the ability by its behaviour because the experimenter has chosen to condition a response that may for some reason conflict with the animal's normal behaviour pattern.

Measurement of Innate or Unlearned Responses.—One of the advantages of this method is the ease with which experiments are usually performed, with respect to both experimental apparatus and time required. Another advantage is the greater probability of working within the actual response repertory of the animal. A common example of this method is the optokinetic response obtainable in most seeing animals when a field with some sort of articulation (*e.g.*, vertical stripes) is moved past the eyes of the animal. Usually if the animal can perceive the changes in the visual field, movements of the eye, the head or the whole body may be observed. With this technique, visual acuity, brightness discrimination, colour sensitivity and other visual phenomena have been explored.

B. SENSORY CAPACITIES OF ANIMALS

Man is the only animal whose behaviour can be described with even approximate completeness, since he is the only one for which objective behaviour observations may be supplemented by subjective knowledge gained personally or by communication with others. The experimenter or observer cannot learn by direct experience what animals of other species see, feel or otherwise sense; he can only find the stimuli to which they react and their methods of reacting. Using all available avenues of approach—observation, physical analysis of the environment, controlled experiments including discriminatory learning when possible—it has been found that many animals live in a sensory world different from that of human beings.

Much of the activity of ants indicates that within their dark nests, and outside for the blind species, ants live in a world of odour shapes somewhat as man lives primarily in a world of light and shade or of colour shapes. For many animals, smell is an important sense; it is blunted in man. Male moths of several species can find appropriate females though the latter may be over a mile away. The physics of the situation is little short of astounding, considering how scarce the minute odour-bearing particles must be, and yet the male is able not only to detect them but also to follow the very low intensity gradient that leads him to their source.

Dogs can be trained to react to a Galton whistle pitched so high that it is inaudible to man. Bats emit and react to supersonic vibrations of the order of 45,000–50,000 cycles per second. Man's hearing stops at about 20,000 cycles per second. Bats avoid obstacles in total darkness apparently by reacting to the radarlike reflections of the supersonic waves they have emitted.

As compared with man, the arthropods, as a rule, are relatively unresponsive to the red end of the spectrum. K. von Frisch failed in attempts to train honeybees to react to red paper when mixed with a series of grays and covered by clean glass; he could train them to find sugar water on the other spectral colours when similarly interspersed among shades of gray. The available experimental evidence indicates that the honeybee reacts to a spectrum of from 2,700–6,770 Å, extending from the ultraviolet region into the red, though hesitatingly at the red end. *Drosophila*, the common fruit fly, reacts to the range of wave lengths from 2,350 Å in the ultraviolet to about 5,780 Å in the yellow. The span to which some vertebrates respond, given in Angstrom units, is: *Phoxinus*, a fish, 3,400–8,000 (near ultraviolet to infrared); the common hen, 5,000–7,000 (green into red); adult man in daylight, 4,000–7,700 (violet through red).

A number of insects and other arthropods have been shown to be sensitive to ultraviolet radiation. Both *Drosophila* and the honeybee appear to find their highest luminosity values of light in short-wave lengths to which man is totally blind. Trigona, a stingless bee from the American tropics, has been trained to react to an ultraviolet pattern.

Enough has been said, perhaps, to document the general principle that it cannot be assumed that other animals, even other mammals, have the same sensory abilities and limitations found in man. One of the problems in comparative animal behaviour is to describe with all the accuracy possible the sensory field of rep-

resentatives of all the major animal phyla and of the minor ones, too, when they are particularly interesting, either for functional or for evolutionary reasons.

C. PHYSICOCHEMICAL PRINCIPLES APPLICABLE TO BEHAVIOUR

The physiology of animal behaviour is very complex. Among the factors to be considered are: (1) the present external environment; (2) environments of the recent and sometimes of the more remote past; (3) the present physiological state; (4) recent physiological states and sometimes those of the more remote past; (5) the processes involved in the resolution of one physiological state into another; (6) the physiology and anatomy of the given animal, especially (7) of the sense organs (receptors), nerves or hormonal conductors (conductors), the central nervous system (adjustor) and the different kinds of effectors.

Considering its complexity, it is impressive to find the extent to which physicochemical principles (the "natural laws" of the older literature) apply in animal behaviour. The following incomplete list is long enough to make the point.

1. Most activities increase in speed with an increase in temperature between the threshold and the optimum points. The formula of Arrhenius and the Van't Hoff coefficient, devised from chemical considerations, holds in many instances.

2. With light, intensity varies inversely as the square of the distance. Animal reactions that are affected by light intensity clearly show the effect of this inverse-square relationship.

3. With light, the product of the strength of the stimulus and the length of time it operates, if constant, give constant results (Bunsen-Roscoe law).

4. The intensity of illumination of a surface element varies with the cosine of the angle of incidence (the cosine law of illumination).

5. Within the same modality and with constant experimental conditions, the ratio between two stimulus magnitudes that are correctly discriminated, in any intermediate proportion of the attempts, is a constant (Weber's law). As several others, this principle does not hold for relatively low or high magnitudes.

6. The stimulating effect of intermittent light equals that of a constant light if both emit the same amount of energy and if the interval between flashes is not too great (Talbot's law).

There is space to record only one illustration. *Limulus*, the horseshoe crab, is a photonegative animal. When it is exposed to light from two sources the animal swings to an orientation between the two beams. This orientation is independent of intensity (*I*) and of duration (*D*) of the light stimulus providing $I \times D$ of one equals $I \times D$ of the other. Under these conditions *Limulus* orients away from the lights and along a line equidistant from both. Given a situation in which $I \times D$ of one differs from $I \times D$ of the other light, the orientation shifts until $ID \times \text{cosine-of-angle-of-incidence}$ of one eye equals the product of similar values for the other eye. The reaction illustrates tropotactic behaviour.

In one of the original experiments, 38 individuals tested gave fairly diagrammatic responses; 10 did not. This serves to introduce a final principle of behaviour: At all levels of the animal kingdom, if closely studied, different individuals of the same kind show distinctly individualistic responses. Despite the remarkable extent to which many animals exhibit complex behaviour patterns that accord with physicochemical principles worked out for nonliving systems, the fact remains that under carefully controlled experimental conditions, animals often react in an unpredictable fashion. This means that even the best analyses of behaviour are incomplete. Such a situation is a cause for neither reproach nor defeatism, rather a stimulus to further study.

III. ANIMAL BEHAVIOUR PATTERNS

A. INHERITED BEHAVIOUR

Inherited behaviour patterns may be divided into four classes: (1) unorganized or poorly organized responses; (2) reflexes proper; (3) reflexlike activities of entire organisms; (4) instincts.

Unorganized Responses.—Unorganized or poorly organized responses are those given by early embryos or by animals such as sponges that have no nervous systems.

Reflexes.—Reflexes proper, or reflex-arc movements, are those usually described, such as the immediate jerking away of the hand on touching a hot stove.

Reflexlike Activities of Entire Organisms.—These may be

unoriented or oriented.

Unoriented.—These include kinesis—undirected speeding or slowing of the rate of locomotion or frequency of change from rest to movement (orthokinesis) or of frequency or amount of turning of the whole animal (klinokinesis); the avoiding or trial-and-error reaction of Jennings), the speed or frequency depending on the intensity of stimulation. Examples of orthokinesis are seen in lampreys, which are more active in high intensities of light, and cockroaches, which are more active in low intensities; flatworms and many fly larvae, among others, show orthokinesis. Klinokinesis is well demonstrated by *Paramecium*.

Oriented.—Among these activities may be included tropisms, taxes and orientations at an angle. Tropisms are those directed growth-curvature movements or other oriented reactions of sessile plants and sessile animals leading to equal intensities of stimulation of symmetrically placed parts of the body. They are shown by many plants and by hydroid animals such as *Eudendrium*.

Taxes may be described as oriented locomotory reactions of motile organisms. They exist in purest form as oriented, forced movements; that is, as reflex actions of entire organisms. When exposed to a single source of stimulation, the body is oriented in line with the source. Movement toward the source is said to be positive; that away from it is negative.

1. Klinotaxis is the achievement of orientation by interruption of regularly alternated lateral deviations of part or all of the body; there seems to be a comparison of intensities of stimulation that are successive in time. Klinotaxis is shown by animals with a single intensity receptor, such as fly larvae, *Euglena* and earthworms (see fig. 1).

2. In tropotaxis, attainment of orientation is direct, resulting from turning toward the less (negative) or more (positive) stimulated side as simultaneous, automatic comparisons of intensities on two sides of the body are made. No deviations (trial movements) are required. Tropotaxis is shown by animals with paired intensity receptors. If exposed to stimulation from two sources, orientation is to some intermediate point and is determined by the relative intensity of the sources. If one receptor is effectively covered, the animal goes around and around in spirals (circus movement). The locomotory reactions that Jacques Loeb called tropisms belong in this category. Tropotaxis is shown by many arthropods, especially insects. The reaction of *Notonecta*, the common back swimmer, to light is a good example.

3. In telotaxis, known only for responses to light, attainment of orientation is direct and again without apparent trial movements. When between lights from two sources, the animal orients to one

FROM S. O. MAST, "LIGHT AND BEHAVIOR OF ORGANISMS" (JOHN WILEY AND SONS, INC.)

FIG. 1.—EUGLENA, IN A CRAWLING STATE, SHOWING DETAILS IN THE PROCESS OF KLINOTACTIC ORIENTATION

light, not to some intermediate point. The animal switches orientation from one source to the other at unpredictable intervals and consequently follows a zigzag course. The response is given to the source as though it were a goal. Bilateral balance is not necessary, and circus movement? if given demonstrate that the animal is reacting tropotactically rather than telotactically. Honeybees (*Apis*) and hermit crabs (*Eupagurus*), among others, show telotaxis.

Orientations at an angle (transverse orientations) may or may not be accompanied by locomotion. They include:

1. The light-compass reaction, much given by foraging insects such as ants and bees that return to a fixed nest. The general principles involved are illustrated in fig. 2, in which an ant returning to nest at N. along a path approximately at right angles to the sun's rays, was covered over for 2.5 hours. On release the ant proceeded not toward the nest but at right angles to the rays of the late afternoon sun.

2. Dorsal (or ventral) transverse reaction is demonstrated when the impact of the stimulus is kept at right angles to both longitudinal and transverse axes of the body. Locomotion need not occur. This reaction is given to light by various aquatic crustaceans such as *Argulus*, the fish louse, and *Artemia*, the brine shrimp, and is given to gravity by crayfish.

Instincts.—Instinctive behaviour represents the most complicated of the inherited, unlearned behaviour patterns. Instincts are set off from kinesis, tropisms and taxes by their greater intricacy. An instinct is a relatively complex activity of an animal that is acting (1) as a whole rather than by parts; (2) as the representative of a species rather than as an individual; (3) without previous experience or without modification caused by experience; and (4) with an end or purpose of which the reacting animal has no knowledge. Care must be taken to avoid confusion with early conditioned behaviour patterns. The difficulty is the greater since exhibition of instincts may be deferred pending the achievement of appropriate states of development. The lack of previous experience or of modification caused by experience before approximately perfect performance is crucial evidence of the action's being instinctive. Mating, nest building and rearing of new brood by a female ant are performed by instinct.

In view of the trend to dismiss instinctive or unlearned behaviour as an unknown and unlikely quantity, it is well to examine in some detail one example. Warblers, spring and summer residents of northern Europe, migrate during September and October to various parts of Africa, and in early spring fly back to their original points of departure. Some migrate over thousands of miles, from Scandinavia to southern Africa. This migration is accomplished by the birds individually; the warblers do not navigate in groups. Somehow the warblers know how to set their course, and this knowledge is not learned because young birds making their first migration reach their goal as surely as do experienced birds.

It has been proved that warblers can orient by the sun, but since these birds fly mainly at night, the question arises, do the warblers navigate by the stars? A systematic study of this question was made, over a period of several years, by means of specially designed cages in an aviary at Freiburg, Ger. It had already been observed that warblers hatched and raised in closed, soundproof chambers, under the illusion of constant summer, would nevertheless become restless during the nights of the year when they would normally be migrating.

To explore the question of orientation, warblers were placed in cages with glass tops so that they could see the sky but nothing else of their surroundings. At the seasons of migration the birds would begin to flutter about the cages and, like compass needles, take up positions pointing in particular directions. The direction in each case was characteristic of the particular species, depending on where the birds of each species migrated. When the stars were hidden by thick clouds, or when the skies were in diffuse light, the birds became disoriented. Birds were placed in a test cage in a planetarium. When the dome was illuminated with diffuse light, the birds would not choose any particular direction, but when the planetarium sky matched the-night sky over Germany the

FIG. 2.—THE LIGHT-COMPASS REACTION GIVEN BY AN ANT

birds took up the proper direction as if seeing the natural sky.

By changing the positions of the planetarium stars, the birds could be made to change their positions and directions of flight. In one experiment with a lesser whitethroat warbler, which normally flies southeast across the Balkans and then turns due south, various positions of the planetarium sky were shown and the flight directions of the bird were observed. Under the approximate latitude of Germany, the warbler faced southeast. But as the sky was shifted, simulating more southerly latitudes, the bird turned more and more in a southern direction. When the longitude was changed to a position corresponding to a point near Lake Balkhash in Siberia, the bird hesitated for a minute and then changed its direction to the west; in natural circumstances, this would mean that the bird was returning to its take-off point in Germany. As the displacement was reduced, the bird shifted its direction gradually toward the south and when the sky again showed the placement of stars for Freiburg at that time of year, the warbler took up the normal southeasterly direction of flight.

This behaviour, confirmed by experiments with other birds, proves that the warblers have a hereditary mechanism for orienting themselves by the stars—an image of the star patterns in the sky coupled with a time sense relating the constellations to the geography of the earth at every time and season.

But what about getting at some of the real underlying mechanisms? Actually, most of the older investigators were willing to discover some such behaviour, call it instinct and then go on with something else. Modern psychology, however, cannot be satisfied by such a mere naming process. For this reason much work in this area of behaviour deals with attempts at finding physiological explanations for instinct. Migration, food hoarding, maternal and sexual behaviour have been studied with this end in view. The direction in which psychologists try to go is something like this: Birds brood their eggs not because of some mystical maternal instinct but because physiological changes occur during the nesting season which cause engorging of the blood capillaries in the breast of the bird. In order to keep this part of the body cool, the bird covers the eggs. Similarly, the eggs are turned because one part of the egg soon gets warm. This would be a fine way of accomplishing the necessary warming and turning of the eggs, but the answer is not always so simple. Nor is this one by any means complete. There are many unanswered parts—why the bird does not merely find some cool stones to brood, or why some birds sit only on their own eggs while others will accept the eggs of almost any bird, and so on.

Another group of students of behaviour believes that the problem of instinct can be approached by analysis of perception and behaviour. Although much more progress needs to be made, something can be said about what is known and what is suspected. A brief sketch of this work follows.

In the 1930s Lorenz suggested that instinctive behaviour is really a complex of several types of activity. Reflexes, taxes and instinctive movements make up the total pattern. The first two processes have been mentioned. The last-named Lorenz considers to be species-specific and always carried out in the same way. These movements are strictly inherited and characteristic of the species.

In most instances it is difficult to isolate and identify the individual behaviour components, but it has been done in certain cases. In these, instinctive movements and taxes were found to be the most important parts of the instinctive behaviour pattern. The instinctive movements themselves are relatively inaccurate and gross; taxes serve to refine them and make them more exact. For example, flies ordinarily clean their wings by passing their hind legs over and under the wings, meanwhile making small scrubbing movements. The gross movements of moving the legs back and forth in the area of the wings are instinctive. The finer scrubbing movements are taxes. To show this it is necessary only to remove the wings from the fly. It will then still attempt to clean its wings periodically and will move its legs in the direction where the wings were; the smaller taxic responses, however, will be missing. This is the key to the major differences between these two components of instinctive behaviour: Instinctive movements are

triggered off by some stimulus situation, but once started can continue to completion. Taxic responses, on the other hand, need continual stimulation and are therefore steered, rather than triggered, by some stimulus.

It is in the nature of this triggering of an instinctive response that the concept of the releaser has been developed. In the lives of most organisms there are types of unlearned behaviour that seem to be set off by extremely simple stimulus situations. In male sticklebacks, for example, the colour red is the releaser of an attack response. During the breeding season all male fish of this species develop bright red bellies. At that time they also drive away from the nesting area any intruding males. This simple stimulus of colour seems to be the key to the attack response. By making all kinds of models and presenting them to male sticklebacks, it can be shown that little else matters but the fact that the model has a red belly. This method of making models which serve as stimuli and then eliminating and adding certain characteristics is peculiar to those investigators who work with instinctive behaviour. In this way the perceptual aspect of behaviour can be analyzed in terms of the necessary stimulus components which result in a response. Most of the data collected by these investigators have been products of this method.

The releaser, however, may be somewhat more complex. It may involve relationships. Fig. 3 shows a bird silhouette. If it is moved overhead in the direction indicated by the arrow on the right, most young game birds will respond with fright reactions. Moved in the opposite direction it does not cause these responses. Apparently, when moved in the former direction it resembles a short-necked bird of prey (hawk) and is responded to in the appropriate manner. Moving in the opposite direction it appears to be merely a long-necked waterfowl and is ignored. The response in this case has been shown to be unlearned and may therefore be considered an instinctive movement.

One other aspect of instinctive movements, also differentiating these reactions from taxes and reflexes, is important. The longer the experimenter waits to elicit a particular instinctive response, the easier it is to set off. For example, in using models to set off the attack response in the stickleback, a model with only a suggestion of red colour will be enough to initiate the attack in a fish that has been undisturbed for some time. If, however, the response is elicited several times in succession then a more ade-

FROM N. TINBERGEN, "THE STUDY OF INSTINCT" (OXFORD UNIVERSITY PRESS, LONDON, 1951)

FIG. 4. — HUMAN BABY AND THREE SUBSTITUTES (LEFT) PRESENTING SIGN STIMULI THAT RELEASE PARENTAL REACTIONS IN MAN, AS COMPARED WITH ADULT MAN AND THREE OTHER ANIMALS (RIGHT) WHICH DO NOT RELEASE PARENTAL REACTIONS

quate colouring becomes necessary. This has been found in all cases where releasers and their appropriate reactions have been observed. In those cases where instinctive movements are involved, Lorenz thinks that this fluctuation of stimulus value is due to the essential accumulation of specific energy for an instinctive movement. When the level of energy is high because the response has not been made for some time, the stimulus need

not be so accurately representative of the ideal one. The response, in fact, may go off without apparent stimulation, in a process called vacuum activity. If the energy level is low, because of repeated stimulation, then the releaser must resemble the normal one more accurately.

By using the method of isola-

tion (i.e., keeping an animal away from species members during its entire life), many of the data in this field have been collected. Because of its comparative newness much remains to be done, but the direction is clear. Problems in research methods make work on humans along this line difficult, but one example can be shown. The feeling for "babyishness" that most people have. If subjects are shown a number of pictures such as those in fig. 4 and asked which one of each pair they like better or think "cuter," most of them invariably choose the pictures in the column at the left. Lorenz thinks that this too is an example of a releaser, and, specifically, one working at the human level. Other examples of such releasers working in human behaviour are under investigation. (See also INSTINCT.)

B. INSTINCTIVE AND LEARNED BEHAVIOUR

The phenomenon of imprinting is an example of behaviour primarily learned, though formerly thought to be instinctive, by which an early experience of a young animal determines its consequent social behaviour. In one of the first experiments investigating this process, Lorenz divided a clutch of eggs laid by a graylag goose into two groups. One group was hatched by the goose, the other was incubator hatched. The goslings hatched by the goose followed it as soon as they could walk; the incubator-hatched offspring, however, were exposed not to the goose but to Lorenz, whom they then followed about as the other group followed the goose. This phenomenon has been observed in animals capable of locomotion shortly after birth.

In a series of experiments investigating this phenomenon, mallard ducklings were imprinted and tested in an apparatus consisting of a circular runway with walls of transparent plastic. The imprinting object was a male mallard decoy, suspended from a motor-driven arm pivoted at the centre of the apparatus. The imprinting was accomplished by placing a visually naïve duckling in the runway about a foot away from the decoy. A loudspeaker in the decoy emitted a recording of a human rendition of the sound "Gock, gock, gock, gock." and after a short interval was moved around the runway. The imprinting period usually lasted 10 minutes. Ducklings were tested for imprinting by placing each one in the apparatus between a male and female decoy and recording the choice of the animal.

To determine the age at which an imprinting exercise was most effective, ducklings were imprinted at various ages after hatching and tested for strength of imprinting. It was found that there is a critical age during which the animals are most strongly imprinted. Some imprinting can occur immediately after hatching, but the maximum score was made by those ducklings exposed to the decoy between 13 and 16 hours after hatching.

It was also found that the strength of imprinting (I) is dependent on the amount of effort (E) exerted by the young animal in following the imprinting object. Groups of ducklings were exposed to the model for the same length of time but were made to follow it for various distances. Up to distances of 50 ft., the strength of imprinting increases with the distance followed. There were no significant differences in the scores of ducklings which had followed the same distance but for different lengths of time. Ducklings were made to climb over four-inch hurdles and to follow the decoy up an inclined plane. The birds which had to climb hurdles or the inclined plane made higher imprinting scores than those which traveled the same distance without obstacles. It was found that the strength of imprinting equals the logarithm of the effort expended by the animal during the imprinting period; i.e., $I = \log E$.

Thus, although learning seems to account almost entirely for imprinting, it is still necessary for some innate reaction to lead to the response of following in the first place, since if the animal does not follow it will not imprint.

The distinction between learned and unlearned behaviour is not so clear-cut as might appear. Instinctive elements enter into intelligent activities, and behaviour patterns that are primarily instinctive do not usually run their course automatically. Often they contain a variable element that is more or less adapted to the particular situation, in addition to the fixed, inherited aspects.

An act A is at one and the same time often a function of a constant C and a variable V ; expressed as a formula it reads $A = f(C, V)$. In simplest cases the constant element is unlearned and the variable is either learned or is related to learned behaviour.

AFTER E. H. HESS, IMPRINTING IN ANIMALS, IN SCIENTIFIC AMERICAN (MARCH 1958)

FIG 5 — CRITICAL AGE AT WHICH DUCKLINGS ARE MOST STRONGLY IMPRINTED IS REFLECTED BY THIS CURVE
Each black dot on the curve is the average test score of the ducklings imprinted at that age

This analysis of action A into these two components is an abstract one. V and C do not represent more or less antagonistic agencies pushing the animal now in this direction, now in that, as they impinge on one another; they are rather two different phases of one whole. In instinctive reactions, C is greater than V , often very much greater; in intelligent behaviour, relations are reversed and V is greater than C .

The nest building of birds provides an interesting test case. The variable element appears in the way in which the individual bird sets about finding a suitable location and then by means of co-ordinated body movements collects available appropriate materials and weaves them into the structure of the nest. The general nest pattern is unlearned; it is representative of the genus or species rather than of the individual. On the other hand, older birds frequently weave more skillfully than do beginners. Nest building of birds thus is neither purely an automatic, inherited reaction nor purely learned behaviour. Both C and V are involved.

The complex activities of other animals, man included, similarly contain both of these elements. In this may be found an answer to one of the questions of the early Darwinians: The behaviour of man differs in degree rather than in kind from that of other animals; the differences, though often very great, are quantitative rather than qualitative.

The recording of total life histories of animals is not new. Indeed it represents many of the earlier attempts to study the behaviour of animals and was particularly carried on by the natural scientists who were called naturalists. Information recorded in such life histories is useful: but in most instances it is not specific enough for the purposes of an analytically oriented science. The ethologists take a new approach to life histories, in which very careful observations are supplemented by laboratory studies in such a way that the developmental schedule of abilities—sensory and motor capacities—is included in an "ethogram." Typical examples of such ethograms are those dealing with several species of birds as well as some rodents and other mammals. In these the kind of material useful to the student of animal behaviour in setting up problems that require prior knowledge of the capacities

of the organism is available for the first time. Some of these ethograms provide insights into the innate behaviour patterns that determine social behaviour in an animal, and the various releasers and answering behaviours which make up such complex behaviour patterns.

C. CONDITIONED OR LEARNED BEHAVIOUR

In contrast with preceding categories, conditioned or learned behaviour is predominantly acquired or strongly modified as a result of individual experience. The following broad categories can be recognized: conditioned reflexes, trial-and-error learning and insight.

Conditioned reflexes or automatisms represent simple associative learning. The unconditioned stimulus (presentation of food to dog) determines the response (secretion of saliva). The conditioned stimulus (ringing of bell), at first in contiguity with the unconditioned stimulus, at length elicits the response when acting alone. As soon as the conditioned stimulus begins to be effective, further improvement comes from trial-and-error learning. Conditioned reflexes are exemplified by the substitution of the sound of a bell for the sight of food to stimulate salivation. Conditioned automatisms are more complex and involve reactions of the entire organism.

Trial-and-error learning, or selective learning, is independent of a specific unconditioned stimulus; it involves reward and punishment as well as contiguity. The animal does not learn something wholly new; rather a response, often a random response, is selected as a result of reward or punishment and becomes dominant. This kind of learning is shown under diverse problem situations in which the animal is not initially acquainted with all elements in the situation.

Insight is shown in those cases in which an animal that is accustomed to all elements in the situation taken separately finds them in new relations to each other. When typically exhibited, after the initial survey, the animal proceeds at once to make a smooth solution, or does so after a motionless pause. Reward speeds the performance (selective learning) and also repays the animal for displaying insight. An example is given with the aid

ADAPTED FROM WOLFGANG KÖHLER, "MENTALITY OF APES" (KEGAN PAUL, TRENCH, TRUBNER AND CO., LTD.)

FIG. 6.—(A) A SMOOTH SOLUTION AS GIVEN BY A DOG OR APE IN CONTRAST WITH (B) THE TRIAL-AND-ERROR BEHAVIOUR OF A HEN UNDER SIMILAR CONDITIONS

of fig. 6. A dog that has had the run of the surrounding yard is at X when he sees food being placed beyond the grill. His smooth solution of the situation is indicated by the curved line. A hen under similar conditions zigzags back and forth until she finds the solution by trial and error or until she ceases to react. These phases of learned behaviour and their general implications are discussed more fully in the article *PSYCHOLOGY, COMPARATIVE*.

ANIMAL BREEDING is the control of propagation of

animals, usually livestock, by man. The science of genetics and knowledge of reproductive physiology are applied to improve animals by selecting the individuals that will produce the next generation and controlling how they will be mated. This article deals with the purposes of animal breeding, the origin of breeds, the steps in selecting breeding stock and the various methods of selection, inbreeding and other systems of mating and the use of artificial insemination. In addition to the cross references to related articles given in the various sections of this article, for discussion of the biologic factors involved in animal breeding the reader is referred to the articles *GENETICS; HEREDITY; VARIATION; SELECTION; REPRODUCTION*. The main breeds of various animals are described in the articles on the animals, as *CATTLE; HORSE; PIG; SHEEP*; etc.

Improvement or favourable change in animals is brought about by changing the inheritance or the environment. The hereditary characteristics are those which come from gene differences and account for common differences in animals as, for example, the white-face characteristic of Hereford cattle. Nonhereditary differences are mainly environmental; e.g., animals poorly fed and managed will not develop to their maximum capacity. Environment, if markedly improved, can bring forth changes in animals with dramatic swiftness, but the changes continue only while the improved environment prevails.

Changes in the hereditary make-up of a population are made slowly, but usually are fairly permanent (see *GENETICS OF POPULATIONS*). Some characteristics may revert to the original level if neglected.

Origin of Breeds.—Breeds were formed usually from small localized groups which were thought to be superior to the prevailing stock. Groups were selected to get a more desirable stock. Certain hereditary traits became characteristic of animals within an area, which tended to distinguish them from others of the same species. A desired type which met the requirements in form or colour was accepted as a pattern and animals of that type were selected for breeding. By this selection, the breed founders made progress toward their goal. Undesirable characteristics were selected against and desirable characteristics were selected for, with the result that animals exhibiting the desirable characteristics became more common.

As a breeder developed animals, he selected in his own herd what he thought was the best breeding stock for the next generation, supplementing it with stock from other sources. As the group improved, it became difficult to find stock outside for further improvement. It then became necessary to use more of the newly developed stock in the breeding program; consequently, inbreeding was not uncommon in the foundation of breeds.

The English began to develop the purebred idea for seed or breeding stock late in the 18th century. As breeds were formed and recognized, herdbooks were started by individuals to maintain pedigree records of selected animals. Breed organizations or record associations later took over control and maintenance of the pedigrees. These records were known as the herdbooks, and entries or pedigree registrations were restricted to those animals with record or registered ancestors. The term purebred, as used in the United States, refers to animals that are registered or are eligible for registry.

As breeds were formed, standards were set mainly for the purpose of selling the breeding stock. The buyers of the stock demanded statements of breeding and also definite characteristics regarded as evidence of pure breeding. Thus, registration of pedigrees in herdbooks and description as to breed characteristics were stimulated.

Defining the Ideal.—The animal breeder had in mind a type or ideal animal, representing particular desirable characteristics, these being determined by the purpose for which the animal was intended. Thus there are two common types of sheep—mutton and wool; two main types of cattle—dairy and beef; and analogous designations for other kinds of livestock. Starting with the animals available, which were quite variable, the early improver had to fashion his plans to include consideration of the feed supply and other environmental factors. The breeder of pet or fancy

stock had mainly the human appeal to consider. With cattle, specialization moved mainly toward the two primary types of beef and dairy, although in some areas the draft type was developed. An animal type must be a compromise since it must suit the purpose or market requirement and also be adapted to the environment, including the feed supply.

Measuring Merit.—A breeding program, to be effective, must include measurements of the individual for comparison with the ideal. This is a more difficult task with some characteristics than with others, since certain features do not lend themselves to objective measurements. The measuring of milk production in terms of quantity and butterfat content was one of the first attempts at production evaluation (*see* DAIRY INDUSTRY). Evaluation of sheep in terms of the quantity and quality of their wool and of swine in terms of litter size are examples of fairly accurate assessments. The form and conformation of a meat animal can be appraised fairly accurately, but seldom can all of the features be measured objectively. While the external anatomical structure permits partial evaluation, the internal physiological functioning of the individual animal is difficult to appraise.

Many of the qualities that make for productivity cannot be determined from the live animal. Age is also a factor in production records. Information from slaughter records or lifetime records can be useful in evaluating an animal's descendants or relatives.

Even with qualities subject to reasonably accurate measurement, such as yearly wool yields, variation occurs and the measured production for one period may not be typical of others. Further, over-all merit is not based on a few characteristics, but on several of them and on their interaction.

Selection.—With an ideal and methods of measurement established, the next step in animal breeding is to choose the breeding stock. The animal breeder bases his choice of breeding stock upon his estimate of the individual's genetic capability to produce the ideal. Merit of the individual, determined from the animal or its relatives, is used as a guide in estimating the breeding value.

It is common to define selection as follows:

Mass selection is the choosing of animals for producing the next generation wholly upon their own individual merit. It is sometimes referred to as phenotypic selection, as it is based on what an animal is and does.

Pedigree selection is based upon the merit of the individual's ancestors.

Family selection refers to selection based mainly upon collateral, or nonlinear, relatives or those descended from the same stock but from a different line.

Progeny testing is a means of estimating an animal's breeding worth and is based on the performance of offspring or lineal or direct descendants.

It is obvious that the various means of estimating breeding worth have advantages and disadvantages. The pedigree or record of ancestry is the first available information, while the progeny test can be made only after offspring have been born and tested. In unselected populations, individuality is generally the most accurate estimate of breeding ability and pedigree the least accurate. Progeny testing may be more accurate than individuality. Many characteristics affecting productivity are related to the reproductive process, and this complicates selection because such qualities (*e.g.*, milk production) may appear in only one sex.

As an animal grows older, progress in growth and development, adaptation to environment, resistance to parasites and disease and long-time productivity are recorded. Pedigree and family information is likewise accumulated. The average merit of the group can change as more individuals become available and their performance becomes known.

Complete certainty as to an animal's breeding ability is never attained except with regard to certain definite simple characteristics affected but little or not at all by environment. For example, the black of the Angus when pure (homozygous) is transmitted to the offspring. The mating of Angus which are not pure (heterozygous) for black may result in the production of both blacks and reds.

In practice, selection usually is based on several characteristics for which improvement is desired. Often an individual may be rated well above the average of the herd in all except one characteristic. Accordingly, selection on the basis of over-all merit has been sought. There is an interrelationship of body parts, a harmonious development which is essential for the proper functioning of any animal. Changing one particular part by selection may disturb the balance between the others. Selection indexes are calculated by evaluating the importance and heritability of each trait included in the index. The index, which considers many characteristics, is an attempt to guide the breeder in making the greatest possible improvement in performance.

Mass Selection.—Selection which is based wholly upon individual merit (phenotypic) involves choosing for breeding all or many of those animals exhibiting variation in the desired direction. Variations of some characteristics are low in heritability, whereas variations in other characteristics are high. With respect to characteristics of low heritability, the offspring will be only a little different from the population from which the parents were selected. Progress made by mass selection is also related to the intensity of selection.

Mass selection is generally most effective with characteristics that appear in varying degrees or quantities in different individuals; *e.g.*, the back fat of a pig. In the case of traits which appear in alternate forms, one form tends to become less prevalent, but progress is slow and the undesired form may still occur frequently. By mass selection characteristics have been sorted out and accumulated, and this has been the principal means of improving domesticated animals.

Pedigree Selection.—Individuals that may appear alike may differ vastly in their ability to transmit qualities to their offspring. Two offspring from the same parents, that is, with identical pedigrees, are not of the same genetic make-up unless they are identical or homozygous twins. If a pedigree is to be of value the productive ability of the ancestors must be known, but even then pedigree selection is weak.

Family Selection.—In animal breeding the term family is used to describe two different kinds of groups in both of which there is high genetic relationship as compared with that of the breed of which they are a part. One family may be a group of close relatives that are not closely bred. Another kind of family is a linebred group which, with selection, has become quite distinctive.

Family selection is most effective when applied to inbred but unrelated lines. Since the family average is based upon the average merit of many individuals descended from some stock within a breed, the differences which are nonhereditary tend to be canceled out, and the individuals are closer genetically than is the case with individuals not belonging to the same family. This type of selection has its greatest value for characteristics that cannot be appraised accurately in the individual. It is also useful with characteristics that cannot be appraised in the young animal. To be fairly accurate with this type of selection, the family must be large enough to provide a representative average. For purposes of comparison, families should be exposed to a similar range of environmental conditions.

Family selection is not commonly used with animals in which there are relatively few full siblings or sibs (offspring of the same parents) and half sibs. It is most useful with animals having a high reproductive rate. A family of merit is made up of numerous animals with desirable qualities. Therefore, in either mass or family selection, many of the same animals would be chosen for breeding. However, an individual somewhat lacking in merit and due to be culled may be retained for breeding because of its family merit.

Progeny Selection.—This is the choosing of breeding stock on the basis of the performance or testing of their offspring. Individuals with desirable offspring are retained in the breeding herd while the ones with less desirable progeny are discarded. This system is especially valuable with features of low heritability that can be measured in young animals. For effective results, a representative sample of the progeny of different sets of parents must be tested under the same range of environment. As the

inheritance comes from both parents, the inheritance contribution from both should be considered. The progeny test results in choosing many of the same animals for the breeding group as would have been chosen under the other selection systems.

Systems of Mating.— After the breeding stock has been chosen, the next step is to decide how they should be mated. Systems of mating range all the way from the mating of closely related individuals, or inbreeding, to the mating of unrelated individuals, as in crossbreeding. Mating systems may also be assortative, that is, based upon similarity of characteristics. The mating system may change the various combinations of genes and thereby alter the range of variation within a group.

In practice, the term inbreeding is usually restricted to the mating of first cousins or closer relatives. Close inbreeding usually produces noticeable results in the first generation. Mild inbreeding may take several generations to produce distinguishable changes in the offspring. Individuals mated at random often bear some remote relationship, but this is not considered inbreeding.

Line breeding is a combination of inbreeding, usually in a fairly mild form, with selection. The purpose of the practice is to preserve and concentrate the good qualities of an ancestor by mating individuals related to that ancestor. By the natural halving process of Mendelian inheritance, characteristics of other ancestors are permitted to recede.

The main consequence of inbreeding and line breeding is to increase homozygosity or genetic purity (*see* INBREEDING). Therefore, it is necessary to form homogeneous families. When families or lines are formed by inbreeding, they become progressively more homozygous and distinct with each successive generation. Recessive characteristics may appear as a result of inbreeding. This may cause the merit of individuals to decline, because dominant characteristics are usually more desirable. However, some undesirable recessive traits may be uncovered by inbreeding, making it possible to use selection against these characteristics more effectively.

Selection and mating programs that involve inbred lines are designed to accumulate in the offspring genes which have a complementary effect.

Outbreeding is the mating of unrelated individuals. It is not uncommon for the progeny to surpass the parent stock in vigour and vitality. Hybrid vigour or heterosis (*see* HYBRIDISM) may be lost in mating the first offspring of the cross among themselves, but it can be maintained reasonably well by the alternate back crossing of two breeds or the rotation crossing of three breeds. Full advantage of crossbreeding is attained by retention of crossbred females for breeding. In meat animals, crossbreeding may result in faster and more economical gains.

The main use of crossbreeding has been in commercial livestock production. Breed crosses are very common throughout the United States in commercial hog production. Crosses between wool- and mutton-type sheep are common in the western range country. The crossbreeding of Brahman or zebu cattle with European breeds is quite-common in the coastal plains of the south. The mule is an outstanding example of a hybrid resulting from a cross between species or an extremely wide outcross. In some such crosses fertility is impaired.

Artificial Insemination.— This is insemination of a breeding female by other than natural mating. The semen of the male is deposited in the reproductive tract of the female at the proper time in her reproductive cycle so as to effect fertilization. It was used long ago by the Arabs in horse breeding. Fowls, rabbits, dogs and other animals have been bred by artificial insemination. Beginning about 1940 the practice became widespread in the United States, particularly with dairy cattle.

Artificial insemination permits extensive use of selected males since more females can be bred to one male by this method than by natural service. It also permits the testing of more offspring of a sire in a shorter period of time and under a wider range of environment. Progeny tests can be more accurate if the offspring are reared in several different herds.

The semen may be collected in a number of ways. The first method used was that of obtaining the semen from a female that

had been served. Later the artificial vagina method was developed. A rubber artificial vagina is used into which the penis is directed when the male mounts another animal or a dummy. Semen can also be secured from the male by electrical stimulation, massage of the male sex organs and other means. In most bull studs, the artificial vagina method of semen collection is preferred.

Since the semen of a bull can be extended or diluted, one ejaculation properly handled may be extended to 100 or more services. Some bulls in artificial breeding associations have served as many as 4,000 cows annually.

Beef-cattle producers have made less use of artificial insemination than dairy farmers, as with the customary methods of beef-cattle management the sire usually runs with the herd. The practice of artificial insemination has been quite successful with horses. With the other common farm animals, the cost of keeping a sire is relatively low and there are technical difficulties which make artificial insemination rather impractical.

The careful collection and distribution of semen and proper handling of the material plus proper and timely insemination by trained personnel are essential for success. In cattle-producing areas organizations have been set up to provide the materials and personnel for the practice of artificial insemination. The semen is diluted and preserved by antibiotics and cooling. Freezing with dry ice has been used as a means of retaining the vitality of semen for over two years. Trained technicians make the actual inseminations and provide breeding supervision. Artificial insemination can be less costly than natural service as it saves the farmer the bother, expense and danger of maintaining a herd sire. Further; properly handled, it may be a means of controlling infectious diseases and certain types of sterility.

Wider use of fewer sires of higher individual merit can make more selective breeding possible. The females, however, must also be carefully chosen for the greatest possible improvement of the herd.

The animal breeder may change the hereditary make-up and the merit of an animal population. The change can be far beyond the limits of variation in the original population. Animal improvement is made by regrouping or forming new combinations of genes resulting in animals with the desirable characteristics that formerly occurred only in separate individuals.

ANIMAL CELL (TISSUE) CULTURE. The method of cultivating animal tissue cells, often referred to as tissue culture, provides a means of permitting cells, tissues and organ fragments to remain alive outside the body and to resume many or all of their functional activities under conditions that may be altered at will.

Because the death of the organism is not necessarily coincident with the death of its parts, the parts, almost without exception, may be isolated from the whole and kept alive, some for limited periods of time and some indefinitely. Thus, a strain of connective tissue cells derived from the heart of an unhatched chick by A. Carrel, in 1912, was kept in a state of active multiplication for 34 years. This and other cell strains carried for shorter periods have provided an abundance of uniform test material for many types of biological investigation. As a result, much new information has been gathered about cells, their special properties and their individual requirements.

History.— The first cell culture experiments were probably made in 1866 by F. D. von Recklinghausen, who kept amphibian blood cells alive in sterile containers under a variety of conditions for as long as 35 days. But the first culture experiments on organized tissues were carried out by W. Roux in 1885. By trans-

ferring the neural plate of a developing chick embryo to a warm saline solution, he was able to prove that the closure of the neural tube is primarily a function of the constituent cells and not, as some had supposed, the direct effect of mechanical pressure exerted by adjacent structures.

In 1898 C. A. Ljunggren made successful transplantations of human skin that had been kept alive for days and weeks in ascitic fluid. Four years later G. Haberlandt published the first of his studies on the isolated vegetative cells of higher plants, and L. Loeb employed blocks of agar and clotted plasma in which small fragments of guinea pig skin were embedded and placed for incubation in subcutaneous pockets of another animal. In 1903 J. Jolly completed an extensive series of observations on the division of amphibian leucocytes cultivated outside the body for one month. Three years later S. P. Beebe and J. Ewing cultivated an infectious lymphosarcoma of a dog in the blood of susceptible and resistant animals. Yet it remained for R. G. Harrison to devise a simple technique that would permit explanted parts to continue to grow and develop outside the organism. In a sense, Harrison's experiments were the logical development of the microsurgical procedures of elimination and transplantation already introduced to experimental embryology; for if it were possible to transplant living tissues and allow them to develop further in new surroundings within the body, it should also be possible to find some external culture medium in which they would likewise grow. When small fragments of undifferentiated tissue from the wall of the nerve cord of amphibian larvae were suspended in hanging drops of clotted lymph, nerve fibres grew into the medium. Harrison published these observations in 1907. His experiments not only gave visual evidence of the origin of nerve fibres, but also provided a striking demonstration of the usefulness of tissue culture in attempts to study the structural elements of higher organisms in relation to their environment.

More precise techniques were developed from these early procedures of Harrison by Carrel, who had been actively engaged in applying the principles of surgery to the physiological study of mammalian organ systems. He was convinced that the greatest hope of arriving at a clearer understanding of growth and organization rested in the study of such structural units as could be isolated from the organism and cultivated in media of known composition. In addition to the developments made in Carrel's laboratory, the original techniques of Harrison were elaborated and improved along somewhat different lines by W. H. and M. R. Lewis, A. Maximow, G. Levi, C. Champy and T. S. P. Strangeways.

Applications. — These early efforts led to the gradual development of culture procedures that are used to advantage in almost every field of experimental biology and medicine, particularly in cytology, histology, embryology, cell physiology, cell pathology, bacteriology, immunology and the study of tumours and viruses.

It has been possible, for example, to study the structural and functional characteristics of the various cell types that comprise the individual; the special potencies of undifferentiated embryonic regions and organ rudiments at various stages of development; the effect of irradiation, temperature and other physical agents on cells; the conditions necessary for tissue grafting; the nature of cell movement; the process of cell division; the properties of pure strains derived by single-cell isolation; the nature of the Golgi elements, the mitochondria and other cytoplasmic inclusions; the elaboration of hormones and other secretion products; the site of, and the conditions necessary to, the formation of various types of immune substances; the elaboration of cytotoxins and the nature of hypersensitivity; the reaction of cells of various types to bacteria and bacterial products; the formation, function and diseases of the blood; the nature of the various forms of energy-producing reactions and other biochemical changes occurring in the culture system; the distribution and utilization of isotopically labeled substances incorporated in the medium; the conditions necessary for the propagation of viruses; the specific action of drugs, antiseptics, antibiotics and other chemical substances on various cell types and organ structures; the similarities and differences between normal cells and malignant cells of similar ori-

gin; the usefulness of cell cultures in the diagnosis of tumours and virus diseases; the transformation of normal cells to malignant cells; the food requirements of the various cell types and the nature of substances required in chemically defined nutritive media; and the microcytology of cells by means of the electron microscope.

Cells and Tissues Cultivated. — The various cell types that have been cultivated *in vitro* (that is, outside the living body, "in glass") include: epithelial cells, connective tissue cells: cartilage and bone cells, nerve cells, muscle cells, reticular cells from bone marrow, lymph nodes and spleen, and leucocytes from the blood, all of which may be derived either from the embryo or the adult. Depending on their origin, some of these cells can be cultivated continuously, whereas others multiply slowly or not at all. There are, in addition, many strains of altered cells under continuous cultivation that cannot readily be identified with any cell type existing in the animal body. Sometimes these altered cells appear during bursts of activity in old cultures undergoing marked cellular degeneration; at other times, healthy cultures become altered. As a rule, these altered cells multiply with great rapidity to yield uniform populations that can be centrifuged and washed and subcultured by quantitative procedures. The techniques have also been used for the cultivation of explanted fragments of complex tissue structures: consisting of a variety of cell types; of parts of mature organs, in which the component tissue structures have already assumed definite form; of developing structures, in which the growing complexity may be studied under controlled conditions; and of malignant cells from many sources. When the culture conditions are optimal, it is often possible to develop clonal populations from single, isolated cells. Although cells and tissues for cultivation are ordinarily taken either at biopsy or soon after death, it is not uncommon to initiate cultures from refrigerated material several days after death.

Nutritive Media. — Until 1950 the nutritive media employed for the cultivation of animal cells *in vitro* were usually derived from the organism and consisted of blood plasma, blood serum, body exudates and water extracts of tissues and organs. As a rule, the tissues were embedded in a permeable, semisolid medium consisting of coagulated plasma diluted with tissue extracts and balanced saline solutions. The fibrin meshwork of the coagulated plasma provided a supporting structure into which and upon which the cells migrated. The plasma was prepared and stored in such a way that it remained fluid until shortly after it came in contact with the other ingredients of the medium. Before it coagulated, the tissues were introduced by means of a spatula or pipette. When fragments of tissues were cultivated in a thin plasma coagulum containing embryo tissue juice or other growth-stimulating substances, the cells migrated out into the medium from all sides to form a colony.

Although the plasma was of any desired origin, adult fowl plasma was generally used because of its unusual firmness upon coagulation. It mattered little that the tissues came from another species. In fact, fowl plasma in combination with horse serum, embryo tissue juice and a buffered saline solution containing glucose provided an excellent medium for most human and animal tissues, regardless of origin. Unfortunately, however, the complexity and variability of these natural media made it difficult to use them in experiments designed to determine the actual substances required by the cells for multiplication and survival.

In 1911 Lewis and Lewis made the first attempts to cultivate animal cells in protein-free media. They found that chick embryo tissues survived for a time in a balanced saline solution supplemented with amino acids and polypeptides, and that media containing glucose or maltose were better than balanced saline solutions alone. Carrel's important discovery, in 1913, that extracts of embryonic tissues contain an abundance of growth-promoting substances made it possible for the first time to propagate animal cells indefinitely and stimulated the search for the particular substances responsible.

Later, Carrel and L. E. Baker made innumerable studies of the effect of pure proteins and their degradation products on the survival of many types of cells, both normal and malignant, and

J. P. M. Vogelaar and E. Erlichman reported a feeding solution for human fibroblasts that consisted of irradiated beef plasma, Witte's peptone, hemin, cystine, insulin, thyroxine, glucose and inorganic salts.

By 1950 considerable progress toward the development of chemically defined media had been made, particularly in the laboratories of A. Fischer, P. R. White and R. C. Parker. The first of the chemically defined media to be used in the large-scale cultivation of body tissues was medium no. 199 of J. F. Morgan, H. J. Morton and Parker. It included an almost complete complement of the known amino acids, vitamins, purines and pyrimidines, a source of fatty acid, certain intermediary metabolites and accessory growth factors, and was used in 1953-54 in many laboratories in which poliomyelitis viruses were propagated in monkey kidney tissues for the manufacture of J. Salk's experimental vaccine (see INFANTILE PARALYSIS). In 1955 G. M. Healy, D. C. Fisher and Parker reported a more adequate medium, no. 858, that was capable of yielding, in one week, nine- and tenfold increases in the population of replicate cultures prepared from washed cell suspensions and of supporting cell multiplication at a slower rate for indefinite periods. Medium 858 contained 62 ingredients consisting of 20 amino acids, 12 vitamins, 7 coenzymes, 2 lipid sources, 5 nucleic acid derivatives, 7 inorganic salts, certain intermediary metabolites and 3 antibiotics to help protect the cultures from contamination by microorganisms. Though only about half as adequate as blood serum as a cell nutrient, this medium served to advantage in studying the effects of a wide variety of additional substances on cells and made it possible for the first time to perform experiments in which radioactive isotopes were used to follow the exchange of substances between cells and their immediate environment. Medium 858 supplemented with horse serum, but without embryo tissue juice, was completely adequate for the continuous maximum propagation of cell strains from sources including chick, mouse, rat, monkey and man.

Types of Cultures.— In the original tissue culture system, Harrison's hanging-drop procedure (fig., A), a fragment of tissue is embedded in a couple of drops of medium on a cover slip that is inverted over the concavity of a depression slide, sealed with paraffin wax and placed in an incubator maintained at or near body temperature. During the period of active growth, the living cells may be studied and photographed under the highest powers of the light microscope, or they may be killed and stained for histological examination. If it is desired to keep the cells alive indefinitely, the medium must be renewed every two or three days because the supply of available oxygen and foodstuffs in the hanging-drop system is extremely limited.

When it is desired to maintain tissue cells in a state of active multiplication in the same container for extended periods, they are placed in specially designed flasks (fig., B and C) or in bottles, test tubes or Petri dishes. During the earlier years of tissue culture, it was common practice to prepare a two-phase medium, one a permeable, semisolid plasma coagulum in which the tissues were embedded, and the other a superimposed fluid phase that was renewed at frequent intervals; e.g., two or three times a week. The purpose of the fluid phase was to remove the waste products from the culture and to provide the cells with the necessary nutrients. The frequency with which the cultures were transferred to fresh containers depended on the nature of the tissue and the rapidity with which the cells were allowed to multiply. Ordinarily, rapidly growing flask cultures were transferred once a week and slowly growing ones once a month.

At the time of transfer, the

plasma coagulum containing the culture was removed from the flask by working it loose with a spatula. Then, after the coagulum had been shaken onto a glass plate, a sharp knife was used to separate the culture from the clot and cut it into fragments that were transferred to fresh containers and new media. In later years it became increasingly common to cultivate cells and tissues in fluid media directly on the surface of the glass, without the use of plasma or other substrates. When fresh tissue fragments, or cells dissociated from tissues by various means, are left undisturbed for a day or two after explanting them to fluid media in suitable containers, the cells migrate over the glass and proceed to multiply. Thereafter, it is only necessary to change the fluid at regular intervals, e.g., twice a week. When well-established strains of free-living cells are propagated in fluid media under optimal conditions, the cell populations may increase 20- to 30-fold or more in a week. Special precautions must be taken, of course, to protect explanted cells and tissues from injury. The glassware and instruments should be sterile and chemically clean, and air-borne contaminants should be avoided. Care should also be taken to provide the cultures with an adequate supply of oxygen and to prevent them from becoming too acid or alkaline.

According to the roller-tube techniques developed by G. O. Gey and W. H. Lewis, fresh tissue fragments, culture transplants or cell suspensions were placed in ordinary test tubes that were rotated at 10-12 r.p.h. in an almost horizontal position to bathe the cells and tissues with the medium. Originally it was customary to prepare the cultures in thin plasma clots and provide a superimposed fluid medium that was renewed at frequent intervals. In later years, the plasma was usually omitted and the tissues were allowed to dry, very slightly, on the inner surface of the tubes before the fluid medium was introduced. Still more recently, it has been found possible to propagate many strains of cells in suspension in fluid media by rotating the tubes horizontally at 50-60 r.p.m. By this process it is possible to cultivate cells that would remain attached to the glass in stationary cultures.

Another method, which is tissue culture in its truest sense, was developed by Strangeways and H. B. Fell for the study of the developmental potencies of undifferentiated embryonic regions. In this instance, the explant is placed on a plasma coagulum in a small watch glass, and the watch glass, in turn, is placed in a Petri dish containing a circular mat of moist absorbent cotton to prevent evaporation (fig., D). More recently, as a means of studying the effect of chemically defined media on development, the explant is placed on a chemically inert, mechanical support that is bathed with the nutrient fluid. At intervals of 48 hours, the entire explant is removed from the support and transferred to a freshly prepared watch glass. In this way, the further development of the explant may be observed over several weeks.

Growth Measurements.— The rate of growth of cell colonies cultivated in plasma has been estimated in several ways: (1) by making periodic measurements of the surface area of the colonies and constructing diagrams in which the increase is expressed as a function of time; (2) by determining the ratio of resting cells to dividing cells in a given area; (3) by weighing the colonies after they have been freed from the plasma coagulum; and (4) by measuring certain chemical changes that occur. The rate of multiplication of cells cultivated directly on glass in fluid media or in suspension can be measured with greater accuracy by a method developed by W. R. Earle and his associates for the preparation and evaluation of replicate cultures. According to this method, washed and continuously stirred suspensions of cells belonging to homogeneous strains may be dispensed with reasonable assurance of uniformity into a series of identical culture containers. The number of cells placed in each culture of the series is estimated by counting the cell nuclei in representative samples of the stirred inoculum. The samples are prepared for counting by treating the cells with citric acid followed by low-speed centrifugation and light staining with crystal violet. The liberated, stained nuclei so obtained are counted in a hemocytometer. At periodic intervals throughout the experiments, the nuclei are freed from the cells of various cultures and counted in the same manner. As a supplementary method, Healy and his associates developed a reliable

ANIMAL COLORATION. Animals exhibit an extraordinary array of colours and colour patterns. The colours include not only reds, yellows, greens and blues but also black, white and grays. The colour patterns are closely related to the form, contours and certain aspects of the habits of the animals.

To the scientist the subject of animal coloration poses innumerable fascinating problems. These fall into two general categories. The first relates to the chemical nature of the pigments themselves, how the animal synthesizes or otherwise derives them and the physical basis of the structural colours. The second relates to uses or functional values of the colours in the life of the animal.

Functions of **Colours** in Animals.—Under this heading are two distinct classes of functions: (a) the value to the organisms of the substances giving rise to these colours: (b) the value of the colours as such to the organisms possessing them. The first has to do with the utilization of substances that happen to be coloured; the second with value of appearance to the animal, regardless of how this is brought about.

The first of these two functions is considered in the article PIGMENT, ANIMAL in connection with the chemistry and physiology of animal pigments. As there stated, some of these coloured substances are physiologically very important to the organisms, for example, in relation to their respiratory function or as products of fundamental metabolic processes.

Most of the pigments clearly have roles related to their specific light-absorbing or -reflecting properties. The ability of the vertebrate eye to respond to light depends upon the presence of two photoreceptive pigments, visual purple (rhodopsin) and visual violet (iodopsin), in the retinal rod and cone cells respectively. In addition, dark pigments commonly form screens that regulate the amount of light entering the eye and restrict the directions from which light may penetrate the eye. Reflecting pigments that comprise the tapetum, giving the "eye-shine" so conspicuous in many nocturnal animals, serve to increase the sensitivity of the eye to weak, nighttime illumination.

Light-absorbing and -reflecting pigments in the skin may be involved in a primitive mechanism for temperature regulation in some cold-blooded species. In cool morning air the skin of the desert-dwelling horned toad is dark and absorbs sun's heat rays; as the temperature rises during the day, the body blanches and reflecting pigments assist in protecting the animal from further heating. A comparable adaptive colour-change in relation to body temperature occurs in fiddler crabs. Some locusts regulate their rate of solar heat absorption by changing their orientation to the sun's rays from broadside when the air is cool to parallel at higher temperatures. White in the animal kingdom is sometimes due to special white substances deposited in the tissues; in other cases it is due to the lack of coloured substances, their place being taken by air. Substitutions of this kind occur in the hair of white mammals and the plumage of white birds. The suggestion often has been made that the white plumage or pelage of arctic animals is of value in retarding the radiation of heat.

Intense solar radiation, especially in the ultraviolet, is injurious to living matter, and hence a very general role of integumentary pigmentation is protection of the cells of the organism by light absorption or reflection. The production of the black pigment, melanin, in human skin in response to sunlight is, therefore, clearly adaptive. Here should be mentioned, too, the dense layer of pigment cells (chromatophores) that lines the peritoneum of many fishes and some other vertebrates. The function of such a layer is not known, though it may well provide added protection from

sunlight for the viscera. Consistent with this protective role of integumentary pigments is a primitive response by the young of numerous colour-changing species; these tend to blanch in darkness and darken in bright light. Colourless or transparent animals are generally found in darkness or in aquatic situations where the ambient water serves as a protective filter.

Cephalopod mollusks, when disturbed, may discharge a dense cloud of black "ink" (melanin) into the water. This is commonly interpreted as a "smoke screen," serving to baffle pursuers.

Concealing Coloration.—The principles of camouflage, which became familiar to the world after World War I, probably have been operating in the animal kingdom from the time that sight originated, with predators relying upon it to capture prey by surprise and prey depending upon it to escape observation by predators.

Naturalists have continually been impressed by the widespread existence of protective coloration, since any collector of living specimens, vertebrate or invertebrate, is constantly balked in his search for organisms that, as he may know, lie before his eyes. The prevailing sandy hues of desert animals, bluish tints of inhabitants of ocean surface waters, the whites of arctic creatures and the greens of animals inhabiting vegetation are familiar to the field naturalist. Less familiar are special cases where extensive areas of black volcanic rock in the desert have influenced appropriate darkening effects in animals that in surrounding areas display the prevailing pale hue. Such examples serve to refute any general explanation of the pallor of desert animals as being the result of either the direct effects of solar radiation or the animal's need for reflecting this from its surface.

There even may be orderly changes in colour during the animal's life cycle, nicely correlated with changes in habits. The common eel is transparent while a pelagic larva, later becoming darkly pigmented as an adult bottom-dweller in shallow water. One species of mollusk is first red as it feeds upon red algae in deep waters, later becoming olive green as it migrates to brown and green algae in shallower locations. The transient spotted or mottled patterns of many helpless young birds or mammals serve to protect them at this vulnerable stage. Annual rhythms of change in coloration occur in many animal inhabitants of the colder latitudes. The dark summer dress of such forms as the hare, ermine, arctic fox, ptarmigan and willow grouse gives way to white at the onset of winter.

The importance of the principle of protective coloration as a factor in evolution was fully recognized by Darwin and some of his contemporaries, and it soon became one of the standard examples of the working of natural selection. It required considerable sophistication for zoologists of a later generation to question the testimony of their senses and to demand that a protective value of coloration be more critically established. However, more extensive knowledge, including experimental evidence showing that protective coloration does in reality protect, led to a return toward the views of Darwin and his followers.

If, in these cases, merely a general resemblance in colour between the organism and its usual environment, had to be considered, some direct physical or chemical influence of the latter upon the former might be sought, as has been done by some critics of natural selection. But frequently the coloration and form of animals assume such highly specialized character as to constitute veritable disguises. Instances of remarkable resemblance to a leaf are known in such diverse groups as insects, fishes, toads and lizards. This disguise is enhanced by habits of posture or movement. Resemblance to the bark of trees, to small twigs or to lichens is frequent. The most striking cases of this specialized resemblance are to be found in the special fauna of the floating seaweed, *Sargassum*, of certain areas of the tropical Atlantic. Here are animals, many of them belonging to widely separated classification subdivisions, not only displaying the colours of the seaweed itself but even copying the white patches of the encrusting bryozoan by which this seaweed is conspicuously mottled. In certain of these animals, too, the skin is extended into long fleshy appendages that closely resemble similar structures upon the fronds of the weed. Anyone seeing these organisms together under nat-

PROTECTIVE COLORATION

Top left, top centre, top right: In a matter of seconds the Anolis, a common lizard, can change its colour to match its environment
Centre left: Measuring worms protect themselves with petals from the wild carrot flower, which they stick to their backs with an adhesive substance flowing from the mouth
Centre right: The slug caterpillar adapts the colour of the leaf on which

it rests, imitating even the veining of the leaf
Bottom left: The walking stick's likeness to the twigs among which it lives helps to protect it from enemies
Bottom right: The Sargassum fish so closely resembles the floating seaweed for which it was named that the animal is almost invisible as it moves slowly through the plant

ural conditions would be unlikely to consider the resemblance fortuitous. Furthermore, any naturalist with much field experience knows that correspondences of this sort are far from being rare or exceptional; specific resemblances to particular natural objects occur with such convincing frequency as to be difficult to interpret in any other terms. We must add that these resemblances in colour and structure are usually correlated with instincts that control the attitude assumed by the animal, *e.g.*, quiescence or movements of a special sort that serve further to deceive the enemy. The walking stick, for example, would not be duly protected by its form unless it also behaved as a stick and reduced its movements to a minimum.

Deflection and Allure.—Two other kinds of functional coloration should be mentioned.

One of these, termed defluctive marks, is illustrated by the very conspicuous "eyespot" on the wings of certain butterflies, believed by some to divert the attack by predatory birds to less vulnerable portions of the insect body; such markings also occur on the posterior parts of the body of fishes, and their effect apparently is to deceive predators as to the orientation of their prey.

A second type is that of alluring coloration. This is seen, for example, in coloured worm- and grub-like processes that protrude near the mouth of certain fishes and reptiles and serve to entice prey into position for easy capture. Another example is the fluke that, upon completing one stage in its life cycle in a snail, invades the snail's tentacles and becomes brightly coloured, thus inviting ingestion by its next host, a sparrow.

Countershading and Disruption.—Another class of camouflage principles was recognized later than those that have to do with general conformity to background or resemblance to specific objects. This concerns colours or patterns that make the organism inconspicuous or unrecognizable regardless of background. For the acceptance of these principles, chief credit must be given to Abbott H. Thayer, an American artist, whose discoveries in this field were first announced in 1896 but were not given wide publicity until 1909. The first of these principles is that of countershading or oblitative shading, which had, however, been clearly stated by E. B. Poulton a few years earlier. This principle is a generalization of the fact that in the great majority of animals, both terrestrial and aquatic, the dorsal surface of the body is more heavily pigmented than the ventral, while there is a gradient of pigmentation from one to the other. Thayer called attention to the fact, which he illustrated by solid models, that such a distribution of pigment makes for minimum visibility, when the animal is lighted, as it most commonly is, from overhead.

Another principle stressed by Thayer, and one that has been widely adopted, is that of disruptive patterns. In such cases the natural continuity of the body's outline is broken by intrusions of black or white or other colour at the margins, or a less conspicuous general colour scheme of the body is nullified to the observer by conspicuous markings that are quite irrelevant to this. The effect is to render an object unrecognizable even though it remains in full view. Under the name coincident disruptive colouring, H. B. Cott discussed a group of cases in which disruptive patterns were carried continuously through regions of the body that are not morphologically continuous, *e.g.*, pigmented bars that run crosswise upon the hind legs of a frog but are evident only when the animal's legs are doubly folded in the resting position. Such colouring effectively obscures the presence of the appendages. Similar pigmented stripes, arranged longitudinally, frequently include the eye, camouflaging what is otherwise a most conspicuous organ. The stripes at the same time divide the body into two or more longitudinal sections and tend to render it unrecognizable as a single organism of familiar form.

Since shadows cast by animals may constitute an effective means of exposure, shadow camouflage has been commonly accomplished by crouching posture, by compressed form of the body or even by the use of special disruptive patterns to produce false shadows.

Adaptive Colour Change.—Many animals, representing several different major subdivisions of the animal kingdom, are able to cause their shades or in some cases their actual colours to con-

form to those of their background. These changes are mediated through the eyes and the central nervous system, in some cases involving endocrine glands. The effector organs are the chromatophores, the highly branched special cells in the skin or elsewhere. The most familiar of these are black, white, yellow and red in colour. Colour changes of this type have been most fully investigated in fishes, Amphibia and reptiles among the vertebrates and in crustaceans and the cephalopod mollusks among the invertebrates. The literature in this field has become very extensive.

Colour changes resulting from chromatophore action are of two kinds. The first are rapid changes, often completed within a few minutes or even seconds. They are brought about by the aggregation or dispersion of pigment granules within the chromatophores. The aggregated condition results in a withdrawal of much of the pigment from view and thus to a paling of the animal. On the other hand, the dispersion of pigment leads to a darkening of the chromatophores and thus of the surface of the body as a whole.

The second type of colour change usually involves an increase or decrease in the number of chromatophores present, as well as in the actual amount of pigment contained in each. Such changes result from prolonged subjection of the animal to the same stimuli that call forth the more familiar, immediate responses. In either case, it is important to note that the shade assumed or the amount of pigment produced is dependent not upon the absolute degree of illumination to which the animal is subjected but upon the albedo of the background, *i.e.*, the ratio of reflected to incident light. The amount of melanin present at the end of four months in one species of fish was found to be about twice as great in specimens kept on black as in those kept on white backgrounds, while the amount of the white pigment guanine was four times as great in the latter as in the former. The differences in appearance of the fish were very striking. The black-adapted specimens were almost completely black, the white-adapted ones were pale gray.

Evidence that this capacity for pigmentary adjustment to background may be of lifesaving value to fishes has been obtained experimentally. Large numbers of fishes that differed widely in the extent to which this adjustment had been carried were subjected to attacks by fish-eating birds and larger fishes. It was found that the ratio between less-adapted to more-adapted fishes among the casualties was consistently high, averaging about two to one.

Aside from such tests, however, the mere existence of the mechanism for adjustable coloration would seem to constitute strong evidence for the effectiveness of protective coloration; this complicated mechanism has evolved independently in several unrelated branches of the animal kingdom. Furthermore, so far as aquatic animals are concerned, no plausible function except concealment has ever been suggested. Two other facts strengthen the argument even more. The adjustment of some fishes and crustaceans to their backgrounds includes pronounced and appropriate changes in colour pattern that can have no significance except as they affect appearance; the old familiar objection to the protective coloration theory that many of the presumed predators are not known to possess colour vision loses its force completely in the face of these facts. Further, it has been observed that crustaceans, fishes and lizards, given a choice, will tend to select a background in harmony with their skin colour.

Warning (Aposematic) Coloration.—Many animals, especially insects, that are edible and inoffensive have developed a superficial resemblance to other species, often widely unrelated to themselves, that are avoided by predators owing to the possession of repellent or dangerous characteristics (see MIMICRY) such as venomous stings or bites, objectionable flavour or poisonous flesh. This earliest discovered (Batesian) type of mimicry is believed to be supplemented by another (Müllerian) type in which a number of species of animals that are similarly obnoxious appear to have adopted a common conspicuous livery, supposed to be recognized by predators as belonging to animals that should be left alone.

It is highly advantageous for aposematic species to have very conspicuous appearances that bear resemblances to other aposematic ones. This is usually achieved through display of bold pat-

terns of combinations of such striking colours as red, yellow, orange, black and white. These stand out conspicuously against the usual green or brownish backgrounds. Such species also tend to have habits that render the colours more conspicuous. Although usually sluggish and indifferent: they tend to move when threatened. Aposematic species are also commonly gregarious. They are typically diurnal in their activity, hiding at night. They also hide during cold or dry periods when, because of a scarcity of other foods, there would be less immunity from potential predators. Avoidance of aposematic species appears in many instances to be a response learned by each individual predator; any learning carry-over would be distinctly advantageous to both the attacker and the attacked. Experiments by a number of naturalists provide evidence indicating that birds, monkeys and perhaps some other animals exercise choice in the selection of insects and tend to reject those that have certain brightly coloured patterns.

Recognition Colours.—This term has been applied to certain cases in which conspicuous markings are displayed. The markings may serve to identify an animal in the eyes of another of the same species, either at the time of mating or when they are flocking together for mutual protection. The white flag of the retreating cottontail rabbit and the showy rumps of some of the deer frequently are cited as examples of aids to identification for mutual protection.

Colour and Sex.—In many species of animals the sexes differ widely in colour. The most familiar examples of this are found among the birds, fishes and insects. In cases where one sex is more highly coloured or more ornate than the other, it is usually the male that is so characterized. In some birds and fishes these sexual differences of colour become greatly emphasized during the breeding season, diminishing or disappearing during the periods of sexual inactivity.

Among birds, colour changes are usually a consequence of feather replacement following the spring molt or less frequently are caused by the shedding of the tips of feathers. The plumage coloration differences between the sexes of birds are variously determined by hormones and genes. In domestic fowl hormones from ovary or testes are the agents, and in the English sparrow the agents are the genes alone. In male weaver finches, pituitary hormones (gonadotrophins) determine the bright coloration, while ovarian hormones inhibit coloration in the female. Similar diversity of control is known for the sex differences in bill colour among birds. Sex hormones appear involved with the colour differences in fishes. In insects, however, the differences depend exclusively on genic control.

A question quite different from that of the physiological basis of sexual colour differences is that of the utility of these colours, if any, to the organism. Are the gorgeous colours of male birds, for example, of advantage to the wearers of these colours? Darwin, as is well known, answered this question in the affirmative with his hypothesis of sexual selection. The showy characters of the male plumage, he contended, arose through the continued selection by the females of the more ornate mates. Darwin was able to point to cases among birds in which competitive display by the males and selection by the females seemed to be incontrovertible facts. The extraordinary perfection to which certain colour schemes have been carried (*e.g.*, in the secondary wing feathers of the male argus pheasant) speaks for a level of aesthetic appreciation that certainly would not have been expected in a bird. However, the range of colour differences that can reasonably be explained by this sexual selection theory is certainly much less extensive than Darwin supposed, and in those cases for which it is regarded as relevant the theory has undergone considerable changes in its formulation. One alternative explanation offered by A. R. Wallace to account for certain sexual differences of coloration in birds would seem to have considerable merit. Wallace contended that some of these differences might be due to an adaptive modification of the brooding female for purposes of concealment. Species with brightly coloured females usually have concealed nests, and in species in which the male is known to brood the eggs this sex possesses a cryptic coloration. Indeed, the suggestion has been made that it might be advantageous to the species for the male to be

more conspicuous during the nesting season in order to divert the attention of predators from the female, who at that time is biologically more important.

It must be admitted that for many of the general differences in coloration among animals no explanation has been found, and, indeed, perhaps no explanation of a specific adaptive nature is called for. A good proportion may eventually be found incidental to the animal's metabolism and simply to have persisted to an extent and in a form permitted by natural selection.

ANIMAL ECOLOGY: see ECOLOGY, ANIMAL.

ANIMAL EDUCATION. Animals are influenced to act in characteristic manners dependent upon learning achieved in various situations. Influences which guide or control learning may arise from experiences in the characteristic environment, from experiences with other animals or through human guidance.

Education through ordinary experience is typified by the manner in which many young vertebrate animals modify their inborn "snapping responses" to small moving objects. At first the young chick pecks at both edible and inedible objects in motion, but after certain kinds of objects (*e.g.*, hairy caterpillars) have been rejected repeatedly in response to their harsh effect in the mouth, these may be avoided while others of different visual appearance are snapped up.

Education through the activities of other animals may occur incidentally, or through individual relationships meriting the term "tuition." Often young mammals are weaned forcibly and thereby stimulated to acquire adult feeding habits, evidently more because physiological changes in the mother cause her to reject their advances than because she has a "teaching" attitude. In birds, parental behaviour frequently influences the appearance of adult behaviour in the young, as when fledgling birds of prey are at first given pieces of flesh and finally intact prey which they must handle independently, or when early flight is stimulated by pulling or forcing the young from the nest. In the higher mammals, situations in which one individual directly stimulates and guides learning in another are not uncommon. For example, a mother monkey may release herself and back away from her infant, thereby impelling it to follow independently. As another instance, in laboratory experiments one chimpanzee in a joint rope-pulling test stimulated its lagging partner by means of an identifiable gesture, a series of gentle taps with one hand. It must be remembered that an untrained animal profits only in a very general way from seeing another perform, unless the essential parts of the act have been learned previously.

An untrained dog which sees another open a door by twisting the knob with his paws is not thereby enabled to duplicate the act, although when tested alone he may be more persistent in his attacks on the door and perhaps work more around the knob than would otherwise be the case.

Education through human guidance in its simplest form, the "conditioned response," requires as basis a response which the animal makes at the outset to some definite excitatory stimulus. For example, to teach a dog to lie down on command, one begins by using the hands gently to force lying down, each time presenting the new stimulus ("lie down") until after many repetitions the words alone are sufficient. Similarly, in circus training the basic responses (*e.g.*, sitting still) essential for complicated training are fixed to particular stimulus cues through a conditioned-response procedure. However, for highly skilled acts a complex routine of special training is necessary, a process in which appro-

private techniques are used to emphasize each step of the serial act and to exclude undesired acts. This holds both for the training of domestic animals and for less ordinary processes such as educating elephants to dance or dogs to lead the blind.

Obviously, the critical limits of animal educability vary in different animal forms, being particularly dependent upon the elaboration of the cerebral cortex in the brain. The cortex of a rat is inferior to that of a dog, for example, and the rat is found correspondingly inferior in learning complex tasks. Furthermore, brain operations reducing the amount of cerebral cortex lower the educability of given individuals. Once the potentialities and capacities of the given animal for new behaviour are known, established principles of learning may be utilized to devise a suitable training program. See PSYCHOLOGY, COMPARATIVE; CONDITIONING; ANIMAL BEHAVIOUR. (T. C. S.)

ANIMAL EXPERIMENTATION. Animal experimentation is the use of animals to study living processes in health and disease. It includes their use for research in the panmedical sciences (including medicine, dentistry, pharmacology, veterinary medicine and the basic biological disciplines): for education and training in these sciences, including the development of surgical skill; for the manufacture of vaccines, toxoids, antiserums, antitoxins and antivenins; for the testing and standardization of drugs, biologicals and food additives; and for the diagnosis of disease.

The most fruitful approach to investigations in the panmedical sciences has been the comparative approach—the study of diverse forms of life to build up basic knowledge. Such investigations include the study of life forms ranging from the ultramicroscopic virus to the gorilla. The most frequently used laboratory animals are frogs, mice, rats, guinea pigs, hamsters, rabbits, chickens, pigeons, dogs, cats, sheep, goats, pigs and monkeys. The particular species used depends upon the nature of the project. The study of enzyme systems may well use one-celled organisms, and the fruit fly has been very helpful in genetic studies. The mouse is the mammal used in the greatest numbers.

The dog has been and continues to be particularly valuable in the development of new techniques in surgery. The basic techniques in chest and heart surgery were developed by use of the dog. Techniques for the prevention and control of shock and for the safe transfusion of blood and blood plasma substitutes were developed largely through experiments on dogs. The dog played a prominent role in the development of brain, bone and abdominal surgery. The dog has played a major role in the development of knowledge of many of the metabolic diseases of man, such as diabetes, pernicious anemia and adrenal cortical insufficiency (Addison's disease). There are more than 1,000,000 diabetics in the United States alone who are living useful and almost normal lives because of work done on the dog. Thousands of lives were saved during World War II as a result of research done on dogs after World War I, particularly beneficial being inquiries into shock and wound infections, each of which caused many deaths in World War I. The benefits of research were illustrated even more dramatically in the Korean war.

One of the less well-known uses of animals is for the routine testing of food additives, drugs and biologicals. Research into problems of food spoilage, processing and distribution, palatability and acceptability, and nutritive quality is a large industry in itself, requiring large numbers of animals. The animals used most commonly for such tests are mice, rats, dogs and monkeys.

The testing of potential new drugs requires large numbers of several species of animals. Every batch of many of these drugs, even after they are accepted for use, must be tested on animals before it is considered safe for man. For example, every batch of each antibiotic must be tested on rabbits to make sure there are no factors present that will produce fever and on mice to make sure that there are no toxic factors; and many antibiotics must be tested on dogs to make sure there are no factors present that will lower the blood pressure. Each batch of corticotrophin (ACTH) must be tested on rabbits, mice, dogs, cockerels, chickens, rats and cats. The 13th edition of the *United States Pharmacopoeia* (U.S.P. XV) lists 168 categories that require testing with

one or more species of animals for safety, potency, antigenicity (the ability to stimulate the organism to produce antibodies) or some other important factor. Other drugs and biologicals not listed in the *Pharmacopoeia* but listed in the *h'atzonal Formulary* or by the Food and Drug Administration or the National Institutes of Health require animals for testing. The use of animals to test drugs and biologicals for safety and potency is widespread and necessary.

Antivivisection Activity.—An account of the prodigious advances in biological and medical knowledge that have followed the use of animal experimentation is convincing proof that it leads to profitable results and will continue to do so. There is not a single modern and substantial item of medical knowledge that does not owe something to animal experiment. Animal experimentation may cause pain to animals, and in any event is a form of using animals not for their own individual advantage but for the advantage of man in his pursuit of knowledge. The justification for using animals in this way depends on the individual's philosophical beliefs, as to man's obligation to animals and as to the rights that animals may be supposed to possess.

The origin of organized opposition to the use of animals in research, called antivivisectionism, came in the middle of the 19th century. At that time the panmedical sciences were benefited by the experimental work of the French genius Claude Bernard, the founder of physiology; his wife and daughter, however, became antivivisection leaders.

A militant organization was founded in England in 1873 under the name of the Society for the Protection of Animals Liable to Vivisection. In 1897 it adopted its present name, the National Antivivisection Society. After the enactment of the Cruelty to Animals Act of 1876, other antivivisection societies were founded in Great Britain, all of them pressing for the total abolition of animal experimentation. In Great Britain, money donated for the abolition of animal experimentation is not tax free.

The first antivivisection society in the United States, the American Antivivisection Society, was founded in 1883. By 1955 there were over 200 antivivisection societies in the United States, including 5 national societies. Antivivisectionists join humane societies and in many cases, because of their zeal, dominate the societies and dictate their policies.

Laws Related to Experiments on Animals.—In most areas of the world, animal experimentation is accepted as approved practice by common law. In a number of countries it is legally defined.

United States.—In the United States, every large teaching hospital has a surgical research laboratory that uses dogs for both teaching and research. The federal Congress can legislate in this matter only for the District of Columbia and for the territories. Bills against animal experimentation were introduced in Congress each biennium after 1897, but none passed. Prior to 1945, six states (Illinois, Maine, Massachusetts, Oklahoma, South Dakota and Washington) had passed laws prohibiting animal experimentation in public schools.

Twelve cities had been supplying dogs to medical schools instead of killing them at municipal pounds. St. Louis, Mo., in 1922 and Chicago, Ill., in 1931 passed specific legislation defining these provisions. No states had passed legislation defining such provisions, although 11 states had endorsed animal experimentation in legal terms.

In 1945 bills to prohibit the use of animals for teaching and research almost passed the legislatures of the states of New York and Massachusetts. In that year the National Society for Medical Research (S.S.M.R.) was founded. Supported chiefly by medical, dental and veterinary schools and research and philanthropic institutions, the N.S.M.R. became active in informing the public about animal experimentation. Within a dozen years from the founding of the N.S.M.R., 9 states (Oklahoma, South Dakota, Wisconsin, Minnesota, Illinois, New York, Delaware, Massachusetts and Ohio) and 28 cities had passed legislation that made unclaimed and unwanted stray animals from their public pounds available to approved research institutions. (S.A.B.R.)

Great Britain.—The law relating to animal experiments is the Cruelty to Animals Act of 1876. It was drafted at a time when the

majority of animal experiments were carried out by physiologists and mere therefore more often than not of an acute surgical nature. Nevertheless, the wording of the act is so flexible, except for a system of certification that has proved cumbersome but by no means unworkable, that it has been possible to adapt it to the vastly changing conditions of animal experimentation.

The act covers experiments on mammals, birds, reptiles, amphibians and fish; invertebrates are not covered by it. All animal experiments under this act must be for the advancement of physiological knowledge, which includes the broad field of biological inquiry, or knowledge useful in saving or prolonging life or alleviating suffering, in man or in animals. It refers only to experiments on living animals of a kind that might cause pain, suffering or appreciable discomfort or departure from normal health. Such experiments must be carried out in places registered by the home office and regarded as suitable for the purpose, and these are regularly inspected by full-time qualified inspectors. Experimenters must hold licences granted by the home office, and they also require certificates controlling the use of anesthetics in any operative procedures from which the animal is allowed to recover: or to allow them to dispense with anesthetics altogether in the case of trivial procedures such as inoculations.

In operations followed by recovery, efficient anesthesia and full aseptic precautions must be observed. If in the course of an experiment the animal comes to suffer severe or enduring pain, and the main result of the experiment has been gained, the licensee must kill the animal forthwith; and he must also kill it regardless of the state of the experiment if severe and enduring pain develops. Today only a small proportion of experiments are performed under total anesthesia from which the animal does not recover. This includes a number used in illustration of lectures to medical and veterinary students.

Additional certificates are required for experiments on horses, asses and mules and, in most cases! on dogs and cats. These species thus have a special measure of protection. Licences and certificates are personal to the holder: who may not delegate his authority under them to another, not even a licence holder.

The act prohibits animal experiments whose object is the acquisition of manual skill, but this does not include research into surgical techniques, which is permissible. It also prohibits the exhibition of experiments to members of the public. A scientist working under home office licence cannot be prosecuted for any offense against the act without the written permission of the home secretary.

There have been no prosecutions under the act of 1876. This is partly due to the way in which British scientists have, by their co-operation, made a difficult law work as it was intended to work, and partly to the fact that the system of licensing places a very powerful sanction in the hands of the home secretary. The revocation of a professional physiologist's licence would be a more serious penalty than the penalties laid down in the act, because it would prevent his following his profession.

There have been two royal commissions on vivisection, one appointed in 1873, which was followed by the passing of the act of 1876, and one in 1906, which reported six years later. After exhaustive inquiries, both supported the need for animal experimentation and approved the ways in which British scientists carried it out. The act has been strictly but sensibly administered, so that it is possible to say that experimental animals enjoy a real and effective measure of protection against anything that could be described as cruelty, while at the same time science is not prevented from pursuing a profitable course. A similar act is in force in Northern Ireland and in the Isle of Man. (W. L.-PR.)

British Commonwealth.—There is no legal protection for laboratory animals in Canada, India, Pakistan, South Africa, New Zealand or Tasmania. In Australia each state has legislation but none has inspection; experimenters are licensed in Queensland (1925) and Western Australia (1920 and regulation in 1944).

In Kenya only licensed persons may use experimental animals. Jamaica has an act passed in 1949 which provides for inspection, licensing of experimenters, registration of laboratories and obligatory keeping of records. Similar acts were passed, during 1957

and 1958, in the Bahamas, British Honduras, Montserrat, St. Vincent, Seychelles, Zanzibar, Fiji and Uganda. In Uganda the use of curare is restricted. At the end of the 1950s legislation was being prepared in Barbados, Grenada, St. Kitts-Nevis-Xnguilla, British Guiana, Hong Kong and Sierra Leone.

Europe.—In Europe there is no legal control of the use of laboratory animals in France, the Netherlands, Spain, Portugal, Greece, Yugoslavia or the U.S.S.R. In the Republic of Ireland the British Cruelty to Animals act of 1876 still applies.

A comprehensive law was passed in Denmark in 1953 and a committee controls the use of vertebrate experimental animals. The duties of this committee include the granting of licences, supervision of experimenters' records (which must contain full details of anesthesia and euthanasia) and unannounced inspection of animals and experimental procedures. The Danish law also lays down that if animals have to recover from operation they are to be nursed carefully and their pain is to be relieved, and that students may not use, or have demonstrated to them, any procedure on a living animal unless that animal is anesthetized and never regains consciousness.

By the Swedish laws of 1944 and 1958 control of laboratory animals is vested in the Swedish Veterinary board, which licenses experimenters and has powers of inspection, which, however, it delegates to the director of each laboratory.

In the Swiss cantons of Basel and Berne laws passed in 1941 provide for unannounced inspection of laboratory animals by visiting committees of scientists and laymen. Both enactments provide for the licensing of experimenters and of laboratories and both contain a clause making good husbandry obligatory. In Vaud (1958) there is licensing of experimenters, and inspection by veterinary surgeons. In Ziirich there is obligatory record keeping and licensing, but no inspection, and there, as in Austria, Czechoslovakia and Italy, an animal may not be used for more than one painful experiment.

In the German Federal Republic (law of 1933 and regulations in 1934 and 1951) invertebrates are protected as well as vertebrates, and there is inspection by state-employed doctors and veterinary surgeons. Italy (1941) made some provision for inspection.

In Austria, Norway and Poland experimenters are licensed. In Belgium, Czechoslovakia and Norway laboratories are registered. In Austria, Denmark and Czechoslovakia the law requires that the minimum number of animals must be used. Experimental animals may not be used at all in Liechtenstein. (F. J. Vr.)

ANIMAL EXTRACTS. The animal kingdom provides a source for a large number of substances having nutritional and therapeutic value. Many of these active substances are complex proteins that have not been synthesized in the chemical laboratory. The structures of some of the hormones and other compounds isolated from animal extracts have been determined, and these compounds have been synthesized by the chemist at a cost much lower than the cost of extraction from the animal organ. The animal extracts are obtained by extraction of the active material from the animal organ with subsequent purification by chemical means; or the secretion, such as bile or pregnant mares' urine, of an organ is extracted and used as the source of the active compounds. Some of the potent adrenal hormones are produced by the perfusion in vitro of animal adrenal glands with blood and subsequent isolation of the crystalline hormones from the perfused blood. Many antibodies against diseases such as tetanus and diphtheria are obtained from the blood of animals inoculated with the organism producing the disease.

Substances such as honey and wax are obtained through the activity of members of the animal kingdom. Some of the common animal extracts are epinephrine, beeswax, cod-liver oil, gelatin, honey, insulin, lard, lanolin, suet, pituitary, testicular and ovarian extracts, pancreatic solution and ox bile.

Pituitary Extracts.—The pituitary gland has anterior and posterior lobes. The posterior pituitary extract exhibits striking physiologic actions on the heart, circulatory system and the smooth muscle of the body. There is a potent antidiuretic substance that increases the reabsorption of water by the kidney. *Diabetes insipidus*, characterized by excessive secretion of urine, is controlled

by injection or nasal insufflation of posterior pituitary extract. In obstetrics it is used to control *post partum* bleeding, or to initiate uterine contractions at term.

The anterior lobe of the pituitary gland also produces many hormones, some of which control the activity of other endocrine glands of the body—for example, the adrenal cortex, thyroid, ovaries and testes. Some of these hormones have been isolated in relatively pure form. Adrenocorticotrophic hormone (ACTH) stimulates the adrenal gland to produce adrenal steroid hormones. These steroid hormones have a wide range of physiologic actions. ACTH has been used in the treatment of rheumatoid arthritis, rheumatic fever and other inflammatory diseases. The pituitary gonadotrophic hormones stimulate the ovaries in females and the testes in males. A gonadotrophic substance elaborated by the placenta also is used clinically, its action being similar to that of the pituitary gonadotrophins.

A hormone with properties of producing growth in animals has been isolated from the anterior pituitary gland. The lactogenic hormone of the anterior pituitary exercises direct control over milk secretion. A thyrotrophic hormone (TSH) finds some use in the diagnosis of thyroid disease. The pituitary hormones cannot be given by mouth since they are proteins and are destroyed by the proteolytic enzymes in the intestine.

Adrenal Extracts.—The adrenal gland is composed of a medulla and a cortex. The medulla produces at least two substances, epinephrine (adrenaline) and norepinephrine (noradrenaline or levarterenol). These compounds have a profound stimulating action on the cardiovascular system and are used as circulatory stimulants in conditions of shock. Epinephrine also is used in the treatment of certain allergic diseases. From the adrenal cortex numerous crystalline steroid compounds have been isolated. The adrenal cortex is essential for life unless adequate hormonal replacement therapy is given. Six of the hormones will maintain the life of an adrenalless animal.

Adrenal cortical extract has been used to treat adrenal insufficiency in man; the adrenal cortical hormones play an important role in many physiological functions in the body, such as salt and water balance, as well as carbohydrate and protein metabolism. Two of the biologically active adrenal cortical steroids, cortisone and compound F, made synthetically, have a profound effect in inhibiting the inflammatory response seen in many diseases. Most of these substances are active when given by mouth.

Gonadal Extracts.—Extracts of the testes and ovaries are rarely used, since the active principles can be made by the chemist. The testicular androgen, testosterone, is used in the treatment of hypogonadism and for the palliative treatment of certain breast cancers. The ovarian hormones, estrogens and progesterone, are used in certain menstrual disorders. Estrogens are helpful in relieving symptoms of the menopause and have been used in controlling certain types of cancer.

Parathyroid Extracts.—The parathyroid glands provide an extract used to treat hypoparathyroidism. This disease is characterized by muscle tetany associated with low blood calcium and high blood phosphorus. A resistance to the hormone develops after a number of injections, and therefore vitamin D compounds have been used for long-term therapy.

Pancreatic Extracts.—The pancreas produces two types of secretions, exocrine and endocrine. The endocrine secretion, insulin, is of great importance in the treatment of *diabetes mellitus*. The isolated hormone can be modified by adding zinc and protamine to produce a much longer-acting preparation; it plays an important role in the control of carbohydrate utilization. The exocrine secretion is made up of a number of enzymes. Two important types, which break down fats and proteins, are secreted in an inactive form but are activated in the intestine.

Thyroid Extract.—The thyroid gland produces a hormone, thyroxine, which is important in regulating the energy metabolism of the body. In certain deficiency states, such as myxedema in adults and cretinism in children, thyroid extract provides adequate replacement therapy. This material may be taken by mouth.

Liver Extracts.—Liver extract was once widely used in the treatment of pernicious anemia, but it has been largely replaced by

crystalline vitamin B₁₂, the active hematopoietic agent in liver extract. Animal bile provides bile acids that have been used in conditions of inadequate secretions of bile by the liver.

See also ENDOCRINOLOGY; HORMONES; and various articles on the individual glands and their secretions.

ANIMAL FEEDS: see FEEDS, ANIMAL.

ANIMAL HEAT. This subject includes the physiology of the body temperature of animals, the paths of heat loss and the heat production that is necessary to maintain body temperature. The invention of the thermometer led to a marked increase in the knowledge of variations in body temperature of man and animals. The use of electrical resistance thermometers, thermocouples and radiometers also contributed measurably to the information concerning variations in different parts of the body, the paths of heat loss and the factors affecting them. The body temperature of man and animals is reliably obtained with a mercury thermometer placed in the rectum. With man the internal temperature is usually taken in the mouth.

Warm- and Cold-blooded Animals.—Animals in general are classified as homiothermic (practically constant body temperature independent of environment) and poikilothermic (body temperatures varying with external temperature). The first class includes the so-called warm-blooded animals, all mammals and birds. The second class includes the so-called cold-blooded animals such as insects, snakes, lizards, tortoises, frogs and fishes. In a study of the rectal, mouth and skin temperatures of several varieties of snakes, turtles and tortoises, Francis G. Benedict found in 1932 that the body temperatures of these animals almost invariably were slightly lower than the temperature of the environment. These animals acted as a wet-bulb thermometer, because all of their heat elimination was by way of vaporization of water. When a snake was placed in a calorimeter to measure its heat elimination, no heat was given off; in fact, it absorbed heat from the surrounding air. Only in the case of a python incubating a group of eggs was the body temperature higher than that of the environment.

A few animals are warm-blooded at one season of the year and cold-blooded at another. The most noted example is the marmot or woodchuck. During the warm period of the year this animal is warm-blooded, but in the fall it goes into a state of hibernation and becomes cold-blooded. The state of hibernation is brought about by absence of food and cold external temperatures. The body temperature in hibernation has been observed to go down to 37° F. with recovery, being usually 2° to 5° F. above that of the environment. Warm-blooded animals can behave as cold-blooded under conditions of anesthesia. Sutherland Simpson demonstrated that when a monkey was kept deeply anesthetized with ether and placed in a cold chamber, its temperature gradually fell. When it had reached a sufficiently low point (87° F.), the use of an anesthetic was no longer necessary. The explanation was that the heat-regulating mechanism had been impaired. In studies on the marmot reported by Benedict in 1938, Nembutal was used to produce narcosis, and the marmots had body temperatures as low as 82° F. and were usually 2° to 4° F. above that of the environment. In man and animals, injuries to or severance of the spinal cord will bring about abolition of the heat-regulating mechanism and an approach to a condition like that of cold-blooded animals. These facts tend to show that the power of maintaining a constant temperature has been a gradual development and that anything that interferes with the working of the higher nerve centres puts the animal back again, for the time being, on to a lower plane of evolution.

Variations in Body Temperature.—The body temperature of animals ranges from 96° F. in the elephant to about 109° F. in small birds. Animals may be classified according to body temperature as follows: 96°–101° F., man, monkey, mule, ass, horse, rat, mouse and elephant; 100°–103° F., cattle, sheep, dog, cat, rabbit and pig; 104°–106° F., turkey, goose, duck, owl, pelican

and vulture; 107°–109° F., chicken, pigeon and several small common birds. The body temperature of a healthy man may range from about 97° F. to 100° F. during the 24 hr.; the rectal temperature is between 1° and 2° F. higher than the mouth temperature. The temperature of infants and young children has a much greater range and changes readily from comparatively slight causes. The average temperature falls slightly from infancy to puberty, levels off and falls again from puberty to old age.

A diurnal variation of body temperature occurs in man and in most animals. In man the lowest body temperature is from 2 to 5 A.M. and the highest from 2 to 5 P.M. With this changing temperature throughout the day it is only coincidence that the temperature may be 98.6° F., which is considered to be normal. In the early morning the oral temperature may be as low as 97° F. and in the afternoon as high as 99° F. without being abnormal. Reversal of the activity from day to night, as in night workers, does not change this rhythm, but on a trip from New Haven, Conn., to Manila, Phil., R. B. Gibson found in 1905 that the rhythm changed with the progressive changes in the hours of night and day. Therefore, it would seem that the daily rhythm of man is affected by cosmic influences and not by cycles of activity. The daily rhythm of body temperature is surprisingly like the rhythm of the daily external temperature at certain times of the year on a different scale.

In women there is a monthly cycle of temperature in relation to menstruation and ovulation. T. T. Zuck in 1938 reported a study of rectal temperatures in women throughout the monthly cycle. Just before menstruation there was a slight fall in morning temperature to 98° F., which continued during menstruation. After menstruation there was usually an additional slight fall followed by a rise to 98° F., followed in turn by an abrupt fall to 97° F. or even lower at the midperiod. Thereafter it usually rose to normal and remained stationary until the next menstrual period. Records of the last menstrual cycles of 20 women identified ovulation with the approximate date of the midperiod low temperature. No pregnancy occurred before the 10th day or after the 20th day regardless of the length of the cycle.

The skin temperature of man is about 7° to 9° F. lower than the internal temperature, which is attained only at a depth of an inch or more (approximately 50% of the body is within one inch of the surface). In the basal state the rectal temperature may be 2° to 4° F. higher than the average body temperature. In fever the two may be practically alike. Men and women vary considerably in their reactions to environmental temperature.

Ingestion of food produces a rise in both skin and rectal temperatures for an hour to two hours, the skin temperature being elevated more than the rectal. Alcohol produces an elevation in skin temperature but a lowering of internal temperature, and therefore is to be avoided during exposure to cold environment. J. H. Weatherby in 1942 found that smoking decreased the skin temperature of the extremities 4° to 13° F., but removal of nicotine from cigarettes almost completely abolished this fall. Cold applications placed in various parts of the body cause a substantial lowering of the temperature of living tissues to a considerable depth from the contacting surfaces. Children about 13 years old had a temperature drop to 95° F. after swimming 45 min. in a pool at 73° F. Variations of external temperature within ordinary limits cause very slight changes although some individuals require a period of adaptation when they change from a temperate climate to a tropical one. Muscular work usually causes a temporary rise in temperature. This rise depends on the duration and severity of the work, the temperature and the per cent humidity of the environment.

Most animals (birds and mammals) have a daily rhythm in body temperature similar to that of man. The breadth of the rhythm varies with the type of animal. Pigs have a range of 2.5° F.; asses 2° F.; dogs and cattle 3.5° F.; and poultry 5° F. Hence man may represent the limit to which an evolutionary trend to homoiothermism has been attained.

Limits Compatible with Life.—There are limits both of heat and cold that a warm-blooded animal can bear. They depend on the classes of animals and upon whether or not they have sweat-

ing mechanisms. The upper survival limit for fever in man is 107° F., but this may rise in premortal states to 110° F. The lower limit of human body temperature varies with the condition of the individual. In diabetic coma a temperature of 92° F. has been recorded with survival after recovery from the coma. Lawrence W. Smith and Temple Fay in 1940 subjected patients with incurable cancer to an artificial hibernation by means of ice packs that reduced their body temperatures to a range from 74° to 90° F. Their studies showed that patients may be kept at body temperatures in the 80s for from 5 to 8 days with recovery.

Cold-blooded animals will survive until the body temperature nearly reaches the freezing point. Small cold-blooded animals therefore descend below the frost line seasonally or like some insects migrate to warmer climates. Cold-blooded animals, on the other hand, have great difficulty surviving body temperatures above 98.6° F. Snakes and lizards in hot deserts will seek shade and if prevented from doing so will die.

Regulation of Body Temperature.—The body temperature of man and animals is maintained by the balance between heat production and heat loss. In cold-blooded animals the heat production varies with the external temperature and in general obeys the Q_{10} law of chemical processes, which is that for an increase of 10° C. (18° F.) the heat generated is about double that of the preceding rate. This law does not hold strictly throughout the range of possible body temperatures of cold-blooded animals. The lower the body temperature, the more rapid is the increase in heat production per degree rise in body temperature. However, even at body temperatures approaching those of the warm-blooded animals the heat production is much lower than that of the warm-blooded animals.

The larger the warm-blooded animal, the greater is the heat production, but the heat production decreases quite regularly per pound of additional body weight. Also, in general, the larger the animal, the lower the heat production per unit of body surface area. It was formerly considered that a general law governed the heat production at rest fasting per unit of body surface; *i.e.*, it was 1.000 cal. per square metre of body surface per 24 hr. in animals exposed to an environmental temperature of 16° C. (61° F.). However, Samuel Brody calculated that the average basal metabolism of the entire range of warm-blooded animals from the mouse to the elephant is equal to 70.5 cal. per 24 hr. per kilogram^{0.73}; *i.e.*, the body weight in kilograms raised to 0.73 power times 70.5 cal. Although man fits into this generalization, his basal heat production is usually referred to body surface. The body surface of man is calculated from the Eugene F. DuBois formula, $A = Wt.^{0.425} \times Ht.^{0.725} \times 71.84$ in which A equals area in square metres, Wt. equals weight in kilograms and Ht. equals height in centimetres. The normal basal heat production of men per 24 hr. varies from 46.0 cal. per square metre at 14–16 years of age to 35.5 at 70–80 years of age. Women have about 5% to 10% lower basal heat production.

The heat produced by various animals has to be eliminated in order to maintain a practically constant body temperature. The paths of heat loss are radiation, convection and vaporization of water. Radiation is actual heat rays, convection is carrying away of heat by air currents, and vaporization of water is heat used in evaporating water from the lungs and skin. In nonsweating animals there is little evaporation of water from the skin. Maintenance of constant body temperature in these animals is brought about in hot weather by increased panting and by increased exposure of the body surface so that radiation and convection are more effective. The cat licks itself in hot weather to increase evaporation, and the dog pants to accomplish the same end.

Domestic cattle do not stand hot weather well because they have few sweat glands, and the amount of panting they can do is sometimes insufficient to keep the body temperature within normal limits. Brody called attention to the ineffectiveness of electric fans in cooling cattle because they may actually increase the skin temperature by blowing hot air on the animals. He recommended use of wet blankets or wet spongy material on cattle in hot weather, together with electric fans. Milk production in cows is seriously affected by high body temperature, and the growth of chickens is

markedly lowered in the hot months. On the contrary, cattle may be wintered at extremely low environmental temperatures in open range without serious injury. They develop highly insulating coats of fur and subcutaneous fat. Cattle native to hot countries withstand hot environments better than those native to temperate countries. The Brahman cattle, *Bos indicus*, are used in sections where high temperatures occur in summer. They probably have more sweat glands than European cattle, *Bos taurus*. Horses, mules and donkeys withstand hot weather much better than other farm animals because they have sweat glands. They, therefore, can be worked much more than cattle.

Poultry are likewise sensitive to hot weather. External temperatures above 80° F. produce disturbances, and temperatures of 100° F. or above cannot be withstood for more than seven hours. Good water supply in which fowls can dip their heads is required. The sheep is outstanding among domestic animals in tolerating hot atmospheres. Panting is not a marked feature since it occurs only at a rectal temperature of 106° F.

The greatest factor in heat regulation is the skin, which is regulated by the vasomotor system and by the nervous mechanism of perspiration. In hot weather the cutaneous blood vessels are dilated and there is increased blood flow so that more heat is eliminated. Contrariwise, in cold weather, the blood vessels of the skin contract, thus lowering the skin temperature and lowering heat loss. At rest in a comfortable environment, man's average loss by radiation is about 53%, by convection 19% and by vaporization 28%. The higher the external temperature the greater is the heat loss by vaporization of water, until at 97° F. external temperature all heat elimination is by vaporization. Above this temperature the body actually absorbs heat from the environment; this absorption is compensated for by increased vaporization.

Men and women behave differently on exposure to different environmental temperatures. J. D. Hardy and E. F. DuBois, in a study of the paths of heat elimination of nude men and women at external temperatures from 72° to 95° F., found that radiation decreased steadily in men until it disappeared at 95° F. In the cold zone, vaporization was about equal in the two sexes, but at 84° F. the men started to sweat whereas the women did not sweat until the external temperature reached 91° to 93° F. The heat loss for women in the cold zone was about 10% less than that of men because their skin temperature was lower than that of men, and in the warm zone the heat loss of most of the women was about 14% to 20% lower than that of men because they did not sweat so much. The comfort zone in which heat production and heat loss were equal had a range of 11° F. in women and only 4° to 5° F. in men. C. P. Yaglou and Anne Messer in 1941 pointed out that if women would dress in winter clothing comparable to that of men, they would be comfortable at 72° F. instead of 76° F. Conversely, if men would discard their coats, vests and collars in hot weather the temperature of buildings could be maintained at 83° F. for comfort instead of 76° to 80° F., and the problem of air conditioning for both sexes would be simplified.

In muscular work in hot, dry climates, enormous quantities of water are necessary to compensate for the loss of heat by vaporization. Losses of three quarts per hour have been recorded. A good acclimatization can be acquired rapidly during the first 7 days and then more gradually up to 23 days. Changes in heart rate are dramatic, as the principal reduction occurs in the first four to five days. The general course of the rectal temperature is downward as normal levels are attained in seven to ten days. Rates of sweating gradually increase. W. Machle and T. F. Hatch stated in 1947 that there was agreement among most observers that performance and appearance of men, degrees of vascular instability and cardiac rate and rectal temperature when evaluated together are so closely related to the state of acclimatization as to comprise the most reliable indexes of the state. Fever in men is caused in some diseases by interference with heat elimination and in others by both an increase in heat production and a lessening of heat elimination. In the human body the heat production follows the law of Q_{10} so that as the body temperature is raised the heat production is raised. T. M. Carpenter found that even in the

range of normal body temperature the heat production varied directly with the body temperature.

All the arrangements in the animal economy for the production and loss of heat are themselves regulated by the central nervous system, and it is considered that the temperature centre is situated in the hypothalamus. See also Index references under "Animal Heat" in the Index volume.

ANIMALS, DISTRIBUTION OF. The subject of animal distribution can be approached from the viewpoint of (1) current spatial distribution; (2) life in past eras, along with the historical factors that molded present zoogeographic patterns; and (3) the environmental factors, both physical and biological (biotic), that channeled animal dispersions in the past and control present distribution. Primary attention is focused in this article on the role that physical environmental factors have played in determining the spread and limitations of animal life (fauna). Necessary data on the origin, rise and present diversity of different animal groups are included, but the history of animal evolution is surveyed primarily in the articles EVOLUTION, ORGANIC; ANIMALS, PHYLOGENY OF; PALEONTOLOGY; and under the names of major animal groups. The present distributions of nonmarine vertebrates are reviewed in ZOOGEOGRAPHY. Biotic factors associated with animal distribution are considered in the articles ECOLOGY, ANIMAL; MARINE BIOLOGY; and PLANKTON; but a section on man as a factor in animal dispersal is included in this article.

This article is divided into the following sections:

- I. Introduction
- II. Animal Distribution in Time
 1. Life in the Early Seas
 2. Movement into Fresh Waters
 3. Movement onto Land
 4. Associated Evolutionary Changes
- III. Geographical Distribution of Living Animals
 1. In the Sea
 2. In Fresh Water
 3. On Land
- IV. Factors Affecting Ecological Distribution of Living Animals
 1. Water
 2. Temperature
 3. Light
 4. Food
 5. Oxygen and Carbon Dioxide
 6. Pressure
- V. Animal Life in the Sea

 3. Topographic Zonation
 - C. Dispersal of Animals on Land
- VIII. Man as a Factor in Animal Distribution

I. INTRODUCTION

Information concerning the generalized adaptations and distribution patterns of different animal groups is basically dependent on the degree to which their systematics and ecology have been studied.

Zoological classification dates officially from 1758, when Linnaeus published his tenth edition of the *Systema naturae* (see ZOOLOGICAL NOMENCLATURE). Prior to this time, there was a considerable body of general observations on animals, but no effective means of codifying these data so that scientists in all parts of the world would know to what species a particular observation referred. Linnaeus catalogued 4,236 animal species, of which 1,222 or nearly 29% were vertebrates. Insects accounted for 1,936 species or 46%, and the other phyla for the remaining 1,078 species.

In the more than 200 years since the *Systema naturae*, the number of known species has increased approximately as shown in fig. 1. Obviously, no catalogue of the more than 1,000,000 described species exists. New species are being named at the rate of more than 10,000 per year, and even estimates of the number of known species vary widely. Various authorities cite the number of known species of fish as low as 20,000 or as high as 40,000; of mollusks between 40,000 and 150,000; and of insects 650,000 to 1,000,000. Part of the problem lies in the fact that in many groups it is not yet known what is a species; many names listed as full species in old monographs actually refer to colour variants or to geographic races of species. Primarily the problem lies in the overwhelming diversity of animal life and in the comparatively small group of scholars attempting to systematize knowledge about animals

Although the number of recognized vertebrate species increased more than 37 times since 1758, the vertebrates, with about 40,000 species, now comprise only about 4.4% of all the known animal species. The proportion of vertebrate species will further decrease in the future since there are probably close to another 1,000,000 species of invertebrates, mainly insects and other land ar-

Estimated Numbers of Known Species of Animals*

Phylum	Number of species
Protozoa (amoebas, parameciums, etc.)	20,000 (± 5,000)
Mesozoa (certain wormlike parasites)	50
Porifera (sponges)	5,000
Coelenterata (corals, jellyfish, etc.)	10,000
Ctenophora (comb jellies)	90 (± 10)
Platyhelminthes (flatworms)	10,000
Nemertina (ribbon worms)	650 (± 100)
Acantocephala (spiny-headed worms)	300
Aschelminthes	
Class Rotifera (wheel animalcules)	1,500
Class Gastrotricha (microscopic aquatic forms)	180 (± 20)
Class Kinorhyncha (small marine forms!)	100
Class Priapulida (aquatic wormlike forms)	6
Class Nematoda (roundworms)	10,000
Class Nematomorpha (hairworms)	75 (± 25)
Entoprocta (microscopic marine forms)	60
Phoronida (sedentary wormlike forms)	15
Ectoprocta (Bryozoa) (moss animals)	3,000
Brachiopoda (lamp shells)	245 (± 25)
Pogonophora (beard worms)	108
Sipunculida (peanut worms)	250
Annelida (segmented worms)	6,200
Mollusca (snails, clams, octopuses, etc.)	80,000 (± 25,000)
Arthropods	
Class Onychophora ("walking worms")	80
Class Tardigrada (bear animalcules)	340
Class Crustacea (shrimps, crabs, etc.)	28,000 (± 2,000)
Class Arachnida (spiders, mites, etc.)	50,000
Class Pentastomida (Linguatulida) (wormlike parasites)	70
Class Pycnogonida ("sea spiders")	500
Class Pauropoda (small wormlike forms)	432
Class Diplopoda (millipedes)	6,300
Class Symphyla ("garden centipedes")	170
Class Chilopoda (centipedes)	1,700
Class Insecta (insects)	850,000 (± 100,000)
Echinodermata (starfish, sea urchins, etc.)	5,600
Chaetognatha (arrow worms)	30
Hemichordata (tongue worms)	80
Chordata	
Subphylum Urochordata (sea squirts)	1,500
Subphylum Cephalochordata (amphioxus)	28
Subphylum Vertebrata	
Classes Agnatha, Placodermi, Chondrichthyes and Osteichthyes (all the fish)	20,000 (± 5,000)
Class Amphibia (frogs, toads, etc.)	2,500
Class Reptilia (snakes, lizards, etc.)	6,000
Class Aves (birds)	8,600
Class Mammalia ("warm-blooded" animals with hair, mammary glands, etc.)	3,500

*The numbers of species given in this table are, as stated earlier, rough estimates that are continually being revised. Differences of opinion of course exist among students of taxonomy as to numbers of phyla and species, names of groups, etc.

thropods, that have not yet been named. While 95% to 99% of the species of land vertebrates are described and classified, probably less than half of the insects and perhaps one tenth of the roundworms (nematodes) have been named.

Only very sketchy knowledge of the numbers and kinds of invertebrate life is available, and recent years have seen the discovery of the following groups: a new phylum (the Pogonophora—beard worms); a class of mollusks (Monoplacophora) thought to have been extinct for 350,000,000 years and found living in the ocean deeps; and a new subclass of phylum Crustacea (Cephalocarida) based on specimens of the genus *Hutchinsonella*, collected in waters off both coasts of North America.

The starting point for almost any biological study is a named and classified organism whose general geographic range has been established and for which some life history information is on

FIG. 1.—INCREASE IN NUMBER OF KNOWN ANIMAL SPECIES

record. Students of vertebrates have much of these basic data available and thus can work on ecological, physiological and behavioural problems. Students of the invertebrates, on the other hand, usually first become involved in the basic task of describing and classifying the organisms they wish to study; only with great difficulty can they attempt detailed distributional or ecological studies.

Data on distribution patterns of living organisms on earth are drawn almost entirely from non-marine vertebrates (see ZOOGEOGRAPHY). The classification of most nonvertebral phyla is too poorly known to enable world-wide distributional studies. Fortunately, ecological information on the basic adaptations of organisms to their environment is more plentiful for the invertebrates than is information on spatial distribution.

II. ANIMAL DISTRIBUTION IN TIME

Life on earth probably originated between 1,500,000,000 and 2,000,000,000 years ago. Only a few scattered fossils provide information about early forms. It is not until comparatively recent times, geologically speaking, about 500,000,000 years ago, that a plentiful fossil record exists. Despite the abundance of fossils laid down since that time the inadequacy of the fossil record cannot be overemphasized. Fossilization is a rare accident, and it would be quite optimistic to say that one out of every 1,000,000 individual animals that ever lived had been preserved as a fossil (see FOSSIL).

Most fossils are of organisms that lived in comparatively shallow waters. Little knowledge is available of the deepwater creatures of the past: two zoological discoveries emphasize this fact. In 1938 a fish subsequently named *Latimeria* was caught off East London, U. of S. Af.; its relatives, the lobefins, or crossopterygian fishes, were known as fossils, and were presumed to have been extinct for 60,000,000 years (see COELACANTH). In 1955 a small mollusk, *Neopilina*, was dredged off the west coast of Costa Rica. Its relatives, the monoplacophorans, disappeared from the fossil record 350,000,000 years ago.

Organisms without skeletons, shells or at least some hard parts will leave few traces in the rocks. A group of soft, wormlike animals, the Onychophora (*Peripatus*), is known from Cambrian fossils and living species, but no fossils are evident in the 500,000,000-year gap between. Similarly, fossils of most worm phyla are very rare.

Despite obvious limitations and inadequacies, the fossil record does show that (1) there has been a definite history of rise, dominance, decline and extinction of animal groups; (2) many types of organisms abundant today were at one time absent or rare; and (3) some creatures that are rare today were formerly common. A brief discussion of a few major changes is given

below. A more complete account is in the article PALEONTOLOGY.

1. Life in the Early Seas.—By the Cambrian period, the first well-documented period, life was already varied. Radiolarian protozoans, many worms, a few echinoderms, many kinds of mollusks, primitive coelenterates, sponges, arthropods, brachiopods and several groups that subsequently became extinct, notably graptolites, trilobites and archaeocyathid sponges, were represented. Ocean reefs in the Early to Middle Cambrian were composed of archaeocyathid sponges; suddenly they died out, possibly having been replaced by calcareous algae.

The largest and perhaps dominant animals of Cambrian seas were the trilobites, primitive arthropods ranging from ¼ in. to 27 in. in size. Already diversified in the Early Cambrian, they rose to and maintained dominance until the Late Ordovician when they began to be replaced by the cephalopods; the trilobites then declined in numbers throughout the Carboniferous and finally became extinct in the Permian. (See TRILOBITA.)

Brachiopods, or lamp shells, were bottom-dwelling organisms, undergoing their greatest differentiation in the Ordovician, becoming most numerous in the Silurian and Devonian, then progressively declining from the Carboniferous to the present. The six superfamilies and perhaps 245 living species contrast with 19 Silurian superfamilies and a total fossil record of over 30,000 species. (See BRACHIOPODA.)

The graptolites, possible primitive relatives of the vertebrates, were tiny bottom-dwelling and planktonic organisms of Early Paleozoic seas. They differentiated in the Cambrian, reached their greatest development in the Ordovician, had a minor resurgence in the Silurian and finally died out in the Lower Carboniferous (Mississippian). (See GRAPTOLITE.)

Late in the Cambrian came the first record of the nautiloid cephalopods. These monsters of the Ordovician seas, some with shells 15 feet long, were the largest shelled invertebrates that ever lived. For a time they replaced the trilobites as the dominant animals, but declined in the Silurian and Devonian. Most forms were extinct by the end of the Paleozoic and only one genus, *Nautilus* (*q.v.*), exists today.

About the same time, the Bryozoa, or "moss animals" appear in the fossil strata. Two bryozoan groups, the Trepostomata and

Cryptostomata, were prominent during the Paleozoic, but died out in the Permian; another group, the Ctenostomata have never been important. The Cyclostomata (a bryozoan order, not to be confused with the class Cyclostomata that includes the lampreys, etc.) were moderately important during the Mesozoic, but have been overshadowed during the Tertiary by the Cheilostomata, which appeared in the Cretaceous and form the bulk of the present-day bryozoan fauna. Throughout their history, bryozoans have been important incrusting organisms. (See BRYOZOA.)

Of the coelenterates, primitive jellyfish forms have been reported from pre-Cambrian beds. The corals, reef-building coelenterates, are conspicuously absent from early rock strata, not appearing until the Lower Ordovician series of Vermont; by the Silurian and Devonian, however, the Tetracoralla and Tabulata were important organisms of the oceans and formed the major portion of extensive fossil reefs. At the close of the Paleozoic, these early coral organisms had declined in prominence and only a few stragglers persisted into the Mesozoic. Few corals are known between the Permian and Middle Triassic. By then the modern groups of corals had developed a calcareous skeleton and gradually begun to build the reefs so characteristic of modern tropical seas. (See COELENTERATA; CORAL; CORAL REEF.)

2. Movement into Fresh Waters.—It is uncertain when the first tentative movements into fresh waters were made by animals. Since animals depend upon plants for food, obviously plants migrated first, but the fossil record is inconclusive concerning the time of the emigration. Probably by the Silurian a good flora and a few animals (brachiopod, phyllocarid and possibly ostracod crustaceans, some mollusks and worms) were established in fresh waters.

The earliest remains of vertebrates are a few fragmentary toothlike structures in the Early Ordovician. More complete fossils occur in Late Ordovician and Early Silurian strata. There is considerable controversy concerning the original habitat of the first vertebrates (see A. S. Romer, 1955, and R. H. Denison, 1956). Probably both the earliest vertebrates and the eurypterids, large scorpionlike arthropods that reached their peak numbers in the Silurian and Devonian, with forms reaching 10 feet in length, were present first in brackish waters near the shore. The earliest vertebrates, the ostracoderms, were small, jawless, fishlike creatures with heavily armoured body covering. They fed by filtering food through their gills. The armour was probably a form of protection against predation by the much larger eurypterids.

Sometime during the latter part of the Silurian, both eurypterids and vertebrates colonized the fresh waters. The primitive, jawless ostracoderms were soon replaced by the jawed placoderms. During the Devonian, fish were common in fresh waters, and placoderms were superseded by the bony fishes (class Osteichthyes) still dominant today.

By the end of the Devonian many major fish groups had differentiated, though the modern bony fishes (teleosts) that now dominate the world of fish appeared only as recently as the Jurassic. Of the early fishes, a few fresh-water and marine relicts such as lampreys; lungfish; sharks and rays; sturgeons; and the coelacanth *Latimeria* still remain. From a stock of the crossopterygians, sometime near the end of the Devonian, came the amphibians, the first vertebrates to move from fresh water to the land. (See FISHES.)

3. Movement onto Land.—The importance of this habitat shift is difficult to overemphasize. By then, plants were undoubtedly well established on land. Although the fossil record for Devonian land invertebrates is sparse and questionable, by the Upper Carboniferous and Permian there is evidence of a rich fauna of insects, land snails, scorpions, spiders, phalangids and mites. Not only were these groups established, but they had diversified considerably. Pennsylvanian strata contain at least three families of land snails, and the Permian beds yield 17 orders of insects, 10 of which still exist today. The origins of these invertebrate forms must have considerably predated the Permian and Carboniferous. Most probably the first invertebrates made the transition from fresh water to land in the Early or Middle Devonian.

All animals moving from water to land faced similar problems,

Geologic Column and Scale of Time

(Ages increase from top downward, as in a sequence of sedimentary rocks)

System and Period	Series and Epoch	Distinctive Records of Life	1000 Years*
CENOZOIC ERA			
Quaternary	Recent	Modern man	11
	Pleistocene	Early man	> 44
Tertiary	Pliocene	Large carnivores	1,000
	Miocene	Whales, apes, grazing forms	(21,000)
	Oligocene	Large browsing mammals	
	Eocene	Rise of flowering plants	(58,000)
	Paleocene	First placental mammals	70,000
MESOZOIC ERA			
Cretaceous		Extinction of dinosaurs, floras with modern aspects	130,000
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals	160,000
Triassic		Appearance of dinosaurs	200,000
PALEOZOIC ERA			
Permian		Conifers abundant, reptiles developed	(230,000) 235,000
Carboniferous			
Upper (Pennsylvanian)		First reptiles, great coal forests	260,000
Lower (Mississippian)		Sharks abundant	285,000
Devonian		Amphibians appeared, fishes abundant	320,000
Silurian		Earliest land plants and animals	350,000 (380,000)
Ordovician		First primitive fishes	400,000
Cambrian		Large faunas of marine invertebrates	(440,000) 500,000
PRE-CAMBRIAN TIME			
		Plants and animals with soft tissues, few fossils	(620,000) (1,420,000)
No known basis for systematic division			1,800,000 (2,680,000) (3,310,000) 3,500,000- 4,000,000

*Italicized figures are from radiocarbon analyses; figures in parentheses are reliable values from radioactive minerals found in rocks that belong in time divisions indicated; plain figures give estimated dates at start of corresponding time units.

and a brief discussion of the necessary adaptations is included below under Animal Life on Land. The stimulus that produced the original invasion of the land is uncertain, but two major theories have been proposed to account for the vertebrate emergence. The most commonly accepted theory, put forward by Romer and summarized in 1958, is that the Devonian red rock beds, where the first amphibian fossils are found, were laid down during periods of increasing drought, and that the crossopterygian-amphibian moved from one drying pond to another in search of moisture and thus gradually became adapted to the rigours of dwelling on land. On the other hand, R. F. Inger in 1937 pointed out that the red beds probably were deposited under constant conditions of humidity; he suggested that the first movements were inspired by a search for food (insects, etc.) across land under conditions of high humidity. At the present time in the humid tropics of southeast Asia and Indonesia, there are several fish genera that venture across land.

The subsequent vertebrate story is well known: the rise of the huge amphibians in the Permian; the appearance of reptiles in the Late Carboniferous and their early radiation in the Permian; and the decline of the amphibians and the rise of the great dinosaurs in the Mesozoic. The end of the Permian saw not only the end of the amphibians as dominant animals but also major changes in the sea, with many bryozoans, trilobites, most nautiloids and corals becoming extinct. (See AMPHIBIA; REPTILES; DINOSAUR.)

The Mesozoic saw the dominance of dinosaurs; the evolution of small mammal forms from the therapsid reptiles in the Late Triassic; the appearance of birds in the Jurassic, opossumlike marsupials and primitive placental mammals in the Early Cretaceous; the great radiation of birds in the Cretaceous; and the sudden extinction of the dinosaurs. Finally, there was the tremendous radiation of mammals during the Tertiary and the appearance of man in very recent times. (See MAMMALIA; BIRD; ANIMALS, PHYLOGENY OF.)

4. Associated Evolutionary Changes.—Compared with the major changes in dominant land species, comparatively minor changes occurred in the oceans from the Mesozoic to the present. The ammonite cephalopods were very important organisms in the Mesozoic, but died out with the dinosaurs at the end of the Cretaceous. Modern groups of corals appeared in the mid-Mesozoic, and modern families of marine snails were common in Cretaceous strata. Many families of marine clams originated in the Paleozoic, and the great majority of families go back well into the Mesozoic. Crustaceans are equally ancient.

Equally significant in any discussion of distribution is the history of land groups other than vertebrates. As mentioned earlier, insects are first known from the Upper Carboniferous and probably first appeared many millions of years before that.

By Late Permian times over one-third of the living orders of insects were established. By the Triassic all the ancient orders (except for the giant dragonflies—order Protodonata, which had wings up to 30 in. in spread) were extinct. The great majority of living orders were present sometime during the Mesozoic. The Tertiary fossil insects belong to modern families or, in many cases, even to modern genera. A few insects found in 50,000,000-year-old Baltic amber apparently belong to living species.

The nonmarine mollusks are equally conservative. A diversified fauna was already established in the Upper Carboniferous, and according to Cretaceous and Paleocene strata modern families and many modern genera were present. Some of these genera live apparently in the same area today that they did in the Paleocene. Species of the Recent epoch are common in Pliocene strata, and comparatively few of the Pleistocene species are extinct.

This conservative state of affairs contrasts greatly with the mammals. In this group orders arose in the Paleocene and modern genera in the very Late Tertiary. The reasons for this are exceedingly complex and a full discussion can be found in Simpson (1953) (see also EVOLUTION, ORGANIC). Basically, a type of organism such as a land snail, a reptile or a mammal will undergo an adaptive radiation, a rapid diversification, geologically speaking, by which it fulfills a role or series of roles in nature. After the rapid evolutionary change that produces a number of different

types, there is a stage, usually several times the length of the "explosive" diversification period, where the groups change only slightly. This stage can persist for long periods of time. Occasionally a group of organisms will have found a very suitable way of life under extremely constant environmental conditions, and under this regime the same genus can persist for millions of years. Opossums have changed but little since the Cretaceous; and virtually unchanged are "the horseshoe crab" (*Limulus*), dating from the Triassic, and *Lingula*, a brachiopod, from the Ordovician.

During rapid differentiation groups tend to spread rapidly as well as evolve quickly. When the initial major outburst is completed, diversification into the minor habitat niches occurs. A plateau of reasonable evolutionary stability is maintained until the opportunity for movement into a new region or a new ecological zone arises. Extinction of a group of animals can happen either through replacement by newly evolved, more efficient types (the Paleozoic cephalopods replaced the trilobites, and the mollusks possibly superceded the brachiopods), or through a change in environmental conditions so that the old group can no longer exist (possibly the great marine extinction at the close of the Permian and the dinosaur extinction at the end of the Cretaceous).

The stage of evolutionary activity that a group is in will have profound effects upon the meaning of current distributions. A group that appears to be in a relatively stable phase may represent a pattern of distribution much older than the pattern of a group that is rapidly evolving. Insects and land snails showed minor evolutionary changes in the Tertiary. They probably underwent their initial explosive evolution well back in the Paleozoic and Mesozoic. Mammals underwent their explosive evolution in the Paleocene and Early Tertiary and have continued to show rapid evolutionary change up to the present day.

III. GEOGRAPHICAL DISTRIBUTION OF LIVING ANIMALS

The distribution patterns of animals of the three main habitats—sea, fresh water and land—are usually discussed separately.

1. In the Sea.—It is significant that discussion of the marine distribution patterns is usually on a vertical, habitat or ecological rather than a geographic basis. The ocean presents a continuous medium only occasionally interrupted by major barriers (land masses). These barriers, in the course of geologic time, often have been lowered through encroachment of the sea across narrow necks of land (Bering strait, Isthmus of Panamá). Since most organisms have some form of floating or swimming larva the barriers in the ocean are more ecological than geographic. Also, the length of time that life has been present in the ocean has allowed the gradual movements of major types into essentially the entire geographic area with ecological conditions that would allow their successful reproduction and sustenance. The lower systematic categories, genera and species, and to a much lesser extent families do show at least partially geographically oriented distribution patterns. No faunal realms in the sea equivalent to Wallace's land divisions have been proposed, but some facets of marine animal geography have been presented by S. P. Ekman (1953).

2. In Fresh Water.—In contrast to the sea is the fresh-water habitat, which is, geologically speaking, extremely ephemeral. Fresh waters have existed for millions of years and have supported organisms since at least the Devonian, but individual lakes and river systems usually have a short life span. There has been a premium on organisms able to (1) pass through salt water barriers; (2) take advantage of passive dispersal by wind or other organisms (insects, birds, mammals, fish) from one body of water to another; (3) withstand a great variety of environmental conditions; and (4) start a permanent population from the introduction of one individual. The relative impermanence of fresh waters and the selection for organisms with at least some of the above attributes have resulted in few major groups of organisms colonizing fresh water. The successful invaders, however, tend to be very widely distributed, show an extreme amount of local variation in small bodies such as ponds and lakes and exhibit often very little specific level differentiation. Some species tend to be

world-wide in distribution, such as the fresh-water sponge, *Ephydatia fluviatilis*; others widely spread over a major geographic area in many types of fresh-water habitats, as for example the finger-nail clams *Pisidium* and *Sphaerium*; still others are confined within major drainage basins, as are most unionid clams and prosobranch snails.

The only important exception to these generalizations concerns the fauna of ancient fresh-water lakes—Baikal in Siberia; Titicaca in Peru; Nyasa and Tanganyika in Africa; Ohrid in Yugoslavia; and Lakes Poso, Towoeti and Matana in the Celebes. These lakes have well differentiated faunas which, though derived from more generalized species found in external drainages, have undergone considerable divergence from both the ancestral form and habits during long isolation in these unusually permanent fresh waters (fig. 2). The major southern land masses: Australia, South America and Africa, have endemic (native and confined) fresh-water fish and mollusk faunas, whereas the North American and Eurasian land masses have a high percentage of groups, and even species, in common.

3. On Land.—The land habitat is much more permanent than the fresh water, but its own special features have drastically affected the evolution and dispersal of land organisms. Water gaps, which usually form almost impassable barriers for terrestrial organisms, divide the land masses into three great blocks. Australia; the Americas; and Eurasia with Africa. It is now rather generally accepted that the rough outline of the present continental masses has persisted through most of geologic time (see ZOOGEOGRAPHY). There have been many minor alterations in contours and several major periods of mountain building. Both the Bering strait and Isthmus of Panamá, for example, have been alternately above and below water frequently during geological time. But at least portions of the main land masses have existed probably since the origin of the land animals and certainly during the major evolution and dispersal of the land vertebrates. These major land masses have at times been isolated from each other for considerable periods by more or less completely impassable water gaps. Notably Australia and, in the mid-Tertiary, South America formed "island continents" For millions of years at least, land mammals were not effectively introduced from other regions.

Evolution proceeded in the northern land masses with the replacement of the early mammals by newer types. The "theatres of evolution" in Australia and South America produced diversification within the primitive stocks. When South America and North America were rejoined in the Late Pliocene and Pleistocene there was a sudden exchange of groups, with many of the more advanced North American types quickly replacing the more primitive South American forms. Xustralia has been effectively shielded from advanced organisms until the coming of man, and its fauna of primitive mammals, insects and other organisms is famous.

Less obviously spectacular than the water gaps but equally important in understanding the distribution and diversity of land animals is the extreme variability of environmental conditions on land. Life is based on chemical reactions in an aqueous medium. On land the availability and retention of water is a critical problem. Extremes in water availability range from scorching deserts with years between rainfalls to areas with over 300 inches of rain annually and a ground humidity at or near saturation. Temperature is relatively constant in the water, but on land it varies widely

from region to region and can fluctuate greatly within an area from season to season or even from day to night. Topographic features influence climate (rainfall, temperature and seasons) greatly and often a few miles is all that separates a near desert from a lush rain forest. These features at least temporarily tend to isolate animals into little groups and lead to extensive adaptations and diversifications in ways and areas of living.

Water gaps isolate geographic areas, and temperature and rainfall levels will generally fall into banded or otherwise zoned geographic patterns. The shifting gaps of water as well as climatic changes have channeled much of terrestrial evolution and dispersal along geographic lines, and the past history of animal dispersal can be glimpsed through a study of the geographic distribution of living organisms. This can be approached on the basis of distribution of animal groups (geographical zoology) or by the study of animal groups of a particular area (zoological geography). This sort of study has been done primarily for the land mammals and birds (see ZOOGEOGRAPHY) with occasional information on the cold-blooded vertebrates.

As mentioned earlier, the inventory of nonvertebral groups is very incomplete. Knowledge of their classification and distribution is so fragmentary that it is not yet possible to analyze fully their present or past distributions as has been done for the better known vertebrates. Evidence gradually accumulating about such diverse groups as termites, caddis flies and land snails suggests that the distribution patterns of the invertebrates show little conformity with the mammalian and bird patterns recognized by classic zoogeographic divisions. In particular, the invertebrate faunas of South America, south Africa and Australia-New Zealand often show striking similarities. Although very few vertebrates show discontinuous distribution in the southern hemisphere, interrupted distribution patterns are normal in many nonvertebral groups.

There is a very simple possible explanation for these differences in animal distribution patterns. The invertebrates and lower vertebrates had their adaptive radiations at a much earlier period than did the birds and mammals. During the Tertiary when sweeping changes in mammalian evolution and distribution were happening, the invertebrates were undergoing comparatively minor changes. They had probably reached more or less of a balance with their environment, and both Tertiary evolutionary changes and geographic dispersal, with obvious exceptions such as movement onto oceanic islands and into previously glaciated areas, were minimal. The present-day patterns of distribution shown by nonvertebral land-dwellers may represent much earlier adaptive radiations and dispersions than do the distribution patterns of mammals. Tertiary rates of evolution of invertebrates were much slower, and thus rates of dispersal may have been equally retarded.

IV. FACTORS AFFECTING ECOLOGICAL DISTRIBUTION OF LIVING ANIMALS

Each of the three major habitats presents its own set of problems for the successful dispersal and maintenance of life; but unless certain basic criteria are satisfied, no life can exist. Under conditions of extreme adversity life cannot survive: new lava flows; craters of active volcanoes; snows of the extreme polar regions or high mountains; springs rich in carbon dioxide; depths of the Black sea, abundant in hydrogen sulfide; and the Dead sea with its high concentrations of chlorides and bromides of magnesium are among the few areas where no animal life can be found.

These regions lack one or more of the following requisites for animal life: (1) an available set of chemicals to allow completion of metabolic activities and reproduction; (2) suitable temperatures for necessary activities; (3) proper density and pressure for chemical activities; (4) supplies of new materials and energy sources with controlled release of energy; and (5) shelter from lethal light rays. Life on earth evolved into the diverse forms seen today in accordance with the principles of the general environment outlined above.

Every species and individual has certain basic requirements, the fulfillment of which must be accomplished before its life cycle can be completed. Each of the many factors affecting the species varies at some time or other, and each species can tolerate a cer-

FIG. 2.— ANCIENT LAKE SPECIATION: (A) TYPICAL THIARID (MELANOIDES TUBERCULATA) (B-E) LAKE TANGANYIKA DERIVATIVES: (B) TIPHOBIA HOREI (C) SPEKIA ZONATA (D) LIMNOTROCHUS KIRKI; (E) PARAMELANIA DAMONI

tain range of variation for each factor. Often the range of tolerated conditions can be greatly extended through avoidance, either a simple movement into a more favourable area or a complex physical adjustment involving a cessation or lowering of activity (dormancy) during the unfavourable period.

Each species has an innate capacity for reproduction far beyond the quantity needed to replace the living generation. Every organism, at some point in its life history, shows the tendency toward or has the capacity for dispersal, the spread by scattering of the original population from an occupied place into new areas. If the dispersed organisms settle in an area where the environment, the totality of factors affecting the organism, is favourable, the distribution, or area occupied by a species at any one moment, will be extended. Often there are barriers that prevent successful dispersal. Organisms are controlled in nature by limiting factors, materials for which there is an irreducible minimum needed or physical conditions that must be maintained within certain limits. The extremes of these factors which are acceptable to the organism represent that organism's limits of tolerance.

Every kind of animal in each of the three major habitats has its own particular limits of tolerance for different factors, its own distribution and pattern of dispersal and its own set of mechanisms for adjusting to or avoiding one or another factor of the environment. There are, however, certain basic adjustments and reactions common to all animals and certain limits of tolerance that cannot be exceeded by any animals. Also, each of the three major habitats presents certain major problems to which different groups of animals have had to adjust.

Basically, all animals must adjust to water, temperature, light, food, oxygen and carbon dioxide factors and to pressure problems in the environment. To indicate the relations of animals to particular factors, a convenient terminology has been established. For example, habitat preferences on land in relation to water supplies are called xerophilous, mesophilous or hygrophilous, going from the driest habitat to the wettest. The range of tolerance, or ecological valence, for any physical factor can be described by the prefixes steno-, meaning narrow, or eury-, meaning wide, Stenothermic, stenohygrous and stenoxymbiont, for example, refer to narrow limits of toleration for variation in warmth, moisture and oxygen supply.

Environmental conditions change greatly not only from place to place but also in one area from season to season. In the temperate and arctic regions the obvious seasonal variation is from warm to cold; in the tropics the variation is often from dry to wet. To survive during seasons when conditions greatly exceed their normal limits of tolerance, animals have developed a remarkable group of responses known collectively as dormancy. These involve varying degrees of slowing or cessation of activity (quiescence), metabolic as well as locomotive. The most commonly known examples are hibernation and estivation.

Hibernation is a general term for winter dormancy and is associated with relatively low temperature and physiologically inaccessible water (snow and ice). Estivation is the term for summer dormancy in the temperate zones and dormancy during the dry season in the tropics; it is associated with relatively high temperature and physically inaccessible water (drought). A bear in its winter den; an earthworm in its mucous cocoon; a tree snail cemented to a limb with saliva; and pond protozoans in cysts are all examples of estivating or hibernating animals.

Two special cases deserve mention, not for being different in kind but because they carry dormancy to extreme lengths. The stage in an insect's (or other arthropod's) life cycle in which the animal is in a physiological state of arrested development is usually termed the diapause. Diapause can occur in the egg, larval, pupal or adult stages of insects. Sometimes it occurs in every generation and sometimes in only one of several generations each year. The line between diapause and quiescence is sometimes tenuous.

Even more striking is the anabiosis of certain protozoans, nematodes, rotifers and tardigrades. They normally live in water films on damp soil or vegetation. As dryness increases they encyst into a resting stage that has almost unbelievable powers of resistance

to freezing, having survived exposure to temperatures of -253° C. (near absolute zero), and to drying, having been revived from dried mud after 27 years. Whether all these processes are physiologically equivalent is still uncertain, but all perform the ecological function of enabling animals to survive unfavourable conditions.

1. Water.—Life began in water and the chemical activities of metabolism generally take place in a watery medium inside the animal. Each animal must maintain the internal watery environment at or near a certain level or die. Although the level of water can vary greatly from one stage in the life cycle to another, it always must be maintained within certain limits. Closely associated with the water supply is the question of proper concentration of salts and ions within the cell; the proportions of these substances in most marine animals are approximately the same as in sea water. In fresh water, the body fluids are hypertonic (more concentrated than the outside medium) and the animal has to prevent too much water from accumulating in the body. On land, animals must conserve water. Water relations are discussed in detail under the major habitats.

2. Temperature.—A distinction must be drawn between the temperature levels at which an organism can maintain normal activities and those which an animal can withstand. (All temperature measurements in this article are given in the Centigrade scale [0° C = 32° F. and 100° C. = 212° F.])

Two blue-green algae, *Phormidium bijahense* and *Oscillatoria filiformis*, live in thermal springs at Yellowstone National park where the temperature is 85.2° C. (about 186° F.), and bacteria have been reported from waters reading 88° C. The upper limit for animals is probably somewhere near 55° C., at which point body chemicals may undergo destructive changes. In East Indian thermal springs, 57 species of animal were found in waters $36-40^{\circ}$ C.; twelve in $41-45^{\circ}$ C.; four in $46-50^{\circ}$ C.; and only four in waters over 50° C. At the other extreme, a cave silphid beetle, *Astagobius angustatus*, carries out its life cycle in ice grottos where the temperature ranges from -1.7° to $+1.0^{\circ}$ C., and the marine clam, *Yoldia arctica*, is found only in waters 0° C. or colder.

Generally most animals are active somewhere between 6° and 35° C. Individual species will have a range of 16° to 20° in which they are active. Most of the known animal species are poikilothermous, that is, they cannot regulate their body temperature except by moving into warmer environments. Birds and mammals are homoiothermous, that is, they are able to regulate their body temperature by an internal physiological control.

Organisms vary greatly in their ability to withstand exposure to temperatures beyond their normal range of activity. Oceanic and tropical species will often die when a change of a few degrees occurs. Temperate and arctic species show a gradation in resistance to freezing. Some organisms (most mammals, some crustaceans) are killed by chilling to a point above actual freezing; others (many mollusks, insects, fish) can survive partial freezing of their tissues and can endure temperatures 20° or 30° below the freezing point of pure water. Finally, there are the anabiotic organisms mentioned above that can withstand temperatures near absolute zero.

3. Light.—Animals must receive their food at least indirectly from plants that depend on light for photosynthetic activity. Besides this secondary dependence on light, most animals have a daily rhythm of activity and recuperation, which is correlated with the alternation of day and night. Many animals orient themselves and move in relation to light. Quite often light seems to be the factor which triggers breeding behaviour and insures that all members of a species will breed at nearly the same time. Some animals need exposure to light in order for the young to develop. Corals with symbiotic algae need light for proper functioning, though this may reflect more directly the need of the algae than the coral.

4. Food.—A sufficient supply of organic food matter must be available before an area is inhabitable by animals. Usually the amount of available food is the deciding factor in controlling the density of life (number of individuals per unit area). Animals may feed on plants (herbivorous), animals (carnivorous) or both (omnivorous) with complete intergradation between categories.

The diet may be limited to one plant or animal (stenophagous) or a variety of prey (eurypagous). The former often, have limited distributions, the latter, wide ones. Animals in caves, ground waters or oceanic deeps are far removed from the plant base of nutrition, but receive organic matter by seepage or gravity.

5. Oxygen and Carbon Dioxide.—Few animals, notably parasites and certain worms and larvae inhabiting waters polluted by garbage, can live without free oxygen. In other cases, however, oxygen is often a limiting factor in aquatic habitats. Polluted waters, sea areas with minimal circulation of water and many fresh-water lake bottoms have little free oxygen and therefore sparse animal populations. Excess carbon dioxide is equally harmful and land areas near fumaroles (holes where carbon dioxide escapes from the earth) form death traps. Carbon dioxide in water often limits the distribution of aquatic organisms. On land, oxygen is plentiful enough to seldom create a problem.

6. Pressure.—Animal life apparently can exist and function only in the range of temperature and pressure in which water is a relatively warm solid (ice) or a cool to warm liquid. On land, pressure is important only in high mountain areas, mainly because of decreased oxygen tension rather than a direct physical effect. Little is known of the effects of pressure on deep-sea organisms. It is known, however, that chemical reactions are speeded or hindered by pressure changes, but the metabolism of deep-sea creatures is essentially unstudied.

V. ANIMAL LIFE IN THE SEA

More than two-thirds of the earth is covered by ocean waters, which reach a greatest depth of 10,863 m. (almost six nautical miles) and an average depth of 3,975 m. (slightly more than two nautical miles). All oceans are connected, though land barriers, some of recent duration, form essentially two main divisions of the oceans—the Atlantic and Arctic with adjacent seas; and the Pacific and Indian oceans. These two divisions are joined in the north by the Bering strait, and in the south by broad bands of water. Smaller seas such as the Mediterranean and Baltic are connected to the major seas by narrow straits. Only a few isolated bodies, such as the Aral and Caspian seas, are separated from the major systems.

Except for those few regions mentioned earlier that are barren of life, animals are found, in widely differing degrees of abundance, throughout all levels and in all seas. The diversity of animal form in the sea is much greater than on the land. Ignoring purely parasitic types, of all the classes of free-living animals, only four—Onychophora, Chilopoda (centipedes), Diplopoda (millipedes) and Amphibia—are completely absent from the sea, while at least 27 seem to be confined to the oceans. Life originated in the ocean and probably was 500,000,000 years old before moving into fresh waters and onto land.

Despite the greater variety of types, the number of species of marine animals is only about one-fifth of the total number of animal species known to scientists. This is correlated with the relative uniformity of habitat conditions and the comparatively minor barriers to dispersal present in the oceans. Only in the transition zones (ecotones) between sea and land (shore areas) and between fresh water and sea (estuaries near river mouths) do conditions fluctuate widely, and here are found species with very limited geographic range because of their restricted dispersal capabilities.

A. CONDITIONS INFLUENCING SEA LIFE

Although living conditions in the sea are uniform compared with conditions on land and in fresh water habitats, there are distinct differences between areas and zones of the sea that profoundly affect the distribution and abundance of life. The basic chemistry and physics of the oceans are discussed in the article OCEAN AND OCEANOGRAPHY; here it is possible only to outline briefly some of the ways in which different chemical and physical factors govern the distribution of marine animals (see also MARINE BIOLOGY).

1. Physical.—Light.—The rate at which the different length rays of light are absorbed in the water depends upon several factors, including the angle at which they strike the water, the degree

of surface disturbance (waves) and the amount of suspended particles in the water. Generally the ocean is divided into three strata of light: (1) The euphotic stratum, variously defined as running from the surface to 30 or 100 m. depth, has abundant light and supports most of the phytoplankton (see PLANKTON) that ultimately provides food for all marine animals—the herbivores and their predators; (2) The dysphotic or twilight stratum extends from 30 or 100 m. down to 200 or 500 m. and has very little light, consequently little phytoplankton, few herbivores and many predators. (3) The aphotic stratum lacks any light other than that provided by luminescent creatures, has no phytoplankton or herbivores, but only predators and scavengers. The euphotic zone is shallowest near the poles, and in polar waters life is densely concentrated in a rather narrow zone compared with tropical oceans.

Pressure and Density.—Most marine organisms are slightly denser than sea water. In order to keep from sinking to the bottom they must have special flotation mechanisms (see Pelagic Division, below). Also the density of sea water supports the bodies of marine animals and minimizes the need for supporting elements. Pressure increases tremendously from the surface to the depths, but seems to have relatively little influence on animal life. Many organisms will travel 400 m. vertically each day, while whales can move from the surface to below 1,600 m. Pressure affects the volume of gases and certain chemicals greatly. Most fish have a swim bladder, an air-filled sac that adjusts the density of the fish to that of sea water and enables it to stay at a given pressure level with a minimum of exertion. Vertical movements require changes in the amount of gas present and this is done by secretion or adsorption of gases through the membranes of the swim bladder. Many deep-sea fishes lack a swim bladder, and those that have one are often ruptured by the expanding gases when brought from the depths to the surface in a collecting net.

Waves, Tides and Currents.—Waves may reach to a depth of 500 m. and the adjustment that sea animals make to them takes several forms. In the areas of wave movement fixed animals such as Alcyonaria (Spongodes) and bryozoans are flexible, and bend with the water motion, as wheat in a wind; corals tend to have a rounded, flattened or thickened mass. In quieter waters the alcyonarians have stiff skeletons, and the corals have lightly calcified, finely branched stalks. In areas of wave pounding, where the force may reach 15 tons per square metre, the animals must protect themselves from injury and from being torn loose. Barnacles cement themselves to the rocks, mussels (*Mytilus*) attach themselves by byssus threads and snails anchor by a muscular foot, as in periwinkles, limpets and abalones.

Tides play an exceedingly important role in the life of shore zones (see Benthic Zone, below).

Ocean currents, continuous flows of water as opposed to the oscillations of tides and waves, mix the waters from different parts of the ocean. This maintains a more or less uniform chemical composition of the water, carries dissolved oxygen to all parts of the ocean and serves to spread the planktonic larvae of marine animals. For example, adult ghost crabs (*Ocypode albicans*) do not live north of New Jersey, but young, swimming stages have been collected off Rhode Island and Massachusetts, where they had been carried by currents from the southern breeding grounds. Currents are based on many factors: variations in temperature, salinity and turbidity; effects of the earth's rotation; and wind, to cite the major examples. The permanent currents (see OCEAN AND OCEANOGRAPHY) have particular impact on marine life, especially the areas of upwelling, where deep waters rich in nutrient are brought up to the surface. This upwelling results in regions that are rich in phytoplankton, herbivores and their predators. Areas off Peru, California and Portugal are good examples of such upwellings.

Heat and Temperature.—Most of the sun's radiated heat falls on the ocean and is used in evaporation of water that eventually drops back on the ocean or on land. While the sun's rays are fundamentally important in life processes, the related phenomenon of temperature is more directly responsible for limitations of animal distribution. Ocean temperatures range from about -3° to 42° C. although surface waters, except in lagoons and tide pools,

seldom reach more than 30° C. Polar and tropical seas are relatively uniform in temperature, whereas temperate latitudes show greater fluctuations. The annual variation on almost $\frac{3}{4}$ of the ocean surface is less than 5°.

Temperature stratification is both horizontal and vertical. Generally, surface temperature decreases from the tropics to the poles, though this is greatly modified by currents that move warm waters toward the polar regions. Since cold water is denser than warm water, a constant flow of cold polar water is pushed down and under by the warmer tropical currents. Even near the surface in tropical waters the temperature drops rapidly. If it is 25° C. at the surface, at 200 m. it may be 20° C.; at 1,200 m. 5° C.; and in the abyssal regions, always 1° to 2° C. Seas, such as the Mediterranean, Gulf of Mexico, Red sea and Caribbean sea, that are connected to the larger masses by shallow straits have warmer bottom layers caused by (1) sinking of partially warmed surface water; (2) inflow of only slightly colder water from the major seas; and (3) exclusion of cold, deep waters by shallow entrances.

Many marine organisms are rigidly limited by water temperatures. The great colonies of reef-growing corals cannot tolerate water cooler than 20° C. and thus are restricted to tropical seas. Nearly all marine distributions can be correlated with temperature. Thus the European oyster (*Ostrea edulis*) breeds in water above 15° C., while the Portuguese oyster (*Ostrea angulata*) requires temperatures above 20° for breeding. Rates of metabolism are also greatly altered by temperature change. Often, size within a species increases from warm to cold waters. The snail *Nassarius clausus* is 12.7 mm. high in waters of the Skagerrak (an arm of the North sea south of Norway) and reaches 38 mm. at Spitsbergen, in the Arctic. The isopod *Serolis bromleyana* measures 16 mm at 739 m. depth and 54 mm. at 3,600 m. The increase in number of vertebrates in related fishes from south to north waters (Jordan's rule) is well documented.

2. Chemical.—Composition of Sea Water.—Sea water is an assemblage of dissolved solids and gases, with a variable amount of suspended inorganic and organic matter. The continuous mixing of waters by currents results in a generally uniform composition. Salinity averages about 3.5%, with local variations caused by melting ice, river inflow or high evaporation. Thus polar surface waters may have a lower salinity because of ice melting, much of the Baltic sea has a lower salinity because of the many rivers it drains, while the Red sea and Mediterranean have slightly higher salinity because of rapid evaporation and little fresh water inflow. Estuaries have lower salinities, grading from that of open ocean water to that of the pure fresh water far upstream. The size and presence of species living in these areas can be closely correlated with the degree of salinity. Some animals, such as the mussel *Mytilus* and the lugworm *Arenicola*, are euryhaline; others, notably reef corals, are stenohaline and can tolerate almost no lowering of salinity.

Animals feed directly or indirectly on plants, and the abundance of plant life determines the numbers of animals. Plants need carbon dioxide, nitrogen compounds, phosphates and many trace chemicals; these elements must be present in the euphotic zone, not in the depths. Ocean areas supplied by river waters (Atlantic, Arctic) receive vast quantities of minerals from the fresh waters. All oceans receive animal waste products and decomposing animal bodies. Much of the latter sink to the ocean floor where the chemicals produced through decomposition are unavailable to plants unless carried up by a vertical current into an upwelling. In a shallow sea where waters are completely mixed decomposition substances are readily available. The great productivity of the North sea (especially along the Dogger bank) and of the waters of the Newfoundland banks are the result of vertical mixing and river inflow. The coasts of Portugal and Peru are rich in marine life because of deep upwellings. In contrast, the open eastern Pacific with few inflowing rivers and no major upwellings is poor in surface life.

Calcium is important to animals in building supporting structures. In sea water calcium sulfate is precipitated by ammonium carbonate into forms used to make spicules, skeletons, shells and armour. This reaction proceeds quickly at 26°–29° C., but very

slowly at low temperatures. Thus the greatest use of calcium by animals occurs in tropical seas. In colder waters animals have soft bodies or skeletons composed primarily of silicon or protein. Calcareous sponges are restricted to shallow waters, and the siliceous hexactinellid sponges are found only in deep waters.

Oxygen is generally mixed in through surface disturbances and carried throughout the oceans by currents of polar surface water. Warm water carries less oxygen than cold water; therefore, warm areas that lack polar currents, such as the eastern Mediterranean, have little oxygen in their depths. If a rich surface fauna showers decomposing animal bodies on an oxygen-poor bottom, poisonous deposits of hydrogen sulfide can accumulate to the point of near exclusion of life (Black sea and some isolated lagoons).

Water Relations.—Exclusive of skeletal structures, the body of marine animals consists of 60% to 96% water. In this body water are suspended complex chemicals (protein, colloids, organic nonelectrolytes and electrolytes) necessary to life. In most marine animals the concentration of these chemicals is at approximately the same level as the salt concentration in sea water (isotonic). If exposed to sea water by a permeable or semipermeable membrane, these cells will neither give water to nor take water from the external environment. The body fluid of most invertebrates varies in concentration as the salinity of sea water changes (poikilostotic). Many marine invertebrates can function in fluctuating salinities by salt loss or by swelling, but most species can stand only slight variations before death ensues. Species in estuarine situations generally can withstand a wide range of salinities, usually by regulating the water loss or intake. These homoiosmotic organisms accomplish this regulation by a variety of means fundamentally similar to those used by fresh-water organisms (see below). Generally the fresh-water forms must prevent or minimize water intake and salt loss, since the concentration in their body fluids is greater than the salinity of the surrounding medium.

Marine vertebrates have the opposite problem: the concentration of their body fluids is well below the salinity of sea water, and they must prevent or minimize water loss and salt intake. Elasmobranch fishes do this by having a relatively impervious body covering, by maintaining a high urea level in the blood and by secreting a dilute urine. Modern bony fishes (teleosts) actively secrete salt through the gills, drink large quantities of water and conserve water by passing little urine. Marine reptiles, birds and mammals have an impervious body covering; breathe air, thus respiratory surfaces are protected from salt water; and generally eat fish whose body fluids have low salt concentrations. Species feeding on invertebrates may satisfy their water needs through metabolizing the fat in their food. E. H. F. Baldwin (1948) gives an excellent summary of osmotic relations of animals.

B. ZONATION OF MARINE ANIMALS

The distributional division of marine animals into benthic (bottom dwellers) and pelagic organisms (ocean dwellers) parallels the strictly ecological distinction of benthos, nekton (swimmers) and plankton (floaters) (see ECOLOGY, ANIMAL). All are terms of convenience, since most benthic species will have a brief floating or swimming larval stage, and some occasionally swim as adults (scallops, flounders). Generally, pelagic species are those permanently independent of any support other than water. Benthic forms are those that rest on the bottom, even if only occasionally.

The ocean habitat can be further divided in several ways. One scheme is presented in the article MARINE BIOLOGY. The area from the high tide mark to the limit of attached plants that carry on photosynthesis is called the littoral zone. The deep-sea province farther out is divided into the archibenthic (to 1,000 m.) and abyssal (below 1,000 m.) zones.

Generally, the limit of the littoral zone is at the edge of the continental shelf, or about 200 m. deep. The littoral zone can be divided into the (1) supratidal splash zone; (2) intertidal zone; (3) shallow-water zone, normally affected by waves; and (4) still water zone, extending to the beginning of the deep-sea province.

1. Pelagic Division.—Living matter is slightly heavier than sea water, and a flotation mechanism to prevent sinking is an essential adaptation for pelagic life. Floating is accomplished in

FROM R. HESSE, W. C. ALLEE AND K. P. SCHMIDT, "ECOLOGICAL ANIMAL GEOGRAPHY": REPRODUCED BY PERMISSION OF JOHN WILEY & SONS, INC.

FIG. 3. — PELAGIC LIFE FLOTATION MECHANISMS SHOWING USE OF BRISTLE-LIKE EXTENSIONS TO RETARD SINKING: (A) MOLLUSK (GLAUCUS); (B) FORAMINIFER (GLOBIGERINA); (C) CRUSTACEAN (CALOCALANUS)

many ways. Reduction in weight through economy in skeletal material is shown by Foraminifera (*e.g.*, *Globigerina*); snails (*e.g.*, heteropods and pteropods); squids (*e.g.*, *Loliginidae*); and fish (*e.g.*, *Crystallogobius*). Reduction in specific gravity through absorption of water is seen among all pelagic coelenterates, chaetognaths, tunicates and many mollusks and fish. Storage of materials lighter than sea water is demonstrated in the ctenophore *Beroë*, the protozoan *Noctiluca* and in the radiolarians; all these organisms contain a special fluid of low specific gravity. Oil droplets are stored by radiolarians and *Noctiluca*. Fat bodies are common in copepods and cladocerans, and enable the huge basking shark (*Cetorhinus maximus*) and ocean sunfish (*Mola mola*) to lie motionless at the ocean surface. Inclusion of air or other gases in part of the body is seen in the air sacs of siphonophores, the air chambers in the shells of the mollusks *Nautilus* and *Spirula* and the air bladder system of bony fishes. Tiny plankton organisms support themselves by increasing their body resistance to sinking through development of long bristles (fig. 3) and by enlarging the ventral surface through flattening of the body, as in jellyfish and many larvae. Support is also gained by muscular action: the oar-shaped limbs of crustaceans; the lashing cilia of larvae and ctenophores; the water-propelling devices of pulsating jellyfishes, tunicates and squids; the undulating fin motions of pelagic cephalopods, heteropods and rays; and the body undulations of fishes, whales and seals. Generally, several mechanisms are combined in one organism.

Herbivores and carnivores of all sizes are found in the pelagic division. The smallest forms are the planktonic animals, whose independent movements are insignificant when compared with wa-

ter motion. The larger forms are the nektonic animals, swimmers that are reasonably independent of currents; strictly speaking, they comprise only certain fishes and cephalopods, marine reptiles and mammals. The categories, however, are not sharply distinguished, such giants as the ocean sunfish being practically planktonic, and most small organisms being capable of some movement in still water. A good review of the plankton is given by A. C. Hardy (1956).

Oceanic pelagic animals spend their entire life in the plankton (holoplanktonic). These species can generally be found in all seas with suitable temperature conditions. Nearer to shore an additional element is present, animals which spend part of their life in the plankton and part on the bottom. They may be planktonic as adults, breeding on the bottom (meroplanktonic), or larval forms of benthic species that are dispersed in the larval stage.

No sponges, ascidians, brachiopods or bryozoans are pelagic as adults, and few actinians, echinoderms; worms (other than chaetognaths), clams; and snails (other than a few opisthobranchs and the heteropods and pteropods) are represented in the pelagic division. Radiolarians, jellyfishes (except *Lucernaria*), siphonophores, most ctenophores, chaetognaths, heteropods, pteropods, salpas and appendiculates are exclusively pelagic. Copepod crustaceans and cephalopods and fish are also important elements.

Below the level of the light penetration, there is still a considerable pelagic fauna consisting of fish, coelenterates, crustaceans, cephalopods and whales. No plant food is available, and the mid-zone pelagic fauna is one of predators. The water is still, except for slight currents, the temperature is uniformly low and the pressure per square inch is great. Luminescent organs are widely developed, and many deep-sea forms have huge eyes that enable them to spot the tiny glow from luminescent organs of other animals. Since sampling of the fauna has been very poor, little is known of deep-sea animals.

2. Benthic Division. — Conditions vary so widely in this division that it is difficult to make generalizations concerning its animal life. Even breaking it into its vertical strata does little to simplify the problem. A. Bruun (1956) provides excellent data on the deep-sea organisms, while C. M. Yonge (1949) treats the seashore and A. C. Hardy (1959) the bottom fauna. Remarks here are limited to a very few generalizations.

Both the number of marine species and the number of individuals are richest in the littoral benthos, especially in the subtidal areas. Problems of survival are the fewest, and both the pelagic and deep-sea faunas seem to be derived evolutionarily from littoral organisms. From the littoral zone, migrations, over geological time, have been made into the tidal zones, onto land, into brackish waters and finally into fresh waters.

The type of bottom has a profound influence on the habits and adaptations of life in the littoral zone. Sand and mud bottoms will have animals modified for burrowing or plowing through the substrate; clams having smooth flat shells, muscular feet for digging and long siphons projecting above the substrate for filtering food and breathing; echinoderms and worms eating their way through the sand and extracting nourishment from the debris; predatory snails, crustaceans and fish feeding on the other organisms.

Rocky shores are characterized by stationary (sessile) animals; attached worms, sponges and coelenterates; mussels anchored by byssal threads; snails secured by a muscular foot; and crabs, snails, fish and a myriad of other animals hiding in every conceivable rock crevice. Many of these organisms filter food from the water washed over them (barnacles, worms, bryozoans, clams); others graze on algae (snails); and many prey on other animals or scavenge (snails, echinoderms, crustaceans).

A coral reef, a special form of rocky shore formed by the calcareous skeletons of coelenterates, shelters an even more diverse fauna than a pure rock shore. Reef-building corals are limited to tropical seas and cannot grow in depths greater than 50 m. because the symbiotic algae associated with the coral-forming animals must have light to carry on photosynthesis. Coral reefs are zoned, with massive, blocklike colonies in the breaker zone and delicate, branched forms in calmer water. Associated animals are similarly

oriented.

The littoral zone is greatly influenced by tidal rhythms and by the light alternations of day and night. Behaviour, breeding and colour are often correlated with light conditions. The tidal fluctuations expose to the air, for varying periods each day, the organisms of the intertidal zone. Many mechanisms for coping with water conservation, temperature variations, feeding problems, reproduction and salinity variations have developed in intertidal animals.

Estuaries, with fluctuating salinity levels, have a highly limited fauna and form a special ecotonal habitat between the sea and fresh water. In tropical and subtropical regions the mangrove with its associated brackish water fauna is a special type of estuarine habitat.

In contrast to the littoral zone the deep-sea area is without light, except for luminescence, and has no plant life. Only scavengers and predators exist in this domain. The recovery of more animals from great depths, due to improved methods of collecting, has proved, contrary to former opinion, that the ocean depths have a diverse fauna. Animals have been collected from 10,190 m. in the Philippine trench.

Abyssal creatures are relatively scarce compared with littoral forms, rather small in size and white or dark monochrome in colour. Many of these forms burrow in bottom ooze, but some, certain crustaceans, walk on stiltlike legs, and others creep over the surface. The topography of the bottom is as varied as that of littoral waters, and life is similarly specialized. The deep basins will often have endemic species, while shallow waters (above 1,000 m.) may have widely distributed forms around the fringes of the deeps. Stalked crinoids and many other ancient groups are confined to deep seas. The deep sea is not just a refuge for ancient types, for relatively modern mollusk groups (turrids) also live there.

Many deep-sea organisms were first recorded from shallow waters in the Arctic and Antarctic, only to be subsequently discovered in the deep seas between. Thus the old idea of bipolarity in distribution of marine animals had to be abandoned.

VI. ANIMAL LIFE IN FRESH WATERS

Probably less than 2% of the earth's surface is covered by inland bodies of water. These are generally small, only 17 lakes and inland seas having areas of more than 10,000 sq.km. An ecological division is made into salt and fresh waters, with the latter divided into lenitic, or standing waters (bog, marsh, swamp, puddle, pond, lake) and lotic or flowing waters (spring, stream, river). Many flowing waters drain great basins and eventually empty into lakes or the seas. Standing waters range from water films after rains, temporary ponds in small depressions that hold water a few weeks a year, permanent pools and small lakes to ancient deepwater lakes.

A. CONDITIONS INFLUENCING FRESH-WATER LIFE

The same factors that limit marine distributions act in fresh waters. Light penetrates very little into fresh water; temperatures fluctuate much more widely than in the ocean; calcium may be abundant (hard water) or absent (soft water); nitrate and phosphate supplies vary widely; some waters become clogged with organic debris; oxygen is abundant in streams but absent from many lake bottoms at least part of the year; currents may be swift or absent; and waters may be polluted by man. In addition, fresh-water life has to contend with the basic problems of osmotic regulation and effective dispersal. All these factors help determine the local distribution of organisms within an area since each species has its own limits of tolerance for variations in these conditions. Equally important in temperate areas is the fact that water is most dense at 4° C. at which temperature it sinks into the warmer water below. Below this temperature, however, water becomes less dense and at 0° C. freezes; therefore ice forms on the surface and, except in very shallow areas, does not reach the bottom. Because of this phenomenon some animals can winter over in the water beneath the ice. In some cases organisms can even withstand freezing in ice for relatively protracted periods.

The fragmentation of fresh waters into small bodies isolated from each other by ocean or land barriers, their very low salt

content and their geologically brief life span have molded the habits of fresh-water organisms and restricted successful colonization to a comparatively few groups. Arthropods, mollusks and vertebrates are the dominant fresh-water organisms. Few sponges, hydrozoans, polychaetes, bryozoans, nemerteans, mysidaceans and amphipods reached fresh waters. Decapod crustaceans and fishes and clams are primarily marine but well represented in fresh water, while nematodes, turbellarians, oligochaetes, leeches, isopods and snails are found in all habitats. Rotifers, cladocerans, water mites and nematomorphs are predominantly fresh water; and tardigrades, gastrotrichs and ciliate and mastigophoran protozoans are more numerous in fresh water than in the sea. Only the branchiopods, except for a few forms, and the syncarid crustaceans are exclusively fresh-water dwellers. Amphibians, which generally must spend part of their life cycle in water, also wander widely on land, where they are most often found only under conditions of high humidity. Although insects are predominantly terrestrial, a few families live in fresh waters and many orders undergo their larval stages there.

B. SPECIAL FACTORS

1. Low Salt Content.— Since the salt content of fresh water is very low compared with both sea water and animal body fluids, there is a constant tendency for water to pass into the animal and dilute the body fluids. This can be combated and minimized by two general methods, a reduction in exposed permeable areas and excretion of copious quantities of very dilute urine. A hardened (chitinous or sclerotized) body covering in invertebrates (leeches, crustaceans, insects), the scales of fish and reptiles, the skin of mammals and the slime covering of eels and snails all represent means of reducing water intake. Gill breathers and forms such as amphibians with unprotected skin surfaces will absorb more water than air breathers or forms with protected body surfaces. Excretion of water is accomplished through the contractile vacuoles of protozoans, flame cells of flatworms (platyhelminthes) and various nephridial and glandular organs of higher animals.

Probably associated with the low salt level of fresh waters are the relatively few and large eggs laid by fresh-water animals as compared with marine relatives. Embryos of marine organisms apparently often absorb chemicals from the water, a feat which could not be accomplished by organisms working against the fresh-water osmotic gradient. Also, while marine organisms depend, to a large extent, on egg or larval dispersal by currents, fresh-water organisms in running waters would be swept away and could not move against the current. Most fresh-water organisms carry the eggs on or in the body or attach them to anchored structures. Compared with marine animals, free-swimming fresh-water larval forms are few; most of the young hatch as miniature replicas of the adult. Clam larvae (glochidia) are free for a while before parasitizing a fish; copepod, branchiopod and ostracod crustaceans, some insects and many amphibians have a free-swimming larval stage.

2. Relative Impermanence of Fresh Waters.— Many fresh-water habitats become dry during part of the year, and numerous adaptations exist for surviving the dry period. The encystment of rotifers, nematodes, tardigrades, protozoans and some copepods has been mentioned previously. Cladocerans, copepods, ostracods, caddis fly larvae, prosobranch snails, clams such as the sphaeriids and *Spatha* and some eels and lungfishes all bury themselves in mud during dry periods. Many water insects, salamanders, frogs and a few fishes (eels, callichthys, Doras) move across land areas to new water basins when their habitats dry out.

Marginal fresh-water habitats (ditches, grassy pools, desert lakes) may have water for only a few weeks a year or perhaps only once in several years. Only the most drought resistant organisms can survive. Certain branchiopods (fairy, tadpole and clam shrimps) exist today perhaps only because of their ability to adapt to this seemingly unfavourable niche. Some branchiopods can remain dormant for 15 years and then complete their life cycle in two weeks when water is available. Temporary ponds that have water for the same few weeks every year can support a diverse fauna consisting of microscopic encysting organisms, pulmonate

snails, flatworms and small crustaceans besides providing breeding grounds for amphibians. Generally, the larger and more permanent bodies of water have more varied and larger faunas. Major river basins and larger lakes have endemic races or species, and very old basins and lakes may have endemic genera.

The encysted species found in water films and temporary pools tend to be world-wide in distribution; those of annual pools may range over one or two continents; those of permanent ponds and lakes may show numerous local varieties but a wide species range; and species found only in rivers may have a range limited to that basin. These distribution patterns are clearly correlated with dispersal capabilities. Encysted species may be blown about with dust particles by the wind or carried in dried mud on birds' feet. Severe storms have even produced showers of fish and frogs; and undoubtedly, many smaller animals are accidentally transported in this fashion. Insects and birds can carry organisms for short distances, and eggs occasionally fasten to their feet. Other species show little capacity for dispersal and are restricted in range.

Fresh-water mollusks show a series of distributional types correlated with dispersal mechanisms. Sphaeriid clams (*Pisidium* and *Sphaerium*) are hermaphroditic, and the young develop inside the adult's body. Ancyloid, physid, lymnaeid and planorboid pulmonate snails are egg-laying hermaphrodites capable of self-fertilization. In the last two families of snails, if self-fertilization is followed by cross-fertilization, there is complete selection for the sperm from the cross-fertilization. This range of reproductive capacity allows not only for population of a new habitat by one individual but also for genetic variety through genetic recombination when more than one snail is present. The snail species named above are the only molluscan inhabitants of temporary ponds; they provide nearly all of the observed cases of accidental transport of mollusks by other organisms. All can burrow and encapsulate in mud and remain dormant for a long time. They are very widely distributed and often show bewildering local variations. In contrast, prosobranch snails have separate sexes and, except for tropical species, very seldom live in dried mud. Some small species can pass through fish or bird digestive tracts unharmed and in this way are distributed, but most species are restricted to definite areas, usually equivalent to drainage patterns. Finally, the larger fresh-water clams, Unionidae and related families, often have a

parasitic glochidial stage during which the larvae attach to fish. The fish can distribute the clams through a lake or river system, but intersystem transport is an extremely rare event. Unionids, because of their restricted distribution, are sometimes used to aid in the interpretation of past stream histories.

C. ZONATION OF FRESH-WATER ANIMALS

Lakes, ponds and oceans are zoned vertically; streams and rivers longitudinally. Lower reaches of streams with their muddy bottoms and much suspended organic material have many slow-moving detritus feeders. Upper parts of the rivers have clearer waters with rocky bottoms and crawling or swift-moving species. Some species may range from head waters to the entrance into a sea, many more are confined to the lower sections. Many fish spend part of their time in the sea and part in fresh water (*e.g.*, salmon). In the tropics many shallow-water marine organisms seem to have recently moved into fresh waters, notably thiarid snails and selachian fishes.

1. Surface Film.—The surface film of water has complex physical properties that enable a special fauna, the neuston, to develop. These are organisms adapted to gliding on top of or clinging to the bottom of the surface film. Gyrinid beetles, the hemipteran water striders, collembolans and even spiders may live on top, while cladocerans, protozoans and occasionally worms, snails, insect larvae and hydras may be attached to the underside.

2. Standing Water.—Standing bodies of water—ponds, swamps, bogs and lakes—have planktonic and bottom-dwellers just as the ocean, and with similar types of adaptations. In shallow areas of abundant plant growth, a rich fauna is present, with burrowing and creeping forms well represented. Normal variations in water levels, however, are such that only organisms capable of moving with the level or of encysting are present. Sessile and sedentary animals are found only in deeper waters. Cold-adapted organisms and detritus feeders (worms, snails, some clams, many protozoans) form the bulk of the deeper fresh-water lake fauna. In northern lakes these animals may live near the shore line, but in deep lakes with warmer surface waters they live only in the depths. Fishes range throughout lakes, often moving vertically with the seasons. Fishes feeding on bottom debris often have beardlike feelers.

Salty lakes can be isolated arms of the sea (Caspian sea) or the result of high evaporation (Great Salt lake). The former have marine animals, the latter a few highly salt-tolerant organisms (notably the brine shrimp *Artemia* and larvae of the dipteran *Ephydra*) derived from fresh-water species.

3. Running Water.—These can be divided into rapids and pools, with extensive transition zones between. Generally, running waters have more oxygen than still waters, a great runoff of chemicals from the land and an animal distribution primarily controlled by currents. Many lake animals exist in pool areas of running waters, but in the rapids of brooks and streams, special adaptations are needed for existence. A few sponges and bryozoans anchor by pedicels to rocks; some clams (*Byssanodonta*) and insects use attachment threads; snails and flatworms, a slimy undersurface; larval insects and mites, clawed legs; and such diverse animals as leeches, larval insects of many kinds, fishes and tadpoles, suction discs (fig. 4). Many of these animals have a flattened body enabling them to fit into narrow crevices; it is usually streamlined with a broadly rounded front and tapering posterior, offering minimum resistance to flowing water. Normally, these forms point upstream and move against the current, staying close to or in contact with a surface.

VII. ANIMAL LIFE ON LAND

Slightly more than one-quarter of the earth's surface is covered by land, which ranges from a few areas below sea level (Death valley) to 29,028 ft. above (Mt. Everest). Terrestrial animal life is most abundant in the tropical, and temperate regions, becoming relatively scarce, both in species and individuals, in colder latitudes and at higher elevations. While many animals can fly or be carried to great heights by air currents, they are land-based for recuperation and breeding. Unlike in the sea and fresh water,

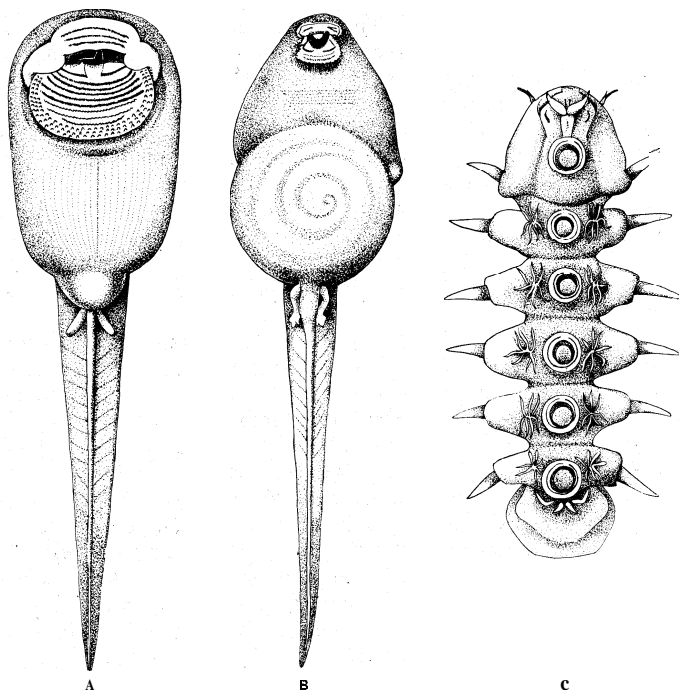

FIG. 4.—COMPARISON OF ADAPTATIONS TO STANDING AND RUNNING WATER: (A) POND TADPOLE (*RANA PAPIENS*); (B) SWIFT STREAM TADPOLE WITH SUCKER (*ASCAPHUS TRUEI*); (C) SWIFT STREAM DIPTERAN LARVA WITH SUCKERS (*LIPONEURA*)

animal life on land is confined to a narrow band extending at most from a few feet below the air-ground surface to the top of the highest vegetation (perhaps 250 ft. in tropical forests).

Vertebrates, arthropods and mollusks are the most successful land groups. Nematodes, oligochaete worms, a very few ostracods, leeches, onychophorans (*Pevipatus*), a few nemerteans and flatworms comprise the other terrestrial organisms. Protozoans, which live only in water films, are not truly terrestrial even though they are found in land habitats. Reptiles, birds and mammals are primarily terrestrial; amphibians usually spend part of their time in the water; and fish only rarely venture onto land. Snails are the only molluscan land dwellers, though a few finger-nail clams (*Sphaerium*) occasionally creep up into wet leaf litter. Most arachnids, millipedes and centipedes live on land, and insects are predominantly terrestrial with many fresh-water and a few marine species. Despite the paucity of major groups, it has been estimated that more than four-fifths of the known animal species are terrestrial. This is the result of the great diversity of land habitats, the many barriers to dispersal and the great variations in physical conditions.

A. BASIC ADAPTATIONS TO TERRESTRIAL LIFE

1. Air.—In moving onto the land, animals gained an abundant oxygen supply, a diffuse medium (air) that allowed quick movements and offered less impediment to vision and a plentiful food supply (green plants). The decreased density of air, however, as contrasted with water created the need for support of the body by the animal itself instead of by the surrounding medium and presented the greatest problem of land animals—preserving an internal water balance. These two factors conditioned terrestrial animal form and adaptation.

Body Support.—Because air cannot support body tissues as does water, the very plastic, gelatinous animals are absent from the land. The tissues of flatworms, earthworms and snails are much firmer in terrestrial species than in water-dwellers. Soft-bodied organisms must rest their entire weight on the ground. Those with supporting structures, arthropods and vertebrates, reduce friction and ease movement by elevating the body on stiffened limbs. This, however, requires limitations of body size, since doubling body size requires a manifold increase in strength of the legs. Thus land animals generally are limited in size compared with oceanic relatives. The largest insect, the six-inch-long Hercules beetle (*Dynastes*) is tiny compared with even a small lobster, and an elephant about 11½ ft. long, weighing almost four tons is a pigmy beside a 100-foot, 106-ton blue whale.

2. Water.—Terrestrial animals must maintain a narrow balance between water taken into the body (with food or by drinking or by absorption through the skin) and water lost to the environment (by excretion, ingestion, respiration or evaporation through the body covering). A few organisms (some snails, amphibians and insects) can survive large changes in the water content of their body, but most organisms must have a nearly constant level or they die.

In water sessile animals could filter prey out of passing currents; but the air has only a small temporary planktonic fauna, and no predatory sessile land animals evolved. A few spiders do strain animals into their webs from air currents, but that is more like a fisherman netting from the sea than a barnacle filtering from the water.

Most types of land-dwelling animals, nematodes, oligochaetes, amphibians, flatworms, leeches, ostracods, isopods (sow bugs), *Pevipatus* and snails are marginally terrestrial. They can be active only during periods when the air in their micro-habitat is nearly saturated with water vapour, and they must encyst or estivate during dry periods. Arthropods and higher vertebrates alone have relatively impermeable cuticles and extensive water-conserving devices; these forms are the most successful land animals. Snails form the other major group, relying on lengthy estivation in their calcareous shell during dry periods. The opening can be sealed either by a disc on the snail's foot (the operculum) in prosobranchs, or by a calcified mucous sheet (the epiphragm) in pulmonates. Several species of snails have been

revived after six years of uninterrupted dormancy, and recorded cases of more than 20 years may be legitimate.

Water-conserving Mechanisms.—The water-conserving mechanisms enabling survival on land are quite varied. Impervious integuments or skins have been developed with great success by many insects, reptiles, birds and mammals. Some mammals and many insects, however, can lose large quantities of water through glandular structures in the integuments. Many land invertebrates and amphibians have a skin almost completely permeable to water and must stay in damp places.

Internal breathing systems are quite effective in reducing water loss. The high oxygen content of air (207 c.c. per litre) as compared with water (less than 7 c.c. per litre) allows terrestrial forms to have much smaller breathing area. Many stenohygric species breathe through their skin, but the most successful groups have the respiratory surface inside the body and connected to the outside by only a small opening. Snails and insects can even close the opening for brief periods to minimize water loss.

Dry body excretions, either in the form of crystalline or highly concentrated urine, help to save body water, as do the egestions of dry feces. Habitat conditions are an influencing factor: animals living in relatively dry situations (*e.g.*, antelopes) pass drier dung than do animals of moister habitats (*e.g.*, tapirs).

Various forms of dormancy, especially estivation or encystment, will allow species to survive when conditions are favourable for activity during only a few weeks each year.

The behaviour patterns of being active at the time of highest humidity (night or the early-morning dew period) or remaining in moist niches (damp pockets in woods or along the edges of ponds) are also common. Some social insects maintain "humidity control" by keeping the air in their enclosed nest and runways at a higher humidity than the outside.

Seasonal migration over a larger or smaller distance to a more favourable habitat is common among mammals and some birds and insects. Use of metabolic water is equally important: many desert animals derive all their water from their plant food, and many organisms use the water obtained from the breaking down of their own body sugars and carbohydrates to satisfy needs.

3. Other Environmental Factors.—Conditions of light, temperature, humidity and substrate vary widely on land and greatly influence the distribution of animals. Light, temperature and humidity change not only from place to place, but from time to time with definite rhythm. The numerous possible combinations of these variable factors have greatly increased the diversity of animal life, particularly when combined with the influence on land animals of barriers to dispersal.

Light.—Length of day quite often triggers mating behaviour and breeding, and exposure to light rays is a major limiting factor for many animals. Few organisms can withstand prolonged exposure to direct sunlight, for they may die either from heat or from actual lethal factors in light rays. Organisms normally exposed to light will have protective pigments not present in secretive organisms. Many animals hide during the day to avoid sunlight.

Temperature.—The extreme recorded temperatures on land surfaces are probably 71.5° C. near Tucson, Ariz., and -67.8° C. in eastern Siberia; the latter area also shows the greatest annual range in mean monthly maximum and minimum, 66.3°. Tropical forest floors may show an annual variation of only 3°, but temperate and cold regions have the seasonal periodicities of hot and cold, that is, summer and winter. In warmer areas temperature may allow activity throughout the year. In colder regions some form of dormancy between warm spells is frequently resorted to. The activity of poikilothermous (so-called cold-blooded) animals is usually governed by environmental temperature levels.

Poikilotherms can regulate their body temperature roughly through behaviour patterns such as moving from sun to shade to keep a constant temperature level. This is effective only part of the year. Generally poikilotherms are larger, more numerous and most varied in the tropics.

Homoiotherms, birds and mammals, control their body temperature through metabolism. In regions where the external tempera-

ture is below that inside their body, they must minimize heat loss. In regions where the external temperature is higher than their body level, they must minimize heat gain.

The line between poikilotherms and homiotherms is indistinct. Young birds cannot regulate their temperature and many mammals and adult birds will vary within several degrees, yet the basic distinction between self-regulation and habitat-regulation is a useful one.

Heat conservation is accomplished in several ways. A shaggy coat of fur or heavy layer of feathers entraps an insulating layer of air next to the skin and thereby cuts loss of body heat. The dense fur of northern animals, wolves, yaks, reindeer and the Siberian tiger contrasts with the few hairs of many southern forms, monkeys, most hoofed mammals and the Bengal tiger.

Heat loss is greater from a body with a high surface-volume ratio than one with a low one. Thus, cold-adapted animals will be bulkier than warm-adapted relatives (Bergmann's rule). This holds true for the races of man, as well as for other animals. Following the same principle, cold-adapted animals have smaller appendages than warm-adapted species (Allen's rule). For example, the length of foxes' ears correlates with climate (fig. 5). Numerous exceptions to these two principles are known, but both Bergmann's and Allen's rules remain useful generalizations.

In tropical areas, species often will have long appendages and high surface-volume ratios. To avoid the sun's heat, many sleep during the day or are active only in shaded areas. Cooling by water evaporation is very effective since for each gram of water evaporated 500 cal. of heat are lost from the body. Sweating through the skin, increased water loss through rapid respiration and periodic immersion in cool water are commonly used cooling mechanisms.

In cold regions many homiotherms hibernate during the winter, partially to escape the severe cold but also because food supplies are limited during the winter period. This is only one example showing how both biotic and physical factors interact to limit a species distribution and behaviour.

Humidity.—Annual rainfall varies from a fraction of an inch to over 300 in. It can be evenly distributed throughout the year or concentrated within a few weeks or months. The latter situation is common in the tropics, with alternating dry and wet seasons providing an ecological equivalent of the hot and cold seasons of northern latitudes. Shaded areas, such as the ground stratum of tropical forests, have higher humidity for much longer periods than the forest canopy or grasslands. The distribution of animals that require a nearly saturated atmosphere will be limited by the time each year that suitable conditions prevail. Periods of dormancy afford survival of many animals over dry spells, but each species requires a certain minimum period suitable for activity in order to survive.

Substrate.—In the ocean and fresh waters most chemical and nutritive materials are suspended in the water. On land these must be obtained directly or indirectly from the substrate. Both physical state and chemical contents of the substrate greatly influence animal life. A barren rock bench or shifting sand dune will harbor little animal life, both for lack of shelter from weather or enemies and for paucity of food. On firm ground, running animals with tiny feet are present; in marshes and on snow or sand, animals with broad, often webbed feet are found. Loose-packed soils with high organic content (forest floor) have millions of burrowing organisms feeding on each other and on decaying matter.

The physical composition and structure of the soils, exceedingly important to animal distribution, is treated in the article SOIL.

Chemical composition is equally important. The availability of lime (calcium) for shells and skeletons limits snail and mam-

mal occurrence. Sodium chloride (common salt) is essential to animals that feed on plants, for it tends to counteract the high potassium content of the plant material. Many trace chemicals are essential to animal functions. The relative acidity or alkalinity of the soil also affects animal distribution. Alkaline and rocky soils hold heat for considerable periods.

Air Masses.—The movements of the great air masses above the earth affect the climate through determining rainfall. They also aid in the dispersal of organisms and are used by birds in flight. Pressure is important primarily in high mountain altitudes and has little direct effect on animal distribution.

B. ZONATION OF LAND ANIMALS

Similarity in (1) ecologic roles and adaptations or (2) systematic affinities and geographic distribution can be emphasized in discussing animal zonation. The former has grown out of ecological science; the latter is the methodology of classical systematics (see ZOOGEOGRAPHY).

The climatic elements of temperature, precipitation and wind are modified by latitude, distribution of the continental land masses, topography, barometric pressure and marine currents. It is possible to recognize areas that have basically similar cyclical variations in temperature, rainfall and light factors. A characteristic form of vegetation and associated animal communities has developed in every area of the world with similar sets of climatic conditions.

There are several ways of classifying these ecologic units, only a few of which are given below. None of these methods is fully satisfactory, primarily because these are not discrete units but patterns of operation that grade into one another. One division recognizes seven major biomes: tundra; taiga (coniferous forest); temperate deciduous forest; desert; tropical grasslands; temperate grasslands; and equatorial forest (fig. 6). These are characterized in the article, ECOLOGY, ANIMAL. Another classification is the division into four biomes (forest, savanna, grassland, desert) with subdivisions into formation classes—geographic units of vegetation showing characteristic responses to a climatic trend of a particular intensity. In mountainous (montane) regions, the life-zone concept of C. H. Merriam, stripped of its theoretical temperature limits, accurately depicts the vertical zonation of plants and animals. It is less effective in dealing with nonmontane distributions.

All these systems are concerned with the idea of ecological equivalence—that grasslands will support grazing animals and

FIG. 6.—PLANT AND ANIMAL COMMUNITIES (BIOMES) OF NORTH AMERICA

forests will have vertical stratification with arboreal and terrestrial forms. Grazing animals have similar teeth and digestive adaptations. Carnivores in all parts of the world, though they belong to very different taxonomic groups, have similar structures.

Equally important is the problem of ecological equivalents in the past. A considerable paleontological literature concerned with the ecological adaptations of past organisms was summarized by G. G. Simpson in 1953. (See Bibliography, below.)

Faunas can be ecologically zoned on the bases of climate, vegetation and topography. Extensive overlaps and intergradations occur, and these divisions present a gross oversimplification (see W. C. Allee and K. P. Schmidt, 1951).

1. Climatic Zonation. — Tropical Faunas. — Rain forests with nearly constant temperature and very high humidity at ground level have abundant rainfall throughout the year. These forests present the most favourable situation for terrestrial life. Dormancy is not needed, except in monsoon forests with dry seasons, and poikilothermic animals can be active during the entire year. Plant food production is continuous and life abounds.

Species are fantastically abundant — perhaps 2,000 species of moths alone having been caught on Barro Colorado Island in the Panama Canal Zone — but individuals are scattered; and it is far easier to collect 100 different species than 100 individuals of a single species. Most groups of poikilotherms reach their maximum size in the tropics.

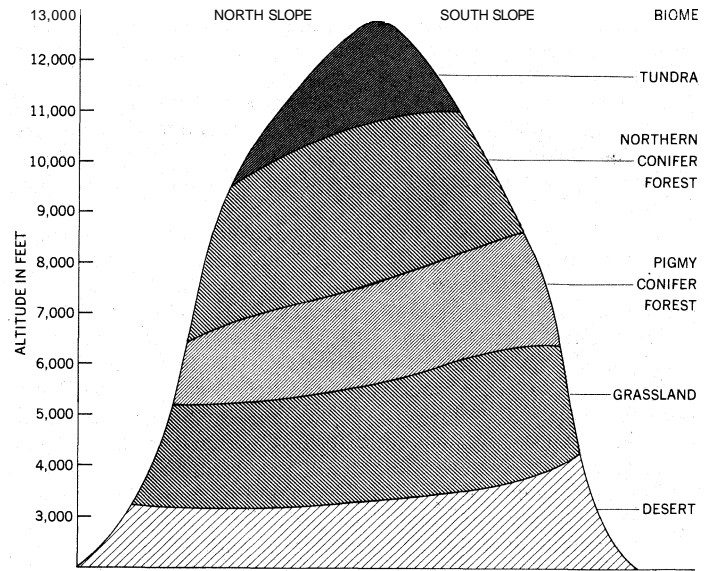

Temperate Faunas. — The alternation of seasons and wide fluctuations in rainfall, light and temperature produce periods of plenty and of famine. The poikilotherms must have a period of dormancy, plant food production is suspended part of the year and homoiotherms must hibernate (mammals) or migrate (birds) during unfavourable conditions. Reproduction becomes restricted to seasonal periodicities. Species are much fewer in number, but, in contrast to the situation that pertains in the tropics, individuals of the same species are easier to find. Turnover of organic matter is much slower because of the dormant season, and climatic variations limit the groups that can inhabit temperate areas.

Polar Faunas. — The extreme changes in environmental conditions limit habitation of the polar areas to very few species. Homoiothermic animals are mainly marine or migratory, breeding during the warm summers. Large-bodied flies (Diptera) and butterflies and moths (Lepidoptera) are the dominant insects, but other poikilotherms are rare. Species are often present in huge numbers, though there is little variety, Greenland having only seven land mammals, for example. The snow-clouded air and lack of plant life in the Antarctic have practically eliminated terrestrial animals. Many arctic animals also live in the alpine zone of mountains.

2. Vegetative Zonation. — Forest Faunas. — Forests are found only where temperatures are above 10° C. during the vegetative season, annual rainfall above 50 cm. (about 20 in.) and humidity more than 50% saturation. In tropical forests arboreal animals are abundant, less so in temperate areas. Ground conditions are uniform, and the soil litter supports an abundant fauna. The animals have acute hearing and gregarious forms are noisy. Flying and running are hampered; gliding and climbing, well developed. In dense forests, conditions remain more uniform; in open forests they vary more widely. Generally, several distinct strata of life from ground to treetop can be recognized.

Open-country Faunas. — In open country, precipitation and/or temperature are lower than in forests, and the vegetation shades from savanna and steppe to desert, depending on rainfall. Protective foliage is absent in dry seasons, and vegetation gives minimum cover at most times. Dry-adapted animals can survive, and running forms are common among birds and mammals. Sight and scent are keenly developed, and gregarious animals are frequent. Burrowing species are common in all groups, and protective colorations are well developed.

3. Topographic Zonation. — Elevation Faunas. — In mountainous areas the abrupt rise in elevation results in lowered temperature and shortening of the warm season. Forest faunas ascend

to the vegetational limit, and then a characteristic alpine fauna and flora appears. The number of species decreases rapidly, but some mammals (e.g., the rabbitlike pika *Ochotona wollastoni*) live as high as about 20,000 ft. on Mt. Everest. During warm periods the strong light rays may heat the ground surface to 40°–50° C., and a considerable fauna of poikilotherms exists at moderate elevations. Mountain species generally bear live young and often seek shelter among rocks. High mountains show an especially clear pattern of zonation (fig. 7).

Island Faunas. — Some islands (Great Britain, Tasmania) formerly have been connected to continents; others (Hawaiian, Society) never have been connected to any land mass. The former group of islands have organisms very similar to those present on the mainland with which they were at one time connected. The latter group (oceanic islands) received its animal and plant life by chance dispersal over oceanic barriers. Few mammals, amphibians and reptiles; some birds and snails; and many insects live on oceanic islands.

Older oceanic islands have a great proliferation of species from a few chance introductions; the original stocks underwent minor adaptive radiations and filled habitat niches normally used by other organisms in balanced continental faunas. The flightless birds on oceanic islands probably could evolve because of the absence of mammalian competition,

C. DISPERSAL OF ANIMALS ON LAND

The division of land areas by oceans into three major blocks; the interruption of land masses by lakes, rivers, high mountain and desert regions; and the climatic zonations all tend to raise barriers to the spread of animals from one area to another. Oceanic barriers are particularly effective, but the fauna of the Hawaiian Islands is testimony to the occasional success of accidental dispersal by organisms across major barriers (see HAWAII: *Animal Life*).

On land most dispersal is the result of individual movement. Given enough time, any species could crawl from one land mass to another as long as conditions for survival were favourable. The world-wide distribution of ancient groups such as *Peripatus* may simply present a function of the time available for their dispersal. Similarly the wide range of amphibian and reptilian families and genera may be a function of the geological age of these groups, and the limited range of mammalian types a function of group youth. Paths for dispersal open to the older groups were closed to the younger ones by the time they evolved.

Floods are an effective means of dispersal for many organisms; the concept of natural rafts of trees carrying mammals or reptiles from a continent to an island has often been postulated. Winds

often carry spiders and small insects. Violent storms may very occasionally transport small invertebrates, birds and even tree branches for thousands of miles; this is probably the way the Hawaiian Islands were populated.

The problems of faunal interchange between continents and islands or between separated or partially connected areas are many, and a good discussion of basic faunal evolution is given by Simpson (1953). Corridors (passageways for whole faunas), filter bridges (conditions that let some groups pass but not others) and "sweepstakes" routes (chance dispersal) are the major means of dispersal patterns. A particular area may have formed a filter bridge at one time and a corridor at another, so that the patterns of past dispersals are exceedingly complex. Present distributions are the result of past dispersals and the success of adaptation to existing environmental conditions.

VIII. MAN AS A FACTOR IN ANIMAL DISTRIBUTION

Over the course of geologic eras animal life has evolved and dispersed into the present distribution patterns; each species not only adjusted to its physical environment, but also to the animals and plants with which it lives. Herbivorous animals have their favourite food plants, their predators and their parasites. Disease organisms have a rough balance between their survival and the death of the species they attack.

Man has been able seriously to interrupt natural patterns by transporting an organism from an area in which it is in balance with physical and biotic factors to an area in which physical factors are favourable and food is available but the predators and parasites that keep it under control are lacking.

Major crop and forest pests—the Hessian fly, Japanese beetle, Colorado potato beetle, grape *Phylloxera*, spruce sawfly and gypsy moth; tree diseases—Dutch elm disease and chestnut blight; nuisance organisms—starlings and sparrows; and literally thousands of other examples testify to the ability of man to spread other organisms. Many serious epidemics of malaria and bubonic plague have been caused through man's accidental transport of infected animals.

Many well-intended transportations have not turned out satisfactorily. Thus, the rabbit in Australia, the giant African snail in the Pacific and the edible snail in California were purposely introduced to serve as food but multiplied beyond expectations to become pests.

The possibilities of further unwelcome introductions is con-

siderable, despite the rigid plant and animal quarantines maintained by almost every country. Man, through transplanting plants and animals, is now involved in one of the major distributional revolutions in the history of the earth. No one knows or can predict how it will end. A good review of some of the problems of man's disruption of natural distribution is given by C. S. Elton (1958).

ANIMALS, DOMESTICATION OF. Domestication implies: (1) tameness; (2) living in or near the dwelling places of man; (3) being kept by man to provide him with food, clothing, power or aesthetic satisfactions; (4) that the animal and its ancestors for many generations have had their movements and matings partially controlled by man; and (5) that the innate mental and physical qualities of the domesticated animal have been changed considerably from those of its wild ancestors.

Not all domesticated animals conform fully to all of this definition. Thus, man generally exercises little control over the movements and matings of the domestic cat. Although tameness is an important part of domestication, some domesticated animals, such as sows with very young pigs, cows with new calves or angry bulls, may be at times more dangerous to an incautious person than most wild animals are. Wild animals such as performing seals and bears sometimes become very tame, but they are not called domesticated. Yet wild elephants in India when caught and tamed are called domesticated.

Because domestication was accomplished in prehistoric times, the methods of doing it can only be surmised from such indirect evidence as the attitudes and habits of primitive peoples concerning the animals around them; paintings or carvings that archaeologists have found in ancient camp sites or tombs; and experiences of those who work in menageries. Presumably the initial steps toward domestication were taken largely through the widespread human practice of making pets of captured young or crippled wild animals. Religious customs, such as totemism, animal cults or the reverence accorded to cattle by the Hindus in India, may have been important. Many wild animals quickly lose much of their fear of man in game refuges. Some domestication deliberately may have been planned to serve definite needs. Prehistoric rock carvings in Egypt show hunters building a fence across the outlet of a steep-walled valley into which they had driven some wild game, presumably to keep a reserve food supply. Some wild species can be tamed easily, while others are extremely intractable. Some possibilities for domestication still may exist, although no important species has come completely from the wild to the domesticated condition within historic times. Perhaps fur-bearing animals, such as mink and foxes raised in captivity, are now being domesticated in the same slow way as cattle and sheep were many thousands of years ago.

The first date of domestication varied in different parts of the

FROM C. BROWN AND R. A. SHEALS IN "JOURNAL OF FORESTRY"

FIG. 8.—SPREAD OF THE GYPSY MOTH, AN ECONOMIC PEST, AT FIVE YEAR INTERVALS, AFTER IT WAS INTRODUCED BY MAN INTO NORTH AMERICA LATE IN THE 19TH CENTURY

world and for different species. Peoples in a paleolithic (Old Stone Age) stage of culture generally had no truly domestic animal except, perhaps, the dog. This was true of the aborigines of Australia when white men first found them. Cattle and sheep were important domestic animals in Europe early in the neolithic (New Stone Age) culture. They may have been brought into Europe already domesticated by people who came from farther east. In Asia Minor they were domesticated by 7000 B.C. Horses first appeared as domesticated animals about 3000 B.C. but long had been hunted widely for food. Mounted invaders from the north brought them into the valleys of the Tigris and Euphrates as early as 2000 B.C. They had reached China well before 1500 B.C. Horses were kept at first for flesh as well as for riding; they were used for war chariots and other transport well before 1500 B.C. The ass was domesticated in southeastern Egypt before 3000 B.C. Cats were domesticated in or near Egypt long before 2000 B.C. Chickens were domesticated in southeastern Asia perhaps by 2500 B.C.

The only animals domesticated in the Americas were the llama, alpaca, guinea pig and turkey. American Indians north of Mexico had no domesticated animals except dogs. African tribes south of the Sahara probably acquired their domesticated animals from the northeast long after civilization had developed in Egypt.

The wild species that were originally tamed may have become extinct (*e.g.*, the *ur* or aurochs from which cattle are descended), or domestication may have changed the animal so that its ancestor cannot be identified with certainty (*e.g.*, the sheep comes from *Ovis ammon* but from which subspecies is uncertain). The dog is zoologically the same as the wolf of the northern hemisphere, although some investigators have argued that the jackal furnished part of the ancestry of some races of dogs in Africa and in southern Asia. The horse is descended from local races of Przewalski's (Przewalski's) horse, which ranged from Poland to Mongolia. The chicken came from the wild jungle fowl still found in India. The local races of swine domesticated during the neolithic around the Baltic, on the northeast shores of the Mediterranean, in southeastern Asia and perhaps elsewhere are not considered to have belonged to one species, *Sus scrofa*.

Formerly it was widely believed that the diversity of form, size, colour and other characteristics within some domesticated species could be explained only by supposing that two or more wild species had been tamed and subsequently intercrossed. This view became less plausible as evidence accumulated to show that each wild species contains much genetic diversity and as it was demonstrated that isolation and continued selection can produce widely contrasting groups from the same initial population. Domestication did not change the laws of inheritance, but man's control over the movements and matings of the animals did increase the isolation of subgroups from each other. Also, domestication made possible wider outcrosses between local races because man in wars or commerce sometimes transports breeding animals over natural barriers that their wild contemporaries would not have crossed. From the very beginning of domestication man must have favoured for breeding purposes those animals that pleased him most. For aesthetic reasons he often desired variety, and for utilitarian reasons he often wanted several types of animals, each specialized for a purpose or set of conditions. This combination of continued artificial selection toward varied goals, inbreeding consequent upon isolation, and occasional wide outcrosses increased greatly the rate at which distinct local races were formed and changed.

ANIMALS, LAWS CONCERNING. Legislation relating to animals is basically similar throughout the common-law countries, although with considerable regional variation. Historically two trends are recognizable: animals have been accorded increasing legal protection, and the principles of liability of those who control animals have been refined and extended. All creatures

other than man are animals in the eyes of the law, but the law is concerned with those considered objects of property, usually excluding insects. They are classed as domestic (*domitae naturae*) and wild (*ferae naturae*); the former are objects of property by reason of ownership, and the latter may become property by reason of reduction to possession.

In determining what rules are applicable where the question is that of liability for injuries to persons or property by animals, the animals are classified by their natures: vicious wild animals; wild animals which have undergone some domestication; domestic animals known by their owners to be vicious; domestic animals not so known; and grazing domestic animals. A person keeps vicious wild animals at his peril and ordinarily is absolutely liable without regard to negligence for any injury done, but the rigour of this doctrine has been modified in some cases to require the existence of negligence. Keeping such animals may also constitute a public or private nuisance. In cases where the ordinarily wild animal has undergone some domestication, the owner is liable for injuries resulting from negligent keeping, unless a propensity of the animal to cause harm is known by the owner, in which case liability may be absolute. If a domestic animal with a known vicious or otherwise dangerous propensity is kept, some jurisdictions charge the keeper with absolute liability; others base liability on negligence. Knowledge of viciousness may be actual or based on the duty of the keeper to observe his animal. In the absence of a propensity toward viciousness, the owner is liable for injury following and foreseeably caused by a failure to exercise the care which a man of ordinary prudence would exercise.

The victim may be without recourse if he has acted negligently so as to contribute to his own injury. Where there are statutes forbidding letting animals run at large, criminal or civil liability may stem from a violation. The question of knowledge in the rules of liability has resulted in much litigation, particularly where dogs are concerned. The dog cases have given rise to the popular saying "Every dog is entitled to one bite"; that is a misconception, for the ordinary rules of liability apply to dogs. In many jurisdictions where the raising of animals is of economic importance, the common-law rule requiring knowledge of a dog's likelihood to do harm has been changed, either to impose absolute liability on the owner for injury to other domestic animals or to provide for judicial trials of dogs which have done certain acts, such as sheep-killing. Some statutes penalize the owner for keeping a vicious dog and may require the dog's destruction. Although liability for animals ordinarily depends upon ownership or control, a person may be liable for selling, without warning to the purchaser, an animal known to be dangerous.

The keeper of a wild animal must keep it penned up and is liable for trespasses (entries upon the land of another) and all resulting damages if he does not. The owner of land upon which wild animals live is not responsible for their natural wanderings unless he can be said to have actual control over them. Under common law the owner or possessors of domestic animals had an absolute duty to keep them off others' lands; this remains the modern rule in Great Britain, the United States and other common-law countries comprising heavily populated areas or agricultural areas where the protection of growing crops is important. Where raising livestock and the like is more important, the tendency has been to reject or modify the rule, and the modifications are extremely varied. Some jurisdictions have adopted the test of negligence, while others have schemes of negligence or absolute liability dependent upon the type of animal or land involved. Some jurisdictions permit recovery only where the injured party has attempted to fence animals out, while others require that animals be fenced in. Trespasses brought about wilfully are always wrongful. Owners of domestic animals may be liable by statute for letting them run at large or wander upon highways. In livestock-raising areas, statutes regulate grazing on open range land, and the government regulates and licenses the use of the public domain lands.

An estray at common law is an animal running at large whose owner is unknown, but not all modern definitions include the latter element. In the absence of a statute limiting the right,

anyone may take up and impound estrays, but the taker does not become the owner simply by that act; public notice must be given about the taking. The taker has a right to compensation for his expenses and to possession until paid, but he may not use the animal for gain. He must take reasonable care of the stray, whose owner may recover it by paying the charges and proving ownership; otherwise, the taker after a time becomes the owner.

In English law the doctrine of distress damage feasant permits the distraint of animal? for the payment of damages caused. A landowner may drive trespassing animals off his property, and municipal authorities may detain and impound them. A pound is a place maintained by public authority for the keeping of animals picked up as estrays or for those running at large unlawfully. It is illegal to release an animal lawfully taken up. An animal may be killed where it is necessary to protect persons or property. For an unnecessary killing the owner may recover the value of the animal, and the killing may be criminal, particularly if malicious.

An agreement to take possession of another's animal is a bailment, which is regulated by contract between the parties, but the bailee is charged with exercising due care. An agreement to keep and care for an animal is a type of contract of bailment called agistment.

Ownership, possession and treatment of animals is the subject of extensive regulation. Commonly, zoning laws and deed restrictions limit the privilege of keeping animals to ordinary pets or nonoffensive agricultural types. In Great Britain and in most municipalities of the United States and Canada dogs are required to be licensed, for which a fee is paid. In the western United States, where livestock may run more or less at large, branding for identification is common, and statutes require registration of brands. Slaughtering animals for consumption is regulated by licensing, rules, reporting requirements and inspection by national and local governments. In the United States and Great Britain national legislation requires health inspection of live animals transported, imported or exported. Diseased animals may be quarantined or destroyed, and owners can be liable for spread of disease and the transportation or sale of diseased animals.

In ancient times animals had no rights under the law, though they could be charged with offenses and formally tried and convicted. Under common law, cruelty to animals was unlawful only when the act caused damage to the owner or constituted a nuisance to the public. Largely as a result of activities of the humane movement beginning in the early 19th century, infliction of unnecessary pain and suffering or wanton abuse of tame or wild animals, such as killing, shooting, starving, beating, overloading or overdriving, have been made criminal offenses (see HUMAN SOCIETIES). Hunting for sport is permitted, regulated and encouraged. The use of captive animals for games such as cockfighting, bearbaiting or bullfighting (which may be national sports in some countries) usually is prohibited. In the United States and Canada the use of animals in rodeos is not by itself cruelty, but such use is prohibited in Great Britain. Injury in the reasonable protection of property is not cruelty, nor in general is experimentation with live animals for scientific purposes (vivisection), but there are antivivisection laws in a few U.S. states. Vivisection is strictly regulated in Great Britain but not completely prohibited. (G. M. Jo.)

ANIMALS, PHYLOGENY OF, the branch of zoology concerned with tracing the lines of descent among animals. Its ideal is to do this at all evolutionary levels and so to give a complete exposition of the relatedness of all the members of the animal kingdom to each other. Phylogeny necessarily rests upon evolution as a fact of nature, but it is not concerned with theories about how evolution has been brought about; phylogenetic conclusions would not be altered by proof of the Darwinian, Lamarckian or any other explanation of evolution. For discussion of the theory of evolution in general, see EVOLUTION, ORGANIC.

Evidence: Paleontology. — The most direct evidence that can be used in phylogeny is that of paleontology, insofar as fossils show the actual changes that have taken place in animals with time. But this evidence is very incomplete. It is most complete

MODIFIED FROM A. S. ROMER, VERTEBRATE PALEONTOLOGY (UNIV. OF CHICAGO PRESS).
 FIG. 1 — ADAPTIVE RADIATIONS OF THE ORDERS OF PLACENTAL MAMMALS. EACH LINE REPRESENTS AN ORDER, ALL OF WHICH CAN BE TRACED BACK INDEPENDENTLY TO NEAR THE BEGINNING OF THE RADIATION.

where changes in species can be followed through long series of sedimentary layers evenly bedded upon each other and clearly laid down without large intermissions. Such complete geological records are rare. One example is in the Devonian rock strata of Iowa, where phylogenetic sequences of brachiopods (small marine animals with shells) have been worked out by Carroll Fenton; others occur in the Cretaceous and some Tertiary formations. Only the phylogeny of closely related species can be studied in these sequences; the periods of their formation are too short for larger results.

Elsewhere, the paleontological record gives occasional forms preserved at longer or shorter intervals, when the conditions for fossilization were favourable, and the paleontologist is forced to base his phylogenetic conclusions on study of their structure. The record is also very incomplete in its preservation of structure; in general, only the hard parts of animals are preserved, soft-bodied animals being rarely fossilized. With so incomplete a record, and since many of the animals of phylogenetic interest in the earlier stages of evolution had no hard skeleton, it is clear that a complete solution of the problems of phylogeny cannot be expected from paleontology alone.

Morphology and Embryology. — In general, related animals show their affinity by similarity of structure, the greater the similarity the closer the relationship. In using this evidence caution is necessary; similarity of structure may be due to causes other than evolutionary closeness. It may, for instance, arise in unrelated animals in response to similar environmental conditions; this is known as parallel evolution. Perhaps, in some cases, it may also arise as the result of inherent tendencies in animals to evolve in determined directions, and not at all in adaptation to the conditions of the environment. This possibility, which is the basis of the evolutionary theory of orthogenesis, is not generally accepted as a reality in evolution.

Special reasons may increase the phylogenetic significance of particular similarities of structure. The fundamental structure of an animal is laid down early in its development, and it is found that the earlier developmental stages of animals have altered less in evolution than have the later stages. Thus, resemblance in fundamental structure, and indeed in larval and embryonic structure in general, is often of special phylogenetic importance. Vestigial organs also provide good evidence. These are organs that are formed in development but later regress (or at least never become functional in the adult). Animals that have the same organ in a fully developed and functional condition are believed to be close to the ancestry of the animals having the vestigial organ. The presence of gill slits in the embryology of mammals and birds is strong evidence for the belief in the evolution of these groups from a fish ancestry. Again, where an organ is of a peculiar structure that has an easy explanation in view of

the structure of some probably ancestral animal, but is otherwise inexplicable, it provides evidence for descent from these ancestors. Thus, the recurrent laryngeal nerve of terrestrial vertebrates passes from the neighbourhood of the brain to the thorax, where it loops round the systemic artery near the heart before returning up the neck to the larynx.

If the evolution of terrestrial vertebrates from fish ancestors is accepted, this extraordinary course is a natural result of the arrangement of the parts in the fishes. It has received no other explanation and must be accepted as evidence for this descent.

In reaching any conclusion in phylogeny other principles are looked to: the later structure always must be such that it can be derived by modification of the presumed earlier structure. And evolution has not always been in the direction of increasing complexity of structure; simplification has frequently occurred.

Conclusions.—In view of the uncertainty of the evidence phylogenetic conclusions always must be tentative; the larger the groups of animals they relate, and the earlier the evolutionary changes by which the groups were separated, the less certain these conclusions will be. It often is possible, however, to collect a body of evidence which, taken as a whole, bases the main conclusions on sure ground and makes it very unlikely that they will be upset or in many cases seriously modified by evidence added in the future. But it must be emphasized that such results can be reached only by a broad consideration of all the available morphological and paleontological evidence.

In one large group of animals, the backboneed animals or vertebrates, knowledge of morphology and paleontology is much more detailed than in any other group of similar size.

VERTEBRATES

When vertebrate evolution is surveyed as a whole, several very distinct types of vertebrate organization stand out: the Agnatha (lampreys, hagfishes and related extinct forms); the various types of true fishes; the amphibians; reptiles; birds; and mammals. Each of these types has become successful in turn and has provided a dominant fauna in its own type of environment. In the Mesozoic era the reptiles were dominant in terrestrial environments; in Tertiary times, the mammals; and from the time of their origin in the Silurian period, fishes have dominated aquatic environments. Broadly, these conclusions are true in spite of frequent reversions of the later groups to earlier environments; many groups of mammals and reptiles have become secondarily aquatic.

Adaptive Radiation.—These main types of vertebrate organization were evolved from each other, but between any two of them the evolutionary changes were very great (see below). Within each of the large vertebrate groups the variation of structure is much less than that between groups, but almost as soon as a group became successful it differentiated into a large number of smaller groups adapted to different habits of life in parts of the wider environment of the dominant group as a whole. This differentiation of a successful group of animals is known as adaptive radiation, and it is to be noted that its changes are as much in adaptation to different habits of life as to environmental conditions.

For the placental mammals each of the smaller groups, the orders, can be traced almost to the beginning of mammalian dominance in the earliest Tertiary times (see fig. 1). The process is equally well displayed in the origin of birds or reptiles, and

similar phylogenetic "trees" can be drawn for these groups. For earlier radiations, however, there is less evidence.

It should be noted that these diagrams are unnaturally simplified. Radiation is a phenomenon that occurs not only at the beginning of the successful career of a group; it continues throughout the group's dominance, each of the adaptive lines frequently giving rise by further subdivision to groups adapted to more restricted environments and habits of life.

The structural changes of adaptive radiation are brought about mostly by alterations in the relative sizes of the parts of the body, alterations produced by changes in the relative growth rates of the parts during development. More fundamental changes, such as the formation of new organs, do not form any large part of the process, though physiological changes are associated with this as with other types of evolutionary change. The very large changes of form that may occur in adaptive radiation are exemplified in a phylogenetic tree of the sharks and rays (see fig. 2).

Evolution of the Main Vertebrate Types.—The process by which the main types of vertebrate organization are evolved appears, at first sight, to be very different from adaptive radiation (see fig. 3). It is so, both in the much greater extent of the structural changes involved and in the evolution of many new organs. In the example of which there is most detailed knowledge, the origin of the mammals from the reptiles, it is evident that early in the radiation of the reptiles one of the radiating lines, the Synapsida, began to show modification in the direction of what was to be mammalian structure. These tendencies are already to be found in some of the earliest members of the group in Permian times. Thereafter some synapsidans became more and more mammallike until toward the end of the Triassic period, when the first animals that can be classified as mammals appeared. Meanwhile the Synapsida as a whole was undergoing typical radiation, and many forms diverged from the line of mammalian descent to become specialized in various directions.

The origin of mammals from reptiles occupied a period of about 40,000,000 years. This is not a surprisingly long time when the great complexity of the changes involved is realized. Almost every organ in the body was altered in structure and there was much evolution of new organs. Nevertheless it may be that the evolutionary changes of this process are the same in nature as those of adaptive radiation, though greatly exaggerated. All changes of structure in organs already present may be produced by alterations in the growth rates of parts of the body, if these are on a sufficiently small and detailed scale; and new organs may be formed by differentiations in originally undifferentiated tissues. But at least these changes were extremely numerous and detailed, and they must have been correlated throughout the evolution so that the animal remained viable. It is not surprising that their evolution required a long time.

It is probable that the evolutionary process is of the same nature in the origin of all the main types of vertebrate organization.

Conclusions.—From this discussion it appears that vertebrate evolution has consisted of a succession of adaptive radiations as each new type became successful and that during each radiation another type was evolved. In the vertebrate phylogenetic tree the succession of radiations and types stands out clearly. It must be noted, however, that in the progress of this evolution the vertebrate has undergone other changes besides adaptation to its environment. It has for instance shown continuous improvement of its organization so that it has been able to live a more active life and one in greater isolation from and independence of its environment. Also, throughout their evolution, vertebrates have invaded and exploited new parts of the earth's surface. Starting as bottom-living and probably mud-eating fishes (Agnatha) that may have been either fresh-water, estuarine or marine, they first, as true fishes, took dominance over all aquatic environments, chiefly in the fresh waters (most early fishes) and later, on two occasions (Chondrichthyes and Teleostei), returning to the sea. The invasion of terrestrial habitats took place in two steps; to semiterrestrial life in the amphibians and to full terrestrial life in the reptiles.

Throughout evolution, passage from one environment to another has occurred more than once in smaller groups; pterodactyls (extinct reptiles) and bats (mammals) as well as birds became aerial. Phylogeny, then, in a successful group such as the vertebrates displays a course of evolution that is not merely a sequence of structural change but a continuous extension of the dominance of the group, resulting from improvement of the organization of its individuals and associated with expansion into new environments and adaptation to new habits of life in these environments.

INVERTEBRATES

In vertebrate evolution a single group of animals all of the same fundamental structure and all clearly the descendants of a single evolutionary line (or phylum) is dealt with. In tracing the invertebrates, however, a considerable number of such lines must be considered, some widespread and dominant, others with few present-day representatives; some as progressive as the vertebrate lines have been, others static and showing little evolutionary change. Consequently the study of phylogeny within these phyla is further complicated by the study of the evolutionary relationships of the phyla to each other.

Since there is no reason to think that the processes of evolution found to have taken place in the vertebrates were peculiar to that group and since knowledge of evolution is much more detailed for the vertebrates than for other animals, it is reason-

able to discuss invertebrate phylogeny in the light of conclusions derived from study of the vertebrates.

Phylogeny Within a Phylum.—It seems probable, then, that evolution within the invertebrate phyla will have proceeded, as in the vertebrate phyla, by a succession of adaptive radiations alternating with development of new types of organization. So far as the evidence goes, it supports this conception. The evolution in the insect orders gives a tree (fig. 4) that resembles that of the mammalian orders (fig. 1) in form. Many orders are traced back nearly to the beginning of insect dominance in the Devonian and Carboniferous, when extensive radiation occurred. There is also evidence of later radiations. For some other invertebrate groups, such as the gastropod mollusks (snails; slugs, etc.), similar trees could be drawn, but

in very many groups the record is too incomplete. It may be assumed, until there is more evidence, that the evolution was of the same type in all.

Relations of Metazoan Phyla to Each Other.—The most difficult problems that phylogeny has to face are those of tracing the relationships of the animal phyla to each other. Here, paleontology is of little help, for the phyla were almost all separated before the period in which fossil-bearing strata were laid, and the animals mere soft-bodied and unlikely to have been preserved.

Thus, in dealing with these questions, phylogeny is forced to rely entirely on the evidence of morphology and embryology, but in many phyla the adult structure has been altered so greatly in evolution that it is difficult to form any but the broadest conclusions by comparison of it between the phyla. It has been noted above that the early stages of the life history alter in general less than does the adult, and it has in fact been found that it is mainly on larval and embryonic structure that students must rely in discussing these basic problems of phylogeny.

The sponges (Parazoa or Porifera) must be set aside; they probably had an origin from unicellular organisms separate from that of all the other multicellular organisms (Metazoa). The sponges are certainly far from the main stock of the animal kingdom.

Adult Structure.—All the Metazoa are probably related. From their adult structure they may be classified on the general complexity of their bodies. Those with two cell layers (diploblastic), ectoderm and endoderm, are separated from those that also have an intermediate cell layer (triploblastic), mesoderm. On this evidence the diploblastic coelenterates are probably a very early offshoot of the metazoan stock: distantly related to the rest of the Metazoa, though it has been suggested that they evolved from an ancestor of the flatworms (Platyhelminthes) by reduction of the mesoderm. In turn, the triploblastic animals with a body cavity lined by epithelium (coelomate) may be separated from those in which such a body cavity is not present (acoelomate). But this distinction is probably not of phylogenetic value, for a coelom has been evolved more than once.

Only one other of these phylogenetic problems can be solved on the evidence of adult structure. This is the relationship of the arthropods to the annelids. Arthropod structure is in all its fundamentals so nearly identical with the simpler structure of the annelids that usually it is assumed that arthropods are descended from animals which, if they were present today, would be called annelids.

Larval Structure.—For further conclusions larval structure must be studied. Comparing development in the various triplo-

FIG 5 — (A) TROCHOPHORE LARVA; (B) PLUTEUS LARVA

egg. The evidence of these characters does not correspond completely in all the phyla, but most of the phyla in which the larvae occur can be assigned to their groups.

The two groups, or superphyla, may be called the Trochophoralia (those having trochophore larvae) and the Plutealia (those having pluteus larvae) (see fig. 6). In some of the smaller phyla developmental as well as adult structure has been so altered in evolution that it is not possible to place them in the scheme with any certainty. This is true of such phyla as the Nematoda, Nematomorpha, Acanthocephala and Rotifera. These and some other small phyla are not included in fig. 6.

These larval resemblances imply descent in each of the two superphyla from an ancestral group that possessed these characters in its larvae. The form of the trees of fig. 6 suggests, when compared with the examples of adaptive radiation already considered, that the phyla diverged by very early radiations in these two groups of multicellular animals.

In each phylum the later development of the larva is characteristic of the phylum and different from that in other phyla. At this stage the organs typical of the phylum are formed; these organs are those required for the habit of life of the more primitive members of the phylum. If ancestral groups radiated to give rise to the early members of the phyla, it would be, on the analogy of vertebrate radiation, by each of the radiating lines becoming adapted to a distinct habit of life. It may be concluded, therefore, that the habits now found characteristic of the phyla were those adopted by their ancestors in this radiation and that the characteristic organs of the phyla were those evolved at that time in adaptation to these habits.

LARVAL CHARACTERISTICS

On the basis of this larval kinship the major phyla may be characterized as follows (fig. 7):

1. Superphylum Trochophoralia
 - a. Platyhelminthes, in which the trochophore (known as Müller's

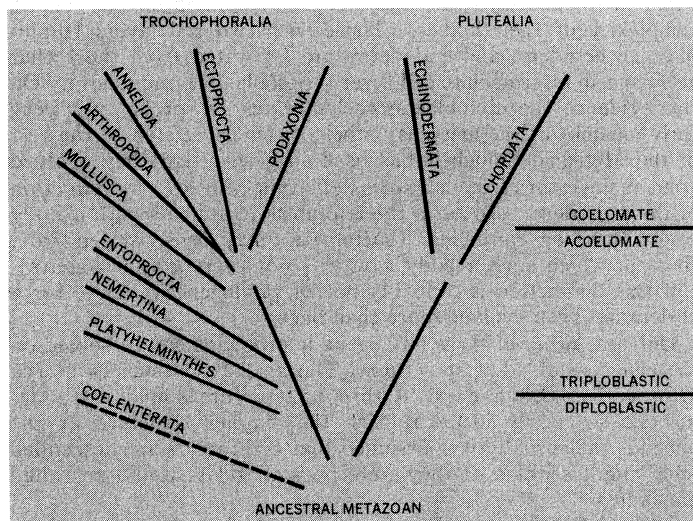

FIG. 6. — PHYLOGENY OF THE METAZOAN PHYLA

blastica phyla. it is found that the phyla fall into two large groups characterized by the presence of a larva of the "trochophore" type in the one, and by one of the "pluteus" type in the other. These two types of larva (fig 5) are distinguished by the position of the ciliated band that forms the locomotory (and feeding) organ of the larva and by other fundamental characters such as the mode of origin of the coelom and the arrangement of the cells in the earliest divisions of the

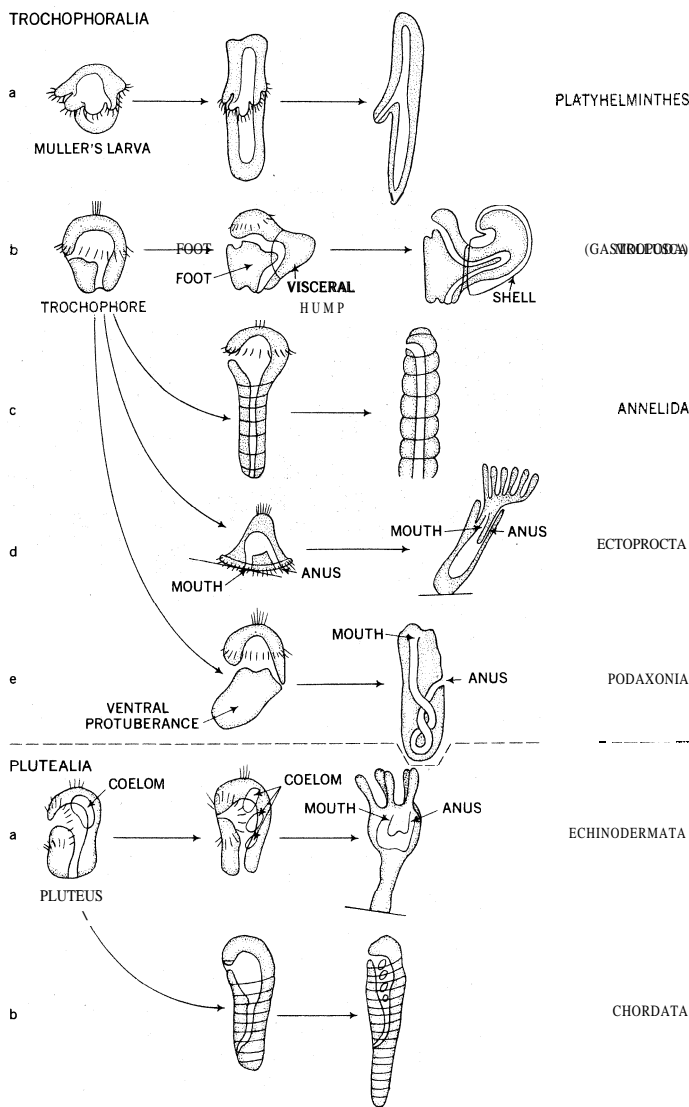

FIG. 7. — LATER DEVELOPMENT IN THE METAZOAN PHYLA

- a. larva) differs in some features from that in other phyla, were animals that took to gliding on their whole ventral surface, became elongate in an anteroposterior direction and flattened dorsoventrally. The Nemertina and Entoprocta were other acoelomate Trochophoralia that evolved in other ways.
- b. Mollusca were also gliding animals but glided on the region between the mouth and anus and not on the whole ventral surface. A ventral protuberance, the foot, was formed and used as the gliding organ. On the dorsal side another protuberance, the visceral hump, developed and became covered by the shell.
- c. Annelida took to a free life, moving by rhythmical contractions of the body, which was formed as an outgrowth in the anal region. Metameric segmentation arose in adaptation to this type of locomotion.
- d. The Ectoprocta (Bryozoa) were a group that became sessile.
- e. Podaxonia (sipunculids and perhaps *Phoronis*, though the latter is placed by some zoologists in the Plutealia) took to living in tubes. A protuberance was formed in the ventral region between the mouth and the anus, and this became covered by a tube.
2. Superphylum Plutealia
 - a. Echinodermata became sessile by an attachment in front of the mouth and developed five-rayed radial symmetry around their free ends.
 - b. Chordata mere free-living with the same type of locomotion as the annelids. They developed metameric segmentation, as annelids did, in adaptation to their mode of locomotion.

The foregoing more or less general view of the probable phylogeny of the animal kingdom must be very tentative and liable to modification with the advance of knowledge in view of the incompleteness of the evidence on which many of the conclusions are based.

ANIMAL SOCIOLOGY: see SOCIOLOGY, ANIMAL.

ANIMAL WORSHIP, a somewhat loose term, covering a wide range of phenomena, from the actual worship of divine animals, conceived as "god-bodies," at one end of the scale, through the representation of gods or spirits in animal form (theriomorphic symbolism), to ceremonial behaviour toward certain animals, living or slain, at the other end.

The sources of animal worship are manifold. Primitive man still is capable of feeling close to the animal world, and this closeness may border on a feeling of near-identity when a particular species or a particular animal is regarded as the ancestor or as the repository of the life power of the group (totemism) or the individual (nagualism). This closeness is also exemplified by the widespread belief in the possibility of transformation from one form to the other; e.g., werewolves. On the other hand the strangeness and mysterious superiority of the animal world (greater strength, extraordinary fertility, swiftness, capacity to fly in the air, sloughing of skin, etc.) render it a treasury of fitting symbols for the essentially mysterious and superior otherness of the holy. Animal forms thus may be even more expressive than human forms of the numinous.

There is, moreover, the magical aspect of much so-called animal worship which is designed to assure a successful hunt and an adequate supply of the species in question (this is generally held to be the significance of the scenes and animals depicted in prehistoric cave art) or, conversely, to provide protection against noxious species.

Ancient Egypt provides the best-known examples of animal worship, both in the sense of statuary and pictorial representations of gods in animal or rather half-animal shape (human bodies with animal heads), and in the actual treatment of particular animals as divine (e.g., the Apis bull). The animal ancestry, or at least animal aspects and symbolism, of many Greek gods is a well-established fact (e.g., Poseidon Hippius, Dionysus as bull or kid, etc.).

Whenever a symbolic relationship between men (individuals or groups) and animals obtains, it may well be permissible to speak of "totemistic psychology," though the theory that totemism is a uniform phenomenon and at the origin of all religion has been rejected (see TOTEMISM). This relationship may be predominantly magical (e.g., concerned with the increase of the species) as among the tribes of central Australia, or it may stress the taboo aspect as in Africa, or it may be focused on a personal guardian spirit or even animal alter ego, such as, for example, the nagual of Central American Indians or the *elanela*, usually a panther or serpent, among the African Fang. Military, medicine, dance and secret societies (e.g., the leopard societies in west Africa or the medicine societies of the North American Pawnee) often have animal names or symbols; the same habit is still alive, though in an attenuated form, among various modern societies, clubs, military units, etc.

Ceremonial behaviour toward animals, as distinct both from worship and from the recognition of a bond of some kind, is a

SEKHMET, EGYPTIAN GOD-DESS OF WAR, WITH HEAD OF LIONESS

characteristic feature of many hunting cultures. Absence of animal husbandry and dependence on the unpredictable appearance of the necessary food supply at the right period are reflected in many myths which assume a kind of primordial covenant between the animal and human worlds, presided over by the "lord of life," or "lord of animals." An adequate supply is assured to the hunter, provided that he observes certain rules and shows due respect to the animal as well as gratitude for its co-operation in going for the kill. Thus certain parts of the animal must be treated or eaten in specified ways (for instance, tobacco may be placed in the mouth of a slain bear as an offering) and circumlocutions are respectfully used when referring to the animal.

Most mammals, birds and reptiles figure in one way or another, in the religious and magical symbolism of mankind, some (e.g., serpents) more frequently than others. But whereas animals play a large role in the ritual practice of many primitive religions and in the symbolism of some of the more highly developed (e.g., Hinduism), actual worship of animals as incarnations or representations of the divine being or power are extremely rare.

ANIMISM, derived from *anima*, "breath" or "soul," is the doctrine of the reality of souls. In biology and psychology it is the view that mind or soul is an immaterial element that co-operates with the body through the brain and nervous system. In philosophy it is the theory that all natural objects are animate, ensouled or spirit-directed from within, and that mental and physical life has as its source or ground soul or spirit. Animism, however, probably will always be known chiefly as the term used by Sir Edward Tylor in *Primitive Culture* (1871) to describe his theory of the origin of religion and the beliefs of primitive peoples.

Tylor's Theory.—Tylor wrote his great work, *Primitive Culture*, in order to prove that religion began in animism. Animism is the attribution of a soul or spirit to living things and inanimate objects. To a full-blown animism nothing is really inanimate; everything is alive with spirit, active or not. Tylor wrote:

It seems as though thinking men, as yet at a low level of culture, were deeply impressed by two groups of biological problems. In the first place, what is it that makes the difference between a living body and a dead one; what causes waking, sleep, trance, disease and death? In the second place, what are those human shapes which appear in dreams and visions? Looking at these two groups of phenomena, the ancient savage philosophers probably made their first step by the obvious inference that every man has two things belonging to him, namely a life and a phantom.

Both life and phantom are perceived to be separable from the body: the life as able to go away and leave it insensible or dead; and the phantom as appearing to people at a distance. The second step taken by "the ancient savage philosophers" was to combine the life and the phantom and thus arrive at "that well-known conception which may be described as an apparitional soul, a ghost-soul." Tylor argued that in further steps of reasoning it was thought that the ghost soul was able to enter into, possess and act in the bodies of beasts, birds, reptiles and plants. But the theory of souls stretches beyond this limit.

Certain high savage races distinctly hold, and a large proportion of other savage and barbarian races make a more or less close approach to, a theory of separable and surviving souls or spirits belonging to sticks and stones, weapons, boats, food, clothes, ornaments, and other objects which to us are not merely soulless but lifeless.

Tylor felt that religion had its origin in early man's attribution of a soul like his own to every sort of living being and physical object around him. Religion is implicit in the experience of an African Negro:

He was going out on important business, but crossing the threshold he trod on this stone and hurt himself. Ha! ha! thought he, art thou there? So he took the stone, and it helped him through his undertaking for days.

Religion is man's establishment of a relationship between himself and the spirits which he felt "possessed, pervaded, crowded"

all nature.

Even though Tylor's theory has impressed anthropologists with its plausibility, it has been widely criticized as too intellectualistic. Was primitive man an "ancient savage philosopher" who felt a rational need to explain death and dreams and developed a theory? Hardly. Religion had a more intuitive, more emotional origin. Furthermore, was Tylor justified in imputing to primitive man a tendency to theorize that nature is universally animated, in all parts "possessed, pervaded, and crowded with spiritual beings"? It began to be felt that the facts are misinterpreted when it is said that the primitive man considers all objects to be alive. Two qualifications of Tylor's theory were seen to be necessary, and both were made by R. R. Marett in 1899 and later in his book *The Threshold of Religion* (1914).

Animatism.—Marett, in the first place, limited the primitive's conception of aliveness to objects that behave in an unusual way or queerly or that seem about to behave thus; such objects the primitive tends to regard as sacred, full of special potency. In the second place, the special potency or aliveness would not necessarily lead primitive man to attribute a soul or spirit to the object; for the notion of being alive is logically distinct from and historically and psychologically more rudimentary than the notion of possessing a soul or spirit. The object might be animated or alive without necessarily having a soul or spirit inside it; no sophisticated distinction between the body of the object and its soul was at first drawn. Marett called this animatism or preanimism. He was led to this view by the Melanesian conception of *mana* (*q.v.*), as it had been described by R. H. Codrington. Marett wrote:

Codrington defines *mana* as follows: "a force altogether distinct from physical power, which acts in all kinds of ways for good or evil, and which is of the greatest advantage to possess or control." . . . He illustrates his point by examples: "If a man has been successful in fighting, it has not been his natural strength of arm, quickness of eye, or readiness of resource that has won success; he has certainly got the *mana* of a spirit or of some deceased warrior to empower him, conveyed in an amulet of stone round his neck or a tuft of leaves in his belt, in a tooth hung upon a finger of his bow hand, or in the form of words with which he brings supernatural assistance to his side. If a man's pigs multiply and his gardens are productive, it is not because he is industrious and looks after his property, but because of the stones full of *mana* for pigs and yams that he possesses. Of course a yam naturally grows when planted, that is well known, but it will not be very large unless *mana* comes into play." (R. R. Marett, *The Threshold of Religion*, London [1914]: Methuen & Co. Ltd., pp. 103-105.)

Mana is, then, "a kind of communicable energy," not a soul. Marett found in *mana* a confirmation of his theory that the primitive mind tends to treat the inanimate, insofar as it is regarded as unusual or sacred, "as if it were animated—that is, alive and endowed with feelings and a will of its own," without being possessed of a soul. He was sure that while animism is characteristic of primitive peoples, it is accompanied, and probably preceded, by animatism.

Prevalence of Animism.—Not only primitives but millions of people in the larger, more complex cultures are animists. They agree in attributing to all sorts of objects a soul or spirit separable from, and destined to survive the destruction or dissolution of, its physical shell or container. This belief is an essential part of their medicine, magic and religion. In general, the larger natural objects that make up the frame of the world are thought to be the abode of spirits; while animals, human beings and certain individual objects have souls, so long, that is, as they are "alive"; after death or departure from the body, souls become spirits or ghosts, until such time as they may gain another body.

In animistic medicine, illness, delirium and insanity are held to result from a mishap occurring to the soul, such as its being lured from its body and trapped or captured; or, again, these states may result from "possession," that is, from the fact that one or more additional souls or spirits have, perhaps with evil intent, entered the body and troubled the soul that belongs in it. In the latter case it becomes the function of the shaman or medicine man to exorcise the invading soul or spirit.

Ancestor worship (*q.v.*) and animism are interrelated phenom-

ena; which is cause and which effect would be hard to determine. The souls of the dead are believed to survive the dissolution of their bodies, to linger near the scene of their former lives and to depend upon the living for food, remembrance and loyalty. This has been the basic factor in the popular religion of China for three millenniums.

Animism is also an aspect of nature worship. Not all nature worship is animistic. Sometimes the object is worshiped for the *mana* in it, its sacredness, its potencies; or, again, the object of worship may be far above the category of souls or spirits—some High God or Originator of all things. In between are all the spirits or souls found in stones, plants, trees, rivers, lakes, mountains, animals and men, and the gods and godlings of the polytheisms, as well as the evil spirits of demonology. See RELIGION: Primitive Religion; see also Index references under "Animism" in the Index volume.

ANIMUCCIA, GIOVANNI (c. 1500-1571), Italian composer, chiefly remembered for his collaboration with St. Philip Neri (*q.v.*), for whose popular services in the Roman oratory of S. Girolamo he wrote a number of *Laudi spirituali*. These performances later gave rise to the oratorio (*q.v.*).

Animuccia was one of the first to simplify the structure of early 16th-century church music. Though he was a prolific master of the traditional Netherlandish style, handling canon and *cantus firmus* with great fluency, his later experiments in short, clear-cut forms, syllabic melody and homophonic declamation may well have influenced Palestrina.

Like his brother Paolo (d. 1563), also a composer, Animuccia was born in Florence. In 1555 he became choirmaster of the Julian chapel, St Peter's, Rome, where he remained until his death in 1571. He published three books of madrigals (1547, 1551, 1554) and a mixed volume with some motets (1548), all in Venice; and in Rome books of Masses (1567), Magnificat (1568), madrigals, motets and *Madrigali spirituali* (1565) and two of *Laudi* (1563, 1570). Many sacred compositions remain unpublished.

(B. L. TR.)

ANION, a negatively charged particle or ion which moves toward the positive electrode or anode during an electrolysis or an electrical discharge. The anion is usually nonmetallic in character and consists of one or more atoms carrying a definite number of negative electric charges (see ELECTRON).

The chloride ion (Cl⁻) and the nitrate ion (NO₃⁻) are both univalent anions, while the sulfate ion (SO₄⁻²) is a bivalent anion. See also CATION.

(J. B. PS.)

ANISE, an annual plant, *Pimpinella anisum* (Umbelliferae, or parsley family), native to the eastern Mediterranean region and extensively cultivated for its seedlike fruits, the anise seed of commerce. The anise plant, up to 2½ ft. tall, has long-stalked basal leaves and shorter-stalked stem leaves. The small flowers, in loose umbels, are yellowish white. The fruits are about ¼ in. long, gray or greenish, ribbed, downy and aromatic. Principal anise-growing regions are southern Europe, southern U.S.S.R., the near east, north Africa, India, Pakistan, China, Chile, Mexico and the United States. Anise seed, or the essential oil therefrom, is used to flavour foods, beverages, medicines and dentifrices. The fruit of a tree (*Illicium verum*) of southeastern China and adjacent Vietnam, is the source of oil of star anise. The flavour and uses of star anise are similar to those of anise.

(J. W. TT.)

ANIUS, in Greek myth, was the son of Apollo and Rhoëa, a descendant of Dionysus. His mother, when pregnant, had been placed in a chest and cast into the sea by her father; floating to Delos she gave birth to Anius, who became a seer and a priest of Apollo. By his wife, Dorippe, Anius had three daughters, Oeno,

Spermo and Elais—that is, Wine, Grain Seed and Oil—who were granted by Dionysus the gift of bringing these three crops to fruition. They supplied both the Greek expedition on its way to Troy and Aeneas in his flight from Troy to Italy. (T. V. B.)

ANJOU, an ancient province of France, approximately corresponding to the modern *département* of Maine-et-Loire (*q.v.*) with the regions of La Flèche and Châteaue-Gontier. The name is ultimately derived from that of the Andes, a Celtic tribe inhabiting the area before the Roman conquest of Gaul. Organized in the Gallo-Roman period as the Civitas Andegavensis and in the Frankish period first as the Pagus Andegavensis and then as the Comitatus Andegavensis, or countship of Anjou, the country was raised to the rank of duchy by King John II of France in 1360.

Anjou was bounded in the north by Maine, in the east by Touraine, in the south by Poitou and in the west by Brittany. Geographically it included the regions of Segré, Baugé, Saumur and the Mauges and the part of the valley of the Loire round Angers (*q.v.*), which was the capital of Anjou.

Earliest History.—Anjou was conquered for the Romans by one of Julius Caesar's lieutenants in 57 B.C. After the unsuccessful rising of the Gallic chieftain Dumnacus in 52 B.C., the country enjoyed peace and prosperity throughout the Gallo-Roman period. In the course of the 5th century, however, at the same time as it was being converted to Christianity, it suffered from barbarian invasions. Under the Merovingians, it formed part of Neustria (*q.v.*). Under the Carolingians, it was administered by a count representing the king.

In 845 Lambert, a former count of Nantes, aided by Nomenoe, the ruler of Brittany, invaded the whole of the western part of Anjou, certain areas of which he occupied. Shortly afterward the Northmen or Normans, moving up the Loire valley, laid waste the entire region. In order to keep the Sormans in check, the Frankish king Charles II the Bald appealed for help to Robert (*q.v.*) the Strong, who engaged them in battle at Brissarthe (866). Robert was killed and his army defeated, and for some years the Normans were masters of Anjou. Angers was recaptured by Charles the Bald in 873, but until the end of the 9th century the Sormans continued to make dangerous incursions into the territory of Anjou.

First Dynasty of Counts.—Under one of the sons of Robert the Strong, Anjou was entrusted to a certain Ingelger, who became the founder of the first Angevin dynasty. Ingelger's son Fulk I the Red rid the country of the Normans and enlarged his domains by taking part of Touraine. He died in 942, and under his successor, Fulk II the Good, the destruction caused by the preceding wars was repaired. Geoffrey I Grisegonelle, who succeeded Fulk II *c.* 960, began the policy of expansion which was to characterize this first feudal dynasty. He helped Hugh Capet to seize the French crown, but died some months after the new king's accession (987).

Geoffrey's successor Fulk III Nerra (le *Noir* or the Black; see FULK NERRA), one of the most remarkable figures of his period and the most powerful member of the dynasty, ruled from 987 to 1010. He finally drove back beyond the frontiers of Anjou the Bretons who were still harassing the country, defeating the count of Rennes, Conan I, at the battle of Conquereuil (992). Having made himself master in the west he turned his attention to the east and came into conflict with the count of Blois Eudes II, over the territory of Saumur and a considerable part of Touraine. He defeated Eudes at Pontlevoy in 1016 and surprised and took Saumur ten years later. Fulk founded several abbeys and built strongly fortified castles of stone (instead of wood) along the border of his territory. He died on his return from a pilgrimage to the Holy Land, having reigned 53 years.

The victory won by Fulk's son Geoffrey II Martel (1040–60; see GEOFFREY) at Nouy (Aug. 21, 1044) assured to the Angevins the possession of the countship of Touraine. Pursuing the policy of expansion begun by his father, Geoffrey annexed the Vendômois and a part of Maine to Anjou. As he left no sons, his two nephews, Geoffrey III the Bearded and Fulk IV le Réchin, shared the succession. However, they soon came into armed conflict and Fulk defeated Geoffrey in 1068. Nevertheless he had to

give up most of the lands which Fulk Nerra had acquired and to defend his fief against the claims of the duke of Normandy. After the death of Fulk IV in 1109 his son Fulk V the Young (see FULK, king of Jerusalem) endeavoured to make good the losses caused by the various wars. He married his son Geoffrey Plantagenet to Matilda, the daughter of Henry I of England and widow of the emperor Henry V. In the crusade Fulk won such a reputation for valour that he was elected king of Jerusalem, where he died.

By his marriage to Matilda, Geoffrey Plantagenet acquired a claim to Normandy and England. Forced to spend his whole life fighting his rivals and the Angevin nobles, he nevertheless succeeded in pacifying Anjou, which in 1151 he left to his son Henry (later Henry II of England), count of Anjou and Maine and duke of Normandy, who married Eleanor (Aliénor) of Aquitaine after the annulment of her marriage to Louis Ist of France. Thus the Anglo-Norman empire of the Plantagenet dynasty was founded, extending from England to the Pyrenees. The existence of this empire was a threat to the Capetian monarchy in France, and the two dynasties entered into a struggle which lasted more than a century.

The Plantagenets never lost interest in the birthplace of their family, and Anjou was administered by a seneschal, who was not, however, always loyal. Henry II took steps to protect the valley of the Loire against flooding by building a dike along the banks of the river. He contributed to the foundation of the Hbte! Dieu (hospital) of Angers and bestowed many gifts upon the abbeys of Anjou, particularly Fontevault, in which his remains lie next to those of Eleanor of Aquitaine.

Philip II Augustus of France conquered Anjou from John of England at the beginning of the 13th century. An attempt by the English to retake Anjou failed when they were defeated at La Roche-aux-Moines in 1214. Anjou was finally attached to the crown of France by the treaty of Paris (1259).

During the 12th and 13th centuries there was an economic expansion in Anjou; wines were already being exported to England and the working of the slate quarries in the region of Angers was begun.

Second Dynasty.—In 1246 Louis IX of France gave Anjou as an appanage to his brother Charles, the future king of Naples and Sicily. Charles was succeeded by his son Charles II and the latter by his son-in-law Charles of Valois, under whose rule the economic and social conditions of the people of Anjou improved.

The son of Charles of Valois became king of France, as Philip VI, in 1328. From that year until 1351 Anjou was once more united to the crown and benefited from royal attention. The Hundred Years' War, however, together with the war of succession in Brittany, brought a return of insecurity. In 1348 the black death inflicted widespread devastation.

Third Dynasty.—John II of France gave the countship of Anjou to his son Louis (see Lours, kings of Naples) in 1351. Thus began the third Angevin dynasty, which was raised to ducal rank in 1360. At this period bands of English soldiers under the command of Sir Robert Knollys were wandering through Anjou, causing great destruction. The later Angevin princes were more interested in the conquest of the kingdom of Naples than in the defense of their duchy, and Louis II, as his father, Louis I, spent most of his life away from Anjou. After his death his widow, Yolande of Aragon, strove to protect Anjou against attacks by the English. In 1421 Thomas duke of Clarence, brother of Henry V of England, was defeated by the Angevin nobles at Baugé. Despite several attempts the English never succeeded in taking possession of Anjou again.

The last of the rulers of Anjou was René I (*q.v.*), whose pleasant disposition, simplicity and taste for literature and the arts endeared him to his subjects. After his death (1480) Anjou was for the last time returned to the crown of France and its fate was thenceforth linked with that of the French kingdom.

Later History.—During the 16th century Anjou played a part in the literary and artistic developments of the Renaissance. Fine châteaux were built, and poets such as Joachim du Bellay took the Loire as a theme for their verses. However, in the second half of the 16th century the country experienced further troubles in

the wars between Catholics and Huguenots. Members of the Holy league in Anjou refused for a long time to recognize Henry IV as king of France and abandoned their struggle only in 1598, shortly before the signing of the Edict of Nantes.

Anjou, then merely a province of France, was again during the 17th century the scene of disorders. In 1620 Marie de Médicis, the mother of Louis XIII. who had received the *gouvernement* of Anjou, rebelled against her son and took refuge in Anjou. After a brief struggle she submitted. More serious were the events which took place in the province during the Fronde. The people rose in revolt in protest against the severe taxes levied on them. and the royal army had to besiege Angers for three weeks before subduing it (1652).

In the 18th century, as a result of the efforts of the intendants of Tours, there was an upsurge of economic activity in Anjou. Roads and canals were built, and the textile industry (located in Cholet and in the district around Angers) and the slate quarries enjoyed great prosperity. On the eve of the Revolution Anjou was a rich province.

Administratively in 1789 Anjou formed two military *gouvernements* (Haut-Anjou and Bas-Anjou). It was part of the *généralité* (financial division) of Tours and comprised five *élections* (districts): Angers, Baugé, Saumur, Montreuil-Bellay, Château-Gontier and a part of the districts of La Flèche and Richelieu. One of the pays de grande gabelle (see GABELLE), it possessed 16 special tribunals or *greniers à sel* (salt warehouses). As regards judicial administration, Anjou was subject to the *parlement* of Paris. There was a presidial court at Angers, another at La Flèche and at Château-Gontier, seneschal's courts at Angers, Saumur, Baugé and Beaufort, and numerous seigniorial courts. Most of Anjou was included in the ecclesiastical diocese of Angers, although several parishes in the southern and western parts of the province belonged to the dioceses of Poitiers, Nantes and La Rochelle. When in 1790 France was divided into *departements*, Anjou, with the exception of La Flèche and Chateau-Gontier, formed the *département* of Maine-et-Loire.

BIBLIOGRAPHY.—*Principal Sources:* For the 10th, 11th and 12th centuries the most important text dealing with Anjou is the chronicle *Gesta consulum Andegavorum* or *Chroniques des comtes d'Anjou*, ed. by P. Marchegay and A. Salmon (1856–71) and by L. Halphen and R. Poupardin (1913). See also L. Halphen, *Étude sur les chroniques des comtes d'Anjou et des seigneurs d'Amboise* (1903).

Later works: The 11th century was treated in detail by L. Halphen in *Le Comté d'Anjou au XI^e siècle* (1906), which has a preface with bibliography and an introduction dealing with the history of Anjou in the 10th century. The work of Célestin Port, *Dictionnaire historique, géographique et biographique de Maine-et-Loire*, 3 vol. (1874–78), and its volume of *Préliminaires* (including a summary of the history of Anjou) contain comprehensive information on Angevin history. See also J. Chartrou, *L'Anjou de 1109 à 1151 . . .* (1928); J. Boussard, *Le Comté d'Anjou sous Henri Plantagenet et ses fils, 1151–1204* (1938) and "La Vie en Anjou aux XI^e et XII^e siècles," *Le Moyen Age*, no. 1–2, 29–68 (1950); J. Levron, *Petite Histoire de l'Anjou* (1947); P. Wagret et al., *Visages de l'Anjou* (1951); J. Boussard, *Le Gouvernement d'Henri II Plantagenet* (1956). (J. LE.)

ANKARA, the second largest province in Turkey. contains the capital city, Ankara (*q.v.*), situated, as other towns, on the green belt which encircles the steppe of central Anatolia and is linked by corridors with the other regions of Anatolia. Pop. (1960) 1,316,983. Area 11,835 sq.mi. The province includes most of ancient Galatia (*q.v.*) and is surrounded by nine other provinces. It is famous for the Angora (Ankara) goat, bred for its long silky hair, which provides mohair, and for the Angora cat, which also has beautiful fur and often eyes of different colours: one blue, one amber. Outside the city there is a carpetmaking industry and local products include honey and a special variety of pear. (A. F. U.)

ANKARA (formerly transliterated ANGORA), the capital city of Turkey and of Ankara province, stands on a rocky hill 500 ft. above the plain and 3,400 ft. above sea level. Its position on the edge of a high inland plateau, with plains to the west and south and mountains to the north, gives it a dry continental climate. Chosen as the new capital by Mustafa Kemal Atatürk because its remoteness from the sea made it easy to defend and officially so designated in Oct. 1923, it reflects the character of modern

BY COURTESY OF TURKISH PRESS BROADCASTING AND TOURIST DEPARTMENT

TEMPLE OF AUGUSTUS AND ROME, ANKARA, TURKEY. RESTORED BY AUGUSTUS, 1ST CENTURY B.C.

Turkey, with its emphasis on planning and westernization. Pop. (1960) 646,151 (mun.).

The old town of Ankara is built on and around the hill on which stands the walled citadel with its inner fort and white tower still standing but its outer walls in ruins. The least densely populated part of the city is the old town which has mainly narrow, winding streets with houses mostly built of mud brick, brick and wood, with tile decorations, though the old houses are interspersed with modern buildings. It includes the commercial quarter and Ulus square, the scene of national celebrations. The most northerly area, untouched by the city's rapid development, contains most of the ancient remains: the temple of Augustus and Rome (possibly 2nd century B.C., later restored by Augustus); the 3rd-century Roman baths; and the Byzantine column of Julian (attributed to the 4th century). In the old town also are the mosques of Arslanhane (1290), Ahi Şeref et Tin (1330), Ahi Elvan (1331–61), and Hacı Bayram (16th century). On the citadel hill is the archaeological museum (1951) containing outstanding Hittite remains. Near the inner citadel is the Alaeddin mosque (1178).

The main north-south artery is Atatiirk boulevard, which runs from Ulus square to the presidential palace on Çankaya hill at the south, passing the National Opera house, the People's house, the ethnographical museum, in front of which is an equestrian statue of Atatiirk by the Italian sculptor Canonica, and the faculty of letters. It then joins the new town (Yenisehir), passing Kizil Ay square, the centre of the most fashionable shopping and residential area. South of this is the Bakanliklar district, where the ministries are grouped, and the diplomatic quarter stretches to the south. The building of the grand national assembly is in the northwest of the city.

On the highest hill, to the west and visible from all parts of the city, is the impressive mausoleum of Atatiirk, completed in 1953. Other modern memorials are the Victory monument, on Ulus square, which commemorates the annihilation of the Greek army in Aug. 1922, and the Confidence monument, at Kizil Ay, with its inscription *Öğün, Çalış, Güven* ("Be Proud, Work, Be Confident"). Atatürk's house, in the grounds of the presidential palace, has become a museum.

Ankara has a university (founded 1946); a national library; a state-subsidized theatre; and a modern radio station. Ankara college, with over 4,000 pupils, boys and girls, is the largest school; the teaching of English is stressed and it has many British teachers. Gençlik parki (Youth park) lies between the railway station, to

the west, and the old town. The racecourse is to the northwest and there are two sports stadiums. A favourite excursion is to Çubuk dam, with casino and restaurant, set amid beautiful scenery 8 mi. to the north.

The city is linked by rail with Istanbul, Izmir and Adana and has road connections to all parts. The airport at Esenboga, 16 mi. distant, is used by regular international services.

History.—The date of Ankara's foundation is uncertain. Archaeological evidence points to its foundation by people living in Anatolia before the Hittites. The name Ankara is derived from Ank, a gorge or ravine. It has been suggested that the citadel was built in the Phrygian period as a fortress at the junction of the east-west and north-south trade routes. The Galatians, who invaded the region in the 3rd century B.C., appear to have founded another city there on the same site. For its early history see ANCYRA, the form of the name known from the end of the 9th century B.C. until its fall to the Seljuk Turks in A.D. 1073.

Captured by the crusader Raymond, count of Toulouse, in 1101 it was reclaimed in 1127 and passed to the emir Gazi of the Danishmend dynasty but about 1150 fell again to the Seljuks. After a period of Mongol domination it was taken in 1356 by Orkhan, the second of the Ottoman sultans, and became part of the Ottoman empire in 1360. Invested again during Tamerlane's Anatolian campaign, and the scene of a Turkish defeat in 1402, it reverted to Ottoman rule in 1403 and became a trading centre on the caravan route to the eastern provinces.

Ankara achieved new importance in 1919 when Atatürk chose it as the seat of the representative body and his military headquarters. In April 1920 the grand national assembly met in Ankara for the first time. The city's progress thereafter was rapid; it was replanned in 1928 with the help of the German engineer H. Jansen and, with its new high buildings and asphalted streets, it had become by the early 1960s the most modern city in Turkey. (A. F. U.)

ANKER, PEDER (1749–1824), Norwegian landowner and ironmaster who played an active part in the movement to bring about a union between Norway and Sweden, was born in Christiania (Oslo) on Dec. 8, 1749. As a landowner he was a pioneer of agricultural experiments, while his iron mill at Baerum became the biggest and most efficient in the country. From 1789 to 1800 he was also in charge of the road building scheme in southeastern Norway and did much to modernize the main roads. During the last seven years of the Dano-Norwegian union Anker belonged to the group which wanted to unite Norway with Sweden, and as a member of the constituent assembly at Eidsvold (1814) he was a leader of the pro-Swedish Union party. From 1814 to 1822 he was the leader of the Stockholm section of the Norwegian cabinet, and his tactful service in that difficult post proved of great value to his successors. He died at Bogstad, near Oslo, on Dec. 10, 1824. (D. MA.)

ANKING (AN-CH'ING), city of Anhwei province, China, on the north bank of the Yangtze river, 150 mi. S.W. of Nanking. Population (1953) 105,300. Before the railroad era, Anking (or Huai-ning as it was known from 1912 to 1949) was an important regional centre and the capital of Anhwei province, whose name is a contraction of *Anking* and *Hweichow*, former name of Sih sien (She-hsien), a town in southern Anhwei. With the advent of modern means of transportation, Anking was bypassed by railroad construction, and the city's importance gradually declined in favour of the railroad towns of Wu-hu (*q.v.*), downstream from Anking, and Kiukiang, upstream. After World War II, the provincial capital passed to Ho-fei. Anking became a local distributing and collecting centre for the rice-growing area on the north bank of the Yangtze. (T. SD.)

ANKLE, the joint which connects the foot with the leg (see JOINTS AND LIGAMENTS).

ANKYLOSIS (ANCHYLOSIS), in medicine, stiffness of a joint, the result of injury or disease. The rigidity may be complete or partial and may be due to inflammation of the tendinous or muscular structures outside the joint or of the tissues of the joint itself. When the structures outside the joint are affected, the term false ankylosis has been used in contradistinction to true ankylosis,

in which the disease is within the joint. When inflammation has caused the joint ends of the bones to be fused together the ankylosis is termed osseous or complete. Excision of a completely ankylosed shoulder or elbow may restore free mobility and usefulness to the limb.

Ankylosis is also used as an anatomical term, bones being said to ankylose when, from being originally distinct, they coalesce, or become so joined together that no motion can take place between them. See JOINTS AND LIGAMENTS, DISEASES AND DISABILITIES OF.

ANKYLOSTOMIASIS: see ANCYLOSTOMIASIS.

ANNA (ANNA IVANOVNA) (1693–1740), empress of Russia from 1730 to 1740, was born in Moscow on Feb. 7 (new style; Jan. 28, old style), 1693, the second daughter of Peter the Great's feeble-minded half brother Ivan V (d. 1696). She spent her girlhood under the conflicting influences of her mother, Praskoviya Fedorovna, née Saltykova, who was a bigoted woman of the old school, and of Peter, who wanted to endow his nieces with western accomplishments. On Nov. 11 (N.S., Oct. 31, O.S.), 1710, Peter married Anna to Frederick William, duke of Courland; but the young duke, whose health had been affected by the lavish wedding celebrations in St. Petersburg, died on the way home. In pursuance of his political aims Peter forced Anna to take up residence at Mitau (Jelgava). In spite of the efficiency of Peter's agent, P. M. Bestuzhev-Ryumin, who acted as her adviser, Anna's residence in Courland was embittered by the permanent inadequacy of her revenue and by political intrigues. After Catherine I (1725–27) had designated Peter's descendants as her successors, Anna's chances of ascending the Russian throne seemed remote. However, in 1730, at the death of Peter II, the supreme privy council, which was composed almost entirely of members of the old nobility, decided to offer the crown to Anna, as the council rightly calculated that she would agree to a drastic limitation of her powers in its favour.

On Feb. 26 (N.S., 15, O.S.), Anna made her public entry into Moscow. Meanwhile the oligarchic aims of the supreme privy council had been countered by claims put forward by the gentry; and on March 8 (N.S., Feb. 25, O.S.), encouraged by appeals in favour of autocracy, Anna tore up the "conditions" that she had signed a month earlier.

The privy council was abolished and the authority of the senate restored (1730). But since Anna was neither equipped nor disposed to deal with state business a cabinet of three ministers was formed (1731). Actually, however, all power was in the hands of Anna's German favourite Ernst Johann Biron (*q.v.*), who had supplanted Bestuzhev in Courland. Although Biron did not hold any responsible posts, his name became associated with all negative features of Anna's reign.

Prompted by dislike and fear, Biron instigated a continuous persecution of the Russian nobility, showing no mercy even to men not involved in the abortive attempt to impose the "conditions" and to keep him away from Russia. The support given by the gentry was rewarded by a gradual mitigation of the burdens imposed by Peter the Great. On the other hand, two new guards regiments with German officers (1730) provided a counterbalance to the old guards, who were the mainstay of the gentry. All external as well as important internal affairs and all military problems were in the care of two other foreigners, Andrei Ivanovich Osterman and Burkhard Christoph Münnich (*q.v.*), who had entered Russian service under Peter. The empress herself was preoccupied with making up for lean years in Courland and had to be incessantly provided with sumptuous entertainments and crude amusements. The increased expenditure of the court, combined with war expenses, led to a relentless extortion of taxes from the peasants—the steady deterioration of whose social status was in contrast with the advantages gained by the upper classes. Against the growing resentment among all groups of the population, the government applied the old remedies—spying, denunciations, torture, banishment and executions—so ruthlessly that posterity remembered them as the special hallmark of the Biron regime.

Even the brilliant military achievements in the War of the

Polish Succession (1733–35) and in the Turkish War (1735–39) did not offset the gloomy picture, particularly since the outcome of the Turkish War scarcely justified the tremendous cost in life and money. Although Münnich had invaded the Crimea and inflicted several heavy defeats upon the Turks, the peace treaty of Belgrade (1739) gave Russia only an area of steppes with no immediate exit to the sea, since Azov (lost by Peter the Great and recaptured in this war) became no man's land. Another change of Russia's frontiers took place in the Caucasus, where Peter's acquisitions on the west coast of the Caspian sea were restored to Persia (1732). Russia's European policy was all the time based on a close alliance with Austria. A commercial treaty concluded by Osterman in 1734 improved Anglo-Russian relations.

The one problem that greatly worried the empress from the start was the succession, which she intended to reserve for a descendant of her father. In Aug. 1740, she made up her mind in favour of the newly born son of her young niece Anna Leopoldovna, whose marriage to Anton Ulrich of Brunswick she had arranged the previous year. On the eve of her death, which occurred in St. Petersburg on Oct. 28 (N.S. 17, O.S.), 1740, Anna appointed Biron to be regent during the infancy of the child, who succeeded her as Ivan VI.

See K. Waliszewski, *L'Héritage de Pierre le Grand* (1900); R. Nisbet Bain, *The Pupils of Peter the Great* (1897). (Lo. L.)

ANNA (ANNA LEOPOLDOVNA) (1718–1746), regent of Russia for her son the emperor Ivan VI (*q.v.*) from Nov. 1730 to Dec. 1741, was the daughter of Catherine, sister of the empress Anna Ivanovna (*q.v.*), and Charles Leopold, duke of Mecklenburg-Schwerin. Born at Rostock, in Mecklenburg, on Dec. 18 (new style; Dec. 7, old style), 1718, she grew up in Russia and in 1739 reluctantly agreed to marry Prince Anton Ulrich of Brunswick (1714–74), a nephew of the Holy Roman emperor Charles VI who had been chosen for her by the empress Anna. On Aug. 23 (S.S.: Xug. 12, O.S.), 1740, Anna gave birth to her son Ivan who on Oct. 16 (K.S.; Oct. 5, O.S.) was proclaimed heir to the Russian throne. Twelve days later the empress Anna died, after having appointed her favourite, E. J. Biron (*q.v.*), as regent. The duchess Anna was soon forced to approach field marshal B. C. Münnich (*q.v.*) for help. At dawn on Nov. 20 (N.S.; Nov. 9, O.S.) Biron was deposed and Anna proclaimed regent (*pravitel'nitsa*). Her ineptitude, however, together with the general dissatisfaction with the German domination in Russia, enabled Peter the Great's daughter Elizabeth (*q.v.*)—who was both popular with the guards and backed by France—to carry out her *coup d'état*, on Dec. 6 (N.S.; Nov. 25, O.S.), 1741. At first Elizabeth intended to send the Brunswick family to Germany, but on their arrival in Riga she became scared by plots, and the whole family was interned in the fortress of Dunamunde (Dec. 1742). In 1744 the prisoners were deported to Kholmogory in the far north, where Anna died in childbed, on March 18 (K.S.; 7, O.S.), 1746. Ivan, from 1756 on in solitary confinement in Schlussemburg, was killed there in 1764.

See A. Brückner, *Die Familie Braunschweig in Russland* (1876). (Lo. L.)

ANNABERG-BUCHHOLZ, a town in the district of Karl-Marx-Stadt, Germany, lies at an altitude of 1,975 ft. in the Erzgebirge mountains 22 mi. S. of Karl-Marx-Stadt. Pop. (1939 est.) 29,341. St. Anne's church, built between 1499 and 1525, has painted reliefs and sculptures dating from the early 16th century. The Erzgebirge museum was founded in 1887.

Annaberg and Buchholz originated as silver-mining towns in 1496 and 1501 respectively and were amalgamated in 1945. They were formerly the centre of the German lace and silver-lace industries.

The town's chief manufactures are now cardboard goods and furnishing fabrics. (K. H. B.)

ANNA COMNENA (1083–after 1148), Byzantine historian whose *Alexiad* is an invaluable source for the period of the first crusade, was the elder daughter of the Emperor Alexius I Comnenus. She was born on Dec. 1, 1083, and received a good education, studying a wide range of subjects including literature and philosophy, history and geography. She also had a fairly ac-

curate knowledge of medicine and nursing. In 1097 she married Nicephorus Bryennius (*q.v.*), and she united with her mother the Empress Irene in a vain attempt to persuade her father, during his last illness, to disinherit his son in favour of her husband. She then conspired to depose her brother, John II Comnenus, after his accession in 1118, and on her failure she retired into a convent, where she wrote the *Alexiad*, the history of her father. This provides a continuation of her husband's work and deals with the period 1069–1118.

Anna had a keen sense of the Greek historical tradition, and the *Alexiad* gives a characteristically Byzantine point of view on the westerners. It also provides a picture of religious and intellectual activities within the empire and reflects the Byzantine conception of the imperial office.

BIBLIOGRAPHY.—For the *Alexiad* see editions by A. Reifferscheid in the Teubner series, 2 vol. (1884); by L. Schofen, vol. 1 (1839), and A. Reifferscheid, vol. 2 (1878), in the Bonn corpus with C. Du Cange's valuable commentary, and in J. P. Migne, *Patrologia Graeca*, vol. 131 (1864); by B. Leib, with French trans., in the Budé series, 3 vol. (1937–45) Eng. trans. by E. A. S. Dawes (1928). See also G. Moravcsik, *Byzantinoturcica*, vol. 1, pp. 219–223, 2nd ed. (1958); G. Ostrogorsky, *History of the Byzantine State*, pp. 311–312 and 333–334 (1916); and the detailed study by G. G. Buckler, *Anna Comnena* (1929). (J. M. Hy.)

ANNALISTS, writers of annals (annales, "chronicles," properly "yearbooks"); a name commonly given to the Roman historians before Livy who drew up the conventional history of Rome from the foundation of the city. The form and content of the latest annalists may be judged from the books of Livy. Yet the term is too general, and it is necessary to distinguish various stages in the development of their work.

Although only scanty records survived from the period before 390 B.C.—and the Gallic sack of Rome in that year cannot be entirely to blame—there is evidence of more authentic tradition from the 4th century. Certainly after c. 300 B.C. the pontifical college kept regular records—the annual tabulae *pontificum*—containing the names of magistrates and notices of public events of religious significance. These tables provided the first *Annales*, from which Quintus Ennius (239–169 B.C.) drew the title of his historical epic. That their character was still sacral in the time of Marcus Porcius Cato (*q.v.*) (called the Censor) (234–149 B.C.) is clear from his *Origines*, and there is little reason to suppose that they were yet published in the form of chronicles.

The first Roman historians were senators, who early in the 2nd century B.C., at the time of the Roman intervention in the east, wrote in Greek in order to interpret the traditions, institutions and policy of Rome to the Hellenistic world. They treated the origins of Rome fully, on the basis of Roman legends and Greek antiquarian studies; the early republic briefly, using such records as they could find, along with their family traditions; and recent and contemporary times again more fully, as they found more material: both in the public records and in personal memoirs that now began to be written (see the article *COMMENTARI*). Among these writers may be named Quintus Fabius Pictor, whose material can be identified in parts of the historian Polybius; L. Cincius Alimentus, who had been a prisoner of Hannibal; P. Cornelius Scipio, the son of Africanus; A. Postumius Albinus; and C. Acilius, whose work was used by Quintus Claudius Quadrigarius and so transmitted to Livy.

Cato brought this type of history to the Roman public by writing his *Origines* in Latin. He treated first the foundation stories of Rome and the Italian peoples—hence the title—and then the important episodes of recent history. This development led to more regular antiquarian research, notably by Lucius Cassius Hemina and L. Calpurnius Piso Frugi (see under *PISO*), who probably wrote in stricter annalistic style. About 123 B.C. the pontifex maximus, P. Mucius Scaevola, published a collection of records in his books, the *Annales Maximae*, covering from the earliest times (ab *initio rerum Romanarum*) to his own day. Although the first part may be open to suspicion, the work as a whole was systematic and authoritative, and it provided the conventional framework of annalistic history from then onward. The formal, even ritualistic, language of much of the later annalistic tradition may be attributed to the influence of the *Annales*

Maximi.

At this time, too, the Roman writers adopted the rhetorical technique of elaborating notices of public business, reports of debates and descriptions of battle scenes, so as to fill out the records, often in anachronistic terms derived from their own political situation. This development may have begun with the Gracchan annalist Gnaeus Aulus Gellius. Certainly it was carried on by the later annalists. Q. Claudius Quadrigarius was sufficiently critical of the early traditions to begin his history as late as the Gallic sack of Rome; he brought it down to Sullan times in at least 23 books, of which Livy made considerable use. A younger contemporary, Valerius Antias, who wrote the history of Rome from the foundation of the city down to his own day in at least 75 books, is notorious for willful exaggeration of casualty figures and distortion of historical material. Livy, however, though he continually cites him as untrustworthy, made extensive use of his narrative. The annalistic tradition was revised by Gaius Licinius Macer (d. 66 B.C.), who studied the evidence of magistrates' lists and wrote with a democratic and family bias; and by Q. Aelius Tubero, who fought on Pompey's side against Caesar. These historians brought the annalists' work down to a point at which Livy could pick it up and transform it from political writing into the national history of Rome. The literary form continued in the imperial historians to the *Annals* of Tacitus.

ANNALS (from Lat. *annus*, "year"), in a precise sense, are records of appointments and other noteworthy events, arranged in a chronological sequence, normally according to solar years. For the Roman compilers of such lists see **ANNALISTS**. In the Christian era (see **CHRONOLOGY**) "Paschal" or "Easter" annals developed in western Europe, mainly during the 8th century, from the practice of noting memoranda in the margins of tables of annual lunations governing the date of Easter. For more complex forms of strictly chronological historiography, see **CHRONICLE**.

ANNAM, the historic kingdom which extended along the coast of Indochina (*q.v.*) roughly between the Song Ma (river) to the north and Cap Bake to the south. Its territory is now divided so that the lesser part, north of latitude 17° N., is in the Communist state of North Vietnam, the rest in South Vietnam. Annam retained its integrity until 1954 after a history of over 21 centuries during which it repeatedly came under imperial Chinese suzerainty. It owed its creation in 207 B.C. to a Chinese general who established himself as a monarch during a period of imperial weakness. It was made a French protectorate in 1883 and its last emperor, Bao Dai, became emperor of all Vietnam before being deposed by popular vote in 1955. See **VIETNAM**.

(E. H. G. D.)

ANNAMESE LANGUAGE: see **VIETNAMESE LANGUAGE**.

ANNAN, a small and royal burgh of Dumfriesshire, Scot., lies on the river Annan, nearly 2 mi. from its mouth which opens into the Solway firth and 16 mi. E.S.E. of Dumfries by road or rail. Pop. (1961) 5,572. The Annan is crossed by a stone road bridge (1824); a railway bridge; and two foot bridges, one a suspension bridge. Shipping accommodation, improved in 1897, gives 15-ft. depth at high water spring tides. Industries include the making of boilers, machinery, cranes, chemicals and gloves. Flour milling and fishing, especially for salmon and shrimps, are important. In the 1950s four atomic reactors were built on the disused Creca airfield at Chapelcross, 3 mi. N.E. of Annan, a border town which was often raided and razed by the English between the 14th and 16th centuries. Gretna Green (*q.v.*) is 8 mi. E., while to the north is Ecclefechan, the birthplace of Thomas Carlyle.

ANNA PERENNA, an old Roman deity of the circle or ring of the year, as the name (per annum) clearly indicates. Her festival, characterized by popular merrymaking, fell on the full moon of the first month (March 15) and was held at the grove of the goddess at the first milestone on the Via Flaminia. Sac-

rifice was offered to her "that the circle of the year might be happily completed." This is all that is known for certain about the goddess and her cult, but the name naturally suggested myth-making, and Anna became a figure in stories in Ovid and in Silius Italicus. The myth related by Ovid in the *Fasti*, that Anna promised to procure Minerva for Mars but instead substituted herself in disguise, is probably an old Italian folk tale. She was occasionally confused with Anna, the sister of Dido. (T. V. B.)

ANNAPOLIS, a city of Maryland, U.S., the capital of the state and seat of Anne Arundel county, is located on the Severn river about 2 mi. from its entrance into Chesapeake bay. 26 mi. S.E. of Baltimore and about the same distance northeast of Washington, D.C. It is a port of entry of the Maryland customs district, the seat of the U.S. Naval academy (see **MILITARY, NAVAL AND AIR ACADEMIES**) and the headquarters of the Severn river naval command. A council-manager form of government has been effective since 1949. The city's population more than doubled within a decade, in part because of the annexation of adjacent areas in May 1950. (For comparative population figures see table in **MARYLAND: Population**.) Since the late 19th century a large proportion of the Annapolis population has been associated with the national and state government activities located there.

Annapolis is one of the most picturesque and historically interesting cities of the United States. The grounds and buildings of the U.S. Naval academy (founded in 1815) occupy a beautiful 309-ac. site on the south bank of the Severn. On an elevation near the centre of the city stands the state house (1772), with its lofty white dome and pillared portico. Nearby are the old state treasury (1737) and St. Anne's Protestant Episcopal church, which was a state church in the later colonial days. More than 60 Annapolis residences were built before the American Revolution, including the homes of three of Maryland's signers of the Declaration of Independence. Outstanding as examples of Georgian architecture in America are the Brice house, Chase house and Hammond-Harwood house. Colonial associations are further preserved by the names of some of the principal streets, such as King George's, Prince George's, Hanover and Duke of Gloucester.

The city harbours several thousand pleasure craft during the season. The harbour is dredged but cannot accommodate deep-draft vessels. There are a number of boat yards, one of which produced several minesweepers during World War II. The seafood industry (crabs and oysters) offers seasonal employment, and there are a number of small manufacturing firms making plastics and instruments. Johns Hopkins university maintains an oceanographic laboratory near Annapolis.

History.—Annapolis was settled in 1649 by Puritan exiles from Virginia. First called Providence, later, Town of Proctor's. Town at the Severn and Anne Arundel Town, it was named Annapolis in 1691, in honour of Princess Anne, then heir to the throne of Great Britain. In the same year it was made the seat of the new (royal) government. It had considerable commerce until Baltimore, in 1780, became a port of entry. The U.S. congress was in session in the state house from Nov. 26, 1783, to June 3, 1784, and it was there that Washington, on Dec. 23, 1783, resigned his commission as commander in chief of the Continental army. The Annapolis convention (*q.v.*) of 1786 was a meeting to which all the states were invited to send delegates to consider measures for the better regulation of commerce; partly because only five states were represented (New York, Pennsylvania, Virginia, New Jersey and Delaware), however, the delegates merely passed a resolution calling for another convention to meet in Philadelphia the following year, to amend the Articles of Confederation. It was this convention that framed the constitution of the United States.

St. John's College.—Chartered in 1784 as a continuation of King William's school, founded by an act of the legislature in 1696, the college occupies a campus of 26 ac. adjoining the grounds of the Naval academy. One of the trees on the campus is believed to be more than 600 years old. The main building, McDowell hall, was built in the 18th century to be the governor's mansion and was the scene of many historic events. In 1937 a unique, unified, all-required curriculum was introduced, built around the reading and discussion of the great books of western civilization,

supplemented by mathematics and language tutorials and by science laboratories. The college, which is private, is nonsectarian and coeducational. The state offers scholarships to students from each of the counties of Maryland and from the city of Baltimore. (R. M. LA.)

ANNAPOLIS CONVENTION, in U.S. history, a gathering of delegates from five states in Sept., 1786, at Annapolis, Md., that was an important rallying point in the movement toward a federal convention to revise the Articles of Confederation (*q.v.*). It was a commercial convention which originated as one of a series of meetings held between Maryland and Virginia concerning the use of waterways lying between the two states. In 1784 George Washington had reaffirmed his long-established interest in improving communication with the west by taking a leading part in promoting plans for improving navigation of the Potomac and Chesapeake waterways. The conference held at Mount Vernon in March 1785 (but in which Washington did not participate), helped to smooth the way for a joint Virginia-Maryland project, but the co-operation of Pennsylvania was seen to be needed because western routes also involved that state. This factor gave James Madison and Washington the idea of using the regional meeting for national purposes. Madison arranged to have an invitation to the Annapolis meeting extended not only to Pennsylvania but to all of the states so that problems of commerce could be discussed on a national scale.

The need for such a meeting had become increasingly evident because of problems confronting foreign and domestic commerce. Since recognition of American independence in 1783, Britain had scorned the idea of a commercial treaty with the new nation, which she termed the "disunited states," by suggesting that not one treaty but 13 would be needed. The Barbary pirates were thwarting the efforts of U.S. citizens to trade with the Mediterranean area. Moreover, America's "perpetual ally," France, was too deeply involved in her own mercantilist policy to have room for commercial "friendship." These foreign factors, as well as the problems connected with interstate commerce, caused the belief to spread that the only solution lay in changing the Articles of Confederation to grant the central government power to regulate commerce.

In spite of the apparent need for concerted action, only Virginia, New Jersey, Delaware, New York and Pennsylvania were represented at Annapolis, Sept. 11–14. No delegates were named from Maryland (nominally the host state of the convention), Connecticut, Georgia or South Carolina. Delegates were chosen from New Hampshire, Massachusetts, Rhode Island and North Carolina but they did not attend. Of the 12 men who went to Annapolis, Alexander Hamilton and James Madison in particular hoped to broaden the agenda to include more than commercial matters and to use the convention as a sounding board for broad revision of the Articles of Confederation. The delegates realized, however, that with only 5 of the 13 states represented they could neither deal with national commercial problems nor recommend changes in the articles. They therefore drew up an address to the states citing the authority given to the New Jersey delegation as a useful example and urging that another meeting of commissioners from all the states be called to examine the defects of the system and design a plan to correct them. In agreeing to this address the delegates stretched their authority to the utmost, but in so doing they in effect issued the call which resulted in the meeting eight months later at Philadelphia where a new federal constitution was drafted. See also UNITED STATES (OF AMERICA): History.

Miller, *Alexander Hamilton: Portrait in Paradox* (1959); Edmund C. Burnett (ed.), *Letters of Members of the Continental Congress*, vol. viii (1936). (H. I. BE.)

ANNAPOLIS ROYAL, Nova Scotia, Can., capital of Annapolis county and till 1750 of Nova Scotia; on an arm of the Bay of Fundy, at the mouth of the Annapolis river, 95 mi. W. of Halifax; on the main Canadian Pacific railway, 63 mi. by steamer from Saint John, N.B. Pop. (1956) 765. It is one of the oldest settlements in North America, founded in 1605 by the French, who

called it Port Royal. It was captured by the British in 1710, ceded to them by the treaty of Utrecht in 1713, and renamed in honour of Queen Anne. Fort Anne, the oldest fortification in North America, is a historical museum. Once the centre of a shipbuilding and lumber industry, the town is now a market town and tourist resort. (C. T. BL.)

ANNAPURNA, a mountain massif, is part of the central section of the Nepal Himalayas. It forms a ridge about 30 mi. long between the basins of the Kali Gandaki and the Maryandi rivers and contains four main summits of which Annapurna I (26,391 ft.) and II (26,041 ft.) stand at the western and eastern ends of the range respectively; III (24,858 ft.) and IV (24,688 ft.) stand between them.

Annapurna I is the 11th highest peak in the world. Before 1950 it was almost unknown to the general public, but in that year it became famous as the first peak more than 8,000 m. (26,246 ft.) high to be climbed. Though greater heights had been reached on mountains before (*e.g.*, by E. F. Norton and T. H. Somervell, who in 1924 reached 28,150 ft. on Mt. Everest), the climbing of the first 8,000-m. peak had long been an ambition of European mountaineers in the Himalayas.

The feat was achieved by a French expedition led by Maurice Herzog. Their original objective was Dhaulagiri which stands to the northwest across the Kali Gandaki, but having failed to find a practicable route up that mountain they turned their attention to Annapurna I. Neither mountain had previously been reconnoitred, and so much time had to be spent upon this task that when at length a route up the northern face of Annapurna was found, very little time was left before the onset of the monsoon. Five camps were established, the highest of which, at 24,600 ft. was occupied on June 2 by Herzog and Louis Lachenal, who reached the summit on the following day. During the course of their withdrawal to Camp IV, the party met with a series of misfortunes with the result that Herzog and Lachenal were severely frostbitten. Annapurna I was the first of the great peaks of the Himalayas to be climbed at the first attempt, a fact which greatly enhanced the quality of the French expedition's achievement.

Annapurna IV was climbed on May 30, 1955, by H. Biller, H. Steinmetz and J. Wellenkamp, and Annapurna II on May 17, 1960, by R. H. Grant and C. J. Bonnington in an expedition led by J. O. M. Roberts.

See *M. Herzog, Annapurna* (1952).

(E. E. SH.)

ANN ARBOR, a city of Michigan, U.S., on the Huron river, 38 mi. W. of Detroit; seat of Washtenaw county. The population of the city of Ann Arbor was 67,340 in 1960 and that of the standard metropolitan statistical area (Washtenaw county) was 172,440. John Allen and Elisha W. Rumsey founded Ann Arbor in 1824 and honoured their wives, both named Ann, in naming the town. It became the county seat in 1827; was incorporated as a village in 1833; and chartered as a city in 1851. The earliest settlers came from New York and Virginia; they were joined later by German and Irish immigrants. Favourably situated on the Huron river, the Territorial road, and the Michigan Central railroad, which brought the first train through from Detroit in 1839, the town became the trading centre of a rich farming area.

The opening of the University of Michigan in Ann Arbor in 1841 largely determined the future of the town. Feeding and housing students and providing for their other needs were important economically. On the other hand, the university made available to townspeople, as well as faculty and students, a great variety of cultural activities not usually enjoyed in a small city. The most noted of its annual programs, attended by persons from all parts of the state, are the drama season, the May music festival, the winter concert series and the lecture course.

Ann Arbor long ago crossed the Huron river and expanded far beyond the limits of the original village. Tree-lined streets, beautiful houses on gentle slopes and the university campus make it an attractive residential community.

About 80 industrial establishments produce tools, bearings, springs, photographic equipment, balers, gauges and instruments for automobiles. (F. CL. B.)

ANNATES, a term with varied meanings, refers in general to

the whole or a part of the first year's fruits of a benefice (q v), to be surrendered by the new incumbent either to the bishop or to the pope (Lat. *annatae*, from *annus*, 'year'; also *primitiae*, first fruits). The first mention of the practice appears in the time of Pope Honorius III (d. 1227). The earliest records show the *annatae* to have been sometimes a privilege conceded to the bishop for a term of years, sometimes a right based on immemorial precedent. In the course of time the popes claimed the privilege for themselves, at first only temporarily, in order to meet particular financial needs. Thus, in 1305, Clement V claimed the first fruits of all vacant benefices in England and in 1319 John XXII those of all Christendom vacated within the next two years. The more usual custom was for the pope to claim the first fruits only of those benefices the appointment of whose incumbents was reserved to himself. Thus arose the historically more significant papal annates.

The system never was applied with uniformity or effectiveness throughout the territories of the church; and the feeling that benefices were excessively reserved with a view to the unnecessary increase of the papal revenues led to such protests as that of the bishops and barons of England, headed by Robert Grosseteste of Lincoln, at the Council of Lyons in 1245. Later, under the Annates Statute of 1534, Henry VIII was to claim the English annates for the crown. With the gradual transformation of the system of benefices, papal annates fell into disuse.

From the time of Benedict XIV (1740-58) the term has referred to the half-portion (*media annata*) of the first year's income from parochial benefices, which, in Italy and the adjacent islands, was to be contributed toward the restoration of the cathedral and collegiate churches of the respective diocese. In the matter of annates the Code of Canon Law provided only that wherever the system still obtained in the form of particular statutes and customs, these should continue to be observed.

See W. E. Lunt (ed and trans.), *Papal Revenues in the Middle Ages*, vol. i, pp. 93-99. and vol. ii, pp. 315-372 (1934). (J. J. RE.)

ANNATTO (ANATTO, ARNOTTO), a colouring matter that was much used by South American Indians for painting their bodies; among civilized communities its principal use is for colouring butter, cheese and varnishes. It is produced from the seeds of *Bixa orellana* (family Bixaceae), a small tree that grows in Central and South America. The seeds are surrounded with a thin coating of a waxy pulp, which is separated from them by washing in water, passing the liquid through a sieve and allowing the suspended pulp to deposit. The water is then drained away and the paste dried, till it is a thick, stiff unctuous mass. In this state it has a dark orange-red colour and is known as roll or flag annatto, according to the form in which it is put up; when further dried it is called cake annatto. It yields a fugitive bright orange colour and is used alone, or with other dyes, in the dyeing of silks and in calico printing. It contains a yellow colouring matter, bixin.

ANNE (1665-1714), queen of Great Britain and Ireland from 1702 to 1714, second daughter of James, duke of York afterward James II, and of Anne Hyde, daughter of the 1st earl of Clarendon, was born on Feb. 6, 1665. She was brought up as a strict Protestant, and as a child formed a friendship with Sarah Jennings (afterward duchess of Marlborough). Later Sarah became Anne's lady of the bedchamber and intimate friend. All deference to the princess' rank was abandoned, and the two ladies called each other (nicknames) Mrs. Morley and Mrs. Freeman. On July 28, 1683, Anne married Prince George of Denmark (1653-1708), brother of King Christian V and second son of King Frederick III, an unpopular union politically, but one of great domestic happiness. Her husband was created earl of Kendal and duke of Cumberland in 1689.

On Feb. 6, 1685, James became king of England. In 1687 a project of settling the crown on the princess, to the exclusion of Mary, on the condition of Anne's embracing Roman Catholicism failed. But the birth of a son to James on June 10, 1688, made the religion of his daughters a matter of less importance. Anne was not present on the occasion, having gone to Bath, "I shall never now be satisfied," Anne wrote to Mary, "whether the child

be true or false. It may be it is our brother, but God only knows." In later years, however, she had no doubt that the Old Pretender was her half brother.

During the events immediately preceding the revolution Anne remained in seclusion. She refused to show any sympathy with the king after William had landed in November (1688) and wrote, with the advice of the Churchills (Marlboroughs), to the prince, declaring her approval of his action. Subsequently the Declaration of Right settled the succession of the crown upon her alter William and Mary and their children.

Between 1684 and 1688 Anne had miscarried four times and given birth to two children who died infants. On July 24, 1689, the birth of a son, William, created duke of Gloucester, who survived his infancy, gave hopes that heirs to the throne under the Bill of Rights might be forthcoming. But Anne's happiness was soon troubled by quarrels with the king and queen. Money appears to have been the first cause of ill-feeling. The granting away by William of the private estate of James, amounting to £22,000 a year, to which Anne had some claim, was a grievance, and a motion brought forward in the house of commons to increase her civil list pension of £30,000, which she enjoyed in addition to £20,000 under her marriage settlement, greatly displeased William and Mary, who regarded it as a plot to make Anne the chief of a separate interest in the state. At the beginning of 1692 the breach between the royal sisters was made final by the dismissal of the duke of Marlborough, justly suspected of Jacobite intrigues, from all his appointments. Anne took the part of her favourites with great zeal against the court, but in all probability was unaware of Marlborough's treason; she retired with Lady Marlborough to the duke of Somerset's residence at Sion house. In Aug. 1693, however, the two sisters were temporarily reconciled, and on the occasion of Mary's last illness and death Anne showed an affectionate consideration.

The death of Mary weakened William's position and made it necessary to cultivate good relations with the princess. At the same time William kept her in the background and refrained from appointing her regent during his absence. In March 1695 after the reinstatement of Marlborough at court Anne gave her support to William's government. Meanwhile, since the birth of the duke of Gloucester, the princess had experienced six more miscarriages and had given birth to two children who survived only a few hours, and the last maternal hope flickered out on the death of the young prince on July 29, 1700. In default of her own issue, Anne acquiesced in the Act of Settlement in 1701 and the substitution of the Hanoverian branch.

On March 8, 1702, Anne became, by King William's death, queen of Great Britain, being crowned on April 23. In her first speech to parliament, as George III afterward, Anne declared her "heart to be entirely English," words which were resented by some as a reflection on the late king. A ministry, mostly Tory, with Lord Godolphin at its head, was established. She obtained a grant of £700,000 a year and hastened to bestow a pension of £100,000 on her husband, whom she created generalissimo of her forces and lord high admiral, while Marlborough obtained the Garter, with the captain-generalship and other prizes, including a dukedom, and the duchess made mistress of the robes with the control of the privy purse.

The queen showed from the first a strong interest in church matters and declared her intention to keep church appointments in her own hands. She detested equally Roman Catholics and dissenters, showed a strong leaning toward the high-church party and gave zealous support to the bill forbidding occasional conformity. In 1704 she announced to the commons her intention of granting to the church the crown revenues, amounting to about £16,000 or £17,000 a year, from tithes and first fruits (paid originally by the clergy to the pope, but appropriated by the crown in 1534), for the increase of poor livings; her gift, under the name of Queen Anne's Bounty (q.v.), still remaining as a testimony of her piety.

This devotion to the church, the strongest of all motives in Anne's conduct, dictated her hesitating attitude toward the two great parties in the state. In 1704 Anne acquiesced in the resignation of Lord Nottingham, the leader of the high Tory party. In

the same year the great victory at Blenheim further consolidated the power of the Whigs and increased the influence of Marlborough, but she long resisted the influence and claims of the junta, as the Whig leaders Lord Somers, Lord Halifax, Robert Walpole, Lord Wharton and the earl of Sunderland were named. Marlborough's successive victories and the factious conduct of the Tories drove Anne farther to the side of the Whigs. But she opposed for some time the inclusion in the government of Sunderland. In 1708 she was forced to dismiss Robert Harley, who, with the aid of Mrs. Masham (*q.v.*), had been intriguing against the government. Abigail Hill, Mrs. (afterward Lady) Masham, a cousin of the duchess of Marlborough, had been introduced by the latter as a poor relation into Anne's service, while Anne was still princess of Denmark. In the summer of 1707 the duchess discovered to her indignation that her protégée had become the instrument of Harley's intrigue. Even after his retirement, Harley remained Anne's secret adviser, and the duchess never regained her former influence. The inclusion in the cabinet of Somers, whom she especially disliked as the hostile critic of Prince George's admiralty administration, was the subject of another prolonged struggle, ending again in the queen's submission, to avoid a motion from the Whigs for the removal of the prince, then actually on his deathbed. He died Oct. 28, 1708. But no reconciliation with the duchess of Marlborough took place. The queen showed her antagonism to the Whig administration on the occasion of the prosecution of Henry Sacheverell (*q.v.*), and the fall of the Whigs followed.

The queen rejoiced at being freed from what she called a long captivity, and the new parliament was returned with a Tory majority. On Jan. 17, 1711, in spite of Marlborough's efforts to ward off the blow, the duchess was compelled to give up her key of office. The queen was now able once more to indulge in her favourite patronage of the church, and by her influence an act was passed in 1712 for building 50 new churches in London. Later, in 1714, she approved the Schism bill. She gave strong support to Harley, now earl of Oxford and lord treasurer, in the intrigues and negotiations for peace. To break down the opposition to the terms of the peace of Utrecht, Marlborough was dismissed on Dec. 31, 1711, from all his employments, while the house of lords was "swamped" by Anne's creation of 12 peers, including Mrs. Masham's husband. The queen's conduct was generally approved, for the nation was now violently adverse to the Whigs, regarded as a war party. The peace of Utrecht was finally signed on March 31, 1713 (old style; April 11, new style).

As the queen's reign drew to its close, rumours were rife on the subject of the succession to the throne. Both Oxford and Viscount Bolingbroke were in communication with the Pretender's party, and on July 27, 1714, Oxford, who had gradually lost influence and quarreled with Bolingbroke was obliged to resign, leaving the supreme power in the hands of Bolingbroke. Anne herself had a natural feeling for her brother, but she had an intense dislike of any successor; and it is certain that religion and political wisdom kept Anne firm to the Protestant succession. Her sudden illness and death frustrated any schemes which Bolingbroke or others might have been contemplating. The final act of her life was to secure the Revolution settlement and the Protestant succession. During a last moment of returning consciousness, she placed the lord treasurer's staff in the hands of the duke of Shrewsbury, and the measures were immediately taken for assuring the succession of the elector. Her death took place on Aug. 1. The elector of Hanover, George Louis, son of the electress Sophia (daughter of Elizabeth, a daughter of James I), peacefully succeeded to the throne as George I.

By character and temperament unfitted to stand alone, Anne had led a life unhappy from its isolation. She had been separated in early years from her parents and sister, and her one great friendship had proved only baneful and ensnaring. Marriage had brought a mournful series of infant funerals. Constant ill-health and suffering had darkened her career. The claims of family attachment, of religion, of duty, of patriotism and of interest had dragged her in opposite directions, and her whole life had been a prey to jealousies and factions, which closed around her at her

accession to the throne and surged to their height when she lay on her deathbed. The modern theory of the relations between the sovereign and the parties had not then been invented; and Anne, like her Hanoverian successors, maintained the struggle, though without success, to rule independently, finding support in Harley. Her motive for getting rid of the Whigs was the wish to escape from the domination of the party, and on the advent to power of the Tories she carefully left some Whigs in their employments, with the aim of breaking party alignments and acting upon what was called a moderate scheme.

Anne was a woman of small ability, of dull mind and of that kind of obstinacy which accompanies weakness of character. She took no interest in the art, the drama or the literature of her day. But she possessed the homely virtues; she was deeply religious, attached to the Church of England and concerned for the efficiency of the ministry; instances abound of her kindness and consideration for others. Her moderation toward the Jacobites in Scotland, after the Pretender's expedition in 1708, was much praised by the duc de Saint-Simon. She surrendered £10,000 a year for public purposes, and in 1706 she presented £30,000 to the officers and soldiers who had lost their horses.

BIBLIOGRAPHY.—H. Paul, *Queen Anne*, rev. ed. (1912); G. M. Trevelyan, *England Under Queen Anne*, 3 vol., with full bibliography (1930-34); R. Walcott, *English Politics in the Early Eighteenth Century* (P. C. Y.; D. TN.) (1956).

ANNE (ANNE BOLEYN or BULLEN) (1507?-1536), second queen consort of Henry VIII of England, was the daughter of Sir Thomas Boleyn (later earl of Wiltshire and Ormonde) and of Elizabeth, daughter of Thomas Howard, earl of Surrey (later duke of Norfolk). According to William Camden she was born in 1507; the evidence adduced by some later writers for an earlier date (1501 or 1502) is not convincing. In 1519 she went with her father to France where she entered the royal service.

By 1522 she was back in England. Her father had long been rising steadily in the royal favour. Her grandfather was one of the king's leading ministers. Her elder sister Mary had been in the king's sister's service in France in 1514 and at a later date became the king's mistress. So Anne herself soon became fairly well known at the English court. The poet Sir Thomas Wyatt was among her admirers and Henry Percy, heir to the earl of Northumberland, sought her in marriage. Cardinal Wolsey, however, broke that match, for the king was apparently planning then to marry Anne to the earl of Ormonde. It is impossible to say when Henry VIII himself began to be attracted by her, nor is it possible to tell whether this passion stimulated or followed upon his final decision to secure the annulment of his marriage to Catherine of Aragon, for his celebrated love letters to Anne are undated, and there is no positive evidence that his infatuation antedated the secret "divorce" proceedings of May 1527. It seems clear, however, that his determination to rid himself of the aging Catherine originated in his desire to beget a legitimate male heir to the throne and that the attractions of Anne strengthened rather than created this determination. After Henry's final separation from Catherine in July 1531, Anne accompanied him on a visit to Francis I in 1532 and about Jan. 25, 1533, Henry secretly married her, the union being made public the following Easter. On May 28 Archbishop Cranmer pronounced the marriage valid and that with Catherine null. In June Anne was crowned and in September she gave birth to a daughter, the future Elizabeth I.

This was a sharp disappointment to Henry and within a few years failure to bear him a son was to prove even more disastrous for Anne than it had proved for Catherine. Anne soon alienated her friends and made many enemies by her arrogance and lack of dignity. Her jealousy showed in spiteful malice toward Catherine and Catherine's daughter Mary and also in reproaches to the king. For Henry's passion soon cooled after marriage and his affections again began to wander. The birth of a son might have held them together but in 1534 Anne apparently had a miscarriage and on Jan. 29, 1536, the day of Catherine's funeral, she gave birth to a dead male child. Meantime she had, it seems, given Henry causes, or at least pretexts, for jealousy, and on May 2 she was committed

to the Tower on a charge of adultery with various men, including her own brother, Lord Rochford. On May 12 Sir Francis Weston, Henry Norris, William Brereton and Mark Smeaton were tried and found guilty of high treason as her lovers.

Three days later Anne and her brother were condemned unanimously by a court of 26 peers presided over by her uncle, the duke of Norfolk, as lord steward. On May 17 her reputed lovers were executed and Cranmer pronounced her marriage with Henry invalid on grounds that were not disclosed. Anne was beheaded on the Tower green on May 19, meeting death with courage and even with jest. Next day Henry VIII was betrothed to Jane Seymour.

Anne's guilt remains unproved. She protested her innocence to her jailer and made no confession on the scaffold. Yet, despite her universal unpopularity and the king's weariness of her, it hardly seems likely that two grand juries, a petty jury and a tribunal of nearly all the lay peers of England should have passed sentence of guilt quite contrary to the evidence—which they had before them and which we do not possess—and that such a sentence should have been concurred in by her own uncle and father.

Anne was described as "not one of the handsomest women in the world; she is of middling stature, swarthy complexion, long neck, wide mouth, bosom not much raised, and in fact has nothing but the English king's great appetite and her eyes, which are black and beautiful and take great effect . . ."

ANNE OF AUSTRIA (1601–1666), queen consort and for a time regent of France, was born at Valladolid on Sept. 22, 1601, the eldest child of Philip III of Spain (of the house of Austria; *i.e.*, of the Habsburg dynasty). On Nov. 28, 1615, she was married, at Bordeaux, to Louis XIII of France. Her married life was unhappy: Louis was morbidly cold in his attitude to her (and to other women), yet expected an heir to be born from his infrequent and ceremonious approaches; Franco-Spanish hostilities in the Thirty Years' War cut her off from overt relations with her dearly loved family in Spain; and the omnipotent minister, the cardinal de Richelieu was concerned to prevent her exercising any rival influence over her husband. Frustrated in her sincere desire to serve France, she was open to the irresponsible advice of the intriguing Marie de Rohan, duchesse de Chevreuse (*q.v.*). Considerable scandal was made out of the duke of Buckingham's indiscreet advances to Anne during his embassy (1625). Further, Anne was suspected of being privy to a conspiracy against the king (1626) and of intending to marry the malcontent Gaston of Orléans, heir presumptive to the throne. She was deeply humiliated in the "affair of Val de Grâce" (1637) when she had to submit to interrogation by the king's ministers on the ground that she was frequenting the convent of Val de Grâce in order to conduct a treasonable correspondence with the Spaniards. Even after the birth of her sons (the future Louis XIV in 1638 and Philippe, later duc d'Orléans, in 1640), her husband remained unfriendly; and in his will he prescribed a council of regency for the child Louis XIV, so as to preclude Anne from being sole regent.

On Louis XIII's death (1643), this will was promptly annulled by the *parlement* of Paris; Anne was declared sole regent; and the ambitious princes, nobles and politicians who had been in disgrace under Richelieu began to demand rewards and favours from the queen in whose interests they claimed to have suffered. Anne disappointed them: able at last to play her due part in affairs of state, she was determined that her son should succeed to the absolute power that Richelieu had won for her husband; and for this she knew that she must rely on the heir to Richelieu's policy, Jules Mazarin (*q.v.*). The crisis came with the complex rebellion of the Fronde (*q.v.*); and Mazarin's eventual triumph would have been impossible without Anne's constant devotion to his guidance. The pamphleteers of the Fronde, of course, alleged that Mazarin was Anne's lover; and later writers, in view of her strong religious principles, have suggested that they were secretly married. There is no need to believe these tales any more than stories designed to show that Louis XIII was not the father of her children (an

allegation often made either in spite against Louis XIV or in connection with the mystery of the Iron Mask, *q.v.*).

Anne's regency ended when Louis XIV was proclaimed of age to rule (1651). She lived to see not only the end of the Fronde but also peace between France and Spain (1659) and Louis XIV's marriage to her brother's daughter (1660). For the rest of Anne's life, moreover, Louis XIV refrained from publicly acknowledging his adulteries, out of respect for her sentiments; and her influence long withheld him from breaking the peace with Spain. She died of cancer of the breast on Jan. 20, 1666, in Paris.

ANNE OF BRITTANY (1477–1514), duchess of Brittany and queen consort of France, was born at Nantes on Jan. 25, 1477, the daughter of Francis II of Brittany and of Margaret of Foix. She succeeded to her father's duchy on Sept. 9, 1488. Brittany at that time enjoyed administrative independence, which the Bretons were anxious to protect against the French king even when this involved relying on foreign support. Anne, despite her youth, was firmly attached to these principles of independence, on which she was always to insist.

Clearly, the future of the duchy depended on her marriage. Alain d'Albret, the Great, with the support of her guardian Jean de Rieux, sought Anne for himself; the house of Rohan advanced rival claims; and in 1489 French troops invaded Brittany to assert King Charles VIII's authority, whereupon Jean de Rieux revolted. Against all these, Anne allied herself with Maximilian of Austria, who married her by proxy on Dec. 19, 1490. But Austrian affairs prevented Maximilian's defending his bride, and in 1491 she was besieged in Rennes and compelled to treat with Charles VIII, whose terms included the rupture of her Austrian marriage and her marriage (Dec. 6, 1491) with himself. The two sovereigns made a reciprocal arrangement as to Brittany, and Charles issued edicts whereby the duchy was recognized to be distinct from the kingdom of France and under a regime of personal union; but if Charles were to predecease her without issue, Anne was to marry the heir to his throne, and if Anne predeceased him, the duchy was to be his entirely.

Charles died without living issue in 1498; and on Jan. 8, 1499, Anne married Louis XII, who had just repudiated Joan of France. The marriage contract declared that Brittany should revert to the second son or to the eldest daughter of the marriage or, failing issue, to Anne's natural heirs. For the rest of her life Anne occupied herself personally with the administration of her duchy; and in 1504 she carried her jealousy of its autonomy to a point altogether prejudicial to the unity of the kingdom by concluding the treaties of Blois with Maximilian, whereby her daughter Claude of France was to marry his grandson Charles. This unpopular agreement, however, was broken, and Anne had to consent to Claude's betrothal (May 21, 1506) to Francis of Angoulême, the future Francis I of France. This led to the definitive union of Brittany and France. Anne died at Blois on Jan. 9, 1514. A devout Catholic and a patroness of the arts, Anne instituted the aueen's maids of honour at the French court.

ANNE OF CLEVES (1515–1557), fourth queen consort of Henry VIII of England, was the second daughter of John, duke of Cleves, and of Mary, only child of William, duke of Jilich and Berg. Born on Sept. 22, 1515, Anne had a narrow upbringing. She learned no language but her own; was proficient in needlework, but had few other accomplishments; and had a meek, gentle temper but no great beauty. Her marriage to Henry VIII was a political arrangement, occasioned by Henry's momentary fear of a possible combination of the Catholic powers against him. Thomas Cromwell wished him to counter this by an alliance with the German Lutherans. Henry

would not make the necessary doctrinal concessions, but did agree (Jan. 1539) to overtures for an alliance with Cleves. Duke John, although father-in-law to the Lutheran elector of Saxony, was not a Lutheran nor a member of the Protestant League of Schmalkalden. He, however, died in Feb. 1539 and was succeeded by his son William, who had also just inherited the duchy of Gelderland and its bitter quarrels with the emperor Charles V. The negotiations therefore proceeded very haltingly, as Henry did not wish to provoke the emperor unnecessarily. But news that Charles was to travel through France, to suppress a revolt at Ghent, suggested an alarmingly close understanding between the emperor and the French. So, on Oct. 6, 1539, the Cleves marriage treaty was signed. Anne landed at Deal on Dec. 27. Henry met her at Rochester on Jan. 1, 1540, and they were married on Jan. 6. The story that Henry found her immediately displeasing and "no better than a Flanders mare!" although plausible, rests largely on evidence written by Cromwell from the Tower of London six months later in the faint hope of earning a pardon. By then the emperor had suppressed Ghent, was threatening Cleves and seemed also to be breaking with France. This revived Henry's hopes of finding safety in the mutual jealousies of the Catholic powers and made him increasingly reluctant to be dragged into needless quarrels with the emperor. The Cleves marriage had become a political embarrassment. Its validity was questioned in parliament on July 6, 1540, convocation annulled it on July 9, and parliament confirmed the annulment a few days later. Anne acquiesced and was rewarded with £4,000 a year in lands, on condition that she stayed in England. She was soon reported to be as joyous as ever and wearing new dresses every day. She lived at Richmond or Bletchingley, with occasional visits to court, until her death at Chelsea on July 16, 1557. (R. B. Wm.)

ANNE OF DENMARK (1574–1619), queen consort of James I of England and VI of Scotland, was the daughter of Frederick II of Denmark and Norway and of Sophia, daughter of Ulric III, duke of Mecklenburg. She was born on Dec. 12, 1574. She was married to James, by proxy, on Aug. 20, 1589, bringing him recognition of Scottish claims to the Orkney and Shetland islands, but no dowry. Storms, for which several supposed witches were burned in Denmark, delayed her voyage to Scotland and James sailed to Norway to meet her. Her Lutheran upbringing and innate frivolity did not endear her to the Calvinistic Scottish Kirk; and in 1595 James entrusted the upbringing of their first son, Henry (1594–1612), to the earl and countess of Mar, with instructions not to give him up to the queen or the estates until he was 18, if James himself should die. In 1603, after Elizabeth I's death, Anne followed James to England and was crowned with him on July 25. Her refusal of the Anglican sacrament on that occasion may have been due to her Lutheran scruples or to her flirtation with Roman Catholicism which was to continue for many years. Nevertheless, she lived in good harmony with the king, though in later years residing mostly apart from him. She favoured the ascendancy of the duke of Buckingham and Spanish marriages for her sons, Henry and Charles (afterward Charles I), and disapproved of her daughter Elizabeth's marriage to the Calvinist elector palatine. On the other hand, she appealed personally to Buckingham to save Sir Walter Raleigh from execution. But her interest in matters of state was spasmodic and her influence slight. Most of her time and energy were devoted to court entertainments, building, dress and jewels. Her patronage certainly contributed to the development of the arts, in particular of the masque; but her extravagant expenditure contributed also to the monarchy's growing financial difficulties and was contrasted unfavourably with the economy of Elizabeth I. She died, after a long illness, on March 2, 1619, and was buried in Westminster abbey. (R. B. Wm.)

ANNE OF FRANCE (by marriage **DAME DE BEAUJEU**) (1461–1522), was the eldest daughter of Louis XI of France and Charlotte of Savoy. After several other plans for her marriage, Louis gave her, in 1474, to Pierre de Bourbon, seigneur de Beaujeu; and on his deathbed he entrusted to Pierre the charge of his 13-year-old son, Charles VIII. Thus from 1483 to the end of 1491 the Beaujeus were to exercise a virtual regency in France.

Anne's energy, strength of will, cunning and political sense en-

abled her to overcome the difficulties threatening the kingdom. Faced with the reaction of all who had suffered from Louis XI's callous oppressions, the Beaujeus managed to promote the king's authority by adroit concessions or, when these failed, by military action: for example, at the meeting of the states-general at Tours (1484) and in the "Mad War" and subsequent Breton campaigns (see *FRANCE: History*). Moreover, in 1491, despite Austrian and English opposition, they concluded the marriage of Charles VIII with Anne (q.v.) of Brittany. But when Charles freed himself from tutelage, his former guardians were exposed to the resentment of the new queen, whose duchy's independence had been compromised.

Pierre, who had become duc de Bourbon in 1488, died in Oct. 1503, leaving Anne to administer the Bourbonnais for their daughter Suzanne (1491–1521) and to protect Bourbon interests against royal encroachments. Suzanne was married to her second cousin Charles de Montpensier (see *BOURBON, CHARLES, DUC DE*; also *BOURBON, Table I*) in 1505; and on Suzanne's death, when King Francis I's mother, Louise of Savoy, was trying to deprive Charles of his inheritance, Anne did not hesitate to encourage her son-in-law to seek support from the king's enemies in defense of his rights. She died at Chantelle on Nov. 14, 1522. There is an edition of the *Enseignements* (instructions) that she wrote for Suzanne by A. M. Chazaud (1878).

ANNEALING, the slow heating and cooling of a metal or alloy, usually to soften it and make it more workable (while cold) in presses, rolls or wire-drawing dies. The term has also been applied to a similar mild heat-treatment of age-hardenable alloys, for example, duralumin (q.v.), which results in hardening. The many varieties of conventional annealing are identified by the equipment used, the object to be attained or the final appearance of the metal.

Process Annealing. — Nearly all metallic alloys are more ductile (workable) when hot than cold; consequently most forging, pressing or rolling is done hot. Hot metal, however, reacts with the air and the resulting surface is unsightly and consumes metal, both effects becoming more objectionable as the part becomes thinner. Therefore much work is done on cold sheet, strip and wire. Here another problem arises: soft and ductile metal becomes harder and less workable as more and more cold work is done on it. Eventually a point is reached where the ductility is "exhausted"; cracking is imminent. If the piece is then heated to a moderate temperature and slowly cooled the original ductility is restored and further work can be safely performed. This is process annealing. Actual heat-treating schedules depend on the alloy, the degree of cold work it has endured and the mechanical and fabrication properties desired. Annealing temperature must be above recrystallization, where microscopic crystals form in the overstrained regions, yet not so high nor held so long that these new crystals can grow to objectionable size. In steels the annealing temperature is usually below the critical temperature required for quench hardening.

Bright Annealing. — Annealing in furnaces open to the air oxidizes the surface of the parts and this oxide has to be removed by cleaning and pickling. This expense can be avoided by annealing in controlled atmospheres where the metal remains bright or nearly so; in other words, the furnace atmosphere is a gas mixture substantially inert to the hot metal during the heating and cooling cycle. Steam is a common atmosphere for bright annealing of brass. Atmospheres for common carbon steels are made by partial combustion of natural gas, and the mixture of nitrogen, hydrogen, carbon oxides and moisture so adjusted that it will neither oxidize the iron nor add or subtract carbon at the surface. Traces of moisture will discolour hot stainless steel, so it is usually bright annealed in cracked ammonia, a mixture of hydrogen and nitrogen gases.

Full Annealing. — This term includes other designations such as malleableizing, isothermal annealing, spheroidizing and solution treatment. In general the heat-treating cycle is designed to

make desirable changes in the microstructure and related properties of the metal, and consequently requires holding at temperatures where changes occur in the mutual solubilities of the microconstituents. A forged blank of tool steel, for example, high enough in carbon so there is excess iron carbide (cementite) in the microstructure, would probably have this constituent in rather massive plates. In such condition it is difficult to machine and responds poorly to hardening treatments; both circumstances can be corrected by changing the form of the excess cementite into a multitude of tiny globules. Such a spheroidizing anneal usually involves alternate slow heatings and coolings through the critical range during which the cementite is first dissolved and then precipitated. Another example of full annealing occurs in the manufacture of malleable iron castings. This high-carbon alloy is cast as brittle "white iron"—that is, all the carbon is held in unstable equilibrium in the microstructure as carbide. The castings, protected in iron boxes (box, or pack, annealing), are pushed slowly through a long furnace, eventually reaching 1,600° F. where all the iron carbide is in solution, and then cooled at a slow rate through the transformation range, whereupon practically all the carbon comes out of solution as elemental carbon. The cold casting contains tiny nodules of graphite in a matrix of soft iron, with a desirable combination of mechanical properties and machinability.

Stress Relief.—This is a type of anneal designed to prevent the bad effects of locked-up internal stresses. Complicated and thin-walled castings have regions which are highly stressed due to differential shrinkage on solidification in unyielding molds. Cold-headed bolts may spontaneously fracture at the ends due to exhaustion of ductility during fabrication. Metal alongside welded joints contains a complex system of thermal stresses. Temperature cycles for stress-relief annealing depend on the metal; it may be as low as 300° F. for copper and 900° F. for gray-iron castings. For steel pieces and weldments it varies from 900° to 1,300° F., depending on the mechanical properties desired in the base metal. Thus, if maximum strength and hardness is necessary, low stress-relieving temperatures would be used.

Furnaces.—Annealing furnaces vary with the product to be handled and the amount of work to be done and include small muffle furnaces for tool-steel blanks, long tunnel kilns through which carloads of castings are pushed, and long or high "continuous" furnaces, with prepared atmospheres contained behind entrance and exit locks. In mass production of sheet or wire the coils are stacked in large cylindrical boxes, the boxes sealed and filled with protective atmosphere; a cylindrical heating cover is then placed over the box. Wire is frequently bright annealed by being drawn, strand by strand, through a long bath—of molten lead or salt. Stress-relieving furnaces for welded boilers or pressure vessels resemble big open rooms with barn-door ends. Pipe joints, welded in the field, are stress relieved by electrical heat from an induction coil wrapped around them. See *METALLURGY: Heat-Treatment*. See also *CAST IRON*; *IRON AND STEEL INDUSTRY*. See also Index references under "Annealing" in the Index volume.

ANNECY, the chief town of the *département* of Haute-Savoie, France, and the seat of a bishopric, is situated on the lake of Annecy 1,470 ft. above sea level and is 338 mi. from Paris by road. Pop. (1954), 30,196. The arcaded streets of the old town, lying below the castle (partly of the 12th and 14th centuries), now used as a refuge for homeless families, are intersected by canals, the chief of which, the Canal du Thiou, empties the waters of the lake into the river Fier. The climate is temperate, especially in the areas which lie below 1,500 ft., and the town is sheltered from violent winds by the mountains that surround it. Traces of the Gallo-Roman *Boutae* have been found nearby; but Annecy itself, after being the chief town of the counts of Genevois (10th century) and belonging after 1401 to the dukes of Savoy, became important only in 1535, when the bishop's see of Geneva was transferred there along with the monastic institutions expelled from Geneva at the Reformation. St. Francis of Sales was bishop

from 1602 to 1622 and founded with St. Jane Frances Chantal the first Congregation of the Visitation. In 1728 Jean Jacques Rousseau, then age 16, found a refuge there with Mme. de Warens. Annecy is joined by direct railway lines to Paris, Lyons, Marseilles and Nice. It is a holiday centre and the tourist trade is its biggest industry. Precision instrument industries also prevail.

ANNELIDA, the segmented worms, a major phylum of the animal kingdom. The name, proposed by Lamarck, is practically synonymous with the obsolete term *Annulata* of Cuvier. The phylum includes marine worms (class *Polychaeta*), earthworms and their allies (class *Oligochaeta*) and leeches (class *Hirudinea*). More precisely, Annelida are serially (metamerically) segmented metazoans having a body cavity (coelom) and movable bristles known as setae (chaetae). The coelom is secondarily occluded in leeches, and setae are lacking in a few specialized forms and in leeches.

I. INTRODUCTION

Annelids range in size from minute marine and fresh-water species to certain giant earthworms best known from Australia, south Africa and South America, and a few large marine polychaetes, as from the coast of California. Free-living polychaetes may be pelagic, inhabiting the open waters of the ocean, or errant, burrowing and wandering near the bottom; sedentary polychaetes inhabit tubes of their own construction. Earthworms burrow in mud, soil or forest litter; many of their smaller relatives are found in fresh water, a few are marine. Leeches are predaceous and often parasitic.

A. STRUCTURE AND FUNCTION

1. Basic Body Plan.—The body of an annelid is described as a tube within a tube. The inner tube, or alimentary canal is separated from the outer tube or body wall by the coelom. A pre-segmental head region is followed by a series of ringlike segments (somites). Each somite is theoretically a complete replica of the one that precedes it. In virtually all species, however, there is some measure of differentiation, and in many sedentary polychaetes this process of regionalization has advanced to a high degree. The differentiation of somites introduces the correlated phenomenon for which W. Bateson coined the term homeosis, the appearance of a structure that, though usually associated with a particular segment, is found upon another. Homeosis includes segmental changes in the position of organs and their segmental repetition or suppression. The phenomenon is of importance in the classification and identification of annelids, since the segment on which an organ occurs is frequently used as a taxonomic character.

2. Body Wall and Musculature.—The epidermis is usually a simple columnar epithelium that secretes a thin cuticle; sometimes, parts of the body are ciliated. Electron microscopy reveals that the cuticle consists of thin layers of protein fibrils whose composition resembles that of collagen, the fibrillar material of vertebrate tendons and white fibrous connective tissue. 4 circular muscle coat underlies the epithelium and is external to the longitudinal musculature; the two muscle layers are of different embryological origin, from mesectoderm and mesoderm respectively. Muscle fibres usually are smooth, rarely with typical cross striations; the contractile elements (myofibrillae) may completely encircle the muscle cell cytoplasm (sarcoplasm), containing the nucleus or nuclei, as in leeches; or the sarcoplasm may be situated laterally, as in earthworms.

3. Setae.—The setae of polychaetes are borne upon projecting lobes (parapodia); in oligochaetes they are embedded in the body wall. Each seta is secreted by a single basal cell situated at the bottom of an epithelial invagination, the setal follicle. The form of the seta is determined by the changing activities of the basal cell, which atrophies when its function is completed. The setae are composed of a chitin-protein complex; in *Sabellaria* and probably also in other annelids the setae receive a superficial coating secreted by the follicle cells. New setae are formed in reserve follicles and move forward to replace the old ones that are discarded. A typical seta has a projecting shaft and a basal portion or hilt sunken within the follicle. In many polychaetes the shaft has a movable blade. The essential difference between the annelidan setae and the hairs, spines and bristles of arthropods (crustaceans, insects, etc.) is that an annelidan seta is embedded in its follicle, thus providing for the insertion of protractor and retractor muscles.

4. Coelom.—Embryologically the body cavity or coelom is a schizocoel, developing as a split in the middle germ layer of the embryo (mesoderm). Corresponding to the segmentation of the body, the coelom is divided typically into compartments by transverse partitions, the septa. Septa may be imperfect or lacking, as in the pelagic polychaete *Tomopteris*, but often they are strongly

muscularized, especially anteriorly, in forms with burrowing habits. Within the coelom is a watery coelomic fluid, one of the functions of which is maintenance of turgor, which, in the absence of a skeleton, gives rigidity to the body. Perforations of the septa permit the flow of coelomic fluid from one segment to another; and in many forms, notably those polychaetes in which the vascular system is reduced and the coelomic fluid must perform respiratory functions, circulation is aided by ciliation of the peritoneum, the lining of the coelom. In some oriental earthworms (*Pheretima* and *Drawida*) the flow of coelomic fluid is regulated by sphincter muscles that guard the septal openings; thus it is possible for one part of the body to remain turgid while the rest of the body is relaxed.

The coelomic fluid of marine polychaetes is of the same osmotic pressure as sea water and contains little or no protein; in earthworms it is more dilute but proteins are present. Coelomic corpuscles are of two main types: (1) leucocytes of various sorts, amoeboid, phagocytic or laden with secretory granules; and (2) chloragogue cells. The chloragogue cells form a special tissue that invests the surface of the intestine, blood vessels and sometimes other organs. Like the vertebrate liver, chloragogue tissue is the site of many phases of intermediary metabolism including the temporary storage of food reserves and the elaboration of nitrogenous excretory products. Coelomic erythrocytes, which occur in some polychaetes, contain a respiratory pigment (see below).

5. Vascular System.—The annelidan vascular system is a closed one. According to A. Lang's trophocoele theory the most primitive part is the peri-intestinal blood plexus. A contractile dorsal vessel collects blood from this plexus and also from the body wall and other organs and pumps it forward to the anterior end. From here it passes by lateral connectives, usually contractile "hearts," to the ventral vessel. The ventral vessel is a thin-walled, noncontractile tube that acts as the main distributing organ. The vascular system may be greatly elaborated or rudimentary; in some leeches it is in open communication with coelomic lacunae, forming a kind of hemocoel. The middle or skeletal coat of the blood vessels is a collagenous membrane covered by the peritoneum and lined by a continuous endothelium. The peritoneal coat may contain smooth or, rarely, cross-striated muscle fibres and contractile Rouget cells like those of vertebrate capillaries.

The heartbeat of *Arenicola* and *Lumbricus* is apparently neurogenic, as in arthropods, rather than myogenic, as in vertebrates and mollusks. (See HEART, COMPARATIVE PHYSIOLOGY OF: Paced-makers).

6. Respiration.—Gaseous exchanges may take place exclusively through the skin (cutaneous respiration), as in earthworms; through gill filaments, as in many polychaetes; or water may be pumped in and out of the rectum (anal respiration), common in aquatic oligochaetes. Oxygen is transported in solution in the blood plasma or coelomic fluid, and in many species these processes suffice. More frequently, however, transportation is supplemented, but never wholly supplanted, by the presence of an oxygen carrier (respiratory pigment). Hemoglobins are of common occurrence and may be found either enclosed in coelomic corpuscles or in solution in the blood plasma. A few polychaetes (e.g., *Terebella*) have both coelomic red blood cells (erythrocytes) and red blood plasma. Chlorocruorins, peculiar to certain tubedwelling polychaetes, are found in the blood plasma; they differ from hemoglobin in the nature of the iron-containing prosthetic group (hemin) and are green in dilute solutions, red in concentrated ones. The blood of *Serpula vermicularis* is remarkable in having two respiratory pigments, hemoglobin and chlorocruorin; related species have the one or the other. The small polychaete *Magelona* is of exceptional interest since it possesses hemerythrin, the respiratory pigment of the distantly related phylum Sipunculida (q.v.), enclosed in enucleated red blood cells. Hemoglobins occurring within coelomic corpuscles are of low molecular weight, one half or one quarter that of human hemoglobin (about 66,000), and therefore containing either two or one, rather than four hemin groups. Plasma pigments have enormous molecular weights, of

FIG. 1.— DIAGRAMS OF ARRANGEMENTS OF EXCRETORY AND GENITAL DUCTS IN PLATYHELMINTHES AND VARIOUS ANNELIDA: (1) PROTONEPHRIDIUM WITH FLAME CELLS; (2) PRIMARY COELOMODUCT; (3) NEPHROMIXIUM; (4) METANEPHRIDIUM; (5) SECONDARY COELOMODUCT; (6) GONAD

Platyhelminthes: (A) Representative plan: closed protonephridia, gonads continuous with their ducts. Annelida: (B) Ancestral plan: closed protonephridia, sex cells liberated into body cavity escape by rupture of body wall or through coelomoduct; (C) many Polychaeta: genital funnel attached to excretory organ forming nephromixium; (D) some Polychaeta: open metanephridium serving both genital and excretory functions; (E) some species of *Tomopteris*: nephromixium and secondary gonoducts; (F) some Polychaeta and most Oligochaeta: excretory organ is open metanephridium, genital ducts are separate; (G) a few Oligochaeta: metanephridium secondarily closed; (H) Hirudinea: nephrostome opens into reduced coelom, but is closed at attachment to blind internal end of nephridial duct

the order of 3,200,000. Their large size serves to prevent diffusion of the pigment through the walls of the blood vessels and to lower the osmotic pressure of the plasma, which otherwise might have a disturbing effect on osmoregulation; enclosure within erythrocytes performs similar functions.

The properties of annelidan respiratory pigments are correlated with the mode of life of the worm. Hemoglobins like that of the lugworm *Arenicola*, which release oxygen to the tissues only under conditions of extreme deficiency, have been thought to serve an emergency reservoir function when the worm is confined to its burrow. Doubts have been cast on this hypothesis, however, and a low tension transport function is favoured. High concentrations of environmental oxygen may be harmful to species adapted to conditions of oxygen deficiency, and it has been suggested that the hemoglobin of an earthworm, which takes up oxygen from a normal atmosphere but releases it only at low internal oxygen tensions, may protect the worm from oxygen poisoning.

7. Digestive System.—The structure of the digestive tract is diversified, according to the mode of life and the food habits of the worm. The pharynx and a restricted rectal invagination are ectodermal in origin. Chitinous jaws are present in most polychaetes and biting leeches, absent in most oligochaetes and sucking leeches. Sedentary polychaetes with a crown of tentacles are often filter feeders. Some polychaetes possess a blind ventral pharyngeal pouch; the calciferous glands of earthworms are specialized esophageal pouches (diverticula). Diverticula of the mid-gut occur both in polychaetes and oligochaetes, but are the exception rather than the rule; leeches have well-developed intestinal diverticula. Digestive enzymes are secreted in the digestive juices, but intracellular digestion, common in many invertebrates, has not been demonstrated.

8. Excretory System.—The excretory organs (nephridia) of annelids are straight, looped or coiled tubes lying in the coelom and opening to the exterior or into the gut. The inner end may be closed by tufts of solenocytes, similar to the flame cells of flatworms, or there may be an open, ciliated funnel (nephrostome). The former condition is termed protonephridial, the latter metanephridial. A pair of protonephridia constitute the excretory system of the typical annelidan larva, and there is reason to believe that this is the primitive condition. According to E. S. Goodrich metanephridia are protonephridia that have acquired an internal opening and both are of ectodermal origin; while coelomoducts are mesodermal funnels that function as reproductive ducts (gonoducts). In some polychaetes a nephromixium is formed by the attachment of a coelomic funnel to the nephridium. A. Meyer advanced an alternative theory: open coelomic funnels are always coelomoducts, thus metanephridia are nephromixia, and the gonoducts of oligochaetes, present in the same segments with such nephridia! must be a secondary acquisition. In the re-

markable nephridia of leeches the nephrostome has no communication with the blind end of the nephridial tube.

Ammonia is the chief nitrogenous excretory product of aquatic species; the urine of earthworms contains both ammonia and urea. As in the vertebrate kidney there are three aspects of nephridial function: filtration, resorption and secretion. Coelomic fluid is filtered through closed solenocytes, but the ciliated funnels of open nephridia can only retain coelomic corpuscles and suspended particles of moderate size. In oligochaetes, whose coelomic fluid contains proteins, there is an active resorption of colloidal particles in the ciliated region of the tubule. In earthworms the tubules also must resorb inorganic ions, since the urine is more dilute than the body fluid. In addition to the activities of the end organ the nephridium is well vascularized and the tubules selectively can eliminate excretory products both from the coelomic fluid and from the blood stream. It has been demonstrated in the polychaete *Arenicola* that particles collected by phagocytic coelomic corpuscles are brought to the nephridia and actively secreted by the tubules.

9. Nervous System.—The brain, situated dorsally at the anterior end, belongs to the presegmental region (episphere) of the larva. It communicates by circumpharyngeal connectives with the ventral nerve cord. The nerve cord, like the brain, is embryologically double; the two halves may become completely fused or may remain separate but united by transverse commissures like the rungs of a ladder. Ganglion cells are concentrated in segmental swellings of the nerve cord.

The brain reaches its highest order of complexity in nonsedentary polychaetes in which 25 pairs of cerebral ganglia have been recognized. Nerve impulses entering from various sense organs are transmitted to association centres in the forebrain (corpora pedunculata, globuli). The forebrain and midbrain together form the primitive ancestral brain (proto- and deutocerebrum). In many polychaetes it has been thought that the first pair of segmental ganglia has become incorporated in the brain, as in the tritocerebrum of arthropods (fig. 2), but the subject is controversial.

The nerve cord of many annelids is provided with giant nerve fibres (neurocords), which may be either simple or compound. Simple neurocords are very large single neurons, their axis cylinders arising from individual giant cells situated in the brain or in segmental ganglia. Compound neurocords, best known among the Oligochaeta, are multiple structures, each axon receiving contributions from numerous cell bodies along its course. Each fibre is formed, moreover, by the end-to-end fusion of segmental components; the intersegmental junction (synapse) can be recognized histologically but offers no barrier to transmission of the nerve impulse, perhaps because of its direct one-to-one relation. The function of giant fibre systems is the mediation of rapid stereotyped responses such as an escape movement, and, in general, these systems are high-speed motor pathways. Vertebrate nerve fibres, which conduct nerve impulses as fast as do

some giant fibres (25 m. per second or about 55 m.p.h.) are of much smaller diameter but are provided with a thick insulating myelin sheath. Experimental studies by T. H. Bullock of giant fibre systems in polychaetes have revealed unforeseen physiological properties involving "cross talk" in the absence of an organized synapse (*q.v.*).

10. Neurosecretion.—Cells whose cytoplasm stains strongly with chromic acid (chromaffin cells), like those of the vertebrate adrenal medulla, occur in the segmental ganglia of many annelids; they contain and probably secrete an adrenalinlike substance. The brain contains neurosecretory cells of several types whose secretory activities can be related to phases of the life cycle. Neurosecretory hormones elaborated in such cells and transmitted by nervous or vascular pathways are concerned in reproduction and perhaps also in growth and regeneration. Surgical removal of the brain of an earthworm inhibits maturation of the gonads and, independently, the development of the clitellum (see below). Conversely, in some polychaetes removal of the brain initiates sexual maturation; in others it evokes correlated changes in body form (see Class Polychaeta: *Structure and Function; Reproduction and Development*, below). Sexual maturation of a headless hindpiece of *Platynereis* can be inhibited by head implantation. Head regeneration, on the other hand, is promoted by such treatment both in polychaetes (*Lycastes*) and earthworms.

11. Sense Organs.—Tactile endings and taste buds are widely distributed, especially at the anterior end of the body. The so-called nuchal organs of sedentary polychaetes are probably chemoreceptors. Organs of equilibrium (statocysts) occur in many polychaetes, either as epidermal invaginations containing sand grains or as closed subepidermal pockets with calcareous granules (statoliths). Eyes are often highly developed, varying from simple pigment spots to elaborate structures with lens and retina. Photoreceptor cells of oligochaetes are located in the skin, and the similar organs of leeches may be arranged in groups forming a direct or inverted compound receptor (fig. 3[D]j).

12. Reproductive System.—The bisexual condition found in most polychaetes is believed to be primitive, but many hermaphroditic forms are known. Oligochaetes and leeches are characteristically hermaphroditic. In many polychaetes the majority of segments are fertile, but there is a tendency toward limitation, a trend that reaches its culmination in oligochaetes. The gonads discharge their products into the coelom or into genital sacs of coelomic origin, where final maturation occurs. Nourishment for the growth of sex cells is provided by the coelomic fluid or mediated by chloragogue cells; the developing eggs of some species have nurse cells. Mature sex products escape through coelomoducts or, in many polychaetes, by rupture of the body wall. The secondary sexual apparatus reaches its highest development in oligochaetes and leeches, whose hermaphroditic condition is adapted to reciprocal copulation.

B. DEVELOPMENT

Annelidan eggs, like those of flatworms and mollusks, exhibit spiral cleavage (fig. 4[A] and 4[B]). The first four cells, called blastomeres, give rise by alternating clockwise and anticlockwise divisions to a cap of smaller cells, termed micromeres, at the animal pole. A ball of cells (solid gastrula) is formed by overgrowth of the micromeres, some of which are arranged in a characteristic pattern, the "annelidan cross."

The typical marine larva is a pelagic trochophore (fig. 4[C] and 4[D]), named from the ciliated band (prototroch) that encircles the equator and divides the body into the episphere, with the apical plate, eyespots and future brain, and the hyposphere with the alimentary canal, protonephridia and other internal organs. Oligochaetes and leeches, which lay eggs enclosed in cocoons, as well as many polychaetes, bypass the free-living larval stage and their development is consequently condensed and modified.

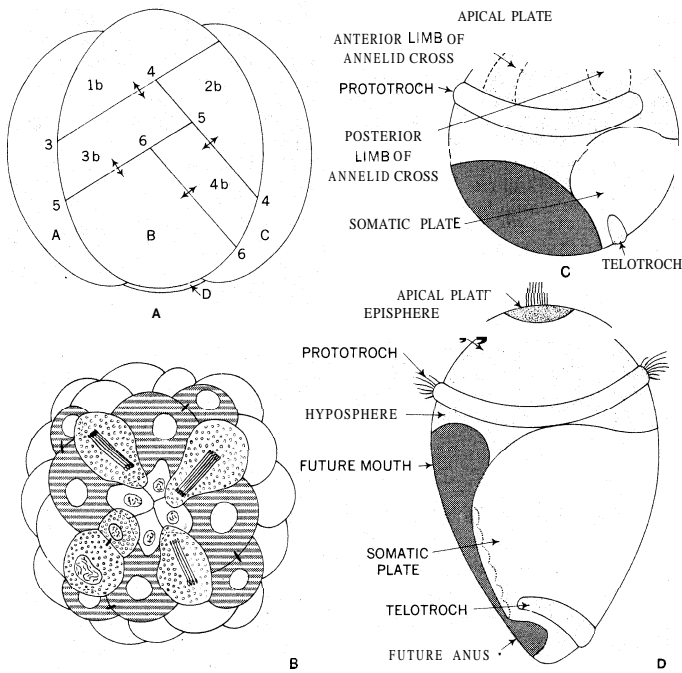

Studies of cell lineage, originating with the pioneer work of E. B. Wilson, reveal that one of the first four cells, the so-called D blastomere, has an especially significant destination. From it is derived micromere 2d, which gives rise to the somatic plate contributing the ectoderm of the adult, and micromere 4d, which divides to form the mother cells (left and right mesoteloblasts) of the future mesoderm.

The somatic plate grows ventrally and in typical annelidan development divides the blastopore into mouth-forming and anus-forming regions. The first three segments are formed practically simultaneously during larval life; in many species there follows a resting stage. At metamorphosis the body begins to grow in length by the addition of new segments derived from the teloblasts or, in more specialized cases, by new contributions from an apical growth zone. (See also INVERTEBRATE EMBRYOLOGY; EMBRYOLOGY, EXPERIMENTAL.)

C. REGENERATION

L. H. Hyman pointed out that annelids are the most highly organized animals capable of complete regeneration. Regenerative abilities are lacking in leeches, however, but most polychaetes and oligochaetes can regenerate an amputated tail. G. B. Moment has shown that in earthworms posterior regeneration ceases when the total number of somites is restored to normal. Ability to replace an amputated head is usually restricted to the anterior part of the body, although genera like *Lumbriculus*, that multiply by asexual fragmentation, can form a new head at almost any level. In forms that possess a definite number of morphologically differentiated head segments, such as the tube-dwelling polychaete *Chaetopterus*, the exact number is regenerated as a unit and posterior regions are then reorganized under the influence of the new head.

In earthworms of the family Lumbricidae regenerated heads usually have fewer segments than normal, and reproductive organs are lacking; but certain kinds of Glossoscolecidae (*Criodrilus*) and Megascolecidae (*Perionyx*) are capable of complete anterior regeneration. In such species a middle portion of the body can re-form a functionally normal individual. An amputated head piece, however, can only regenerate a useless second head, directed

FIG. 4.—ANNELIDAN DEVELOPMENT

(A) Diagram of spiral cleavage (numbers and lower-case letters, used to indicate the sequence of cleavage, are discussed in text); (B) developing egg of *Polygordius* with micromeres arranged in the "annelidan cross" (stippled), apical view; (C, D) development of a polychaete: larval ectoderm (stippled), blastopore field (shaded)

backward; and conversely, an amputated tail another tail.

G. E. Gates obtained reversal of polarity in the oriental earthworm *Perionyx excavatus*. In this species an anterior piece of the body will regenerate a head at both ends when the cuts are made simultaneously; if the newly formed anterior head is then removed, the posterior head becomes dominant and evokes tail regeneration at the anterior cut surface.

The morphological regulation of the regenerating head or tail presents complex problems. M. Avel has shown that in earthworms the ventral body wall plays a major role in the regeneration of the ectomesoderm; the digestive tube is necessary for the regeneration of the endoderm; but a new brain may be formed from regenerated ectoderm. Head regeneration, however, is defective in the absence of a nerve cord at the cut surface, and neurosecretory functions of the brain also have been implicated. A number of polychaetes and lower oligochaetes possess mesodermal regeneration cells known as neoblasts, which migrate to the site of injury; the number of somites in the regenerating tail of *Lumbriculus* can be modified experimentally by increasing or decreasing the number of neoblasts.

The phenomena of annelid regeneration appear to indicate a physiological dominance of the anterior end, in accordance with C. M. Child's theory of the axial metabolic gradient (see REGENERATION).

D. BIOCHEMISTRY

M. Durchon and M. Lafon studied the chemical composition of representative annelids in different phases of their life cycle. The role of the chloragogue tissue in carbohydrate, nitrogen and fat metabolism has been studied most thoroughly in earthworms (see Class *Oligochaeta*). Biochemical investigations concerning the axial metabolic gradient have shown that enzyme systems that regulate intracellular tissue metabolism are less concentrated in the middle region of the body than at either the anterior or posterior end.

The contractile mechanism of annelidan muscle depends on an actomyosin-myosin system similar to that found in other animals (see MUSCLE AND MUSCULAR SYSTEM: *Chemical Changes*). The

acceptors of energy-rich phosphate, studied by J. Roche and his co-workers, present an interesting facet of comparative biochemistry: the muscle phosphagen of sedentary polychaetes contains an otherwise unknown monosubstituted guanidine, taurocyamine; nonsedentary polychaetes have glycoyamine; and in earthworms a new compound, lumbricine, has been demonstrated. Some species utilize the vertebrate phosphagen, creatine phosphate and/or arginine phosphate (see BIOCHEMISTRY).

E. PHYSIOLOGICAL ECOLOGY

The body fluids of marine polychaetes are isosmotic with sea water and, since the osmotic pressure of the internal medium follows that of the environment, such species can withstand only moderate changes of external salinity over a narrow range. The ability of certain polychaetes to survive in brackish or even in fresh water and of aquatic oligochaetes to live exclusively in fresh water requires a physiological regulation of the internal medium. Such regulation may be facultative (optional) or obligatory.

A typical marine polychaete such as *Nereis cultrifera*, which is not adapted to fluctuations of salinity, will die in 20% sea water because it swells up and bursts as a result of uncontrolled intake of water (endosmosis). On the other hand, races of *N. diversicolor* that are capable of tolerating intertidal changes of salinity in estuarine waters can make the necessary adjustment to lowered salinity through an ability to excrete excess water; the nephridia of such species are enlarged.

Changes in tissue salinity tolerance are involved in long-term obligatory adaptation. E. A. Pora compared physiological races of *N. diversicolor* from the Black sea and adjacent salt lake of Eforia. The former races are strictly adapted to a relatively low salinity (about 19 parts per thousand); the latter to an abnormally high one (about 40 parts per thousand).

Adaptations of the respiratory pigments to oxygen deficient environments have been treated under Structure and Function: Respiration, and the temperature-humidity relations of earthworms are discussed under Class Oligochaeta: Ecology: Adaptation to Environment.

F. FOSSIL ANNELIDS

Burrows interpreted as those of wormlike creatures are known as early as the Pre-Cambrian, over 500,000,000 years ago, and a glimpse of the rich invertebrate life of the Middle Cambrian seas is preserved in the Burgess shales of British Columbia. C. D. Walcott, who discovered these remains, described several genera of segmented worms provided with parapodium-like projecting lobes on all segments. Some resemble living forms such as scale worms and the sea mouse, *Aphrodite*. A *Nereis*-like form, *Sprigina floundersi*, has been described from the Lower Cambrian of South Australia. Calcareous tubes similar to those of modern polychaetes such as *Serpula* and *Spirorbis* are found in various geological periods, while others, similar to the trumpet tubes of *Cornulites*, belong to extinct genera. The shells of Paleozoic brachiopods and bivalve mollusks are occasionally marked by U-shaped mud-blisters (Caulostrepis) similar to those made by the polychaete *Polydora*, a modern-day pest of oysters.

Jurassic crinoids were infested by parasites belonging to the aberrant polychaete family Myzostomidae. The chitinous jaws of polychaetes, minute shiny black denticles known as scolecodonts, occur in marine sediments from the end of the Cambrian onward.

Denticles called conodonts, which differ from scolecodonts both in chemical composition and mode of formation, formerly were thought to represent the jaws of extinct annelids that flourished in the Paleozoic era and disappeared early in the Mesozoic. They are calcified not chitinous and occur in pairs or in groups of pairs often of diverse form. It is evident from their structure that they were covered by a secretory integument that deposited new lamellae on the outer surface. This and other considerations preclude comparison with the teeth of fishes, but in rare instances they appear to be attached to an ill-defined calcified plate. Independent reviews by W. Gross and F. H. T. Rhodes concluded that the conodonts probably represent an extinct class, Conodontida, of jawless vertebrates. Most records of fossil oligochaetes are doubt-

ful, but L. S. B. Leakey mentions an earthworm from the Lower Miocene of Kenya, the habitat of the ape man *Proconsul*.

G. CLASSIFICATION AND RELATIONSHIPS

The present article recognizes three classes: Polychaeta (including Archannelida and Myzostomidae), Oligochaeta and Hirudinea. The Polychaeta are primarily marine; they are the most numerous, the most diverse and phylogenetically the oldest annelids. The Archannelida, formerly regarded as primitive, appear to comprise a miscellany of divergent types related to Polychaeta but difficult to classify on account of their partly degenerate and partly persistent larval features. The Hirudinea are closely related to the Oligochaeta, so closely that there is scarcely a single peculiarity of the leeches that does not find its counterpart among parasitic oligochaetes. The latter, for example, may possess suckers or biting jaws, and the body cavity may be partly occluded. W. Michaelsen united the Oligochaeta and Hirudinea into one class, the Clitellata, named for the girdle, or clitellum, which in both groups secretes the egg cocoon. On the other hand, leeches constitute a well-defined assemblage that is more conveniently treated as a separate class.

The greatest gulf in intra-annelidan phylogeny is that which divides the polychaetes from the oligochaetes. In the past it was customary to unite these two groups in the class Chaetopoda, on account of the presence of setae. The leeches were thus artificially separated from the oligochaetes, their closest relatives.

The Echiurida (*q.v.*) are closely related to the Annelida; they possess setae but lack segmentation, probably as the result of secondary suppression. The Sipunculida (*q.v.*) are more highly modified, lacking both setae and recognizable segmentation, so that their annelidan affinities are obscured. Both Echiurida and Sipunculida have features in common with the Mollusca (*q.v.*), but the early developmental stages of mollusks and annelids are so similar that few would deny their fundamental affinities. E. Reisinger pointed out that most theories regarding the origin of the Annelida are untenable; the most acceptable is that which relates the trochophore larva to some ancestral turbellarian of the phylum Platyhelminthes (*q.v.*).

The nervous system of the annelidan larva is especially significant; its plan differs radically from that of the adult and resembles that of the platyhelminth. In passing, it must also be noted that setae of the annelidan type are present in one apparently wholly unrelated phylum, the Brachiopoda (*q.v.*).

The gap between Annelida and Arthropoda (*q.v.*) is bridged by intermediate features of the Onychophora (*q.v.*), a group that has become highly specialized at a low level of arthropodan evolution.

Arthropods have jointed appendages that may be compared with parapodia. The arthropodan coelom is reduced and its place is taken by an open vascular system (hemocoel); the blood is received directly into the heart through openings called ostia, a condition not paralleled among Annelida. Arthropods must be regarded as the culmination of annelidan evolution, a point of view that provides some justification for their union in a phylum Articulata, proposed long ago by Cuvier. See also ANIMALS, PHYLOGENY OF.

II. CLASS POLYCHAETA

Polychaeta is the largest class of the phylum Annelida, comprising 67 families. The name refers to the numerous tufts of setae at the sides of the body. Polychaetes are widely distributed over the world in marine habitats at all depths but chiefly in less than 200 fathoms; a few live in brackish to fresh water and very few in moist earth. Certain groups, as eunicids and fireworms, predominate in tropical waters; others, as bamboo worms and ampharetids are most numerous in cold seas. Tomopterids and alciopids are entirely pelagic (open oceans forms), and many other kinds are pelagic in larval stages. Most benthonic (living in a substratum) species are limited by kinds of sediments; some are rock borers and others are associated with hosts of other animal kinds.

Among the polychaetes are commensals and parasites; the separation between these two modes of life is arbitrary. True commensalism, in which both species of the pair benefit, is almost nonexistent; in many of these relationships, as between polynoids and echinoderms or sponges, the annelid usually benefits. Cases numbering 50 species in ten families have been enumerated with their hosts. Parasitism, which may be endoparasitic (living within the tissues of the host) or ectoparasitic (externally attached) have been cited for 24 species in ten families, with the most numerous in the superfamily Eunicina.

A. STRUCTURE AND FUNCTION

1. External Features.—The body form (fig. 5) varies greatly, depending on whether the polychaete is errant, sedentary or pelagic. Diversity in shape is illustrated in some of the common group names, such as proboscis worm, bamboo worm, sea mouse, feather duster and shield worm. Polychaetes vary in length from under an inch (some sphaerodorids) to more than 20 ft. (some Eunicina). Colour and pattern, from brilliant to dull, differ according to species; they are due both to presence of pigment and phenomena of light refraction. Luminescence may heighten the display. Pelagic species are sometimes glass-clear.

The outer surface of the body may be provided with cilia, stiff hairs, sensory papillae, scutes or other projecting parts. The body itself consists of head, trunk and tail, or more appropriately prostomium with associated parts, metastomium (which may be divisible into thorax and abdomen) and pygidium. The preoral portion or prostomium may be a simple lobe or highly developed; it is followed by the first segment or peristomium, surrounding the ventral mouth, and by successive segments which may be similar or differentiated. A pair of palpi (outgrowths of the peristomium) may adjoin the mouth. The pygidium is a posterior pore which may be either unadorned or surrounded by cirri, plaques or other parts.

The number of segments is either few and limited (some polynoids) or many and unlimited (many polychaetes). Increase in the number of segments occurs usually in the growth region, immediately in front of the pygidium. The outer layer of the body wall is epithelial; this is succeeded by circular, longitudinal and oblique muscular layers.

FIG. 5.—EXTERNAL STRUCTURE AMONG POLYCHAETES

Free-living forms: (A) *Glycinde* and (B) *Phyllo*, lateral view of anterior ends. Parasitic and commensal forms: (C) *Spinther alaskensis*, probably parasitic on sponge, dorsal view; (D) *Protis pacifica*, with four calcareous tubes attached to clam, with which it is commensal

2. Parapodia.—Each body segment following the peristomium is, in most cases, provided with characteristic paired appendages or parapodia. These fleshy, lateral outgrowths (fig. 6) of the body wall are variously developed; they may be prominent and ornate or reduced to low hooked ridges or rounded tori. Fascicles of extensile setae and embedded supporting rods (acicula) emerge from parapodia in an upper (notopodial) and a lower (neuropodial) branch, or the upper branch may be lacking. Associated with the parapodia are various epithelial outgrowths modified as presetal and postsetal lobes, dorsal and ventral cirri, branchiae (gills), tentacles, elytra or other parts.

3. Setae.—These segmentally arranged tufts of bristles or hooks differ in form and function and provide a remarkably ac-

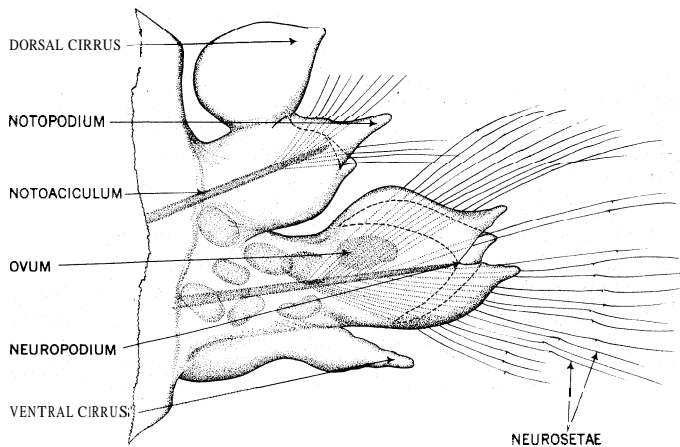

curate means of species differentiation. A simple seta originates as a secretion of an invaginated epidermal cell that encloses a ciliary apparatus from which the base of the seta arises and a lacuna in which the seta develops and through which it pushes to the exterior (fig. 7).

Composite or pointed setae are formed from two or more such processes juxtaposed on each other; ornamentations are the result of modifications of simple setae. Setae are named for their structure or form; some are called capillary setae, paleae, lyre, uncini, platelets and brushes. Most frequently present are the hairlike capillary setae.

4. Branchiae.—These structures, sometimes called gills, are lacking in smaller forms where respiration is accomplished through the skin surface. In most polychaetes gills occur as epithelial outgrowths penetrated by a vascular loop. They may be simple filaments or tufts or pectinately divided or spiraled projections (*Diopatra*); they may be stationary or eversible. In position the gills are near the anterior end of the body. The tentacular crown of sabellids and serpulids functions both for food gathering and respiration. In ampharetids and flabelligerids the gills are outgrowths of the peristomium and are retractile into the oral aperture.

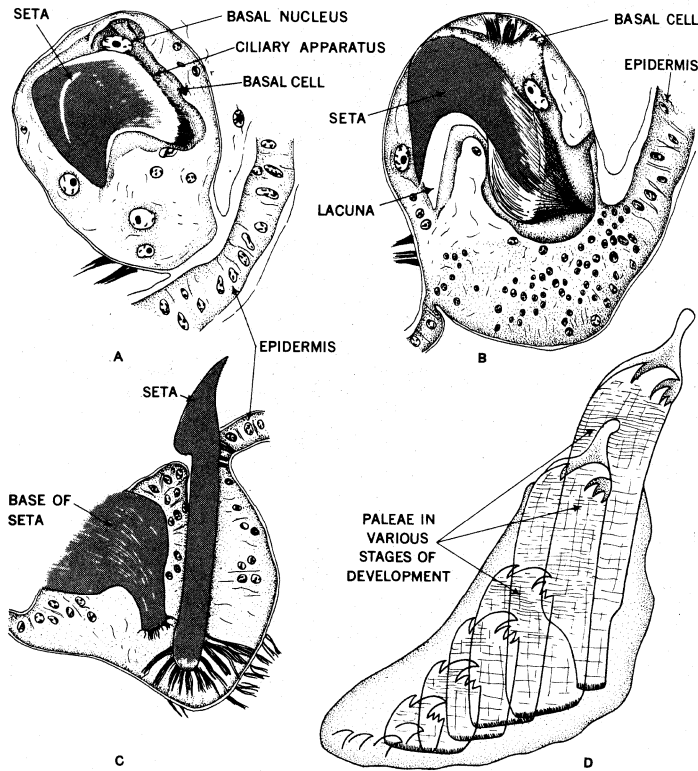

5. Sense Organs.—These organs function as light, chemical and touch receptors. They include the eyes, lateral organs, dorsal ciliated ridges, statocysts or otocysts, taste buds, various kinds of papillae, stiff hairs and others. The eyes (fig. 8) range from simple pigment spots to complex lenticular organs most highly developed in pelagic species. In location they may be prostomial, peristomial (terebellids), segmental at the sides of the body (opheliids) or pygidial (sabellids). In *Sabella* they occur on the tentacular crown.

Lateral organs are segmentally arranged ciliated pouches (eversible or stationary) usually located at the sides of the body. They

 (A) Early, (B) intermediate and (C) final stages in development of uncinus in *Sabellia*; (D) series of developing paleae in *Sabellaria*

are innervated by the ventral cord and function to supply the parapodia and other parts of the metasome with sensory parts. Dorsal sense organs of various kinds occur as simple ciliated mounds or grooves (fig. 9) or have accessory parts. They have access to the exterior without action of muscles. Incorporated in caruncles they attain their most remarkable development in errant polychaetes, especially amphinomids (fig. 10). Nuchal organs of the head are homologous with dorsal sensory organs of body segments.

Touch receptors may occur in diffuse (flabelligerids) or segmental arrangement as stiff hairs or modified cirri (nephtyids). Statocysts or otocysts function for maintaining equilibrium. Many other organs are found among many errant polychaetes that evert the proboscis.

6. Internal Structure.— The alimentary, vascular, excretory, nervous, respiratory, musculature and reproductive systems represent many modifications from a simple system. A coelomic epithelium lines the more or less spacious body cavity. Successive

body segments are separated from each other by transverse septa, which correspond to the external intersegmental grooves. Muscle tissue is smooth or partly striated.

7. Digestive System.— The mouth is bounded by upper, lower and sometimes an inner lip enclosing ventral mucous glands. In some sedentary sorts, as terebellids (fig. 11), much of the thoracic space is occupied by nephridia and the heart, but in locomotory polychaetes this space is taken over by an eversible pharynx or proboscis.

The esophagus, of variable length, is followed by the stomach region, which may be partly muscularized, and the intestine. The fore stomach secretes enzymes that are strong in starch, (amylase) protein (protease) or fat (lipase) digesting actions.

8. Vascular System.— All the blood vessels may be contractile. The chief contractile vessel, however, is the dorsal longitudinal one. Peristaltic contractile waves pass forward as far as the heart body. Peritoneal cilia aid in the movement of the fluid.

The walls of the blood vessels consist of three layers, a middle skeletal coat covered on the outside by peritoneum and on the inside by endothelium. The skeletal coat consists of a homogeneous collagenous membrane that becomes longitudinally folded when

 FIG. 9.— DORSAL SENSE ORGANS OF VARIOUS POLYCHAETES (SHADED)
 (A) *Polydora*; (B) *Scoleleps*; (C) *Disoma*; (D) *Scoloplos*; (E) *Chaetopterus*

the vessel contracts. The peritoneum is a muscle-epithelium; a peritoneal covering is absent or incomplete in sabellids, thus the cell bodies of the muscle fibres project on the vessel. Tissues lying within the blood system are present in some serpulids; they may function as blood-forming (hemopoietic) organs, as valves controlling the direction of blood flow, as structures transporting substances or as centres concerned with breaking down hemoglobin.

The colour of the blood is clear; green or red, the change resulting from increasing intensities of chlorocruorin, a respiratory protein, chemically similar to hemoglobin; it occurs dissolved in the blood or in corpuscles. Both chlorocruorin and hemoglobin

FIG. 10.—CARUNCLES WITH INCORPORATED NUCHAL ORGANS
Anterior ends of (A) *Eurythoe complanata* and (B) *Hermodice carunculata* (enlarged)

may be present in *Serpula*; the presence of one or the other has no genetic relationship. The oxygen affinity of chlorocruorin is lower than that of hemoglobins.

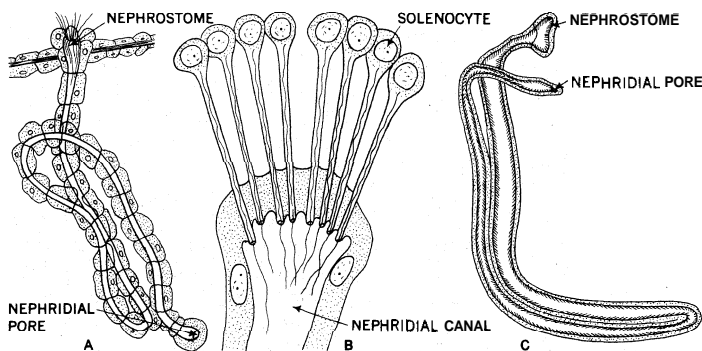

Heart Body.—Loose spongy tissue, localized to form a strand, is present in an anterior part of the dorsal vessel in many sedentary polychaetes; this is the heart body, formed from an infolding of extravascular epithelium. It participates in excretion or food storage. Typically present are brown granules that are blood pigment derivatives, coproporphyrin and tricarboxylic porphyrin. In cirratulids the heart body extends through that region of the dorsal vessel where branches are given off to the gills. When the dorsal vessel contracts, its lumen is completely obliterated by pressure against the more rigid heart body.

9. Excretory System.—Nephridia (fig. 12), sometimes called segmental organs, include protonephridia and metanephridia. Protonephridia start blindly within the body and are provided with vibratile cells (solenocytes); they are characteristic of nephtyids, glycerids, phyllodocids and some pelagic polychaetes. Metanephridia are tubules that are more or less coiled and open internally

as a funnel or nephrostome. They occur in some errant forms, most sedentary ones and some archiannelids. Although nephridia may be segmental, a pair to a segment (many errant forms), they may also be multiple to diffuse (capitellids) or reduced to one or a few in anterior segments (sedentary forms). They function to collect and transport waste products from the coelom to the exterior, through nephridiopores that are usually located near a part of the parapodium.

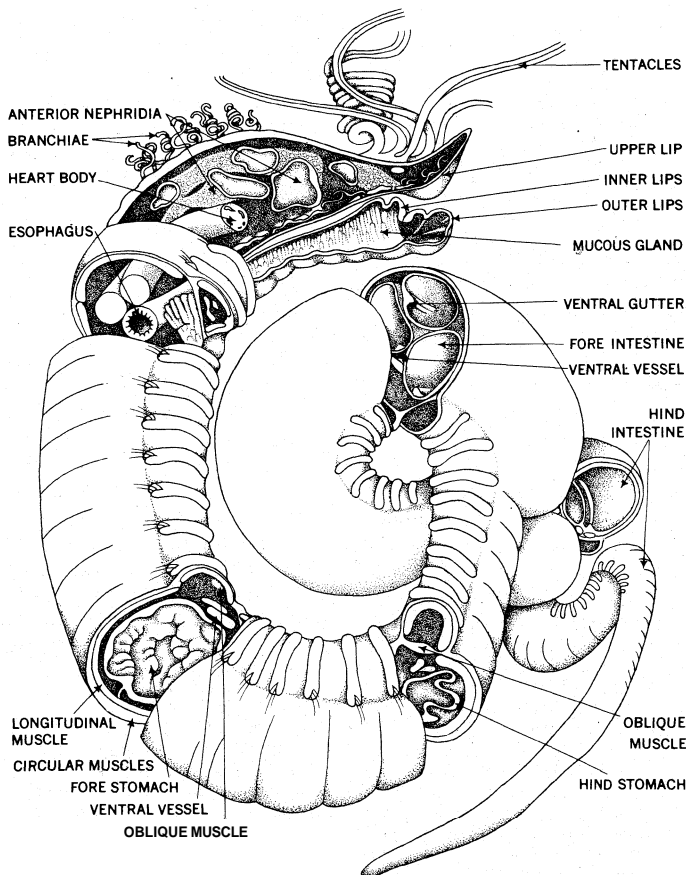

10. Nervous System.—A dorsal brain or supra-esophageal ganglion in the prostomium innervates the eyes, palpi, antennae and nuchal organs; it is connected to a ventral subesophageal ganglion and paired cords (fig. 13) that may be widely separated or fused to form a single cord. Lateral nerve branches extend to the various body parts. The ventral cord may be embedded in the epithelium or lie freely in the coelomic cavity.

Giant Nerve Fibres (Axons).—These are widespread among polychaetes and form a conspicuous part of the central nervous

FIG. 11.—MAIN REGIONS OF ALIMENTARY TRACT OF AMPHITRITE JOHNSTONI (DIAGRAMMATIC DISSECTION)

system. Their occurrence presumably has no phylogenetic significance. In some species the giant axons are intrasegmental and enter peripheral nerves; in others they are intersegmental (see *Nervous System*, above). Giant axons measure from a few microns to a millimetre across and attain their greatest size in *Myxicola*. Both unicellular and multicellular kinds occur (fig. 13). They function to conduct impulses leading to quick body contraction and thereby aid the worm to escape a danger. Among the polychaetes measured rates of conduction vary from about 6½ ft. per second to over 65 ft. in *Myxicola*.

11. Neurosecretion.—Neurosecretory centres are found in the most primitive part of the brain. Neurosecretory cells are morphologically similar to neurons; they consist of fine projections (an axon and neurofibrillae) and a cell body whose cytoplasm contains Nissl bodies: small darkly staining granules. These cells do not innervate an end organ but terminate in the walls of blood vessels, in other internal fluid systems or in the epidermis; they secrete biologically active substances that aggregate in microscopic droplets or granules. Evidence shows that neurosecretory cells may be derived from epidermal secretory cells that have been incorporated into the central nervous system. Their function has been discussed above in the introductory section.

12. Reproduction and Development.—Paired reproductive organs are found in most of the segments of the body. Gonads first appear on septa of certain segments. The undeveloped eggs (ova) are shed into the coelom where they are nourished by special nurse cells or other coelomic inclusions. Ripe ova and sperm may leave the body through special gonoducts or through nephridial pores, or they may be shed through rupture of the body wall. Methods of reproduction are diverse. Major body changes may precede the emission of gametes. The two most profound body changes are those concerned in epitoky and stolonization. Epitoky in nereids and syllids (fig. 14) is a morphological and anatomical differentiation of the region where genital products are concentrated. Stolonization, or strobilation, in syllids (fig.

FROM J. A. C. NICOL, "QUARTERLY REVIEW OF BIOLOGY," VOL. 23, NO. 4 (1948)

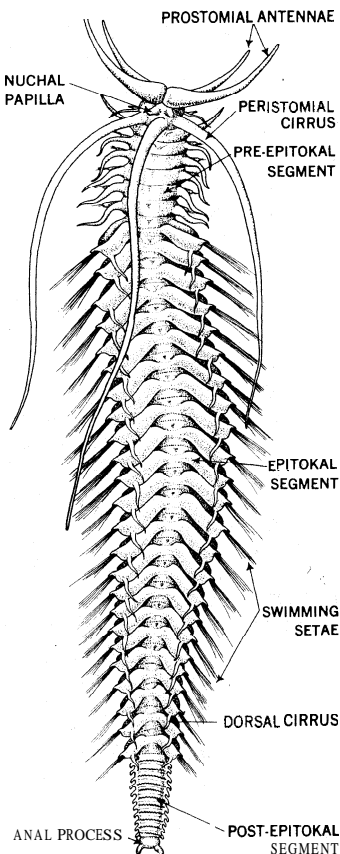

FIG. 13.—NERVOUS SYSTEMS OF POLYCHAETES (DIAGRAMMATIC) Giant fibres of (A) *Clymene*, (B) *Sabella* and (C) *Myxicola*; (D) nerve cord of *Myxicola infundibulum*, cross section

15) is an isolation of the tail region giving rise to new worms, distinct from the stock. In nereids surgical removal of a part of the brain effects precocious development of epitoky without influencing sexual development. In some syllids removal of the proventriculus zone inhibits strobilation. It is presumed that a hormonal secretion produced in an anterior region is involved.

Some hermaphroditic (both male and female in the same individual) species (for example, *Ophryotrocha*) show marked sexual variability; male or female forms may exist in association with hermaphroditic forms. Some hermaphroditic populations are limited as to numbers of various forms: others have varying numbers; the first type of group is called a balanced population, the second unbalanced. The hypothesis that these populations are determined genetically is considered the simplest explanation of sexual variability. Experiments on *Ophryotrocha* suggest that racial differences may exist in the age when passage from male to female phases can occur.

Studies on sperm have demonstrated the presence of at least 12 forms, all primitive. Total length varies from a few microns to 133 microns (*Dinophilus*). The most primitive sperms are retained in groups which retain the primitive discharge of sperm freely into the water. The fertilized ovum, unless provided with much yolk, usually gives rise, through spiral cleavage, to a pelagic ciliated larva called a trochophore. Both the mouth and anus may be derived from the blastopore or the anus may arise secondarily. In larval development the entire body originates from a single cell; in regeneration the entire body may derive from a few anterior segments. The trochophore stage is followed by a polytroch having a few segments, and this in turn by various larval, free-swimming stages. Metamorphosis, in some polychaetes, takes place in capsules or cocoons, in others within the parent's body. Larvae of some polychaetes practice cannibalism.

13. Luminescent Structures.—Light-producing structures are found in unrelated groups. The best known examples occur in polynoids, pelagic polychaetes, chaetopterids, cir-

BY COURTESY OF OLGA HARTMAN
FIG. 14.—POLYBOSTRICHUS STAGE IN *AUTOLYTUS*, DORSAL VIEW

ratulids and terebellids. In polynoids the phenomenon is intracellular; the lower surface of some scales have photocytes (modified epidermal cells) which luminesce when stimulated (fig. 16). In chaetopterids the process is extracellular, involving the discharge of a luminescent secretion from some segments and antennae.

B. CLASSIFICATION

The Polychaeta are most conveniently divided into the Errantia, or free-moving worms, having successive segments similar, and the Sedentaria, or tube-dwelling worms, usually having the body divided into an anterior thoracic and a posterior abdominal region. This separation into two major groups is only approximate since many representatives of Errantia occupy tubes, and some Sedentaria may be errant in habit. Further, the division of the body into thorax and abdomen is sometimes obscure or altogether absent in the Sedentaria. The terms Phanerocephala (meaning visible headed worms) and Cryptocephala (meaning head covered) are also unreliable because the cephalic structures are sometimes not distinguishable although they may be uncovered.

ratulids or microscopic. The Errantia comprise 33 families, parasitic polychaetes 3 families, Sedentaria 28 and Archiannelida 3. Separation to genera and species is less difficult, especially when accompanied with illustrated keys and geographic lists of species.

An indispensable guide for any study of the polychaetes, and especially for their systematic study on a world-wide scale is provided in O. Hartman's *Literature of the Polychaetous Annelids*, consisting of a Bibliography (1951) and Catalogue (1959). The Bibliography brings together the systematic literature from the time of Linnaeus, and the Catalogue presents, in uniform style, the facts of the establishment of the systematic categories, including higher family through specific and varietal levels. Citation is provided for all original names, with place of origin of species, and synonyms, complying with formats as currently used.

C. ABERRANT GROUPS

1. **Myzostomidae**.—The Myzostomidae are an aberrant family, associated with echinoderms, chiefly crinoids and less often brittle stars and sea stars. They are external or internal parasites. About 123 species have been listed, of which 117 are *Myzostomum*, 2 are *Protomyzostomum*, 2 are *Mesomyzostomum* and one is *Stelechopus*. Generally the body is discoid to oblong, depressed and bilaterally symmetrical. Length varies from one-half to about nine millimetres, and the male may be only one-fifth as long as the female individual. Segments are few and setae are modified as hooks. Reproduction is largely hermaphroditic.

See G. Jagersten, *Arkiv for Zoologi*, vol. 29A, pp. 1-35 (1937), and vol. 31 (1939); R. von Stummer-Traunfels, *Handbuch der Zoologie*, vol. 3, pp. 132-310 (1926). (Both of these works give extensive accounts and lists of references.)

2. **Archiannelida**.—Three families are recognized; the Nerilidae with 5 species in 3 genera; the Protodrilidae with 32 species in 3 or 5 genera; and the Dinophilidae with 8 or 9 species in 3 genera. Some older names, *Archichaetopoda* and *Protochaeta*, refer to species of *Saccocirrus*, and the group name *Trichotoma* refers to *Dinophilus*. They are characterized for their small size, reduced organ systems and aberrant modifications; they do not represent a homogeneous group. The organization of the body plan is much like that of typical polychaetes, but parapodia and setae may be reduced or lacking.

BIBLIOGRAPHY.—F. Hemplemann, *Handbuch der Zoologie*, vol. 2, Lieferung 13, pp. 155-161 (1931) gives a good review of the group. R. G. Aiyar and K. H. Alikunhi, "On Some Archiannelids of the Madras Coast," *Proc. Nat. Inst. Sci. India*, vol. 10, pp. 133-140 (1944) reviews the Polygordiidae. E. W. MacBride, *Text-book of Embryology*, pp. 131-153 (1914) summarizes the results on development of *Polygordius*; this is criticized by A. Soderstrom, *Das Problem der Polygordius-endolarve*, pp. 1-168 (1924) and upheld by R. Woltereck in the same publication. C. Shearer, "The Problem of Sex-Determination in *Dinophilus gyrotilatus*," *Quart. J. Micr. Sci.*, vol. 57, pp. 329-371 (1912) gives an account of development and sex-determination.

(O. HN.)

III. CLASS OLIGOCHAETA

This group of annelids comprises more than 3,250 species of chiefly terrestrial, mud-living or fresh-water worms; a few are marine or parasitic. Oligochaetes vary in size from minute aquatic species scarcely $\frac{1}{25}$ in. in length to the largest earthworms, some of which measure several feet and may be an inch in diameter.

A. STRUCTURE AND FUNCTION

1. **External Features**.—The anterior end is without palpi or tentacles. The presegmental region, or prostomium, is a simple lobe overhanging the mouth; sometimes it is prolonged as a tentacle-like proboscis (fig. 17[R]), occasionally it is absent. The anus is terminal or, rarely, displaced dorsally (Branchiobdellidae, Acanthobdellidae and *Glyphidrilus*). The body is usually cylindrical, sometimes flattened, rarely with projecting gills or processes. The primary segmentation is usually conspicuous, but in some of the larger forms there is a secondary annulation of the anterior end. External regionalization is rare; but

species, however, do not have exactly the same number. In Branchiobdellidae and Acanthobdellidae the presence of a terminal sucker leads to a leechlike standardization of the number of segments.

2. **Setae**.—The setae, embedded in the body wall, are sometimes absent, as in the enchytraeid *Achaeta* and in Branchiobdellidae. They may be simple or ornamented, S-shaped (sigmoid), forked or hairlike. The lumbricine arrangement (fig. 18[D]), two pairs of sigmoid setae on every segment except the first, is possibly primitive. In the small aquatic species each pair may be represented by a fan of setae, only functionally comparable with the polychaete parapodium. The perichaetine arrangement (fig.

18[E]) occurs in some terrestrial oligochaetes; a ring of small sigmoid setae encircles each segment. Many unrelated genera of the Megascolecidae possess this modification.

Transitional conditions are not uncommon; the New Zealand genus *Decachaetus* has five pairs of setae per segment, and in some genera setal multiplication may affect only the middle and posterior segments. The perichaetine arrangement has appeared independently in the neotropical genus *Periscolex* (Glossoscolecidae), and setal multiplication reinforces the ventral holdfast organ of the ectoparasitic enchytraeid *Aspidodrilus*.

So-called penial setae may be associated with the openings of the male ducts, and genital or copulatory setae may occur on other segments. The replacement of sigmoid by modified setae during maturation takes place in periodic stages representing increasing degrees of transformation.

3. Body Wall.—A simple columnar epithelium with interspersed glandular and sensory cells secretes a thin cuticle. In *Aeolosoma* the prostomium is ciliated below. The epidermis of earthworms assumes a pseudostratified appearance because of the presence of numerous small basal cells. Epidermal thickenings are found in species of the genus *Peloscolex* (Tubificidae). The muscular coats are arranged as in other annelids. J. Hansen studied the peculiar smooth muscle fibres by phase-contrast and electron microscopy.

4. Clitellum.—All oligochaetes possess, at sexual maturity, a glandular development of the epithelium, the girdle or clitellum, which secretes the egg capsule. The clitellum may be saddle-

shaped or ring-shaped; in the lower oligochaetes it consists of a single layer of modified epithelial cells in the region of the genital pores; in Aeolosomatidae it is restricted to a ventral patch. The clitellum of earthworms occupies several segments, and in species of the family Lumbricidae it may be situated far behind the male pores. In contrast to the clitellum of the lower oligochaetes, the earthworm clitellum is composed of many cell layers; three major cell types secrete the slime tube, the chitinous capsule and the albumin of the cocoon. A clitellum may develop in total castrates, but co-ordinated maturation of the gonads and the clitellum is regulated by neurosecretion (see *Introduction*).

5. Coelom.—The body cavity is well developed and segmentally partitioned by septa. The body wall of *Acunthobdella* is thickened and the coelom correspondingly reduced; the coelom of the remarkable lumbricid *Agriodrilus*, from Lake Baikal, is obliterated in front of the genital segments; such modifications foreshadow the condition in leeches.

The coelom often communicates with the exterior by pores, regulated by sphincter muscles; some aquatic species possess a pore on the prostomium or in the first intersegmental furrow. Dorsal pores are found in the intersegmental grooves of many terrestrial species. Coelomic fluid may be ejected through these pores or, in some earthworms, through special openings in the floor of the pharynx and at the anus. The fluid discharged by earthworms may be milky, mucilaginous, sometimes coloured and malodorous. K. N. Bahl has shown that the coelomic plasma of *Pheretima* is hypotonic to the blood and contains protein.

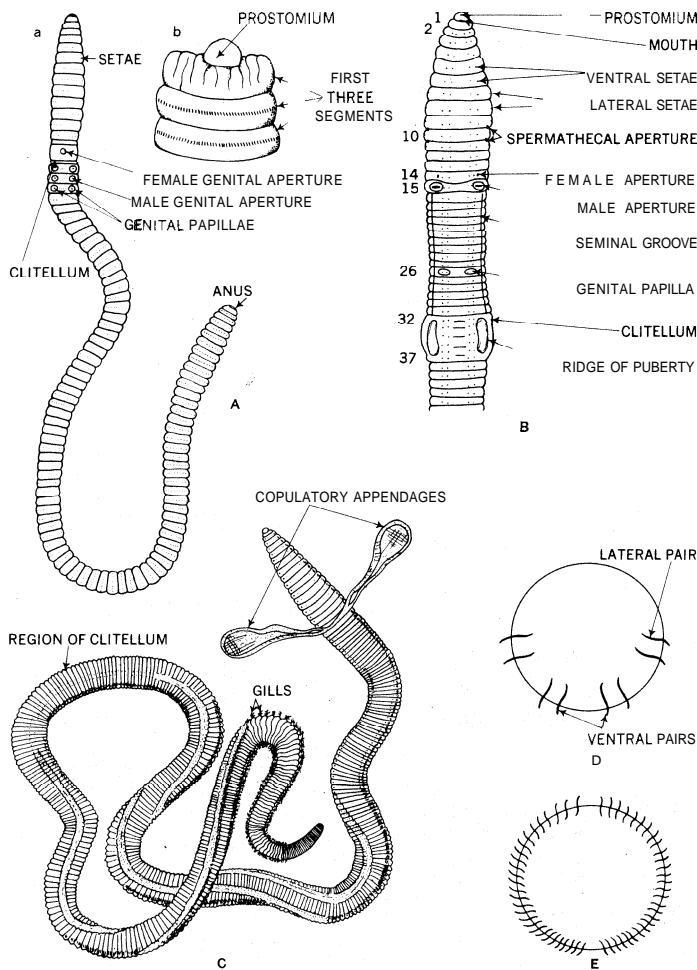

Formed elements in coelomic fluid consist of coelomocytes, bacteria, granules of pigment and fragments of degenerating muscle (sarcolytes). The bacteria are typical soil species. Some of the leucocytes resemble types found in human blood; lymphocytes and monocytes are amoeboid and phagocytic, taking up foreign particles which are carried to the nephridia or the body wall. The granulocytes are mostly acidophilic and nonphagocytic. Eleocytes of the brandling, *Eisenia foetida*, contain yellow oil droplets which, when liberated, are responsible for the evil-smelling odour of the fluid ejected by this species. The phosphorescent discharge of certain earthworms, e.g. *Microscolex phosphoreus*, is caused by the liberation of granules from special coelomic corpuscles and is attributed to a luciferin-luciferase reaction (see *BIOLUMINESCENCE*). Megascolecid earthworms have other cells, lamprocytes and linocytes, of unknown function. Coelomic glands, present in many earthworms, have been variously described as phagocytic or as leucocyte-producing organs.

6. Chloragogue Tissue.—This tissue is a derivative of the peritoneum that invests the coelomic surface of the intestine, dorsal blood vessel and other organs. The club-shaped cells of chloragogue tissue, laden with yellowish-brown globules (chloragogosomes) project into the body cavity. In well-fed worms the cytoplasm is rich in glycogen and fat droplets; these storage products are depleted during starvation. Enzyme systems concerned with fat and carbohydrate metabolism are present. Chloragogue tissue also participates in nitrogen metabolism; it contains and can synthesize urea.

P. Semal-van Gansen showed that the chloragogosomes are composed of excretory material: purine (probably heteroxanthine), chromolipid and a silicate. Cells loaded with such material drop into the coelom and are phagocytized or form conglomerates known as brown bodies.

7. Digestive System.—The mouth opens into a muscular, protrusible pharynx; chitinous jaws are absent, except in Branchiobdellidae. Chromophilic glands secrete a saliva that contains mucin and has a protein-digesting action. A narrow esophagus passes backward through the genital segments. A muscular gizzard with a cuticular lining is present in the majority of earthworms and a few of the smaller oligochaetes. The gizzard is pregenital or esophageal in typical Glossoscolecidae (fig. 19[D]) and Megascolecidae as well as in the supposedly ancestral Haplotaxidae. An esophageal gizzard is often metamerically repeated in two or three successive segments, but genera showing this modification are not necessarily related.

Lumbricidae have a postgenital dilated crop followed by a pre-

intestinal gizzard. In Moniligastridae there is a series of pre-intestinal gizzards, and such have been independently evolved in some Eudrilidae and in at least one genus of the Megascolecidae (*Plionogastev*).

Esophageal glands may secrete a protein-digesting enzyme; the esophageal stomach of the carnivorous naid *Chaetogaster* digests protein in strongly acid media. A sphincter valve separates the esophagus from the intestine.

The intestine is usually a straight tube but diverticula occur in various genera. A longitudinal fold, the typhlosole (fig. 19[A]), hangs downward into the intestinal lumen; it is sometimes absent. The intestinal epithelium is ciliated and glandular; each gland cell is surrounded by ciliated cells that contain contractile fibrils. According to N. Millott these fibrils assist in the extrusion of secretory products. The absorptive surface of the typhlosole and anterior intestine may have a brush border; fat resorption is restricted to this region.

Intestinal digestive enzymes show optimal activity in a nearly neutral medium, corresponding to that of the gut. Among less familiar enzymes, cellulose- and chitin-digesting ones are present. The gut of an earthworm also plays a role in the regulation of osmotic pressure, assisting the nephridia in the elimination of water.

8. Calciferous Glands.—Calciferous glands are peculiar to certain earthworms; they are absent in aquatic and mud-living

oligochaetes, in enchytraeids, which inhabit the soil, and also in some of the more primitive genera of true earthworms. In their simplest type they are outpouchings of the esophagus, with an internally folded lining epithelium whose projecting lamellae increase the area of the secretory surface (fig. 19[B]); in more elaborate forms the gland communicates with the lumen of the esophagus by a duct (fig. 19[C]).

Calciferous glands are well vascularized; C. Myot showed that they secrete calcium carbonate as amorphous granules that are transformed into calcite crystals in the lumen. A primary function of the calciferous glands, originally suggested by Darwin, appears to be the excretion of calcium. X-ray photographs of worms fed on acid peat show little calcite, but secretion recommences when calcium salts are provided. Neutralization of the gut contents is at most an incidental function.

At high carbon dioxide (CO₂) tensions, such as might exist in waterlogged soil, the ability to bind and excrete toxic carbonic acid as relatively insoluble calcium carbonate may be important; surgical removal of the calciferous glands impairs this function. Blood calcium increases under abnormally high CO₂ tensions, and the conversion of calcite to soluble calcium bicarbonate may participate in regulating the pH of the blood.

9. Vascular System.—In the simplest oligochaetes (fig. 20[A]) the vascular system consists of a contractile dorsal vessel arising directly from the peri-intestinal blood sinus, a ventral distributing vessel and segmental connectives, at least at the anterior end. In higher oligochaetes the dorsal vessel extends the whole length of the body, receiving tributaries from the sinus, and a subneural vessel often is present. The dorsal vessel arises embryologically by the union of left and right halves and may remain double along part of its course.

In many of the lower oligochaetes and in Lumbricidae one or more pairs of contractile lateral hearts connect the dorsal with the ventral vessel. Megascolecidae have esophageal hearts, and some Tubificidae have intestinal hearts connecting the dorsal gut sinus with the ventral vessel; latero-esophageal hearts receive blood both from the sinus and from the dorsal vessel (fig. 20[B]). The dorsal vessel of the Lumbriculidae has peculiar blind contractile appendages.

The blood is colorless in some Microdrili; usually it contains hemoglobin in solution in the plasma (see *Introduction*). According to K. N. Bahl the blood carries nitrogenous excretory products to the nephridia. Only a small part of the osmotic pressure of the blood, which is much less than that of marine worms, is accounted for by chlorides. The only blood corpuscles are phagocytic amoebocytes. Blood glands occur in *Pheretima*, and in a number of lower oligochaetes the dorsal blood vessel contains a cardiac body similar to that of polychaetes.

10. Respiration.—Small aquatic species have anal respiration, in which water is pumped in and out of a rectal chamber. Some Naididae have anal gills (fig. 17[F]), and respiratory outgrowths of the body wall occur in a few aquatic genera (fig. 17[D] and 18[C]). In earthworms respiratory exchanges take place through the skin, which is well vascularized and must be kept moist. Earthworms can withstand considerable periods without oxygen, during which time they accumulate lactic acid and build up an oxygen debt.

11. Excretory System.—The primitive (holonephric) condition is one pair of nephridia per segment. A typical nephridium (fig. 21[A]) consists of: a preseptal funnel (nephrostome); an intracellular duct which penetrates the septum; and a coiled tube of varying complexity situated in the segment posterior to that of the funnel. Following the thin tube is usually a ciliated region and, beyond this, a wide tube. The nephridial duct frequently terminates in a dilated, bladderlike vesicle; nephridial pores are commonly situated on the anterior margins of the segments.

Modifications of nephridia in the small aquatic species are chiefly in the directions of simplification. The multicellular horseshoe-shaped upper lip of the funnel (meganephrostome) is replaced by a few marginal cells (mesonephrostome), or is absent (micronephrostome). Occasionally the internal opening is closed (*Chaetogaster*, *Acantlozobdella*). In earthworms not only is the complexity of the individual nephridium increased but in many

forms there is a multiplication and differentiation of nephridial types within a segment (meronephric conditions).

Following the terminology of K. N. Bahl, nephridia that open to the exterior are termed exonephric; those that communicate with the esophagus, esophageal; and those that open into the intestine: enteronephric.

Sephridial multiplication may affect the whole nephridium; e.g., *Tritogenia* has two, and *Perionyx (=Lampito) dubius* has five pairs of complete nephridia per segment. Alternatively, multiplication may affect only the funnel (fig. 21[C]) or only the tubule (fig. 21[D]). In transitional conditions nephridial multiplication tends to be suppressed at the posterior end, the exact opposite of setal multiplication. *Howascolex digaster* is holonephric behind the clitellum, meronephric anteriorly; and many meronephric genera retain one pair of large, open meganephridia (in addition to the numerous closed micronephridia) at the posterior end (fig. 21[B]). A highly evolved meronephric genus such as *Pheretima* has tufted pharyngeal nephridia, closed integumentary exonephridia and open septal enteronephridia.

Bahl showed that the function of an enteronephric system is conservation of water, which is resorbed by the gut from the hypotonic urine. Exonephridia may communicate with longitudinal ducts that run in the body wall and open at the anus; among species having such a system *Allolobophora antipae* is holonephric, *Hoplochaetella bifoveata* meronephric. Nephridial physiology is discussed in the *Introduction*.

12. Nervous System.—The central nervous system consists of a bilobed brain or supra-esophageal ganglion, circumpharyngeal connectives and a ventral nerve cord. In Aeolosomatidae both the brain and ventral nerve cord remain united with the epidermis. Each segmental ganglion gives off nerves (Fig. 22[B]) that supply subepidermal and intermuscular nerve plexuses. The visceral nerve plexus is connected with the central nervous system anteriorly (fig. 22[A]) and also segmentally by augmentor and depressor reflex pathways. Giant fibres are of the multicellular type (fig. 22[C]). In *Lumbricus* the median giant fibre receives sensory messages chiefly from the anterior half of the body and transmits them posteriorly. The two lateral fibres are connected with each other at regular intervals and behave physiologically as a unit; their sensory field is chiefly posterior and they transmit messages forward to effector organs in the anterior part of the body.

13. Sense Organs.—Free nerve endings ramify among the epithelial cells. They probably respond to tactile stimuli and perhaps also to heat and pain. Epithelial sense organs resembling taste buds occur in the skin and also inside the mouth cavity; their appearance suggests that they are chemoreceptors. Certain Eudrilidne have encapsulated sense organs resembling Pacinian corpuscles (receptors of pressure in vertebrates). Naididae may have projecting sensory hairs, and the prostomial sensory pits of Aeolosomatidae are regarded as sense organs. Photoreceptor organs (fig. 3[C]) are special cells that contain a lenslike refractile body; in earthworms they are most abundant at the anterior and posterior ends; in some of the lower oligochaetes they are grouped to form eyespots.

Earthworms are very sensitive to vibrations but indifferent to sound waves; tubificids are said to respond to vibrations in the audible range of man. The chemical sense in oligochaetes is well developed and discrimination of acidity and alkalinity is more acute than in man; salt and quinine are distasteful, oxalic acid is attractive. The branding responds positively to manure water. Earthworms respond negatively to strong light but are attracted to weak illumination; they are insensitive to the red end of the spectrum. All oligochaetes are strongly thigmotactic (attracted to surfaces).

Earthworms are capable of learning; in a classical experiment R. M. Yerkes offered *Eisenia foetida* a T-shaped maze in which one path, with sandpaper, gave an electric shock; they soon learned to avoid the sandpaper path even when no electric shock was given. These investigations have since been confirmed and elaborated.

There are two sorts of locomotion in oligochaetes, peristaltic

and looping. The latter, found in comparatively few forms (Chaetogaster, Branchiobdellidae), is similar to the looping movements of leeches. The peristaltic movements of an earthworm are tactile reflexes initiated by contact of the ventral surface with the substratum; the movements occur equally well after decapitation but are abolished by removal of the ventral nerve cord. A wave of thinning passes backward, followed by a wave of thickening. The thickened region, braced by the setae, is at rest with respect to the ground and forms a sort of foot. As a result of this the next contraction of the circular muscles forces the parts of the body in front of the foot to move forward. The mouth is used as a holdfast sucker when an earthworm ascends a vertical surface.

14. **Reproduction and Development.**—Reproductive System—Oligochaetes are primarily hermaphroditic; secondary suppression of the male organs is correlated with parthenogenesis (see below). The gonads are normally restricted to a few segments; however, the testes of *Chaetogaster orientalis*, and both testes and ovaries of species of *Aeolosoma* are proliferated in many segments. This condition, reminiscent of that in polychaetes, is probably secondary. The testes are situated in front of the ovaries. Backward extension of testicular tissue into the seminal vesicles (see below) of the lumbricid *Agriodrillus* may indicate the mode of origin of the postovarian testes of leeches.

Lower oligochaetes have one pair of testes and one pair of ovaries, in successive segments (fig. 23[A]), and the families may be related to each other by segmental (homeotic) displacement of the genital organs (fig. 25). Earthworms appear to be descended from a form in which the position of the gonads was stabilized but metamericly repeated. Haplotaxidae exhibit an

ancestral type, with two pairs of testes in segments 10 and 11 (holandry) and two pairs of ovaries in segments 12 and 13 (hologyny). Either the posterior or anterior pair of testes may be suppressed (proandry, metandry), and the majority of earthworms retain only the posterior pair of ovaries (metagyny). The acanthodriline *Diplocardia sandersi* is hologynous.

Developing clusters of sperm (sperm morulae) are frequently stored in septal pouches known as seminal vesicles or sperm sacs. The testes, together with the male funnels, may be enclosed in testis sacs that communicate with the seminal vesicles. In Aeolosomatidae male ducts are absent and the nephridia are thought to transport the spermatozoa. In other oligochaetes the sperm duct is provided with a fluted, convoluted funnel, iridescent in mature forms because of the optical effect of the tails of the innumerable spermatozoa that cling to its surface.

Except in the families of the group Lumbriculina, the sperm duct penetrates the septum to which the funnel is attached and the male pore is one (lower oligochaetes) or more (earthworms) segments behind the last pair of testes. Sometimes the external opening of the male duct is enlarged to form a muscular atrium, and there may be an eversible penis.

Euprostates, glandular enlargements or diverticula of the atrium, occur in Moniligastridae and Eudrilidae. Megascolecid prostates are of different origin; primitive members of the family have two pairs of tubular glands on the segments in front of and behind the male pores respectively (acanthodriline arrangement) (fig. 23[Ba]). Either the posterior or the anterior pair may be suppressed (microscolecine and balantine reduction respectively). The union of male and prostatic ducts (megascolecine condition) could represent the culmination of either microscolecine or balantine evolution (fig. 23[Bb]). Tubular prostates are replaced by branching racemose glands in the subfamily Megascolecinae.

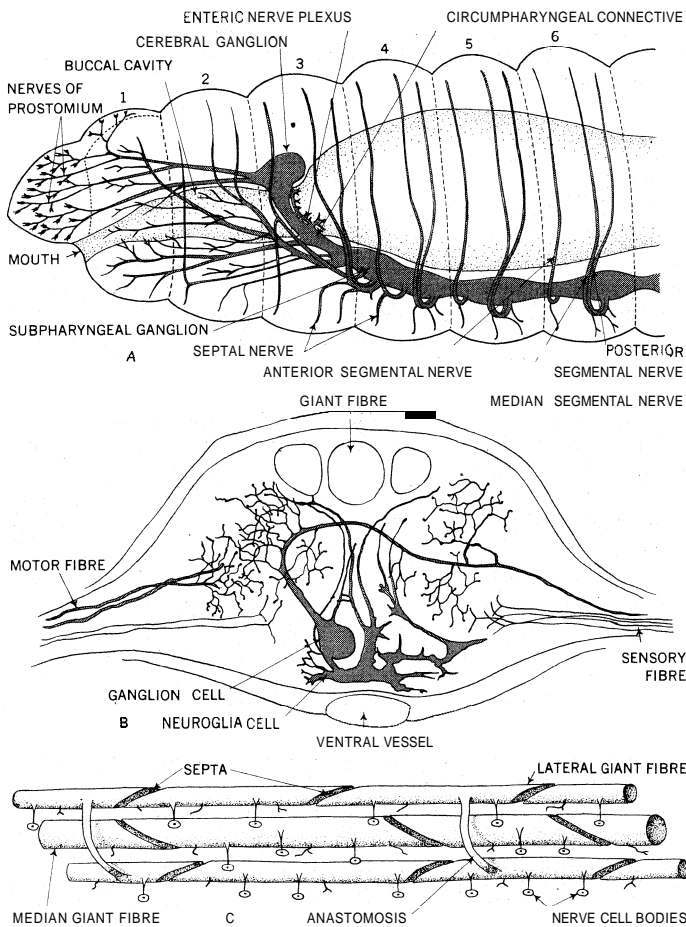

The female organs are usually simple. Septal outpouchings known as ovisacs, well developed in the lower oligochaetes, are very small in earthworms. The oviduct, like the typical sperm duct, perforates the septum to which the funnel is attached and the oviducal pore is on the segment immediately following that of the gonad. In Aeolosomatidae the oviduct is degenerate.

Spermathecae, varying in position, number and form, are pouches into which the spermatozoa are received during copulation. They are rarely absent and frequently possess an elaborate structure. In Enchytraeidae and a few Lumbriculidae they may communicate with the esophagus by an internal opening. The greatest elaboration of the female organs is found in Eudrilidae, in which the spermathecae communicate with a closed ovarian system (fig. 23[C]).

Sexual Reproduction.—Copulation is reciprocal and takes place in a head-to-tail position, the two ventral surfaces in contact. In lower oligochaetes there is a direct apposition of male and spermathecal pores, and the spermatozoa, often enclosed in packets called spermatophores, are injected into the receptacles (fig. 23[D]). This procedure is retained, in principle, in Megascolecidae and Eudrilidae. In Glossoscolecidae and Lumbricidae sperm transference takes place in the clitellar region, remote from the male pores, and the spermatozoa are carried along external grooves (fig. 18[C]).

The clitellum secretes the egg capsule and, in earthworms, albuminous material for nourishment of the embryos. Eggs are passed into the cocoon, which is then slipped forward and receives the spermatozoa as it passes the spermathecal openings (fig. 24[A]).

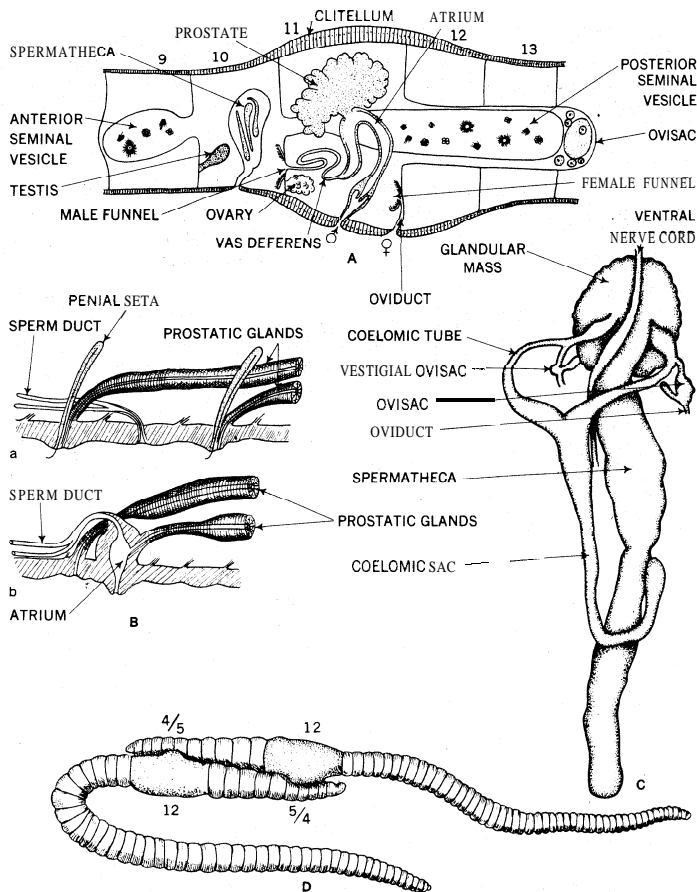

Parthenogenesis.—In many genera individuals isolated from others of their kind lay self-fertilized eggs that are capable of development. The phenomenon, first observed by L. Cernovitov in *Tubifex*, has been discovered in a number of families, including earthworms. Self-copulation can occur in lower oligochaetes with intromittent penes, as shown by K. Gavrillov for *Limnodrilus inversus*. In other cases, in which the testis segments contain ripe spermatozoa, a process of internal fertilization has been suggested; migratory oocytes of a uniparental race of *Eukerria saltensis* are either fertilized in the seminal vesicles or, more probably, chemically stimulated to undergo parthenogenetic development.

 schematic representation of giant fibre system in *Lumbricus*

Parthenogenesis in earthworms may be facultative or obligatory; in the latter case ripe spermatozoa are lacking, so any form of self-fertilization is excluded. The phenomenon is correlated with polyploidy (multiple sets of chromosomes) and is accompanied by

progressive stages of degeneration of the male reproductive organs, (well illustrated by polymorphic variants of *Pheretima* described by G. E. Gates). Attempts by F. André to obtain parthenogenetic development of eggs of an obligatorily cross-fertilizing species (*Eisenia foetida*), after removal of the testes, resulted in non-viable embryos, some having single (haploid) and others double (diploid) sets of chromosomes.

Asexual Reproduction.—Members of the group *Naidina* normally reproduce by paratomy, miscalled budding (fig. 17[B] and 17[C]); sexual reproduction is exceptional. In paratomy chains are formed by the development of new individuals while the older ones are still united. In a few forms asexual reproduction is by fragmentation (architomy) (fig. 17[E]). Architomy is the usual method of reproduction in *Lumbriculus variegatus* and the only method in *Enchytraeus fragmentosus* (which lacks sex organs). Asexual fission is related to the general capacity to replace lost parts (see *Introduction: Regeneration*).

Embryology.—The cocoons are ovoid and drawn out at the ends: they vary with the size of the worm. The cocoon of the giant Gippsland earthworm, *Megascolides australis*, may be two inches in length. The eggs of lower oligochaetes are yolky and contain sufficient nourishment for the growth of the embryo; in earthworms nourishment is supplied by an albuminous secretion of the clitellum. Development takes place entirely within the

cocoon and there is no free-living larval stage.

Segmentation of the ovum is interpreted as a highly modified form of spiral cleavage (fig. 24[B]). In addition to the mesoteloblasts there are three or four pairs of ectoteloblasts (fig. 24[E]), representing the somatic plate of the typical polychaete embryo. All investigators agree that the pair of ectoteloblasts nearest the midventral line are neuroblasts. Most agree that the ectodermal germ bands give rise to the circular musculature and setal sacs, but there is a divergence of opinion regarding the origin of the nephridia.

Proponents of Goodrich's theory of nephridial homology (see *Introduction*) agree with F. Vejdovsky that the nephridia are derived wholly from ectoteloblasts. Others follow R. S. Bergh in deriving the nephridia from the mesoderm. However this may be, newer investigations appear to indicate that each nephridium or, in meronephric species, each segmental nephridial cord arises from a single cell, the nephroblast; the view propounded by E. B. Wilson, that the funnel is mesodermal and the tubule ectodermal, has not received support.

A Penners showed experimentally that an embryo of *Tubifex* lacking ectoteloblasts may regenerate the missing tissues from the mesoderm, but in the absence of mesoteloblasts there is no regeneration of the mesoderm. Mesoderm is necessary moreover for the harmonic organization of the embryo; in its absence nervous and other ectoteloblastic tissues may differentiate, but they are not organized and no somites are developed.

Embryos of earthworms begin to ingest albumin at a very early stage. They are frequently provided with excretory osmoregulators (fig. 24[C]) derived from blastomeres that play no further part in morphogenesis. P. G. Svetlov found that regulators are necessary because the fluid inside the cocoon is isosmotic with the soil solution and hypotonic to the embryo plasma; regulators are absent in *Eisenia foetida*, which maintains a high intracapsular osmotic pressure.

B. ECOLOGY

1. Zoogeography.—The small aquatic species are widely distributed and subject to ecological rather than geographical limitations. Terrestrial forms, with the exception of a few wandering (peregrine) species of wide distribution, show a high degree of geographical limitation (endemicity). The land masses of the southern hemisphere possess a relict fauna (Phreodrilidae, Haplotaxidae, Acanthodrilinae). The northern temperate regions appear to be the home of Enchytraeidae, Lumbriculidae and Lumbricidae. The neotropical region is characterized especially by the Glossoscolecinae, the Ethiopian region by Onerodrilinae and Eudrilidae. The Megascolecinae reach their maximum development in the orient and Moniligastridae are endemic to this region.

2. Adaptation to Environment.—Adaptation of the respiratory pigments to oxygen deficient environments is discussed in the *Introduction*. Some lower oligochaetes resist drying by encystment, which can be induced in *Aeolosoma* by low temperature. Earthworms can withstand a considerable loss of body water; 48.5% of the body weight in *Pheretima hupeiensis*, 63.5% in *Allobophora caliginosa*. Drying stimulates some earthworms to enter into a period of sexual regression known as the diapause: they coil themselves in self-cemented earthen capsules and may become so dry as to be brittle. Regeneration in such species is restricted, unexpectedly, to the diapause. Earthworms are intolerant of high temperatures and are equally sensitive to extreme cold. W. C. Grant found that the upper lethal temperature (50% mortality after 24 hours) varies with the species and with prior temperature acclimation. In *Pheretima hupeiensis* adapted to 4° C. (39.2° F.) the upper lethal temperature is 19.4° C. (about 67° F.), whereas in those adapted to 22° C. (71.6° F.) it is 24.9° C. (about 77° F.). *Eisenia foetida* can withstand up to 26.3° C. (about 79° F.) when preadapted at 22° C. L. T. Hogben and R. L. Kirk found that worms can keep their bodies cool in a warm environment by constant evaporation of water from the skin. Soil relations and other aspects of earthworm biology are reviewed in the article EARTHWORM.

3. Parasites.—Oligochaetes are parasitized by gregarine Protozoa such as *Monocystis*, which live in the seminal vesicles; by nematodes such as *Pelodera* which are found in the nephridial vesicles; by fly larvae and by various other organisms.

C. CLASSIFICATION

W. B. Benham (1890) proposed two groups of oligochaetes: Microdrili (small species with short sperm ducts, a single-layered clitellum and large ovisacs) and Megadrili (earthnorms). The distinction is a convenient but inadequate one. The system of family groupings suggested by W. Michaelsen appears more nearly to reflect natural relationships among the oligochaetes and is adopted, in an abridged form, in this article.

Group 1: *Naidina*.—These are minute fresh-water species reproducing mostly by asexual fission. Setae are usually in fanlike bundles, and the excretory organs are micronephrostomal.

Aelosomatidae have few segments and are characterized by coloured droplets in the skin; supposedly primitive characters, resembling those of Archiannelida, are: a ciliated prostomium; ciliated prostomial pits; a dorsal blood vessel restricted to the anterior third of the body; multiple production of germ cells in many segments; and nephridia thought to function as male ducts. Michaelsen regarded this family as ancestral, but J. Stephenson argued that these apparently primitive features resulted from secondary simplification, degeneration or the persistence of larval characters.

Naididae are less peculiar; they possess one pair of testes and one pair of ovaries, usually in segments 5 and 6; the male pores are one segment behind the testes; spermathecae are located in the region of the genital segments. Homeotic displacement of the gonads in *Opistocysta* (testes in segment 7, ovaries in 8) offers a transition between Naididae and Tubificidae (see below). An endoparasitic naid *Schmardiella* is found in the ureters of tree toads (*Hyla* species); A. Lutz described its maturation to a free-living form with anal gills.

Group 2: *Tubificina*.—These forms resemble naids but are larger. The gonads are usually located in segments 10 and 11. Tubificidae frequently inhabit tubes in the bottom of lakes and streams; their projecting tails serve to permit anal respiration.

Phreodrilidae have the testes in segment 11 and the ovaries in 12.

Group 3: *Enchytraeina*.—Enchytraeidae are small opaque white or reddish worms with simple setae. The gonads, usually in segments 11 and 12, may be displaced forward; spermathecae are anterior, in segment 5. Many species are terrestrial, and they form an important component of the soil fauna; others are aquatic fresh-water or littoral marine species. Many aberrant forms are included in this family: *Aspidodrilus*, ectoparasitic on west African earthworms, has a flat body and ventral suckerlike holdfast organ; *Pelmatodrilus*, a parasite of Jamaican earthworms, is somewhat similar; *Parergodrilus*, still regarded by some as an archiannelid, has only 13 segments; the ovaries and testes are fused into a single hermaphroditic gonad.

Group 4: *Lumbriculina*.—Setae, when present, are simple; the male pore is in the same segment as the testes or, when more than one pair of testes are present, in the same segment as the last pair; the excretory organs are mesonephrostomal, or the funnel may be absent (*Acanthobdella*).

Lumbriculidae are small or medium-sized mud-dwelling species in which the number and arrangement of the gonads and spermathecae are highly variable but, typically, there are two pairs of testes. For this reason Michaelsen regarded Lumbriculidae as ancestral to earthworms, and Stephenson suggested that all oligochaetes might be derived from them. Against this theory is their geographical distribution (northern hemisphere) and also the unusual position of the male pores in relation to the testis segments.

Branchiobdellidae are ectoparasitic on the gills of fresh-water crayfishes. In these worms setae are lacking; the body is divided into a head region, probably of four somites, and a trunk of 11; there is a posterior sucker.

Acanthobdellidae are leechlike; the total number of somites is 30 instead of 34 as in true leeches. Setae are present on five

anterior segments; there is a well-developed coelom; and the reproductive organs resemble those of oligochaetes rather than leeches. The only known species, *Acanthobdella peledina*, is ectoparasitic on fishes of the salmon family.

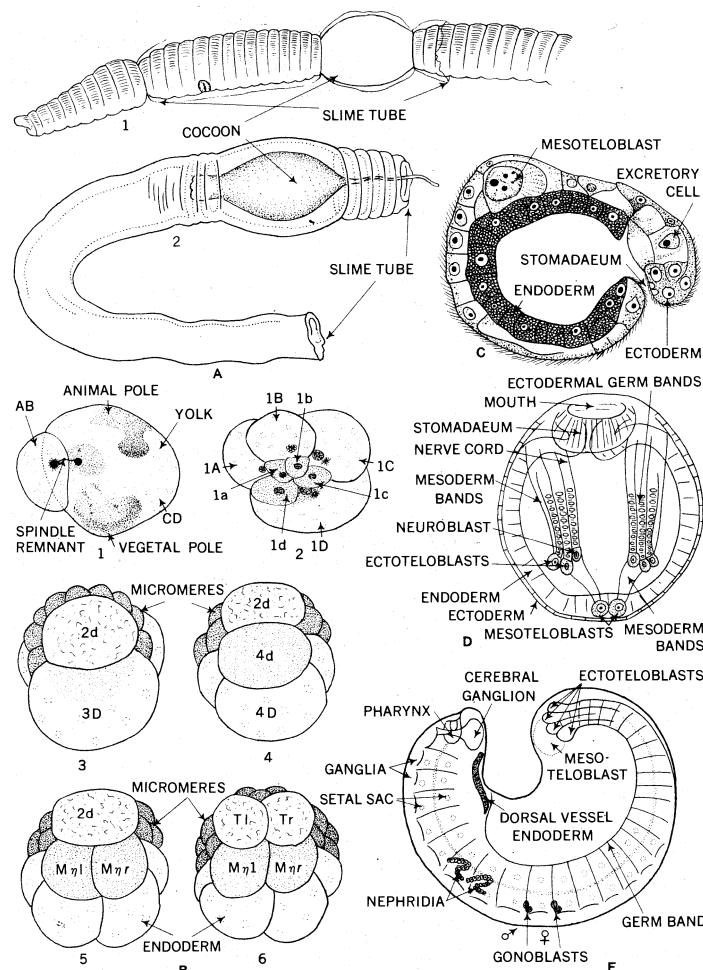

Group 5: *Haplotaxina*.—Haplotaxidae are in many respects transitional between lower oligochaetes and true earthworms; there is an esophageal gizzard, and the nephridia are meganephrostomal. Some species are holandric and hologynous (two pairs of testes and two pairs of ovaries); the male pores are one segment behind the corresponding pair of testes. The clitellum consists of a single cell layer and the eggs are yolky.

Moniligastridae, with a moniliform (beadlike) series of pre-intestinal gizzards, are larger forms with many anatomical peculiarities.

Aliuroididae and the closely related Syngenodrilidae appear to provide a connecting link between Haplotaxidae and true earthworms in view of the fact that the male ducts traverse more than one segment before they open on the body surface.

Group 6: *Megascolecina*.—This group comprises earthworms in which the male pores are usually on segment 18, immediately behind the clitellum, but may be segmentally displaced. Prostatic glands are normally present adjacent to or associated with the male pores.

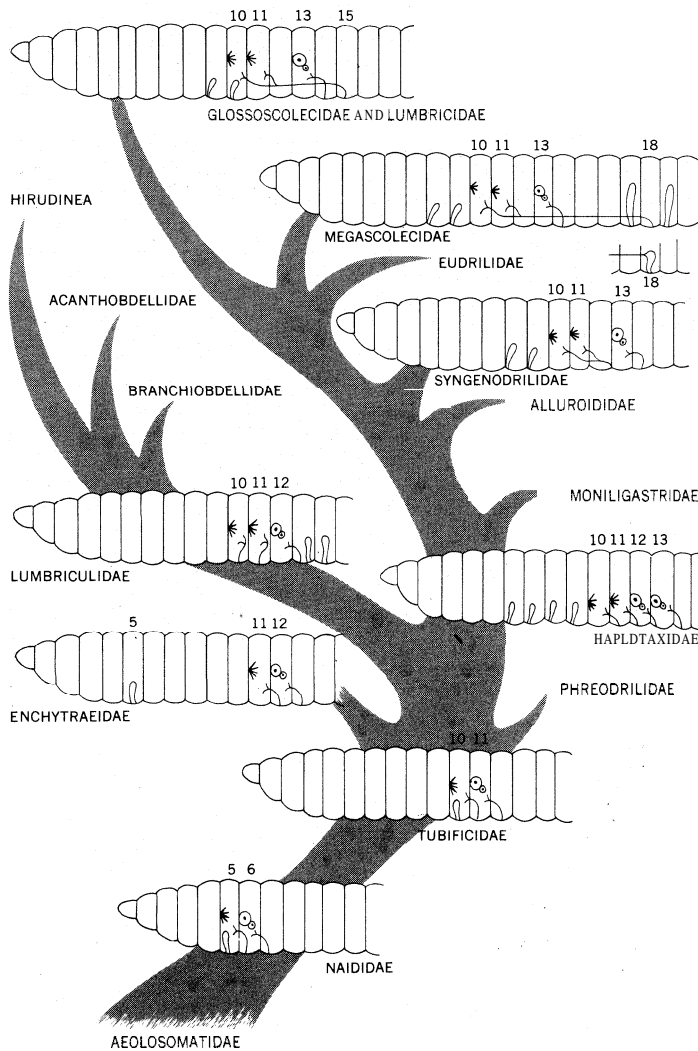

Nearly half of the known species of oligochaetes belong to the

FIG. 25.—PHYLOGENY OF THE OLIGOCHAETA

The families Aeolosomatidae and Naididae, here shown at the roots of the family tree, are more probably secondarily simplified (see text).

family Megascolecidae. Ancestral megascolecids (subfamily Acanthodrilinae) are characterized by acanthodriline genitalia, subject to microscopically reduced or megascolecine reduction; tubular prostates; and, in more primitive genera, absence of calciferous glands. Octochaetinae are meronephric acanthodrilines, but the subfamily is probably polyphyletic (derived by convergent evolution from more than one ancestral type). Ocerodrilinae are holonephric, but differ from Acanthodrilinae in having only two pairs of hearts and a more anterior intestinal origin; ventral calciferous glands are usually present in segments 9 and/or 10. Megascolecinae comprise species with racemose prostates; they may be holonephric or meronephric. Parallel evolution has so obscured the relationships of the genera that the true status of a megascolecid species may be difficult to assess.

Eudrilidae possess euprostates and show a remarkable specialization of the female reproductive organs.

Group 7: Lumbricina.—Prostatic glands, so characteristic of the Megascolecina, are usually absent; some genera, however, possess complex intromittent organs. A trend toward specialization of the method of sperm transference during copulation, best known in the family Lumbricidae, appears to have resulted in a high degree of variability of the accessory genitalia.

Glossoscolecidae, with five subfamilies, retain a pregenital esophageal gizzard; sometimes the gizzard is segmentally repeated in successive segments, often it is lacking. Many members attain a large size; *Hormogaster* is the largest European earthworm.

Lumbricidae appear to have originated from glossoscolecoid ancestors by the development of a pre-intestinal, postgenital giz-

zard; the clitellum is behind the male pores, which are usually on segment 15.

The presumed interrelationships of the families of Oligochaeta are shown in fig. 25.

IV. CLASS HIRUDINEA

The Hirudinea are the leeches, distinguished from the other segmented worms by the following characteristics: a sucker or suckerlike depression at the anterior end of the body and a well-developed sucker at the posterior end, a constant number of body segments, no setae or true parapodia (although some species have gills)! a hermaphroditic reproductive system and a body cavity largely filled with soft tissue.

Among the various families of leeches the Glossiphoniidae are found in fresh water and feed upon amphibians, fish, snails, turtles and water fowl; Piscicolidae occur in both salt and fresh water and feed upon crustaceans, fishes and turtles; Hirudidae are found in fresh water and subsist upon the blood of mammals, including man; the Haemadipsidae, the true land leeches, also feed upon mammalian blood; and the Erpobdellidae, which includes the fresh-water wormlike leeches and the jawless land leeches, are carnivorous and voracious, swallowing various kinds of crustaceans, insect larvae, snails and worms. Some of the erpobdellids are true burrowers.

A. STRUCTURE AND FUNCTION

1. External Features.—Leeches vary in length from less than

$\frac{1}{2}$ in. to about 17 in. and in form are elongate, egg-shaped or leaflike, the length and shape of the body varying considerably with the degree of individual contraction. Differences in body shape are noticeable among the members of different families. Because leeches have no caudal growth, the number of segments being fixed at 34, increase in length results from the subdivision and elongation of the rings (annuli) into which the segments are divided. The number of annuli per segment in the mid-body region is typical for any given species, three and five being commonest; but the number of annuli comprising the anterior and posterior segments is reduced. Small retractile, whitish clusters of sensory cells (sensillae), are arranged transversely on the annuli circling the nerve ganglia (see below). Eyes, which are modified sensillae, commonly vary from one to five pairs, placed anteriorly (some species have more than five pairs). The clitellar region extends from segment X through XII and contains the male and female genital openings. Because of its lighter colouring the clitellum contrasts sharply with the adjacent darker regions during periods of sexual activity. The clitellar secretions produce the cocoon.

2. Body Wall.—The skin of leeches consists of two layers of cells: (1) the epidermis, consisting of a single layer of epithelium covered by a cuticle, and (2) the dermis, consisting of fibrous connective tissue. The underlying musculature of the body wall is powerfully developed, consisting of an outer circular layer, intermediate crossed diagonals and an inner, much thicker longitudinal layer. Also there are dorsoventral and transverse muscles in the body cavity and special muscles of the suckers, alimentary canal, nervous system, circulatory organs and genitals.

3. Body Cavity.—The coelom—so spacious in other annelids—is largely replaced by muscles and the encroachment of connective tissues; it is reduced to a system of small spaces, the whole constituting the lymphatic system. Organs, connected by capillaries, often lie in the coelom. In the Glossiphoniidae there are five main longitudinal canals or lacunae with intermediate or connecting channels and fine hypodermal capillaries situated in the periphery of the body in the dermal connective tissue; the hypodermal capillaries assist in respiration. Many Piscicolidae possess contractile lateral lacunae and/or special pulsatile vesicles, which assist in the circulation of coelomic fluid. In the Arhynchobdellae the coelom is still further reduced and much of it is taken over by the vascular system; it is also invaded by the so-called botryoidal tissue of pigmented and vacuolated cells largely excretory in function.

Somites indicated by Roman numerals, annuli by Arabic ones. Position of gonopores on ventral side shown by the symbols ♂ (male) and ♀ (female)

4. Nervous System.—The nervous system consists of a chain of 34 ganglia connected by a double nerve cord. The first 6 ganglia are aggregated to form the cephalic mass and the last 7 a similar posterior mass, the remaining 21 (7 through 27) being segmentally spaced between them.

5. Digestive System.—The alimentary canal can be divided into the following regions. oral chamber, buccal sinus, pharynx, esophagus, stomach, intestine, rec-

FIG 27 — CHARACTERISTIC FORMS OF LEECHES

tum and anus. The oral chamber is the cavity of the oral sucker, into which the mouth opens and is connected with the buccal sinus. In arhynchobdellid leeches the buccal sinus is a restricted chamber housing the jaws (when present), and in the Rhynchobdellae a space around the pharynx, which is thereby freed as a protrusible proboscis. Salivary glands secreting substances having both antiseptic and anticoagulant properties open either on the jaws or proboscis of blood-consuming leeches. The esophagus connects the pharynx with the stomach, which in predaceous leeches is tubular and simply chambered, without pouches (caeca) or with only a posterior pair. In the bloodsucking leeches the stomach becomes a spacious crop with lateral, paired caeca for the storage of an amount of dehydrated blood sufficient, perhaps, to nourish the animal for a year or more. A muscular sphincter separates the storage stomach from the intestine, the principal digestive and absorptive region. The intestine, usually a straight, more or less chambered tube may in some species bear four paired caeca laterally. A simple rectum leads to the dorsally situated anus.

6. Vascular System.—A separate vascular system, containing colourless blood, is present in the Rhynchobdellae and consists of a dorsal and a ventral vessel connected at the extremities by paired loops. Anteriorly a portion of the dorsal vessel is contractile and functions as a heart. Farther back the dorsal vessel is continuous with a blood sinus surrounding the gut, the peristaltic contractions of which force the blood anteriorly. In the arhynchobdellids the capillary network is exceedingly rich and is formed in part by botryoidal tissue. On the transverse connecting vessels of many Erpobdellidae are paired contractile sacs serving as hearts. The blood consists of plasma and amoebocytes. In the Rhynchobdellae the blood is colourless and contains only relatively few amoebocytes; in the Arhynchobdellae it consists of the same elements, but the plasma is red as a result of the presence of dissolved hemoglobin.

7. Excretory System.—The nephridia are paired, metameric convoluted tubules formed of tubular cells that are placed end-to-end like a drainpipe. The tubules, often highly branched, originate internally as a ciliated and often much lobed funnel that opens within a lacuna; in some cases the origin may be a blind end with no opening internally. Externally a nephridium opens through a vesicle, the opening of which is on the ventrolateral surface. The number of nephridia varies with the species from 10 to 17 pairs, the latter number being the most frequent.

8. Reproduction and Development.—In all leeches the internal sexual organs are paired, but the terminal parts and external genital openings are single. In the male system the testes, enclosed in coelomic sacs, are multiple, usually in segmental pairs. On each side of the body a small sperm duct from each testis enters a larger duct that becomes enlarged and often much convoluted anteriorly to form a seminal vesicle or epididymis. Each of the two epididymides leads to a muscular, often bulbous ejaculatory duct, which opens into the median terminal organ or atrium, variously provided with glands. The female reproductive organs consist of a pair of elongated coelomic sacs, the ovisacs; these, which contain the true ovaries, unite anteriorly to form a common oviducal passage that opens to the exterior by the genital pore. In those forms in which fertilization occurs through copulation, this common passage serves as a vagina.

Reproduction in leeches is exclusively sexual. Fertilization

FROM HARDING AND MOORE, "HIRUDINEA," FAUNA OF BRITISH INDIA, BY COURTESY OF THE SECRETARY OF STATE FOR INDIA IN COUNCIL

FIG. 28.—INTERNAL ANATOMY OF TEN-EYED LEECH, DIAGRAMMATIC DISSECTION IN DORSAL VIEW. SOMITES INDICATED BY ROMAN NUMERALS

occurs in two different forms, depending upon whether or not a male copulatory organ is present. In the Rhynchobdellae and the Erpobdellidae sperm transfer is accomplished by spermatophores or sperm packets; these are implanted by one leech onto the body of another, in some groups on a localized area underlaid by a special sperm conducting tissue that readily disintegrates (histolyzes) when sperm is applied. Sperm, forced out of the spermatophores, penetrate the partially histolyzed tissues and enter the ovaries, resulting in fertilization. In the Hirudidae and the Haemadipsidae direct copulation occurs, the sperm being transmitted by the penis of one animal into the vagina of another. Eggs are usually deposited in cocoons, soon after fertilization. Cocoons may be borne by the parent animal, attached to a host (in parasitic species) or to a foreign object or deposited in damp earth. The number of eggs deposited in a cocoon varies from one to more than 100, depending upon the species. Development is direct, there being no larval stages.

B. IMPORTANCE TO MAN

The medicinal use of leeches dates from antiquity, having reached its peak in the first half of the 19th century in Europe. While the European *Hirudo medicinalis* was the species commonly employed, in Africa, Australia, India, Japan, Mexico and the United States, native species were also used. Since a satisfactory disinfection of the leech is impossible, occasionally septicemia developed from the wound, resulting in the death of the patient.

Aside from their medical use, which includes the hirudin extracted from the leech head and used as a blood anticoagulant, leeches have very little value to man. Their importance as food for fish and waterfowl is not great and this is usually offset by the damage they do to their hosts.

See the article LEECH for a discussion of the distribution,

the ecology and the economics of the class Hirudinea.

C. CLASSIFICATION

The class Hirudinea is commonly divided into two orders: the Rhynchobdellae, characterized by a muscular protrusible proboscis including the families Glossiphoniidae and Piscicolidae; and the Arhynchobdellae, which lack a proboscis, comprising the families Hirudidae, Haemadipsidae and Erpobdellidae. Some authors recognize three additional families, Americobdellidae, Semiscolecoideae and Xerobdellidae, to accommodate a few species that because of their secretive habits and localized distribution fit somewhat uncomfortably in the conventional arhynchobdellid families.

Autrum, "Hirudinea-Egel," *Handbuch der Zoologie*, Bd. 2, Lief. 17, Teil 8, pp. 119-352 (1932-34). (Ma. C. M.)

ANNEXATION, a formal act whereby a state proclaims its sovereignty over territory hitherto outside its domain. Unlike cession, where territory is given or sold by means of a treaty, annexation is a unilateral act made effective by actual possession and legitimized by general recognition.

Annexation is frequently preceded by conquest, a process by which a state ousts the existing government within a territory and places in authority its own military forces, thus setting up a condition of military occupation. Conceivably, as in the German conquest of Austria in 1938, this conquest may be accomplished by the threat of force without active hostilities. This military occupation does not *ipso facto* constitute annexation, nor will it necessarily lead to annexation. The military occupation of German territory by the United States, Great Britain, France and the Soviet Union after the cessation of hostilities in World War II was not in itself annexation, nor was it followed by annexation. To the contrary, the joint allied declaration of June 5, 1945, which announced the supreme authority of the occupying powers, expressly denied any intention to annex. For military occupation to eventuate in annexation an official announcement is necessary, to the effect that the sovereign authority of the annexing state has been established and will be maintained in the future.

Conquest and annexation may be limited to only a portion of the territory of a state but such acquisition is usually effected by cession by means of a treaty. An official announcement of annexation, before conquest has been completed, has long been deemed irregular and, according to the widely accepted Stimson doctrine of 1932, annexation following completed conquest should not be recognized if the conqueror has violated an antiwar obligation. The Italian annexation of Ethiopia in 1936, before conquest had been effected, was widely condemned and was not recognized by many states including the United States.

Conditions may exist which obviate the necessity for conquest prior to annexation. For instance, where a state already has a protectorate over a territory its authority there may be sufficient to sustain annexation. In 1910, as an example, Japan converted its protectorate of Korea into an annexed colony by means of proclamation. Preceding its annexation of the Svalbard Islands in 1925, Norway eliminated its competitors by means of a treaty in which they agreed to Norwegian possession. Annexation by the United States of Hawaii in 1898 was a peaceful act, based upon the willing acceptance by the Hawaiian government of C.S. authority.

The formalities of annexation are not defined by international law; whether it be done by one authority or another within a state is a matter of constitutional law. The annexation of Ethiopia was accomplished by a decree issued by the king of Italy on May 9, 1936. Joint resolutions of congress were the means by which the United States annexed Texas in 1845 and Hawaii in 1898. Subsequent recognition of annexation by other states may be explicit or implied. See CONQUEST.

ANNICERIS (? fl. late 4th century B.C.), Greek philosopher, probably lived under Ptolemy I of Egypt. He gave his name to a

sect of the Cyrenaics (*q.v.*), re-establishing the original doctrine in face of the innovations of Theodorus and of Hegesias. Against the former he emphasized that pleasure was to be found not only in sensual enjoyment but also in feelings of friendship, gratitude, patriotism, etc., apart from any benefits that they might secure. He also denied that to have understanding was adequate for a happy life, thinking that a habit must be formed before a man can feel no qualms in disregarding a false public opinion. Against the pessimist Hegesias he insisted on the value of positive pleasure as distinguished from the absence of pain. (F. H. SH.)

ANNISTON, a city of Alabama, U.S., 61 mi. N.E. of Birmingham, on the slope of Blue mountain, seat of Calhoun county. (For comparative population figures see table in ALABAMA: Population.) Anniston makes nearly a third of the U.S. cast-iron soil pipe supply, and produces textiles, apparel and chemical products. Founded in 1872 as a company town by the Woodstock Iron company, it was chartered as a city in 1879 and opened to the public in 1882. The (Protestant Episcopal) Church of St. Michael and All Angels and the Regar Museum of Natural History with its famous habitat bird groups are points of interest. Nearby Fort McClellan, a permanent post of the U.S. army, is headquarters for the women's army corps and the chemical corps training command. (J. A. TR.)

ANNO (HANNO), **SAINT** (c. 1010–1075), archbishop of Cologne, prominent in the political struggles of the Holy Roman empire, was born c. 1010 into a Swabian family and educated at Bamberg. He became confessor to the emperor Henry III, who appointed him archbishop of Cologne in 1056. Anno was the leader of the party that abducted the young king Henry IV from his mother Agnes. He then seized the regency, but was compelled to share it with Adalbert (*q.v.*), the powerful archbishop of Bremen. In 1064 he left the court but recovered some of his former influence on Henry when Adalbert fell in 1066. His most important service was his action at the Council of Mantua (May 1064), when he secured the recognition of Alexander II as pope against his rival Honorius, who was originally a nominee of the German court. He was killed at Cologne on Dec. 4, 1075, and canonized in 1183. His feast day is Dec. 4.

ANNOBÓN: see SPANISH GUINEA.

ANNONA, Roman personification of the grain supply, originally associated with Ceres. Her attributes in works of art and on imperial coins were a grain bushel, a ship's prow pointing to the transport of the grain over the sea, ears of grain and a horn of plenty (*cornu copiae*).

The Latin word itself has various meanings: (1) the produce of the year's harvest; (2) all means of subsistence, especially grain stored in the public granaries for provisioning the city; (3) the market price of commodities, especially grain; (4) a direct tax in kind, levied in republican times in several provinces, chiefly employed in imperial times for distribution among officials and the support of the soldiery.

In order to insure a supply of grain sufficient to enable it to be sold at a very low price, it was procured in large quantities from Umbria, Etruria and Sicily. Almost down to the time of the empire, the care of the grain supply formed part of the duties of the aediles (*q.v.*), and possibly of certain special commissaries. As a consequence of the second Punic War, Roman agriculture was at a standstill; accordingly, recourse was had to Sicily and Sardinia (the first two Roman provinces) in order to keep up the supply of grain; a tax of one-tenth was imposed on it, and its export to any country except Italy forbidden. The price at which the grain was sold was always moderate; the grain law of Gracchus (123 B.C.) made it absurdly low, and Clodius (58 B.C.) bestowed it gratuitously. The number of the recipients of this gift grew so enormously that both Caesar and Augustus were obliged to reduce it. From the time of Augustus to the end of the empire the number of those who were entitled to receive a monthly allowance of grain on presenting a ticket was 200,000. A *praefectus annonae* was appointed by Augustus to superintend the grain supply. He was assisted by a large staff in Rome and the provinces. In the 3rd century bread formed the dole. The office lasted until the latest times of the empire.

ANNONACEAE, the custard apple family, an important group of dicotyledonous plants (those having two seed leaves) allied to the magnolias (*q.v.*). The Annonaceae are chiefly tropical shrubs and trees and comprise about 80 genera and 820 species. The leaves are simple, entire and alternate; the flowers are regular, usually with three sepals and six petals, the latter brown or tawny yellow, not showy; the stamens numerous; and the fruit an aggregation of berries (syncarp) in which the seeds are embedded or dry or capsular. Many species are grown for their edible fruits, for perfume and for ornament. A few extend into temperate regions, as the North American paw-paw (*Asimina triloba*), found northward to New York and Michigan. Many valuable fruits belong to the genus *Annona*; among these are the cherimoya (*A. cherimola*) of the American tropics, now cultivated in the southern United States: the custard apple or bullock's-heart (*A. reticulata*), of tropical America; the sugar apple, sweetsop or ate (*A. squamosa*), cultivated throughout the tropics; the soursop or *guanábana* (*A. muricata*), widely grown in tropical lands; the *ilama* (*A. diversifolia*) of Mexico and Guatemala; the alligator apple, or corkwood (*A. glabra*), of tropical America and the *posh-té* (*A. scleroderma*) of Guatemala and Mexico. The *biribá* (*Rollinsia deliciosa*) and related species are highly esteemed fruits from Brazil to Central America. A tree (*Porcelia saffordiana*) of Bolivia, named and described in 1927, bears immense fruits sometimes attaining 40 lb. weight. The ylang-ylang (*Canarium odoratum*), native to the East Indies, is the source of the famous perfume of Malaysia and the Philippines. The exceedingly fragrant climbing ylang-ylang (*Artabotrys uncinatus*), native to India and China, is sparingly planted in southern Florida. See CHERIMOYA; CUSTARD APPLE; SWEETSOP.

ANNUITY, in the simplest sense of the word, denotes a payment made yearly, as, for example, under a contract to provide retirement income. The term is also applied to any series of periodic payments made at regular, fixed intervals. Thus, an annuity may be payable every two years, every year, every half-year, quarterly, monthly or at other intervals. The length of the interval is called the annuity period. The size of an annuity may be described by referring either to the amount of each payment or to the amount payable in a year, the latter amount being called the annual rent. For example, a particular annuity may be described as an annuity calling for payments of \$25 every quarter or a quarterly annuity with annual rent of \$100.

In technical terminology an annuity is said to be payable during a given status, this being a word equally appropriate when the annuity is payable for a definite term of years and when payment is dependent upon some contingency. The most general definition of an annuity is, therefore, a series of payments made at regular intervals during the continuance of a given status.

There are two main classes of annuities: annuities certain and contingent annuities. Under an annuity certain the payments are to continue for a specified number of payments, and calculations are based on the assumption that each payment is certain to be made when due. With a contingent annuity each payment is contingent on the continuance of a given status. The most common form of contingent annuity is a life annuity, under which each payment is contingent on the survival of one or more specified persons. The person to whom an annuity is payable is the annuitant and the life involved is the nominee. A person who purchases an annuity on his own life is both annuitant and nominee.

Annuities certain issued in Great Britain are normally for terms of from 10 to 25 years, but shorter or longer contracts are available. The annuity payments continue for the whole of the term of years arranged at the outset whether or not the annuitant survives that period. Only the interest content of each annuity payment is assessable for income tax, and owing to this favourable taxation basis annuities certain were, until 1956 (when the Finance act extended this taxation basis to ordinary "purchased" life annuities), largely used in conjunction with a deferred annuity, the payments under which were arranged to commence at the expiration of the annuity certain period.

A perpetuity is a special case of an annuity certain and is defined as an annuity that is to continue forever. Perhaps the best-

known example of a perpetuity would be the interest payments on British Consols (*q.v.*). Since these obligations of the government have no maturity date, it is intended that the interest payments will be continued indefinitely.

Definitions. — This section is devoted to definitions of some of the more common terms used to describe various types of annuities.

Under an annuity immediate the first payment is due one period after the date of the agreement.

Under an annuity due the first payment is due at the date of the agreement; *i.e.*, immediately.

Under a deferred annuity the first payment is due at some future time other than one period after the date of the agreement. If the first payment is due more than one period after the date of the agreement, the annuity can be described as either a deferred annuity due or a deferred annuity immediate. For example, an annuity with the first payment due in two years with payments due annually thereafter can be described as an annuity due deferred two years or as an annuity immediate deferred one year.

The words "immediate" and "due" may be unfortunate since an annuity due means an annuity under which the first payment is due immediately. There is, however, a reason for this seemingly odd choice of words. The reason is historical. A person was said to enter upon an annuity immediately if he received his first payment at the end of one year. The annuity was said to be deferred if the first payment was due later than at the end of one year. The concept of an annuity with the first payment due immediately was not important until the development of life insurance. Since life insurance premiums are paid in advance, the premium payments represent an annuity with the first payment due immediately. Thus the original terms were "annuity immediate" and "deferred annuity." When it became necessary to have a term to describe an annuity with the first payment due immediately, the word "immediate" was not available.

In Great Britain the first payment under a deferred annuity is made at the completion of the deferred term of years. For example, the first payment under an annuity deferred ten years would be made on the tenth anniversary of the inception of the annuity contract. A deferred annuity is usually purchased on an annual premium basis payable during the term of deferment, and a substantial volume of these contracts was effected after World War II in connection with occupational pension arrangements. An "approved" deferred annuity is one granted in accordance with provisions laid down in the Finance act of 1956, by which self-employed persons and others not entitled to benefit under schemes set up by their employers are enabled to obtain relief from income tax and surtax, on the whole of the premiums paid, so as to provide themselves with pensions on retirement. The annuity must be in "approved" form; it must, for instance, be noncommutable and nonassignable.

Unless otherwise stated, the first payment under an annuity in Great Britain is assumed to be made at the end of the first year in the case of yearly annuity and at the end of the first interval in the case of an annuity payable by half-yearly, quarterly or monthly installments.

Under a single life annuity each payment is contingent on the survival of a specified person.

Under a joint life annuity each payment is contingent on the survival of two or more specified persons.

Under a joint and survivor annuity payments are continued as long as any of the specified persons is alive. This type of annuity is a common option under pension plans, the specified lives usually being the pensioner and spouse.

Under a joint and two-thirds survivor annuity the full payment is made as long as both specified persons are alive with a two-thirds payment continued to the survivor after the first death. This type of annuity is a common option under pension plans, the theory being that living expenses for one person are about two-thirds as much as for two persons.

Under a whole life annuity (or straight life annuity) payments are made for the life of the specified person. The term "life annuity," without further qualification, almost always means a whole

life annuity on a single life. In addition, the absence of the word "joint" in any life annuity term almost always implies a single life.

Under a temporary life annuity each payment is contingent on the survival of a specified person and, in addition, the total payments are limited to some fixed number. Thus, in an annual 15-year temporary life annuity, no more than 15 payments will be made even if the person survives beyond the 15-year period.

Under an annuity for ten years certain and life thereafter payments for the first ten years are guaranteed and subsequent payments are contingent upon survival. The abbreviation "10cc" is frequently used in the United States for this annuity, the "cc" standing for certain and continuous. Although ten years is a common certain period, any other certain period is possible.

Under a refund annuity payments are continued for life with a guarantee that, in the event of death before total payments have amounted to the consideration paid for the annuity, payments will be continued until the total payments do amount to the consideration.

A cash-refund annuity in the United States is the same as a refund annuity except that any excess of consideration over total payments is paid in a lump sum at death rather than spread out over the regular payment intervals.

The general definition of a reversionary annuity is that payments depend on the existence of a particular status after the failure of another status. In the simple case of two persons, for example, there might be an agreement to make payments to B after the death of A. If B dies before A, no payments would be made. If a son is responsible for the support of a parent and wants to protect the parent against the son's early death, a reversionary annuity will provide this protection at comparatively small expense. Only a few life insurance companies, however, will issue this type of policy.

Although the original definition of a variable annuity was any annuity under which the payments varied in size, the term has come to have a more precise meaning: payments under a variable annuity vary as the market value of the fund varies. Since a variable annuity fund is invested in equities, the annuity payments vary with stock market quotations. The theory is that variations in the cost of living follow, in a general way, variations in the stock market, so that the variable annuity is a hedge against inflation.

The first large-scale use of variable annuities in the United States was made by the College Retirement Equities fund (C.R.E.F.), the companion organization to the Teachers Insurance and Annuity association (T.I.A.A.). Participation in T.I.A.A. and C.R.E.F. plans is limited to college and university staff members. C.R.E.F. commenced operations July 1, 1952.

Variable annuities were introduced into Great Britain in 1957. Only a few of the British life offices are interested in this type of annuity, for which there has been but little demand. Variable deferred annuities have inland revenue approval as a means of providing pensions "approved" under the Finance act of 1956. Under one such plan both the annuity and the premium that pays for it are expressed as a cash sum equal to the price of a stated number of trust units. According to another plan the benefits depend on the experience of a fund invested mainly in high-grade equities, created for the purpose and operated on a "mutual" basis, with the company taking such amounts as necessary to cover management expenses.

There has been considerable difference of opinion as to whether life insurance companies should issue variable annuities. The major argument in favour is, of course, that a retired person living on his annuity payments needs protection from inflation, that the variable annuity offers more protection than any other practical plan and that life insurance companies are the only organizations equipped, by knowledge and legal sanction, to issue annuities. Some of the arguments against life insurance companies issuing variable annuities to the general public are: (1) fear that the general public may not understand that payments can go down as well as up; (2) fear that increasing popularity of the variable annuity will result in pressures on the stock market and

be self-defeating; and (3) reluctance to abandon the fixed-dollar philosophy under which the life insurance business has prospered.

Calculations of Present Values.—Over the years, techniques have been developed and tables prepared to simplify the necessary calculations in connection with annuities certain and life annuities. Although a full discussion is necessarily beyond the scope of this article, this section will be devoted to a brief discussion of the computation of the present value of (1) an n -year annuity certain immediate; and (2) a whole life annuity immediate to a life aged x , the annual payment being one in both cases.

The symbol $a_{\overline{n}|}$ represents the present value of the n -year annuity certain immediate. This present value must be the sum of the present values of each of the n payments; that is, $a_{\overline{n}|} = v + v^2 + v^3 + \dots + v^n$ where v is the reciprocal of $1 + i$, i being the rate of interest. By using the formula for the sum of a geometric

$$\text{progression, we have } a_{\overline{n}|} = \frac{1 - v^n}{i}.$$

The symbol a_x represents the present value of the life annuity immediate. This present value is the sum of the present values of all possible payments. By reasoning that the present value of a particular payment is the present value, discounted at interest only, multiplied by the probability that the payment will be made,

$$\text{we have } a_x = v \frac{l_x + 1}{l_x} + v^2 \frac{l_x + 2}{l_x} + \dots \text{ where } l_x \text{ is the number of}$$

persons alive at age x according to the mortality table used. By multiplying numerator and denominator of each term by v^x and defining the commutation symbols $D_x = v^x l_x$ and $N_x = D_x + D_{x+1} + \dots$ (to the end of the mortality table), we have

$$a_x = \frac{N_{x+1}}{D_x}.$$

Mortality Tables.—Scientific observation has shown that variations in rates of mortality are attributable to certain well-defined causes. The methods adopted in compiling the information so obtained into tables of mortality have progressed from crude beginnings to a state closely approaching perfection. In its simplest form a mortality table purports to show the life history, or a portion of the life history, of a body of lives unaffected by any influence other than death; because such tables are a record of life history they are sometimes termed life tables.

Work on reversionary payments carried out by Richard Price, published in Great Britain in 1771 (fourth and best-known edition, 1783), contained the Northampton table—the first mortality table recognized and adopted as a basis for the purpose of calculations of life assurance. In 1808, when British government annuities were first established, the annuity tables used were computed upon the Northampton table. However, a fallacy in their method of construction, together with the fact that the table was intended to be conservative for life insurance, resulted in annuities being granted at prices much below their value and the country sustained a loss of about £2,000,000 before the error was rectified. The reason the Northampton table was conservative for life insurance was that mortality according to the table was heavier than that actually experienced. Thus the death claims actually experienced were less than those contemplated in the premiums, the difference being a source of margin to the company.

In the case of annuities the reverse is true. If the table shows mortality heavier than that experienced, the annuity payments will be greater than contemplated in the premiums and the issuing company (or government) will lose money. In short, a mortality table is conservative for insurance if the mortality rates are heavy but it is conservative for annuities if the rates are light.

There were four investigations into the mortality of persons who had purchased annuities from the British government. The period under observation extended from 1808 to 1875. The first investigation was made by John Finlaison and resulted in a new scheme being introduced in 1829. The mortality tables adopted were those constructed by Finlaison from an observation up to the end of 1822 of the duration of the lives of annuitants. Two main facts emerged from this investigation and have been confirmed

by subsequent experience: (1) annuitants as a class are remarkable for their longevity; and (2) the vitality of females is appreciably superior to that of males, so that separate mortality tables must be prepared for each sex. Further investigations were conducted by A. G. Finlaison and A. J. Finlaison, the son and the grandson of John Finlaison.

The effect of "selection" on annuitants' mortality was first taken into account by A. J. Finlaison when actuary to the National Debt office. He investigated the annuities granted by the national debt commissioners from 1808 to 1875. An annuity is not likely to be purchased on the life of a person thought to be in poor health and, as a result, the mortality experienced for several years after the date of purchase is likely to be lighter than that of the general body of annuitants of the same age. Finlaison found that the effects of selection were discernible for four years following the date of purchase and he recommended that revised tables based on the resulting select rates of mortality should be adopted. There followed many well-known mortality tables, the Carlisle table, the English Life tables, the Seventeen Offices' table, the Institute of Actuaries tables and the British Offices' tables.

Following an investigation of annuitant mortality experienced by British life offices during the years 1900–20, it was recommended that selection after the first year be ignored and that annuity values be based not on the rates of mortality derived directly from the observed experience but on these rates modified to allow for progressive future improvement in longevity. These recommendations were adopted and resulted in the publication in 1925 of the $a(m)$ and $a(f)$ tables. These tables gave only projected rates of mortality and annuity values derived from them. After the 1900–20 investigations, mortality experience was kept under continuous observation and, following a break during World War II, a further investigation was commenced in 1949 by the Institute and Faculty of Actuaries, which resulted in the $a(55j)$ tables for annuitants being published in 1953. These tables, which have been generally adopted, were compiled from data supplied by the life offices and make allowance for the future reduction in mortality.

A mortality table, partly based upon the experience of assured lives in the Mutual Life Insurance Company of New York and partly on previous tables, was compiled by a U.S. actuary, Shepard Homans, and published in 1868. It was subsequently employed by all New York companies and, with the Seventeen Offices' table, became the standard adopted by a large number of U.S. companies. The experience upon which the elaborate Thirty American Offices' tables were constructed, under the superintendence of Levi W. Meech, was, up to the time of its publication in 1881, the largest ever published. It extended over a period of 30 years to the end of 1874.

Until 1899, when McClintock's Annuity table was published, annuity values in the United States were based largely on British experience. In 1920 Arthur Hunter prepared a table based on the experience of 20 of the principal U.S. companies under annuities issued in the United States. Called the American Annuitants' Mortality table, it was used with various modifications as a basis for premiums by U.S. companies until 1938. The Combined Annuity Mortality table published in 1928 and the 1937 Standard Annuity Mortality table published in 1938 were both based on the American Annuitants' Mortality table, with allowances for decreases in mortality.

In 1919 Wilmer A. Jenkins and Edward A. Lew, in a paper before the Society of Actuaries, made an important contribution to the study of mortality among annuitants. In addition to preparing the annuity table for 1949, which was designed to reflect mortality experience in that year, they also gave projection factors to provide for probable decreases in future mortality rates.

An outstanding feature of the annuity business in the United States has been the rapid development of group annuities since the early 1930s. A typical group annuity contract covers employees of a common employer under one master contract and provides annuity payments beginning at retirement. After 1938 most companies based their premiums for group annuities on the 1937 Standard Annuity Mortality table, or a modification; but by the

middle 1950s many companies had shifted to the Group Annuity table for 1951, which was prepared by Ray M. Peterson and published in 1952. By the early 1960s various modifications of the 1951 table reflecting changes in mortality rates were in common use. See also DEATH RATE; LIFE EXPECTANCY; LIFE INSURANCE; PENSIONS; SOCIAL SECURITY.

ANNULMENT, in marriage law, signifies a judicial declaration that a marriage was null and void *ab initio* ("from the beginning"), as distinguished from divorce, the legal act by which a valid marriage is dissolved.

In the view of Christianity marriage is indissoluble, either completely, as under the doctrine of the Roman Catholic Church, or at least on principle, so that during the joint lifetime of both spouses it can be dissolved only, as in the Eastern Church, for adultery or, as in the Lutheran or Reformed view, only for adultery or other misconduct of the gravest kind. However, in order to be indissoluble the marriage must be valid. A situation may outwardly appear to be a marriage and yet not constitute a marriage within the meaning of the law of the church or the state. Rules meticulously indicating what does and what does not constitute a marriage were elaborated by the theological and legal scholars of the medieval church, in whose canon law they became crystallized. In postmedieval developments the rules were modified in many respects in the laws of the various churches and, even more, in the secular legislation of modern states. But in the ecclesiastical law of all Christian churches, as well as in all those secular laws in which marriage is treated as not freely dissoluble, the distinction between valid and invalid marriages is still of significance. In the Christian view the essential element of marriage is the free will of both parties to take each other as husband and wife; *i.e.*, to create a relationship of lasting and full community of life within which the procreation of children is permissible without sin and in which the parties have mutual and exclusive rights to their bodies. Where such mutual consent is absent, no marriage can exist. Since under the view developed by the church the procreation of children is an essential element of marriage, impotency to perform the marital act, but not impotency to procreate children, is also regarded as preventing the conclusion of a valid marriage. To these requirements the Roman Catholic Church, most Protestant churches and the secular laws of all western countries (with the sole exception of, as of 1958, 17 states of the United States) have added the further requirement of a ceremony to be conducted in accordance with the law of the church or state in question. Further requirements for the validity of a marriage have been added by the policies of churches and states to prohibit certain marriages as religiously or socially undesirable—for instance, marriages between a brother and his sister or between other persons closely related by blood.

However, not all prohibited marriages are necessarily invalid. In their rules about impediments to marriage the canonists developed a distinction between two groups of obstacles. Some impediments were regarded as so grave that their existence would not only subject the guilty parties to punishment but would also render the attempted marriage null and void. Other prohibitions were to be observed in the sense that no priest should officiate in their celebration and that the celebration knowingly concluded in spite of them would subject the guilty party to punishment. But the marriage, although it should not have been concluded, would be valid nevertheless. Impediments of the former, more serious character were called *impedimenta matrimonii dirimentia*, those of

the latter *impedimenta matrimonii impediencia*. The distinction is still significant in modern canon law as well as in the secular laws, especially of England, Scotland, the commonwealth countries and the United States. Under all these laws a marriage between a brother and his sister is not only both prohibited and punishable if the parties knew of their blood relationship but is also null and void even if the parties were ignorant of their blood relationship. But a marriage concluded without the parties' first having obtained a medical certificate, though punishable in a considerable number of states of the United States, is nevertheless valid.

Positive law determines not only which violations shall render a marriage invalid, and whether a particular kind of a ceremony shall be necessary for the conclusion of a valid marriage, but also what exactly constitutes that free exchange of mutual consent without which the conclusion of a valid marriage is not possible. The religious and secular laws vary greatly in this respect. The fact, for instance, that the marital consent of one party was induced by his or her mistake about a personal characteristic of the other party does not render that consent invalid under the law of the Roman Catholic Church, as laid down in the *Codex iuris canonici* of 1917, or of the secular laws of England or Illinois, while it is regarded as sufficient to allow an annulment under the laws of New York or of Germany if it is of so serious a nature that it would have prevented a reasonable person acting under the circumstances from entering upon the marriage in question. Ignorance of the other party's suffering from incurable cancer is thus irrelevant under the first-named laws, while it may be relevant under the latter.

Under the canon law a marriage is either valid or invalid. If it is valid, it has all its legal effects; if it is invalid, it has none at all. However, if there exists the outward appearance of a marriage the relation is presumed to be that of a valid marriage, and as long as both parties are alive neither of them nor any third person may deny its existence or derive any benefits from its invalidity. Neither party, *e.g.*, may remarry a third person. This presumption of validity is removed only when the invalidity of the marriage has been authoritatively declared by a court, and such a judgment of nullity is to be rendered only in proceedings specially instituted and conducted for the purpose of ascertaining the validity or invalidity of a marriage that has come to be questioned. Such a nullity suit may be instituted either by one of the parties or by a special official, the promoter of justice (*promotor iustitiae*), who is under a duty to do so where the continuance of an apparent marriage would amount to a scandal, for instance because of incest or bigamy.

In the secular laws of the Anglo-American countries these rules have been modified so that the validity of a relationship appearing to be a marriage may be attacked collaterally, a procedure allowed only under certain circumstances in the canon law after one of the parties to the relationship has died. Under these laws the question of the validity of a marriage may thus be raised and decided in any proceedings in which it appears to be relevant; *e.g.*, in those concerning the distribution of the estate of a decedent. If a relative of the decedent alleges that his marriage was invalid and that the person claiming to be his widow is therefore not entitled to a share in the estate, a decision may be rendered by the probate court in the course of the administration of the estate. Direct attack, *i.e.*, proceedings directly aimed at declaring the invalidity of a marriage, is also possible, but in Anglo-American law such an action, called a nullity suit, can be brought about only if one party to the marriage relationship is the petitioner and the other the respondent. If H, for instance, discovers that at the time of the celebration of his marriage to W there was still living a prior spouse of hers from whom no valid divorce had been obtained, H may simply leave W and enter upon a new marriage with another woman. However, he will do so at his risk. Some court may later hold a different opinion about W's freedom to marry H and, consequently, about the validity or invalidity of H's marriage to W and of his new marriage to his second wife. If a court should find that H's second marriage was bigamous, he may be punishable for bigamy, the children of his second marriage may be illegitimate, and upon his death his second wife may find

herself to be without any rights to a pension or to survivor's benefits under social security. If H wishes to act safely he should bring, before remarrying, a nullity suit against W. If in that suit his marriage to W is declared null and void, he can remarry without running the risk of his new marriage being held bigamous and invalid.

Under canon law a marriage is either valid or void; *i.e.*, invalid. However, certain cases came to be treated in such a special way that they appeared to constitute a third category, *viz.*, that of the voidable marriage. It was seen that under canon law the invalidity of a marriage could not be raised by anyone until it had been authoritatively declared in a judgment of nullity, and that the proceedings to obtain such a decree could be instituted only by one of the two parties to the marriage in question or by the promoter of justice. However, in certain situations the power to institute nullity proceedings is reserved to one of the two parties to the marriage, to the exclusion of the other and of the promoter of justice. These are the cases in which only one party's consent was not given freely, especially those in which the consent was brought about by coercion or by fraud of so serious a nature as to deprive the consent of its legal effectiveness. To let the party who has worked the coercion or fraud benefit from his own wrong and allow him to free himself of the marriage if it turns out to be disappointing would be unjust. Besides, the party coerced or defrauded may nevertheless desire to uphold the marriage. In such cases the power to initiate a suit for nullity is reserved to the party whose freedom the law seeks to protect. It is his decision whether or not he wishes the court to render that decree, without which no one may treat the marriage as invalid. In addition, if he desires such a decree he must act speedily upon the termination of the coercive situation or the discovery of the fraud. If he does not act at that time he is regarded as having ratified the marriage and neither he nor anyone else can at any time contest the validity of the marriage.

To these cases of coercion and fraud the secular laws have added that of nonage. Nobody but the party who was below the proper age at the time of the conclusion of the marriage can initiate the proceedings to have it declared void. Decrees rendered in proceedings initiated by the only party empowered to initiate them are frequently called decrees of annulment. In secular law, especially that of England but to some extent also in that of the United States, voidable marriages, being subject to annulment, have come to be clearly distinguished from void marriages, subject to be declared null and void by a decree of nullity or to be held void upon collateral attack. A decree of annulment is still similar to a decree of nullity in that it has retroactive effect. Once it is rendered or, more precisely, once it has become effective, the marriage is treated as if it had never existed. It also resembles, however, a decree of divorce in that the marriage must be treated as valid until it is annulled. In many respects annulment has thus been assimilated to divorce. Since annulment blots out the marriage retroactively, it seems that there is no place for any claims for maintenance or alimony. Worst of all, the children of the relationship are illegitimate. These harsh results have in most jurisdictions been removed by legislation or by judicial practice, and this tendency has come to make itself felt not only in cases of annulment but also of nullity.

In English law the Matrimonial Causes act, 1950, re-enacting the relevant provisions of the Matrimonial Causes act, 1938, sets out a number of additional grounds on which a marriage shall be voidable. These are: (1) that the marriage has not been consummated owing to the willful refusal of the respondent to consummate the marriage; (2) that either party to the marriage was at the time of the marriage of unsound mind or mentally defective, or subject to recurrent fits of insanity or epilepsy; (3) that the respondent was at the time of the marriage suffering from venereal disease in a communicable form; or (4) that the respondent was at the time of the marriage pregnant by some person other than the petitioner. These grounds are subject to certain provisos, namely: (a) that the petitioner was at the time of the marriage ignorant of the facts alleged; (b) that proceedings were instituted within a year from the date of the marriage; and (c) that

marital intercourse with the consent of the petitioner has not taken place since the discovery by the petitioner of the existence of the grounds for a decree. See also DIVORCE; MARRIAGE.

Frank, supplement (1938); W. T. Nelson, *Divorce and Annulment*, 3 vol., 2nd ed. (1945–58). (M. RN.)

ANNUNCIATION, the announcement made by the angel Gabriel to the Virgin Mary of the incarnation of Christ (Luke i, 26–38). The feast of the Annunciation in the Christian church is celebrated on March 25 (Lady day). The first authentic allusions to the feast (apart from the Gelasian and Gregorian sacramentaries, in both of which it is mentioned) are in acts of the council of Toledo (656) and of the Trullan council (692).

ANNUNZIO, GABRIELE D': see D'ANNUNZIO, GABRIELE.

ANOA, a diminutive dark-brown buffalo confined to dense, mature forests of Celebes Island. It weighs about 600 lb. and measures about 40 in. at the shoulder. The straight, sharp-tipped horns are about 15 in. long. Its scientific name is *Anoa depressicornis*. Cultivation restricts the anoa to the island's protective interior. A mountain variety, measuring only 30 in. in height, is the smallest of all buffalo. Anoa are shy but vicious when harassed. A closely related species, *Anoa mindorensis*, occurs in the Philippine Islands. (H. K. B.)

ANODE, a positive electrode, the terminal from which electrons leave an electrolyte, electron tube, or any direct current load and return to the battery or other energy source. See BATTERY; ELECTROCHEMISTRY; see also Index references under "Anode" in the Index volume.

ANODYNE, anything that relieves pain. The term is commonly applied to medicines that lessen the sensibility of the brain or nervous system, such as morphia, etc.

ANOINTING, the ritual application of oil or fat. Like baptism (*q.v.*), the process of anointing is very nearly universal in the history of religion, although both the cultic practice followed and the sacred substance employed vary from one religion to another. It is possible to recognize three distinct, though not separate, meanings ascribed to ritual anointings by the devotees of various religions.

1. Anointing as healing. The medicine man of a tribe may be both its priest and its physician; "salvation" literally means "healing" or restoration to soundness. In the practice of ritual anointing this conjunction of religion and medicine is clear. Anointing seems intended to apply the power of natural and supernatural forces to the sick and thus to ward off the baneful influences of diseases and of demons.

2. Anointing as consecration. In preparation for battle, in danger from wild animals, in the hour of death (see EXTREME UNCTION) and at other special times anointing is used to endow an ordinary person with special holiness. He is "set aside" for a particular relation to that which is regarded as holy and good (see also CONFIRMATION). Anointing as consecration is frequently applied not only to persons but to objects as well. Altars, sacred vessels and temples, sometimes even weapons and items of clothing, are anointed to dedicate them to the service of the divine and to assure and symbolize the presence and pleasure of the divine in the holy place (see also CONSECRATION).

3. Anointing as ordination. Over and above the consecration applied to ordinary men, anointing has a place in the particular rituals by which certain men receive positions of eminence. In many religions priests are inducted into their sacred office with a holy chrism (see CHRISM). In ancient Israel and in various Christian cultures, the king was anointed in the rite of coronation (*q.v.*) as the one chosen of God to rule over the people.

See F. W. Puller, *The Anointing of the Sick in Scripture and Tradition* (1904). (J. J. PS.)

ANOMALY, a deviation from a regular, usual or expected pattern of action or result. As originally used in astronomy, anomaly described the nonuniform (anomalous) apparent motions of celestial bodies. In modern astronomical usage, the true

anomaly is the angle between the radii drawn from the sun to a planet and to the perihelion point (the point in orbit closest to the sun). The mean anomaly is the angle between the radii drawn from the sun to the perihelion and to a point moving in the orbit at a uniform rate corresponding to the period of revolution of the planet. The eccentric anomaly is the eccentric angle defined in elementary conics.

(R. L. DE.)

ANOMOEANS (from Gr. *anomoios*, "unlike"), a religious sect of the 4th century, representing an extreme form of Arianism (*q.v.*). Arianism held that the essential difference between God and Christ was that God had always existed while Christ was created by God. Aetius, the founder of the Anomoeans, reasoned that the doctrine carried to its logical conclusion must mean that God and Christ could not be alike. *Agennesia* ("innascibility," self-existence) being part of the essence of God, Christ could not be like God because he lacked this necessary quality. Aetius' chief convert and the second great leader of the Anomoeans was Eunomius, after whose death (c. 393) the sect soon became defunct.

ANONYMOUS AND PSEUDONYMOUS LITERATURE. Because much early literature was orally transmitted and was therefore remembered for its own sake, not the author's, the names of early poets and storytellers—if known at all—were often forgotten, so that traditional poetry (*e.g.*, *Beowulf*, the ballads, the Norse sagas, *q.v.*) is usually anonymous. However, since classical times some authors have deliberately hidden their identity by withholding their names or using assumed names.

The reasons for this are various. In political and religious controversy it may be unsafe or unwise to publish the writer's name. The *Marprelate Tracts* (1588–89) by the pseudonymous Martin Marprelate (*see* MARPRELATE CONTROVERSY), attacking the episcopacy in somewhat ribald fashion, resulted in the rack for the printers and hanging for the supposed author. The letters of Junius (*q.v.*), published in the *London Public Advertiser* (1769–72), attacking the government of the day, have been attributed to or claimed by some 50 authors.

When it was not considered respectable for women to be writers, the author's identity was often hidden under the titlonym "A Lady." Other women writers adopted masculine names; *e.g.*, George Eliot (Mary Anne Evans) and George Sand (Amandine Lucile Aurore Dudevant). Some authors writing in more than one kind of literature prefer to keep their literary careers separate by using pseudonyms: the detective-story writer "Nicholas Blake" is the poet C. Day Lewis. Others prefer to adopt pseudonyms in deference to their professional standing; *e.g.*, James Bridie (the Scottish physician, O. H. Mavor).

In the 16th and 17th centuries, the golden age of pseudonyms, most writers used one at some stage in their careers—one of the more bizarre examples was "Aceeffghhiillmmnoorrssstuu," an alphabetical anagram of the name Christoffel von Grimmelshausen. A more predictable later derivation is Mark Twain (Samuel Langhorne Clemens) from the call meaning "two fathoms deep" used on Mississippi river boats. Initials are sometimes derived from the author's name, *e.g.*, "A.E.H.," Housman's initials, while others are quite unconnected, *e.g.*, "Y.Y.," used by Robert Lynd.

In the 19th and 20th centuries Scots authors were said to use pseudonyms most, with Poles coming next. Voltaire (François Marie Arouet) used at least 137 pseudonyms and Benjamin Franklin 57.

ANOPHELES, a genus of mosquitoes, species of which are the only known vectors of malaria. A few *Anopheles* also transmit filariasis and encephalitis. *See* MOSQUITO; MALARIA.

ANOPLURA, an order of small, wingless insects comprising the sucking lice, having mouth parts modified for puncturing skin and sucking blood. Xnoplura are all ectoparasites (external parasites) on mammals, and some transmit diseases. *See* LOUSE.

ANORTHITE, a silicate of aluminum and calcium. Anorthite crystallizes in the triclinic system and has the chemical composition $\text{CaAl}_2\text{Si}_2\text{O}_8$. It is the calcium end member of the plagioclase series of feldspars (*see* FELDSPAR).

Pure anorthite is quite rare in nature, but is readily synthesized. The name is usually reserved for those solid solutions ranging in composition from pure anorthite to a mixture containing 10% of the albite (sodium) molecule. Such anorthite occurs in some gabbros and basalts, and also in contact metamorphosed limestones.

ANORTHOCLASE, the name given by the pioneer petrologist Karl (Harry) Rosenbusch in 1885 to include triclinic potash-soda feldspars that for reasons of symmetry should show cleavage angles different from 90° but which frequently do not show any measurable difference, although the deviation can be as high as about 4° (*see* FELDSPAR: *Unmixing at Low Temperature*).

The form development is variable! but the best-known crystals have a characteristic habit, giving rise to lozenge- or rhomb-shaped individuals. Anorthite is confined to alkaline igneous rocks; it appears in the larvikites and foyaitic rocks of Norway and Madagascar, as a prominent constituent of the rhomb-porphry lavas of Norway and of the alkaline lavas of the island of Pantelleria (southwest of Sicily) and in the kenyte lavas of Mt. Kenya (Kenya) and of Mt. Erebus (Antarctica).

It is customary to call anorthoclase those feldspars which have a composition between Or_4Ab_6 and $\text{Or}_1\text{Ab}_9 \pm$, an An content that may reach 20% (Or = KAlSi_3O_8 , Ab = $\text{NaAlSi}_3\text{O}_8$, An = $\text{CaAl}_2\text{Si}_2\text{O}_8$) and which show evidence of deviation from monoclinic to triclinic symmetry. Such evidence may be obtained by optical or X-ray methods. The optical evidence may be obscured by submicroscopical twinning produced by a displacive transformation whose temperature (lying between below 0° C. and approximately 1,000° C., *i.e.*, near the melting point) is a function of the potassium/sodium ratio and of the aluminum/silicon order-disorder distribution. The transformation temperature varies inversely as the potassium/sodium ratio and as the degree of aluminum/silicon disorder. In addition, anorthoclase is usually submicroscopically unmixed into potash-rich and sodium-rich domains and for this reason may exhibit a bluish schiller. According to the aluminum/silicon distribution within the structure and on the kind and coarseness of twinning and of unmixing, the optical properties vary considerably and cannot be considered to be significant for a definite phase. Usually, anorthoclase appears optically negative with $2V \approx 50^\circ$. (F. H. L.)

ANOSMIA is lack of the sense of smell. This deficiency may be due to nasal obstruction or to disease of the nerves concerned in smelling. It is sometimes a manifestation of hysteria. In the first category, the common cold in the head is the most usual cause. Other frequent causes are adenoids, deviated septum and inflammation of the nasal passages.

Of nervous diseases causing anosmia, brain tumours are the commonest. Any brain lesion must be on both sides of the cortex in order to completely obliterate the sense of smell. *See* also OLFACTORY SYSTEM; SMELL AND TASTE.

ANOUILH, JEAN (1910–), French playwright who emerged as one of the foremost figures of the French theatre after World War II and whose work achieved great popularity also in other European countries and in the United States, was born on June 23, 1910, at Bordeaux. Anouilh came to the theatre by way of the post of secretary to the actor-producer Louis Jouvet. His first play to be staged was *L'Hermine* (1932; Eng. trans., *The Ermine*, 1958). This inaugurated a long series of dramatic works (published, according to his own classification, as *Pièces noires*,

1942; *Pièces roses*, 1942; *Nouvelles Pièces noires*, 1947; *Pièces brillantes*, 1951; and *Pièces grinçantes*, 1956), of which the dominant theme is a desperate and hopeless quest for an absolute purity and integrity. Little known before 1944, when his *Antigone* (Eng. trans., 1946; ed. by W. M. Landers, 1954), taken first for a Vichyite play and later for a Resistance play, brought him success, he rapidly won international fame. He has been considered both as the last of the *avant-garde* dramatists of the 1930s and as the first of the post-1945 generation.

Though Anouilh owes much as a dramatist to Jean Giraudoux and Luigi Pirandello, the intellectual content of his work links him to Albert Camus and Jean-Paul Sartre, particularly to the negative aspects of their thought. An anarchist, but not a revolutionary, he struck a resounding note in the 1930s with his passionate indictment of social evils. But the indictment became less convincing each time it was repeated and the message to which the *Pièces noires* and *Pièces roses* had seemed to point was never given. Instead, Anouilh whittled down his heroes' stature, and in the *Pièces brillantes* and the *Pièces grinçantes* mocked at the purity and integrity for which his earlier heroes and heroines had striven in vain. Bitter criticism of human nature (in *Arddle*, 1948; *La Valse des Torkadors*, 1951, Eng. trans.; *The Waltz of the Toreadors*, 1956; and *Orniße*, 1955) replaced the social criticism of the *Pièces noires*—*L'Hermine*, *La Sauvage* (written, 1934), *Eurydice* (1941; Eng. trans., *Point of Departure*, 1951; U.S. title *Legend of Lovers*, 1952)—or the *Pièce rose*, *Le Rendez-vous de Senlis* (written 1937, performed 1941).

While his conception of the human predicament as pointless and absurd is made clear even in his first play, Anouilh did not formulate it explicitly until *Roméo et Jeannette* (1945; Eng. trans., 1958) in which he suggested that this life, pointless though it be, should nevertheless be accepted and lived, not renounced. He went further in *L'Alouette* (1953; Eng. trans., *The Lark*, 1955); here Jeanne d'Arc is proud of her achievements and loves mankind with all its failings. However, like his *Antigone*, his *sauvage* and other earlier heroes, she is not prepared to live a life of humiliating compromise. Fundamentally an escapist, Anouilh claimed the right to repudiate society (*Y'avait un prisonnier*, 1935), life itself (*Antigone*) or one's own past and personality (*Le Voyageur sans bagage*, 1937).

A brilliant technician: Anouilh has successfully attempted a variety of types of plays: serious dramas constructed with classical simplicity of form: comedy ballet (*Le Bal des voleurs*, written in 1932, Eng. trans. *Thieves' Carnival*, 1952) and comedies of plot enlivened by the mistaken identities of traditional comedy (*L'Invitation au château*, 1947, Eng. trans., *Ring Round the Moon*, 1950).

See *Hubert Gignoux, Jean Anouilh (1946)*. (D. Ks.)

ANOXIA: see HYPOXIA.

ANSA, in astronomy, one of the apparent ends of the rings of Saturn as seen in perspective from the Earth: so-called because, viewed through the earlier telescopes, they looked like handles projecting from the planet.

ANSBACH, a town of Germany which after partition of the nation following World War II was located in the *Land* of Bavaria of the Federal Republic of Germany. It lies 27 mi. S.W. of Nürnberg on the Rezat river, 1,509 ft. above sea level in beautiful forest land. Pop. (1959 est.) 32,754. The 12th-century Romanesque Protestant church of St. Gumbertus was restored in the baroque style. Raspar Hauser (*q.v.*) was killed in Ansbach and a museum dedicated to him is near the *Schloss* (castle). The latter, an 18th-century structure, was the palace of the margraves of Brandenburg-Ansbach and adjoining it is a public park with fine trees. Ansbach has metal, cardboard, leather and plastic industries. It was first mentioned about A.D. 750 and was a Hohenzollern residence from 1331 until 1791 when it became Prussian. In 1806 it passed to Bavaria. Queen Caroline, consort of George II of Great Britain, was born there in 1683. Today the town is the scene of the annual Bach music festival. (H. J. DA.)

ANSELM, SAINT (1033–1109), archbishop of Canterbury, theologian and first of the scholastic philosophers, is one of the most important thinkers between Augustine and Thomas Aquinas.

In philosophy he is considered the author of the ontological argument for the existence of God (see THEISM). He was born in Piedmont, at Aosta, a town of strategic importance in Roman and medieval times because it stood at the juncture of the Great and Little St. Bernard routes. Ermenberga, his mother, belonged to a noble Burgundian family of Aosta and possessed considerable property. Gondolfo, his father, was a Lombard nobleman, who destined his son for a career in politics and opposed Anselm's choice of the monastic life. Anselm received an excellent classical training and was considered one of the best Latinists of his day. His writings excel in clarity and the precise use of words. As a result perhaps of his intense study as a young man, he was plagued with ill-health in his later years.

In 1056 Anselm left Aosta to enter the Norman Benedictine monastery of Bec (situated between Rouen and Lisieux), because of the reputation of its prior, Lanfranc (*q.v.*). En route he learned that Lanfranc was in Rome, so he tarried at Lyons, Cluny and Avranches, before entering Bec in 1060; he took his monastic vows in 1061. His intellectual ability and solid piety brought his election as prior, when Lanfranc became abbot of Caen (1066). He became abbot of Bec in 1078.

Under Anselm, Bec became a centre of monastic learning. Though Lanfranc had been a great theologian, Anselm far excelled his master. During his abbotship he composed his *Monologion* and *Proslogion*. Through benefactions of William I the Conqueror, Bec received lands in Normandy and England. Anselm made three visitations of the abbey's English lands, and when founding the priory at Chester he was named archbishop of Canterbury (March 1093) by the tyrannous William II (William Rufus), who had succeeded his father. The king had kept the see vacant since the death of Lanfranc, had stolen its revenues and pillaged its lands.

With reluctance and prompted by a desire to reform the English church, Anselm accepted the new post. He refused consecration until William restored the Canterbury lands and acknowledged Urban II, then opposed by the antipope Clement III. William, in fear of death from an illness, agreed and Anselm was consecrated Dec. 4, 1093. On his recovery, however, William showed his insincerity. He demanded an excessive sum of money from the new archbishop, who refused to pay it lest it look like simony. William blocked Anselm when he sought to go to Rome for the pallium, the symbol of papal approval of his archiepiscopal appointment. The Conqueror had often interfered in the English church, but his son sought its complete domination. William refused to accept Urban II, lest his control be weakened. He forbade Anselm to receive the pallium, for this implied royal recognition of Urban. Anselm insisted that such recognition was an ecclesiastical, not a secular matter. After two years of dispute the English bishops at the synod of Rockingham (March 11, 1095) sided with the king and abandoned Anselm. When the papal legate brought the pallium from Rome, Anselm refused to accept it from William lest it appear that he owed his spiritual authority to the king. He took it from the altar and placed it on his own shoulders (1095). William ultimately allowed Anselm to leave for Rome, but on his departure seized the lands of Canterbury.

Anselm attended the council of Bari (1098) and presented to the pope his grievances against the king. He also took an active part in the sessions and defended the traditional doctrine of the *Filioque* against the Greeks. The Bari council reapproved the decrees against lay investiture. At the end of the year, Anselm withdrew to the village of Liberi, near Capua, and completed his *Cur Deus Homo*, prior to attending a council at the Lateran at Easter 1099.

On the murder of William Rufus (1100), his brother Henry seized the throne, as Henry I. To win ecclesiastical support, Henry summoned Anselm to England, where the archbishop became for a time one of his most loyal supporters. Anselm broke with the king, however, when Henry insisted on his right to invest prelates with the spiritual insignia of their office. Three times the king sought an exemption, but Rome refused. During the controversy, Anselm was in exile from April 1103 to Aug. 1106. The dispute was settled at the synod of Westminster (1107). The king renounced investiture of bishops and abbots with the ring and crosier, but demanded that they do homage to him prior to consecration. The

Westminster agreement was a model for the Concordat of Worms (1122), which settled for a time the lay investiture controversy. (See also *INVESTITURE*.)

Anselm spent his last two years in peace and died on April 21, 1109. In 1163, with new canons requiring papal approval for canonizations, Archbishop Thomas Becket referred his cause to Rome. Anselm was probably canonized at this time, for the Canterbury records of 1170 make frequent mention of the pilgrimages to his new shrine in the cathedral. For several centuries he was venerated locally. Clement XI extended his mass and office to the whole church in 1720, when he declared him a doctor of the church. His feast day is April 21.

The singular position of Anselm in theology and philosophy is based not only on his confidence in human reason to investigate even the divine mysteries but on his insight into the metaphysical and unitative character of being as a perfection. Though he often blends theology and philosophy, he is aware of the different principles underlying them. He betrays that hardy belief in the unity of truth which characterizes 12th- and 13th-century thought. He is a man of new ideas and new approaches.

Anselm's theory of knowledge is found in his *De Veritate* (1080), in which he shows that rectitude of thought and action arise from their agreement with the objective order of existence. Moral truth is the willing by the will of what-ought-to-be, but this is taught it by the mind. God is the supreme being and the supreme truth, and even reason puts man into contact with the whole order of being. Though Anselm holds that faith enlightens reason, the latter has its own principles of operation.

The *Monologion* (1077) was written at the request of certain monks of Bec; it is essentially a meditation by reason on the existence and the attributes of God. Nowhere in theology is there a more penetrating study of the divine attributes. Moving from an analysis of the inequalities of perfection, Anselm argues to the existence of an absolute norm by which the mind judges inequality. This norm is God, the absolute, ultimate, integrating standard of all perfection.

In the *Proslogion* or *Alloquium de Dei Existentia* (1078), Anselm attempts one all-inclusive proof for the existence of God. Chapters 2-3 give this ontological argument; the remaining 23 chapters treat the divine perfections. The essential significance of his proof lies in Anselm's discussion of being, which God possesses in its fullness. Even the fool has an idea of a being greater than which no other being can be conceived to exist. Such a being must really exist, for the very idea of such a being implies existence, otherwise it would not be an idea of a being greater than which no other being exists. The ontological argument is in the tradition of thinkers who hold that there must be some immediate idea of God in human experience.

Anselm was answered by Gaulino, a monk of Marmoutier, who denied in his *Liber pro Insuperante* that such an idea includes existence in the objective order. No direct intuition of God includes his existence. Anselm answered in his *Liber Apologeticus* that his argument is valid precisely because it deals with a necessary being. Bonaventura, John, Duns Scotus, Descartes, Malbranche, Leibniz and Hegel have defended the Anselmian argument; Thomas Aquinas and Kant refute it.

The *Cur Deus Homo* (1097-99) is the classic treatment of the Redemption. Sin was a formal affront to the divinity; man, as man, cannot make reparation. Nor is simple pardon adequate, for this does not change a man interiorly. The instrument of the Redemption must be the God-Man, by whose infinite merits man is purified in an act of co-operative re-creation. Anselm rejects the idea that man through sin owes a debt to the Devil, and puts the essence of the redemption for the individual in his union with Christ in the Eucharist, to which baptism opens the way. See also *SCHOLASTICISM*.

The best edition of Anselm's complete works is F. S. Schmitt's *Sancti Anselmi Opera Omnia* (1938-51), a definitive work with excellent notes. The best French translation is A. Rousseau, *Saint Anselme, Oeuvres philosophiques* (1947). In English, S. N. Deane's *Saint Anselm* (1935) contains the *Proslogion*, *Monologion*, *Liber pro Insuperante* of Gaulino and the *Liber Apologeticus*; the

Proslogion is also found in A. Pegis, *Wisdom of Catholicism* (1919). English selections are in R. McKeon, *Selections From Medieval Philosophers* (1929).

ANSELM OF LAON (ANSELME DE LAON) (d. 1117), French theologian, apparently studied at Bec under St. Anselm (*q.v.*) and like him became eminent in early scholasticism. In the final quarter of the 11th century Anselm of Laon taught with distinction at Paris, where with Guillaume de Champeaux he supported realism. Toward the close of the century, he returned to his native Laon, where his theological and exegetical school became famous. Peter Abelard came to Laon to continue his studies, and John of Salisbury referred to the late Anselm and his brother Rudolph as "those most brilliant lights of the Gauls." Anselm's *Interlinear Glosses*, a commentary on the entire Vulgate Bible, became a leading medieval authority. Some of his scriptural commentaries were ascribed to other writers, notably St. Anselm of Canterbury. His known works were published by J. P. Migne in *Patrologia Latina*, vol. clxii. (D. L. MCG.)

ANSELME (FATHER ANSELME OF THE VIRGIN MARY; originally PIERRE DE GUIBOURS) (1625-1694), French genealogist and friar, whose history of the French royal family and nobility is a valuable source of detailed and out-of-the-way information, was born in Paris in 1625. He entered the order of Barefooted Augustinian in 1644. His whole life was devoted to the study of genealogy. The first instalment of his most important work, *Histoire généalogique et chronologique de la maison royale de France, des pairs, grands officiers de la couronne et de la maison du roy: et des anciens barons du royaume*, appeared in 1674. After Pkre Anselme's death in Paris at the Couvent des Petits Peres, Jan. 17, 1694, the work was continued by Honoré Caille, seigneur du Fourny, who had encouraged its publication, and by two other Augustinian friars at the Couvent des Petits Pères, Père Ange de Sainte-Rosalie and Pkre Simplicien.

The third, and most complete edition (1726-33), consisted of nine folio volumes, and has remained a primary source, despite its inaccuracies! partly because its notes embody exact references to many original documents.

ANSERMET, ERNEST (1883-), Swiss conductor known for his authoritative interpretations of the works of Stravinsky and other 20th-century composers and for his keen intellectual approach to problems of contemporary musical aesthetics, was born at Vevey, Nov. 11, 1883. He studied at Lausanne and from 1906 to 1910 was professor of mathematics there. Later he studied music with A. Gédalge in Paris. He gained his experience as a conductor in Germany. About 1914 he met Stravinsky and in 1915 he became conductor of Diaghilev's Russian ballet. In 1918 he founded the Orchestre de la Suisse Romande in Geneva. He frequently toured Europe and the United States and introduced works by Stravinsky, Prokofiev, Hindemith and Bartok, as well as by the Swiss composers, Honegger and Frank Martin. He also recorded many orchestral works by French and Russian composers. His own works include a symphonic poem, settings of poems by Baudelaire and the orchestration of Debussy's *Épigraphes antiques*.

See E. Ansermet, *L'Expérience musicale et le monde d'aujourd'hui* (1948); *Hommage à Ernest Ansermet* (1943). (E. LR.)

ANSGAR (ANSKAR OF ANSCHAR), **SAINT** (801-865), Frank-

ish missionary, the first archbishop of Hamburg and the apostle of Scandinavia, was born in 801. He received training at Corbie in Picardy and taught in the monastic school at Corvey ("New Corbie") in Westphalia as a young man. When Harald, an exiled Danish king, appealed to the emperor Louis I for support and accepted Christianity, Ansgar was attached to him to assist him in spreading the faith in his dominions. Harald seems never again to have had power beyond the Danish borders, but under his protection Ansgar began missionary work in Schleswig from 826. In 829–831, hearing that King Björn was not unfavourable to Christianity, he transferred his activities to Sweden. In 832 Ansgar was consecrated archbishop of Hamburg, but in 848 his see was transferred to Bremen. His suggested field of activity was all the peoples of the north, but political conditions enforced limitation. Denmark, however, was now united under King Haarik (Horec) I, who allowed Ansgar's work in Schleswig to be renewed and a church to be built in the town of Schleswig. His successor Haarik II also approved of Ansgar's work. The mission in Sweden had been extinguished by the expulsion of Bishop Gautbert in 845, but Ansgar sent a hermit, Ardgar, to revive it in 851 and himself visited the Swedish mission in 853–854. He died at Bremen on Feb. 3, 865.

The Swedish mission founded by Ansgar seems to have died out after the time of his successor Rimbart, who nourished it assiduously. Christianity probably then existed only sporadically in Sweden till the mission of Odinkar (c. 975). In Schleswig, similarly, there is no evidence that the early mission had permanent results.

A work by Ansgar on the miracles of St. Willehad is extant. His own life is known in considerable detail from the biography by Rimbart, his successor in the see of Bremen. The tone of Rimbart's last chapters suggests that veneration of Ansgar as a saint began soon after his death. His feast is celebrated at various places on Feb. 3, on Feb. 4 or on Sept. 9.

See E. de Moreau, *Saint Anschaire* (1930). (AL. C.)

ANSHAN (ANZAN), an ancient city and country in southwestern Iran, closely associated with Elam (*q.v.*). Probably it was situated north of Elam, but its exact location is unknown. Anshan came into prominence about 2350 B.C. as an enemy of the Mesopotamian dynasty of Akkad. The third dynasty of Ur (c. 2130–2030 B.C.) sent merchants and expeditions to it. Its greatest days were in the 13th and 12th centuries when, as "kings of Anshan and Susa," Elamite rulers periodically raided Babylonian cities. A revived Elamite dynasty bore the same title in its contests with Assyria between 750 and 650, but about 675 B.C. the country appears to have come under the control of Achaemenid Persians, who bore the title "kings of Anshan" down to the accession of Darius I (522 B.C.). After this date, Anshan is virtually unknown to history. (G. G. CA.)

AN-SHAN, the industrial centre of Liaoning province in south Manchuria, 60 mi. S. of Mukden on the east side of the Manchurian plain. Pop. (1953) 548,900; (1957 est.) 805,000. Iron ores have been worked at An-shan since the 10th century, but the modern discovery was by the Japanese in 1909. The South Manchurian Railway company began steel production there in 1919 and steadily expanded its capacity. An-shan contributed large quantities of iron and steel to the Japanese war effort between 1940 and 1945. Soviet Russia stripped the installations after World War II, but the Chinese Communists had restored them by 1952. Continuous expansion occurred after 1952 and by 1956 An-shan was China's primary iron and steel producer. Much of the iron ore is of low grade and requires enrichment to working quality. Cement and refractory plants, coke ovens, blast furnaces, steel converters and mills for the production of rails, bars, sheets and seamless tubing make up the heart of the complex. (J. E. SR.)

ANSON, ADRIAN CONSTANTINE (1851–1922), U.S. baseball player and manager, known as "Cap" in his early days and "Pop" in his later ones, was an outstanding hitter in the 19th century with a lifetime batting average of .340. He was born in Marshalltown, Ia., on April 11, 1851. While playing with the Forest City team of Rockford, Ill., in the season of 1871, he came to the attention of the Philadelphia Athletics in the National

association, and from the 1872 through the 1875 season he caught, played first, second and third base, shortstop and in the outfield for that club. In 1876 when A. G. Spalding, star pitcher of the Boston team in the National association, was approached to become manager of the Chicago team, he in turn got Anson to join it as the team switched to the newly formed National league in the season of 1876. From 1876 through 1878 Anson was team captain, caught, played second and third base and in the outfield. In the 1879 season Anson became manager after Spalding's retirement and thereafter played only at first base, except that in both 1883 and 1884 he pitched but without record. He retired as a player after the 1897 season but was a nonplaying manager for the New York team in the National league in 1898. During his 27 seasons, the longest playing span of any major league baseball player, Anson won batting championships in 1879, 1881, 1887 and 1888; his 3,524 hits put him second only to Ty Cobb in number of hits made in a major league career. He threw and batted right handed. As a manager, Anson led the Chicago team to league pennants in 1880, 1881, 1882, 1885 and 1886. In 1888–89 he was part of the first baseball tour of the world, playing with his Chicago team against a team of other National league players. Anson was elected city clerk of Chicago in 1905 and served a two-year term. He died there on April 14, 1922. In 1939 he was elected to the Baseball Hall of Fame, the 17th player so honoured.

ANSON, GEORGE ANSON, BARON (1697–1762), British admiral, known from his reforms while a member of the board of admiralty as "father of the navy," was born on April 23, 1697. His mother was the sister-in-law of one lord chancellor (Lord Macclesfield) and his wife the daughter of another (Lord Hardwicke). He entered the navy in 1712 and became a captain at the age of 26. He is best known for his voyage around the world in the "Centurion" between 1740 and 1744. This voyage was inspired by the success of the privateer Woodes Rogers in 1704, but as a piece of naval strategy it was ill-conceived. The ships were badly equipped and manned, and out of the six that sailed, only the flagship returned. After a disastrous voyage around Cape Horn, Anson successfully raided the coast of Chile but nearly perished in crossing the Pacific, reaching Tinian Island just in time to save the health of his few remaining men. He then took the "Centurion" to Macao, whence he sailed to capture (1743) the Manila galleon "Nuestra Señora de Cobadonga," valued at £400,000. He sold the prize and cargo at Canton, the "Centurion" being the first British warship to enter Chinese waters. He returned to England with the specie payments on June 15, 1744. The voyage is a classical instance of the incidence of scurvy (*q.v.*): out of the 1,955 men who left England, 1,051 died, chiefly of scurvy. These losses inspired James Lind to discover the cure of lemon juice, which he published in *A Treatise on the Scurvy* (1753). The book was dedicated to Anson, who appointed Lind to the new naval hospital at Haslar in Hampshire.

In 1745 Anson was promoted to the board of admiralty, on which he sat, with only a brief interval, until his death in 1762. During this time he served twice at sea: in 1747, when by brilliant tactics he captured six out of the nine French warships escorting a convoy off Cape Finisterre, for which he was made Baron Anson, and again in 1758. His reforms at the admiralty included the classification of warships into six rates, distinguishing line-of-battle ships from the frigates of the fifth and sixth rates, which continued as long as the navy fought under sail, and the revision (1749) of the articles of war, which lasted with little change until the Naval Discipline act of 1865. Anson was instrumental in introducing a blue and white uniform for officers in 1748 and he created the permanent corps of marines under the direction of the admiralty in 1755. The increased efficiency of the navy in the Seven Years' War is mainly to be attributed to his administrative work, and, regarding strategy, he was largely responsible for the maintenance of a western squadron to blockade Brest, which was the key to British maritime success. He died during the war on June 6, 1762.

In society he was cold and reserved, so that he made as many enemies as he did friends. His character had little public appeal but his talents as an administrator and strategist were of the highest order, as Pitt recognized in a posthumous tribute: "To his

wisdom, to his experience and care the nation owes the glorious successes of the last war."

BIBLIOGRAPHY.—There are contemporary narratives of the voyage around the world by Pascoe Thomas (1745) and by Anson's chaplain, Richard Walter (1748). See also H. B. T. Somerville, *Commodore Anson's Voyage* (1934); Sir J. Barrow, *Life of George Lord Anson* (1839); W. V. Anson, *Life of Admiral Lord Anson* (1912); S. W. C. Pack, *Admiral Lord Anson* (1960). (C. C. ANSON, SIR WILLIAM REYNELL, BART. (1843–1914), English jurist and author of a noted study of the British constitution, was born in Walberton, Sussex, son of the second baronet. Educated at Eton and at Balliol college, Oxford, he became in 1874 Vinerian reader in English law at Oxford, a post which he held until he became in 1881 warden of All Souls college. He identified himself both with local and university interests, becoming an alderman of the city of Oxford (1892), chairman of quarter sessions for the county (1894), vice-chancellor of the university (1898–99) and chancellor of the diocese of Oxford (1899). In that year he was returned, without opposition, as M.P. for the university in the Liberal Unionist interests, and consequently resigned the vice-chancellorship.

In parliament he preserved an active interest in education, being a member of the newly created consultative committee of the board of education in 1900, and in 1902 he became parliamentary secretary. He took an active part in the foundation of a school of law at Oxford, and his volumes on *The Principles of the English Law of Contract* (1884) and on *The Law and Custom of the Constitution*, in two parts, "The Parliament" and "The Crown" (1886–92), are standard works, available in numerous revised editions.

ANSONIA, an industrial city of New Haven county, Conn., U.S., is situated on the Naugatuck river about 10 mi. N.W. of New Haven.

Originally a part of the township of Derby, Ansonia was incorporated as a separate township in 1889 and chartered as a city in 1893. It was actually settled, however, in 1843 when Anson Greene Phelps (1781–1853) of New York city refused to pay an exorbitant price for land in Derby and established a factory at Ansonia in which he manufactured copper and brass goods. The settlement was named in Phelps's honour. Heavy machinery was manufactured there as early as 1848. These two industries remained dominant, though numerous other metal products were also produced. Ansonia and the neighbouring cities of Derby and Shelton form one of the important industrial communities of the state. For comparative population figures see table in **CONNECTICUT: Population**. (R. Lo.)

ANSTEY, CHRISTOPHER (1724–1805), English poet whose poem *The New Bath Guide* went through more than 30 editions between 1766 and 1830, was born on Oct. 31, 1724, at Brinkley, Cambridgeshire, and educated at Eton and King's college, Cambridge. In 1754 Anstey succeeded to an independent income, in 1756 he married and in 1770 he settled permanently in Bath. *The New Bath Guide, or Memoirs of the B . . . r . . . d Family* (1766) is really a short epistolary novel in verse, the purpose of which is to satirize different aspects of Bath life. It is compounded from two sources: first, the type of versified caricature best known through poems like Swift's *The Lady's Dressing Room* (1732); and second, works like Goldsmith's *Citizen of the World* (1762) which use the ironic device of introducing an innocent countryman or foreigner to sophisticated pleasures. In the *Guide*, Simkin, a naïve countryman, is introduced to Bath and recounts his impressions in light anapaestic verse. Much of the poem's charm arises from Anstey's mastery of the difficult and somewhat repetitive anapaestic measure, but the element of parody, together with the simple caricature and occasional accurate delineation of scenes well known to 18th-century readers, helps to explain the poem's popularity. Anstey sustained his success with *An Election Ball in Poetical Letters From Mr. Inkle at Bath to Hir Wife at Gloucester* (1776). He died in Bath in 1805.

See M. S. Day, "Anstey and Anapaestic Satire in the Late Eighteenth Century" in *A Journal of English Literary History*, vol. xv (1948). (J. N. C.)

ANT. The ants are one of several groups of social insects

that belong to the order Hymenoptera.

General.—The more than 5,000 known species of ants, including the 600 species and subspecies in the U.S., are classified in seven subfamilies of the family Formicidae (see last section below).

The ancestors of the ants are believed to have been solitary, fossorial wasps. Nothing is known about the initial evolution of ants, for no fossils antedating the Early Tertiary period (about 70,000,000 years ago) have yet been found. By that time the ants had reached the evolutionary level that they occupy today. Some of the beautifully preserved Baltic amber ants (Oligocene, about 35,000,000 years ago) are so nearly identical with present-day forms that there is room for the view that the fossil and its living counterpart are specifically identical.

Ants are heat-loving insects and only a few of them can endure cold climates. It follows that the greatest diversity of genera and species is found in the tropics and that the representation steadily decreases with an increase in distance north or south from the tropics. The number of ants in arctic or alpine regions is extremely low, and the group appears to be absent over great areas north of the Arctic circle.

The habits of ants vary endlessly, and it has been suggested that this may be partly due to their method of handling their larvae. Unlike the bees and the social wasps, ants do not enclose their larvae in individual cells. This gives them a flexibility in dealing with both larvae and nest that the other two groups lack. In extreme cases there will be no fixed nest, as in the Dorylinae, who carry the larvae with them during the nomadic phase. Despite their ability to utilize all sorts of nest sites most ants nest in the ground. Thus the majority of them still follow the pattern of their fossorial ancestors, who dug a burrow in the soil, provisioned it and laid their eggs therein.

Similarities and Differences.—It is difficult to give criteria by which any ant can be recognized because of the marked caste differences they show. In most ant colonies three castes (male, female and worker) are present, but in many of them the worker caste is polymorphic and has produced subcastes (major, medium, minor) that can be strikingly dissimilar. This structural diversity is often so great that it is impossible to associate the several castes of a species unless they are taken together in the nest.

Stages of Development.—All castes pass through the same stages of development: the egg hatches into a grublike larva; the larva, after a period of growth, changes into a pupa, and the pupa transforms into an adult. The structural differences that distinguish the castes first appear in the pupal stage, but other significant differences exist from the time the egg is laid. The eggs that develop into males are unfertilized, hence they contain only half as many chromosomes as does a fertilized egg; the characteristics of the male are determined by the chromosomal condition of the egg from which it develops. All fertilized eggs contain a double set of chromosomes, and all such eggs develop into females. The females are of two sorts: some are capable of mating, others are not. The queen, who can mate, is ordinarily winged at maturity. The worker, who cannot mate, never has wings and its simplified thorax is very different from that of the winged queen. Flight plays a large part in the mating reactions of most queen ants, but the lack of it does not explain the inability of the worker to mate. There are a number of ants in which the queen is wingless and has a worker type of thorax. These flightless queens can mate because they have a sac, the seminal receptacle, in which sperm cells are stored during copulation. In the worker this sac is vestigial or absent, hence the worker cannot store sperm. Although the worker cannot produce fertilized eggs it is not a sterile female, for it has functional ovaries and can lay unfertilized eggs that develop into males. But it is unable to lay fertilized eggs, which is the principal function of the queen. Each colony produces males and potential queens at certain times each year, usually in warm weather.

Establishing a Colony.—If a potential queen is to lay fertilized eggs, she must be inseminated, and, since most queens are winged, this ordinarily leads to a complicated set of responses known as the marriage flight. The virgin queen mates with a single male, who also is winged, and the two take off coupled together.

FIG. 1.— EIGHT CASTES OF HARVESTER ANT (*PHÉIDOLE TEPICANA* PERGANDE)
(A) soldier; (B-E) intermediate workers; (F) typical worker; (G) male;
(H) queen after loss of wings

During their flight the male transfers to the seminal receptacle of the queen all the sperm cells she will have for the rest of her life. Observations on queens in artificial nests have shown that this supply of sperm cells can last for at least 15 years. Since the only function of the male is to inseminate the queen, he is discarded at the end of the marriage flight and promptly dies. This leaves nest-founding entirely to the queen. Each of the many potential queens that becomes fertilized is capable of setting up (or taking over) a nest of her own, provided she survives. The primary objective of the newly fertilized queen is to find a spot where she can safely raise her brood, although this is by no means all that is involved in nest-founding. Ants rarely move their nests after the colony has been established, hence a satisfactory nest site must not only provide immediate protection for the queen but also must later meet the requirements of the developing colony. When these requirements are exacting, the response of the female must be exact. Thus the queen of an arboreal species that can survive only in trees must seek out this environment at the time of nest-founding. It may, therefore, be said that the distribution and the environmental relationships of any species of ant represent the selective effect of the environment on the nest-founding responses of the female during the course of the species' evolution.

Soon after the marriage flight the queen's wings fall off or she pulls them off. The bulky wing muscles then begin to degenerate and are slowly converted into salivary secretions. At this time the queen's ovaries become functional and egg-laying begins. Later these eggs hatch into larvae, which must be fed. In primitive ants the queen will leave the nest at this time and forage for food to give to the larvae. In specialized ants the queen rarely behaves in this fashion. After she has selected a nest site she never leaves it. Thus her first larvae are fed on salivary secretions derived from the degenerating wing muscles. In this type of nest-founding the queen usually eats some of her own eggs. Those that survive transform into very small workers called minims. Once the minims have been produced the queen's greatest difficulty is over, for the minims leave the nest and forage for food and the colony is well on its way to successful establishment. The colony and its queen, who continues to lay eggs fertilized by the stored sperm of her dead mate, may survive for 10 or 15 years.

Trophallaxis.—It is important to understand why the queen tends the brood during nest-founding and why the workers do so after the nest has been established. Affection for the brood is not the reason, for the nest-founding queen normally eats some of her own eggs, and the workers, if prevented from foraging, will eat

the brood rather than starve. The brood is tended because those who tend it wish to eat certain secretions that the larvae produce when fed. Food given to the larvae is thus exchanged for edible secretions produced by the larvae. This food exchange is called trophallaxis, and it is the basis of ant society. Anything that affects trophallaxis is certain to produce drastic results in the life of the colony; many of the most remarkable habits of ants are measures that cover impaired trophallaxis.

When a great disparity exists between the size of the queen and that of the worker, the queen may be too large to tend her larvae. In the genus *Carebara* the queen may be more than 2,000 times as large as the minute larvae from which the tiny workers are produced. Just before the queen of *Carebara* begins her marriage flight a few workers lock their mandibles on her tarsal hairs. This response is often misdirected, for the workers will also seize the tarsal hairs of the male, and those who do are discarded with him when the marriage flight ends. But the queen's little passengers can tend her brood as soon as she starts to lay eggs. Without them there could be no nest-founding in *Carebara*, since trophallaxis between the queen and her larvae is mechanically impossible.

At the other extreme are the diminutive queens (*Formica*, *Bothriomyrmex*, etc.) whose limited wing musculature cannot furnish enough salivary secretion to bring through the first brood. These little queens may be smaller than their own workers and are not easily recognized as queens. This may help them gain entry into the host nest, for all such queens must have aid in raising their first brood and all depend upon the workers of some other species for this aid. To secure it the little queen must enter the host nest and remain in it until she has replaced her own nest odour with that of the host species. If she can avoid being killed during this period, which she often does by hiding, she will be accepted by the host workers, who will tend her brood. The intruding queen may then dispose of the rightful queen by violence (in *Bothriomyrmex* she climbs on the back of the rightful queen and slowly chews her victim's head off) or she may make herself so attractive to the host workers that they allow their own queen to die of neglect. As the intruder's offspring mature, a mixed colony results, but this is temporary since the host workers ultimately die. Here again this behaviour results from the inability of the diminutive queen to carry on trophallaxis with her larvae during nest-founding.

The most spectacular habits resulting from inability to perform trophallaxis are those of the so-called "slave-making" species in the genera *Polyergus*, *Harpagoxenus*, *Strongylognathus*, *Formica* and *Leptothorax*. These intruding queens are highly pugnacious and can force their way into the host nest. If the queen's entry is resisted she quickly kills any host workers who oppose her. Her ferocity at this time is astonishing, and the surviving host workers soon cease to combat her and try to save their brood. But the intruding queen appropriates all the brood that she can find and guards it so that the host workers cannot recover it. This brood contains pupae, some of which soon transform into host workers who accept the intruder as their queen. By this time the disorganization of the host nest is often so great that the host queen may die of neglect, but if she lives the intruding queen finally kills her and disposes of any hostile workers who still remain in the nest. These complex responses provide the intruding queen with host workers who will care for the brood that she is unable to tend. But the matter does not end here, for workers produced by such queens repeat in large part the nest-founding activities of their queen. At certain times they will force their way into a nest of the host species, kill any opponents that resist them and appropriate their brood. This brood is then carried back to the raider's own nest, where it transforms into workers of the host species. Such mixed colonies are often permanent, for new workers of the host continue to emerge from the brood brought back to the raider's nest. In *Polyergus* the mixed colony must be maintained, for the workers of *Polyergus* feed neither their larvae nor themselves, a deficiency that is rectified by the activities of the host workers. Here trophallaxis has totally broken down, for neither the queen nor the worker of *Polyergus* exchanges food with the larvae.

Liquid Food.—Much of the evolutionary advance that marks the higher groups of ants is attributable to one notable improvement in their trophallaxis—they have developed a method of feeding their larvae liquid food. If the larvae can only be given solid food, which is the primitive condition, many easily secured liquid foods (the nectar of flowers, the sugary honeydew secretions of aphids, the juices of fruits, etc.) cannot be used in trophallaxis. To feed the larvae liquid food the worker must make use of a complex abdominal structure, the proventriculus. This combination valve and pump occurs at the posterior end of the crop. Liquid foods that enter the crop can be stored there indefinitely if the proventriculus is kept closed. Enough of this food to keep the worker alive can be admitted to the mid-gut if the proventriculus is briefly opened. Or, if the proventriculus performs its pumping function, part or all of the food in the crop can be forced back into the mouth. This is called regurgitation, and regurgitation is necessary for trophallaxis when liquid foods are employed. The regurgitated food can be fed not only to the larvae but also to any member of the colony. Experiments with liquid food containing tracers have shown that regurgitation may distribute such food to every adult member of the colony in three or four hours.

Food Storage in Repletes.—Certain ants that live in arid areas (*Myrmecocystus*, *Leptomymex* and a few species of *Camponotus*) take advantage of the storage function of the crop to produce a remarkable kind of worker called a replete. The prospective replete is fed large amounts of honeydew or other sugary liquids by the other workers. The storage of these liquids in the crop causes it to become so greatly distended that the abdominal sclerites are forced apart. The engorged replete finally has an abdomen about the size and shape of a large garden pea, made translucent and swollen to the bursting point by the distended crop full of honey. The repletes attach themselves to the ceilings of special chambers. for the enormous abdomen makes locomotion difficult, and supply liquid food by regurgitation as needed. Despite this remarkable adaptation many honey ants also store dead insects in their nests, for few ants are so stereotyped in their diet that they rely on a single kind of food.

ROSS E. HUTCHINS
FIG. 2.—HONEY ANT REPLETE (*MYRMECOCYSTUS*) HANGING FROM CEILING OF ANT CHAMBER

Ants as Nuisances.—A notable exception to the generalization that ants eat a varied diet is the fungus ant, of which the leaf cutters of the genus *Atta* are the most spectacular. These ants eat only a fungus that they raise in their nests. The workers cut pieces from leaves, bring them to the nest, chew them into a spongy compost and raise the fungus garden on it. Since the nests of *Atta* are usually populous, these ants may strip a small tree overnight, hence they are sometimes a pest to fruit growers. But in most cases they are no more than a nuisance: and this is true of most ants for these insects seldom cause extensive damage unless they are introduced into an area from a foreign source. If an ant is notably insectivorous, as are the army ants of the American tropics, it is usually regarded as beneficial despite the nuisance it causes. Instead of being a dreaded scourge these highly efficient insect exterminators are often welcomed by people who live where they occur. For the temporary inconvenience caused by the intrusion of a column of army ants into a house is outweighed by the fact that when the ants leave the house will be free from insects and other unwelcome arthropods.

Exterminating a Colony.—If an ant colony is to be exterminated the queen must be killed. Since she retires to the most obscure part of the nest when disturbed, the most lethal poisons (hydrocyanic acid gas, DDT and the nerve gas derivatives) may

fail to reach her. A more certain method involves the use of poison bait, a method based on the fact that the queen receives more food than any individual worker. If the concentration of poison in the bait is correct (usually about 2% of some form of arsenic) it will not kill the foraging workers but will kill the queen when the workers feed it to her. The main difficulty with this method, aside from its slowness, is that no one bait will attract all ants equally. But, since few ants that are nuisances refuse sugar baits, these generally prove effective if consistently used.

FIG. 3.—ANANT LIFTING A STONE, MANY TIMES ITS OWN WEIGHT. UP AND OUT OF ITS BURROW

CLASSIFICATION

In the discussion of the subfamilies, the following definitions apply. The petiole is the slender, waistlike part that connects the thorax with the large, terminal gaster. Primary monomorphism is the primitive evolutionary condition of the worker caste in which all the workers are of the same size and not notably smaller than the queen. The next higher condition is polymorphism, in which the workers vary notably in size and often in structure as well. A fully developed polymorphic worker caste contains minors, medias and majors. If the medias drop out a dimorphic worker caste of minors and majors results. If both medias and majors drop out, the worker caste has reached a condition of secondary monomorphism, where all the workers are the same size but notably smaller than the queen. While it cannot be claimed that the worker caste invariably passes through these stages as evolution proceeds, enough species have done so to make the condition of the worker caste a reasonably good index of the degree of evolution.

The family Formicidae is made up of the following seven subfamilies:

Ponerinae.—Petiole of two segments, the second often not clearly set off from the gaster. Sting present and functional. Pupae usually enclosed in cocoons. Worker caste monomorphic (primary), rarely polymorphic. Uniformly carnivorous. Many of the larger ponerines have atrocious stings and use them freely. In areas where such ants occur the natives detest and fear them.

Cerapachyinae.—Petiole as in the ponerines. Sting present and functional. Pupae, where known, enclosed in cocoons. Worker caste monomorphic (primary). Carnivorous and living largely upon other ants whose nests they raid. A small and little-known subfamily that combines ponerine and doryline features.

Dorylinae.—Petiole of two segments, the second usually, but not always, clearly set off from the gaster. Sting present and functional. Pupae naked or enclosed in cocoons. Worker caste polymorphic or monomorphic (secondary?). Carnivorous and nomadic. The African "drivers" and the Neotropical "army ants" belong to this subfamily. The doryline queen always lacks wings and has a voluminous gaster capable of great distention during periods of active egg-laying.

Pseudomyrmicinae.—Petiole of two segments. Sting present and functional. Pupae never enclosed in cocoons. Worker caste monomorphic (primary). Omnivorous. Mainly arboreal although some species live in the hollow stems of sedges and grasses. Most members of this subfamily are slender, agile ants with large eyes. Some of the species are very pugnacious and sting severely.

Myrmicinae.—Petiole of two segments. Sting always present but not always functional. Pupae never enclosed in cocoons. Worker caste polymorphic, dimorphic or monomorphic (secondary). Widely diverse food preferences. In this subfamily there are harvesters, fungus growers, slave makers, thief ants, guest ants, arboreals and workerless parasites. One group of genera has become secondarily carnivorous and feeds entirely on collembola. This is the largest subfamily and most diverse one, both in structure and habits. It has produced a number of species that are regarded as pests. The "grease ants," "pavement ants" and "fire ants" belong to this subfamily.

Dolichoderinae.—Petiole of one segment. Sting vestigial, except in one genus. Pupae never enclosed in cocoons. Worker caste mainly monomorphic (secondary), occasionally polymorphic, rarely dimorphic. Omnivorous. These ants possess repugnatorial glands that produce a powerful odour that repels other ants. This subfamily is a highly successful one, although it lacks the great structural diversity of Llyrmicinae. The habits of the Dolichoderinae are also rather uniform, but the group has produced arboreal species, a genus that has repletes and one whose female is a temporary social parasite. The "Argentine ant" belongs to this subfamily.

Formicinae.—Petiole of one segment. Sting absent, the poison sac much modified. Pupae usually enclosed in cocoons. Worker caste polymorphic or monomorphic (secondary) or occasionally dimorphic. Omnivorous. This is the second largest subfamily. While it has produced a number of species whose structure is greatly modified, in the main the structure is rather uniform throughout the subfamily. Nevertheless this subfamily shows a considerable range of habits. There are species that produce repletes, slave makers, temporary social parasites and arboreal species with widely different habits. One group of arboreals makes a nest of leaves, which they "sew" together with silk produced by the larvae. An unusually large proportion of the species in this subfamily are able to tolerate cold climates. It follows that most people who live in north temperate areas derive their concept of ants from this subfamily. Often it is based on the "carpenter ant," which is a widespread and troublesome member of this group.

ANTA, in architecture, the slightly projecting pilaster strip at the extremity of a wall that flanks a porch or part of a porch. It is a masonry development from early wooden structural posts used, as in the Heraeum at Olympia, to reinforce the brick walls. The term is also used in modern work to describe any pilaster

(LEFT) ANTA AND COLUMN. TEMPLE OF NIKE APTEROS. ATHENS: (RIGHT) ANTAE AND COLUMNS IN ANTIS. TEMPLE OF RAMESES III AT MEDINET HABU, EGYPT

whose detail resembles that of a true anta. Columns set between antae are termed "in antis." See GREEK ARCHITECTURE.

ANTACIDS, medicines that reduce acidity by decomposing or neutralizing, and therefore eliminating, an excess of free acid. Those most generally used are salts; e.g., sodium bicarbonate.

ANTAEUS, in Greek mythology, a giant of Libya, the son of Poseidon and Ge. He compelled all strangers who were passing through the country to wrestle with him, and as, if thrown, he derived fresh strength whenever he touched his mother earth, he proved invincible. Heracles, in combat with him, discovered

the source of his strength and, lifting him up from the earth, crushed him to death. His tomb was shown at Tingis (Tangier).

ANTAKYA: see ANTIOCH.

ANTALCIDAS (d. 367 B.C.), son of Leon, Spartan soldier and diplomatist who gave his name to the peace of Antalcidas of 386 B.C. between Greece and Persia, which ended the Corinthian War (see GREECE: History). Athens had profited from Persian friendship after the Athenian admiral Conon's victory over the Spartans at Cnidus in 394, and to counter this Antalcidas was sent to Sardis in 392 with an offer to recognize Persian sovereignty in Asia Minor. The Athenians and other Greek states sent counter-embassies. Tiribazus, the satrap of Lydia, approved of Antalcidas' offer and imprisoned Conon (who led the Athenian embassy), but the Persian king Artaxerxes II (q.v.) recalled Tiribazus while the peace Artaxerxes eventually proposed was rejected by the Athenians. In 388, when Antalcidas was Spartan admiral, the plan was revived. Antalcidas, with Syracusan support, got control of the Hellespont, and Athens was forced to accept the "King's peace" or "peace of Antalcidas" (spring 386). Asia Minor and Cyprus were to be Persian and all cities of Greece were to be autonomous. Nominally a general Greek settlement, this was in fact a bargain between Persia and Sparta, ruthlessly exploited in Greece by Sparta under Agesilaus II (q.v.). Antalcidas is said to have committed suicide after the conference at Susa in 367, when in other circumstances Artaxerxes II supported Thebes. (A. As.)

ANTALYA (ADALIA), an ancient seaport and capital of an *il* (province) of the same name on the southern coast of Turkey. Pop. (1960) 50,963. The walled city occupies the summit of a low cliff overlooking the harbour, which is protected by extensions of the fortifications. The modern town spreads westward along the cliff, with municipal buildings and gardens, a market and hotels. There are considerable remains of the Roman occupation, including "Hadrian's gate" in the north wall and a fragmentary temple of Diana. There are also Seljuk buildings, in one of which, a medrese with a fine minaret, is a museum. Antalya is accessible from the interior only by road from the railroad at Burdur (75 mi.) or from Mersin by the new coastal road. The harbour is suitable only for small coastal steamers. There is an airport 4¼ mi. from the town.

Founded in the 2nd century B.C. by Attalus II, king of Pergamum, the town was bequeathed by his family to the Romans. As the biblical Attaleia it was the port from which SS. Paul and Barnabas sailed to Antioch. In A.D. 135 Hadrian made it the capital of a senatorial province, Pamphylia. A Byzantine stronghold in the 10th century, it was taken by Kilij Arslan in 1207 and became the first Seljuk port on the Mediterranean. After the fall of the Rum sultanate, it changed hands many times, being successively occupied by the Mongols, the Karamanoglu, the Venetians and the Genoese. It was incorporated in the Ottoman empire in the 15th century.

ANTALYA *il*, containing two *kaza* (districts), consists mostly of a crescent-shaped coastal plain hemmed in by the Taurus mountains. Its population in 1960 was 418,355. It has become a tourist area because it is easily accessible by motor road from Antalya city, and because of such well-known historical sites as Aspendus (q.v.) with its finely preserved Roman theatre, Perga (q.v.), Sillium, Side near Manavgat, excavated by Turkish archaeologists, and the picturesque Seljuk fortress and harbour at Alanya (Ala'iyya).

(S. H. LL.)

ANTANANARIVO (Fr. TANANARIVE), the capital of the Malagasy Republic (Madagascar) and the seat of the French high commissioner. It is centrally situated about 90 mi. from the island's eastern coast. The climate is tropical with a cool, dry season and a warm season that brings torrential rains. The average temperature is 65° F. The population increased rapidly during the 20th century. In 1901 there were 56,000 inhabitants and in 1960 the figure had grown to 247,917.

The town, formerly called Analamanga ("the blue forest"),

stands on the highest of 12 hills in the midst of a mountainous region comprising Tananarive province (area 22,042 sq.mi.; 1960 pop. 1,209,168), of which Antananarivo is the administrative seat. Avenues and flights of steps lead up the steeper hillslopes to a rocky ridge (4,694 ft.) which rises more than 600 ft. above the fertile plains of the Ikopa to the west. High on this ridge is the rova or royal estate with its towered palaces built by the Imerina kings. Lower on the hillside, in the district off the Place Colbert, are the banks and administrative buildings, and lower still, at the level of the rice fields, is the commercial quarter. Public buildings include the French residency and the Anglican and Roman Catholic cathedrals. In addition to many missionary schools there are research institutes, an observatory and schools of law and medicine; the university has faculties of science and literature. Antananarivo is the distributing centre for an extensive rice-growing region. Its industries include tobacco and food processing, and factories produce leather goods, clothing and foodstuffs.

Air travel is of paramount importance. The airports at Ivato and Arivonimano are about 25 mi. and 38 mi. respectively from the town. Antananarivo is linked by rail with Tamatave (*q.v.*), the island's chief port, on the eastern coast and with Antsirabe to the south. Main roads from the north, south and east coasts converge at Antananarivo, the only road to the Mozambique channel being merely track for part of the way.

Founded in the 17th century, Antananarivo was for a long time the capital of the Hova chiefs, but it advanced in importance as those chiefs made themselves sovereigns of the greater part of Madagascar. In 1794, with the capture of the town by Andrianampoinimerina, prince of Ambohimanga, the town's precedence in Imerina (the central district) was established. The first Frenchmen penetrated to Antananarivo in 1777, and in 1832 arrived the French artisan Jean Laborde who introduced many industries. Both Protestant and Catholic missionaries began to settle there in

the 1820s. Because of its politico-economic importance and its central position, Antananarivo was selected as its headquarters by the French command when it was set up in 1895. See also MADAGASCAR. (J. AR.)

ANTARAH (ANTAR; Arab. 'ANTARAH IBN SHADDAD AL-'ABSI), Arab poet and warrior of the second half of the 6th century, famous both for his poetry and as a figure in Arabic legend, comparable with Hercules in Greek mythology or Samson in the Old Testament. His father was of the tribe of 'Abs and his mother a Negro slave. He loved his cousin 'Abla, but his request for her hand was refused because, not being acknowledged by his father, he was regarded as a slave. He won his father's recognition when, as he relates in one of his poems, the 'Absites were attacked and a fierce engagement ensued in which Antarah refused to join, saying, "A slave does not know how to fight"; whereupon his father cried, "Charge, you are free!" Many of his exploits were performed in the war between the tribes of 'Abs and Dhobyān, which began over a contest of horses and was called after their names the war of Dahis and Ghabra. He died in extreme old age in a fight against the tribe of Tai. The most famous of his poems (which are chiefly concerned with fighting or with his love for 'Abla) is contained in the collection of pre-Islamic odes known as the *Mu'allaqat* (*q.v.*). The romance of his life, *Sirat 'Antar ibn Shaddad*, was long handed down by oral tradition and has grown to immense proportions. It recounts heroic deeds against great odds, the slaying of a lion by the tearing apart of its jaws and an adventurous excursion into Persia, where Khosrau II showed him favour.

BIBLIOGRAPHY.—Edition of poems by Mohammed al-'Inani (1911) and by W. Ahlwardt in the *Diwan of the Six Ancient Arabic Poets* (1870). *Sirat 'Antar ibn Shaddad* was publ. in 32 vol. (1889-94); partial Eng. trans. by Terrick Hamilton, *'Antar, a Bedoueen Romance*, 4 vol. (1820); French trans. by L. M. Devic, *Les Aventures d'Antar* (1878), re-issued as *Poème héroïque arabe* (1898). (E. S. AH.)
